Name lpadmin – configure the LP print service

Synopsis

```
lpadmin -p printer {options}

lpadmin -x dest

lpadmin -d [dest]

lpadmin -S print-wheel -T [-A alert-type] [-W minutes]
     [-Q requests]
```

Description `lpadmin` configures the LP print service by defining printers and devices. It is used to add and change printers, to remove printers from service, to set or change the system default destination, to define alerts for printer faults, and to mount print wheels.

Options The `lpadmin` command has options for:

- Adding or changing a printer
- Removing a printer destination
- Setting or changing the system default destination
- Setting an alert for a print wheel

The options for each of the above categories are specified in the following subsections.

Several options support the use of lists. A list might contain, for example, user names, printers, printer forms, or content types. A list of multiple items can have the form of either comma-separated names or have the entire list enclosed by double quotes with a space between each name. For example, both lists below are acceptable:

```
one,two,three
"one two three"
```

Adding or Changing a Printer

The first form of the `lpadmin` command (`lpadmin -p` *printer* {*options*}) configures a new printer or changes the configuration of an existing printer. It also starts the print scheduler.

When creating a new printer, one of three options (`-v`, `-U`, or `-s`) must be supplied. In addition, only one of the following can be supplied: `-e`, `-i`, or `-m`; if none of these three options is supplied, the model standard is used. The `-h` and `-l` options are mutually exclusive. Printer and class names must be no longer than 14 characters and must consist entirely of the characters `A-Z`, `a-z`, `0-9`, dash (`-`) and underscore (_). If `-s` is specified, the following options are invalid: `-A`, `-e`, `-F`, `-h`, `-i`, `-l`, `-M`, `-m`, `-o`, `-U`, `-v`, and `-W`.

The following options can appear in any order.

`-A` *alert-type* [`-W` *minutes*]
The `-A` option is used to define an alert that informs the administrator when a printer fault is detected, and periodically thereafter, until the printer fault is cleared by the administrator. The *alert-types* are:

`mail` Send the alert message using mail (see `mail(1)`) to the administrator.

`write`	Write the message to the terminal on which the administrator is logged in. If the administrator is logged in on several terminals, one is chosen arbitrarily.
`quiet`	Do not send messages for the current condition. An administrator can use this option to temporarily stop receiving further messages about a known problem. Once the fault has been cleared and printing resumes, messages are sent again when another fault occurs with the printer.
`showfault`	Attempt to execute a fault handler on each system that has a print job in the queue. The fault handler is `/etc/lp/alerts/printer`. It is invoked with three parameters: *printer_name*, `date`, *file_name*. The *file_name* is the name of a file containing the fault message.
`none`	Do not send messages; any existing alert definition for the printer is removed. No alert is sent when the printer faults until a different alert-type (except `quiet`) is used.
shell-command	Run the *shell-command* each time the alert needs to be sent. The shell command should expect the message in standard input. If there are blank spaces embedded in the command, enclose the command in quotes. Notice that the `mail` and `write` values for this option are equivalent to the values `mail` *user-name* and `write` *user-name* respectively, where *user-name* is the current name for the administrator. This is the login name of the person submitting this command unless he or she has used the `su` command to change to another user ID. If the `su` command has been used to change the user ID, then the *user-name* for the new ID is used.
`list`	Display the type of the alert for the printer fault. No change is made to the alert.

When a fault occurs, the printing subsystem displays a message indicating that printing for a specified printer has stopped and the reason for the stoppage. The message also indicates that printing will restart in a few minutes and that you can enter an `enable` command if you want to restart sooner than that.

Following a fault that occurs in the middle of a print job, the job is reprinted from the beginning. An exception to this occurs when you enter a command, such as the one shown below, that changes the page list to be printed.

```
% lp -i request-id -P ...
```

For a given print request, the presence of multiple reasons for failure indicate multiple attempts at printing.

The LP print service can detect printer faults only through an adequate fast filter and only when the standard interface program or a suitable customized interface program is used. Furthermore, the level of recovery after a fault depends on the capabilities of the filter.

If, instead of a single printer, the keyword `all` is displayed in an alert, the alert applies to all printers.

If the `-W` option is not used to arrange fault alerting for *printer*, the default procedure is to mail one message to the administrator of *printer* per fault. This is equivalent to specifying `-W once` or `-W 0`. If *minutes* is a number greater than zero, an alert is sent at intervals specified by *minutes*.

`-c` *class*
Insert *printer* into the specified *class*. *class* is created if it does not already exist. This option requires the `-U` *dial-info* or `-v` *device* options.

`-D` *comment*
Save this *comment* for display whenever a user asks for a full description of *printer* (see `lpstat(1)`). The LP print service does not interpret this comment.

`-e` *printer*
Copy the interface program of an existing *printer* to be the interface program for *printer*. (Options `-i` and `-m` must not be specified with this option.)

`-f allow:`*form-list*
`-f deny:`*form-list*
Allow or deny the forms in *form-list* to be printed on *printer*. By default no forms are allowed on a new printer.

For each printer, the LP print service keeps two lists of forms: an "allow-list" of forms that can be used with the printer, and a "deny-list" of forms that cannot be used with the printer. With the `-f allow` option, the forms listed are added to the allow-list and removed from the deny-list. With the `-f deny` option, the forms listed are added to the deny-list and removed from the allow-list.

If the allow-list is not empty, only the forms in the list can be used on the printer, regardless of the contents of the deny-list. If the allow-list is empty, but the deny-list is not, the forms in the deny-list cannot be used with the printer. All forms can be excluded from a printer by specifying `-f deny:all`. All forms can be used on a printer (provided the printer can handle all the characteristics of each form) by specifying `-f allow:all`.

The LP print service uses this information as a set of guidelines for determining where a form can be mounted. Administrators, however, are not restricted from mounting a form on any printer. If mounting a form on a particular printer is in disagreement with the information in the allow-list or deny-list, the administrator is warned but the mount is accepted. Nonetheless, if a user attempts to issue a print or change request for a form and printer combination that is in disagreement with the information, the request is accepted

only if the form is currently mounted on the printer. If the form is later unmounted before the request can print, the request is canceled and the user is notified by mail.

If the administrator tries to specify a form as acceptable for use on a printer that does not have the capabilities needed by the form, the command is rejected.

Notice the other use of `-f`, with the `-M` option, below.

The `-T` option must be invoked first with `lpadmin` to identify the printer type before the `-f` option can be used.

`-F` *fault-recovery*
This option specifies the recovery to be used for any print request that is stopped because of a printer fault, according to the value of *fault-recovery*:

`continue`	Continue printing on the top of the page where printing stopped. This requires a filter to wait for the fault to clear before automatically continuing.
`beginning`	Start printing the request again from the beginning.
`wait`	Disable printing on *printer* and wait for the administrator or a user to enable printing again. During the wait, the administrator or the user who submitted the stopped print request can issue a change request that specifies where printing should resume. (See the `-i` option of the `lp` command.) If no change request is made before printing is enabled, printing resumes at the top of the page where stopped, if the filter allows; otherwise, the request is printed from the beginning.

`-h`
Indicate that the device associated with the printer is hardwired. If neither of the mutually exclusive options, `-h` and `-l`, is specified, `-h` is assumed.

`-i` *interface*
Establish a new interface program for *printer*. *interface* is the pathname of the new program. (The `-e` and `-m` options must not be specified with this option.)

`-I` *content-type-list*
Allow *printer* to handle print requests with the content types listed in a *content-type-list*.

The type `simple` is recognized as the default content type for files in the UNIX system. A `simple` type of file is a data stream containing only printable ASCII characters and the following control characters:

Control Char	Octal Value	Meaning
BACKSPACE	10	Move back one char, except

Control Char	Octal Value	Meaning
		at beginning of line
TAB	11	Move to next tab stop
LINEFEED	12	Move to beginning of
(newline)		next line
FORMFEED	14	Move to beginning of
		next page
RETURN	15	Move to beginning of
		current line

To prevent the print service from considering `simple` a valid type for the printer, specify either an explicit value (such as the printer type) in the *content-type-list*, or an empty list. If you do want `simple` included along with other types, you must include `simple` in the *content-type-list*.

In addition to content types defined by the print administrator, the type `PostScript` is recognized and supported by the Solaris print subsystem. This includes filters to support `PostScript` as the printer content type.

The type `any` is recognized as a special content type for files. When declared as the input type for a printer, it signals the print sub-system not to do any filtering on the file before sending it to the printer.

Except for `simple` and `any`, each *content-type* name is determined by the administrator. If the printer type is specified by the `-T` option, then the printer type is implicitly considered to be also a valid content type.

`-l`
Indicate that the device associated with *printer* is a login terminal. The LP scheduler (`lpsched`) disables all login terminals automatically each time it is started. (The `-h` option must not be specified with this option.)

`-m` *model*
Select *model* interface program, provided with the LP print service, for the printer. (Options `-e` and `-i` must not be specified with this option.)

`-M -f` *form-name* [`-a` [`-o filebreak`]] [`-t` *tray-number*]]
Mount the form *form-name* on *printer*. Print requests that need the pre-printed form *form-name* is printed on *printer*. If more than one printer has the form mounted and the user has specified `any` (with the `-d` option of the `lp` command) as the printer destination, then the print request is printed on the one printer that also meets the other needs of the request.

The page length and width, and character and line pitches needed by the form are compared with those allowed for the printer, by checking the capabilities in the `terminfo` database for the type of printer. If the form requires attributes that are not available with the printer, the administrator is warned but the mount is accepted. If the form lists a print wheel as mandatory, but the print wheel mounted on the printer is different, the administrator is also warned but the mount is accepted.

If the `-a` option is given, an alignment pattern is printed, preceded by the same initialization of the physical printer that precedes a normal print request, with one exception: no banner page is printed. Printing is assumed to start at the top of the first page of the form. After the pattern is printed, the administrator can adjust the mounted form in the printer and press return for another alignment pattern (no initialization this time), and can continue printing as many alignment patterns as desired. The administrator can quit the printing of alignment patterns by typing `q`.

If the `-o filebreak` option is given, a formfeed is inserted between each copy of the alignment pattern. By default, the alignment pattern is assumed to correctly fill a form, so no formfeed is added.

If the `-t` *tray-number* option is specified, printer tray *tray-number* is used.

A form is "unmounted" either by mounting a new form in its place or by using the `-f none` option. By default, a new printer has no form mounted.

Notice the other use of `-f` without the `-M` option above.

`-M -S` *print-wheel*
Mount the *print-wheel* on *printer*. Print requests that need the *print-wheel* are printed on *printer*. If more than one printer has *print-wheel* mounted and the user has specified `any` (with the `-d` option of the `lp` command) as the printer destination, then the print request is printed on the one printer that also meets the other needs of the request.

If the *print-wheel* is not listed as acceptable for the printer, the administrator is warned but the mount is accepted. If the printer does not take print wheels, the command is rejected.

A print wheel is "unmounted" either by mounting a new print wheel in its place or by using the option `-S none`. By default, a new printer has no print wheel mounted.

Notice the other uses of the `-S` option without the `-M` option described below.

`-n` *ppdfilename*
Specify a PPD file for creating and modifying printer queues. *ppdfilename* is the full path and file name to the PPD file. Used in conjunction with the `-p`, `-d`, `-x`, or `-S` options.

`-o` *option*
The `-o` option defines default printer configuration values given to an interface program. The default can be explicitly overwritten for individual requests by the user (see `lp(1)`), or taken from a preprinted form description (see `lpforms(1M)` and `lp(1)`).

There are several options which are predefined by the system. In addition, any number of key-value pairs can be defined. See the section "Predefined Options Used with the `-o` Option", below.

`-P` *paper-name*
Specify a paper type list that the printer supports.

`-r` *class*
Remove *printer* from the specified *class*. If *printer* is the last member of *class*, then *class* is removed.

`-S` *list*
Allow either the print wheels or aliases for character sets named in *list* to be used on the printer.

If the printer is a type that takes print wheels, then *list* is a comma or space separated list of print wheel names. These are the only print wheels considered mountable on the printer. (You can always force a different print wheel to be mounted.) Until the option is used to specify a list, no print wheels are considered mountable on the printer, and print requests that ask for a particular print wheel with this printer are rejected.

If the printer is a type that has selectable character sets, then *list* is a list of character set name "mappings" or aliases. Each "mapping" is of the form *known-name=alias* The *known-name* is a character set number preceded by `cs` (such as `cs3` for character set three) or a character set name from the `terminfo` database entry `csnm`. See `terminfo(4)`. If this option is not used to specify a list, only the names already known from the `terminfo` database or numbers with a prefix of `cs` is acceptable for the printer. If *list* is the word `none`, any existing print wheel lists or character set aliases are removed.

Notice the other uses of the `-S` with the `-M` option described above.

The `-T` option must be invoked first with `lpadmin` to identify the printer type before the `-S` option can be used.

`-s` *system-name*
The `-s` option can be used for both remote or local printers. For remote printers:

`-s` *system-name*[`!`*printer-name*] (UUCP format)
`-s` *printer-name*`@`*system-name* (RCMD format)

Make a remote printer (one that must be accessed through another system) accessible to users on your system. *system-name* is the name of the remote system on which the remote printer is located it. *printer-name* is the name used on the remote system for that printer. For example, if you

want to access *printer1* on *system1* and you want it called *printer2* on your system:

`-p` *printer2* `-s` *system1*`!`*printer1*

`-p` *printer2* `-s` *printer1*`@`*system1*

`-s` *scheme*`://`*end-point* (URI format)

Make a remote printer (one that must be accessed through another system) accessible to users on your system. The supported schemes include `lpd` and `ipp`. Specify URI's using the `lpd` format as follows:

`lpd://`*server*`/`*printers*`/`*queue*`[#Solaris]`

URI's using the `ipp` format are defined by the remote print server. They are generally of the format:

`ipp://`*server*`/`*printers*`/`*queue*

In either case, *server* specifies the hostname or IP address of the remote print server, *queue* specifies the name of the print queue on the remote print server, and the optional `#Solaris`specifies that the remote print server is a Solaris server when `lpd` URI format is being used.

For example:

`-p` *printer* `-s lpd://`*server*`/`*printers*`/`*queue*`#Solaris`
`-p` *printer* `-s ipp://`*server*`/`*printers*`/`*queue*

For local printers:

`-s "localhost"` Use `localhost` for the *system-name* to be used by the print service. In an environment where the nodename is variable, print queues are invalidated when the nodename changes. Using `localhost` as the *system-name* allows print queues to be maintained across changing nodenames. The *system-name*, as used by the print service, is only set to `localhost` when explicitely set with this option; by default, `lpadmin` sets *system-name* to *nodename*. For example, if you want to configure a new printer on the local system, and want it called *printer3*:

`-p` *printer3* `-s` *localhost* `-v` *device*

This option should never be used when creating name service maps.

`-T` *printer-type-list*
Identify the printer as being of one or more *printer-type*s. Each *printer-type* is used to extract data from the `terminfo` database; this information is used to initialize the printer before printing each user's request. Some filters might also use a *printer-type* to convert content for the printer. If this option is not used, the default *printer-type* is `unknown`. No information is extracted from `terminfo` so each user request is printed without first initializing the printer. Also, this option must be used if the following are to work: `-o cpi`, `-o lpi`, `-o` width, and `-o length` options of the `lpadmin` and `lp` commands, and the `-S` and `-f` options of the `lpadmin` command.

If the *printer-type-list* contains more than one type, then the *content-type-list* of the `-I` option must either be specified as `simple`, as empty (`-I ""`), or not specified at all.

`-t`*number-of-trays*
Specify the number of trays when creating the printer.

`-u allow:`*login-ID-list*
`-u deny:`*login-ID-list*
Allow or deny the users in *login-ID-list* access to the printer. By default all users are allowed on a new printer. The *login-ID-list* argument can include any or all of the following constructs:

login-ID	a user on any system
system-name`!`*login-ID*	a user on system *system-name*
system-name`!all`	all users on system *system-name*
`all!`*login-ID*	a user on all systems
`all`	all users on all systems

For each printer, the LP print service keeps two lists of users: an "allow-list" of people allowed to use the printer, and a "deny-list" of people denied access to the printer. With the `-u allow` option, the users listed are added to the allow-list and removed from the deny-list. With the `-u deny` option, the users listed are added to the deny-list and removed from the allow-list.

If the allow-list is not empty, only the users in the list can use the printer, regardless of the contents of the deny-list. If the allow-list is empty, but the deny-list is not, the users in the deny-list cannot use the printer. All users can be denied access to the printer by specifying `-u deny:all`. All users can use the printer by specifying `-u allow:all`.

The `-U` option allows your print service to access a remote printer. (It does not enable your print service to access a remote printer service.) Specifically, `-U` assigns the "dialing" information *dial-info* to the printer. *dial-info* is used with the `dial` routine to call the printer. Any network connection supported by the Basic Networking Utilities works.

dial-info can be either a phone number for a modem connection, or a system name for other kinds of connections. Or, if `-U direct` is given, no dialing takes place, because the name `direct` is reserved for a printer that is directly connected. If a system name is given, it is used to search for connection details from the file `/etc/uucp/Systems` or related files. The Basic Networking Utilities are required to support this option. By default, `-U direct` is assumed.

`-v` *device*
Associate a *device* with *printer*. *device* is the path name of a file that is writable by `lp`. Notice that the same *device* can be associated with more than one printer.

`-v` *scheme*`://`*end-point*
Associate a network attached device with printer.

scheme is the method or protocol used to access the network attached device and *end-point* is the information necessary to contact that network attached device. Use of this device format requires the use of the `uri` interface script and can only be used with the `smb` scheme at this time.

For example:

```
# lpadmin -p queue -v smb://smb-service/printer -m uri
```

See the `/usr/sfw/man/man1m/smbspool.1m` man page for details.

Removing a Printer Destination

The `-x` *dest* option removes the destination *dest* (a printer or a class), from the LP print service. If *dest* is a printer and is the only member of a class, then the class is deleted, too. If *dest* is `all`, all printers and classes are removed. If there are no remaining local printers and the scheduler is still running, the scheduler is shut down.

No other *options* are allowed with `-x`.

Setting/Changing the System Default Destination

The `-d` [*dest*] option makes *dest* (an existing printer or class) the new system default destination. If *dest* is not supplied, then there is no system default destination. No other *options* are allowed with `-d`.

Setting an Alert for a Print Wheel

`-S` *print-wheel* [`-A` *alert-type*] [`-W` *minutes*] [`-Q` *requests*] `-T`
The `-S` *print-wheel* option is used with the `-A` *alert-type* option to define an alert to mount the print wheel when there are jobs queued for it. If this command is not used to arrange alerting for a print wheel, no alert is sent for the print wheel. Notice the other use of `-A`, with the `-p` option, above.

The *alert-types* are:

`mail`	Send the alert message using the `mail` command to the administrator.
`write`	Write the message, using the `write` command, to the terminal on which the administrator is logged in. If the administrator is logged in on several terminals, one is arbitrarily chosen.

`quiet` Do not send messages for the current condition. An administrator can use this option to temporarily stop receiving further messages about a known problem. Once the *print-wheel* has been mounted and subsequently unmounted, messages are sent againwhen the number of print requests reaches the threshold specified by the `-Q` option.

`none` Do not send messages until the `-A` option is given again with a different *alert-type* (other than `quiet`).

shell-command Run the *shell-command* each time the alert needs to be sent. The shell command should expect the message in standard input. If there are blanks embedded in the command, enclose the command in quotes. Notice that the `mail` and `write` values for this option are equivalent to the values `mail` *user-name* and `write` *user-name* respectively, where *user-name* is the current name for the administrator. This is the login name of the person submitting this command unless he or she has used the `su` command to change to another user ID. If the `su` command has been used to change the user ID, then the *user-name* for the new ID is used.

`list` Display the type of the alert for the print wheel on standard output. No change is made to the alert.

The message sent appears as follows:

```
The print wheel print-wheel needs to be mounted
on the printer(s):
printer(integer1requests) integer2 print requests
await this print wheel.
```

The printers listed are those that the administrator had earlier specified were candidates for this print wheel. The number *integer1* listed next to each printer is the number of requests eligible for the printer. The number *integer2* shown after the printer list is the total number of requests awaiting the print wheel. It is less than the sum of the other numbers if some requests can be handled by more than one printer.

If the *print-wheel* is `all`, the alerting defined in this command applies to all print wheels already defined to have an alert.

If the `-W` option is not given, the default procedure is that only one message is sent per need to mount the print wheel. Not specifying the `-W` option is equivalent to specifying `-W once` or `-W 0`. If *minutes* is a number greater than zero, an alert is sent at intervals specified by *minutes*.

If the `-Q` option is also given, the alert is sent when a certain number (specified by the argument *requests*) of print requests that need the print wheel are waiting. If the `-Q` option is not given, or *requests* is 1 or `any` (which are both the default), a message is sent as soon as

anyone submits a print request for the print wheel when it is not mounted.

Predefined Options Used with the -o Option

A number of options, described below, are predefined for use with `-o`. These options are used for adjusting printer capabilities, adjusting printer port characteristics, configuring network printers, and controlling the use of banner. The `-o` also supports an arbitrary *keyword=value* format, which is referred to below as an undefined option.

Adjusting Printer Capabilities

The `length`, `width`, `cpi`, and `lpi` parameters can be used in conjunction with the `-o` option to adjust printer capabilities. The format of the parameters and their values is as follows:

`length=`*scaled-decimal-number*
`width=`*scaled-decimal-number*
`cpi=`*scaled-decimal-number*
`lpi=`*scaled-decimal-number*

The term *scaled-decimal-number* refers to a non-negative number used to indicate a unit of size. The type of unit is shown by a "trailing" letter attached to the number. Three types of *scaled-decimal-numbers* can be used with the LP print service: numbers that show sizes in centimeters (marked with a trailing `c`); numbers that show sizes in inches (marked with a trailing `i`); and numbers that show sizes in units appropriate to use (without a trailing letter), that is, lines, characters, lines per inch, or characters per inch.

The option values must agree with the capabilities of the type of physical printer, as defined in the terminfo database for the printer type. If they do not, the command is rejected.

The defaults are defined in the `terminfo` entry for the specified printer type. The defaults can be reset by:

`lpadmin -p` *printername* **`-o length=`**
`lpadmin -p` *printername* **`-o width=`**
`lpadmin -p` *printername* **`-o cpi=`**
`lpadmin -p` *printername* **`-o lpi=`**

Adjusting Printer Port Characteristics

You use the `stty` keyword in conjunction with the o option to adjust printer port characteristics. The general form of the `stty` portion of the command is:

`stty="'`*stty-option-list*`'"`

The *stty-option-list* is not checked for allowed values, but is passed directly to the `stty` program by the standard interface program. Any error messages produced by `stty` when a request is processed (by the standard interface program) are mailed to the user submitting the request.

The default for `stty` is:

```
stty="'9600 cs8 -cstopb -parenb ixon
     -ixany opost -olcuc onlcr
     -ocrnl -onocr
     -onlret -ofill nl0 cr0 tab0 bs0 vt0 ff0'"
```

The default can be reset by:

```
lpadmin -p printername -o stty=
```

Configuring Network Printers

The `dest`, `protocol`, `bsdctrl`, and `timeout` parameters are used in conjunction with the `-o` option to configure network printers. The format of these keywords and their assigned values is as follows:

```
dest=string protocol=string bsdctrl=string \
     timeout=non-negative-integer-seconds
```

These four options are provided to support network printing. Each option is passed directly to the interface program; any checking for allowed values is done there.

The value of `dest` is the name of the destination for the network printer; the semantics for value `dest` are dependent on the printer and the configuration. There is no default.

The value of option `protocol` sets the over-the-wire protocol to the printer. The default for option `protocol` is `bsd`. The value of option `bsdctrl` sets the print order of control and data files (BSD protocol only); the default for this option is `control file first`. The value of option `timeout` sets the seed value for backoff time when the printer is busy. The default value for the `timeout` option is `10` seconds. The defaults can be reset by:

```
lpadmin -p printername -o protocol=
lpadmin -p printername -o bsdctrl=
lpadmin -p printername -o timeout=
```

Controlling the Use of the Banner Page

Use the following commands to control the use of the banner page:

```
lpadmin -p printer -o nobanner
lpadmin -p printer -o banner
lpadmin -p printer -o banner=always
lpadmin -p printer -o banner=never
lpadmin -p printer -o banner=optional
```

The first and fifth commands (`-o nobanner` and `-o banner=optional`) are equivalent. The default is to print the banner page, unless a user specifies `-o nobanner` on an `lp` command line.

The second and third commands (`-o banner` and `-o banner=always`) are equivalent. Both cause a banner page to be printed always, even if a user specifies `lp -o nobanner`. The root user can override this command.

The fourth command (`-o banner=never`) causes a banner page never to be printed, even if a user specifies `lp -o banner`. The root user can override this command.

Undefined Options

The `-o` option supports the use of arbitrary, user-defined options with the following format:

key=*value*	Each *key*=*value* is passed directly to the interface program. Any checking for allowed values is done in the interface program. Any default values for a given *key*=*value* option are defined in the interface program. If a default is provided, it can be reset by typing the key without any value: `lpadmin -p` *printername* `-o` *key*=
`lpadmin -p` *printer* `-o foo | nofoo`	Sets boolean values `foo=true | foo=false`.

Examples In the following examples, *prtr* can be any name up to 14 characters and can be the same name as the `ping(1M)` name.

EXAMPLE 1 Configuring an HP Postscript Printer with a Jet Direct Network Interface

The following example configures an HP postscript printer with a jet direct network interface:

```
example# lpadmin -p prtr -v /dev/null -m netstandard \
          -o dest=ping_name_of_prtr:9100 -o protocol=tcp -T PS -I \
           postscript
example# enable prtr
example# accept prtr
```

EXAMPLE 2 Configuring a Standard Postscript Network Printer

The following example configures a standard postscript network printer:

```
example# lpadmin -p prtr -v /dev/null -m netstandard \
         -o dest=ping_name_of_prtr -T PS -I postscript
example# enable prtr
example# accept prtr
```

Exit Status The following exit values are returned:

`0`	Successful completion.
non-zero	An error occurred.

System Administration Guide: Basic Administration

Notes When using lpadmin to provide access to a remote printer, remote configuration data is stored in `/etc/printers.conf`. This data includes a `bsdaddr` and a `printer-uri-supported` attribute. The data in this file can be shared through the use of a network name service or replicated across multiple systems. If the data is shared, it is important to make sure that the `bsdaddr` and `printer-uri-supported` contain hostname information that is correctly resolved on all hosts sharing this data. Also, the `printer-uri-supported` is the preferred means of accessing remote print service. The `bsdaddr` is supplied for backward compatability with Solaris 2.6-10 systems.

Name lpfilter – administer filters used with the LP print service

Synopsis

```
/usr/sbin/lpfilter -f filter-name
     {- | -i | -l | -x | -F pathname}
```

Description The `lpfilter` command is used to add, change, delete, or list a filter used with the LP print service. These filters convert the content of a file to have a content type acceptable to a printer.

Options Arguments consist of the `-f`*filter-name* option and exactly one of the arguments appearing within braces (`{ }`) in the SYNOPSIS.

–	Adds or changes a filter as specified from standard input. The format of the input is specified below. If `-f all` is specified with the – option, the specified change is made to all existing filters. This is not useful.
`-f` *filter-name*	Specifies the *filter-name* of the filter to be added, changed, reset, deleted, or listed. The filter name `all` is a special filter name defined below. The `-f` option is required.
`-F` *pathname*	Adds or changes a filter as specified by the contents of the file *pathname*. The format of the file's contents is specified below. If `-f all` is specified with the `-F` option, the specified change is made to all existing filters. This is not useful.
`-i`	Resets a filter to its default settings. Using `-f all` with the `-i` option restores all filters for which predefined settings are available to their original settings.
`-l`	Lists a filter description. Using `-f all` with the `-l` option produces a list of all filters.
`-x`	Deletes a filter. Using `-f all` with the `-x` option results in all filters being deleted.

Usage

Adding or Changing a Filter

The filter named in the `-f` option is added to the filter table. If the filter already exists, its description is changed to reflect the new information in the input.

When – is specified, standard input supplies the filter description. When `-F` is specified, the file *pathname* supplies the filter description. One of these two options must be specified to add or change a filter.

When an existing filter is changed with the `-F` or – option, lines in the filter description that are not specified in the new information are not changed. When a new filter is added with this command, unspecified lines receive default values. See below.

Filters are used to convert the content of a request from its initial type into a type acceptable to a printer. For a given print request, the LP print service knows the following:

- The content type of the request (specified by `lp -T` or determined implicitly).
- The name of the printer (specified by `lp -d`).
- The printer type (specified by `lpadmin -T`).

  The printer type is intended to be a printer model, but some people specify it with a content type even though `lpadmin -I` is intended for this purpose.
- The content types acceptable to the printer (specified by `lpadmin -I`).

  The values specified by the `lpadmin -T` are treated as if they were specified by the `-I` option as well.
- The modes of printing asked for by the originator of the request (specified by various options to `lp`).

The system uses the above information to construct a list of one or more filters that converts the document's content type into a content type acceptable to the printer and consumes all `lp` arguments that invoke filters (`-y` and `-P`).

The contents of the file (specified by the `-F` option) and the input stream from standard input (specified by –) must consist of a series of lines, such that each line conforms to the syntax specified by one of the seven lines below. All lists are comma or space separated. Each item contains a description.

`Input types:` *content-type-list*
`Output types:` *content-type-list*
`Printer types:` *printer-type-list*
`Printers:` *printer-list*
`Filter type:` *filter-type*
`Command:` *shell-command*
`Options:` *template-list*

`Input types` — This gives the content types that can be accepted by the filter. The default is `any`. The document content type must be a member of this list for the initial filter in the sequence.

`Output types` — This gives the content types that the filter can produce from any of the input (content) types. The default is `any`. The intersection of the output types of this list and the content types acceptable to the printer (from `lpadmin -I` and `lpadmin -T`) must be non-null for the last filter in the sequence. For adjacent filters in the sequence, the intersection of output types of one and the input types of the next must be non-null.

`Printer types` — This gives the printer types for which this printer can be used. The LP print service will restrict the use of the filter to these printer types (from `lpadmin -T`). The default is `any`.

`Printers` This gives the names of the printers for which the filter can be used. The LP print service will restrict the use of the filter to just the printers named. The default is `any`.

`Filter type` This marks the filter as a `slow` filter or a `fast` filter. Slow filters are generally those that take a long time to convert their input (that is, minutes or hours). They are run before the job is scheduled for a printer, to keep the printers from being tied up while the filter is running. If a listed printer is on a remote system, the filter type for it must have the value `slow`. That is, if a client defines a filter, it must be a slow filter. Fast filters are generally those that convert their input quickly (that is, faster than the printer can process the data), or those that must be connected to the printer when run. Fast filters will be given to the interface program to run while connected to the physical printer.

`Command` This specifies which program to run to invoke the filter. The full program pathname as well as fixed options must be included in the *shell-command*; additional options are constructed, based on the characteristics of each print request and on the `Options` field. A command must be given for each filter. The command must accept a data stream as standard input and produce the converted data stream on its standard output. This allows filter pipelines to be constructed to convert data not handled by a single filter.

`Options` This is a comma-separated list of templates used by the LP print service to construct options to the filter from the characteristics of each print request listed in the table later. The `-y` and `-P` arguments to the `lp` command cause a filter sequence to be built even if there is no need for a conversion of content types.

In general, each template is of the following form:

keyword pattern = *replacement*

The *keyword* names the characteristic that the template attempts to map into a filter-specific option; each valid *keyword* is listed in the table below.

A *pattern* is one of the following: a literal pattern of one of the forms listed in the table, a single asterisk (`*`), or a regular expression. If *pattern* matches the value of the characteristic, the template fits and is used to generate a filter-specific option. The *replacement* is what will be used as the option.

Regular expressions are the same as those found on the `regexp(5)` manual page. This includes the `\(...\)` and `\`*n* constructions, which can be used to extract portions of the *pattern* for copying into the *replacement*, and the `&`, which can be used to copy the entire *pattern* into the *replacement*.

The *replacement* can also contain a *; it too, is replaced with the entire *pattern*, just like the & of regexp(5).

The keywords are:

lp Option	Characteristic	*keyword*	Possible *patterns*
-T	Content type (input)	INPUT	content-type
Not applicable	Content type (output)	OUTPUT	content-type
not applicable	Printer type	TERM	printer-type
-d	Printer name	PRINTER	*printer-name*
-f, -o cpi=	Character pitch	CPI	integer
-f, -o lpi=	Line pitch	LPI	integer
-f, -o length=	Page length	LENGTH	integer
-f, -o width=	Page width	WIDTH	integer
-P	Pages to print	PAGES	page-list
-S	Character set Print wheel	CHARSET CHARSET	character-set-name print-wheel-name
-f	Form name	FORM	form-name
-y	Modes	MODES	mode
-n	Number of copies	COPIES	*integer*

Resetting a Filter to Defaults If the filter named is one originally delivered with the LP print service, the -i option restores the original filter description.

Deleting a Filter The -x option is used to delete the filter specified in filter-name from the LP filter table.

Listing a Filter Description The -l option is used to list the description of the filter named in filter-name. If the command is successful, the following message is sent to standard output:

```
Input types: content-type-list
Output types: content-type-list
Printer types: printer-type-list
```

```
Printers: printer-list
Filter type: filter-type
Command: shell-command
Options: template-list
```

If the command fails, an error message is sent to standard error.

Large File Behavior

See largefile(5) for the description of the behavior of `lpfilter` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples

EXAMPLE 1 Printing with the landscape option

For example, the template

```
MODES landscape = -l
```

shows that if a print request is submitted with the `-y landscape` option, the filter will be given the option `-l`.

EXAMPLE 2 Selecting the printer type

As another example, the template

```
TERM * = -T *
```

shows that the filter will be given the option `-T` *printer-type* for whichever *printer-type* is associated with a print request using the filter.

EXAMPLE 3 Using the keywords table

Consider the template

```
MODES prwidth\=\(.*\) = -w\1
```

Suppose a user gives the command

```
lp -y prwidth=10
```

From the table above, the LP print service determines that the `-y` option is handled by a `MODES` template. The `MODES` template here works because the pattern prwidth=) matches the prwidth=10 given by the user. The replacement -w1 causes the LP print service to generate the filter option `-w10`. If necessary, the LP print service will construct a filter pipeline by concatenating several filters to handle the user's file and all the print options. See sh(1) for a description of a pipeline. If the print service constructs a filter pipeline, the `INPUT` and `OUTPUT` values used for each filter in the pipeline are the types of input and output for that filter, not for the entire pipeline.

Exit Status

The following exit values are returned:

`0` Successful completion.

non-zero An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpsu

See Also `lp(1)`, `sh(1)`, `lpadmin(1M)`, `attributes(5)`, `largefile(5)`, `regexp(5)`

System Administration Guide: Basic Administration

Notes If the `lp` command specifies more than one document, the filtering chain is determined by the first document. Other documents may have a different format, but they will print correctly only if the filter chain is able to handle their format.

Name lpforms – administer forms used with the LP print service

Synopsis

```
lpforms -f form-name option

lpforms -f form-name -A alert-type [-P paper-name [-d]]
     [-Q requests] [-W minutes]
```

Description The `lpforms` command administers the use of preprinted forms, such as company letterhead paper, with the LP print service. A form is specified by its *form-name*. Users may specify a form when submitting a print request (see `lp(1)`). The argument `all` can be used instead of *form-name* with either of the command lines shown above. The first command line allows the administrator to add, change, and delete forms, to list the attributes of an existing form, and to allow and deny users access to particular forms. The second command line is used to establish the method by which the administrator is alerted that the form *form-name* must be mounted on a printer.

Options The following options are supported:

`-f` *form-name* Specify a form.

The first form of `lpforms` requires that one of the following *option*s (—, `-l`, `-F`, `-x`) must be used:

`-F` *pathname* To add or change form *form-name*, as specified by the information in *pathname*.

— To add or change form *form-name*, as specified by the information from standard input.

`-l` To list the attributes of form *form-name*.

`-x` To delete form *form-name* (this option must be used separately; it may not be used with any other option).

The second form of the `lpforms` command requires the `-A` *alert-type* option. The other options are optional.

`-A` *alert-type* Defines an alert to mount the form when there are queued jobs which need it.

`-P` *paper-name* [`-d`] Specify the paper name when creating the form. If `-d` is specified, this paper is the default.

`-Q` *requests* An alert will be sent when a certain number of print requests that need the form are waiting.

`-W` *minutes* An alert will be sent at intervals specified by minutes.

Usage

Adding or Changing a Form

The `-F` *pathname* option is used to add a new form, *form-name*, to the LP print service, or to change the attributes of an existing form. The form description is taken from *pathname* if the `-F` option is given, or from the standard input if the – option is used. One of these two options must be used to define or change a form.

pathname is the path name of a file that contains all or any subset of the following information about the form.

`Page length:` *scaled-decimal-number1*
`Page width:` *scaled-decimal-number2*
`Number of pages:` *integer*
`Line pitch:` *scaled-decimal-number3*
`Character pitch:` *scaled-decimal-number4*
`Character set choice:` *character-set/print-wheel* `[mandatory]`
`Ribbon color:` *ribbon-color*
`Comment:`
comment
`Alignment pattern: [`*content-type*`]`
content

The term "scaled-decimal-number" refers to a non-negative number used to indicate a unit of size. The type of unit is shown by a "trailing" letter attached to the number. Three types of scaled decimal numbers can be used with the LP print service: numbers that show sizes in centimeters (marked with a trailing `c`); numbers that show sizes in inches (marked with a trailing `i`); and numbers that show sizes in units appropriate to use (without a trailing letter); lines, characters, lines per inch, or characters per inch.

Except for the last two lines, the above lines may appear in any order. The `Comment:` and *comment* items must appear in consecutive order but may appear before the other items, and the `Alignment pattern:` and the *content* items must appear in consecutive order at the end of the file. Also, the *comment* item may not contain a line that begins with any of the key phrases above, unless the key phrase is preceded with a > sign. Any leading > sign found in the *comment* will be removed when the comment is displayed. There is no case distinction among the key phrases.

When this command is issued, the form specified by *form-name* is added to the list of forms. If the form already exists, its description is changed to reflect the new information. Once added, a form is available for use in a print request, except where access to the form has been restricted, as described under the `-u` option. A form may also be allowed to be used on certain printers only.

A description of each form attribute is below:

`Page length` and `Page Width`
: Before printing the content of a print request needing this form, the generic interface program provided with the LP print service will initialize the physical printer to handle pages *scaled-decimal-number1* long, and

	scaled-decimal-number2 wide using the printer type as a key into the terminfo(4) database. The page length and page width will also be passed, if possible, to each filter used in a request needing this form.
`Number of pages`	Each time the alignment pattern is printed, the LP print service will attempt to truncate the *content* to a single form by, if possible, passing to each filter the page subset of 1-*integer*.
`Line pitch` and `Character pitch`	Before printing the content of a print request needing this form, the interface program provided with the LP print service will initialize the physical printer to handle these pitches, using the printer type as a key into the terminfo(4) database. Also, the pitches will be passed, if possible, to each filter used in a request needing this form. *scaled-decimal-number3* is in lines-per-centimeter if a `c` is appended, and lines-per-inch otherwise; similarly, *scaled-decimal-number4* is in characters-per-centimeter if a `c` is appended, and characters-per-inch otherwise. The character pitch can also be given as `elite` (12 characters-per-inch), `pica` (10 characters-per-inch), or `compressed` (as many characters-per-inch as possible).
`Character set choice`	When the LP print service alerts an administrator to mount this form, it will also mention that the print wheel *print-wheel* should be used on those printers that take print wheels. If printing with this form is to be done on a printer that has selectable or loadable character sets instead of print wheels, the interface programs provided with the LP print service will automatically select or load the correct character set. If `mandatory` is appended, a user is not allowed to select a different character set for use with the form; otherwise, the character set or print wheel named is a suggestion and a default only.
`Ribbon color`	When the LP print service alerts an administrator to mount this form, it will also mention that the color of the ribbon should be *ribbon-color*.
`Comment`	The LP print service will display the *comment* unaltered when a user asks about this form (see lpstat(1)).

`Alignment pattern`	When mounting this form, an administrator can ask for the *content* to be printed repeatedly, as an aid in correctly positioning the preprinted form. The optional *content-type* defines the type of printer for which *content* had been generated. If *content-type* is not given, `simple` is assumed. Note that the *content* is stored as given, and will be readable only by the user `lp`.

When an existing form is changed with this command, items missing in the new information are left as they were. When a new form is added with this command, missing items will get the following defaults:

```
Page Length: 66
Page Width: 80
Number of Pages: 1
Line Pitch: 6
Character Pitch: 10
Character Set Choice: any
Ribbon Color: any
```

Deleting a Form

LP print service: The `-x` option is used to delete the form *form-name* from the LP print service.

Listing Form Attributes

The `-l` option is used to list the attributes of the existing form *form-name*. The attributes listed are those described under `Adding and Changing a Form,` above. Because of the potentially sensitive nature of the alignment pattern, only the administrator can examine the form with this command. Other people may use the `lpstat(1)` command to examine the non-sensitive part of the form description.

Allowing and Denying Access to a Form

The `-u` option, followed by the argument `allow:`*login-ID-list* or `-u deny:`*login-ID-list* lets you determine which users will be allowed to specify a particular form with a print request. This option can be used with the `-F` or – option, each of which is described above under `Adding or Changing a Form`.

The *login-ID-list* argument may include any or all of the following constructs:

login-ID	A user on any system
system_name`!`*login-ID*	A user on system *system_name*
system_name`!all`	All users on system *system_name*
`all!`*login-ID*	A user on all systems
`all`	All users on all systems

The LP print service keeps two lists of users for each form: an "allow-list" of people allowed to use the form, and a "deny-list" of people that may not use the form. With the `-u allow` option, the users listed are added to the allow-list and removed from the deny-list. With the `-u deny`

option, the users listed are added to the deny-list and removed from the allow-list. (Both forms of the `-u` option can be run together with the `-F` or the – option.)

If the allow-list is not empty, only the users in the list are allowed access to the form, regardless of the content of the deny-list. If the allow-list is empty but the deny-list is not, the users in the deny-list may not use the form, (but all others may use it). All users can be denied access to a form by specifying `-f deny:all`. All users can be allowed access to a form by specifying `-f allow:all`. (This is the default.)

Setting an Alert to Mount a Form

The `-f` *form-name* option is used with the `-A` *alert-type* option to define an alert to mount the form when there are queued jobs which need it. If this option is not used to arrange alerting for a form, no alert will be sent for that form.

The method by which the alert is sent depends on the value of the *alert-type* argument specified with the `-A` option. The *alert-types* are:

`mail` Send the alert message using the `mail` command to the administrator.

`write` Write the message, using the `write` command, to the terminal on which the administrator is logged in. If the administrator is logged in on several terminals, one is arbitrarily chosen.

`quiet` Do not send messages for the current condition. An administrator can use this option to temporarily stop receiving further messages about a known problem. Once the form *form-name* has been mounted and subsequently unmounted, messages will again be sent when the number of print requests reaches the threshold specified by the `-Q` option.

`showfault` Attempt to execute a form alert handler on each system that has a print job for that form in the queue. The fault handler is `/etc/lp/alerts/form`. It is invoked with three parameters: *form_name*, `date`, *file_name*. *file_name* is the name of a file containing the form alert message.

`none` Do not send messages until the `-A` option is given again with a different *alert-type* (other than `quiet`).

shell-command Run the *shell-command* each time the alert needs to be sent. The shell command should expect the message in standard input. If there are blank spaces embedded in the command, enclose the command in quotes. Note that the `mail` and `write` values for this option are equivalent to the values `mail` *login-ID* and `write` *login-ID* respectively, where *login-ID* is the current name for the administrator. This will be the login name of the person submitting this command unless he or she has used the `su` command to change to another login-ID. If the `su` command has been used to change the user ID, then the *user-name* for the new ID is used.

`list` Display the type of the alert for the form on standard output. No change is made to the alert.

The message sent appears as follows:

```
The form form-name
needs to be mounted on the printer(s): printer (integer1 requests).
integer2 print requests await this form.
Use the ribbon-color ribbon. Use the print-wheel print wheel, if appropriate.
```

The printers listed are those that the administrator has specified as candidates for this form. The number *integer1* listed next to each printer is the number of requests eligible for the printer. The number *integer2* shown after the list of printers is the total number of requests awaiting the form. It will be less than the sum of the other numbers if some requests can be handled by more than one printer. The *ribbon-color* and *print-wheel* are those specified in the form description. The last line in the message is always sent, even if none of the printers listed use print wheels, because the administrator may choose to mount the form on a printer that does use a print wheel.

Where any color ribbon or any print wheel can be used, the statements above will read:

```
Use any ribbon.
Use any print-wheel.
```

If *form-name* is `any`, the *alert-type* defined in this command applies to any form for which an alert has not yet been defined. If *form-name* is `all`, the *alert-type* defined in this command applies to all forms.

If the `-W` *minutes* option is not given, the default procedure is that only one message will be sent per need to mount the form. Not specifying the `-W` option is equivalent to specifying `-W once` or `-W 0`. If *minutes* is a number greater than `0`, an alert will be sent at intervals specified by *minutes*.

If the `-Q` *requests* option is also given, the alert will be sent when a certain number (specified by the argument *requests*) of print requests that need the form are waiting. If the `-Q` option is not given, or the value of *requests* is `1` or `any` (which are both the default), a message is sent as soon as anyone submits a print request for the form when it is not mounted.

Listing the Current Alert

The `-f` option, followed by the `-A` option and the argument `list` is used to list the *alert-type* that has been defined for the specified form *form-name*. No change is made to the alert. If *form-name* is recognized by the LP print service, one of the following lines is sent to the standard output, depending on the type of alert for the form.

- `When` *requests* `requests are queued: alert with` *shell-command* `every` *minutes* `minutes`
- `When` *requests* `requests are queued: write to` *user-name* `every` *minutes* `minutes`
- `When` *requests* `requests are queued: mail to` *user-name* `every` *minutes* `minutes`
- `No alert`

The phrase `every` *minutes* `minutes` is replaced with `once` if *minutes* (`-W`*minutes*) is 0.

Terminating an Active Alert

The `-A quiet` option is used to stop messages for the current condition. An administrator can use this option to temporarily stop receiving further messages about a known problem. Once the form has been mounted and then unmounted, messages will again be sent when the number of print requests reaches the threshold *requests*.

Removing an Alert Definition

No messages will be sent after the `-A none` option is used until the `-A` option is given again with a different *alert-type*. This can be used to permanently stop further messages from being sent as any existing alert definition for the form will be removed.

Large File Behavior

See `largefile(5)` for the description of the behavior of `lpforms` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Exit Status

The following exit values are returned:

`0` Successful completion.

non-zero An error occurred.

Files

`/etc/lp/alerts/form` Fault handler for `lpform`.

Attributes

System Administration Guide: Basic Administration

Name lpget – get printing configuration

Synopsis

```
lpget [-k key] [destination... | list]
```

Description The `lpget` utility reads printing configuration information from the configuration databases in `$HOME/.printers`, `/etc/printers.conf`, `printers.conf.byname`, and `printers.org_dir` printer. This information, called a *configuration report*, is displayed to the standard output. See `printers(4)` and `printers.conf(4)` for information about the printer configuration databases.

`lpget` displays a configuration report for all keys for the specified destination or destinations by default. Use the `-k` option to display a configuration report for specific keys. Use the `list` operand to display a configuration report for all configured destinations.

Options The following option is supported:

`-k` *key* Displays a configuration report for *key*. See `printers.conf(4)` for information about specifying *key*.

Operands The following operands are supported:

destination Displays a configuration report for *destination*. Destination can be either a printer of a class of printers. See `lpadmin(1M)`. Specify *destination* using atomic or POSIX-style (*server*:*destination*) names. See `printers.conf(4)` for information regarding the naming conventions for atomic names and `standards(5)` for information concerning POSIX.

`list` Displays a configuration report for all configured destinations.

Examples

EXAMPLE 1 Displaying a Configuration Report for the `bsdaddr` Key

The following example displays a configuration report for the `bsdaddr` key for printer `catalpa`.

```
example% lpget -k bsdaddr catalpa
```

EXAMPLE 2 A Configuration Report for all Keys for all Configured Destinations

The following example displays a configuration report for all keys for all configured destinations.

```
example% lpget list
```

Exit Status The following exit values are returned:

`0` Successful completion.

non-zero An error occurred.

Files

`/etc/printers.conf`	System printer configuration database.
`$HOME/.printers`	User-configurable printer database.
`printers.conf.byname`	NIS version of `/etc/printers.conf`.
`printers.org_dir`	NIS+ version of `/etc/printers.conf`.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpcu
Stability Level	Stable

See Also `ldap(1)`, `lp(1)`, `lpc(1B)`, `lpq(1B)`, `lpr(1B)`, `lpstat(1)`, `lpadmin(1M)`, `lpset(1M)`, `printers(4)`, `printers.conf(4)`, `attributes(5)`, `standards(5)`

System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)

Notes Be mindful of the following if the LDAP database is used as the name service. If the `ldapclient(1M)` server is a replica LDAP server, LDAP printer database updates may not appear immediately, as the replica server may not not have been updated by the master server and can be out of sync. For example, a printer that you deleted by using `lpset(1M)` may still appear in the printer list you display with `lpget` until the replica is updated from the master. Replica servers vary as to how often they are updated from the master. Refer to the *System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)* for more information on LDAP replication.

Name lpmove – move print requests

Synopsis

```
lpmove [request-ID] destination
lpmove source destination
```

Description The `lpmove` command moves print requests queued by `lp(1)` or `lpr(1B)` between destinations.

The first form of `lpmove` moves specific print requests (*request-ID*) to a specific *destination*.

The second form of the `lpmove` command moves all print requests from one destination (*destination1*) to another (*destination2*). This form of `lpmove` also rejects new print requests for *destination1*.

`lpmove` moves individual requests or entire queues only within an instance of a print service, not between a local and a remote queues or local queues on different instances of a print service. Requests can only be moved if the print service or protocol supports it. The LP print server and IPP print protocol both support moving requests between queues. The BSD print protocol does not.

When moving requests, `lpmove` does not check the acceptance status of the destination to which the print requests are being moved (see `accept(1M)`). `lpmove` does not move requests that have options (for example, content type or requiring a special form) that cannot be handled by the new destination.

Operands The following operands are supported:

request-ID The specific print request to be moved. Specify *request-ID* as the identifier associated with a print request as reported by `lpstat`. See `lpstat(1)`.

destination The name of the printer or class of printers (see `lpadmin(1M)`) to which `lpmove` moves a *specified* print request. Specify *destination* using atomic, URI-style (*scheme*://*endpoint*), POSIX-style (*server*:*destination*) syntax.

source The name of the destination from which `lpmove` moves *all* print requests. Specify *destination* using atomic, URI-style (*scheme*://*endpoint*), POSIX-style (*server*:*destination*) syntax.

See `printers.conf(4)` for information regarding the naming conventions for atomic names and `standards(5)` for information regarding POSIX.

Exit Status The following exit values are returned:

`0` Successful completion.

non-zero An error occurred.

Files

`/etc/printers.conf`	System printer configuration database
`$HOME/.printers`	User-configurable printer database
`ou=printers`	LDAP version of `/etc/printers.conf`

`printers.conf.byname` NIS version of `/etc/printers.conf`

`printers.org_dir` NIS+ version of `/etc/printers.conf`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWlp-cmds
Interface Stability	Obsolete

See Also `lp(1)`, `lpr(1B)`, `lpstat(1)`, `accept(1M)`, `lpadmin(1M)`, `lpsched(1M)`, `printers.conf(4)`, `attributes(5)`, `standards(5)`

System Administration Guide: Printing

Notes When IPP is in use, the user is prompted for a passphsrase if the remote print service is configured to require authentication.

Name lpsched – start the LP print service

Synopsis

```
lpsched [-f num_filters] [-n num_notifiers] [-p fd_limit]
     [-r reserved_fds]
```

Description The `lpsched` command starts or restarts the LP print service.

The `lpshut` command stops the LP print service. Printers that are restarted using `lpsched` reprint (in their entirety) print requests that were stopped by `lpshut`. See `lpshut(1M)`.

It is recommended that you start and stop the LP print service using `svcadm(1M)`. See `NOTES`.

Options The following options are supported:

`-f` *num_filters* Specifies the number of concurrent slow filters that may be run on a print server. A default value of `1` is used if none is specified. Depending on server configuration, a value of `1` may cause printers to remain idle while there are jobs queued to them.

`-n` *num_notifiers* Specifies the number of concurrent notification processes that can run on a print server. A default value of `1` is used when none is specified.

`-p` *fd_limit* Specifies the file descriptor resource limit for the `lpsched` process. A default value of `4096` is used if none is specified. On extremely large and active print servers, it may be necessary to increase this value.

`-r` *reserved_fds* Specifies the number of file descriptors that the scheduler reserves for internal communications under heavy load. A default value of `2` is used when none is specified. It should not be necessary to modify this value unless instructed to do so when troubleshooting problems under high load.

Exit Status The following exit values are returned:

`0` Successful completion.

non-zero An error occurred.

Files `/var/spool/lp/*` LP print queue.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpsu

See Also `lp(1)`, `svcs(1)`, `lpstat(1)`, `lpadmin(1M)`, `lpmove(1M)`, `lpshut(1M)`, `svcadm(1M)`, `attributes(5)`, `smf(5)`

System Administration Guide: Basic Administration

Notes The `lpsched` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/application/print/server
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

Name lpset – set printing configuration in /etc/printers.conf or other supported databases

Synopsis

```
lpset [-n system | nisplus | fnsldap] [-x]
     [ [-D binddn] [-w passwd] [-h ldaphost]]
     [-a key=value] [-d key] destination
```

Description The `lpset` utility sets printing configuration information in the system configuration databases. Use `lpset` to create and update printing configuration in `/etc/printers.conf`, or `printers.org_dir` (NIS+). See `nsswitch.conf(4)` and `printers.conf(4)`.

Only a superuser or a member of Group 14 may execute `lpset`.

Options The following options are supported:

`-n system|nisplus|ldap` Create or update the configuration information for the *destination* entry in `/etc/printers.conf`, `printers.org_dir` (NIS+), or LDAP printer contexts. `system` specifies that the information is created or updated in `/etc/printers.conf`. `nisplus` specifies that the information is created or updated in the `printers.org_dir` NIS+ table. `ldap` specifies that the information is written to an LDAP server. See Notes.

If `-n` is not specified, `system` is the default.

`-x` Remove all configuration for the *destination* entry from the database specified by the `-n` option.

`-a` *key*=*value* Configure the specified *key*=*value* pair for the *destination*. See `printers.conf(4)` for information regarding the specification of *key*=*value* pairs.

`-d` *key* Delete the configuration option specified by *key* for the *destination* entry. See `printers.conf(4)` for information regarding the specification of *key* and *key*=*value* pairs.

`-D binddn` Use the distinguished name (DN) `binddn` to bind to the LDAP directory server.

`-w passwd` Use `passwd` as the password for authentication to the LDAP directory server.

`-h ldaphost` Specify an alternate host on which the LDAP server is running. This option is only used when `ldap` is specified as the naming service. If this option is not specified, the default is the current host system.

Operands The following operand is supported:

destination Specifies the entry in `/etc/printers.conf`, `printers.org_dir`, or LDAP, in which to create or modify information. *destination* names a printer of class of

printers. See lpadmin(1M). Each entry in printers.conf describes one destination. Specify *destination* using atomic names. POSIX-style destination names are not acceptable. See printers.conf(4) for information regarding the naming conventions for atomic names and standards(5) for information regarding POSIX.

Examples

EXAMPLE 1 Removing All Existing Printing Configuration Information

The following example removes all existing printing configuration information for destination dogs from /etc/printers.conf:

```
example% lpset -x dogs
```

EXAMPLE 2 Setting a key=value Pair

The following example sets the user-equivalence=true *key=value* pair for destination tabloid in the NIS+ context:

```
example% lpset -n nisplus -a user-equivalence=true tabloid
```

EXAMPLE 3 Setting a key=value Pair in LDAP

```
example% lpset -n ldap -h ldapl.xyz.com -D "cn=Directory Manager" \
   -w passwd -a key1=value1 printer1
```

Exit Status

The following exit values are returned:

0	Successful completion.
non-zero	An error occurred.

Files

/etc/printers.conf	System configuration database.
printer.org_dir (NIS+)	NIS+ version of /etc/printers.conf.

Attributes

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpcu
Stability Level	Stable

See Also

ldap(1), lp(1), lpc(1B), lpq(1B), lpr(1B), lpstat(1), ldapclient(1M), lpadmin(1M), lpget(1M), nsswitch.conf(4), printers(4), printers.conf(4), attributes(5), standards(5)

System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)

Notes If the `ldap` database is used, the printer administrator should be mindful of the following when updating printer information.

1. Because the domain information for the printer being updated is extracted from the `ldapclient(1M)` configuration, the LDAP server being updated must host the same domain that is used by the current `ldapclient(1M)` server.
2. If the LDAP server being updated is a replica LDAP server, the updates will be referred to the master LDAP server and completed there. The updates might be out of sync and not appear immediatedly, as the replica server may not have been updated by the master server. For example, a printer that you deleted by using `lpset` may still appear in the printer list you display with `lpget` until the replica is updated from the master. Replica servers vary as to how often they are updated from the master. See *System Administration Guide: Printing* for information on LDAP server replication.
3. Although users can use the LDAP command line utilities `ldapadd(1)` and `ldapmodify(1)` to update printer entries in the directory, the preferred method is to use `lpset`. Otherwise, if the `ldapadd` and `ldapmodify` utilities are used, the administrator must ensure that the `printer-name` attribute value is unique within the `ou=printers` container on the LDAP server. If the value is not unique, the result of modifications done using `lpset` or the Solaris Print Manager, `printmgr(1M)` may be unpredictable.

Name lpshut – stop the LP print service

Synopsis

```
lpshut
```

Description The `lpshut` command stops the LP print service.

Printers that are printing when `lpshut` is invoked stop printing. Start or restart printers using `lpsched(1M)`.

Exit Status The following exit values are returned:

`0` Successful completion.

non-zero An error occurred.

Files `/var/spool/lp/*` LP print queue.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpsu

See Also `lp(1)`, `lpstat(1)`, `lpadmin(1M)`, `lpmove(1M)`, `lpsched(1M)`, `attributes(5)`

System Administration Guide: Basic Administration

Name lpsystem – register remote systems with the print service

Description The `lpsystem` command is obsolete, and could be removed at any time. The print system no longer uses the information generated by `lpsystem`. See `lpadmin(1M)`, `lpusers(1M)` or `printers.conf(4)` for equivalent functionality.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpcu
Stability Level	Obsolete*

* This command could be removed at any time.

See Also `lpadmin(1M)`, `lpusers(1M)`, `printers.conf(4)`, `attributes(5)`

Name lpusers – set printing queue priorities

Synopsis

```
lpusers -d priority-level
lpusers -q priority-level -u login-ID-list
lpusers -u login-ID-list
lpusers -q priority-level
lpusers -l
```

Description The `lpusers` command sets limits to the queue priority level that can be assigned to jobs submitted by users of the LP print service.

The first form of the command (with `-d`) sets the system-wide priority default to *priority-level*, where *priority-level* is a value of 0 to 39, with 0 being the highest priority. If a user does not specify a priority level with a print request (see `lp(1)`), the default priority level is used. Initially, the default priority level is 20.

The second form of the command (with `-q` and `-u`) sets the default highest *priority-level* (0-39) that the users in *login-ID-list* can request when submitting a print request. The *login-ID-list* argument may include any or all of the following constructs:

login-ID	A user on any system
system_name`!`*login-ID*	A user on the system *system_name*
system_name`!all`	All users on system *system_name*
`all!`*login-ID*	A user on all systems
`all`	All users on all systems

Users that have been given a limit cannot submit a print request with a higher priority level than the one assigned, nor can they change a request that has already been submitted to have a higher priority. Any print requests submitted with priority levels higher than allowed will be given the highest priority allowed.

The third form of the command (with `-u`) removes any explicit priority level for the specified users.

The fourth form of the command (with `-q`) sets the default highest priority level for all users not explicitly covered by the use of the second form of this command.

The last form of the command (with `-l`) lists the default priority level and the priority limits assigned to users.

Options The following options are supported:

`-d` *priority-level*	Set the system-wide priority default to *priority-level*.

`-l`	List the default priority level and the priority limits assigned to users.
`-q` *priority-level*	Set the default highest priority level for all users not explicitly covered.
`-q` *priority-level* `-u` *login-ID-list*	Set the default highest *priority-level* that the users in *login-ID-list* can request when submitting a print request.
`-u` *login-ID-list*	Remove any explicit priority level for the specified users.

Exit Status The following exit values are returned:

`0`	Successful completion.
non-zero	An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpsu

See Also `lp(1)`, `attributes(5)`

Name lu – FMLI-based interface to Live Upgrade functions

Synopsis `/usr/sbin/lu`

Description Sun no longer recommends use of the `lu` command. The `lu` command displays a character user interface (CUI). The underlying command sequence for the CUI--typically `lucreate`, `luupgrade`, and `luactivate`--is straightforward to use. The `SEE ALSO` section below highlights the full Solaris Live Upgrade command set.

The `lu` program is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `lu` program is a Forms and Menu Language Interpreter-based user interface. (See `fmli(1)` for a description of the Forms and Menu Language Interpreter.) `lu` enables you to create and upgrade boot environments (BEs) and perform other administrative tasks on BEs. The `lu` program performs a subset of the functions provided by the Live Upgrade command-line utilities.

Users of `lu` should be aware of the following:

- `lu` is a deprecated interface. It will be replaced in the future and should not be depended on for critical functionality.
- All new Live Upgrade features are being implemented in the Live Upgrade command–line utilities. No new features are being made available in `lu`.
- The `lu` command is not internationalized. It will not be internationalized in a future release.

`lu` should be used for learning or experimenting only. For any production use or to use the full capabilities of Live Upgrade, use the Live Upgrade command-line utilities.

Invocation of the `lu` command requires root privileges.

The `lu` command accepts no arguments. After invoking `lu`, you receive a display with the following options:

Activate — Activate a boot environment. This option designates that the system boot from the specified BE upon next reboot. This option is equivalent to the command-line `luactivate(1M)` utility.

Cancel — Cancel a copy job. Live Upgrade allows you to schedule the copy, upgrade, and flash functions (all described below) at a later time. The cancel function enables you to cancel a scheduled job. This function is equivalent to the command-line `lucancel(1M)` utility.

Compare — Compare the contents of BEs. Enables you to obtain a detailed comparison of two BEs. Equivalent to the command-line `lucompare(1M)` utility.

Copy	Start/schedule a copy. Copies the contents of one BE to another. Equivalent of the command-line `lumake(1M)` utility. At any time, you can have only one Live Upgrade operation scheduled.
Create	Create a boot environment. Implements a subset of the functions performed by the command-line `lucreate(1M)` utility.
Current	Display the name of the current boot environment. Equivalent of the command-line `lucurr(1M)` utility.
Delete	Delete a boot environment. Equivalent of the command-line `ludelete(1M)` utility.
List	List the file systems of a boot environment. Equivalent of the command-line `lufslist(1M)` utility.
Rename	Change the name of a boot environment. Equivalent of the command-line `lurename(1M)` utility.
Status	List the status of all boot environments. Equivalent of the command-line `lustatus(1M)` utility.
Upgrade	Upgrade a boot environment or upgrade the OS on an inactive BE. This option enables you to upgrade to a new operating system or install new packages or patches on a specified BE. Implements a subset of the functions performed by the command-line `luupgrade(1M)` utility. Note that if you are performing an upgrade that requires more than one CD, you must use the `-i` option of `luupgrade`.
Flash	Flash a boot environment. This option enables you to install an operating system on a BE from a flash archive. You can perform the same function with `luupgrade(1M)`.
Help	Displays help information. There are also context-specific help screens for many of the options.
Exit	Exit `lu`.

Navigation You navigate through `lu`'s various screens using arrow keys and function keys (usually F2 through F9 on the keyboard of a Sun desktop system). Available key functions are displayed at the base of the `lu` screen. You can use Ctrl-F, plus a number key, to duplicate a function key. For example, press Ctrl-F and the number key `2` to duplicate the F2 key.

In a screen for a given option, you can press Esc to obtain context-specific help.

Display Issues When viewing the FMLI interface remotely, such as over a `tip` line, you might need to set the `TERM` environment variable to `VT220`. When using the FMLI interface in a CDE environment use `dtterm`, rather than `xterm`, as the value of the `TERM` variable.

The `lu` command supports only single-byte environments.

Common Functions

Most of the options listed above offer the following functions. These functions are accessible through function keys indicated at the base of the screen.

Choice — Available to you whenever you have a field that can be filled in. Pressing the Choice function key gives you a popup screen displaying a list of alternatives. For example, for options involving copying or upgrading BEs, you receive a list of available BEs. You can then use arrow and function keys to make a selection from this popup. The choice function is useful because it prevents you from selecting an invalid alternative. In our example, it prevents you from choosing a BE that is not available for a copy or upgrade operation. Such non-availability might occur when a BE is in the midst of an upgrade.

Cancel — Cancel an operation.

Save — Proceed with an operation.

Other Functions

The "Create" option, described above, offers the following functions:

Split — Split a file system. For example, you can split a `/` file system into `/`, `/usr`, and `/var`. To split a file system, you must have disk slices available on which to mount the separated file system(s). If you do not, `lu` invokes the `format(1M)` utility, in which you can use the `partition` option to create a new disk slice.

Merge — Join one or more file systems with its (or their) parent file system. For example, using a source BE that has separate `/`, `/usr`, and `/var` file systems, you can merge these file systems under `/` on a target BE.

Files

`/etc/lutab` — list of BEs on the system

Solaris Installation Guide

Warnings

The `lu` command is a deprecated interface. See DESCRIPTION.

Name luactivate – activate a boot environment

Synopsis

```
/usr/sbin/luactivate [-l error_log] [-o outfile] [-s]
     [BE_name] [-X]
```

Description The `luactivate` command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `luactivate` command, with no arguments, displays the name of the boot environment (BE) that will be active upon the next reboot of the system. When an argument (a BE) is specified, `luactivate` activates the specified BE.

`luactivate` activates a BE by making the BE's root partition bootable. On an x86 machine, this might require that you take steps following the completion of `luactivate`. If so, `luactivate` displays the correct steps to take.

To successfully activate a BE, that BE must meet the following conditions:

- The BE must have a status of "complete," as reported by `lustatus(1M)`.
- If the BE is not the current BE, you cannot have mounted the partitions of that BE (using `lumount(1M)` or `mount(1M)`).
- The BE you want to activate cannot be involved in an `lucompare(1M)` operation.

After activating a specified BE, `luactivate` displays the steps to be taken for fallback in case of any problem on the next reboot. Make note of these instructions and follow them exactly, if necessary.

Note – Before booting a new BE, you must run `luactivate` to specify that BE as active. `luactivate` performs a number of tasks, described below, that ensure correct operation of the BE. In some cases, a BE is not bootable until after you have run the command.

The `luactivate` command performs the following tasks:

- The first time you boot from a newly created BE, Live Upgrade software synchronizes this BE with the BE that was last active. (This is not necessarily the BE that was the source for the newly created BE.) *Synchronize* here means that certain system files and directories are copied from the last-active BE to the BE being booted. (See `synclist(4)`.) Live Upgrade software does not perform this synchronization after a BE's initial boot, unless you use the `-s` option, described below.
- If `luactivate` detects conflicts between files that are subject to synchronization, it issues a warning and does not perform the synchronization for those files. Activation can complete successfully, in spite of such a conflict. A conflict can occur if you upgrade one BE or another to a new operating system version or if you modify system files (for example, `/etc/passwd`) on one of the BEs.

- `luactivate` checks to see whether upgrade problems occurred. For example, packages required for the correct operation of the operating system might be missing. This package check is done for the global zone as well as all non-global zones inside of the BE. The command can issue a warning or, if a BE is incomplete, can refuse activation.
- `luactivate` determines whether the bootstrap program requires updating and takes steps to update if necessary. If a bootstrap program changed from on operating release to another, an incorrect bootstrap program might render an upgraded BE unbootable. See `installboot(1M)`.
- `luactivate` modifies the root partition ID on a Solaris x86 disk to enable multiple BEs to reside on a single disk. In this configuration, if you do not run `luactivate`, booting of the BE will fail. See `fmthard(1M)` and `dkio(7I)`.

The `luactivate` command requires root or equivalent privileges.

Options The `luactivate` command has the following options:

`-l` *error_log* Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.

`-o` *outfile* All command output is sent to *outfile*, in addition to where it is sent in your current environment.

`-s` Causes synchronization to occur (see DESCRIPTION) even if next boot of a specified BE is not the first boot of that BE. Use this option with great caution, because you might not be aware or in control of changes that might have occurred in the last-active BE.

If using `-s`, take special care when booting to an earlier release of Solaris than what is installed on the last-active BE. For example, consider that the last-active BE contains Solaris 9 and you want to activate a BE that contains Solaris 2.6. If you forced synchronization with the `-s` option, the BE containing Solaris 2.6 might be synchronized with files that, while compatible with Solaris 9, might not work under Solaris 2.6.

`-X` Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.`<*num*>, where <*num*> is the version number of the DTD file.

Operands *BE_name* Name of the BE to be activated.

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Files

`/etc/lutab`	list of BEs on the system
`/usr/share/lib/xml/dtd/lu_cli.dtd.<num>`	Live Upgrade DTD (see `-X` option)

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWlu

See Also `lucancel(1M)`, `lucompare(1M)`, `lucreate(1M)`, `lucurr(1M)`, `ludelete(1M)`, `ludesc(1M)`, `lufslist(1M)`, `lumake(1M)`, `lumount(1M)`, `lurename(1M)`, `lustatus(1M)`, `luupgrade(1M)`, `lutab(4)`, `attributes(5)`, `live_upgrade(5)`, `zones(5)`

Notes After entering `init 6`, if an activated BE fails to boot, consult `/var/svc/log/rc6.log` on the current BE for possible obstacles.

Name lucancel – cancel a scheduled Live Upgrade copy/create procedure

Synopsis

```
/usr/sbin/lucancel [-l error_log] [-o outfile] [-X]
```

Description The `lucancel` command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `lucancel` command cancels a boot environment (BE) creation or upgrade that was scheduled in the FMLI-based interface, `lu(1M)`, or the repopulation of a BE, scheduled with `lumake(1M)`. Note that Sun recommends against the use of the `lu` command.

`lucancel` does not cancel a job that is active (that is, is in the process of creation or repopulation).

The `lucancel` command requires root privileges.

Options The `lucancel` command has the following options:

`-l` *error_log* Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.

`-o` *outfile* All command output is sent to *outfile*, in addition to where it is sent in your current environment.

`-X` Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.`<*num*>, where <*num*> is the version number of the DTD file.

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Files `/etc/lutab` list of BEs on the system

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWluu

See Also `luactivate(1M)`, `lucompare(1M)`, `lucreate(1M)`, `lucurr(1M)`, `ludelete(1M)`, `ludesc(1M)`, `lufslist(1M)`, `lumake(1M)`, `lumount(1M)`, `lurename(1M)`, `lustatus(1M)`, `luupgrade(1M)`, `lutab(4)`, `attributes(5)`, `live_upgrade(5)`

Name lucompare – compare boot environments

Synopsis

```
/usr/sbin/lucompare [-i infile | -t] [-o outfile] BE_name
     [-X]

/usr/sbin/lucompare [-C file [-o outfile]] [-X]
```

Description The `lucompare` command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `lucompare` command compares the contents of the current boot environment (BE) with the contents of another BE. With the `-C` option, `lucompare` compares file statistics so that you can determine which files have changed on a BE since a specified time, such as the creation time of a BE. A specified BE must be inactive and in the complete state, as reported by the `lustatus(1M)` command. Also, a BE cannot have a copy job scheduled, which is also reported by `lustatus(1M)`. A specified BE cannot have any partitions mounted with `lumount(1M)` or `mount(1M)`.

For each file system defined for a specified BE, `lucompare` compares all files with the files with the same pathnames in the current BE. The files present in the active BE, but not in the specified BE, and vice-versa, are reported. You also have the option to specify a list of files to be compared.

If you specify the `-C` option, instead of doing an absolute comparison of the current BE with a target BE, `lucompare` compares the files in a specified BE with the list of files recorded in a file. When a BE is created, `lucreate(1M)` creates a file named :<*BE_name*> in `/etc/lu/compare`. You can use the `-C` option to compare the files in a specified BE to this snapshot in `/etc/lu/compare` or you can compare the BE to a file previously created with the `-o` option. Comparing a BE to its own snapshot in `/etc/lu/compare` enables you to determine which files have changed on the BE since its creation.

By default, the output of `lucompare` is written to stdout. With the `-C` option, you must use the `-o` option to specify an output file. The output for `lucompare` is a list of files that differ in permissions, owner, group, or sum, along with the reason for difference. The output format is shown below:

```
> active BE
< BE_name
reason
> file_name:owner:group:number_of_links:mode:type: size
or major_minor number:checksum
< file_name:owner:group:number_of_links:mode:type: size
or major_minor number:checksum
```

The above fields are obtained from the `stat(2)` structure of the file.

The *type* field can be one of the following:

`SYMLINK` symbolic link

FIFO	FIFO file
CHRSPC	character special
BLKSPC	block special
DIR	directory
REGFIL	regular file
UNKNOW	unknown file type

`lucompare` computes checksums only if the file on the specified BE matches its counterpart on the active BE in all of the fields described above. If the checksums differ, `lucompare` appends the differing checksums to the entries for the compared files.

The `lucompare` command requires root privileges.

Options The `lucompare` command has the following options:

`-C` *file*	Compare file statistics of BE with those recorded in *file*. *file* can be the snapshot created at BE creation time, `/etc/lu/compare/:`<*BE_name*>, or a file previously created with the `-o` option. You must use the `-o` option with this option.
`-i` *infile*	Compare files listed in *infile*. The files to be compared should be an absolute filename. If the entry in the file is a directory, then comparison is recursive with respect to the directory. Mutually exclusive of `-t`.
`-o` *outfile*	Send output of differences to *outfile*. You must use this option if you use `-C`.
`-t`	Compare only nonbinary files. This is achieved by performing a `file(1)` command on each file in the tree walk and only comparing text files. Mutually exclusive of `-i`.
`-X`	Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.`<*num*>, where <*num*> is the version number of the DTD file.

Operands

BE_name	Name of the BE to which the active BE will be compared. You cannot specify a BE that is involved in another Live Upgrade operation, or specify a BE for which you have mounted partitions (using `lumount(1M)` or `mount(1M)`).

Examples **EXAMPLE 1** Checking Differences Since BE Creation

The following command lists the differences in the BE `s8u5` between its creation time and the present.

```
# lucompare -C /etc/lu/compare/:s8u5 -o /var/tmp/compare.out s8u5
```

EXAMPLE 1 Checking Differences Since BE Creation *(Continued)*

Note that `/etc/lu/compare/:s8u5` is the file created by `lucreate` upon creation of a BE. The list of differences is sent to `/var/tmp/compare.out`.

Exit Status

The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Files

`/etc/lutab`	list of BEs on the system
`/usr/share/lib/xml/dtd/lu_cli.dtd.`*<num>*	Live Upgrade DTD (see `-X` option)

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWluu

See Also

`luactivate(1M)`, `lucancel(1M)`, `lucreate(1M)`, `lucurr(1M)`, `ludelete(1M)`, `ludesc(1M)`, `lufslist(1M)`, `lumake(1M)`, `lumount(1M)`, `lurename(1M)`, `lustatus(1M)`, `luupgrade(1M)`, `lutab(4)`, `attributes(5)`, `live_upgrade(5)`

Notes

The `lucompare` command makes no attempt to reconcile any differences it detects between BEs.

Name lucreate – create a new boot environment

Synopsis

```
/usr/sbin/lucreate [-A BE_description] [-c BE_name]
     [-C ( boot_device | - )] -n BE_name
     [-f exclude_list_file] [-I] [-l error_log]
     [-o outfile] [-s ( - | source_BE_name )]
     [ [-M slice_list_file [-M]...]
     [-m mount_point:device [,volume]:fs_options[:zonename] [-m...]]] |
     [-p zfs_root_pool]
     [-x exclude [-x]...] [-X] [-y include [-y]...]
     [-Y include_list_file] [-z filter_list]
```

Description The `lucreate` command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature and its associated terminology.

The `lucreate` command offers a set of command line options that enable you to perform the following functions:

- Create a new boot environment (BE), based on the current BE.
- Create a new BE, based on a BE other than the current BE.
- Join or separate the file systems of a BE onto a new BE. For example, join `/var` and `/opt` under `/`, or separate these directories to be mounted under different disk slices.
- Specify separate file systems belonging to a particular zone inside of the new BE. (See `zones(5)`.)
- Create the file systems for a BE, but leave those file systems unpopulated.

If `lucreate` is invoked without the `-m`, `-M`, or `-p` options (described below), it brings up an FMLI-based interface that provides curses-based screens for Live Upgrade administration. Note that the FMLI-based interface does not support all of the Live Upgrade features supported by the command-line version of `lucreate`. Also, Sun is not committed to ongoing development of the FMLI-based interface.

With the `-p` option, `lucreate` supports the creation of BEs on ZFS file systems. The source BE can be a UFS root file system on a disk slice or a ZFS file system in an existing ZFS storage pool. `lucreate` provides a convenient means of migrating a BE from a UFS root file system to a ZFS root file system. You cannot create a BE on a UFS file system from a source BE on a ZFS file system.

The creation of a BE includes selecting the disk or device slices for all the mount points of the BE. Slices can be physical disks or logical devices, such as Solaris Volume Manager volumes. You can also change the mount points of the BE using the SPLIT and MERGE functions of the FMLI-based configuration screen.

Upon successful creation of a BE, you can use lustatus(1M) to view the state of that BE and lufslist(1M) to view the BE's file systems. You can use luupgrade(1M) to upgrade the OS on that BE and luactivate(1M) to make a BE active, that is, designate it as the BE to boot from at the next reboot of the system.

Note – Before booting a new BE, you must run `luactivate` to specify that BE as active. `luactivate` performs a number of tasks that ensure correct operation of the BE. In some cases, a BE is not bootable until after you have run the command. See luactivate(1M) for a list of the operations performed by that command.

The `lucreate` command makes a distinction between the file systems that contain the OS—`/`, `/usr`, `/var`, and `/opt`—and those that do not, such as `/export`, `/home`, and other, user-defined file systems. The file systems in the first category cannot be shared between the source BE and the BE being created; they are always copied from the source BE to the target BE. By contrast, the user-defined file systems are shared by default. For Live Upgrade purposes, the file systems that contain the OS are referred to as non-shareable (or *critical*) file systems; other file systems are referred to as shareable. A non-shareable file system listed in the source BE's `vfstab` is copied to a new BE. For a shareable file system, if you specify a destination slice, the file system is copied. If you do not, the file system is shared.

When migrating from a UFS-based BE to a ZFS-based BE, you cannot migrate shared UFS file systems to ZFS. Also, when the source and destination BEs are both ZFS-based, you cannot copy shared file systems. Such file systems can only be shared.

The `lucreate` command copies all non-global zones from the current BE to the BE being created. For non-global zones residing in a non-shared file system, the new BE gets a copy of the zone in its non-shared file system. For non-global zones residing in a shared file system, `lucreate` makes a copy of the zone for the new BE in that shared file system and uses a different zonepath (see zoneadm(1M)) for the zone. The zonepath used is of the form *zonepath*`-newBE`. This prevents BEs from sharing the same non-global zone in the shared file system. When the new BE gets booted, the zone in the shared file system belonging to the new BE has its zonepath renamed to *zonepath* and the zone in the shared file system belonging to the original BE has its zonepath renamed to *zonepath*`-origBE`.

If a zone exists in a non-shared file system, the zone is automatically copied when the UFS root file system is migrated to a ZFS root file system. If a zone exists in a shared UFS file system, to migrate to a ZFS root file system, you must first upgrade the zone, as in previous Solaris releases. A zone in a non-shared file system within a ZFS BE is cloned when upgrading to a ZFS BE within the same ZFS pool.

The `lucreate` command supports a limited subset of Solaris Volume Manager functions. In particular, using `lucreate` with the `-m` option, you can:

- Create a mirror.
- Detach existing SVM concatenations from mirrors. Similarly, you can attach existing Solaris Volume Manager concatenations to mirrors. These can be mirrors that were created in Solaris Volume Manager or those created by `lucreate`.

- Create a single-slice concatenation and attach a single disk slice to it.
- Detach a single disk slice from a single-slice concatentation.
- Attach multiple single-slice concatenations to a mirror. `lucreate` can attach as many of these concatenations as are allowed by Solaris Volume Manager.

`lucreate` does not allow you to attach multiple disk slices or multiple storage devices to a concatenation. Similarly, it does not allow you to detach multiple slices or devices from a concatenation.

If you use Solaris Volume Manager volumes for boot environments, it is recommended that you use `lucreate` rather than Solaris Volume Manager commands to manipulate these volumes. The Solaris Volume Manager software has no knowledge of boot environments, whereas the `lucreate` command contains checks that prevent you from inadvertently destroying a boot environment by, for example, overwriting or deleting a Solaris Volume Manager volume.

If you have already used Solaris Volume Manager software to create complex Solaris Volume Manager volumes (for example, RAID-5 volumes), Live Upgrade will support the use of these. However, to create and manipulate these complex objects, you must use Solaris Volume Manager software. As described above, the use of Solaris Volume Manager software, rather than the `lucreate` command, entails the risk of destroying a boot environment. If you do use Solaris Volume Manager software, use `lufslist(1M)` to determine which devices are in use for boot environments.

Except for a special use of the `-s` option, described below, you must have a source BE for the creation of a new BE. By default, it is the current BE. You can use the `-s` option to specify a BE other than the current BE.

When creating a new BE on a UFS file system, `lucreate` enables you to exclude and include certain files from the source BE. You perform this inclusion or exclusion with the `-f`, `-x`, `-y`, `-Y`, and `-z` options, described below. See the subsection on combining these options, following OPTIONS, below.

By default, all swap partitions on a UFS-based source BE are shared with a UFS-based target BE. For UFS-based target BEs, you can use the `-m` option (see below) to specify an additional or new set of swap partitions on the source BE for sharing with the target. When a UFS-based source BE is copied to a ZFS target BE, `lucreate` creates in the new BE a swap area and a dump device on separate ZFS volumes. When both the source and target BEs are ZFS-based and are in the same pool, both BEs use the same swap volume. If source and target are in different pools, a new swap volume is created in the pool of the target BE.

The `lucreate` command allows you to assign a description to a BE. A description is an optional attribute of a BE that can be of any format or length. It might be, for example, a text string or binary data. After you create a BE, you can change a BE description with the `ludesc(1M)` utility.

The `lucreate` command requires root privileges or that you assume the Primary Administrator role.

Options The `lucreate` command has the options listed below. Note that a BE name must not exceed 30 characters in length and must consist only of alphanumeric characters and other ASCII characters that are not special to the Unix shell. See the "Quoting" section of `sh(1)`. The BE name can contain only single-byte, 8–bit characters; it cannot contain whitespace characters.

Omission of `-m`, `-M`, and `-p` options (described below) in an `lucreate` command line invokes the FMLI-based interface, which allows you to select disk or device slices for a UFS-based BE.

`-A` *BE_description*
Assigns the *BE_description* to a BE. *BE_description* can be a text string or other characters that can be entered on a Unix command line. See `ludesc(1M)` for additional information on BE descriptions.

`-c` *BE_name*
Assigns the name *BE_name* to the current BE. This option is not required and can be used only when the first BE is created. For the first time you run `lucreate`, for a UFS-based BE, if you omit `-c`, `lucreate` supplies a default name according to the following rules:

1. If the physical boot device can be determined, the base name of that device is used to name the new boot environment. For example, if the physical boot device is `/dev/dsk/c0t0d0s0`, `lucreate` names the new boot environment `c0t0d0s0`.
2. If the physical boot device cannot be determined, the operating system name (from `uname -s`) and operating system release level (from `uname -r`) are combined to produce the name of the new boot environment. For example, if `uname -s` returns `SunOS` and `uname -r` returns `5.9`, then `lucreate` assigns the name `SunOS5.9` to the new boot environment.
3. If `lucreate` can determine neither boot device nor operating system name, it assigns the name `current` to the new boot environment.

For a ZFS-based BE, the default BE name is the base name of the root file system.

If you use the `-c` option after the first boot environment is created, the option is ignored if the name specified is the same as the current boot environment name. If the name is different, `lucreate` displays an error message and exits.

`-C` (*boot_device* | –)
Provided for occasions when `lucreate` cannot figure out which physical storage device is your boot device. This might occur, for example, when you have a mirrored root device on the source BE on an x86 machine. The `-C` specifies the physical boot device from which the source BE is booted. Without this option, `lucreate` attempts to determine the physical device from which a BE boots. If the device on which the root file system is located is not a physical disk (for example, if root is on a Solaris Volume Manager volume) and `lucreate` is able to make a reasonable guess as to the physical device, you receive the query:

```
Is the physical device devname the boot device for
the logical device devname?
```

If you respond `y`, the command proceeds.

If you specify `-C` *boot_device*, `lucreate` skips the search for a physical device and uses the device you specify. The – (hyphen) with the `-C` option tells `lucreate` to proceed with whatever it determines is the boot device. If the command cannot find the device, you are prompted to enter it.

If you omit `-C` or specify `-C` *boot_device* and `lucreate` cannot find a boot device, you receive an error message.

Use of the `-C` – form is a safe choice, because `lucreate` either finds the correct boot device or gives you the opportunity to specify that device in response to a subsequent query.

`-f` *exclude_list_file*
Use the contents of *exclude_list_file* to exclude specific files (including directories) from the newly created BE. *exclude_list_file* contains a list of files and directories, one per line. If a line item is a file, only that file is excluded; if a directory, that directory and all files beneath that directory, including subdirectories, are excluded.

This option is not supported when the source BE is on a ZFS file system.

`-I`
Ignore integrity check. Prior to creating a new BE, `lucreate` performs an integrity check, to prevent you from excluding important system files from the BE. Use this option to override this integrity check. The trade-off in use of this option is faster BE creation (with `-I`) versus the risk of a BE that does not function as you expect.

`-l` *error_log*
Error messages and other status messages are sent to *error_log*, in addition to where they are sent in your current environment.

`-m` *mount_point*:*device*[,*volume*]:*fs_option*[:*zonename*]
[`-m` *mount_point*:*device*:*fs_option*[:*zonename*]] ...
Specifies the `vfstab(4)` information for a new UFS-based BE. The file systems specified as arguments to `-m` can be on the same disk or can be spread across multiple disks.

The `-m` option is not supported for BEs based on ZFS file systems. This option also does not support EFI-labeled disks.

mount_point can be any valid mount point or – (hyphen), indicating a swap partition. The *device* field can be one of the following:

- The name of a disk slice, of the form `/dev/dsk/c`*num*`t`*num*`d`*num*`s`*num*.
- The name of a Solaris Volume Manager volume, of the form `/dev/md/dsk/d`*num*.
- The name of a Solaris Volume Manager disk set, of the form `/dev/md/`*setname*`/dsk/d`*num*.

- The name of a Veritas volume, of the form `/dev/vx/dsk/`*dgname*`/`*volname*.
- The keyword `merged`, indicating that the file system at the specified mount point is to be merged with its parent.
- The keyword `shared`, indicating that all of the swap partitions in the source BE are to be shared with the new BE.

The `-m` option enables you to attach a physical disk device to a Solaris Volume Manager single–slice concatenation or attach a Solaris Volume Manager volume to a mirror. Both operations are accomplished with the `attach` keyword, described below. With this option, you have the choice of specifying a concatentation or mirror or allowing `lucreate` to select one for you. To specify a concatenation or mirror, append a comma and the name of the Solaris Volume Manager logical device to the device name to which the logical device is being attached. If you omit this specification, `lucreate` selects a concatenation or mirror from a list of free devices. See EXAMPLES.

The *fs_option* field can be one or more of the keywords listed below. The first two keywords specify types of file systems. The remaining keywords specify actions to be taken on a file system. When you specify multiple keywords, separate these with a comma.

`ufs` Create the file system as a UFS volume.

`vxfs` Create the file system as a Veritas device.

`preserve` Preserve the file system contents of the specified physical storage device. Use of this keyword presumes that the device's file system and its contents are appropriate for the specified mount point. For a given mount point, you can use preserve with only one device. This keyword enables you to bypass the default steps of creating a new file system on the specified storage device, then copying the file system contents from the source BE to the specified device. When you use `preserve`, `lucreate` checks that the storage device's contents is suitable for a specified file system. This check is limited and cannot guarantee suitability.

`mirror` Create a mirror on the specified storage device. The specified storage device must be a correctly named (for example, `/dev/md/dsk/d10`) logical device that can serve as a mirror. In subsequent `-m` options, you must specify `attach` (see below) to attach at least one physical device to the new mirror.

`attach` Attach a physical storage device, contained by a volume, to the mirror or single-slice concatenation associated with a specified mount point. When using `attach`, if you want to attach a disk to a specific mirror or concatenation, you append a comma and the name of that logical device to the device name. If you omit the comma and the concatentation name, `lucreate` selects a free mirror or single-slice concatenation as the container volume for the storage device. See EXAMPLES.

`lucreate` allows you to create only concatenations that contain a single physical drive and allows you to attach up to four such concatenations to a mirror.

`detach` Detach a physical storage device from the mirror or concatenation associated with a specified mount point.

The optional *zonename* field specifies the name of an installed non-global zone. It is used to specify a separate file system that belongs to the particular zone, named *zonename*, that exists in the new BE being created.

At minimum, you must specify one disk or device slice, for root. You can do this with `-m`, `-M` (described below), or in the FMLI-based interface. You must specify an `-m` argument for each file system you want to create on a new BE. For example, if you have three file systems on a source BE (say, `/`, `/usr`, and `/var`) and want these three entities as separate file systems on a new BE, you must specify three `-m` arguments. If you were to specify only one, in our example, `/`, `/usr`, and `/var` would be merged on the new BE into a single file system, under `/`.

When using the `-m` option to specify swap partition(s), you can designate device(s) currently used for swap on any BE and any unused devices. Regarding swap assignments, you have the following choices:

- Omit any specification of swap devices, in which case all swap devices associated with the source BE will be used by the new BE.
- Specify one or more swap devices, in which case the new BE will use only the specified swap devices and not automatically share the swap devices associated with the source BE.
- Specify one or more swap devices and use the syntax `-m –:shared:swap`, in which case the new BE will use the specified swap devices and will share swap devices with the source BE.

See EXAMPLES, below.

`-M` *slice_list*

List of `-m` options, collected in the file *slice_list*. Specify these arguments in the format specified for `-m`. Comment lines, beginning with a hash mark (#), are ignored. The `-M` option is useful where you have a long list of file systems for a BE. Note that you can combine `-m` and `-M` options. For example, you can store swap partitions in *slice_list* and specify `/` and `/usr` slices with `-m`.

The `-M` option is not supported for BEs based on ZFS file systems.

The `-m` and `-M` options support the listing of multiple slices for a given mount point. In processing these slices, `lucreate` skips any unavailable slices and selects the first available slice. See EXAMPLES.

`-n` *BE_name*
The name of the BE to be created. *BE_name* must be unique on a given system.

`-o` *outfile*
All command output is sent to *outfile*, in addition to where it is sent in your current environment.

`-p` *zfs_root_pool*
Specifies the ZFS pool in which a new BE will reside.

This option can be omitted if the source and target BEs are within the same pool.

The `-p` option does not support the splitting and merging of file systems in a target BE that is supported by the `-m` option.

`-s` (– | *BE_name*)
Source for the creation of the new BE. This option enables you to use a BE other than the current BE as the source for creation of a new BE.

If you specify a hyphen (`-`) as an argument to `-s`, `lucreate` creates the new BE, but does not populate it. This variation of the `-s` option is intended for the subsequent installation of a flash archive on the unpopulated BE using `luupgrade(1M)`. See `flar(1M)`.

`-x` *exclude*
Exclude the file or directory *exclude* from the newly created BE. If *exclude* is a directory, `lucreate` excludes that directory and all files beneath that directory, including subdirectories.

This option is not supported when the source BE is on a ZFS file system.

`-X`
Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.`<*num*>, where <*num*> is the version number of the DTD file.

`-y` *include*
Include the file or directory *include* in the newly created BE. If *include* is a directory, `lucreate` includes that directory and all files beneath that directory, including subdirectories.

This option is not supported when the source BE is on a ZFS file system.

`-Y` *include_list_file*
Use the contents of *include_list_file* to include specific files (including directories) from the newly created BE. *include_list_file* contains a list of files and directories, one per line. If a line item is a file, only that file is included; if a directory, that directory and all files beneath that directory, including subdirectories, are included.

This option is not supported when the source BE is on a ZFS file system.

`-z` *filter_list_file*
filter_list_file contains a list of items, files and directories, one per line. Each item is preceded by either a +, indicating the item is to be included in the new BE, or -, indicating the item is to be excluded from the new BE.

This option is not supported when the source BE is on a ZFS file system.

Combining File Inclusion and Exclusion Options

When a source BE is on a UFS file system, the `lucreate` command allows you to include or exclude specific files and directories when creating a new BE. You can include files and directories with:

- the `-y` *include* option
- the `-Y` *include_list_file* option
- items with a leading + in the file used with the `-z` *filter_list* option

You can exclude files and directories with:

- the `-x` *exclude* option
- the `-f` *exclude_list_file* option
- items with a leading – in the file used with the `-z` *filter_list* option

If the parent directory of an excluded item is included with include options (for example, `-y` *include*), then only the specific file or directory specified by *exclude* is excluded. Conversely, if the parent directory of an included file is specified for exclusion, then only the file *include* is included. For example, if you specify:

```
-x /a -y /a/b
```

all of `/a` except for `/a/b` is excluded. If you specify:

```
-y /a -x /a/b
```

all of `/a` except for `/a/b` is included.

Examples

The `lucreate` command produces copious output. In the following examples, this output is not reproduced, except where it is needed for clarity.

EXAMPLE 1 Creating a New Boot Environment for the First Time

The following command sequence creates a new boot environment on a machine on which a BE has never been created. All non-shareable (critical) file systems are mounted under `/`.

```
# lucreate -c first_disk -m /:/dev/dsk/c0t4d0s0:ufs -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

The following command, like the preceding, creates a new boot environment on a machine on which a BE has never been created. However, the following command differs in two respects: the `-c` option is omitted and the `/usr` file system is mounted on its own disk slice, separate from `/`.

EXAMPLE 1 Creating a New Boot Environment for the First Time *(Continued)*

```
# lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
-n second_disk
lucreate: Please wait while your system configuration is determined.
many lines of output
lucreate: Creation of Boot Environment c0t4d0s0 successful.
```

In the absence of the `-c` option, `lucreate` assigns the name `c0t4d0s0`, the base name of the root device, to the new boot environment.

The same command is entered, with the addition of `-c`:

```
# lucreate -c first_disk -m /:/dev/dsk/c0t4d0s0:ufs \
-m /usr:/dev/dsk/c0t4d0s1:ufs -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

Following creation of a BE, you use `luupgrade(1M)` to upgrade the OS on the new BE and `luactivate(1M)` to make that BE the BE you will boot from upon the next reboot of your machine. Note that the swap partition and all shareable file systems for `first_disk` will be available to (shared with) `second_disk`.

```
# luupgrade -u -n second_disk \
-s /net/installmachine/export/solarisX/OS_image
many lines of output
luupgrade: Upgrade of Boot Environment <second_disk> successful.

# luactivate second_disk
```

See `luupgrade(1M)` and `luactivate(1M)` for descriptions of those commands.

EXAMPLE 2 Creating a BE Using a Source Other than the Current BE

The following command uses the `-s` option to specify a source BE other than the current BE.

```
# lucreate -s third_disk -m /:/dev/dsk/c0t4d0s0:ufs \
-m /usr:/dev/dsk/c0t4d0s1:ufs -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

EXAMPLE 3 Migrating a BE from a UFS Root File System to a ZFS Root File System

The following command creates a BE of a ZFS root file system from a UFS root file system. The current BE, `c1t0d0s0`, containing a UFS root file system, is identified by the `-c` option. The new BE, `zfsBE`, is identified by the `-n` option. A ZFS storage pool must exist before the `lucreate` operation and must be created with slices rather than whole disks to be upgradeable and bootable.

```
# zpool create rpool mirror c1t0d0s0 c2t0d0s0
# lucreate -c c1t0d0s0 -n zfsBE -p rpool
```

EXAMPLE 3 Migrating a BE from a UFS Root File System to a ZFS Root File System *(Continued)*

Note that if the current BE also resides on the ZFS pool `rpool`, the `-p` option could be omitted. For example:

```
# lucreate -n zfsBE
```

EXAMPLE 4 Creating a BE from a Flash Archive

Performing this task involves use of `lucreate` with the `-s` – option and `luupgrade`.

```
# lucreate -s - -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
-n second_disk
brief messages
lucreate: Creation of Boot Environment <second_disk> successful.
```

With the `-s` option, the `lucreate` command completes it work within seconds. At this point, you can use `luupgrade` to install the flash archive:

```
# luupgrade -f -n second_disk \
-s /net/installmachine/export/solarisX/OS_image \
-J "archive_location http://example.com/myflash.flar"
```

See `luupgrade(1M)` for a description of that command.

EXAMPLE 5 Sharing and Adding Swap Partitions

In the simplest case, if you do not specify any swap partitions in an `lucreate` command, all swap partitions in the source BE are shared with the new BE. For example, assume that the current BE uses `/dev/dsk/c0t4d0s7` as its swap partition. You enter the command:

```
# lucreate -n second_disk -m /:/dev/dsk/c0t4d0s0:ufs
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

Upon conclusion of the preceding command, the partition `/dev/dsk/c0t4d0s7` will be used by the BE `second_disk` when that BE is activated and booted.

If you want a new BE to use a different swap partition from that used by the source BE, enter one or more `-m` options to specify a new partition or new partitions. Assume, once again, that the current BE uses `/dev/dsk/c0t4d0s7` as its swap partition. You enter the command:

```
# lucreate -m /:/dev/dsk/c0t0d0s0:ufs -m -:/dev/dsk/c0t4d0s1:swap \
 -m -:/dev/dsk/c0t4d0s2:swap -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

Upon activation and boot, the new BE `second_disk` will use `/dev/dsk/c0t4d0s1` and `/dev/dsk/c0t4d0s2` and will not use `/dev/dsk/c0t4d0s7`, the swap partition used by the source BE.

EXAMPLE 5 Sharing and Adding Swap Partitions *(Continued)*

Assume you want the new BE `second_disk` to share the source BE's swap partition *and* have an additional swap partition. You enter:

```
# lucreate -m /:/dev/dsk/c0t0d0s0:ufs -m -:/dev/dsk/c0t4d0s1:swap \
 -m -:shared:swap -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

Upon activation and boot, the new BE `second_disk` will use for swapping `/dev/dsk/c0t4d0s7`, shared with the source BE, and, in addition, `/dev/dsk/c0t4d0s1`.

EXAMPLE 6 Using Swap Partitions on Multiple Disks

The command below creates a BE on a second disk and specifies swap partitions on both the first and second disks.

```
# lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m -:/dev/dsk/c0t4d0s1:swap \
 -m -:/dev/dsk/c0t0d0s1:swap -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

Following completion of the preceding command, the BE `second_disk` will use both `/dev/dsk/c0t0d0s1` and `/dev/dsk/c0t4d0s1` as swap partitions. These swap assignments take effect only after booting from `second_disk`. If you have a long list of swap partitions, it is useful to use the `-M` option, as shown below.

EXAMPLE 7 Using a Combination of `-m` and `-M` Options

In this example, a list of swap partitions is collected in the file `/etc/lu/swapslices`. The location and name of this file is user-defined. The contents of `/etc/lu/swapslices`:

```
-:/dev/dsk/c0t3d0s2:swap
-:/dev/dsk/c0t3d0s2:swap
-:/dev/dsk/c0t4d0s2:swap
-:/dev/dsk/c0t5d0s2:swap
-:/dev/dsk/c1t3d0s2:swap
-:/dev/dsk/c1t4d0s2:swap
-:/dev/dsk/c1t5d0s2:swap
```

This file is specified in the following command:

```
# lucreate -m /:/dev/dsk/c02t4d0s0:ufs -m /usr:/dev/dsk/c02t4d0s1:ufs \
-M /etc/lu/swapslices -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

The BE `second_disk` will swap onto the partitions specified in `/etc/lu/swapslices`.

EXAMPLE 8 Copying Versus Sharing

The following command copies the user file system `/home` (in addition to the non–shareable file systems `/` and `/usr`) from the current BE to the new BE:

```
# lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
-m /home:/dev/dsk/c0t4d0s4:ufs -n second_disk
```

The following command differs from the preceding in that the `-m` option specifying a destination for `/home` is omitted. The result of this is that `/home` will be shared between the current BE and the BE `second_disk`.

```
# lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
-n second_disk
```

EXAMPLE 9 Using Solaris Volume Manager Volumes

The command shown below does the following:

1. Creates the mirror `d10` and establishes this mirror as the receptacle for the root file system.
2. Attaches `c0t0d0s0` and `c0t1d0s0` to single-slice concatenations `d1` and `d2`, respectively. Note that the specification of these volumes is optional.
3. Attaches the concatenations associated with `c0t0d0s0` and `c0t1d0s0` to mirror `d10`.
4. Copies the current BE's root file system to mirror `d10`, overwriting any `d10` contents.

```
# lucreate -m /:/dev/md/dsk/d10:ufs,mirror \
-m /:/dev/md/dsk/d1:attach \
-m /:/dev/dsk/c0t1d0s0,d2:attach -n newBE
```

The following command differs from the preceding only in that concatenations for the physical storage devices are not specified. In this example, `lucreate` chooses concatenation names from a list of free names and attaches these volumes to the mirror specified in the first `-m` option.

```
# lucreate -m /:/dev/md/dsk/d10:ufs,mirror \
-m /:/dev/dsk/c0t0d0s0:attach \
-m /:/dev/dsk/c0t1d0s0:attach -n newBE
```

The following command differs from the preceding commands in that one of the physical disks is detached from a mirror before being attached to the mirror you create. Also, the contents of one of the physical disks is preserved. The command does the following:

1. Creates the mirror `d10` and establishes this mirror as the receptacle for the root file system.
2. Detaches `c0t0d0s0` from the mirror to which it is currently attached.
3. Attaches `c0t0d0s0` and `c0t1d0s0` to concatenations `d1` and `d2`, respectively. Note that the specification of the these concatenations is optional.
4. Preserves the contents of `c0t0d0s0`, which presumes that `c0t0d0s0` contains a valid copy of the current BE's root file system.

EXAMPLE 9 Using Solaris Volume Manager Volumes *(Continued)*

5. Attaches the concatenations associated with `c0t0d0s0` and `c0t1d0s0` (`d1` and `d2`) to mirror `d10`.

```
# lucreate -m /:/dev/md/dsk/d10:ufs,mirror \
-m /:/dev/dsk/c0t0d0s0,d1:detach,attach,preserve \
-m /:/dev/dsk/c0t1d0s0,d2:attach -n newBE
```

The following command is a follow-on to the first command in this set of examples. This command detaches a concatenation (containing `c0t0d0s0`) from one mirror (`d10`, in the first command) and attaches it to another (`d20`), preserving its contents.

```
# lucreate -m /:/dev/md/dsk/d20:ufs,mirror \
-m /:/dev/dsk/c0t0d0s0:detach,attach,preserve -n nextBE
```

The following command creates two mirrors, placing the `/` file system of the new BE on one mirror and the `/opt` file system on the other.

```
# lucreate -m /:/dev/md/dsk/d10:ufs,mirror \
-m /:/dev/dsk/c0t0d0s0,d1:attach \
-m /:/dev/dsk/c1t0d0s0,d2:attach \
-m /opt:/dev/md/dsk/d11:ufs,mirror \
-m /opt:/dev/dsk/c2t0d0s1,d3:attach \
-m /opt:/dev/dsk/c3t1d0s1,d4:attach -n anotherBE
```

EXAMPLE 10 Invoking FMLI-based Interface

This example is included for historical purposes as the `lu` interface is now obsolete.

The command below, by omitting `-m` or `-M` options, invokes `lu`, the FMLI-based interface for Live Upgrade operations.

```
# lucreate -n second_disk
```

The preceding command uses the current BE as the source for the target BE `second_disk`. In the FMLI interface, you can specify the target disk slices for `second_disk`. The following command is a variation on the preceding:

```
# lucreate -n second_disk -s third_disk
```

In the preceding command, a source for the target BE is specified. As before, the FMLI interface comes up, enabling you to specify target disk slices for the new BE.

EXAMPLE 11 Merging File Systems

The command below merges the `/usr/opt` file system into the `/usr` file system. First, here are the disk slices in the BE `first_disk`, expressed in the format used for arguments to the `-m` option:

EXAMPLE 11 Merging File Systems *(Continued)*

```
/:/dev/dsk/c0t4d0s0:ufs
/usr:/dev/dsk/c0t4d0s1:ufs
/usr/opt:/dev/dsk/c0t4d0s3:ufs
```

The following command creates a BE `second_disk` and performs the merge operation, merging `/usr/opt` with its parent, `/usr`.

```
# lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
-m /usr/opt:merged:ufs -n second_disk
```

EXAMPLE 12 Splitting a File System

Assume a source BE with `/`, `/usr`, and `/var` all mounted on the same disk slice. The following command creates a BE `second_disk` that has `/`, `/usr`, and `/var` all mounted on different disk slices.

```
# lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
/var:/dev/dsk/c0t4d0s3:ufs -n second_disk
```

This separation of a file system's (such as root's) components onto different disk slices is referred to as splitting a file system.

EXAMPLE 13 Specifying Alternative Slices

The following command uses multiple `-m` options as alternative disk slices for the new BE `second_disk`.

```
# lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /:/dev/dsk/c0t4d0s1:ufs \
-m /:/dev/dsk/c0t4d0s5:ufs -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

The preceding command specifies three possible disk slices, `s0`, `s1`, and `s5` for the `/` file system. `lucreate` selects the first one of these slices that is not being used by another BE. Note that the `-s` option is omitted, meaning that the current BE is the source BE for the creation of the new BE.

EXAMPLE 14 Specifying Separate File Systems for Non-Global Zones

The following command specifies a separate file system belonging to the zone, `zone1`, within the new BE, `second_disk`.

```
# lucreate -n second_disk -m /:/dev/dsk/c0d0s3:ufs \
-m /export/home:/dev/dsk/c0d0s5:ufs:zone1
```

The zone named `zone1`, inside the new BE, has a separate disk slice allocated for its `/export/home` file system.

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Files

`/etc/lutab`	list of BEs on the system
`/usr/share/lib/xml/dtd/lu_cli.dtd.<num>`	Live Upgrade DTD (see `-X` option)

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWlu

See Also `luactivate(1M)`, `lucancel(1M)`, `lucompare(1M)`, `lucurr(1M)`, `ludelete(1M)`, `ludesc(1M)`, `lufslist(1M)`, `lumake(1M)`, `lumount(1M)`, `lurename(1M)`, `lustatus(1M)`, `luupgrade(1M)`, `zfs(1M)`, `zpool(1M)`, `zoneadm(1M)`, `lutab(4)`, `attributes(5)`, `live_upgrade(5)`, `zones(5)`

Notes As is true for any Solaris operating system upgrade (and not a feature of Live Upgrade), when splitting a directory into multiple mount points, hard links are not maintained across file systems. For example, if `/usr/test1/buglist` is hard linked to `/usr/test2/buglist`, and `/usr/test1` and `/usr/test2` are split into separate file systems, the link between the files will no longer exist. If `lucreate` encounters a hard link across file systems, the command issues a warning message and creates a symbolic link to replace the lost hard link.

`lucreate` cannot prevent you from making invalid configurations with respect to non-shareable file systems. For example, you could enter an `lucreate` command that would create separate file systems for `/` and `/kernel`—an invalid division of `/`. The resulting BE would be unbootable. When creating file systems for a boot environment, the rules are identical to the rules for creating file systems for the Solaris operating environment.

Mindful of the principle described in the preceding paragraph, consider the following:

- In a source BE, you must have valid `vfstab` entries for every file system you want to copy to or share with a new BE.
- You cannot create a new BE on a disk with overlapping partitions (that is, partitions that share the same physical disk space). The `lucreate` command that specifies such a disk might complete, but the resulting BE would be unbootable.

Note – As stated in the description of the `-m` option, if you use Solaris Volume Manager volumes for boot environments, use `lucreate` rather than Solaris Volume Manager commands to manipulate these volumes. The Solaris Volume Manager software has no knowledge of boot environments; the `lucreate` command contains checks that prevent you from inadvertently destroying a boot environment by, for example, overwriting or deleting a Solaris Volume Manager volume.

For versions of the Solaris operating system prior to Solaris 10, Live Upgrade supports the release it is distributed on and up to three marketing releases back. For example, if you obtained Live Upgrade with Solaris 9 (including a Solaris 9 upgrade), that version of Live Upgrade supports Solaris versions 2.6, Solaris 7, and Solaris 8, in addition to Solaris 9. No version of Live Upgrade supports a Solaris version prior to Solaris 2.6.

Starting with version 10 of the Solaris operating system, Live Upgrade supports the release it is distributed on and up to two marketing releases back. For example, if you obtained Live Upgrade with Solaris 10 (including a Solaris 10 upgrade), that version of Live Upgrade supports Solaris 8 and Solaris 9, in addition to Solaris 10. For instructions on adding Live Upgrade packages for the release you want to install, see *Solaris 10 5/08 Installation Guide: Solaris Live Upgrade and Upgrade Planning*.

Correct operation of Solaris Live Upgrade requires that a limited set of patch revisions be installed for a given OS version. Before installing or running Live Upgrade, you are required to install the limited set of patch revisions. Make sure you have the most recently updated patch list by consulting `http://sunsolve.sun.com`. Search for the infodoc 72099 on the SunSolve web site.

Name lucurr – display the name of the active boot environment

Synopsis

```
/usr/sbin/lucurr [-l error_log] [-m mount_point]
     [-o outfile] [-X]
```

Description The `lucurr` command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `lucurr` command displays the name of the currently running boot environment (BE). If no BEs are configured on the system, `lucurr` displays the message "No Boot Environments are defined". Note that `lucurr` reports only the name of the current BE, not the BE that will be active upon the next reboot. Use `lustatus(1M)` or `luactivate(1M)` for this information.

The `lucurr` command requires root privileges.

Options The `lucurr` command has the following options:

`-l` *error_log* — Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.

`-m` *mount_point* — Returns the name of the BE that owns *mount_point*, where *mount_point* is the mount point of a BE's root file system. This can be a mount point of the current BE or the mount point of a BE other than the current BE. If the latter, the file system of the BE must have been mounted with `lumount(1M)` or `mount(1M)` before entering this option.

`-o` *outfile* — All command output is sent to *outfile*, in addition to where it is sent in your current environment.

`-X` — Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.`<*num*>, where <*num*> is the version number of the DTD file.

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Files

`/etc/lutab`	list of BEs on the system
`/usr/share/lib/xml/dtd/lu_cli.dtd.`<*num*>	Live Upgrade DTD (see `-X` option)

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWluu

See Also luactivate(1M), lucancel(1M), lucompare(1M), lucreate(1M), ludelete(1M), ludesc(1M), lufslist(1M), lumake(1M), lumount(1M), lurename(1M), lustatus(1M), luupgrade(1M), lutab(4), attributes(5), live_upgrade(5)

Name ludelete – delete a boot environment

Synopsis

```
/usr/sbin/ludelete [-l error_log] [-o outfile] BE_name [-X]
```

Description The `ludelete` command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `ludelete` command deletes all records associated with a boot environment (BE) on all defined complete BEs. A complete BE is one that is not participating in an `lucreate(1M)`, `luupgrade(1M)`, or `lucompare(1M)` operation. Use `lustatus(1M)` to determine a BE's status. You can delete neither the current BE, nor the BE that will become current upon the next reboot.

`ludelete` does not alter any files on the BE being deleted.

The `ludelete` command requires root privileges.

Options The `ludelete` command has the following options:

`-l` *error_log* Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.

`-o` *outfile* All command output is sent to *outfile*, in addition to where it is sent in your current environment.

`-X` Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.`<*num*>, where <*num*> is the version number of the DTD file.

Operands *BE_name* Name of the BE to be deleted.

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Files

`/etc/lutab`	list of BEs on the system
`/usr/share/lib/xml/dtd/lu_cli.dtd.`<*num*>	Live Upgrade DTD (see `-X` option)

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWluu

See Also lu(1M), luactivate(1M), lucancel(1M), lucompare(1M), lucreate(1M), lucurr(1M), ludesc(1M), lufslist(1M), lumake(1M), lumount(1M), lurename(1M), lustatus(1M), luupgrade(1M), lutab(4), attributes(5), live_upgrade(5)

Name ludesc – display or set boot environment description

Synopsis

```
/usr/sbin/ludesc {-A BE_description} | {-f {filename | -}}
     [-l error_log] [-o outfile] [-X]

/usr/sbin/ludesc -n BE_name [-f filename | -]
     [-l error_log] [-o outfile] [-X]

/usr/sbin/ludesc -n BE_name [-l error_log] [-o outfile]
     [-X] BE_description
```

Description The `ludesc` command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `ludesc` command allows you to manipulate boot environment (BE) descriptions. A BE description is an optional attribute of a BE. It can be text or binary data. For example, it might be a string such as "S9 beta test BE" or it might be a file that contains 8–bit multi-byte characters. The `ludesc` command in general and the options to manipulate binary-format descriptions in particular are suitable for use in programs.

You create a BE description using `ludesc` or `lucreate(1M)`. Only `ludesc` allows you to change a BE description or add a description following BE creation.

While a BE description is associated with a BE name, it is not interchangeable with that name. No Live Upgrade command allows you to specify a BE description instead of a BE name when performing an operation on a BE.

A shell might restrict what you enter for a BE description (in both `ludesc` and `lucreate(1M)`). In entering a description, use the following guidelines:

- Always enclose a description in single quotes ('), unless the description includes a single quote.
- If your description includes a single quote, enclose the description in double quotes ("). You then must use an escape sequence (usually a backslash [\]) to enter a character that is special to the shell. See `sh(1)` for a list of special characters and a description of the escape sequence mechanism.

Descriptions that include many special characters might be more conveniently inserted in a file (`-f` option) than entered on a command line (`-A` option).

When `ludesc` outputs a BE description, it does so exactly as the description was entered. Because of this feature, a description that is a text string does not have a concluding newline, which means the system prompt immediately follows the last character of the description.

The `ludesc` command requires root privileges.

Options The `ludesc` command has the following options:

`-A` *BE_description*	Displays the BE name associated with *BE_description*.
`-f` {*filename* | –}	Specify the BE description contained in *filename* or read from `stdin`. When used without `-n`, displays the BE name associated with the specified BE description. Used with `-n`, changes the description for the specified BE to the description specified with `-f`.
`-l` *error_log*	Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.
`-n` *BE_name*	With no other arguments, displays the BE description for the specified BE. With the `-f` option or the *BE_description* operand, changes the description for the specified BE to that specified with `-f` or *BE_description*.
`-o` *outfile*	All command output is sent to *outfile*, in addition to where it is sent in your current environment.
`-X`	Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.`<*num*>, where <*num*> is the version number of the DTD file.

Operands *BE_description* Used only with the `-n` option. *BE_description* replaces the current BE description for the specified BE.

Examples The following are examples of the use of `ludesc`.

EXAMPLE 1 Basic Use

The first command, below, assigns a description to a BE. The second command returns the name of the BE associated with the specified description. The last command returns the description associated with a specified BE.

```
# ludesc -n first_disk 'Test disk'
Setting description for boot environment <first_disk>.
Propagating the change of BE description to all BEs.

# ludesc -A 'Test disk'
first_disk
#

# ludesc -n first_disk
Test disk#
```

As seen above and noted in the DESCRIPTION, `ludesc` does not append a newline to the display of BE description that is a text string.

EXAMPLE 2 Using Binary Files

The following commands are analogs of the preceding examples, substituting a binary file–here, a file containing a description in Russian, using the Cyrillic alphabet—for a text string. In the third command, note the use of a file to capture output. Sending output of a binary file to the console can produce erratic results.

```
# ludesc -n first_disk -f arrayBE.ru
Setting description for boot environment <first_disk>.
Propagating the change of BE description to all BEs.

# ludesc -f arrayBE.ru
first_disk

# ludesc -n first_disk > /tmp/arrayBE.out
```

Exit Status

The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Files

`/etc/lutab`	list of BEs on the system
`/usr/share/lib/xml/dtd/lu_cli.dtd.`*<num>*	Live Upgrade DTD (see `-X` option)

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWluu

Name lufslist – list configuration of a boot environment

Synopsis

```
/usr/sbin/lufslist [-l error_log] [-o outfile] BE_name [-X]
```

Description The `lufslist` command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `lufslist` command lists the configuration of a boot environment (BE). The output contains the disk slice (file system), file system type, and file system size for each BE mount point. The output also notes any separate file systems that belong to a non-global zone inside the BE being displayed.

The following is an example of `lufslist` output, which shows a separate filesystem for the zone, `zone1`, within the BE being displayed.

```
# lufslist BE_name
Filesystem             fstype       size(Mb) Mounted on
--------------------------------------------------------------------
/dev/dsk/c0t0d0s1      swap           512.11 -
/dev/dsk/c0t4d0s3      ufs           3738.29 /
/dev/dsk/c0t4d0s4      ufs            510.24 /opt

              zone zone1 within boot environment BE_name
/dev/dsk/c0t4d0s7      ufs            7000.48 /export
```

File system type can be `ufs`, `swap`, or `vxfs`, for a Veritas file system. Under the `Filesystem` heading can be a disk slice or a logical device, such as a disk metadevice used by volume management software.

The `lufslist` command requires root privileges or the Primary Administrator role.

Options The `lufslist` command has the following options:

`-l` *error_log* Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.

`-o` *outfile* All command output is sent to *outfile*, in addition to where it is sent in your current environment.

`-X` Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.`<*num*>, where <*num*> is the version number of the DTD file.

Operands *BE_name* Name of the BE for which file systems are to be reported. You cannot specify a BE that is involved in another Live Upgrade operation.

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Files

`/etc/lutab`	list of BEs on the system
`/usr/share/lib/xml/dtd/lu_cli.dtd.`<*num*>	Live Upgrade DTD (see `-X` option)

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWluu

See Also `luactivate(1M)`, `lucancel(1M)`, `lucompare(1M)`, `lucreate(1M)`, `lucurr(1M)`, `ludelete(1M)`, `ludesc(1M)`, `lumake(1M)`, `lumount(1M)`, `lurename(1M)`, `lustatus(1M)`, `luupgrade(1M)`, `lutab(4)`, `attributes(5)`, `live_upgrade(5)`, `zones(5)`

Name lumake – populate a boot environment

Synopsis

```
/usr/sbin/lumake [-l error_log] [-o outfile] [-s source_BE] -n BE_name
     [-X]

/usr/sbin/lumake [-l error_log] -t time [-o outfile]
     [-s source_BE] -n BE_name [-m email_address] [-X]
```

Description The `lumake` command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `lumake` command populates (that is, copies files to) the file systems of a specified boot environment (BE) by copying files from the corresponding file systems of the active or a source (`-s`) BE. Any existing data on the target BE are destroyed. All file systems on the target BE are re-created.

The target BE must already exist. Use `lucreate(1M)` to create a new BE.

The `lumake` command requires root privileges.

Options The `lumake` command has the following options:

`-n` *BE_name* — Name of the BE to be populated.

`-s` *source_BE* — The optional name of a source BE. If you omit this option, `lumake` uses the current BE as the source. A BE must have the status "complete" before you can copy from it. Use `lustatus(1M)` to determine a BE's status.

`-l` *error_log* — Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.

`-o` *outfile* — All command output is sent to *outfile*, in addition to where it is sent in your current environment.

`-t` *time* — Setup a batch job to populate the specified BE at a specified time. The time is given in the format specified by the `at(1)` man page. At any time, you can have only one Live Upgrade operation scheduled. You can use `lucancel(1M)` to cancel a scheduled `lumake` operation.

`-m` *email_address* — Allows you to email `lumake` output to a specified address upon command completion. There is no checking of *email_address*. Use this option in conjunction with `-t`, to obtain notification of batch command completion. If you use `-m` with options other than `-t`, no email is sent.

`-X` — Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.`<*num*>, where <*num*> is the version number of the DTD file.

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Files

`/etc/lutab`	list of BEs on the system
`/usr/share/lib/xml/dtd/lu_cli.dtd.<num>`	Live Upgrade DTD (see `-X` option)

Name lumount, luumount – mount or unmount all file systems in a boot environment

Synopsis

```
/usr/sbin/lumount [-l error_log] [-o outfile] BE_name
     [mount_point] [-X]

/usr/sbin/lumount

/usr/sbin/luumount [-f]
     { [-n] BE_name | [-m] mount_point | block_device}
     [-l error_log] [-o outfile] [-X]
```

Description The `lumount` and `luumount` commands are part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `lumount` and `luumount` commands enable you to mount or unmount all of the file systems in a boot environment (BE). This allows you to inspect or modify the files in a BE while that BE is not active. By default, `lumount` mounts the file systems on a mount point of the form `/.alt.`*BE_name*, where *BE_name* is the name of the BE whose file systems are being mounted. See NOTES.

`lumount` and `luumount` also mount or unmount all installed non-global zones within the BE. For each running, mounted, or ready non-global zone in the current BE, `lumount` mounts all file systems in the mounted BE that belong to the non-global zone, at the specified mount point in the non-global zone. This provides the non-global zone administrator access to the corresponding file systems that exist in the mounted BE.

When invoked with no arguments, `lumount` returns the name(s) of the mounted BEs on a system.

The `lumount` and `luumount` commands require root privileges or the Primary Administrator role.

Options The `lumount` and `luumount` commands have the following options:

`-f`	For `luumount` only, forcibly unmount a BE's file systems after attempting (and failing) an unforced unmount. This option is analogous to the `mount(1M)` `-f` option.
`-l` *error_log*	Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.
`-m` *mount_point*	`luumount` unmounts the file systems of the BE that owns *mount_point*. See description of *mount_point* under OPERANDS, below. The use of `-m` is optional when specifying a mount point for `luumount`.
`-n` *BE_name*	Name of the BE whose file systems will be unmounted. See description of *BE_name* under OPERANDS, below. The use of `-n` is optional when specifying a BE name for `luumount`.

`-o` *outfile* — All command output is sent to *outfile*, in addition to where it is sent in your current environment.

`-X` — Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.`<*num*>, where <*num*> is the version number of the DTD file.

For `luumount`, if you supply an argument and specify neither `-m` nor `-n`, the command determines whether your argument is a BE name, a mount point, or a block device. If it is one of these three and the argument is associated with a BE that has mounted file systems, `luumount` unmounts the file systems of that BE. Otherwise, `luumount` returns an error.

Operands

BE_name — Name of the BE whose file systems will be mounted or unmounted. This is a BE on the current system other than the active BE. Note that, for successful completion of an `lumount` or `luumount` command, the status of a BE must be complete, as reported by `lustatus(1M)`. Also, none of the BE's disk slices can be mounted (through use of `mount(1M)`).

mount_point — For `lumount`, a mount point to use instead of the default `/.alt.`*BE_name*. If *mount_point* does not exist, `lumount` creates it. For `luumount`, the BE associated with *mount_point* will have its file systems unmounted. Note that default mount points are automatically deleted upon unmounting with `luumount`. Mount points that you specify are not deleted.

block_device — For `luumount` only, *block_device* is the root slice of a BE, such as `/dev/dsk/c0t4d0s0`. `luumount` unmounts the file systems of the BE associated with *block_device*.

Examples

EXAMPLE 1 Specifying a Mount Point

The following command creates the mount point `/test` and mounts the file systems of the BE `second_disk` on `/test`.

```
# lumount second_disk /test
/test
```

You can then `cd` to `/test` to view the file systems of `second_disk`. If you did not specify `/test` as a mount point, `lumount` would create a default mount point named `/.alt.second_disk`.

If you have installed non-global zones on your system, this command will also mount all non-global zones in `second_disk` inside their corresponding non-global zones in the currently running system at the mount point `/test` (or `/.alt.second_disk` if a mount point was not specified).

EXAMPLE 2 Unmounting File Systems

The following command unmounts the file systems of the BE `second_disk`. In this example, we `cd` to `/` to ensure we are not in any of the file systems in `second_disk`.

EXAMPLE 2 Unmounting File Systems *(Continued)*

```
# cd /
# luumount second_disk
#
```

If `/dev/dsk/c0t4d0s0` were the root slice for `second_disk`, you could enter the following command to match the effect of the preceding command.

```
# cd /
# luumount /dev/dsk/c0t4d0s0
#
```

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Files

`/etc/lutab`	list of BEs on the system
`/usr/share/lib/xml/dtd/lu_cli.dtd.<num>`	Live Upgrade DTD (see `-X` option)

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWluu

See Also `luactivate(1M)`, `lucancel(1M)`, `lucompare(1M)`, `lucreate(1M)`, `lucurr(1M)`, `ludelete(1M)`, `ludesc(1M)`, `lufslist(1M)`, `lumake(1M)`, `lurename(1M)`, `lustatus(1M)`, `luupgrade(1M)`, `lutab(4)`, `attributes(5)`, `live_upgrade(5)`, `zones(5)`

Notes If a BE name contains slashes (/), `lumount` replaces those slashes with colons in a default mount point name. For example:

```
# lumount 'first/disk'
/.alt.first:disk
```

Name lurename – change the name of a boot environment

Synopsis

```
/usr/sbin/lurename -e BE_name -n new_name [-l error_log]
     [-o outfile] [-X]
```

Description The `lurename` command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `lurename` command renames the boot environment (BE) *BE_name* to *new_name*.

The string *new_name* must not exceed 30 characters in length and must consist only of alphanumeric characters and other ASCII characters that are not special to the Unix shell. See the "Quoting" section of `sh(1)`. The BE name can contain only single-byte, 8–bit characters. It cannot contain whitespace characters. Also, *new_name* must be unique on the system.

A BE must have the status "complete" before you rename it. Use `lustatus(1M)` to determine a BE's status. Also, you cannot rename a BE that has file systems mounted with `lumount(1M)` or `mount(1M)`.

Renaming a BE is often useful when you upgrade the BE from one Solaris release to another. For example, following an operating system upgrade, you might rename the BE `solaris7` to `solaris8`.

The `lurename` command requires root privileges.

Options The `lurename` command has the options listed below.

`-e` *BE_name* — Name of the BE whose name you want to change.

`-l` *error_log* — Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.

`-n` *new_name* — New name of the BE. *new_name* must be unique on a given system.

`-o` *outfile* — All command output is sent to *outfile*, in addition to where it is sent in your current environment.

`-X` — Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.`<*num*>, where <*num*> is the version number of the DTD file.

Exit Status The following exit values are returned:

`0` — Successful completion.

`>0` — An error occurred.

Files

`/etc/lutab`	list of BEs on the system
`/usr/share/lib/xml/dtd/lu_cli.dtd.<num>`	Live Upgrade DTD (see `-X` option)

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWluu

See Also `luactivate(1M)`, `lucancel(1M)`, `lucompare(1M)`, `lucreate(1M)`, `lucurr(1M)`, `ludelete(1M)`, `ludesc(1M)`, `lufslist(1M)`, `lumake(1M)`, `lumount(1M)`, `lustatus(1M)`, `luupgrade(1M)`, `lutab(4)`, `attributes(5)`, `live_upgrade(5)`

Name lustatus – display status of boot environments

Synopsis

```
/usr/sbin/lustatus [-l error_log] [-o outfile] [BE_name]
     [-X]
```

Description The `lustatus` command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `lustatus` command displays the status information of the boot environment (BE) *BE_name*. If no BE is specified, the status information for all BEs on the system is displayed.

The headings in the `lustatus` information display are described as follows:

`Boot Environment Name` Name of the BE.

`Is Complete` Indicates whether a BE is able to be booted. Any current activity or failure in an `lucreate(1M)` or `luupgrade(1M)` operation causes a BE to be incomplete. For example, if there is a copy operation proceeding on or scheduled for a BE, that BE is considered incomplete.

`Active Now` Indicates whether the BE is currently active. The "active" BE is the one currently booted.

`Active On Reboot` Indicates whether the BE becomes active upon next reboot of the system.

`Can Delete` Indicates that no copy, compare, or upgrade operations are being performed on a BE. Also, none of that BE's file systems are currently mounted. With all of these conditions in place, the BE can be deleted.

`Copy Status` Indicates whether the creation or repopulation of a BE is scheduled or active (that is, in progress). A status of `ACTIVE`, `COMPARING` (from `lucompare(1M)`), `UPGRADING`, or `SCHEDULED` prevents you performing Live Upgrade copy, rename, or upgrade operations.

The following is an example `lustatus` display:

```
Boot Environment     Is       Active Active    Can    Copy
Name                 Complete Now    On Reboot Delete Status
-------------------- -------- ------ --------- ------ ----------
disk_a_S7            yes      yes    yes       no     -
disk_b_S7db          yes      no     no        no     UPGRADING
disk_b_S8            no       no     no        no     -
S9testbed            yes      no     no        yes    -
```

Note that you could not perform copy, rename, or upgrade operations on `disk_b_S8`, because it is not complete, nor on `disk_b_S7db`, because a Live Upgrade operation is pending.

The `lustatus` command requires root privileges.

Options The `lustatus` command has the following options:

`-l` *error_log* Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.

`-o` *outfile* All command output is sent to *outfile*, in addition to where it is sent in your current environment.

`-X` Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.`<*num*>, where <*num*> is the version number of the DTD file.

Operands *BE_name* Name of the BE for which to obtain status. If *BE_name* is omitted, `lustatus` displays status for all BEs in the system.

Exit Status The following exit values are returned:

`0` Successful completion.

>`0` An error occurred.

Files

`/etc/lutab`	list of BEs on the system
`/usr/share/lib/xml/dtd/lu_cli.dtd.`<*num*>	Live Upgrade DTD (see `-X` option)

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWluu

See Also `luactivate(1M)`, `lucancel(1M)`, `lucompare(1M)`, `lucreate(1M)`, `lucurr(1M)`, `ludesc(1M)`, `ludelete(1M)`, `lufslist(1M)`, `lumake(1M)`, `lumount(1M)`, `lurename(1M)`, `luupgrade(1M)`, `lutab(4)`, `attributes(5)`, `live_upgrade(5)`

Name luupgrade – installs, upgrades, and performs other functions on software on a boot environment

Synopsis

```
/usr/sbin/luupgrade [-iIufpPtTcC] [options]
```

Description The `luupgrade` command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `luupgrade` command enables you to install software on a specified boot environment (BE). Specifically, `luupgrade` performs the following functions:

- Upgrades an operating system image on a BE (`-u` option). The source for the image can be any valid Solaris installation medium, including a Solaris Flash archive.
- Extract a Solaris Flash archive onto a BE (`-f` option). (See `flar(1M)`.)
- Add a package to (`-p`) or remove a package from (`-P`) a BE.
- Add a patch to (`-t`) or remove a patch from (`-T`) a BE.
- Check (`-C`) or obtain information about (`-I`) packages.
- Check an operating system installation medium (`-c`).

Before using `luupgrade`, you must have created a BE, using the `lucreate(1M)` command. You can upgrade only BEs other than the current BE.

The functions described in the preceding list each has its own set of options, which are described separately for each function.

Note that, for successful completion of an `luupgrade` operation, the status of a BE must be complete, as reported by `lustatus(1M)`. Also, the BE must not have any mounted disk slices, mounted either with `lumount(1M)` or `mount(1M)`.

`luupgrade` allows you to install an operating system image from a different marketing release of the Solaris operating system from the release running on the machine from which you invoke `luupgrade`. This feature has the following conditions:

- You can install Live Upgrade packages (`SUNWluu`, `SUNWlur`, and `SUNWlucfg`) from a given release of the Solaris operating system on a machine running a previous release. You can install these packages on a machine running a version of Solaris that is up to three releases prior to the release of the Live Upgrade packages. Live Upgrade is not supported on Solaris releases prior to Solaris 2.6. Thus, you can, for example, install Solaris 2.9 packages on Solaris 2.8, 2.7, and 2.6 machines.
- You can upgrade to a release of the Solaris operating system that is the same as the release of the Live Upgrade packages installed on a machine. This feature allows you to upgrade to Solaris upgrade releases within a marketing release. For example, if have the Solaris 9 FCS Live Upgrade packages installed on a machine, you can use `luupgrade` to upgrade a BE to the Solaris 9 update 3 release of the Solaris operating system.

See the *Solaris Installation Guide* for instructions on installing Live Upgrade packages.

The `luupgrade` command requires root privileges.

Options that Apply to All Uses

The following options are available for all uses of `luupgrade`:

`-l` *error_log* — Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.

`-o` *outfile* — All command output is sent to *outfile*, in addition to where it is sent in your current environment.

`-N` — Dry-run mode. Enables you to determine whether your command arguments are correctly formed. Does not apply to the `-c` (check medium) function.

`-X` — Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.`<*num*>, where <*num*> is the version number of the DTD file.

Upgrading an Operating System Image

The `luupgrade` command uses `-u` to upgrade an operating system image. The syntax is as follows:

```
luupgrade -u -n BE_name -k autoreg_file [ -l error_log ]
     [ -o outfile ][-N] -s os_image_path [ -j profile_path [-D] ]
```

The first option, `-u`, indicates the function to perform—to install an OS image. The remaining options for this use of `luupgrade`, shown above, are described as follows:

`-n` *BE_name* — Name of the BE to receive an OS upgrade.

`-k` *autoreg_file* — Path to auto-registration information file. See `sysidcfg(4)` for a list of valid keywords for use in this file.

`-s` *os_image_path* — Path name of a directory containing an OS image. This can be a directory on an installation medium such as a DVD or CD, or can be an NFS or UFS directory.

`-j` *profile_path* — Path to a JumpStart profile. See the section "JumpStart Profile Keywords," below, for a list of valid keywords for use in a profile invoked by `luupgrade`. See `pfinstall(1M)` and the Solaris installation documentation for information on the JumpStart software.

`-D` — Tests the profile values provided with `-j` against the disk configuration of the specified BE. The upgrade is not performed. The effect of this option is a dry run to test your profile. `luupgrade` creates log files, specified in its output, which allow you to examine the command's results.

Before upgrading a boot environment, do the following:

- Run `analyze_patches`.

- Install Live Upgrade packages for the operating system version to which you are upgrading.

The `analyze_patches` command is available in the `/Misc` directory on the Solaris software DVD (formerly the Solaris installation CD). This command determines which patches would be removed as a result of the upgrade. Then, following the upgrade, you can reinstall the list of patches provided by `analyze_patches`.

The Live Upgrade packages, `SUNWluu`, `SUNWlur`, and `SUNWlucfg`, are available on the Solaris software DVD (or CD, depending on the Solaris version). Before running `luupgrade` with the `-u` option, ensure that you have installed the packages from the version of Solaris to which you want to upgrade.

Note that if you are upgrading from a medium with multiple components, such as from multiple DVDs, use `luupgrade` with the `-i` option, as described in the section below, to install software from the second and any following media.

Continuing an Upgrade by Running an Installer Program

The `luupgrade` command uses `-i` to run an installer program. As discussed below, its primary use is following an invocation of `luupgrade` with the `-u` option. The syntax for `-i` is as follows:

```
luupgrade -i -n BE_name [ -l error_log ] [ -o outfile ] [ -N ]
-s installation_medium [ -O "installer_options" ]
```

The first option, `-i`, indicates the function to perform—to run an installer program on the installation medium specified with `-s`. The remaining options for this use of `luupgrade`, shown above, are described as follows:

`-n` *BE_name*	Name of the BE on which software is to be installed.
`-O` "*installer_options*"	Options passed directly to the Solaris installer program. See `installer(1M)` for descriptions of the installer options.
`-s` *installation_medium*	Path name of an installation medium. This can be a DVD, CD, or an NFS or UFS directory.

With the `-i` option, `luupgrade` looks for an installation program on the specified medium and runs that program.

The primary use of the `-i` option is to upgrade an operating system image from a multiple–component medium, such as multiple DVDs. In this use, an `luupgrade` command with the `-i` option follows an invocation of `luupgrade` with `-u`. See EXAMPLES. The `-u` option is described above.

Installing from a Solaris Flash Archive

The `luupgrade` command uses `-f` to install an operating system from a Solaris Flash archive. Note that installing an archive overwrites all files on the target BE. The syntax is as follows:

```
luupgrade -f -n BE_name [ -l error_log ] [ -o outfile ] [ -N ] [-D]
-s os_image_path ( -a archive | -j profile_path | -J "profile" )
```

The first option, `-f`, indicates the function to perform—to install an OS from a Solaris Flash archive. The remaining options for this use of `luupgrade`, shown above, are described as follows:

`-n` *BE_name*	Name of the BE to receive an OS installation.
`-D`	Tests the profile values provided with `-j` or `-J` against the disk configuration of the specified BE. The upgrade is not performed. The effect of this option is a dry run to test your profile. `luupgrade` creates log files, specified in its output, which allow you to examine the command's results.
`-s` *os_image_path*	Path name of a directory containing an OS image. This can be a directory on an installation medium, such as a DVD or CD, or can be an NFS or UFS directory.
`-a` *archive*	Path to the Solaris Flash archive when the archive is available on the local file system. You must specify one of `-a`, `-j`, or `-J`.
`-j` *profile_path*	Path to a JumpStart profile that is configured for a Solaris Flash installation. See the section "JumpStart Profile Keywords," below, for a list of valid keywords for use in a profile invoked by `luupgrade`. See `pfinstall(1M)` and the Solaris installation documentation for information on the JumpStart software. You must specify one of `-a`, `-j`, or `-J`.
`-J` *"profile"*	Entry from a JumpStart profile that is configured for a Solaris Flash installation. The only valid keyword for this option is `archive_location`. See `pfinstall(1M)` and the Solaris installation documentation for information on the JumpStart software. You must specify one of `-a`, `-j`, or `-J`.

Note that the version of the OS image specified with `-s` must be identical to the version of the OS contained in the Solaris Flash archive specified with the `-a`, `-j`, or `-J` options.

Adding or Removing Packages

The `luupgrade` command uses `-p` to add a package and `-P` to remove a package. The syntax is as follows:

For adding packages:

```
luupgrade -p -n BE_name [ -l error_log ][ -o outfile ] [ -N ]
 -s packages_path [ -O "pkgadd_options" ] [ -a admin ]
[ pkginst [ pkginst...]]
```

For removing packages:

```
luupgrade -P -n BE_name [ -l error_log ][ -o outfile ] [ -N ]
[ -O "pkgrm_options" ] [ pkginst [ pkginst...]]
```

The first option, `-p`, to add packages, or `-P` to remove packages, indicates the function to perform. The remaining options for this use of `luupgrade`, shown above, are described as follows:

`-n` *BE_name*	Name of the BE to which packages will be added or from which packages will be removed.
`-s` *packages_path*	(For adding packages only.) Path name of a directory containing packages to add. You can substitute `-d` for `-s`. The `-d` support is for `pkgadd(1M)` compatibility.
`-d` *packages_path*	Identical to `-s`. Use of `-s` is recommended.
`-O` "*pkgadd_options*" or "*pkgrm_options*"	Options passed directly to `pkgadd` (for `-p`) or `pkgrm` (for `-P`). See `pkgadd(1M)` and `pkgrm(1M)` for descriptions of the options for those commands.
`-a` *admin*	(For adding packages only.) Path to an admin file. Identical to the `pkgadd -a` option. Use of the `-a` option here is identical to `-O` "`-a` *admin*"
pkginst [*pkginst...*]	Zero or more packages to add or remove. For adding packages, the default is to add all of the packages specified with the `-s` option, above. Separate multiple package names with spaces.

It is critically important that any packages you add be compliant with the SVR4 Advanced Packaging Guidelines. See WARNINGS, below.

Adding or Removing Patches

The `luupgrade` command uses `-t` to add a patch and `-T` to remove a patch. The syntax is as follows:

For adding patches:

```
luupgrade -t -n BE_name [ -l error_log ][ -o outfile ] [ -N ]
-s patch_path [ -O "patchadd_options" ] [ patch_name [ patch_name...]]
```

For removing patches:

```
luupgrade -T -n BE_name [ -l error_log ][ -o outfile ] [ -N ]
[ -O "patchrm_options" ] [ patch_name [ patch_name...]]
```

The first option, `-t`, to add patches, or `-T` to remove patches, indicates the function to perform. The remaining options for this use of `luupgrade`, shown above, are described as follows:

`-n` *BE_name*	Name of the BE to which patches will be added or from which patches will be removed.
`-s` *patch_path*	(For adding patches only.) Path name of a directory containing patches to add or path name of a patch_order file.
`-O` "*patchadd_options*" or "*patchrm_options*"	Options passed directly to `patchadd` (for `-p`) or `patchrm` (for `-P`). See `patchadd(1M)` or `patchrm(1M)` for a description of these options.
patch_name [*patch_name...*]	Zero or more patches to add or remove. For adding patches, the default is to add all of the patches specified with the `-s` option, above. Separate multiple patch names with spaces.

It is critically important that any patches you add be compliant with the SVR4 Advanced Packaging Guidelines. See WARNINGS, below.

Checking or Returning Information on Packages

Use the `-C` to perform a `pkgchk(1M)` on all or the specified packages on a BE. Use the `-I` option to perform a `pkginfo(1)`.

For performing a `pkgchk`:

```
luupgrade -C -n BE_name [ -l error_log ][ -o outfile ] [ -N ]
[ -O "pkgchk_options" ][ pkginst [ pkginst...]]
```

For performing a `pkginfo`:

```
luupgrade -I -n BE_name [ -l error_log ][ -o outfile ] [ -N ]
[ -O "pkginfo_options" ][ pkginst [ pkginst...]]
```

The first option, `-C`, for `pkgchk`, or `-I`, for `pkginfo`, indicates the function to perform. The remaining options for this use of `luupgrade`, shown above, are described as follows:

`-n` *BE_name*	Name of the BE on which packages will be checked or on whose packages information will be returned.
`-O` "*pkgchk_options*" or "*pkginfo_options*"	Options passed directly to `pkgchk` (for `-C`) or `pkginfo` (for `-I`). See `pkgchk(1M)` or `pkginfo(1)` for a description of these options.
pkginst [*pkginst...*]	Zero or more packages to check or for which to have information returned. If you omit package names, `luupgrade` returns information on all of the packages on the BE. Separate multiple

package names with spaces.

Checking an OS Installation Medium

With the `-c` option, `luupgrade` allows you to check that a local or remote medium, such as a DVD or CD, is a valid installation medium. The `-c` option returns useful information about the specified medium. The syntax for this use of `luupgrade` is as follows:

```
luupgrade -c [ -l error_log ] [ -o outfile ] -s path_to_medium
```

The first option, `-c`, indicates the function to perform—to check on an installation medium. The `-s` option, shown above, is described as follows:

`-s` *path_to_medium* Path name to an installation medium such as a DVD or CD.

JumpStart Profile Keywords

This section specifies the Solaris JumpStart keywords that can be used in a profile with `luupgrade`, using the `-j` option in conjunction with the `-u` (upgrade) or `-f` (flash) options. For `-u`, there are no required keywords. For `-f`, you must specify a value for `install_type`: `flash_install` for a full flash archive or `flash_update` for a differential flash archive. Also for the `-f` option with the `-j` option, you must specify the `-a` (archive location) option or specify the `archive_location` keyword in your profile.

The `archive_location` keyword is the only valid argument for the `-J` option.

The following optional keywords are sometimes used in profiles used with the `-u` and `-f` options:

`cluster` Designates the software group to add to the system.

`geo` Designates the regional locale or locales that you want to install on or add to a system. See the *Solaris Installation Guide* for a list of possible values.

`isa_bits` Specifies whether 64–bit or 32–bit packages are to be installed. Valid values are `64` and `32`.

`locale` Designates the locale packages you want to install on or add to a system. See the *Solaris Installation Guide* for a list of possible values.

`package` Specifies a package to be added to or deleted from a system.

The following keywords must not be used in a profile used with `luupgrade`:

- `boot_device`
- `dontuse`
- `fdisk`
- `filesys`
- `layout_constraint`
- `noreboot`
- `partitioning`
- `root_device`
- `usedisk`

See the *Solaris Installation Guide* for descriptions of all JumpStart profile keywords and instructions for creating a JumpStart profile.

Examples

EXAMPLE 1 Removing, then Adding Packages

The following example removes from then adds a set of packages to a boot environment.

```
# luupgrade -P -n second_disk SUNWabc SUNWdef SUNWghi
```

Now, to add the same packages:

```
# luupgrade -p -n second_disk -s /net/installmachine/export/packages \
SUNWabc SUNWdef SUNWghi
```

The following command adds the `-O` option to the preceding command. This option passes arguments directly to `pkgadd`.

```
# luupgrade -p -n second_disk -s /net/installmachine/export/packages \
-O "-r /net/testmachine/export/responses" SUNWabc SUNWdef SUNWghi
```

See `pkgadd(1M)` for a description of the options for that command.

EXAMPLE 2 Upgrading to a New OS from a Combined Image

The following example upgrades the operating environment on a boot environment. The source image is stored as a combined image on a remote disk or on a DVD.

```
# luupgrade -u -n second_disk \
-s /net/installmachine/export/solarisX/OS_image
```

Following the command above you could enter the command below to activate the upgraded BE.

```
# luactivate second_disk
```

Then, upon the next reboot, `second_disk` would become the current boot environment. See `luactivate(1M)`.

EXAMPLE 3 Upgrading to a New OS from Multiple CDs

The following example is a variation on the preceding. The OS upgrade resides on two CDs. To begin the upgrade on a SPARC machine, you enter:

```
# luupgrade -u -n second_disk -s /cdrom/cdrom0/s0
```

On x86 machines, replace the `s0` in the argument to `-s` with `s2`.

When the installer is finished with the contents of the first CD, insert the next CD in the drive and enter the following:

EXAMPLE 3 Upgrading to a New OS from Multiple CDs *(Continued)*

```
# luupgrade -i -n second_disk -s /cdrom/cdrom0 \
-O "-nodisplay -noconsole"
```

Note the use of `-i` rather than `-u` in the preceding. Were there additional CDs, you would enter the same command as the one immediately above. The `-O` options, above, are passed to `installer(1M)`. If you omit these options, a graphical interface is invoked following the insertion and reading of the second CD. See `installer(1M)` for a description of the `-O` options.

Note that a multiple-CD upgrade is not complete until you have entered and completed `luupgrade` commands for all of the CDs in a set. Following installation of packages from a CD, you might receive a message such as:

`WARNING: <`*num*`> packages must be installed on boot environment <`*disk_device*`>.`

Such a message indicates the requirement that you install packages from one or more additional CDs, as in the example above. If you do not complete package installation, you will not be able to use `luactivate` to activate (designate for booting) the upgraded BE.

EXAMPLE 4 Upgrading Using a JumpStart Profile

The following example command uses the `-D` option to test the profile `/home2/profiles/test.profile`.

```
# luupgrade -u -n second_disk \
-s /net/installmachine/export/solarisX/OS_image \
-j /home2/profiles/test.profile -D
```

Assuming the results of this command were acceptable, you could omit the `-D` in the preceding command to perform the upgrade.

EXAMPLE 5 Installing a New OS from a Solaris Flash Archive

The following example installs the operating environment on a boot environment, using a Solaris Flash archive. The file pointed to by `-J` is a JumpStart profile that specifies a flash installation.

```
# luupgrade -f -n second_disk \
-s /net/installmachine/export/solarisX/OS_image \
-J "archive_location http://example.com/myflash.flar"
```

The following command differs from the preceding only in that `-j` replaces `-J`. You could append the `-D` option to either of these commands to test the profile prior to actually performing the flash installation.

```
# luupgrade -f -n second_disk \
-s /net/installmachine/export/solarisX/OS_image \
```

EXAMPLE 5 Installing a New OS from a Solaris Flash Archive *(Continued)*

```
-j /net/example/flash_archives/flash_gordon
```

Either of the preceding commands works for a full or differential flash installation. Whether a flash installation is differential or full is determined by the value of the `install_type` keyword in the profile. See "JumpStart Profile Keywords," above.

EXAMPLE 6 Obtaining Information on Packages

The following example runs a `pkgchk` on the packages `SUNWluu`, `SUNWlur`, and `SUNWlucfg`, passing to `pkgchk` the `-v` option.

```
# luupgrade -C -n second_disk -O "-v" SUNWluu SUNWlur SUNWlucfg
```

The following command runs `pkginfo` on the same set of packages:

```
# luupgrade -I -n second_disk -O "-v" SUNWluu SUNWlur SUNWlucfg
```

For both commands, if the package names were omitted, `luupgrade` returns package information on all of the packages in the specified BE. See `pkgchk(1M)` and `pkginfo(1)` for a description of the options for those commands.

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Files

`/etc/lutab`	list of BEs on the system
`/usr/share/lib/xml/dtd/lu_cli.dtd.<num>`	Live Upgrade DTD (see `-X` option in "Options that Apply to All Uses," above)

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWluu

See Also `installer(1M)`, `luactivate(1M)`, `lucancel(1M)`, `lucompare(1M)`, `lucreate(1M)`, `lucurr(1M)`, `ludelete(1M)`, `ludesc(1M)`, `lufslist(1M)`, `lumake(1M)`, `lumount(1M)`, `lurename(1M)`, `lustatus(1M)`, `lutab(4)`, `sysidcfg(4)`, `attributes(5)`, `live_upgrade(5)`, `zones(5)`

Warnings For adding packages or patches (`-p`, `-P`, `-t`, or `-T`), `luupgrade` requires packages or patches that comply with the SVR4 Advanced Packaging Guidelines and the guidelines spelled out in Appendix C of the *Solaris 10 Installation Guide: Basic Installations*. This means that the package or patch is compliant with the `pkgadd(1M)` or `patchadd(1M)` `-R` option, described in

the man pages for those utilities. While nearly all Sun packages and patches conform to these guidelines, Sun cannot guarantee the conformance of packages and patches from third-party vendors. Some older Sun packages and patches might not be `-R` compliant. If you encounter such a package or patch, please report it to Sun. A non-conformant package can cause the package- or patch-addition software in `luupgrade` to fail or, worse, alter the current BE.

Notes For versions of the Solaris operating system prior to Solaris 10, Live Upgrade supports the release it is distributed on and up to three marketing releases back. For example, if you obtained Live Upgrade with Solaris 9 (including a Solaris 9 upgrade), that version of Live Upgrade supports Solaris versions 2.6, Solaris 7, and Solaris 8, in addition to Solaris 9. No version of Live Upgrade supports a Solaris version prior to Solaris 2.6.

Starting with version 10 of the Solaris operating system, Live Upgrade supports the release it is distributed on and up to two marketing releases back. For example, if you obtained Live Upgrade with Solaris 10 (including a Solaris 10 upgrade), that version of Live Upgrade supports Solaris 8 and Solaris 9, in addition to Solaris 10.

Correct operation of Solaris Live Upgrade requires that a limited set of patch revisions be installed for a given OS version. Before installing or running Live Upgrade, you are required to install the limited set of patch revisions. Make sure you have the most recently updated patch list by consulting `http://sunsolve.sun.com`. Search for the infodoc 72099 on the SunSolve web site.

Name luxadm – administer Sun Fire 880 storage subsystem and FC_AL devices

Synopsis

```
luxadm [options]... subcommand [options]... enclosure
     [,dev] | pathname...
```

Description The `luxadm` program is an administrative command that manages the SENA, Sun Fire 880 internal storage subsystem, and individual Fiber Channel Arbitrated Loop (FC_AL) devices. `luxadm` performs a variety of control and query tasks depending on the command line arguments and options used.

The command line must contain a subcommand. The command line may also contain options, usually at least one enclosure name or pathname, and other parameters depending on the subcommand. You need specify only as many characters as are required to uniquely identify a subcommand.

Specify the device that a subcommand interacts with by entering a pathname. For the SENA subsystem, a disk device or enclosure services controller may instead be specified by entering the World Wide Name (WWN) for the device or a port to the device. The device may also be specified by entering the name of the SENA enclosure, and an optional identifier for the particular device in the enclosure. The individual FC_AL devices may be specified by entering the WWN for the device or a port to the device.

Pathname Specify the device or controller by either a complete physical pathname or a complete logical pathname.

For SENA, a typical physical pathname for a device is:

```
/devices/sbus@1f,0/SUNW,socal@1,0/sf@0,0/ssd@w2200002037000f96,
         0:a,raw
```

For all SENA IBs (Interface Boards) and Sun Fire 880 SES device controllers on the system, a logical link to the physical paths is kept in the directory `/dev/es`. An example of a logical link is `/dev/es/ses0`.

The WWN may be used in place of the pathname to select an FC_AL device, SENA subsystem IB, or Sun Fire 880 internal storage subsystem. The WWN is a unique 16 hexadecimal digit value that specifies either the port used to access the device or the device itself. A typical WWN value is:

```
2200002037000f96
```

See NOTES for more information on the WWN formats.

For a disk in a Sun Fire 880 internal storage subsystem, a typical physical pathname is:

```
/devices/pci@8,600000/SUNW,qlc@2/fp@0,0/ssd@w2100002037a6303c,0:a
```

and a typical logical pathname is:

```
/dev/rdsk/c2t8d0s2
```

For individual FC_AL devices, a typical physical pathname is:

```
/devices/sbus@3.0/SUNW,socal@d,10000/sf@0,0/ssd@w2200002037049fc3,0:a,raw
```

and a typical logical pathname is:

```
/dev/rdsk/c1t0d0s2
```

Enclosure For SENA, a device may be identified by its enclosure name and slotname:

box_name[,f*slot_number*]
box_name[,r*slot_number*]

box_name is the name of the SENA enclosure, as specified by the `enclosure_name` subcommand. When used without the optional *slot_number* parameter, the *box_name* identifies the SENA subsystem IB.

`f` or `r` specifies the front or rear slots in the SENA enclosure.

slot_number specifies the slot number of the device in the SENA enclosure, `0-6` or `0-10`.

For a Sun Fire 880 internal storage subsystem, a device may also be identified by its enclosure name and slot name. However, there is only one set of disks:

box_name[,s*slot_number*]

box_name is the name of the Sun Fire 880 enclosure, as specified by the `enclosure_name` subcommand. When used without the optional *slot_number* parameter, *box_name* identifies the Sun Fire 880 internal storage subsystem enclosure services device. Use *s* to specify the disk slot number in the Sun Fire 880 internal storage subsystem, `0 - 11`.

See `disks(1M)` and `devlinks(1M)` for additional information on logical names for disks and subsystems.

Options The following options are supported by all subcommands:

`-e` Expert mode. This option is not recommended for the novice user.

`-v` Verbose mode.

Options that are specific to particular subcommands are described with the subcommand in the `USAGE` section.

Operands The following operands are supported:

enclosure The *box_name* of the SENA or Sun Fire 880 internal storage subsystem.

fibre_channel_HBA_port The path to the host controller port. A typical path is:

```
/devices/pci@8,600000/pci@1/SUNW,qlc@4/fp@0,0:devctl
```

pathname The logical or physical path of a SENA IB, Sun Fire 880 internal storage subsystem, or disk device. *pathname* can also be the WWN of a SENA IB, SENA disk, or individual FC_AL device.

Usage

Subcommands

`display` *enclosure*[,*dev*] . . . | *pathname* . . .
`display -p` *pathname* . . .
`display -r` *enclosure*[,*dev*] . . . | *pathname* . . .
`display -v` *enclosure*[,*dev*] . . . | *pathname* . . .

Displays enclosure or device specific data.

Subsystem data consists of enclosure environmental sense information and status for all subsystem devices, including disks.

Disk data consists of inquiry, capacity, and configuration information.

`-p` Displays performance information for the device or subsystem specified by *pathname*. This option only applies to subsystems that accumulate performance information.

`-r` Displays error information for the FC_AL device specified by the pathname, or, if the path is a SENA, for all devices on the loop. The `-r` option only applies to SENA subsystems and individual FC_AL devices.

`-v` Displays in verbose mode, including mode sense data.

`download` [`-s`] [`-f` *filename_path*] *enclosure*. . .

Download the prom image pointed to the SENA subsystem Interface Board unit or the Sun Fire 880 internal storage subsystem specified by the enclosure or pathname.

When the SENA's download is complete, the SENA will be reset and the downloaded code executed. If no

filename is specified, the default prom image will be used. The default prom image for the SENA is in the directory `usr/lib/locale/C/LC_MESSAGES` and is named `ibfirmware`

When the Sun Fire 880 internal storage subsystem's download is complete, the subsystem resets and the downloaded code begins execution. The default firmware image for the Sun Fire 880 internal storage subsystem is in: `/usr/platform/SUNW,Sun-Fire-880/lib/image`

`-s` Save. The `-s` option is used to save the downloaded firmware in the FEPROM. If `-s` is not specified, the downloaded firmware will not be saved across power cycles.

The `-s` option does not apply to the Sun Fire 880 internal storage subsystem as it always stores downloaded firmware in the flash memory.

When using the `-s` option, the `download` subcommand modifies the FEPROM on the subsystem and should be used with *caution*.

`enclosure_name` *new_name enclosure* | *pathname*

Change the enclosure name of the enclosure or enclosures specified by the enclosure or pathname. The new name (*new_name*) must be 16 or less characters. Only alphabetic or numeric characters are acceptable. This subcommand applies only to the SENA and the Sun Fire 880 internal storage subsystem.

`failover primary` | `secondary` *pathname*

Select which Sun Storage T3 storage array partner group controller accesses a given logical volume. If `primary` is specified, the logical volume is accessed through the primary controller. If

`secondary` is specified, the logical volume is accessed through the secondary controller specified by *pathname*.

`fcal_s_download` [`-f` *fcode-file*]

Download the fcode contained in the file *fcode-file* into *all* the FC100/S Sbus Cards. This command is interactive and expects user confirmation before downloading the fcode.

Use `fcal_s_download` *only* in single-user mode. Using `fcal_s_download` to update a host adapter while there is I/O activity through that adapter *will* cause the adapter to reset. Newly updated FCode will not be executed or visible until a system reboot.

`-f` *fcode-file* — When invoked without the `-f` option, the current version of the fcode in each FC100/S Sbus card is printed.

`fcode_download -p`
`fcode_download -d` *dir-name*

Locate the installed FC/S, FC100/S, FC100/P, or FC100/2P host bus adapter cards and download the FCode files in *dir-name* to the appropriate cards. The command determines the correct card for each type of file, and is interactive. User confirmation is required before downloading the FCode to each device.

Use `fcode_download` to load FCode only in single-user mode. Using `fcode_download` to update a host adapter while there is I/O activity through that adapter causes the adapter to reset. Newly updated FCode will not be executed or visible until a system reboot.

`-d` *dir-name* — Download the FCode files contained in the directory *dir-name* to the appropriate adapter cards.

`-p` — Prints the current version of FCode loaded on each card. No download is performed.

`inquiry` *enclosure*[,*dev*] . . . | *pathname* . . . — Display the inquiry information for the selected device specified by the enclosure or pathname.

`insert_device` [*enclosure*,*dev* . . .] — Assist the user in the hot insertion of a new device or a chain of new devices. Refer to `NOTES` for limitations on hotplug operations. This subcommand applies only to the SENA, Sun Fire 880 internal storage subsystem, and individual FC_AL drives. For the SENA, if more than one enclosure has been specified, concurrent hot insertions on multiple busses can be performed. With no arguments to the subcommand, entire enclosures or individual FC_AL drives can be inserted. For the SENA or the Sun Fire 880 internal storage subsystem, this subcommand guides the user interactively through the hot insertion steps of a new device or chain of devices. If a list of disks was entered it will ask the user to verify the list of devices to be inserted is correct, at which point the user can continue or quit. It then interactively asks the user to insert the disk(s) or enclosure(s) and then creates and displays the logical pathnames for the devices.

`led` *enclosure*,*dev* . . . | *pathname*. . .
Display the current state of the LED associated with the disk specified by the enclosure or pathname. This subcommand only applies to subsystems that support this functionality.

`led_blink` *enclosure,dev . . .* | *pathname . . .*
Requests the subsystem to start blinking the LED associated with the disk specified by the enclosure or pathname. This subcommand only applies to subsystems that support this functionality.

`led_off` *enclosure,dev . . .* | *pathname . . .*
Requests the subsystem to disable (turn off) the LED associated with the disk specified by the enclosure or pathname. On a SENA subsystem, this may or may not cause the LED to turn off or stop blinking depending on the state of the SENA subsystem. Refer to the SENA Array Installation and Service Manual (p/n 802-7573). This subcommand only applies to subsystems that support this functionality.

`led_on` *pathname . . .*
Requests the subsystem to enable (turn on) the LED associated with the disk specified by the pathname. This subcommand only applies to subsystems that support this functionality.

`power_off` [`-F`] *enclosure*[,*dev*] . . . | *pathname . . .*
When a SENA is addressed, this subcommand causes the SENA subsystem to go into the power-save mode. The SENA drives are not available when in the power-save mode. When a drive in a SENA is addressed the drive is set to the drive off/unmated state. In the drive off/unmated state, the drive is spun down (stopped) and in bypass mode. This command does not apply to the Sun Fire 880 internal storage subsystem.

`-F` The force option only applies to the SENA. Instructs `luxadm` to attempt to power off one or more devices even if those devices are being used by this host (and are, therefore, busy).

Warning: Powering off a device which has data that is currently being used will cause unpredictable results. Users should attempt to power off the device normally (without `-F`) first, only resorting to this option when sure of the consequences of overriding normal checks.

`power_on` *enclosure*[`,`*dev*] . .
Causes the SENA subsystem to go out of the power-save mode, when this subcommand is addressed to a SENA.. When this subcommand is addressed to a drive the drive is set to its normal start-up state. This command does not apply to the Sun Fire 880 internal storage subsystem.

`probe` [`-p`]
Finds and displays information about all attached SENA subsystems, Sun Fire 880 internal storage subsystems, and individual FC_AL devices, including the logical pathname, the WWNs, and enclosure names. This subcommand warns the user if it finds different SENAs with the same enclosure names.

`-p` Includes the physical pathname in the display.

`qlgc_s_download` [`-f` *fcode-file*]
Download the FCode contained in the file *fcode-file* into all the FC100/P, FC100/2P PCI host adapter cards. This command is interactive and expects user confirmation before downloading the FCode to each device. Only use `qlgc_s_download` in single-user mode. Using `qlgc_s_download` to update a host adapter while there is I/O activity through that adapter will cause the adapter to reset. Newly updated FCode will not be executed or visible until a system reboot.

`-f` *fcode-file* When invoked without the `-f` option, the current version of the FCode in each FC100/P, FC100/2P PCI card is printed.

`release` *pathname*
Release a reservation held on the specified disk. The pathname should be the physical or logical pathname for the disk.

This subcommand is included for historical and diagnostic purposes only.

`remove_device` [`-F`] *enclosure*[,*dev*] . . . | *pathname* . . .
Assists the user in hot removing a device or a chain of devices. This subcommand can also be used to remove entire enclosures. This subcommand applies to the SENA, Sun Fire 880 internal storage subsystem, and individual FC_AL drives. Refer to `NOTES` for limitations on hotplug operations. For the SENA, Sun Fire 880 internal storage subsystem, and individual FC_AL devices, this subcommand guides the user through the hot removal of a device or devices. During execution it will ask the user to verify the list of devices to be removed is correct, at which point the user can continue or quit. It then prepares the disk(s) or enclosure(s) for removal and interactively asks the user to remove the disk(s) or enclosure(s).

For Multi-Hosted disk, the steps taken are:

- Issue the `luxadm remove_device` command on the first host. When prompted to continue, wait.
- Issue the `luxadm remove_device` command on the secondary hosts. When prompted to continue, wait.
- Continue with the `remove_device` command on the first host. Remove the device when prompted to do so.
- Complete the `luxadm remove_device` command on the additional hosts.

`-F` Instructs `luxadm` to attempt to hot plug one or more devices even if those devices are being used by this host (and are, therefore, *busy* or *reserved*), to *force* the hotplugging operation.

Warning: Removal of a device which has data that is currently being used will cause unpredictable results. Users should attempt to hotplug normally (without `-F`) first, only resorting to this option when sure of the consequences of overriding normal hotplugging checks.

`reserve` *pathname*
: Reserve the specified disk for exclusive use by the issuing host. The pathname used should be the physical or logical pathname for the disk.

  This subcommand is included for historical and diagnostic purposes only.

`set_boot_dev` [`-y`] *pathname*
: Set the boot-device variable in the system PROM to the physical device name specified by *pathname*, which can be a block special device or the pathname of the directory on which the boot file system is mounted. The command normally runs interactively requesting confirmation for setting the default boot-device in the PROM. The `-y` option can be used to run it non-interactively, in which case no confirmation is requested or required.

`start` *pathname*
: Spin up the specified disk(s) in a SENA.

`stop` *pathname...*
: Spin down the specified disks in a SENA.

SENA, Sun Fire 880 Internal Storage Subsystem, and Individual FC_AL Drive Expert Mode Subcommands

The following subcommands are for expert use only, and are applicable only to the SENA, Sun Fire 880 internal storage subsystem, and fiber channel loops. They should only be used by users that are knowledgeable about the SENA subsystem and fiber channel loops.

If you specify a disk to an expert subcommand that operates on a bus, the subcommand operates on the bus to which the specified disk is attached.

`-e bypass [-ab]` *enclosure,dev*
`-e bypass -f` *enclosure*
: Request the enclosure services controller to set the LRC (Loop Redundancy Circuit) to the bypassed state for the port and device specified.

  This subcommand supports the following options:

  `-a`
  : Bypass port `a` of the device specified.

  `-b`
  : Bypass port `b` of the device specified.

`-e dump_map` *fibre_channel_HBA_port*
: Display WWN data for a target device or host bus adapter on the specified fibre channel port. If there are no target devices on the specified port, an error is returned.

`-e enable [-ab]` *enclosure,dev*

`-e enable -f` *enclosure*

Request the enclosure services controller to set the LRC (Loop Redundancy Circuit) to the enabled state for the port and device specified.

This subcommand supports the following options:

`-a` Enable port `a` of the device specified.

`-b` Enable port `b` of the device specified.

`-e forcelip` *enclosure*[`,`*dev*] `...` | *pathname* `...`

Force the link to reinitialize, using the Loop Initialization Primitive (LIP) sequence. The enclosure or pathname can specify any device on the loop. Use the pathname to specify a specific path for multiple loop configurations.

This is an expert only command and should be used with caution. It will reset all ports on the loop.

`-e rdls` *enclosure*[`,`*dev*] `...` | *pathname* `...`

Read and display the link error status information for all available devices on the loop that contains the device specified by the enclosure or pathname.

Other Expert Mode Subcommands

See `NOTES` for limitations of these subcommands. They should only be used by users that are knowledgeable about the systems they are managing.

These commands do not apply to the Sun Fire 880 internal storage subsystem.

`-e bus_getstate` *pathname* Get and display the state of the specified bus.

`-e bus_quiesce` *pathname* Quiesce the specified bus.

`-e bus_reset` *pathname* Reset the specified bus only.

`-e bus_resetall` *pathname* Reset the specified bus and all devices.

`-e bus_unquiesce` *pathname* Unquiesce the specified bus. the specified device.

`-e dev_getstate` *pathname* Get and display the state of the specified device.

`-e dev_reset` *pathname* Reset the specified device.

`-e offline` *pathname*	Take the specified device offline.
`-e online` *pathname*	Put the specified device online.

Examples

EXAMPLE 1 Displaying the SENAs and Individual FC_AL Devices on a System

The following example finds and displays all of the SENAs and individual FC_AL devices on a system:

```
example% luxadm probe
```

EXAMPLE 2 Displaying a SENA or Sun Fire 880 Internal Storage Subsystem

The following example displays a SENA or Sun Fire 880 internal storage subsystem:

```
example% luxadm display /dev/es/ses0
```

EXAMPLE 3 Displaying Two Subsystems

The following example displays two subsystems using the enclosure names:

```
example% luxadm display BOB system1
```

EXAMPLE 4 Displaying Information about the First Disk

The following example displays information about the first disk in the front of the enclosure named `BOB`. Use `f` to specify the front disks. Use `r` to specify the rear disks.

```
example% luxadm display BOB,f0
```

EXAMPLE 5 Displaying Information on a Sun Fire 880 Internal Storage Subsystem

The Sun Fire 880 internal storage subsystem has only one set of disks. In this case, use *s* to specify the slot:

```
example% luxadm display BOB,s0
```

EXAMPLE 6 Displaying Information about a SENA disk, an Enclosure, or an Individual FC_AL Drive

The following example displays information about a SENA disk, an enclosure, or an individual FC_AL drive with the port WWN of `2200002037001246`:

```
example% luxadm display 2200002037001246
```

EXAMPLE 7 Using Unique Characters to Issue a Subcommand

The following example uses only as many characters as are required to uniquely identify a subcommand:

```
example% luxadm disp BOB
```

EXAMPLE 8 Displaying Error Information

The following example displays error information about the loop that the enclosure BOB is on:

```
example% luxadm display -r BOB
```

EXAMPLE 9 Downloading New Firmware into the Interface Board

The following example downloads new firmware into the Interface Board in the enclosure named BOB (using the default path for the file to download):

```
example% luxadm download -s BOB
```

EXAMPLE 10 Displaying Information from the SCSI Inquiry Command

The following example displays information from the SCSI inquiry command from all individual disks on the system, using only as many characters as necessary to uniquely identify the inquiry subcommand:

```
example% luxadm inq /dev/rdsk/c?t?d?s2
```

EXAMPLE 11 Hotplugging

The following example hotplugs a new drive into the first slot in the front of the enclosure named BOB:

```
example% luxadm insert_device BOB,f0
```

The following example hotplugs a new drive into the first slot in the Sun Fire 880 internal storage subsystem named SF880-1:

```
example% luxadm insert_device SF880-1,s0
```

EXAMPLE 12 Running an Expert Subcommand

The following example runs an expert subcommand. The subcommand forces a loop initialization on the loop that the enclosure BOB is on:

```
example% luxadm -e forcelip BOB
```

EXAMPLE 13 Using the Expert Mode Hot Plugging Subcommands

An example of using the expert mode hot plugging subcommands to hot remove a disk follows. See NOTES for hot plugging limitations.

The first step reserves the SCSI device so that it can't be accessed by way of its second SCSI bus:

```
example# luxadm reserve /dev/rdsk/c1t8d0s2
```

EXAMPLE 14 Taking the Disk to be Removed Offline

The next two steps take the disk to be removed offline then quiesce the bus:

EXAMPLE 14 Taking the Disk to be Removed Offline *(Continued)*

```
example# luxadm -e offline /dev/rdsk/c1t8d0s2
example# luxadm -e bus_quiesce /dev/rdsk/c1t8d0s2
```

EXAMPLE 15 Unquiescing the Bus

The user then removes the disk and continues by unquiescing the bus, putting the disk back online, then unreserving it:

```
example# luxadm -e bus_unquiesce /dev/rdsk/c1t8d0s2
example# luxadm -e online /dev/rdsk/c1t8d0s2
example# luxadm release /dev/rdsk/c1t8d0s2
```

Environment Variables

See `environ(5)` for a description of the `LANG` environment variable that affects the execution of `luxadm`.

Exit Status

The following exit values are returned:

`0` Successful completion.

`–1` An error occurred.

Files

`usr/lib/firmware/fc_s/fc_s_fcode`

`usr/lib/locale/C/LC_MESSAGES/ibfirmware`

Attributes

See `attributes(5)` for descriptions of the following attributes:

usr/sbin

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWluxop

SENA Array Installation and Service Manual (p/n 802-7573).

RAID Manager 6.1 Installation and Support Guide Answerbook

RAID Manager 6.1 User's Guide Answerbook

Notes

See the *SENA Array Installation and Service Manual* for additional information on the SENA. Refer to *Tutorial for SCSI use of IEEE Company_ID*, R. Snively, for additional information regarding the IEEE extended WWN. See `SEE ALSO`. Currently, only some device drivers support hot plugging. If hot plugging is attempted on a disk or bus where it is not supported, an error message of the form:

```
luxadm: can't acquire "PATHNAME": No such file or directory
```

will be displayed.

You must be careful not to quiesce a bus that contains the root or the `/usr` filesystems or any swap data. If you do quiesce such a bus a deadlock can result, requiring a system reboot.

Name m64config, SUNWm64_config – configure the M64 Graphics Accelerator

Synopsis

```
/usr/sbin/m64config [-defaults] [-depth 8 | 24 | 32]
     [-dev device-filename] [-file machine | system]
     [-prconf] [-propt]
     [-res video-mode [now | try] [noconfirm | nocheck ]]

/usr/sbin/m64config [-prconf] [-propt]

/usr/sbin/m64config [-help] [-res ?]
```

Description `m64config` configures the M64 Graphics Accelerator and some of the X11 window system defaults for M64.

The first form of `m64config` stores the specified options in the OWconfig file. These options will be used to initialize the M64 device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots.

The second and third forms which invoke only the `-prconf`, `-propt`, `-help`, and `-res ?` options do not update the OWconfig file. Additionally, for the third form all other options are ignored.

Options may be specified for only one M64 device at a time. Specifying options for multiple M64 devices requires multiple invocations of `m64config`.

Only M64-specific options can be specified through `m64config`. The normal window system options for specifying default depth, default visual class and so forth are still specified as device modifiers on the `openwin` command line. See the *OpenWindows Desktop Reference Manual* for details.

The user can also specify the OWconfig file that is to be updated. By default, the machine-specific file in the `/etc/openwin` directory tree is updated. The `-file` option can be used to specify an alternate file to use. For example, the system-global OWconfig file in the `/usr/openwin` directory tree can be updated instead.

Both of these standard OWconfig files can only be written by root. Consequently, the `m64config` program, which is owned by the root user, always runs with `setuid` root permission.

Options

`-defaults`
: Resets all option values to their default values.

`-depth 8 | 24 | 32`
: Sets the depth (bits per pixel) on the device. Possible values are `8`, `24`, or `32` (where `32` uses 24 bits per pixel). Log out of the current window system session and log back in for the change to take effect. `24` or `32` enables TrueColor graphics in the window system, at the expense of screen resolution.

The 32 setting enables simultaneous 8– and 24–bit color windows on m64 devices that support it. With setting 32, -propt shows depth 32 and -prconf shows depth 24. To check window depth, use the xwininfo utility. The xwininfo utility is usually shipped in the package containing frame buffer software (such as SUNWxwplt).

The maximum resolution that is available with 24 bits per pixel depends on the amount of memory installed on the PGX card. For 2-MB PGX cards, the maximum available resolution is 800x600. For 4-MB cards, it is 1152x900. For 8-MB cards, it is 1920x1080. If there is not enough memory for the specified combination of resolution and depth, m64config displays an error message and exits.

-dev *device-filename*
Specifies the M64 special file. If not specified, m64config will try /dev/fbs/m640 through /dev/fbs/m648 until one is found.

-file machine| system
Specifies which OWconfig file to update. If machine, the machine-specific OWconfig file in the /etc/openwin directory tree is used. If system, the global OWconfig file in the /usr/openwin directory tree is used. If the file does not exist, it is created. This option has no effect unless other options are specified. The default is *machine*.

-help
Prints a list of the m64config command line options, along with a brief explanation of each.

-prconf
Prints the M64 hardware configuration. The following is a typical display using the -prconf option:

```
--- Hardware Configuration for /dev/fbs/m640 ---
ASIC: version 0x41004754
DAC: version 0x0
PROM: version 0x0
Card possible resolutions: 640x480x60, 800x600x75, 1024x768x60
    1024x768x70, 1024x768x75, 1280x1024x75, 1280x1024x76
    1280x1024x60, 1152x900x66, 1152x900x76, 1280x1024x67
    960x680x112S, 960x680x108S, 640x480x60i, 768x575x50i
    1280x800x76, 1440x900x76, 1600x1000x66, 1600x1000x76
    vga, svga, 1152, 1280, stereo, ntsc, pal
Monitor possible resolutions: 720x400x70, 720x400x85, 640x480x60
    640x480x67, 640x480x72, 640x480x75, 800x600x56, 800x600x60
    800x600x72, 800x600x75, 832x624x75, 1024x768x85, 1024x768x60
    1024x768x70, 1024x768x75, 1280x1024x75, 1280x1024x76,
     1152x900x66, 1152x900x76, 1280x1024x67, 960x680x112S
    vga, svga, 1152, 1280, stereo
Possible depths: 8, 24
Current resolution setting: 1280x1024x76
Current depth: 8
```

`-propt`
Prints the current values of all M64 options in the OWconfig file specified by the `-file` option for the device specified by the `-dev` option. Prints the values of options as they will be in the OWconfig file after the call to `m64config` completes. The following is a typical display using the `-propt` option:

```
--- OpenWindows Configuration for /dev/fbs/m640 ---
OWconfig: machine
Video Mode: not set
Depth: 8
```

`-res` *video-mode* [`now` | `try` [`noconfirm` | `nocheck`]]
Specifies the video mode used to drive the monitor connected to the specified M64 device. Video modes are built-in. *video-mode* has the format of *width*x*height*x*rate*. *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh. As a convenience, `-res` also accepts formats with `@` preceding the refresh rate instead of `x`. For example, `1280x1024@76`.

A list of valid video modes is obtained by issuing the following command: `m64config -res '?'`. Note that the `?` must be quoted. Not all resolutions are supported by both the video board and by the monitor. `m64config` will not permit you to set a resolution the board does not support, and will request confirmation before setting a resolution the monitor does not support.

`Symbolic names`

For convenience, some video modes have symbolic names defined for them. Instead of the form *width*x*height*x*rate*, one of these names may be supplied as the argument to `-res`. The meaning of the symbolic name `none` is that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.

Name	Corresponding Video Mode
`svga`	1024x768x60
`1152`	1152x900x76
`1280`	1280x1024x76
`none`	(video mode currently programmed in device)

The `-res` option also accepts additional sub-options immediately following the video mode specification. Any or all of these may be present.

`nocheck` If present, the normal error checking based on the monitor sense code will be suspended. The video mode specified by the user will be accepted regardless of whether it is appropriate for the currently attached monitor.

This option is useful if a different monitor is to be connected to the M64 device. *Use of this option implies* `noconfirm` *as well.*

`noconfirm` Using the `-res` option, the user could potentially put the system into an unusable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this, the default behavior of `m64config` is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. The noconfirm option instructs `m64config` to bypass this confirmation and to program the requested video mode anyway. This option is useful when `m64config` is being run from a shell script.

`now` If present, not only will the video mode be updated in the OWconfig file, but the M64 device will be immediately programmed to display this video mode. (This is useful for changing the video mode before starting the window system).

It is inadvisable to use this sub-option with `m64config` while the configured device is being used (for example, while running the window system); unpredictable results may occur. To run `m64config` with the `now` sub-option, first bring the window system down. If the `now` sub-option is used within a window system session, the video mode will be changed immediately, but the width and height of the affected screen won't change until the window system is exited and reentered again. Consequently, this usage is strongly discouraged.

`try` If present, the specified video mode will be programmed on a trial basis. The user will be asked to confirm the video mode by typing `y` within 10 seconds. Or the user may terminate the trial before 10 seconds are up by typing any character. Any character other than 'y' or carriage return is considered a no and the previous video mode will be restored and `m64config` will not change the video mode in the OWconfig file (other options specified will still take effect). If a carriage return is typed, the user is prompted for a yes or no answer on whether to keep the new video mode.

This sub-option should not be used with `m64config` while the configured device is being used (for example, while running the window system) as unpredictable results may occur. To run `m64config` with the `try` sub-option, the window system should be brought down first.

Defaults For a given invocation of `m64config` command line if an option does not appear on the command line, the corresponding OWconfig option is not updated; it retains its previous value.

When the window system is run, if an M64 option has never been specified by `m64config`, a default value is used. The option defaults are as follows:

Option	Default
`-dev`	`/dev/fbs/m640`
`-file`	machine
`-res`	none

The default for the `-res` option of none means that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.

This provides compatibility for users who are used to specifying the device resolution through the PROM. On some devices (for example, GX) this is the only way of specifying the video mode. This means that the PROM ultimately determines the default M64 video mode.

Examples

EXAMPLE 1 Switching the Monitor Type

The following example switches the monitor type to the maximum resolution of `1280` x `1024` at `76` Hz:

```
example% /usr/sbin/m64config -res 1280x1024x76
```

Name mail.local – store mail in a mailbox

Synopsis `/usr/lib/mail.local [-f` *sender*`] [-d]` *recipient*

Description `mail.local` reads the standard input up to an end-of-file and appends it to each user's mail file (mailbox). This program is intended to be used by `sendmail(1M)` as a mail delivery agent for local mail. It is not a user interface agent.

Messages are appended to the user's mail file in the `/var/mail` directory. The user must be a valid user name.

Each delivered mail message in the mailbox is preceded by a "Unix From line" with the following format:

`From` *sender_address time_stamp*

The *sender_address* is extracted from the SMTP envelope address (the envelope address is specified with the `-f` option).

A trailing blank line is also added to the end of each message.

The mail files are locked with a `.lock` file while mail is appended.

The mail files are created with mode `660`, owner is set to *recipient*, and group is set to `mail`. If the "biff" service is returned by `getservbyname(3SOCKET)`, the biff server is notified of delivered mail. This program also computes the `Content-Length:` header which will be used by the mailbox reader to mark the message boundary.

Options The following options are supported:

`-f` *sender*	Specifies the "envelope from address" of the message. This flag is technically optional, but should be used.
`-d`	Specifies the recipient of the message. This flag is also optional and is supported here for backward compatibility. That is, `mail.local` *recipient* is the same as `mail.local -d` *recipient*.
`-l`	Turn on LMTP mode.
`-r` *from*	Specify the sender's name (for backward compatibility).
`-7`	Do not advertise 8BITMIME support in LMTP mode.
`-b`	Return a permanent error instead of a temporary error if a mailbox exceeds quota.

Operands The following operand is supported:

recipient	The recipient of the mail message.

Environment Variables

`TZ` Used to set the appropriate time zone on the timestamp.

Exit Status

The following exit values are returned:

`0` Successful operation.

`>0` An error occurred.

Files

`/tmp/local.`*XXXXXX* temporary files

`/tmp/lochd.`*XXXXXX* temporary files

`/var/mail/`*user_name* user's mail file

Attributes

Name makedbm – make a dbm file, or get a text file from a dbm file

Synopsis

```
makedbm [-b] [-l] [-s] [-E] [-i yp_input_file]
     [-o yp_output_name] [-d yp_domain_name]
     [-m yp_master_name] [-S delimiter]
     [-D number_of_delimiters] infile outfile

makedbm [-u dbmfilename]
```

Description The `makedbm` utility takes the *infile* and converts it to a pair of files in `ndbm` format (see `ndbm(3C)`), namely *outfile*`.pag` and *outfile*`.dir`. Each line of the input file is converted to a single `dbm` record. All characters up to the first TAB or SPACE form the key, and the rest of the line is the data. If a line ends with '\' (backslash), the data for that record is continued on to the next line. `makedbm` does not treat '#' (pound-sign) as a special character.

Because `makedbm` is mainly used in generating `dbm` files for the NIS name service, it generates a special entry with the key *yp_last_modified*, which is the date of *infile* (or the current time, if *infile* is '–'). The entries that have keys with the prefix *yp_* are interpreted by NIS server utilities.

Options The following options are supported:

`-b`	Insert the `YP_INTERDOMAIN` into the output. This key causes `ypserv(1M)` to use DNS for host name and address lookups for hosts not found in the maps.
`-d` *yp_domain_name*	Create a special entry with the key *yp_domain_name*.
`-D` *number_of delimiters*	Specify *number_of_delimiters* to skip before forming the key.
`-E`	Delimiters are escaped.
`-i` *yp_input_file*	Create a special entry with the key *yp_input_file*.
`-l`	Lower case. Convert the keys of the given map to lower case, so that, for example, host name matches succeed independent of upper or lower case distinctions.
`-m` *yp_master_name*	Create a special entry with the key *yp_master_name*. If no master host name is specified, *yp_master_name* is set to the local host name.
`-o` *yp_output_name*	Create a special entry with the key *yp_output_name*.
`-s`	Secure map. Accept connections from secure NIS networks only.
`-S` *delimiter*	Specify the *delimiter* to use instead of the default delimiter for forming the key.
`-u` *dbmfilename*	Undo a `dbm` file. Prints out the file in text format, one entry per line, with a single space separating keys from values.

Operands The following operands are supported:

infile Input file for `makedbm`. If *infile* is '–' (dash), the standard input is read.

outfile One of two output files in `ndbm` format: *outfile*`.pag` and *outfile*`.dir`.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

Name makemap – create database maps for sendmail

Synopsis

```
makemap [-N] [-d] [-f] [-o] [-r] [-s] [-v] [-C file]
     [-c cachesize] [-D commentchar] [-e] [-l] [-t delim]
     [-u] mantype mapname
```

Description `makemap` creates the database maps used by the keyed map lookups in `sendmail(1M)`. `makemap` reads from the standard input and outputs to the specified *mapname*.

In all cases, `makemap` reads lines from the standard input consisting of two words separated by whitespace. The first is the database key, the second is the value. The value may contain `%`*n* strings to indicated parameter substitution. Literal percents should be doubled (`%%`). Blank lines and lines beginning with `#` are ignored.

`makemap` handles three different database formats. Database format is selected using the *maptype* parameter. See `OPERANDS`.

Options The following options are supported:

`-c` *cachesize*	Use the specified hash and B-Tree cache size (*cachesize*).
`-C` *file*	Use the specified sendmail configuration file (*file*) for looking up the TrustedUser option.
`-d`	Allow duplicate keys in the map. This is only allowed on B-Tree format maps. If two identical keys are read, both be inserted into the map.
`-D` *commentchar*	Use the specified character to indicate a comment (which is ignored) instead of the default of '`#`'.
`-e`	Allow empty value (right hand side).
`-f`	Normally, all upper case letters in the key are folded to lower case. This flag disables that behavior. This is intended to mesh with the `-f` flag in the `K` line in `sendmail.cf`. The value is never case folded.
`-l`	List supported map types.
`-N`	Include the null byte that terminates strings in the map. This must match the `-N` flag in the `K` line in `sendmail.cf`
`-o`	Append to an old file. This allows you to augment an existing file.
`-r`	Allow replacement of existing keys. Normally `makemap` complains if you repeat a key, and does not do the insert.
`-s`	Ignore safety checks on maps being created. This includes checking for hard or symbolic links in world writable directories.
`-t` *delim*	Use the specified delimiter (*delim*) instead of whitespace.

`-u` Dump (unmap) the content of the database to standard output. Note that, if the `-t` option is also provided, the specified delimiter is used when the content is dumped instead of whitespace.

`-v` Verbosely print what it is doing.

Operands The following operands are supported:

mapname File name of the database map being created.

maptype Specifies the database format. The following *maptype* parameters are available:

`dbm` Specifies DBM format maps.

`btree` Specifies B-Tree format maps.

`hash` Specifies hash format maps.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsndmu

See Also `editmap(1M)`, `sendmail(1M)`, `attributes(5)`

Name makeuuid – generate Universal Unique Identifiers

Synopsis

```
makeuuid [-e ether] [-n count] [-R root]
```

Description The `makeuuid` command generates UUIDs (Universal Unique Identifiers) conforming to the OSF DCE specification for UUIDs. The specification states:

"A UUID is an identifier that is unique across both space and time, with respect to the space of all UUIDs. A UUID can be used for multiple purposes, from tagging objects with an extremely short lifetime, to reliably identifying very persistent objects across a network.

"The generation of UUIDs does not require a registration authority for each single identifier. Instead, it requires a unique value over space for each UUID generator. This spatially unique value is [normally] specified as an IEEE 802 address, which is usually already applied to network-connected systems."

The `makeuuid` command generates one or more UUIDs on the standard output.

Options The `makeuuid` command supports the following options:

`-e` *ether* Supplies an alternate address to be used in the generation of the UUIDs. Normally, the system's Ethernet address is acquired and used during the generation of a UUID. However, this requires root privileges to open and read the network devices. If this is not possible, you must supply an alternate Ethernet address.

`-n` *count* Generate multiple UUIDs. This option generates the specified number of UUIDs, one per line. Using this form is more efficient than, and functionally equivalent to, calling the `makeuuid` command multiple times. This can be used, for example, when a large number of UUIDs need to be generated for a given application.

`-R` *root* Use *root* as the root filesystem path when updating the shared state file (see FILES). The shared state file must be writable by the user running `makeuuid`, otherwise no UUIDs will be generated and the command will return in failure.

Note – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.

Usage Normally, you run the `makeuuid` command with root privileges, as the Ethernet address and state files can be easily accessed and updated. If this is not possible, you must use the `-R` and `-e` options to specify an alternate root and Ethernet address to use when calculating the UUIDs.

Examples **EXAMPLE 1** Generating Multiple UUIDs

The following command generates 3000 UUIDs:

```
example# makeuuid -n 3000
```

EXAMPLE 2 Invoking Without Root Privileges

If you cannot obtain root privileges, you must specify an alternate Ethernet address and state file location:

```
example% makeuuid -e 11:22:33:44:55:66 -R /export/root/example2
```

See the caveat on the use of the `-R` option in the description of that option, above.

Exit Status The following exit values are returned:

`0` Successful completion.

`1` Out of memory.

`–1` Invalid Ethernet address given or access denied.

Files

`/var/sadm/system/uuid_state` UUID state file. Use of time values is one way that UUID generators, such as `makeuuid`, guarantee uniqueness. A state file is a mechanism that allows `makeuuid` to "remember" the last time value it used so it can increment that value for use in a new UUID. See the Internet Draft "UUIDs and GUIDs," dated February 4, 1998, for details on the state file mechanism.

Name masfcnv – SNMP configuration migration script

Synopsis

```
/usr/sfw/lib/sma_snmp/masfcnv [-cimnrs] [-l agentmaster]
     [-p enabledisableerror] [-t noneadd]
     [-u agentmastererror] [-y agentmastererror]

masfcnv [-V]

masfcnv [-?]
```

Description The `masfcnv` script is used to assist the system administrator in migrating an existing set of configuration files for the Sun SNMP Management Agent for Sun Fire and Netra Systems (MASF) to the Systems Management Agent (SMA).

The script accepts as input the currently installed set of MASF and SMA configuration files and outputs a new set of SMA configuration files. Existing SMA configuration files are backed up by appending `.bak` to the filename. The administrator can choose to output the new configuration to standard output, instead of replacing the current configuration, by specifying the `-n` option.

The migration script must be run as the superuser. Failure to do so causes the script to exit with an error message. Before running the script you should ensure that both the SMA and MASF agents are not running. If the agents are running they will be shut down by the script.

The migration script installs a new startup script for the MASF agent in `/etc/init.d`, as well as a backup of the old script. During migration, MASF will be configured as an AgentX subagent of SMA. All migration settings will be migrated to the SMA configuration file.

The migration script aborts if any unrecognized directives are found in either the MASF configuration files or the SMA configuration files. This can be overridden with the `-i` option. If this option is selected, the behavior is to retain unrecognized directives that were present in the SMA configuration, but remove those present in the MASF configuration.

The migration script then proceeds to migrate access control and trap configuration. As a side effect of running the migration script, the following directives might be expanded by the script into multiple directives with an equivalent interpretation:

- `rwcommunity`
- `rocommunity`
- `rwuser`
- `rouser`
- `trapcommunity`
- `trapsink`
- `trap2sink`
- `informsink`

Access Control Migration

Access control directives are expanded into the equivalent com2sec, group, access and view directives. Existing group names are renamed by prepending a prefix to avoid conflict with any which may already be defined in SMA.

When migrating SNMPv1 or v2c access control, a conflict can occur if both MASF and SMA configuration files have defined access permissions for the same community and source address. The default behavior is to abort with a message, unless a use of the `-y` option specifies otherwise. If `-y agent` is specified then the MASF configuration takes precedence. If `-y master` is specified then the SMA configuration is retained.

When migrating USM configuration (SNMPv3), a conflict can occur if both SMA and MASF configurations define a user with the same `securityName`. If this occurs, the behavior of the script is determined by the `-u` option. If `-u agent` is specified, the configuration of the user defined in the MASF configuration files is the one that is retained. Otherwise, if the `-u master` option is specified, the use defined in the SMA configuration files is retained.

By default, the migration script attempts to migrate USM users from MASF to SMA. The script determines whether there are any SNMPv3 users present in the SMA configuration and whether the default `engineID` has been overridden in the SMA configuration files. If neither of these conditions obtain, then the any `usmUser` statements containing localized authentication keys can be migrated to SMA, along with the MASF `engineID`. This results in the `engineID` of the SMA master agent changing.

If the script determines that there are existing SNMPv3 users or a manually configured `engineID` present in the SMA configuration, only those users defined in `createUser` statements are transferred. Those users that were defined in `usmUser` statements are transferred but will have their passwords reset to a random value. You should notify your users of their new password or reset the password yourself by editing the newly-generated configuration file.

Trap/Inform Migration

The migration script performs a check to determine whether a trap destination defined for MASF is already specified in an existing SMA `trapsink`, `trap2sink` or `informsink` directive. If this is the case, then the directive in the MASF configuration will be discarded to avoid duplicate traps/informs being received.

`trapsink`, `trap2sink` and `informsink` directives specified in the existing SMA configuration are considered valid destinations for MASF traps/informs and will receive them from the MASF subagent after migration.

If the `-t none` option was specified on the command line, the migration script carries over any remaining MASF trap/inform directives without modification.

If the `-t add` option was specified (the default), the migration script expands any `trapsink`, `trap2sink`, or `informsink` directives to use the `TARGET-MIB` and `NOTIFICATION-MIB`. The `TARGET-MIB` specifies targets using IP addresses, so it might be desirable to use the `-t none` option if, for example, the network allocates IP addresses to hostnames dynamically by means of DHCP.

The expanded directives defines filters specific to the MASF agent so that traps from other subagents will not be received by migrated trap destinations. Existing filters present in the SMA configuration are, by default, not modified and might or might not receive MASF traps, depending upon the filters that were originally defined for them.

If the `-l` option is specified, any filters already defined in the `TARGET-MIB` and the `NOTIFICATION-MIB` for SMA are extended to include traps from MASF. In the event that a trap destination is already configured in the `TARGET-MIB` with the same target address and community as an existing MASF trap/inform sink, a conflict will arise.

If `-l agent` was specified and a conflict arises, the migration script uses the target SNMP parameters (that is, the SNMP version and choice of trap/inform) defined by the MASF `trap/informsink` directive to send traps to this destination. Otherwise, if the `-l master` option was specified, the conflict will be resolved using the target SNMP parameters specified in the SMA configuration.

Miscellaneous

If the migration script encounters in the MASF configuration file any of the directives listed below and the directives are either not present or differ from the SMA configuration, the script will log a warning message.

- `syslocation`
- `syscontact`
- `sysname`
- `sysservices`
- `agentgroup`
- `agentuser`
- `authtrapenable`

Options

The following options are supported:

`-?`
`--help`

Displays usage information.

`-c`
`--no-community`

Do not transfer v1/v2c communities.

`-i`
`--ignore-unrecognized-directives`

Continue processing if unrecognized directives are present.

`-l agent | master`
`--master-trap-target=agent | master`

If `agent` is specified, the existing SMA trap targets will be configured to receive traps that were previously sent to destinations for the Sun Fire SNMP agent. If `master` is specified, the targets will be configured to receive Sun Fire SNMP traps, but existing SNMP target parameters will be used.

`-m`
`--no-usmuser`
: Do not transfer usm (v3) users.

`-n`
`--dry-run`
: Run the migration without modifying any files. If an error arises, continue processing. This can be used to determine the likely migration issues.

`-p enable | disable | error`
`--use-agent-port=enable | disable | error`
: Indicates whether the port originally used by the Sun Fire SNMP agent should be used by the SMA agent after migration (if the two agents are using different ports). If `enable` is specified, then the port used by the Sun Fire SNMP agent will also be used by the SMA agent after migration. If `disable` is specified, the ports used by SMA will not be updated by the migration tool. If the `error` option is specified and the SMA agent is not already using the same ports as those used by the original Sun Fire SNMP agent, an error is reported and the migration process is terminated. If no option is specified the default behavior is equivalent to the `error` flag.

`-r`
`--no-trap`
: Do not transfer trap destinations.

`-s`
`--skip-user`
: If a user is found in the MASF configuration file that cannot be created in the new configuration because of a change in the engine ID, then output a message indicating that the user could not be migrated (needs to be manually recreated) and continue processing. If this option is not present, the migration tool will consider such a situation as an error and abort.

`-t none | add`
`--trap-filter=none | add`
: If `none` is specified then the script will copy trap directives directly. The administrator might need to manually update the

configuration file to ensure traps are only delivered to their intended destinations. If `add` is specifed, trap filters will be constructed so that traps originating from the original Sun Fire SNMP agent are delivered only to the destinations that originally received them. The default behavior is `add`.

`-u agent | master | error`
`--select-user=agent | master | error`

Specifies that if a user with the same name is found in both configuration files that the conflict is to be resolved using the specified configuration file as input. Selecting a user from a particular will also cause the group declaration for that user to be taken from the same file. If `agent` is specified then the user will be taken from the configuration file for the Sun Fire SNMP Agent. If `master` is specified, the user will be taken from the SMA configuration. Otherwise, if `error` is given, the script will terminate. If this option is not present, the default behavior is equivalent to the `error` flag.

`-V`
`--version`

Display the version of this script.

`-y agent | master | error`
`--select-community=agent | master | error`

Examples

EXAMPLE 1 Simplest Case

The command shown below is appropriate for a simple migration. The migration fails if there are any potential conflicts.

```
# masfcnv
```

EXAMPLE 2 Migrating Such That MASF Settings Override

To migrate the MASF configuration such that it will always succeed, that MASF settings will override in the event of a conflict with SMA, and that access will still be provided on the original MASF port, enter:

```
# masfcnv -is -l agent -p enable -u agent -y agent
```

EXAMPLE 3 Dry Run, Retaining SMA Settings

To attempt a dry run and migrate the configuration such that any conflicts will be resolved by retaining existing SMA settings, enter:

```
masfcnv -l master -u master -y master
```

Exit Status

`0`	Success.
`non-zero`	A problem occurred during migration.

Files

`/etc/sma/snmp/snmpd.conf` `/var/sma_snmp/snmpd.conf`	SMA configuration files
`/etc/opt/SUNWmasf/conf/snmpd.conf` `/var/opt/SUNWmasf/snmpd.dat`	MASF configuration files
`/tmp/sma_migration.log`	`masfcnv` log file

Name mdlogd – Solaris Volume Manager daemon

Synopsis

```
mdlogd
```

Description `mdlogd` implements a simple daemon that watches the system console looking for messages written by the Solaris Volume Manger. When a Solaris Volume Manager message is detected, `mdlogd` sends a generic SNMP trap.

To enable traps, you must configure `mdlogd` into the SNMP framework. See *Solaris Volume Manager Administration Guide*.

Usage `mdlogd` implements the following SNMP MIB:

```
SOLARIS-VOLUME-MGR-MIB DEFINITIONS ::= BEGIN
        IMPORTS
                enterprises FROM RFC1155-SMI
                DisplayString FROM SNMPv2-TC;

        -- Sun Private MIB for Solaris Volume Manager

        sun       OBJECT IDENTIFIER ::= { enterprises 42 }
        sunSVM       OBJECT IDENTIFIER ::= { sun 104 }

        -- this is actually just the string from /dev/log that
        -- matches the md: regular expressions.
        -- This is an interim SNMP trap generator to provide
        -- information until a more complete version is available.

        -- this definition is a formalization of the old
        -- Solaris DiskSuite mdlogd trap mib.

        svmOldTrapString OBJECT-TYPE
                        SYNTAX DisplayString (SIZE (0..255))
                        ACCESS read-only
                        STATUS mandatory
                        DESCRIPTION
                        "This is the matched string that
                         was obtained from /dev/log."
        ::= { sunSVM 1 }

Solaris Volume Manager Administration Guide

Name mdmonitord – daemon to monitor metadevices

Synopsis

```
/usr/sbin/mdmonitord [-t time_interval]
```

Description The `mdmonitord` utility is part of Solaris Volume Manager. It monitors and checks RAID1 (mirrors), RAID5 and hot spares.

There are two methods for checking:

- At fixed time intervals.
- When a RAID-1 (mirror), RAID-5, or hot spare fails. A failure generates an error event which triggers a check of these metadevices.

Options The following options are supported:

`-t` Time interval in seconds. The default value is 0, which causes probes to occur only upon an error. If you want to run `mdmonitord` at a regular interval, a value of 1800 (seconds, every half hour) is recommended as a starting point.

Exit Status The following exit values are returned:

`0` Successful completion.

>0 An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmdu

See Also `svcs(1)`, `metaclear(1M)`, `metadb(1M)`, `metadetach(1M)`, `metahs(1M)`, `metainit(1M)`, `metaoffline(1M)`, `metaonline(1M)`, `metaparam(1M)`, `metarecover(1M)`, `metarename(1M)`, `metareplace(1M)`, `metaroot(1M)`, `metaset(1M)`, `metassist(1M)`, `metastat(1M)`, `metasync(1M)`, `metattach(1M)`, `svcadm(1M)`, `md.tab(4)`, `md.cf(4)`, `mddb.cf(4)`, `md.tab(4)`, `attributes(5)`, `smf(5)`, `md(7D)`

Solaris Volume Manager Administration Guide

Notes Since frequent probes can affect performance, it is recommended that the intervals between probes be limited.

The `mdmonitord` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/system/mdmonitor
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

Name medstat – check the status of mediator hosts for a given diskset

Synopsis

```
/usr/sbin/medstat [-q] -s setname
```

Description If a specified diskset has been configured for mediators, `medstat` attempts to contact these hosts to see if they are accessible and returns the results of the communication.

Options

`-q` This optional argument disables the printing of informative text. When used with `-q`, `medstat` still prints error messages and returns a result code.

`-s` *setname* Specifies the name of a diskset on which `medstat` will work.

Examples **EXAMPLE 1** Checking diskset

This example checks the mediator hosts for the selected diskset.

```
# medstat -s relo-red
```

The name of the diskset is `relo-red`. The `medstat` command prints the status for each mediator host. Additionally, if the mediator quorum is met, either through a "golden" mediator host or because half+1 of the mediator hosts respond, the exit code is 0. If the quorum is not met, then the exit code is 1. If no mediator hosts have been configured for the named diskset, the exit code is 2. The status field will contain one of the following values: Unreachable, Bad, Fatal, or Ok, where Unreachable indicates an RPC/communication problem, Bad indicates an error in the mediator data, Fatal indicates any other error condition, and Ok indicates no error conditions.

Files

`/etc/lvm/meddb` Contains the mediator data for a host that has been selected as a mediator host.

Exit Status The following exit values are returned:

`0` Successful completion.

>0 An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmdu
Interface Stability	Evolving

See Also `metaclear(1M)`, `metadb(1M)`, `metadetach(1M)`, `metahs(1M)`, `metainit(1M)`, `metaoffline(1M)`, `metaonline(1M)`, `metaparam(1M)`, `metareplace(1M)`, `metaroot(1M)`, `metaset(1M)`, `metastat(1M)`, `metasync(1M)`, `metattach(1M)`, `md.cf(4)`, `md.tab(4)`, `mddb.cf(4)`, `meddb(4)`, `mediator(7D)`

Sun Cluster documentation, *Solaris Volume Manager Administration Guide*

Notes This command is designed for use in the high availability product.

Name metaclear – delete active metadevices and hot spare pools

Synopsis

```
/usr/sbin/metaclear -h

/usr/sbin/metaclear [-s setname] -a [-f]

/usr/sbin/metaclear component

/usr/sbin/metaclear [-s setname] [-f] metadevice...
 hot_spare_pool...

/usr/sbin/metaclear [-s setname] -r [-f] metadevice...
 hot_spare_pool...

/usr/sbin/metaclear [-s setname] -p component

/usr/sbin/metaclear [-s setname] -p metadevice
```

Description The `metaclear` command deletes the specified metadevice or *hot_spare_pool.*, or purges all soft partitions from the designated component. Once a metadevice or hot spare pool is deleted, it must be re-created using `metainit` before it can be used again.

Any metadevice currently in use (open) cannot be deleted.

Options Root privileges are required for all of the following options except `-h`.

`-a`	Deletes all metadevices and configured hot spare pools in the set named by `-s`, or the local set by default.
`-f`	Deletes (forcibly) a metadevice that contains a subcomponent in an error state.
`-h`	Displays usage message.
`-p`	Deletes (purges) all soft partitions from the specified metadevice or component.
`-r`	Recursively deletes specified metadevices and hot spare pools, but does not delete metadevices on which others depend.
`-s` *setname*	Specifies the name of the diskset on which `metaclear` will work. Using the `-s` option causes the command to perform its administrative function within the specified diskset. Without this option, the command performs its function on local metadevices and/or hot spare pools.

Operands

metadevice ...	Specifies the name(s) of the metadevice(s) to be deleted.
component	Specifies the `c*d*t*s*` name(s) of the components containing soft partitions to be deleted.

hot_spare_pool ... Specifies the name(s) of the hot spare pools to be deleted in the form `hsp`*nnn*, where *nnn* is a number in the range 000-999.

Examples

EXAMPLE 1 Deleting Various Devices

The following example deletes a metadevice named `d10`.

```
# metaclear /dev/md/dsk/d10
```

The following example deletes all local metadevices and hot spare pools on the system.

```
# metaclear -a
```

The following example deletes a mirror, `d20`, with an submirror in an error state.

```
# metaclear -f d20
```

The following example deletes a hot spare pool, `hsp001`.

```
# metaclear hsp001
```

The following example deletes a soft partition, `d23`.

```
# metaclear d23
```

The following example purges all soft partitions on the slice `c2t3d5s2` if those partitions are not being used by other metadevices or are not open.

```
# metaclear -p c2t3d5s2
```

The following example purges soft partitions from a metadevice.

```
# metaclear -p d2
d3: Soft Partition is cleared
d4: Soft Partition is cleared
d5: Soft Partition is cleared
```

Exit Status

The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Attributes

See `attributes(5)` for descriptions of the following attributes:

Solaris Volume Manager Administration Guide

Name metadb – create and delete replicas of the metadevice state database

Synopsis

```
/sbin/metadb -h

/sbin/metadb [-s setname]

/sbin/metadb [-s setname] -a [-f] [-k system-file] mddbnn

/sbin/metadb [-s setname] -a [-f] [-k system-file]
     [-c number] [-l length] slice...

/sbin/metadb [-s setname] -d [-f] [-k system-file] mddbnn

/sbin/metadb [-s setname] -d [-f] [-k system-file] slice...

/sbin/metadb [-s setname] -i

/sbin/metadb [-s setname] -p [-k system-file]
     [mddb.cf-file]
```

Description The `metadb` command creates and deletes replicas of the metadevice state database. State database replicas can be created on dedicated slices, or on slices that will later become part of a simple metadevice (concatenation or stripe) or RAID5 metadevice. Do not place state database replicas on fabric-attached storage, SANs, or other storage that is not directly attached to the system and available at the same point in the boot process as traditional SCSI or IDE drives. See `NOTES`.

The metadevice state database contains the configuration of all metadevices and hot spare pools in the system. Additionally, the metadevice state database keeps track of the current state of metadevices and hot spare pools, and their components. Solaris Volume Manager automatically updates the metadevice state database when a configuration or state change occurs. A submirror failure is an example of a state change. Creating a new metadevice is an example of a configuration change.

The metadevice state database is actually a collection of multiple, replicated database copies. Each copy, referred to as a replica, is subject to strict consistency checking to ensure correctness.

Replicated databases have an inherent problem in determining which database has valid and correct data. To solve this problem, Volume Manager uses a *majority consensus algorithm*. This algorithm requires that a majority of the database replicas be available before any of them are declared valid. This algorithm strongly encourages the presence of at least three initial replicas, which you create. A consensus can then be reached as long as at least two of the three replicas are available. If there is only one replica and the system crashes, it is possible that all metadevice configuration data can be lost.

The majority consensus algorithm is conservative in the sense that it will fail if a majority consensus cannot be reached, even if one replica actually does contain the most up-to-date data. This approach guarantees that stale data will not be accidentally used, regardless of the failure scenario. The majority consensus algorithm accounts for the following: the system will

stay running with exactly half or more replicas; the system will panic when less than half the replicas are available; the system will not reboot without one more than half the total replicas.

When used with no options, the `metadb` command gives a short form of the status of the metadevice state database. Use `metadb -i` for an explanation of the flags field in the output.

The initial state database is created using the `metadb` command with both the `-a` and `-f` options, followed by the slice where the replica is to reside. The `-a` option specifies that a replica (in this case, the initial) state database should be created. The `-f` option forces the creation to occur, even though a state database does not exist. (The `-a` and `-f` options should be used together only when no state databases exist.)

Additional replicas beyond those initially created can be added to the system. They contain the same information as the existing replicas, and help to prevent the loss of the configuration information. Loss of the configuration makes operation of the metadevices impossible. To create additional replicas, use the `metadb -a` command, followed by the name of the new slice(s) where the replicas will reside. All replicas that are located on the same slice must be created at the same time.

To delete all replicas that are located on the same slice, the `metadb -d` command is used, followed by the slice name.

When used with the `-i` option, `metadb` displays the status of the metadevice state databases. The status can change if a hardware failure occurs or when state databases have been added or deleted.

To fix a replica in an error state, delete the replica and add it back again.

The metadevice state database (`mddb`) also contains a list of the replica locations for this set (local or shared diskset).

The local set `mddb` can also contain host and drive information for each of the shared disksets of which this node is a member. Other than the diskset host and drive information stored in the local set `mddb`, the local and shared diskset `mddb`s are functionality identical.

The `mddb`s are written to during the resync of a mirror or during a component failure or configuration change. A configuration change or failure can also occur on a single replica (removal of a `mddb` or a failed disk) and this causes the other replicas to be updated with this failure information.

Options Root privileges are required for all of the following options except `-h` and `-i`.

The following options can be used with the `metadb` command. Not all the options are compatible on the same command line. Refer to the `SYNOPSIS` to see the supported use of the options.

`-a`
Attach a new database device. The `/kernel/drv/md.conf` file is automatically updated with the new information and the `/etc/lvm/mddb.cf` file is updated as well. An alternate way to create replicas is by defining them in the `/etc/lvm/md.tab` file and specifying the assigned name at the command line in the form, `mddb`*nn*, where *nn* is a two-digit number given to the replica definitions. Refer to the `md.tab(4)` man page for instructions on setting up replicas in that file.

`-c` *number*
Specifies the number of replicas to be placed on each device. The default number of replicas is 1.

`-d`
Deletes all replicas that are located on the specified *slice*. The `/kernel/drv/md.conf` file is automatically updated with the new information and the `/etc/lvm/mddb.cf` file is updated as well.

`-f`
The `-f` option is used to create the initial state database. It is also used to force the deletion of replicas below the minimum of one. (The `-a` and `-f` options should be used together only when no state databases exist.)

`-h`
Displays a usage message.

`-i`
Inquire about the status of the replicas. The output of the `-i` option includes characters in front of the device name that represent the status of the state database. Explanations of the characters are displayed following the replica status and are as follows:

`d`
replica does not have an associated device ID.

`o`
replica active prior to last `mddb` configuration change

`u`
replica is up to date

`l`
locator for this replica was read successfully

`c`
replica's location was in `/etc/lvm/mddb.cf`

`p`
replica's location was patched in kernel

`m`
replica is master, this is replica selected as input

`r`
replica does not have device relocation information

`t`
tagged data is associated with the replica

`W`
replica has device write errors

`a`
replica is active, commits are occurring to this

`M`
replica had problem with master blocks

`D`
replica had problem with data blocks

`F`
replica had format problems

`S`
replica is too small to hold current database

`R`
replica had device read errors

`B`
tagged data associated with the replica is not valid

`-k` *system-file*
Specifies the name of the kernel file where the replica information should be written. The default *system-file* is `/kernel/drv/md.conf`. This option is for use with the local diskset only.

`-l` *length*
Specifies the size of each replica. The default *length* is 8192 blocks, which should be appropriate for most configurations. "Replica" sizes of less than 128 blocks are not recommended.

`-p`
Specifies updating the system file (`md.conf`) in the current working directory with entries from the `/etc/lvm/mddb.cf` file. This option is normally used to update a newly built system before it is booted for the first time. If the system has been built on a system other than the one where it will run, the location of the `mddb.cf` on the local machine can be passed as an argument. The system file to be updated can be changed using the `-k` option. This option is for use with the local diskset only.

`-s` *setname*
Specifies the name of the diskset on which the `metadb` command will work. Using the `-s` option will cause the command to perform its administrative function within the specified diskset. Without this option, the command will perform its function on local database replicas.

slice
Specifies the logical name of the physical slice (partition), such as `/dev/dsk/c0t0d0s3`.

Examples

EXAMPLE 1 Creating Initial State Database Replicas

The following example creates the initial state database replicas on a new system.

```
# metadb -a -f c0t0d0s7 c0t1d0s3 c1t0d0s7 c1t1d0s3
```

The `-a` and `-f` options force the creation of the initial database and replicas. You could then create metadevices with these same slices, making efficient use of the system.

EXAMPLE 2 Adding Two Replicas on Two New Disks

This example shows how to add two replicas on two new disks that have been connected to a system currently running Volume Manager.

```
# metadb -a c0t2d0s3 c1t1d0s3
```

EXAMPLE 3 Deleting Two Replicas

This example shows how to delete two replicas from the system. Assume that replicas have been set up on `/dev/dsk/c0t2d0s3` and `/dev/dsk/c1t1d0s3`.

```
# metadb -d c0t2d0s3 c1t1d0s3
```

Although you can delete all replicas, you should never do so while metadevices still exist. Removing all replicas causes existing metadevices to become inoperable.

Files

`/etc/lvm/mddb.cf`
Contains the location of each copy of the metadevice state database.

`/etc/lvm/md.tab`
Workspace file for metadevice database configuration.

`/kernel/drv/md.conf`
Contains database replica information for all metadevices on a system. Also contains Solaris Volume Manager configuration information.

Exit Status

The following exit values are returned:

`0`
successful completion

`>0`
an error occurred

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm
Interface Stability	Committed

Solaris Volume Manager Administration Guide

Notes Replicas cannot be stored on fabric-attached storage, SANs, or other storage that is not directly attached to the system. Replicas must be on storage that is available at the same point in the boot process as traditional SCSI or IDE drives. A replica can be stored on a:

- Dedicated local disk partition
- Local partition that will be part of a volume
- Local partition that will be part of a UFS logging device

Name metadevadm – update metadevice information

Synopsis

```
/usr/sbin/metadevadm  [-h] [-n] [ [-l]-r] [-s setname]
 [-u disk_specifier] [-v]
```

Description The `metadevadm` command facilitates the administration of device ID entries in Solaris Volume Manager. Use this command when the pathname stored in the metadevice state database no longer correctly addresses the device or when a disk drive has had its device ID changed.

This command requires root privileges.

Options The following options are supported.

`-h` Provide a help display.

`-l` Specify that `metadevadm` log to `syslog(3C)`. `metadevadm` logs to the the `DAEMON` facility at the `ERR` level by default. See `syslog.conf(4)` for additional information on changing logging levels.

Use this option anytime. It is most useful in startup scripts and less useful interactively.

`-n` Emulate the effect of a command, without making any changes to the system.

`-r` Recompute the pathname and disk specifier (including slice) associated with all devices in the metadevice state database if the device supports device IDs. If a device does not support device IDs or the device is not available, then no action is taken for that device.

Use this option when the disk has been moved or readdressed.

This option is run automatically at boot time to detect device ID changes and update the state database.

`-s` *setname* Specify the name of the disk set on which `metadevadm` works. This option causes the command to perform its administrative function within the specified disk set. Without this option, the command performs its function on devices in the local disk set.

`-u` *disk_specifier* Obtain the device ID associated with the *disk_specifier* (for example, `c1t2d0`) of a device and update the metadevice state database. If the device ID has not changed this option does nothing. Use this option when a disk drive has had its

device ID changed during a firmware upgrade or due to changing the controller of a storage subsystem.

`-v` Execute in verbose mode. This option has no effect when used with `-u`. Verbose is the default.

Examples

EXAMPLE 1 Updating Device ID of Disk

The following example updates the device `c2t3d0`:

```
# metadevadm -u c2t3d0
Updating SLVM device relocation information for c2t3d0.
Old device reloc information: id1928019239129312301201201001201209139 8
New device reloc information: id1938019239129312301201201001201209139 8
```

The following example is a variation of the preceding, using the full pathname.

```
# metadevadm -u /dev/dsk/c2t3d0
```

The following example uses the `-n` option, which means that the command is emulated, but does not take effect. Note that when the `-v` option is used with `-u`, `-v` has no effect (verbose is the default).

```
# metadevadm -u -v -n c2t3d0
Updating SLVM device relocation information for c2t3d0.
Old device reloc information: id1928019239129312301201201001201209139 8
New device reloc information: id1938019239129312301201201001201209139 8
```

EXAMPLE 2 Recomputing Pathnames

In the following example, all device names are valid.

```
# metadevadm -r
Disk movement detected.
Updating device names in SLVM.
```

In the following example, once again device names are valid.

```
# metadevadm -r -v
Disk movement detected.
Updating device names in SLVM.
c0t0d0s0 changed to c0t0d1s0 from device relocation information
id12098123lkmklsdjaasdkfjadfjakds
```

In the following example, `metadevadm` detects an invalid device name.

```
# metadevadm -r
Invalid device relocation information detected in SLVM.
Please check status of following disk(s):
c3t0d0
```

Return Values The following exit values are returned:

`0` Command was successful.

`1` `metadevadm` encountered an error condition.

`2` An invalid device ID was detected when using the `-r` option. This is for use in the `rc2.d` script. See `init.d(4)`.

Solaris Volume Manager Administration Guide

Name metahs – manage hot spares and hot spare pools

Synopsis

```
/usr/sbin/metahs [-s setname] -a all component

/usr/sbin/metahs [-s setname] -a hot_spare_pool [component]

/usr/sbin/metahs [-s setname] -d hot_spare_pool [component]

/usr/sbin/metahs [-s setname] -d all component

/usr/sbin/metahs [-s setname] -e component

/usr/sbin/metahs [-s setname] -r hot_spare_pool component-old

/usr/sbin/metahs [-s setname] -r all component-old
 component-new

/usr/sbin/metahs [-s setname] -i [hot_spare_pool]...
```

Description The `metahs` command manages existing hot spares and hot spare pools. It is used to add, delete, enable, and replace components (slices) in hot spare pools. Like the `metainit` command, the `metahs` command can also create an initial hot spare pool. The `metahs` command does not replace a component of a metadevice. This function is performed by the `metareplace` command.

Hot spares are always in one of three states: available, in-use, or broken. Available hot spares are running and ready to accept data, but are not currently being written to or read from. In-use hot spares are currently being written to and read from. Broken hot spares are out of service and should be repaired. The status of hot spares is displayed when `metahs` is invoked with the `-i` option.

Solaris Volume Manager supports storage devices and logical volumes, including hot spares, greater than 1 terabyte (TB) when Solaris 10 is running a 64-bit kernel.

If a system with large volumes or hot spares is rebooted under a 32-bit Solaris 10 kernel, the large volumes are visible through `metastat` output, but they cannot be accessed, modified or deleted, and no new large volumes can be created. Any volumes or file systems on a large volume in this situation are also unavailable. If a system with large volumes is rebooted under a version of Solaris prior to Solaris 10, Solaris Volume Manager will not start. All large volumes must be removed before Solaris Volume Manager runs under another version of the Solaris Operating Environment.

Options Root privileges are required for any of the following options except `-i`.

The following options are supported:

`-a all` *component*
: Add *component* to all hot spare pools. `all` is not case sensitive.

`-a` *hot_spare_pool* [*component*]
: Add the *component* to the specified *hot_spare_pool*. *hot_spare_pool* is created if it does not already exist.

`-d all` *component*
Delete *component* from all the hot spare pools. The *component* cannot be deleted if it is in the in-use state.

`-d` *hot_spare_pool* [*component*]
Delete *hot_spare_pool*, if the *hot_spare_pool* is both empty and not referenced by a metadevice. If *component* is specified, it is deleted from the *hot_spare_pool*. Hot spares in the in-use state cannot be deleted.

`-e` *component*
Enable *component* to be available for use as a hot spare. The *component* can be enabled if it is in the broken state and has been repaired.

`-i` [*hot_spare_pool* `. . .`]
Display the status of the specified *hot_spare_pool* or for all hot spare pools if one is not specified.

`-r all` *component-old component-new*
Replace *component-old* with *component-new* in all hot spare pools which have the component associated. Components cannot be replaced from any hot spare pool if the old hot spare is in the in-use state.

`-r` *hot_spare_pool component-old component-new*
Replace *component-old* with *component-new* in the specified *hot_spare_pool*. Components cannot be replaced from a hot spare pool if the old hot spare is in the in-use state.

`-s` *setname*
Specify the name of the diskset on which `metahs` works. Using the `-s` option causes the command to perform its administrative function within the specified diskset. Without this option, the command performs its function on local hot spare pools.

Operands The following operands are supported:

component	The logical name for the physical slice (partition) on a disk drive, such as `/dev/dsk/c0t0d0s2`.
hot_spare_pool	Hot spare pools must be of the form `hsp`*nnn*, where *nnn* is a number in the range 000-999.

Examples **EXAMPLE 1** Adding a Hot Spare to a Hot Spare Pool

The following example adds a hot spare `/dev/dsk/c0t0d0s7` to a hot spare pool `hsp003`:

```
# metahs -a hsp003 c0t0d0s7
```

When the hot spare is added to the pool, the existing order of the hot spares already in the pool is preserved. The new hot spare is added at the end of the list of hot spares in the hot spare pool specified.

EXAMPLE 2 Adding a Hot Spare to All Currently Defined Pools

This example adds a hot spare to the hot spare pools that are currently defined:

```
# metahs -a all c0t0d0s7
```

The keyword `all` in this example specifies adding the hot spare, `/dev/dsk/c0t0d0s7`, to all the hot spare pools.

EXAMPLE 3 Deleting a Hot Spare

This example deletes a hot spare, `/dev/dsk/c0t0d0s7`, from a hot spare pool, `hsp003`:

```
# metahs -d hsp003 c0t0d0s7
```

When you delete a hot spare, the position of the remaining hot spares in the pool changes to reflect the new order. For instance, if in this example `/dev/dsk/c0t0d0s7` were the second of three hot spares, after deletion the third hot spare would move to the second position.

EXAMPLE 4 Replacing a Hot Spare

This example replaces a hot spare that was previously defined:

```
# metahs -r hsp001 c0t1d0s0 c0t3d0s0
```

In this example, the hot spare `/dev/dsk/c0t1d0s0` is replaced by `/dev/dsk/c0t3d0s0`. The order of the hot spares does not change.

Exit Status

The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Solaris Volume Manager Administration Guide

Warnings Do not create large (>1 TB) volumes if you expect to run the Solaris Operating Environment with a 32-bit kernel or if you expect to use a version of the Solaris Operating Environment prior to Solaris 10.

REFERENCE

System Administration Commands - Part 2

Name metaimport – imports disk sets into existing Solaris Volume Manager configurations

Synopsis

```
metaimport  -s setname [-n] [-v] [-f] [disks]...

metaimport  -r [disks]...

metaimport  -V

metaimport  -?
```

Description The `metaimport` command allows the importing of disk sets, including replicated disk sets, into an existing Solaris Volume Manager configuration. Replicated disk sets are disk sets created using remote replication software.

The default Solaris Volume Manager configuration specifies a maximum number of disk sets that can be configured. The `metaimport` command fails if importing the disk set would result in exceeding the number of disk sets configured on the system. To increase the number of disk sets allowed on a system, see the *Solaris Volume Manager Administration Guide*.

Use `metaset(1M)` or `metastat(1M)` to view the configuration of the imported set.

You must run `metaimport` as root.

`metaimport` requires a functional Solaris Volume Manager configuration before it runs.

Options The following options are supported:

`-f` Force the import, even if a quorum of replicas from the imported disk set is not available. This option could result in corrupt configurations and should only be used when `metaimport` fails with the "Insufficient quorum detected; exiting" error. If only a partial disk set is available, this option might be necessary to successfully import. Some or all data could be corrupted or unavailable when importing a partial set or a set lacking a replica quorum.

`-n` Does not actually perform the operation, but shows the output or errors that would have resulted from the operation, had it been run.

`-r` Report on the non-configured disk sets found on the system. If no disk device or LUN is specified, `metaimport` reports on all non-configured disk sets attached to the system. When the name of one disk is specified, `metaimport` reports on the disk set (or virtual LUN) containing the specified disk. If two or more disks are specified, metaimport reports on the set (or sets, if they belong to different disk sets) containing the specified disks. If two or more disks are specified, `metaimport` reports on the set (or sets, if they belong to different disk sets) containing the specified disks.

`-s` *setname*	Specify the disk set name to use when importing. The imported disk set will be called *setname*, without regard to the name it may have had on a different system.
`-v`	Verbose. Provides detailed information about the `metadb` replica location and status.
`-V`	Version information.
`-?`	Display a help message.

Examples

EXAMPLE 1 Importing a Disk Set

The following example creates a disk set called `blue` and identifies `c1t5d0` as a disk containing a state database replica from the disk set being imported.

```
# metaimport -s blue c1t5d0
```

EXAMPLE 2 Reporting Disk Sets to Import

The following example scans all disks and LUNs attached to the system and configured as part of the system. It scans for disks that could be part of a disk set to be imported. Components that are already part of the Solaris Volume Manager configuration are ignored.

This use of `metaimport` provides suggested forms of the `metaimport` command to use to actually import the disk sets that have been found. You can specify a component on the command line to reduce the scope of the scan and generate results more quickly.

```
 # metaimport -r
```

Exit Status

`0`	Successful completion.
`>0`	An error occurred.

Solaris Volume Manager Administration Guide

Name metainit – configure metadevices

Synopsis

```
/sbin/metainit  -h

/sbin/metainit  [generic options] concat/stripe  numstripes
 width  component... [-i  interlace]

/sbin/metainit  [width  component... [-i  interlace]]
 [-h  hot_spare_pool]

/sbin/metainit  [generic options] mirror  -m  submirror
 [read_options] [write_options] [pass_num]

/sbin/metainit  [generic options] RAID  -r  component...
 [-i  interlace] [-h  hot_spare_pool] [-k] [-o  original_column_count]

/sbin/metainit  [generic options] hot_spare_pool
 [hotspare...]

/sbin/metainit  [generic options] metadevice-name

/sbin/metainit  [generic options] -a

/sbin/metainit  [generic options] softpart  -p [-e]
 component [-A  alignment] size

/sbin/metainit  -r
```

Description The `metainit` command configures metadevices and hot spares according to the information specified on the command line. Alternatively, you can run `metainit` so that it uses configuration entries you specify in the `/etc/lvm/md.tab` file (see `md.tab(4)`). All metadevices must be set up by the `metainit` command before they can be used.

Solaris Volume Manager supports storage devices and logical volumes greater than 1 terabyte (TB) when a system runs a 64-bit Solaris kernel. Support for large volumes is automatic. If a device greater than 1 TB is created, Solaris Volume Manager configures it appropriately and without user intervention.

If a system with large volumes is rebooted under a 32–bit Solaris kernel, the large volumes are visible through `metastat` output. Large volumes cannot be accessed, modified or deleted, and no new large volumes can be created. Any volumes or file systems on a large volume in this situation are unavailable. If a system with large volumes is rebooted under a version of Solaris prior to the Solaris 9 4/03 release, Solaris Volume Manager does not start. You must remove all large volumes before Solaris Volume Manager runs under an earlier version of the Solaris Operating System.

If you edit the `/etc/lvm/md.tab` file to configure metadevices, specify one complete configuration entry per line. You then run the `metainit` command with either the `-a` option, to activate all metadevices you entered in the `/etc/lvm/md.tab` file, or with the metadevice name corresponding to a specific configuration entry.

`metainit` does not maintain the state of the volumes that would have been created when `metainit` is run with both the `-a` and `-n` flags. Any volumes in `md.tab` that have dependencies on other volumes in `md.tab` are reported as errors when `metainit -a -n` is run, although the operations might succeed when `metainit -a` is run. See `md.tab(4)`.

Solaris Volume Manager never updates the `/etc/lvm/md.tab` file. Complete configuration information is stored in the metadevice state database, not `md.tab`. The only way information appears in `md.tab` is through editing it by hand.

When setting up a disk mirror, the *first* step is to use `metainit` create a one-on-one concatenation for the root slice. See `EXAMPLES`.

Options The following options are supported:

Generic Options Root privileges are required for all of the following options except `-h`.

The following generic options are supported:

`-f` Forces the `metainit` command to continue even if one of the slices contains a mounted file system or is being used as `swap`, or if the stripe being created is smaller in size than the underlying soft partition. This option is required when configuring mirrors on root (`/`), `swap`, and `/usr`.

`-h` Displays usage message.

`-n` Checks the syntax of your command line or `md.tab` entry without actually setting up the metadevice. If used with `-a`, all devices are checked but not initialized.

`-r` Only used in a shell script at boot time. Sets up all metadevices that were configured before the system crashed or was shut down. The information about previously configured metadevices is stored in the metadevice state database (see `metadb(1M)`).

`-s` *setname* Specifies the name of the diskset on which `metainit` works. Without the `-s` option, the `metainit` command operates on your local metadevices and/or hotspares.

Concat/Stripe Options The following concat/stripe options are supported:

concat/stripe Specifies the metadevice name of the concatenation, stripe, or concatenation of stripes being defined.

numstripes Specifies the number of individual stripes in the metadevice. For a simple stripe, *numstripes* is always 1. For a concatenation, *numstripes* is equal to the number of slices. For a concatenation of stripes, *numstripes* varies according to the number of stripes.

width Specifies the number of slices that make up a stripe. When *width* is greater than 1, the slices are striped.

component The logical name for the physical slice (partition) on a disk drive, such as `/dev/dsk/c0t0d0s0`. For RAID level 5 metadevices, a minimum of three slices is necessary to enable striping of the parity information across slices.

`-i` *interlace* Specifies the interlace size. This value tells Solaris Volume Manager how much data to place on a slice of a striped or RAID level 5 metadevice before moving on to the next slice. *interlace* is a specified value, followed by either 'k' for kilobytes, 'm' for megabytes, or 'b' for blocks. The characters can be either uppercase or lowercase. The *interlace* specified cannot be less than 16 blocks, or greater than 100 megabytes. If *interlace* is not specified, it defaults to 16 kilobytes.

`-h` *hot_spare_pool* Specifies the *hot_spare_pool* to be associated with the metadevice. If you use the command line, the hot spare pool must have been previously created by the `metainit` command before it can be associated with a metadevice. The *hot_spare_pool* must be of the form `hsp`*nnn*, where *nnn* is a number in the range 000-999. Use `/-h hsp`*nnn* when the concat/stripe being created is to be used as a submirror.

Mirror Options The following mirror options are supported:

mirror `-m` *submirror*

Specifies the metadevice name of the mirror. The `-m` indicates that the configuration is a mirror. *submirror* is a metadevice (stripe or concatentation) that makes up the initial one-way mirror. Solaris Volume Manager supports a maximum of four-way mirroring. When defining mirrors, first create the mirror with the `metainit` command as a one-way mirror. Then attach subsequent submirrors using the `metattach` command. This method ensures that Solaris Volume Manager properly syncs the mirrors. (The second and any subsequent submirrors are first created using the `metainit` command.)

read_options

The following read options for mirrors are supported:

`-g` Enables the geometric read option, which results in faster performance on sequential reads.

`-r` Directs all reads to the first submirror. This should only be used when the devices comprising the first submirror are substantially faster than those of the second mirror. This flag cannot be used with the `-g` flag.

If neither the `-g` nor `-r` flags are specified, reads are made in a round-robin order from all submirrors in the mirror. This enables load balancing across the submirrors.

write_options

The following write options for mirrors are supported:

`-S` Performs serial writes to mirrors. The first submirror write completes before the second is started. This can be useful if hardware is susceptible to partial sector failures. If `-S` is not specified, writes are replicated and dispatched to all mirrors simultaneously.

pass_num
A number in the range 0-9 at the end of an entry defining a mirror that determines the order in which that mirror is resynced during a reboot. The default is 1. Smaller pass numbers are resynced first. Equal pass numbers are run concurrently. If 0 is used, the resync is skipped. 0 should be used only for mirrors mounted as read-only, or as `swap`.

RAID Level 5 Options

The following RAID level 5 options are available:

RAID `-r`
Specifies the name of the RAID level 5 metadevice. The `-r` specifies that the configuration is RAID level 5.

`-k`
For RAID level 5 metadevices, informs the driver that it is not to initialize (zero the disk blocks) due to existing data. Only use this option to recreate a previously created RAID level 5 device.

Use the `-k` option with extreme caution. This option sets the disk blocks to the `OK` state. If any errors exist on disk blocks within the metadevice, Solaris Volume Manager might begin fabricating data. Instead of using the `-k` option, you might want to initialize the device and restore data from tape.

`-o` *original_column_count*
For RAID level 5 metadevices, used with the `-k` option to define the number of original slices in the event the originally defined metadevice was grown. This is necessary since the parity segments are not striped across concatenated devices.

Use the `-o` option with extreme caution. This option sets the disk blocks to the `OK` state. If any errors exist on disk blocks within the metadevice, Solaris Volume Manager might begin fabricating data. Instead of using the `-o` option, you might want to initialize the device and restore data from tape.

Soft Partition Options

The following soft partition options are supported:

softpart `-p` [`-e`] *component* [`-A` *alignment*] *size*
The *softpart* argument specifies the name of the soft partition. The `-p` specifies that the configuration is a soft partition.

The `-e` specifies that the entire disk specified by *component* as `c*t*d*` should be repartitioned and reserved for soft partitions. The specified component is repartitioned such that slice 7 reserves space for system (state database replica) usage and slice 0 contains all remaining space on the disk. Slice 7 is a minimum of 4MB, but can be larger, depending on the disk geometry. The newly created soft partition is placed on slice 0 of the device.

The *component* argument specifies the disk (`c*t*d*`), slice (`c*t*d*s*`), or meta device (`d*`) from which to create the soft partition. The *size* argument determines the space to use for the soft partition and can be specified in `K` or `k` for kilobytes, `M` or `m` for megabytes, `G` or `g` for gigabytes, `T` or `t` for terabyte (one terabyte is the maximum size), and `B` or `b` for blocks (sectors). All values represent powers of 2, and upper and lower case options are equivalent. Only integer values are permitted.

The `-A` alignment option sets the value of the soft partition extent alignment. This option used when it is important specify a starting offset for the soft partition. It preserves the data alignment between the metadevice address space and the address space of the underlying physical device. For example, a hardware device that does checksumming should not have its I/O requests divided by Solaris Volume Manager. In this case, use a value from the hardware configuration as the value for the alignment. When you use this option in conjunction with a software I/O load, the alignment value corresponds to the I/O load of the application. This prevents I/O from being divided unnecessarily and affecting performance.

The literal `all`, used instead of specifying size, specifies that the soft partition should occupy all available space on the device.

Hot Spare Pool Options The following hot spare pool options are supported:

hot_spare_pool [*hotspare...*]
When used as arguments to the `metainit` command, *hot_spare_pool* defines the name for a hot spare pool, and *hotspare...* is the logical name for the physical slice(s) for availability in that pool. *hot_spare_pool* is a number of the form `hsp`*nnn*, where *nnn* is a number in the range 000-999.

`md.tab` File Options The following `md.tab` file options are supported:

metadevice-name
When the `metainit` command is run with a *metadevice-name* as its only argument, it searches the `/etc/lvm/md.tab` file to find that name and its corresponding entry. The order in which entries appear in the `md.tab` file is unimportant. For example, consider the following `md.tab` entry:

```
d0 2 1 c1t0d0s0 1 c2t1d0s0
```

When you run the command `metainit d0`, it configures metadevice `d0` based on the configuration information found in the `md.tab` file.

`-a`
Activates all metadevices defined in the `md.tab` file.

`metainit` does not maintain the state of the volumes that would have been created when `metainit` is run with both the `-a` and `-n` flags. If a device `d0` is created in the first line of the `md.tab` file, and a later line in `md.tab` assumes the existence of `d0`, the later line fails when `metainit -an` runs (even if it would succeed with `metainit -a`).

Examples

EXAMPLE 1 Creating a One-on-One Concatenation

The following command creates a one-on-one concatenation for the root slice. Such a command is the first step you take when setting up a mirror for the root slice (and any other slice that cannot be unmounted). The `-f` option is required it create a volume with an existing file system, such as root(`/`).

```
# metainit -f d1 1 1 c0t0d0s0
```

The preceding command makes `d1` a one-on-one concatenation, using the root slice. You can then enter:

```
# metainit d0 -m d1
```

...to make a one-way mirror of the root slice.

EXAMPLE 2 Concatenation

All drives in the following examples have the same size of 525 Mbytes.

This example shows a metadevice, `/dev/md/dsk/d7`, consisting of a concatenation of four slices.

```
# metainit d7 4 1 c0t1d0s0 1 c0t2d0s0 1 c0t3d0s0 1 /dev/dsk/c0t4d0s0
```

The number 4 indicates there are four individual stripes in the concatenation. Each stripe is made of one slice, hence the number 1 appears in front of each slice. The first disk sector in all of these devices contains a disk label. To preserve the labels on devices `/dev/dsk/c0t2d0s0`, `/dev/dsk/c0t3d0s0`, and `/dev/dsk/c0t4d0s0`, the metadisk driver must skip at least the first sector of those disks when mapping accesses across the concatenation boundaries. Because skipping only the first sector would create an irregular disk geometry, the entire first cylinder of these disks is skipped. This allows higher level file system software to optimize block allocations correctly.

EXAMPLE 3 Stripe

This example shows a metadevice, `/dev/md/dsk/d15`, consisting of two slices.

```
# metainit d15 1 2 c0t1d0s0 c0t2d0s0 -i 32k
```

The number 1 indicates that one stripe is being created. Because the stripe is made of two slices, the number 2 follows next. The optional `-i` followed by `32k` specifies the interlace size as 32 Kbytes. If the interlace size were not specified, the stripe would use the default value of 16 Kbytes.

EXAMPLE 4 Concatentation of Stripes

This example shows a metadevice, `/dev/md/dsk/d75`, consisting of a concatenation of two stripes of three disks.

EXAMPLE 4 Concatentation of Stripes *(Continued)*

```
# metainit d75 2 3 c0t1d0s0 c0t2d0s0 \
      c0t3d0s0 -i 16k \
      3 c1t1d0s0 c1t2d0s0 c1t3d0s0 -i 32k
```

On the first line, the `-i` followed by 16k specifies that the stripe interlace size is 16 Kbytes. The second set specifies the stripe interlace size as 32 Kbytes. If the second set did not specify 32 Kbytes, the set would use the default interlace value of 16 Kbytes. The blocks of each set of three disks are interlaced across three disks.

EXAMPLE 5 Mirroring

This example shows a two-way mirror, `/dev/md/dsk/d50`, consisting of two submirrors. This mirror does not contain any existing data.

```
# metainit d51 1 1 c0t1d0s0
# metainit d52 1 1 c0t2d0s0
# metainit d50 -m d51
# metattach d50 d52
```

In this example, two submirrors, `d51` and `d52`, are created with the `metainit` command. These two submirrors are simple concatenations. Next, a one-way mirror, `d50`, is created using the `-m` option with `d51`. The second submirror is attached later using the `metattach` command. When creating a mirror, any combination of stripes and concatenations can be used. The default read and write options in this example are a round-robin read algorithm and parallel writes to all submirrors.

EXAMPLE 6 Creating a metadevice in a diskset

This example shows a metadevice, `/dev/md/dsk/d75`, consisting of a concatenation of two stripes within a diskset called `set1`.

```
# metainit -s set1 d75 2 3 c2t1d0s0 c2t2d0s0 \
      c2t3d0s0 -i 32k
# metainit -s set1 d51 1 1 c2t1d0s0
# metainit -s set1 d52 1 1 c3t1d0s0
# metainit -s set1 d50 -m d51
# metattach -s set1 d50 d52
```

In this example, a diskset is created using the `metaset` command. Metadevices are then created within the diskset using the `metainit` command. The two submirrors, `d51` and `d52`, are simple concatenations. Next, a one-way mirror, `d50`, is created using the `-m` option with `d51`. The second submirror is attached later using the `metattach` command. When creating a mirror, any combination of stripes and concatenations can be used. The default read and write options in this example are a round-robin read algorithm and parallel writes to all submirrors.

EXAMPLE 7 RAID Level 5

This example shows a RAID level 5 device, `d80`, consisting of three slices:

```
# metainit d80 -r c1t0d0s0 c1t1d0s0 c1t3d0s0 -i 20k
```

In this example, a RAID level 5 metadevice is defined using the `-r` option with an interlace size of 20 Kbytes. The data and parity segments are striped across the slices, `c1t0d0s0`, `c1t2d0s0`, and `c1t3d0s0`.

EXAMPLE 8 Soft Partition

The following example shows a soft partition device, `d1`, built on metadevice `d100` and 100 Mbytes (indicated by `100M`) in size:

```
# metainit d1 -p d100 100M
```

The preceding command creates a 100 Mbyte soft partition on the `d100` metadevice. This metadevice could be a RAID level 5, stripe, concatenation, or mirror.

EXAMPLE 9 Soft Partition on Full Disk

The following example shows a soft partition device, `d1`, built on disk `c3t4d0`:

```
# metainit d1 -p -e c3t4d0 9G
```

In this example, the disk is repartitioned and a soft partition is defined to occupy all 9 Gbytes of disk `c3t4d0s0`.

EXAMPLE 10 Soft Partition Taking All Available Space

The following example shows a soft partition device, `d1`, built on disk `c3t4d0`:

```
# metainit d1 -p -e c3t4d0 all
```

In this example, the disk is repartitioned and a soft partition is defined to occupy all available disk space on slice `c3t4d0s0`.

EXAMPLE 11 Hot Spare

This example shows a two-way mirror, `/dev/md/dsk/d10`, and a hot spare pool with three hot spare components. The mirror does not contain any existing data.

```
# metainit hsp001 c2t2d0s0 c3t2d0s0 c1t2d0s0
# metainit d41 1 1 c1t0d0s0 -h hsp001
# metainit d42 1 1 c3t0d0s0 -h hsp001
# metainit d40 -m d41
# metattach d40 d42
```

In this example, a hot spare pool, `hsp001`, is created with three slices from three different disks used as hot spares. Next, two submirrors are created, `d41` and `d42`. These are simple

EXAMPLE 11 Hot Spare *(Continued)*

concatenations. The `metainit` command uses the `-h` option to associate the hot spare pool `hsp001` with each submirror. A one-way mirror is then defined using the `-m` option. The second submirror is attached using the `metattach` command.

EXAMPLE 12 Setting the Value of the Soft Partition Extent Alignment

This example shows how to set the alignment of the soft partition to 1 megabyte.

```
# metainit -s red d13 -p c1t3d0s4 -A 1m 4m
```

In this example the soft partition, `d13`, is created with an extent alignment of 1 megabyte. The `metainit` command uses the `-A` option with an alignment of `1m` to define the soft partition extent alignment.

Files

`/etc/lvm/md.tab`
: Contains list of metadevice and hot spare configurations for batch-like creation.

Warnings

This section contains information on different types of warnings.

Devices and Volumes Greater Than 1 TB

Do not create large (>1 TB) volumes if you expect to run the Solaris Operating Environment with a 32–bit kernel or if you expect to use a version of the Solaris Operating Environment prior to Solaris 10.

Multi-Way Mirror

Do not use the `metainit` command to create a multi-way mirror. Rather, create a one-way mirror with `metainit` then attach additional submirrors with `metattach`. When the `metattach` command is not used, no resync operations occur and data could become corrupted.

If you use `metainit` to create a mirror with multiple submirrors, the following message is displayed:

```
WARNING: This form of metainit is not recommended.
The submirrors may not have the same data.
Please see ERRORS in metainit(1M) for additional information.
```

Truncation of Soft Partitions

When creating stripes on top of soft partitions it is possible for the size of the new stripe to be less than the size of the underlying soft partition. If this occurs, `metainit` fails with an error indicating the actions required to overcome the failure.

If you use the `-f` option to override this behavior, the following message is displayed:

```
WARNING: This form of metainit is not recommended.
The stripe is truncating the size of the underlying device.
Please see ERRORS in metainit(1M) for additional information.
```

Write-On-Write Problem

When mirroring data in Solaris Volume Manager, transfers from memory to the disks do not all occur at exactly the same time for all sides of the mirror. If the contents of buffers are changed while the data is in-flight to the disk (called write-on-write), then different data can end up being stored on each side of a mirror.

This problem can be addressed by making a private copy of the data for mirror writes, however, doing this copy is expensive. Another approach is to detect when memory has been modified across a write by looking at the dirty-bit associated with the memory page. Solaris Volume Manager uses this dirty-bit technique when it can. Unfortunately, this technique does not work for raw I/O or direct I/O. By default, Solaris Volume Manager is tuned for performance with the liability that mirrored data might be out of sync if an application does a "write-on-write" to buffers associated with raw I/O or direct I/O. Without mirroring, you were not guaranteed what data would actually end up on media, but multiple reads would return the same data. With mirroring, multiple reads can return different data. The following line can be added to `/etc/system` to cause a stable copy of the buffers to be used for all raw I/O and direct I/O write operations.

```
set md_mirror:md_mirror_wow_flg=0x20
```

Setting this flag degrades performance.

Exit Status

The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Solaris Volume Manager Administration Guide

Limitations

Recursive mirroring is not allowed; that is, a mirror cannot appear in the definition of another mirror.

Recursive logging is not allowed; that is, a trans metadevice cannot appear in the definition of another metadevice.

Stripes, concatenations, and RAID level 5 metadevices must consist of slices only.

Mirroring of RAID level 5 metadevices is not allowed.

Soft partitions can be built on raw devices, or on stripes, RAID level 5, or mirrors.

RAID level 5 or stripe metadevices can be built directly on soft partitions.

Notes Trans metadevices have been replaced by UFS logging. Existing trans devices are *not* logging--they pass data directly through to the underlying device. See `mount_ufs(1M)` for more information about UFS logging.

Name metaoffline, metaonline – place submirrors offline and online

Synopsis

```
/usr/sbin/metaoffline  -h

/usr/sbin/metaoffline  [-s setname] [-f] mirror submirror

/usr/sbin/metaonline  -h

/usr/sbin/metaonline  [-s setname] mirror submirror
```

Description The `metaoffline` command prevents Solaris Volume Manager from reading and writing to the submirror that has been taken offline. While the submirror is offline, all writes to the mirror will be kept track of (by region) and will be written when the submirror is brought back online. The `metaoffline` command can also be used to perform online backups: one submirror is taken offline and backed up while the mirror remains accessible. (However, if this is a two-way mirror, data redundancy is lost while one submirror is offline.) The `metaoffline` command differs from the `metadetach` command because it does not sever the logical association between the submirror and the mirror. To completely remove a submirror from a mirror, use the `metadetach` command.

A submirror that has been taken offline will only remain offline until the `metaonline` command is invoked or the system is rebooted.

When the `metaonline` command is used, reading from and writing to the submirror resumes. A resync is automatically invoked to resync the regions written while the submirror was offline. Writes are directed to the submirror during resync. Reads, however, will come from a different submirror. Once the resync operation completes, reads and writes are performed on that submirror. The `metaonline` command is only effective on a submirror of a mirror that has been taken offline.

The `metaoffline` and `metaonline` commands can not be used on RAID 1 volumes in application-based recovery (ABR) mode.

A submirror that has been taken offline with the `metaoffline` command can only be mounted as read-only.

Options Root privileges are required for all of the following options except `-h`.

`-f`	Forces offlining of submirrors that have slices requiring maintenance.
`-h`	Displays usage message.
`-s` *setname*	Specifies the name of the diskset on which `metaoffline` and `metaonline` will work. Using the `-s` option will cause the command to perform its administrative function within the specified diskset. Without this option, the command will perform its function on local metadevices.
mirror	Specifies the metadevice name of the mirror from which the submirror will be either taken offline or put online.

submirror Specifies the metadevice name of the submirror to be either taken offline or put online.

Examples

EXAMPLE 1 Taking a Submirror Offline

This example takes one submirror, `d9`, offline from mirror `d10`.

```
# metaoffline d10 d9
```

Exit Status

The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Solaris Volume Manager Administration Guide

Notes

The `metaonline` and `metaoffline` commands are not applicable to mirrors in application-based recovery (ABR) mode.

Name metaparam – modify parameters of metadevices

Synopsis

```
/usr/sbin/metaparam  -h

/usr/sbin/metaparam  [-s setname] [concat/stripe or
 RAID5 options] concat/stripe RAID

/usr/sbin/metaparam  [-s setname] [mirror options]
 mirror
```

Description The `metaparam` command is used to display or modify current parameters of metadevices.

If just the metadevice is specified as an argument to the `metaparam` command, the current settings are displayed.

The `metaparam` command enables most metadevice (volume) parameters to be changed. Only the interlace value cannot be changed by `metaparam`, because it is established when the metadevice is created and cannot be changed thereafter.

Options Root privileges are required for all of the options.

The following options are supported:

`-h` Displays usage message.

`-s` *setname* Specify the name of the diskset on which `metaparam` works. Using the `-s` option causes the command to perform its administrative function within the specified diskset. Without this option, the command performs its function on local metadevices.

Concat/STRIPE Or Raid5 Options

–`h` *hot_spare_pool* | `none` Specifies the hot spare pool to be used by a metadevice. If `none` is specified, the metadevice is disassociated with the hot spare pool assigned to it. If the metadevice is currently using a hot spare, then `metaparam` cannot replace the hot spare pool.

concat/stripe | *RAID* Specifies the metadevice name of the concatenation, stripe, or concatenation of stripes, or of the RAID5 metadevice.

Mirror Options

–`r roundrobin | geometric | first` Modifies the read option for a mirror. The `-r` option must be followed by either `roundrobin`, `geometric`, or `first`. `roundrobin`, which is the default action under the `metainit` command, specifies reading the disks in a round-robin (load balancing) method. `geometric` allows for faster

	performance on sequential reads. `first` specifies reading only from the first submirror.
`–w parallel | serial`	Modifies the write option for a mirror. The `-w` option must be followed by either `parallel` or `serial`. `parallel`, the default action under the `metainit` command, specifies that all writes are parallel. `serial` specifies that all writes are serial.
`-p` *pass_number*	A number from 0-to-9 that specifies the order in which a mirror is resynced during reboot. The default is 1. Smaller pass numbers are resynced first. Equal pass numbers are run concurrently. If 0 is used, the mirror resync is skipped. 0 should only be used for mirrors mounted as read-only, or as `swap`.
mirror	Specifies the metadevice name of the mirror.

Examples

EXAMPLE 1 Associating Hot Spare Pool with RAID5 Metadevice

This example associates a hot spare pool, `hsp005`, with a RAID5 metadevice, `d80`.

```
# metaparam -h hsp005 d80
```

EXAMPLE 2 Changing Read Option to Geometric

This example changes the read option on a mirror `d50` from the default of roundrobin to geometric.

```
# metaparam -r geometric d50
```

Exit Status

The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Attributes

Solaris Volume Manager Administration Guide

Name metarecover – recover soft partition information

Synopsis

```
/sbin/metarecover [-n] [-v] [-s setname] component -p

/sbin/metarecover [-n] [-v] [-s setname] component -p
 {-d}

/sbin/metarecover [-n] [-v] [-s setname] component -p
 {-m}
```

Description The `metarecover` command scans a specified component to look for soft partition configuration information and to regenerate the configuration.

Options The following options are supported:

`-d` Recover soft partitions in the metadevice state database from the extent headers on the device. Options `-d` and `-m` are mutually exclusive.

`-m` Regenerate the extent headers and reapplies them to the underlying device based on the soft partitions listed in the metadevice state database. Options `-d` and `-m` are mutually exclusive.

`-n` Do not actually perform the operation. Show the output or errors that would have resulted from the operation, had it been run.

`-p` Regenerate soft partitions based on the metadevice state database or extent headers on the underlying device. If neither `-d` nor `-m` are specified, this option compares the soft partition information in the metadevice state database to the extent headers.

`-s` *setname* Specify the name of the diskset on which `metarecover` works. Using the `s` option causes the command to perform its function within the specified diskset. Without the `-s` option, the `metarecover` command operates on the metadevices and/or hot spare pools in the local diskset.

This option is required to recover former `sps` from a diskset component or raw-device. *setname* must be identical to the former *setname* in which the `sps` were created. The set numbers, however, seem irrelevant.

`-v` Verbose mode, displaying the changes being made.

Operands The following operand is supported:

component Specifies the `c*t*d*s*` number of the disk or slice containing the partitions, or the device name (for example, `d10`) of the metadevice containing the partitions.

component can be a slice name, component name, `/dev/dsk path`, or `/dev/rdsk path`.

Examples

EXAMPLE 1 Updating Metadevice State Database Based on Disk Extent Headers

A disk containing soft partitions is moved from one system to another. The system administrator would like to use the existing soft partitions. `metarecover` updates the metadevice state database based on the extent headers on the disk.

```
# metarecover -v c0t3d0s2 -p -d
```

EXAMPLE 2 Updating Metadevice State Database Based on Incomplete Soft Partition Creation

A system crashes in the middle of creating a new soft partition. The soft partition is in the creating state and the driver does not let that device be opened. `metarecover` rewrites the extent headers for the partially created soft partition and mark it as `Okay`.

```
# metarecover -v c0t3d0s2 -p -m
```

EXAMPLE 3 Updating Extent Headers Based on Metadevice State Database

Someone accidentally overwrote a portion of a disk leaving extent headers destroyed. `metarecover` rewrites the extent headers to ensure a valid soft partition configuration, though user data is not recovered.

```
# metarecover -v d5 -m
```

EXAMPLE 4 Validating Soft Partition Configuration

To validate the existing soft partition configuration, use `metarecover` with only the `-p` flag.

```
# metarecover c0t3d0s2 -p
```

Exit Status

The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Solaris Volume Manager Administration Guide

Name metarename – rename metadevice or switch layered metadevice names

Synopsis

```
/usr/sbin/metarename [-s setname] metadevice1 metadevice2

/usr/sbin/metarename [-s setname] [-f] -x metadevice1
 metadevice2

/usr/sbin/metarename -h
```

Description There are two ways to use `metarename`, one with and one without the `-x` option. The first method (without `-x`) renames an existing metadevice to a new name. This makes managing the metadevice namespace easier. The metadevice being renamed cannot be mounted or open, nor can the new name already exist. For example, to rename a metadevice that contains a mounted file system, you would first need to unmount the file system.

With the second way to use `metarename`, using the `-x` option, `metarename` switches (exchanges) the names of an existing layered metadevice and one of its subdevices. In Solaris Volume Manager terms, a layered metadevice can be either a mirror or a trans metadevice. The `-x` option enables you to switch the metadevice names of a mirror and one of its submirrors, or a trans metadevice and its master device.

`metarename -x` makes it easier to mirror or unmirror an existing stripe or concatenation, and to remove a trans device.

When used to mirror an existing stripe or concatenatation, you must stop access to the device. For example, if the device contains a mounted file system, you must first unmount the file system before doing the rename.

You can also use the `metarename -x` command to untrans a trans metadevice from an existing device. This applies only to the master device. You cannot remove a logging device with `metarename`. Before you can rename a trans device, you must detach the logging device. Then you must stop access to the trans metadevice itself.

You cannot rename or switch metadevices that are in an error state or that have subcomponents in an error state, or metadevices actively using a hot spare replacement.

You can only switch metadevices that have a direct child/parent relationship. You could not, for example, directly exchange a stripe in a mirror that is a master device with the trans metadevice.

You must use the `-f` flag when switching members of a trans metadevice.

Only metadevices can be switched, not slices.

Options The following options are supported:

`-f`
: Force the switching of trans metadevice members.

`-h`
: Display a help message.

`-s` *setname*
Specifies the name of the diskset on which `metarename` will work. Using the `-s` option will cause the command to perform its administrative function within the specified diskset. Without this option, the command will perform its function on the local metadevices.

`-x`
Exchange the metadevice names *metadevice1* and *metadevice2*.

metadevice1
Specifies the metadevice to be renamed or switched.

metadevice2
Specifies the target metadevice name for the rename or switch operation.

Examples

EXAMPLE 1 Renaming a Metadevice

This example renames a metadevice named `d10` to `d100`. Note that `d100` must not exist for the rename to succeed.

```
# metarename d10 d100
```

EXAMPLE 2 Creating a Two-Way Mirror

This example creates a two-way mirror from an existing stripe named `d1` with a mounted file system, `/home2`.

```
# metainit d2 1 1 c13d0s1
# metainit -f d20 -m d1
# umount /home2
# metarename -x d20 d1
# metattach d1 d2
# mount /home2
```

First, a second concatenation `d2`, is created. (`d1` already exists.) The `metainit` command creates a one-way mirror, `d20`, from `d1`. Next, you umount the file system and switch `d1` for `d20`, making `d1` the top-level device (mirror). You attach the second submirror, `d2`, to create a two-way mirror. Lastly, you remount the file system.

EXAMPLE 3 Mounting a Mirrored File System on Stripe

This example takes an existing mirror named `d1` with a mounted file system, and ends up with the file system mounted on a stripe `d1`.

```
# umount /fs2
# metarename -x d1 d20
# metadetach d20 d1
# metaclear -r d20
# mount /fs2
```

First, you unmount the file system, then switch the mirror `d1` and its submirror `d20`. This makes the mirror into `d20`. Next, you detach `d1` from `d20`, then delete the mirror `d20` and its

EXAMPLE 3 Mounting a Mirrored File System on Stripe *(Continued)*

other submirror. You then remount the file system.

EXAMPLE 4 Deleting a Trans Metadevice

This example deletes a trans metadevice named `d10` while its mount point is `/myhome`. The master device, which is a stripe, is named `d2`. The logging device, also a stripe, is named `d5`.

```
# umount /myhome
# metadetach d10
# metarename -f -x d10 d2
# metaclear d2
# metaclear d5
# fsck /dev/md/dsk/d10
# mount /myhome
```

You umount the file system first, then detach the trans metadevice's logging device. The trans metadevice is switched with the master device, making the trans metadevice `d2` and the underlying stripe `d10`. You clear the trans metadevice `d2` and the logging device `d5`. `d10` must be `fsck`'d, and then the file system is remounted.

Exit Status

The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Solaris Volume Manager Administration Guide

Limitations

Renaming and exchanging metadevice names can only be used for metadevices. A physical slice cannot be renamed to a metadevice, nor can a metadevice be exchanged with a physical slice name.

Metadevice names are strings of the pattern *d<xyz>* where *xyz* is a value between `0` and `8192`. You cannot use logical names for metadevices.

Notes Trans metadevices have been replaced by UFS logging. Existing trans devices are *not* logging--they pass data directly through to the underlying device. See `mount_ufs(1M)` for more information about UFS logging.

Name metareplace – enable or replace components of submirrors or RAID5 metadevices

Synopsis

```
/usr/sbin/metareplace -h

/usr/sbin/metareplace [-s setname] -e mirror component

/usr/sbin/metareplace [-s setname] mirror component-old
 component-new

/usr/sbin/metareplace [-s setname] -e RAID component

/usr/sbin/metareplace [-s setname] [-f] RAID component-old
 component-new
```

Description The `metareplace` command is used to enable or replace components (slices) within a submirror or a RAID5 metadevice.

When you replace a component, the `metareplace` command automatically starts resyncing the new component with the rest of the metadevice. When the resync completes, the replaced component becomes readable and writable. If the failed component has been hot spare replaced, the hot spare is placed in the available state and made available for other hot spare replacements.

Note that the new component must be large enough to replace the old component.

A component may be in one of several states. The `Last Erred` and the `Maintenance` states require action. Always replace components in the `Maintenance` state first, followed by a resync and validation of data. After components requiring maintenance are fixed, validated, and resynced, components in the `Last Erred` state should be replaced. To avoid data loss, it is always best to back up all data before replacing `Last Erred` devices.

Options Root privileges are required for all of the following options except `-h`.

`-e` Transitions the state of *component* to the available state and resyncs the failed component. If the failed component has been hot spare replaced, the hot spare is placed in the available state and made available for other hot spare replacements. This command is useful when a component fails due to human error (for example, accidentally turning off a disk), or because the component was physically replaced. In this case, the replacement component must be partitioned to match the disk being replaced before running the `metareplace` command.

`-f` Forces the replacement of an errored component of a metadevice in which multiple components are in error. The component determined by the `metastat` display to be in the "Maintenance" state must be replaced first. This option may cause data to be fabricated since multiple components are in error.

`-h` Display help message.

`-s` *setname*	Specifies the name of the diskset on which `metareplace` will work. Using the `-s` option will cause the command to perform its administrative function within the specified diskset. Without this option, the command will perform its function on local metadevices.
mirror	The metadevice name of the mirror.
component	The logical name for the physical slice (partition) on a disk drive, such as `/dev/dsk/c0t0d0s2`.
component-old	The physical slice that is being replaced.
component-new	The physical slice that is replacing *component-old*.
RAID	The metadevice name of the RAID5 device.

Examples

EXAMPLE 1 Recovering from Error Condition in RAID5 Metadevice

This example shows how to recover when a single component in a RAID5 metadevice is errored.

```
# metareplace d10 c3t0d0s2 c5t0d0s2
```

In this example, a RAID5 metadevice `d10` has an errored component, `c3t0d0s2`, replaced by a new component, `c5t0d0s2`.

EXAMPLE 2 Use of `-e` After Physical Disk Replacement

This example shows the use of the `-e` option after a physical disk in a submirror (a submirror of mirror `d11`, in this case) has been replaced.

```
# metareplace -e d11 c1t4d0s2
```

Note: The replacement disk must be partitioned to match the disk it is replacing before running the `metareplace` command.

Exit Status

The following exit values are returned:

`0`	Successful completion.
`>0`	An error occurred.

metarename(1M), metaroot(1M), metaset(1M), metassist(1M), metastat(1M), metasync(1M), metattach(1M), md.tab(4), md.cf(4), mddb.cf(4), md.tab(4), attributes(5), md(7D)

Solaris Volume Manager Administration Guide

Name metaroot – setup system files for root (/) metadevice

Synopsis

```
/usr/sbin/metaroot  -h

/usr/sbin/metaroot  [-n] [-k system-name] [-v vfstab-name]
 [-c mddb.cf-name] [-m md.conf-name] [-R root-path] device
```

Description The `metaroot` command edits the `/etc/vfstab` and `/etc/system` files so that the system may be booted with the root file system (`/`) on an appropriate metadevice. The only metadevices that support the root file system are a stripe with only a single slice or a mirror on a single-slice stripe.

If necessary, the `metaroot` command can reset a system that has been configured to boot the root file system (`/`) on a metadevice so that it uses a physical slice.

Options Root privileges are required for all of the following options except `-h`.

The following options are supported:

`-c` *mddb.cf-name* — Use *mddb.cf-name* instead of the default `/etc/lvm/mddb.cf` file as a source of metadevice database locations.

`-h` — Display a usage message.

`-k` *system-name* — Edit a user-supplied *system-name* instead of the default `/etc/system` system configuration information file.

`-m` *md.conf-name* — Edit the configuration file specified by *md.conf-name* rather than the default, `/kernel/drv/md.conf`.

`-n` — Print what would be done without actually doing it.

`-R` *root-path* — When metaroot modifies system files, it accesses them in their relative location under *root-path*.

The `-R` option cannot be used in combination with the `-c`, `-k`, `-m`, or `-v` options.

Note – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.

`-v` *vfstab-name* — Edit *vfstab-name* instead of the default `/etc/vfstab` table of file system defaults.

Operands The following operands are supported:

device — Specifies either the metadevice or the conventional disk device (slice) used for the root file system (`/`).

Examples

EXAMPLE 1 Specifying Root File System on Metadevice

The following command edits `/etc/system` and `/etc/vfstab` to specify that the root file system is now on metadevice `d0`.

```
# metaroot d0
```

EXAMPLE 2 Specifying Root File System on SCSI Disk

The following command edits `/etc/system` and `/etc/vfstab` to specify that the root file system is now on the SCSI disk device `/dev/dsk/c0t3d0s0`.

```
# metaroot /dev/dsk/c0t3d0s0
```

Files

`/etc/system`	System configuration information file. See `system(4)`.
`/etc/vfstab`	File system defaults.
`/etc/lvm/mddb.cf`	Metadevice state database locations.
`/kernel/drv/md.conf`	Configuration file for the metadevice driver, `md`.

Exit Status

The following exit values are returned:

`0`	Successful completion.
`>0`	An error occurred.

Attributes

See `attributes(5)` for descriptions of the following attributes:

Solaris Volume Manager Administration Guide

Name metaset – configure disk sets

Synopsis

```
/usr/sbin/metaset  -s setname [-M-a -h hostname]

/usr/sbin/metaset  -s setname -A{enable | disable}

/usr/sbin/metaset  -s setname [-A{enable | disable}]
 -a -h hostname...

/usr/sbin/metaset  -s setname -a [-l length] [-L] drivename...

/usr/sbin/metaset  -s setname -C {take | release |
 purge}

/usr/sbin/metaset  -s setname -d [-f] -h hostname...

/usr/sbin/metaset  -s setname -d [-f] drivename...

/usr/sbin/metaset  -s setname -j

/usr/sbin/metaset  -s setname -r

/usr/sbin/metaset  -s setname -w

/usr/sbin/metaset  -s setname -t [-f] [-u tagnumber]
 [y]

/usr/sbin/metaset  -s setname -b

/usr/sbin/metaset  -s setname -P

/usr/sbin/metaset  -s setname -q

/usr/sbin/metaset  -s setname -o [-h hostname]

/usr/sbin/metaset  [-s setname]

/usr/sbin/metaset  [-s setname] -a | -d [ [m] mediator_host_list]
```

Description The `metaset` command administers sets of disks in named disk sets. Named disk sets include any disk set that is not in the local set. While disk sets enable a high-availability configuration, Solaris Volume Manager itself does not actually provide a high-availability environment.

A single-owner disk set configuration manages storage on a SAN or fabric-attached storage, or provides namespace control and state database replica management for a specified set of disks.

In a shared disk set configuration, multiple hosts are physically connected to the same set of disks. When one host fails, another host has exclusive access to the disks. Each host can control a shared disk set, but only one host can control it at a time.

When you add a new disk to any disk set, Solaris Volume Manager checks the disk format. If necessary, it repartitions the disk to ensure that the disk has an appropriately configured reserved slice 7 (or slice 6 on an EFI labelled device) with adequate space for a state database replica. The precise size of slice 7 (or slice 6 on an EFI labelled device) depends on the disk geometry. For tradtional disk sets, the slice is no less than 4 Mbytes, and probably closer to 6

Mbytes, depending on where the cylinder boundaries lie. For multi-owner disk sets, the slice is a minimum of 256 Mbytes. The minimal size for slice 7 might change in the future. This change is based on a variety of factors, including the size of the state database replica and information to be stored in the state database replica.

For use in disk sets, disks must have a dedicated slice (six or seven) that meets specific criteria:

- The slice must start at sector 0
- The slice must include enough space for disk label
- The state database replicas cannot be mounted
- The slice does not overlap with any other slices, including slice 2

If the existing partition table does not meet these criteria, or if the -L flag is specified, Solaris Volume Manager repartitions the disk. A small portion of each drive is reserved in slice 7 (or slice 6 on an EFI labelled device) for use by Solaris Volume Manager. The remainder of the space on each drive is placed into slice 0. Any existing data on the disks is lost by repartitioning.

After you add a drive to a disk set, it can be repartitioned as necessary, with the exception that slice 7 (or slice 6 on an EFI labelled device) is not altered in any way.

After a disk set is created and metadevices are set up within the set, the metadevice name is in the following form:

`/dev/md/`*setname*`/{dsk,rdsk}/d`*number*

where *setname* is the name of the disk set, and *number* is the number of the metadevice (`0-127`).

If you have disk sets that you upgraded from Solstice DiskSuite software, the default state database replica size on those sets is 1034 blocks, not the 8192 block size from Solaris Volume Manager. Also, slice 7 on the disks that were added under Solstice DiskSuite are correspondingly smaller than slice 7 on disks that were added under Solaris Volume Manager.

If disks you add to a disk set have acceptable slice 7s (that start at cylinder 0 and that have sufficient space for the state database replica), they are not reformatted.

Hot spare pools within local disk sets use standard Solaris Volume Manager naming conventions. Hot spare pools with shared disk sets use the following convention:

setname`/hsp`*number*

where *setname* is the name of the disk set, and *number* is the number of the hot spare pool (0-999).

Multi–node Environment

To create and work with a disk set in a multi—node environment, `root` must be a member of Group 14 on all hosts, or the `/.rhosts` file must contain an entry for all other host names. This is not required in a SunCluster 3.x enviroment.

Tagged data

Tagged data occurs when there are different versions of a disk set's replicas. This tagged data consists of the set owner's nodename, the hardware serial number of the owner and the time it was written out to the available replicas. The system administer can use this information to determine which replica contains the correct data.

When a disk set is configured with an even number of storage enclosures and has replicas balanced across them evenly, it is possible that up to half of the replicas can be lost (for example, through a power failure of half of the storage enclosures). After the enclosure that went down is rebooted, half of the replicas are not recognized by SVM. When the set is retaken, the `metaset` command returns an error of "stale databases", and all of the metadevices are in a read-only state.

Some of the replicas that are not recognized need to be deleted. The action of deleting the replicas also causes updates to the replicas that are not being deleted. In a dual hosted disk set environment, the second node can access the deleted replicas instead of the existing replicas when it takes the set. This leads to the possibility of getting the wrong replica record on a disk set take. An error message is displayed, and user intervention is required.

Use the `-q` to query the disk set and the `-t`, `-u`, and `-y`, options to select the tag and take the disk set. See `OPTIONS`.

Mediator Configuration

SVM provides support for a low-end HA solution consisting of two hosts that share only two strings of drives. The hosts in this type of configuration, referred to as *mediators* or mediator hosts, run a special daemon, `rpc.metamedd(1M)`. The mediator hosts take on additional responsibilities to ensure that data is available in the case of host or drive failures.

A mediator configuration can survive the failure of a single host or a single string of drives, without administrative intervention. If both a host and a string of drives fail (multiple failures), the integrity of the data cannot be guaranteed. At this point, administrative intervention is required to make the data accessible. See `mediator(7D)` for further details.

Use the `-m` option to add or delete a mediator host. See `OPTIONS`.

Options

The following options are supported:

`-a`

Add drives or hosts to the named set. For a drive to be accepted into a set, the drive must not be in use within another metadevice or disk set, mounted on, or swapped on. When the drive is accepted into the set, it is repartitioned and the metadevice state database replica (for the set) can be placed on it. However, if a slice 7 (or slice 6 on an EFI labelled device), starts at cylinder 0, and is large enough to hold a state database replica, then the disk is not repartioned. Also, a drive is not accepted if it cannot be found on all hosts specified as part of the set. This means that if a host within the specified set is unreachable due to network problems, or is administratively down, the add fails.

`-a` | `-d` | `-m` *mediator_host_list*
Add (`-a`) or delete (`-d`) mediator hosts to the specified disk set. A *mediator_host_list* is the `nodename(4)` of the mediator host to be added and (for adding) up to two other aliases for the mediator host. The nodename and aliases for each mediator host are separated only by commas. Up to three mediator hosts can be specified for the named disk set. Specify only the nodename of that host as the argument to `-m` to delete a mediator host.

In a single `metaset` command you can add or delete three mediator hosts. See `EXAMPLES`.

`-A {enable | disable}`
Specify auto-take status for a disk set. If auto-take is enabled for a set, the disk set is automatically taken at boot, and file systems on volumes within the disk set can be mounted through `/etc/vfstab` entries. Only a single host can be associated with an auto-take set, so attempts to add a second host to an auto-take set or attempts to configure a disk set with multiple hosts as auto-take fails with an error message. Disabling auto-take status for a specific disk set causes the disk set to revert to normal behavior. That is, the disk set is potentially shared (non-concurrently) among hosts, and unavailable for mounting through `/etc/vfstab`.

`-b`
Insure that the replicas are distributed according to the replica layout algorithm. This can be invoked at any time, and does nothing if the replicas are correctly distributed. In cases where the user has used the `metadb` command to manually remove or add replicas, this command can be used to insure that the distribution of replicas matches the replica layout algorithm.

`-C {take | release | purge}`
Do not interact with the Cluster Framework when used in a Sun Cluster 3 environment. In effect, this means do not modify the Cluster Configuration Repository. These options should only be used to fix a broken disk set configuration. This option is not for use with a multi-owner disk set.

take
Take ownership of the disk set but do not inform the Cluster Framework that the disk set is available

release
Release ownership of the disk set without informing the Cluster Framework. This option should only be used if the disk set ownership was taken with the corresponding `-C take` option.

purge
Remove the disk set without informing the Cluster Framework that the disk set has been purged

`-d`

Delete drives or hosts from the named disk set. For a drive to be deleted, it must not be in use within the set. The last host cannot be deleted unless all of the drives within the set are deleted. Deleting the last host in a disk set destroys the disk set.

This option fails on a multi-owner disk set if attempting to withdraw the master node while other nodes are in the set.

`-f`

Force one of three actions to occur: takes ownership of a disk set when used with `-t`; deletes the last disk drive from the disk set; or deletes the last host from the disk set. Deleting the last drive or host from a disk set requires the `-d` option.

When used to forcibly take ownership of the disk set, this causes the disk set to be grabbed whether or not another host owns the set. All of the disks within the set are taken over (reserved) and fail fast is enabled, causing the other host to panic if it had disk set ownership. The metadevice state database is read in by the host performing the take, and the shared metadevices contained in the set are accessible.

You can use this option to delete the last drive in the disk set, because this drive would implicitly contain the last state database replica.

You can use `-f` option to delete hosts from a set. When specified with a partial list of hosts, it can be used for one-host administration. One-host administration could be useful when a host is known to be non-functional, thus avoiding timeouts and failed commands. When specified with a complete list of hosts, the set is completely deleted. It is generally specified with a complete list of hosts to clean up after one-host administration has been performed.

`-h` *hostname...*

Specify one or more host names to be added to or deleted from a disk set. Adding the first host creates the set. The last host cannot be deleted unless all of the drives within the set have been deleted. The host name is not accepted if all of the drives within the set cannot be found on the specified host. The host name is the same name found in `/etc/nodename`.

`-j`

Join a host to the owner list for a multi-owner disk set. The concepts of take and release, used with traditional disk sets, do not apply to multi-owner sets, because multiple owners are allowed.

As a host boots and is brought online, it must go through three configuration levels to be able to use a multi-owner disk set:

1. It must be included in the cluster nodelist, which happens automatically in a cluster or single-node sitatuion.
2. It must be added to the multi-owner disk set with the `-a -h` options documented elsewhere in this man page
3. It must join the set. When the host is first added to the set, it is automatically joined.

On manual restarts, the administrator must manually issue

`metaset -s` *multinodesetname* `-j`

to join the host to the owner list. After the cluster reconfiguration, when the host reenters the cluster, the node is automatically joined to the set. The `metaset -j` command joins the host to all multi-owner sets that the host has been added to. In a single node situation, joining the node to the disk set starts any necessary resynchronizations.

`-L`

When adding a disk to a disk set, force the disk to be repartitioned using the standard Solaris Volume Manager algorithm. See `DESCRIPTION`.

`-l` *length*

Set the size (in blocks) for the metadevice state database replica. The length can only be set when adding a new drive; it cannot be changed on an existing drive. The default (and maximum) size is 8192 blocks, which should be appropriate for most configurations. Replica sizes of less than 128 blocks are not recommended.

`-M`

Specify that the disk set to be created or modified is a multi-owner disk set that supports multiple concurrent owners.

This option is required when creating a multi-owner disk set. Its use is optional on all other operations on a multi-owner disk set and has no effect. Existing disk sets cannot be converted to multi-owner sets.

`-o`

Return an exit status of `0` if the local host or the host specified with the `-h` option is the owner of the disk set.

`-P`

Purge the named disk set from the node on which the `metaset` command is run. The disk set must not be owned by the node that runs this command. If the node does own the disk set, the command fails.

If you need to delete a disk set but cannot take ownership of the set, use the `-P` option.

This option is not for use with a multi-owner disk set.

`-q`

Displays an enumerated list of tags pertaining to ‘‘tagged data'' that can be encountered during a take of the ownership of a disk set.

This option is not for use with a multi-owner disk set.

`-r`

Release ownership of a disk set. All of the disks within the set are released. The metadevices set up within the set are no longer accessible.

This option is not for use with a multi-owner disk set.

`-s` *setname*
Specify the name of a disk set on which `metaset` works. If no *setname* is specified, all disk sets are returned.

`-t`
Take ownership of a disk set safely. If `metaset` finds that another host owns the set, this host is not be allowed to take ownership of the set. If the set is not owned by any other host, all the disks within the set are owned by the host on which `metaset` was executed. The metadevice state database is read in, and the shared metadevices contained in the set become accessible. The `-t` option takes a disk set that has stale databases. When the databases are stale, `metaset` exits with code 66, and prints a message. At that point, the only operations permitted are the addition and deletion of replicas. Once the addition or deletion of the replicas has been completed, the disk set should be released and retaken to gain full access to the data.

This option is not for use with a multi-owner disk set.

`-u` *tagnumber*
Once a tag has been selected, a subsequent take with `-u` *tagnumber* can be executed to select the data associated with the given *tagnumber*.

w
Withdraws a host from the owner list for a multi-owner disk set. The concepts of take and release, used with traditional disk sets, do not apply to multi-owner sets, because multiple owners are allowed.

Instead of releasing a set, a host can issue

```
metaset -s multinodesetname -w
```

to withdraw from the owner list. A host automatically withdraws on a reboot, but can be manually withdrawn if it should not be able to use the set, but should be able to rejoin at a later time. A host that withdrew due to a reboot can still appear joined from other hosts in the set until a reconfiguration cycle occurs.

`metaset -w` withdraws from ownership of all multi-owner sets of which the host is a member. This option fails if you attempt to withdraw the master node while other nodes are in the disk set owner list. This option cancels all resyncs running on the node. A cluster reconfiguration process that is removing a node from the cluster membership list effectively withdraws the host from the ownership list.

`-y`
Execute a subsequent take. If the take operation encounters “tagged data," the take operation exits with code 2. You can then run the `metaset` command with the `-q` option to see an enumerated list of tags.

Examples

EXAMPLE 1 Defining a Disk Set

This example defines a disk set.

```
# metaset -s relo-red -a -h red blue
```

The name of the disk set is `relo-red`. The names of the first and second hosts added to the set are `red` and `blue`, respectively. (The hostname is found in `/etc/nodename`.) Adding the first host creates the disk set. A disk set can be created with just one host, with the second added later. The last host cannot be deleted until all of the drives within the set have been deleted.

EXAMPLE 2 Adding Drives to a Disk Set

This example adds drives to a disk set.

```
# metaset -s relo-red -a c2t0d0 c2t1d0 c2t2d0 c2t3d0 c2t4d0 c2t5d0
```

The name of the previously created disk set is `relo-red`. The names of the drives are `c2t0d0`, `c2t1d0`, `c2t2d0`, `c2t3d0`, `c2t4d0`, and `c2t5d0`. There is no slice identifier ("s*x*") at the end of the drive names.

EXAMPLE 3 Adding Multiple Mediator Hosts

The following command adds three mediator hosts to the specified disk set.

```
# metaset -s mydiskset -a -m myhost1,alias1 myhost2,alias2 myhost3,alias3
```

EXAMPLE 4 Purging a Disk Set from the Node

The following command purges the disk set `relo-red` from the node:

```
# metaset -s relo-red -P
```

EXAMPLE 5 Querying a Disk Set for Tagged Data

The following command queries the disk set `relo-red` for a list of the tagged data:

```
# metaset -s relo-red -q
```

This command produces the following results:

```
The following tag(s) were found:
 1 - vha-1000c - Fri Sep 20 17:20:08 2002
 2 - vha-1000c - Mon Sep 23 11:01:27 2002
```

EXAMPLE 6 Selecting a tag and taking a Disk set

The following command selects a tag and takes the disk set `relo-red`:

```
# metaset -s relo-red -t -u 2
```

EXAMPLE 7 Defining a Multi-Owner Disk Set

The following command defines a multi-owner disk set:

```
# metaset -s blue -M -a -h hahost1 hahost2
```

The name of the disk set is `blue`. The names of the first and second hosts added to the set are `hahost1` and `hahost2`, respectively. The hostname is found in `/etc/nodename`. Adding the first host creates the multi-owner disk set. A disk set can be created with just one host, with additional hosts added later. The last host cannot be deleted until all of the drives within the set have been deleted.

Files

`/etc/lvm/md.tab` Contains list of metadevice configurations.

Exit Status

The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Attributes

See `attributes(5)` for descriptions of the following attributes:

Solaris Volume Manager Administration Guide

Notes

Disk set administration, including the addition and deletion of hosts and drives, requires all hosts in the set to be accessible from the network.

Name metassist – automated volume creation utility to support Solaris Volume Manager

Synopsis

```
metassist -V

metassist -?

metassist create [-v n] [-c] -F config_file

metassist create [-v n] [-c | -d] -F request_file

metassist create [-v n] [-c | -d] [-f] [-n name] [-p datapaths]
 [-r redundancy] [-a available [,available,...]]
 [-u unavailable [,unavailable,...]] -s setname
 -S size

metassist create -?
```

Description The `metassist` command provides assistance, through automation, with common Solaris Volume Manager tasks.

SUBCOMMANDS The following subcommands are supported:

`create` The `create` subcommand creates one or more Solaris Volume Manager volumes. You can specify this request on the command line or in a file specified on the command line.

If you create a volume using the command line, you can specify the characteristics of the volume in terms of the desired quality of service it will provide - its size, the number of redundant copies of the data it contains, the number of data paths by which it is accessible, and whether faulty components are replaced automatically. The diskset in which the volume will reside and the volume's size must be specified on the command line in this form of the command.

If you create a volume using a request in a file, you can specify the characteristics of the volume in terms of the quality of service they provide, as on the command line. Alternatively, the file can specify the types and component parts of the volume, (for example, mirrors, stripes, concatenations, and their component slices). The file may also specify volumes partly in terms of their types and partly in terms of their component parts, and may specify the characteristics of more than one volume. All volumes specified in a file must reside in the same diskset, whose name must be specified in the file.

If you specify the `-c` or `-d` option on the command line, the command runs without creating an actual volume or volumes. Instead, it outputs either a a Bourne shell command script (`-c` option) or a volume configuration (`-d` option). The command script, when run, creates the

specified volume or volumes. The volume configuration specifies the volume or volumes in complete detail, naming all their components.

The input file given on the command line can take one of the following forms:

- a volume request, which specifies a request for a volume with explicit attributes and components, or matching a given quality of service
- a volume configuration, produced by a previous execution of the command

Options The following option is mandatory if you specify a volume request or volume configuration in a file:

`-F` *config_file* | *request_file*
Specify the volume request or volume configuration file to process. If *config_file* or *request_file* is `-`, it is read from standard input.

The `-d` option cannot be specified when *inputfile* is a volume configuration file.

The following options are mandatory if you specify a volume request on the command line:

`-s` *set*
Specify the disk set to use when creating volumes. All the volumes and hot spare pools are created in this disk set. If necessary, disks are moved into the diskset for use in the volumes and hot spare pools. If the diskset doesn't exist the command creates it. This option is required. `metassist` works entirely within a named disk set. Use of the local, or unnamed disk set, is not allowed.

`-S` *size*
Specify the size of the volume to be created. The size argument consists of a numeric value (a decimal can be specified) followed by KB, MB, GB, or TB, indicating kilobytes, megabytes, gigabytes, or terabytes, respectively. Case is ignored when interpreting this option. This option is required.

The following options are optional command line parameters:

`-a` *device1*`,`*device2*`, . . .`
Explicitly specify the devices that can be used in the creation of this volume. Named devices may be controllers or disks. Only used when specifying a volume on the command line.

`-c`
Output the command script that would implement the specified or generated volume configuration. The command script is not run, and processing stops at this stage.

`-d`
Output the volume configuration that satisfies the specified or generated volume request. No command script is generated or executed, and processing stops at this stage.

`-f`
Specify whether the volume should support automatic component replacement after a fault. If this option is specified, a mirror is created and its submirrors are associated with a hot spare.

`-n` *name*
Specify the name of the new volume. See `metainit(1M)` for naming guidelines.

`-p` *n*
Specify the number of required paths to the storage volume. The value of *n* cannot be greater than the number of different physical paths and logical paths to attached storage. Only used when specifying a volume on the command line.

`-r` *n*
Specify the redundancy level (`0`-`4`) of the data. The default is `0`. Only used when specifying a volume on the command line. If redundancy is `0`, a stripe is created. If redundancy is `1` or greater, a mirror with this number of submirrors is created. In this case, the volume can suffer a disk failure on *n*`-1` copies without data loss. With the use of hot spares (see the `-f` option), a volume can suffer a disk failure on *n*`+hsps-1` volumes without data loss, assuming non-concurrent failures.

`-u` *device1*`,`*device2*`,...`
Explicitly specify devices to exclude in the creation of this volume. Named devices can be controllers or disks. You can use this option alone, or to exclude some of the devices listed as available with the `-a` option, Only used when specifying a volume on the command line.

`-v` *value*
Specify the level of verbosity. Values from `0` to `2` are available, with higher numbers specifying more verbose output when the command is run. `-v 0` indicates silent output, except for errors or other critical messages. The default level is `1`.

`-V`
Display program version information.

`-?`
Display help information. This option can follow a subcommand for subcommand-specific help.

Examples

EXAMPLE 1 Creating a Mirror

The following example creates a two-way, 36Gb mirror on available devices from controller 1 and controller 2. It places the volume in diskset `mirrorset`.

```
# metassist create -r 2 -a c1,c2 -s mirrorset -S 36G
```

EXAMPLE 2 Creating a Mirror with Additional Fault Tolerance

The following example creates a two-way, 36Gb mirror on available devices from controller 1 and controller 2. It provides additional fault tolerance in the form of a hot spare. It places the volume in diskset `mirrorset`.

EXAMPLE 2 Creating a Mirror with Additional Fault Tolerance *(Continued)*

```
# metassist create -f -r 2 -a c1,c2 -s mirrorset -S 36GB
```

EXAMPLE 3 Creating a Three-way Mirror and Excluding Devices

The following example creates a three-way, 180Gb mirror from storage devices on controller 1 or controller 2. It excludes the disks `c1t2d0` and `c2t2d1` from the volume. It places the volume in diskset `mirrorset`.

```
metassist create -r 3 -a c1,c2 -u c1t2d0, c2t2d1 \
    -s mirrorset -S 180GB
```

EXAMPLE 4 Determining and Implementing a Configuration

The following example determines and implements a configuration satisfying the request specified in a request file:

```
# metassist create -F request.xml
```

EXAMPLE 5 Determining a Configuration and Saving It in a volume-config File

The following example determines a configuration which satisfies the given request. It saves the configuration in a volume-config file without implementing it:

```
# metassist create -d -F request.xml > volume-config
```

EXAMPLE 6 Determining a Configuration and Saving It in a Shell Script

The following example determines a configuration which satisfies the given request. It saves the configuration in a shell script without implementing it:

```
# metassist create -c -F request.xml > setupvols.sh
```

EXAMPLE 7 Implementing the Given volume-config

The following example implements the given volume-config:

```
# metassist create -F config.xml
```

EXAMPLE 8 Converting the Given volume-config to a Shell Script

The following example converts the given volume-config to a shell script that you can run later:

```
# metassist create -c -F config.xml > setupvols.sh
```

Exit Status

The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Files `/usr/share/lib/xml/dtd/volume-request.dtd`

`/usr/share/lib/xml/dtd/volume-defaults.dtd`

`/usr/share/lib/xml/dtd/volume-config.dtd`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmdr

See Also `mdmonitord(1M)`, `metaclear(1M)`, `metadb(1M)`, `metadetach(1M)`, `metahs(1M)`, `metainit(1M)`, `metaoffline(1M)`, `metaonline(1M)`, `metaparam(1M)`, `metarecover(1M)`, `metarename(1M)`, `metareplace(1M)`, `metaroot(1M)`, `metaset(1M)`, `metastat(1M)`, `metasync(1M)`, `metattach(1M)`, `md.tab(4)`, `md.cf(4)`, `mddb.cf(4)`, `md.tab(4)`, `volume-config(4)`, `volume-request(4)`, `attributes(5)`, `md(7D)`

Notes The quality of service arguments are mutually exclusive with the `-F` *inputfile* argument.

When specifying a request file or quality of service arguments on the command line, the `/etc/default/metassist.xml` file is read for global and per-disk set defaults.

Characteristics of this file are specified in the DTD, in `/usr/share/lib/xml/dtd/volume-defaults.dtd`.

Characteristics of the XML request file are specified in the DTD, in `/usr/share/lib/xml/dtd/volume-request.dtd`.

Characteristics of the XML configuration file are specified in the DTD, in `/usr/share/lib/xml/dtd/volume-config.dtd`.

This command must be run as root.

This command requires a functional Solaris Volume Manager configuration before it runs.

Name metastat – display status for metadevice or hot spare pool

Synopsis

```
/usr/sbin/metastat  -h

/usr/sbin/metastat  [-a] [-B] [-c] [-i] [-p] [-q] [-s setname]
 [-t] [metadevice...] [hot_spare_pool...]

/usr/sbin/metastat  [-a] [-B] [-c] [-i] [-p] [-q] [-s setname]
 component...
```

Description The `metastat` command displays the current status for each metadevice (including stripes, concatenations, concatenations of stripes, mirrors, RAID5, soft partitions, and trans devices) or hot spare pool, or of specified metadevices, components, or hot spare pools.

It is helpful to run the `metastat` command after using the `metattach` command to view the status of the metadevice.

`metastat` displays the state of each Solaris Volume Manager RAID-1 volume on the system. The possible states include:

`Okay`	The device reports no errors.
`Needs maintenance`	A problem has been detected. This requires that the system administrator replace the failed physical device. Volumes displaying `Needs maintenance` have incurred no data loss, although additional failures could risk data loss. Take action as quickly as possible.
`Last erred`	A problem has been detected. Data loss is a possibility. This might occur if a component of a submirror fails and is not replaced by a hot spare, therefore going into `Needs maintenance` state. If the corresponding component also fails, it would go into `Last erred` state and, as there is no remaining valid data source, data loss could be a possibility.
`Unavailable`	A device cannot be accessed, but has not incurred errors. This might occur if a physical device has been removed with Solaris Dynamic Reconfiguration (DR) features, thus leaving the Solaris Volume Manager volume unavailable. It could also occur if an array or disk is powered off at system initialization, or if a >1TB volume is present when the system is booted in 32-bit mode. After the storage has been made available, run the `metastat` command with the `-i` option to update the status of the metadevices. This clears the unavailable state for accessible devices.

See the *Solaris Volume Manager Administration Guide* for instructions on replacing disks and handling volumes in Needs maintenance or Last erred states.

Options The following options are supported:

`-a` Display all disk sets. Only metadevices in disk sets that are owned by the current host are displayed.

`-B` Display the current status of all of the 64-bit metadevices and hot spares.

`-c` Display concise output.

There is one line of output for each metadevice. The output shows the basic structure and the error status, if any, for each metadevice.

The `-c` output format is distinct from the `-p` output format. The `-p` option does not display metadevice status and is not intended as human-readable output.

`-h` Display usage message.

`-i` Check the status of RAID-1 (mirror) volumes, RAID-5 volumes, and hot spares. The inquiry checks each metadevice for accessibility, starting at the top level metadevice. When problems are discovered, the metadevice state databases are updated as if an error had occurred.

`-p` Display the list of active metadevices and hot spare pools in the same format as `md.tab`. See `md.tab(4)`.

The `-p` output is designed for snapshotting the configuration for later recovery or setup.

`-q` Display the status for metadevices without the device relocation information.

`-s` *setname* Specify the name of the disk set on which `metastat` works. Using the `-s` option causes the command to perform its administrative function within the specified disk set. Without this option, the command performs its function on metadevices and hot spare pools in the local disk set.

`-t` Display the current status and timestamp for the specified metadevices and hot spare pools. The timestamp provides the date and time of the last state change.

Operands The following operands are supported:

component — Display the status of the component hosting a soft partition, including extents, starting blocks, and block count.

hot_spare_pool — Display the status of the specified hot spare pool(s).

metadevice — Display the status of the specified metadevice(s). If a trans metadevice is specified, the status of the master and log devices is also displayed. Trans metadevices have been replaced by UFS logging. See `NOTES`.

Examples **EXAMPLE 1** Output Showing Mirror with Two Submirrors

The following example shows the partial output of the `metastat` command after creating a mirror, `d0`, consisting of two submirrors, `d70` and `d80`.

```
# metastat d0
d0: Mirror
    Submirror 0: d80
      State: Okay
    Submirror 1: d70
      State: Resyncing
    Resync in progress: 15 % done
    Pass: 1
    Read option: roundrobin (default)
    Write option: parallel (default)
    Size: 2006130 blocks
    .
    .
    .
```

EXAMPLE 2 Soft Partition on Mirror with Submirror

The following example shows the partial output of the `metastat` command after creating a soft partition, `d3`, on concat `d2`, which is built on a soft partition.

```
# metastat
d2: Concat/Stripe
    Size: 204800 blocks
    Stripe 0:
        Device              Start Block  Dbase State        Hot Spare
        d0                         0     No    Okay

d0: Soft Partition
    Component: c0t3d0s0
    Status: Okay
    Size: 204800 blocks
        Extent              Start Block  Block count
             0                     129       204800
```

EXAMPLE 2 Soft Partition on Mirror with Submirror *(Continued)*

```
d3: Soft Partition
    Component: d2
    Status: Okay
    Size: 202752 blocks
         Extent              Start Block  Block count
              0                     129       202752
```

EXAMPLE 3 Trans Metadevice

The following example shows the output of the `metastat` command after creating a trans metadevice.

```
# metastat
d2: Concat/Stripe
    Size: 204800 blocks
    Stripe 0:
        Device              Start Block  Dbase State        Hot Spare
        d0                         0     No    Okay

d0: Soft Partition
    Component: c0t3d0s0
    Status: Okay
    Size: 204800 blocks
        Extent              Start Block  Block count
             0                     129       204800

d3: Soft Partition
    Component: d2
    Status: Okay
    Size: 202752 blocks
         Extent              Start Block  Block count
              0                     129       202752
```

EXAMPLE 4 Multi-owner disk set

The following example shows the output of the `metastat` command with a multi-owner disk set and application-based mirror resynchronization option. Application-based resynchronization is set automatically if needed.

```
# metastat -s oban
oban/d100: Mirror
    Submirror 0: oban/d10
      State: Okay
    Submirror 1: oban/d11
      State: Okay
    Pass: 1
```

EXAMPLE 4 Multi-owner disk set *(Continued)*

```
    Read option: roundrobin (default)
    Write option: parallel (default)
    Resync option: application based
    Owner: None
    Size: 1027216 blocks (501 MB)

oban/d10: Submirror of oban/d100
    State: Okay
    Size: 1027216 blocks (501 MB)
    Stripe 0:
        Device     Start Block  Dbase     State Reloc Hot Spare
        c1t3d0s0          0     No         Okay

oban/d11: Submirror of oban/d100
    State: Okay
    Size: 1027216 blocks (501 MB)
    Stripe 0:
        Device     Start Block  Dbase     State Reloc Hot Spare
        c1t4d0s0          0     No         Okay
```

Warnings `metastat` displays states as of the time the command is entered. It is unwise to use the output of the `metastat -p` command to create a `md.tab(4)` file for a number of reasons:

- The output of `metastat -p` might show hot spares being used.
- It might show mirrors with multiple submirrors. See `metainit(1M)` for instructions for creating multi-way mirrors using `metainit` and `metattach`.
- A slice may go into an error state after `metastat -p` is issued.

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmdr
Stability	Evolving

See Also `mdmonitord(1M)`, `metaclear(1M)`, `metadb(1M)`, `metadetach(1M)`, `metahs(1M)`, `metainit(1M)`, `metaoffline(1M)`, `metaonline(1M)`, `metaparam(1M)`, `metarecover(1M)`,

metarename(1M), metareplace(1M), metaroot(1M), metaset(1M), metassist(1M), metasync(1M), metattach(1M), md.tab(4), md.cf(4), mddb.cf(4), md.tab(4), attributes(5), md(7D)

Solaris Volume Manager Administration Guide

Notes Trans metadevices have been replaced by UFS logging. Existing trans devices are *not* logging--they pass data directly through to the underlying device. See mount_ufs(1M) for more information about UFS logging.

Name metasync – handle metadevice resync during reboot

Synopsis

```
/usr/sbin/metasync  -h

/usr/sbin/metasync  [-s setname] [buffer_size] metadevice

/usr/sbin/metasync  [-s setname] -r [buffer_size]

/usr/sbin/metasync  -p metadevice
```

Description The `metasync` command starts a resync operation on the specified *metadevice*. All components that need to be resynced are resynced. If the system crashes during a RAID5 initialization, or during a RAID5 resync, either an initialization or resync restarts when the system reboots.

Applications are free to access a metadevice at the same time that it is being resynced by `metasync`. Also, `metasync` performs the copy operations from inside the kernel, which makes the utility more efficient.

Use the `-r` option in boot scripts to resync all possible submirrors.

Options The following options are supported:

`-h` Displays usage message.

`-p` *metadevice* Regenerates parity information for RAID5 metadevices.

`-s` *setname* Specifies the name of the diskset on which `metasync` will work. Using the `-s` option will cause the command to perform its administrative function within the specified diskset. Without this option, the command will perform its function on local metadevices.

`-r` Specifies that the `metasync` command handle special resync requirements during a system reboot. `metasync -r` should only be invoked from the `svc:/system/mdmonitor` service. The `metasync` command only resyncs those metadevices that need to be resynced. `metasync` schedules all the mirror resyncs according to their pass numbers.

To override the default buffer_size value used by the `svc:/system/mdmonitor` service, you can edit `/etc/system` to specify:

```
set md_mirror:md_resync_bufsz = 2048
```

so that resyncs occur as quickly as possible.

Operands *buffer_size* Specifies the size (number of 512-byte disk blocks) of the internal copy buffer for the mirror resync. The size defaults to 128 512-byte disk blocks (64 Kbytes). It can be no more than 2048 blocks. For best performance (quickest completion of the resync), 2048 blocks is the recommended

size.

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmdu

See Also `mdmonitord(1M)`, `metaclear(1M)`, `metadb(1M)`, `metadetach(1M)`, `metahs(1M)`, `metainit(1M)`, `metaoffline(1M)`, `metaonline(1M)`, `metaparam(1M)`, `metarecover(1M)`, `metarename(1M)`, `metareplace(1M)`, `metaroot(1M)`, `metaset(1M)`, `metassist(1M)`, `metastat(1M)`, `metattach(1M)`, `md.tab(4)`, `md.cf(4)`, `mddb.cf(4)`, `md.tab(4)`, `attributes(5)`, `md(7D)`

Solaris Volume Manager Administration Guide

Notes The `metasync` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/system/mdmonitor
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

Name metattach, metadetach – attach or detach a metadevice

Synopsis

```
/usr/sbin/metattach [-h]

/usr/sbin/metattach [-s setname] mirror [metadevice]

/usr/sbin/metattach [-s setname] [-i interlace] concat/stripe
 component...

/usr/sbin/metattach [-s setname] RAID component...

/usr/sbin/metattach [-s setname] [-A alignment] softpart
 size | all

/usr/sbin/metadetach [-s setname] [-f] mirror submirror

/usr/sbin/metadetach [-s setname] [-f] trans
```

Description `metattach` adds submirrors to a mirror, grows metadevices, or grows soft partitions. Growing metadevices can be done without interrupting service. To grow the size of a mirror or trans, the slices must be added to the submirrors or to the master devices.

Solaris Volume Manager supports storage devices and logical volumes greater than 1 terabyte (TB) when a system runs a 64-bit Solaris kernel. Support for large volumes is automatic. If a device greater than 1 TB is created, Solaris Volume Manager configures it appropriately and without user intervention.

If a system with large volumes is rebooted under a 32–bit Solaris kernel, the large volumes are visible through `metastat` output. Large volumes cannot be accessed, modified or deleted, and no new large volumes can be created. Any volumes or file systems on a large volume in this situation are also unavailable. If a system with large volumes is rebooted under a version of Solaris prior to the Solaris 9 4/03 release, Solaris Volume Manager does not start. You must remove all large volumes before Solaris Volume Manager runs under an earlier version of the Solaris Operating System.

Solaris Volume Manager supports one-to-four-way mirrors. You can only attach a metadevice to a mirror if there are three or fewer submirrors beneath the mirror. Once a new metadevice is attached to a mirror, `metattach` automatically starts a resync operation to the new submirror.

`metadetach` detaches submirrors from mirrors and logging devices from trans metadevices.

When a submirror is detached from a mirror, it is no longer part of the mirror, thus reads and writes to and from that metadevice by way of the mirror are no longer performed through the mirror. Detaching the only existing submirror is not allowed. Detaching a submirror that has slices reported as needing maintenance (by `metastat`) is not allowed unless the `-f` (force) flag is used.

`metadetach` also detaches the logging device from a trans. This step is necessary before you can clear the trans volume. Trans metadevices have been replaced by UFS logging. Existing

trans devices are not logging. They pass data directly through to the underlying device. See `mount_ufs(1M)` for more information about UFS logging.

Detaching the logging device from a busy trans device is not allowed unless the `-f` (force) flag is used. Even so, the logging device is not actually detached until the trans is idle. The trans is in the *Detaching* state (`metastat`) until the logging device is detached.

Options Root privileges are required for all of the following options except `-h`.

The following options are supported:

`-A` *alignment*
: Set the value of the soft partition extent alignment. Use this option when it is important specify a starting offset for the soft partition. It preserves the data alignment between the metadevice address space and the address space of the underlying physical device.

  For example, a hardware device that does checksumming should not have its I/O requests divided by Solaris Volume Manager. In this case, use a value from the hardware configuration as the value for the alignment. When using this option in conjunction with a software I/O load, the alignment value corresponds to the I/O load of the application. This prevents I/O from being divided unnecessarily and affecting performance.

`-f`
: Force the detaching of metadevices that have components that need maintenance or are busy. You can use this option only when a mirror is in a maintenance state that can be fixed with `metareplace(1M)`. If the mirror is in a maintenance state that can only be fixed with `metasync(1M)` (as shown by the output of `metastat(1M)`), `metadetach -f` has no effect, because the mirrors must be resynchronized before one of them can be detached.

`-h`
: Display a usage message.

`-i` *interlace*
: Specify the interlace value for stripes, where `size` is a specified value followed by either `k` for kilobytes, `m` for megabytes, or `b` for blocks. The units can be either uppercase or lowercase. If *size* is not specified, the size defaults to the interlace size of the last stripe of the metadevice. When an interlace size change is made on a stripe, it is carried forward on all stripes that follow.

`-s` *setname*
: Specify the name of the diskset on which the `metattach` command or the `metadetach` command works.. Using the `-s` option causes the command to perform its administrative function within the specified diskset. Without this option, the command performs its function on local metadevices.

Operands The following operands are supported:

component
The logical name for the physical slice (partition) on a disk drive, such as `/dev/dsk/c0t0d0s2`, being added to the concatenation, stripe, concatenation of stripes, or RAID5 metadevice.

concat/stripe
The metadevice name of the concatenation, stripe, or concatenation of stripes.

log
The metadevice name of the logging device to be attached to the trans metadevice.

metadevice
The metadevice name to be attached to the mirror as a submirror. This metadevice must have been previously created by the `metainit` command.

mirror
The name of the mirror.

RAID
The metadevice name of the RAID5 metadevice.

size | *all*
The amount of space to add to the soft partition in `K` or `k` for kilobytes, `M` or `m` for megabytes, `G` or `g` for gigabytes, `T` or `t` for terabytes, and `B` or `b` for blocks (sectors). All values represent powers of 2, and upper and lower case options are equivalent. Only integer values are permitted. The literal `all` specifies that the soft partition should grow to occupy all available space on the underlying volume.

softpart
The metadevice name of the existing soft partition.

submirror
The metadevice name of the submirror to be detached from the mirror.

trans
The metadevice name of the trans metadevice (not the master or logging device).

Examples

EXAMPLE 1 Concatenating a New Slice to a Metadevice

This example concatenates a single new slice to an existing metadevice, `d8`. Afterwards, you would use the `growfs(1M)` command to expand the file system.

```
# metattach d8 /dev/dsk/c0t1d0s2
```

EXAMPLE 2 Detaching Logging Device from Trans Metadevice

This example detaches the logging device from a trans metadevice `d9`. Notice that you do not have to specify the logging device itself, as there can only be one.

```
# metadetach d9
```

EXAMPLE 3 Expanding a RAID5 Metadevice

This example expands a RAID5 metadevice, `d45`, by attaching another slice.

```
# metattach d45 /dev/dsk/c3t0d0s2
```

When you add additional slices to a RAID5 metadevice, the additional space is devoted to data. No new parity blocks are allocated. The data on the added slices is, however, included in the overall parity calculations, so it is protected against single-device failure.

EXAMPLE 4 Expanding a Soft Partition

The following example expands a soft partition, `d42`, attaching all space available on the underlying device.

```
# metattach d42 all
```

When you add additional space to a soft partition, the additional space is taken from any available space on the slice and might not be contiguous with the existing soft partition.

EXAMPLE 5 Adding Space to Two-Way Mirror

This example adds space to a two-way mirror by adding a slice to each submirror. Afterwards, you would use the `growfs(1M)` command to expand the file system.

```
# metattach d9 /dev/dsk/c0t2d0s5
# metattach d10 /dev/dsk/c0t3d0s5
```

This example tells the mirror to grow to the size of the underlying devices

```
# metattach d11
```

This example increases the size of the UFS on the device so the space can be used.

```
# growfs -M /export /dev/md/dsk/d11
```

EXAMPLE 6 Detaching a Submirror from a Mirror

This example detaches a submirror, `d2`, from a mirror, `d4`.

```
# metadetach d4 d2
```

EXAMPLE 7 Adding Four Slices to Metadevice

This example adds four slices to an existing metadevice, `d9`. Afterwards, you would use the `growfs(1M)` command to expand the file system.

```
# metattach d9 /dev/dsk/c0t1d0s2 /dev/dsk/c0t2d0s2 \\
     /dev/dsk/c0t3d0s2 /dev/dsk/c0t4d0s2
```

EXAMPLE 8 Setting the Value of the Soft Partition Extent Alignment

This example shows how to set the alignment of the soft partition to 1mb when the soft partition is expanded.

EXAMPLE 8 Setting the Value of the Soft Partition Extent Alignment *(Continued)*

```
# metattach -s red -A 2m d13 1m
```

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Solaris Volume Manager Administration Guide

Warnings This section provides information regarding warnings for devices greater than 1 TB and for multi-way mirrors.

Devices and Volumes Greater Than 1 TB

Do not create large (>1 TB) volumes if you expect to run the Solaris Operating System with a 32-bit kernel or if you expect to use a version of the Solaris Operating System prior to Solaris 9 4/03.

Multi-Way Mirrors

When a submirror is detached from its mirror, the data on the metadevice might not be the same as the data that existed on the mirror prior to running `metadetach`. In particular, if the `-f` option was needed, the metadevice and mirror probably do not contain the same data.

Notes Trans metadevices have been replaced by UFS logging. Existing trans devices are *not* logging. They pass data directly through to the underlying device. See `mount_ufs(1M)` for more information about UFS logging.

Name mib2c – produces template code from MIB definitions

Synopsis

```
/usr/sfw/bin/mib2c [-h] -c configfile [-f outname] [-i]
     [-q] [-S var=val] mibnode [mibnode]...
```

Description The `mib2c` tool is designed to take a portion of the MIB tree (as defined by a MIB file) and generate the template C code necessary to implement the corresponding MIB module.

To implement a new MIB module, three files are necessary:

- MIB definition file
- C header file
- C implementation file

The `mib2c` tool uses the MIB definition file to produce the two C code files. Thus, `mib2c` generates a template that you can edit to add logic necessary to obtain information from the operating system or application to complete the module.

The operand *mibnode* is the top level MIB node for which you want to generate code. You must give `mib2c` a MIB node (for example, `ifTable`), not a MIB file, on the command line. This distinction is a common source of user error.

The `mib2c` tool accepts both SMIv1 and SMIv2 MIBs.

`mib2c` needs to be able to find and load a MIB file in order to generate C code for the MIB. To enable `mib2c` to find the MIB file, set the `MIBS` environment variable to include the MIB file you are using. An example of setting this environment variable is:

```
MIBS=+NET-SNMP-TUTORIAL-MIB
```

or

```
MIBS=ALL
```

The first example ensures that `mib2c` finds the `NET-SNMP-TUTORIAL-MIB` MIB, in addition to the default MIB modules. The default list of MIB modules is set when the suite is first configured and built. The list corresponds to the list of modules that the agent supports. The second example ensures that `mib2c` finds all MIBs in the search location for MIB files. The default search location for MIB files is `DATADIR/snmp/mibs`. This search location can be modified by the `MIBDIRS` environment variable.

Both the MIB files to be loaded and the MIB file search location can also be configured in the `snmp.conf` file. Please see `snmp.conf(4)` for more information.

The generated `.c` and `.h` files are created in the current working directory.

Options The following options are supported:

`-h` Display a help message.

`-c` *configfile* Use *configfile* when generating code. These files are searched for first in the current directory and then in the `DATADIR` directory, which is where the default `mib2c` configuration files are located. Running `mib2c` without the `-c` *configfile* option displays a description of the valid values for *configfile*, that is, the available configuration files, including new ones that you might have created.

For example:

```
% mib2c ifTable
```

...displays the contents of the `mib2.conf` file, which displays hints on choosing the best *configfile* option for the *mibnode*.

The following values are supported for *configfile*:

```
mib2c.scalar.conf
mib2c.int_watch.conf
mib2c.iterate.conf
mib2c.create-dataset.conf
mib2c.array-user.conf
mib2c.column_defines.conf
mib2c.column_enums.conf
```

See EXAMPLES for commands you can use to generate code for scalar objects, tables, header files, and for SunOS 4.x code.

`-f` *outname* Places the output code into *outname*.c and *outname*.h. In most cases, `mib2c` places the output code into files with names that correspond to the group names for which it is generating code.

`-i` Do not run indent in the resulting code. Omitting this option results in `indent` error messages. These can safely be ignored. For example:

```
% /usr/sfw/bin/mib2c -c mib2c.scalar.conf ifTable
writing to ifTable.h
writing to ifTable.c
running indent on ifTable.h
indent: Command line: unknown parameter "-orig"
running indent on ifTable.c
indent: Command line: unknown parameter "-orig"
% ls
ifTable.c   ifTable.h
% rm i*
% /usr/sfw/bin/mib2c -c mib2c.scalar.conf -i ifTable
writing to ifTable.h
writing to ifTable.c
```

In the first invocation of `mib2c`, above, the `indent` errors are of no consequence.

`-q`	Run in "quiet" mode, which minimizes the status messages `mib2c` generates.
`-S` *var=val*	Preset a variable *var* in the `mib2c.*.conf` file to the value *val*. None of the existing `mib2c` configuration files (`mib2c.*.conf`) currently makes use of this feature. Consider this option available only for future use.

Examples

EXAMPLE 1 Generating Code for Scalar Objects

If you are writing code for some scalars, run:

```
% mib2c -c mib2c.scalar.conf mibnode
```

If you want to magically "tie" integer variables to integer scalars, use:

```
% mib2c -c mib2c.int_watch.conf mibnode
```

EXAMPLE 2 Generating Code for Tables

Consider the case where:

- You need to "iterate" over your table data to find the correct data for the SNMP row being accessed.
- Your table data is not kept within the agent (for example, it is in the kernel and not in the memory of the agent itself).

Under such conditions, use a command such as:

```
% mib2c -c mib2c.iterate.conf mibnode
```

You can find a similar example in `agent/mibgroup/mibII/vacm_context.c`.

If your table data is kept in the agent (that is, it is not located in an external source) and is purely data-driven (that is, you do not need to perform any work when a set occurs), you can use a command such as the following:

```
% mib2c -c mib2c.create-dataset.conf mibnode
```

See `agent/mibgroup/examples/data_set.c` for a similar example.

If your table data is kept in the agent (that is, it is not located in an external source) and you can keep your data sorted by the table index, but you do need to perform work when a set occurs, use a command such as the following:

```
% mib2c -c mib2c.array-user.conf mibnode
```

EXAMPLE 3 Generating Header File Definitions

To generate just a header with a define for each column number in your table, enter a command such as:

EXAMPLE 3 Generating Header File Definitions *(Continued)*

```
% mib2c -c mib2c.column_defines.conf mibnode
```

To generate only a header with a define for each enum for any column containing enums, enter:

```
% mib2c -c mib2c.column_enums.conf mibnode
```

EXAMPLE 4 Generating Code for the SunOS 4.X Line of Code

The following command generates code for SunOS 4.x:

```
% mib2c -c mib2c.old-api.conf mibnode
```

EXAMPLE 5 Generating Code for `ucdDemoPublic`

The command below generates C template code for the header and implementation files to implement `UCD-DEMO-MIB::ucdDemoPublic`.

```
% mib2c -c mib2c.scalar.conf ucdDemoPublic

writing to ucdDemoPublic.h
writing to ucdDemoPublic.c
running indent on ucdDemoPublic.h
running indent on ucdDemoPublic.c
```

The resulting `ucdDemoPublic.c` and `ucdDemoPublic.h` files are generated in the current working directory.

EXAMPLE 6 Generating Code for `tcpConnTable`

The command below generates C template code for the header and implementation files for the module to implement `TCP-MIB::tcpConnTable`.

```
% mib2c -c mib2c.iterate.conf tcpConnTable

writing to tcpConnTable.h
writing to tcpConnTable.c
running indent on tcpConnTable.h
running indent on tcpConnTable.c
```

The resulting `tcpConnTable.c` and `tcpConnTable.h` files are generated in the current working directory.

Exit Status

`0` Successful completion.

`1` A usage syntax error. A usage message is displayed.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

See Also snmpcmd(1M), snmp.conf(4), attributes(5)

Name mib2mof – generate MOF file(s) from input SNMP MIB file(s)

Synopsis

```
/usr/sadm/bin/mib2mof [-n] [-d directory] [-q] [-c] [-a]
     [-h] files
```

Description The `mib2mof` utility reads input Management Information Base (MIB) files and produces one or more Managed Object Format (MOF) files. MOF files contain a Common Information Model (CIM) class declaration that represents the MIB for the Solaris Simple Network Management Protocol (SNMP) provider. The SNMP provider allows Web-Based Enterprise Management (WBEM) applications to access SNMP device information.

SNMP scalar variables map to properties in the CIM class. Qualifiers on each property convey the following MIB information for each scalar variable:

- syntax
- read/write access
- OID (Object IDentifier)
- description (optional)
- index (if the variable is within a group [sequence] that defines a row)

The syntax of an SNMP scalar variable is represented in a CIM class by the property's CIM datatype. All properties are marked with write access (true or false).

The following table shows how a Solaris SNMP datatype in a MIB maps to a Web-Based Enterprise Management (WBEM) CIM datatype and then to an SNMP datatype used by the WBEM SNMP API:

SNMP SMI Datatype	SNMP Ver.	CIM Datatype	SNMP API Object type
INTEGER	v1	sint32	SnmpInt
OCTET STRING	v1	string	SnmpString
OBJECT IDENTIFIER	v1	string	SnmpOid
IpAddress	v1	string	SnmpIpAddress
Counter	v1	uint32	SnmpCounter
Gauge	v1	uint32	SnmpGauge
TimeTicks	v1	uint32	SnmpTimeticks
Opaque	v1	sint8[]	SnmpOpaque
DisplayString - see OCTET STRING	v1		
NetworkAddress - see IpAddress	v1		
Counter32 - see Counter	v2		
Counter64	v2	uint64	SnmpCounter64
Integer32	v2	sint32	SnmpInt
Gauge32 - see Gauge	v2		
Unsigned32	v2	uint32	SnmpGauge
TruthValue	v2	sint32	SnmpInt
BITS - see OCTET STRING	v2		

The `mib2mof` utility includes its required `Solaris_SNMPmib_core.txt` file (containing core `MIB` definitions), installed in `/usr/sadm/mof`. The `mib2mof` utility looks first for `mib` core file in local directory. If this file is not found in the local directory, `mib2mof` looks in `/usr/sadm/mof`.

A MOF file is generated for each SNMP group and table row sequence (that is, the columns in one row) found in the supplied MIBs. (This does not include the core MIB definitions contained in the `Solaris_SNMPmib_core.txt file`.)

There is no MOF file or property for an SNMP table - all table access is through the rows and columns of the table, and the SNMP variable for the table is marked as inaccessible in the MIB.

The MOF file created contains a CIM class that represents an SNMP group or row and a CIM class to represent a CIM association. The output file name (and CIM class) is of the format <SNMP_><MIB name><Group name>.mof.

Options The following options are supported:

`-a` Generate MOF files for all of the input MIB files. If `-a` is not given, a MOF file is generated only for the last file of the input list.

`-c` Do not use the default `Solaris_SNMPmib_core.txt` definitions file shipped with the Solaris SNMP Provider for WBEM. If this option is specified, you must specify another `MIB_CORE` definitions file as one of the input files.

`-d` *directory* Generate output MOF files in the specified directory.

`-h` Show how to invoke `mib2mof` and list its arguments.

`-n` Parse the input MIB files without generating any output.

`-q` Include the DESCRIPTION clause of `SNMP OBJECT-TYPE` as a qualifier in the generated MOF file.

Operands The following operands are supported:

files List of SNMP MIB files to be converted.

Exit Status The `mib2mof` utility terminates with exit status `0`.

Attributes See `attributes(5)` for descriptions of the following attributes:

Name mibiisa – Sun SNMP Agent

Synopsis

```
mibiisa [-ar] [-c config-dir] [-d debug-level] [-p port]
     [-t cache-timer]
```

Description The `mibiisa` utility is an RFC 1157-compliant SNMP agent. It supports MIB-II as defined in *RFC 1213*, with Sun extensions under Sun's enterprise number. The MIB (Management Information Base) is both readable and writable. The `mibiisa` utility supports all SNMP protocol operations including GET-REQUEST, GETNEXT-REQUEST, SET-REQUEST, GET-REPLY, and TRAP.

The SMA (Systems Management Agent) is the default SNMP agent in Solaris. MIB-II subagent `mibiisa` does not run by default. To enable `mibiisa`, rename the configuration file from `/etc/snmp/conf/mibiisa.rsrc-` to `/etc/snmp/conf/mibiisa.rsrc`. SMA has the capability to handle any MIB-II requests. See `netsnmp(5)`.

The `mibiisa` utility supports the coldStart, linkUp, linkDown, and authentication traps. The authentication trap may be disabled by a command-line switch, which itself may be overridden by a management station writing to a MIB variable in the standard SNMP MIB group.

The `mibiisa` utility supports four distinct views of the MIB. The view used for any request is determined by the community string contained in that request.

To enhance security, `mibiisa` supports an option to block all writes to the MIB. You can also limit the set of management stations from which the agent will accept requests in the configuration file used when starting the `mibiisa`. See the Security section for more information.

Unless overridden, `mibiisa` uses UDP port 161, the standard SNMP port. The `mibiisa` utility issues traps through the same port on which it receives SNMP requests.

The `mibiisa` utility must run with super-user privileges and is typically started at system startup via `/etc/rc3.d`. `mibiisa` may not be started using `inetd(1M)`. When started, `mibiisa` detaches itself from the keyboard, disables all signals except `SIGKILL`, `SIGILL`, `SIGUSR1`, and `SIGUSR2`, and places itself in the background.

Options The following options are supported by `mibiisa`:

`-a` Disable the generation of authentication traps. However, an SNMP manager may write a value into `snmpEnableAuthenTraps` to enable or disable authentication traps.

`-c` *config-dir* Specify a directory where it expects `snmpd.conf` file, on startup. The default directory is `/etc/snmp/conf`.

`-d` *debug-level* Debug. A value of 0 disables all debug and is the default. Levels 1 through 3 represent increasing levels of debug output. When `mibiisa` receives the

signal `SIGUSR1`, it resets the debug-level to 0. When `mibiisa` receives the signal `SIGUSR2`, it increments the debug-level by one.

Debug output is sent to the standard output in effect at the time `mibiisa` is started. No matter what debug level is in effect, certain significant events are logged in the system log.

`-p` *port* — Define an alternative UDP port on which `mibiisa` listens for incoming requests. The default is UDP port 161.

`-r` — Place the MIB into read-only mode.

`-t` *cache-timer* — By default, information fetched from the kernel is considered to be valid for 45 seconds from the time it is retrieved. This cache lifetime may be altered with this parameter. You cannot set *cache-timer* to any value less than 1.

Configuration File

The `snmpd.conf` file is used for configuration information. Each entry in the file consists of a keyword followed by a parameter string. The keyword must begin in the first position. Parameters are separated from the keyword and from one another by white space. Case in keywords is ignored. Each entry must be contained on a single line. All text following (and including) a pound sign (#) is ignored. Keywords currently supported are:

`sysdescr`	The value to be used to answer queries for sysDescr.
`syscontact`	The value to be used to answer queries for sysContact.
`syslocation`	The value to be used to answer queries for sysLocation.
`trap`	The parameter names one or more hosts to receive traps. Only five hosts may be listed.
`system-group-read-community`	The community name to get read access to the system group and Sun's extended system group.
`system-group-write-community`	The community name to get write access to the system group and Sun's extended system group.
`read-community`	The community name to get read access to the entire MIB.
`write-community`	The community name to get write access to the entire MIB (implies read access).
`trap-community`	The community name to be used in traps.
`kernel-file`	The name of the file to use for kernel symbols.
`managers`	The names of hosts that may send SNMP queries. Only five hosts may be listed on any one line. This keyword may be repeated for a total of 32 hosts.

`newdevice` — The additional devices which are not built in SNMPD. The format is as follows: *newdevice* `type` *speed name* where *newdevice* is the keyword, `type` is an integer which has to match your schema file, *speed* is the new device's speed, and *name* is this new device's name.

An example `snmpd.conf` file is shown below:

```
sysdescr        Sun SNMP Agent, Sun Fire 4800, Company
                   Property Number 123456
syscontact      Cliff Claven
sysLocation     Room 1515, building 1
#
system-group-read-community     public
system-group-write-community    private
#
read-community  all_public
write-community all_private
#
trap            localhost
trap-community  SNMP-trap
#
#kernel-file    /vmunix
#
managers        lvs golden
managers        swap
```

Installation The `mibiisa` utility and its configuration file, `snmpd.conf`, may be placed in any directory. However for Solaris 2.4 and subseqent releases, use `/usr/lib/snmp` for `mibiisa` itself and `/etc/snmp/conf` for the configuration file. You can modify the configuration file as appropriate. If you make any changes to `snmpd.conf` file keyword values, you must kill and restart `mibiisa` for the changes to take effect.

Your `/etc/services` file (or NIS equivalent) should contain the following entries:

```
snmp                161/udp                             # Simple Network Mgmt
                                                        Protocol
snmp-trap           162/udp             snmptrap        # SNMP trap (event)
                                                        messages
```

The following is an example for Solaris 2.*x* and releases compatible with Solaris 2.*x*, such as Solaris 9:

```
#
# Start the SNMP agent
#
```

```
if [ -f /etc/snmp/conf/snmpd.conf -a -x
   /usr/lib/snmp/mibiisa ];
then
/opt/SUNWconn/snm/agents/snmpd
echo 'Starting SNMP-agent.'
```

Security SNMP, as presently defined, offers relatively little security. The `mibiisa` utility accepts requests from other machines, which can have the effect of disabling the network capabilities of your computer. To limit the risk, the configuration file lets you specify a list of up to 32 manager stations from which `mibiisa` will accept requests. If you do not specify any such manager stations, `mibiisa` accepts requests from anywhere.

The `mibiisa` utility also allows you to mark the MIB as "read-only" by using the `-r` option.

`mibiisa` supports four different community strings. These strings, however, are visible in the configuration file and within the SNMP packets as they flow on the network.

The configuration file should be owned by, and readable only by super-user. In other words the mode should be:

```
−rw−−−−−−−−  1 root         2090 Oct 17 15:04 /etc/snmp/conf/snmpd.conf
```

Managers can be restricted based on the community strings. This can be configured by creating an optional secondary configuration file `/etc/snmp/conf/mibiisa.acl`. To enable such a restriction, add the security line in the `/etc/snmp/conf/mibiisa.rsrc` file.

An example `mibiisa.acl` file is as follows:

```
acl = {
        {
                communities = public
                access = read-only
                managers = xyz
        }
        {
                communities = private
                access = read-write
                managers = abc,pqrs
        }
}
```

An example `mibiisa.rsrc` file is as follows:

```
resource =
{
        {
                registration_file = "/etc/snmp/conf/mibiisa.reg"
                security = "/etc/snmp/conf/mibiisa.acl"
                policy = "spawn"
                type = "legacy"
```

```
                command = "/usr/lib/snmp/mibiisa -r -p $PORT"
        }
}
```

Mib This section discusses some of the differences between the `mibiisa` MIB and the standard MIB-II (as defined in RFC 1213).

The following variables are read-only in the `mibiisa` MIB:

```
sysName
atIfIndex
ipDefaultTTL
```

These variables are read-write in the standard MIB-II.

The `mibiisa` MIB Address Translation tables support limited write access: only atPhysAddress may be written, either to change the physical address of an existing entry or to delete an entire ARP table entry.

The `mibiisa` MIB IP Net to Media table supports limited write access: only ipNetToMediaPhysAddress and ipNetToMediaType may be written, either to change the physical address of an existing entry or to delete an entire ARP table entry.

The following variables are read-write in the `mibiisa` MIB; however, these variables have fixed values. Any new values "set" to them are accepted, but have no effect:

```
ipRoutIfIndex
ipRouteMetric1
ipRouteMetric2
ipRouteMetric3
ipRouteMetric4
ipRouteType
ipRouteAge
ipRouteMask
ipRouteMetric5
```

The following `mibiisa` MIB variable reflects the actual state of the related table entry. "Sets" are accepted but have no effect:

```
tcpConnState
```

The following `mibiisa` MIB variables are readable, but return a fixed value:

`icmpInDestUnreachs`	Returns 1
`icmpInTimeExcds`	Returns 1
`icmpInParmProbs`	Returns 1
`icmpInSrcQuenchs`	Returns 1

icmpInRedirects	Returns 1
icmpInEchos	Returns 1
icmpInEchoReps	Returns 1
icmpInTimestamps	Returns 1
icmpInTimestampReps	Returns 1
icmpInAddrMasks	Returns 1
icmpInAddrMaskReps	Returns 1
icmpOutDestUnreachs	Returns 1
icmpOutTimeExcds	Returns 1
icmpOutParmProbs	Returns 1
icmpOutSrcQuenchs	Returns 1
icmpOutRedirects	Returns 1
icmpOutEchos	Returns 1
icmpOutEchoReps	Returns 1
icmpOutTimestamps	Returns 1
icmpOutTimestampReps	Returns 1
icmpOutAddrMasks	Returns 1
icmpOutAddrMaskReps	Returns 1
ifInUnknownProtos	Returns 0
ipAdEntBcastAddr	Returns 1
ipAdEntReasmMaxSiz	Returns 65535
ipRouteMetric1	Returns −1
ipRouteMetric2	Returns −1
ipRouteMetric3	Returns −1
ipRouteMetric4	Returns −1
ipRouteAge	Returns 0
ipRouteMetric5	Returns −1
ipNetToMediaType	Returns (3) dynamic
ipRoutingDiscards	Returns 0

The following variables return a fixed value of `0` for drivers not conforming to the GLD framework (see `gld(7D)`), including the old LAN drivers on SPARC machines:

`ifInOctets`	Returns 0
`ifInNUcastPkts`	Returns 0
`ifInDiscards`	Returns 0
`ifOutOctets`	Returns 0
`ifOutNUcastPkts`	Returns 0
`ifOutDiscards`	Returns 0

Schema Attributes

The following describes the attributes in the group and table definitions in the `/var/snmp/mib/sun.mib` file.

system

The `system` group reports statistics about a particular system (for example, a workstation or a printer).

`sysDescr` – A textual description of the entity. This value should include the full name and version identification of the system's hardware type, software operating-system, and networking software. This value must only contain printable ASCII characters. (string[255])

`sysObjectID` – The vendor's authoritative identification of the network management subsystem contained in the entity. This value is allocated within the SMI enterprises subtree (1.3.6.1.4.1) and provides an easy and unambiguous means for determining what type of equipment is being managed. For example, if vendor “Flintstones, Inc.” was assigned the subtree 1.3.6.1.4.1.4242, it could assign the identifier 1.3.6.1.4.1.4242.1.1 to its “Fred Router.” (objectid)

`sysUpTime` – Time (in hundredths of a second) since the network management portion of the system was last reinitialized. (timeticks)

`sysContact` – The textual identification of the contact person for this managed node, together with information on how to contact this person. (string[255])

`sysName` – An administratively-assigned name for this managed node. By convention, this is the node's fully-qualified domain name. (string[255])

`sysLocation` – The physical location of this node (for example, “telephone closet, 3rd floor” (string[255]))

`sysServices` – A value indicating the set of services that this entity primarily offers. (int) The value is a sum. This sum initially takes the value zero. Then, for each layer L in the range 1 through 7 for which this node performs transactions, 2 raised to (L - 1) is added to the sum. For example, a node that performs primarily routing functions would have a value of 4

(2**(3-1)). In contrast, a node that is a host offering application services would have a value of 72 (2**(4-1) + 2**(7-1)). Note that in the context of the Internet suite of protocols, values should be calculated accordingly:

Layer	Functionality
1	physical (such as repeaters)
2	datalink/subnetwork (such as bridges)
3	internet (such as IP gateways)
4	end-to-end (such as IP hosts)
7	applications (such as mail relays)

For systems including OSI protocols, Layers 5 and 6 may also be counted.

interfaces The `interfaces` group reports the number of interfaces handled by the agent.

`ifNumber` – The number of network interfaces, regardless of their current state, present on this system. (int)

ifTable The `ifTable` is a table of interface entries. The number of entries is given by the value of ifNumber.

`ifIndex` – A unique value for each interface. Its value ranges between 1 and the value of ifNumber. The value for each interface must remain constant at least from one reinitialization of the entity's network management system to the next reinitialization. (int)

`ifDescr` – A textual string containing information about the interface. This string should include the name of the manufacturer, the product name, and the version of the hardware interface. (string[255])

`ifType` – The type of interface, distinguished according to the physical/link protocol(s) immediately below the network layer in the protocol stack. (enum)

`ifMtu` – The size of the largest datagram that can be sent/received on the interface, specified in octets. For interfaces used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface. (int)

`ifSpeed` – An estimate of the interface's current bandwidth in bits-per-second. For interfaces that do not vary in bandwidth, or for those where no accurate estimation can be made, this object should contain the nominal bandwidth. (gauge)

`if1hysAddress` – The interface's address at the protocol layer immediately below the network layer in the protocol stack. For interfaces without such an address (for example, a serial line), this object should contain an octet string of zero length. (octet[128])

`ifAdminStatus` – The desired state of the interface. The testing(3) state indicates that no operational packets can be passed. (enum)

`if OperStatus` – The current operational state of the interface. The testing(3) state indicates that no operational packets can be passed. (enum)

`ifLastChange` – The value of sysUpTime at the time the interface entered its current operational state. If the current state was entered prior to the last reinitialization of the local network management subsystem, then this object contains a zero value. (timeticks)

`ifInOctets` – The total number of octets received on the interface, including framing characters. (counter) Returns a fixed value of 0.

`ifInUcastPkts` – The number of subnetwork-unicast packets delivered to a higher-layer protocol. (counter)

`ifInNUcastPkts` – The number of non-unicast (that is, subnetwork- broadcast or subnetwork-multicast) packets delivered to a higher-layer protocol. (counter) Returns a fixed value of 0.

`ifInDiscards` – The number of inbound packets chosen to be discarded, even though no errors had been detected to prevent their being deliverable to a higher-layer protocol. One possible reason for discarding such a packet could be to free up buffer space. (counter) Returns a fixed value of 0.

`ifInErrors` – The number of inbound packets that contained errors preventing them from being deliverable to a higher-layer protocol. (counter)

`ifInUnknownProtos` – The number of packets received via the interface that were discarded because of an unknown or unsupported protocol. (counter) Returns a fixed value of 0.

`ifOutOctets` – The total number of octets transmitted out of the interface, including framing characters. (counter) Returns a fixed value of 0.

`ifOutUcastPkts` – The total number of packets that higher-level protocols requested be transmitted to a subnetwork-unicast address, including those that were discarded or not sent. (counter)

`ifOutNUcastPkts` – The total number of packets that higher-level protocols requested be transmitted to a non- unicast (that is, a subnetwork-broadcast or subnetwork-multicast) address, including those that were discarded or not sent. (counter) Returns a fixed value of 0.

`ifOutDiscards` – The number of outbound packets that were chosen to be discarded even though no errors had been detected to prevent their being transmitted. One possible reason for discarding such a packet could be to free up buffer space. (counter) Returns a fixed value of 0.

`ifOutErrors` – The number of outbound packets that could not be transmitted because of errors. (counter)

`ifOutQLen` – The length of the output packet queue (in packets). (gauge)

`ifSpecific` – A reference to MIB definitions specific to the particular media being used to realize the interface. For example, if the interface is realized by an Ethernet, then the value of this object refers to a document defining objects specific to Ethernet. If this information is not present, its value should be set to the OBJECT IDENTIFIER { 0 0 }, which is a syntactically valid object identifier. Any conformant implementation of ASN.1 and BER must be able to generate and recognize this value. (objectid)

atTable `atTable` Address Translation tables contain the NetworkAddress to physical address equivalences. Some interfaces do not use translation tables for determining address equivalences (for example, DDN-X.25 has an algorithmic method). If all interfaces are of this type, then the Address Translation table is empty, that is, has zero entries.

`atIfIndex` – The interface on which this entry's equivalence is effective. The interface identified by a particular value of this index is the same interface as identified by the same value of ifIndex. (int)

`atPhysAddress` – The media-dependent physical address. (octet[128]) Setting this object to a null string (one of zero length) has the effect of invaliding the corresponding entry in the atTable object. That is, it effectively dissociates the interface identified with said entry from the mapping identified with said entry. It is an implementation-specific matter as to whether the agent removes an invalidated entry from the table. Accordingly, management stations must be prepared to receive tabular information from agents that corresponds to entries not currently in use. Proper interpretation of such entries requires examination of the relevant atPhysAddress object.

`atNetAddress` – The NetworkAddress (that is, the IP address) corresponding to the media-dependent physical address. (netaddress)

ip The `ip` group reports statistics about the Internet Protocol (IP) group.

`ipForwarding` – The indication of whether this entity is acting as an IP gateway in respect to the forwarding of datagrams received by, but not addressed to, this entity. IP gateways forward datagrams. IP hosts do not— except those source-routed via the host. (enum)

Note that for some managed nodes, this object may take on only a subset of the values possible. Accordingly, it is appropriate for an agent to return a “badValue” response if a management station attempts to change this object to an inappropriate value.

`ipDefaultTTL` – The default value inserted into the Time-To-Live field of the IP header of datagrams originated at this entity, whenever a TTL value is not supplied by the transport layer protocol. (int)

`ipInReceives` – The total number of input datagrams received from interfaces, including those received in error. (counter)

`ipInHdrErrors` – The number of input datagrams discarded due to errors in their IP headers, including bad checksums, version number mismatch, other format errors, time-to-live exceeded, errors discovered in processing their IP options, and so on. (counter)

`ipInAddrErrors` – The number of input datagrams discarded because the IP address in their IP header's destination field was not a valid address to be received at this entity. This count includes invalid addresses (for example, 0.0.0.0) and addresses of unsupported Classes (for example, Class E). For entities that are not IP Gateways and therefore do not forward datagrams, this counter includes datagrams discarded because the destination address was not a local address. (counter)

`ipForwDatagrams` – The number of input datagrams for which this entity was not their final IP destination, as a result of which an attempt was made to find a route to forward them to that final destination. In entities that do not act as IP Gateways, this counter will include only those packets that were Source-Routed via this entity, and the Source- Route option processing was successful. (counter)

`ipInUnknownProtos` – The number of locally-addressed datagrams received successfully but discarded because of an unknown or unsupported protocol. (counter)

`ipInDiscards` – The number of input IP datagrams for which no problems were encountered to prevent their continued processing, but which were discarded, for example, for lack of buffer space. Note that this counter does not include any datagrams discarded while awaiting reassembly. (counter)

`ipInDelivers` – The total number of input datagrams successfully delivered to IP user-protocols (including ICMP). (counter)

`ipOutRequests` – The total number of IP datagrams that local IP user-protocols (including ICMP) supplied to IP in requests for transmission. Note that this counter does not include any datagrams counted in ipForwDatagrams. (counter)

`ipOutDiscards` – The number of output IP datagrams for which no problem was encountered to prevent their transmission to their destination, but which were discarded (for example, for lack of buffer space). Note that this counter would include datagrams counted in ipForwDatagrams if any such packets met this (discretionary) discard criterion. (counter)

`ipOutNoRoutes` – The number of IP datagrams discarded because no route could be found to transmit them to their destination. Note that this counter includes any packets counted in ipForwDatagrams which meet this “no-route” criterion. Note that this includes any datagrams that a host cannot route because all its default gateways are down. (counter)

`ipReasmTimeout` – The maximum number of seconds that received fragments are held while they are awaiting reassembly at this entity. (int)

`ipReasmReqds` – The number of IP fragments received that needed to be reassembled at this entity. (counter)

`ipReasmOKs` – The number of IP datagrams successfully reassembled. (counter)

`ipReasmFails` – The number of failures detected by the IP reassembly algorithm, for whatever reason: timed out, errors, and the like. Note that this is not necessarily a count of discarded IP fragments since some algorithms (notably the algorithm in RFC 815) can lose track of the number of fragments by combining them as they are received. (counter)

`ipFragOKs` – The number of IP datagrams that have been successfully fragmented at this entity. (counter)

`ipFragFails` – The number of IP datagrams that have been discarded because they needed to be fragmented at this entity but could not be, for example, because their "Don't Fragment" flag was set. (counter)

`ipFragCreates` – The number of IP datagram fragments that have been generated as a result of fragmentation at this entity. (counter)

`ipRoutingDiscards` – The number of routing entries that were chosen to be discarded even though they were valid. One possible reason for discarding such an entry could be to free-up buffer space for other routing entries. (counter) Returns a fixed value of 0.

ipAddrTable `ipAddrTable` is a table of addressing information relevant to this entity's IP addresses.

`ipAdEntAddr` – The IP address to which this entry's addressing information pertains. (netaddress)

`ipAdEntIfIndex` – The index value that uniquely identifies the interface to which this entry is applicable. The interface identified by a particular value of this index is the same interface as identified by the same value of ifIndex. (int)

`ipAdEntNetMask` – The subnet mask associated with the IP address of this entry. The value of the mask is an IP address with all the network bits set to 1, and all the hosts bits set to 0. (netaddress)

`ipAdEntBcastAddr` – The value of the least-significant bit in the IP broadcast address used for sending datagrams on the (logical) interface associated with the IP address of this entry. For example, when the Internet standard all-ones broadcast address is used, the value will be 1. This value applies to both the subnet and network broadcasts addresses used by the entity on this (logical) interface. (int) Returns a fixed value of 1.

`ipAdEntReasmMaxSize` – The size of the largest IP datagram that this entity can reassemble from incoming IP fragmented datagrams received on this interface. (int) Returns a fixed value of 65535.

ipRouteTable The `ipRouteTable` is this entity's IP Routing table.

`ipRouteDest` – The destination IP address of this route. An entry with a value of 0.0.0.0 is considered a default route. Multiple routes to a single destination can appear in the table, but

access to such multiple entries is dependent on the table- access mechanisms defined by the network management protocol in use. (netaddress)

`ipRouteIfIndex` – The index value that uniquely identifies the local interface through which the next hop of this route should be reached. The interface identified by a particular value of this index is the same interface as identified by the same value of ifIndex. (int)

`ipRouteMetric1` – The primary routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route's ipRouteProto value. If this metric is not used, its value should be set to –1. (int) Returns a fixed value of –1.

`ipRouteMetric2` – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route's ipRouteProto value. If this metric is not used, its value should be set to –1. (int) Returns a fixed value of –1.

`ipRouteMetric3` – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route's ipRouteProto value. If this metric is not used, its value should be set to –1. (int) Returns a fixed value of –1.

`ipRouteMetric4` – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route's ipRouteProto value. If this metric is not used, its value should be set to –1. (int) Returns a fixed value of –1.

`ipRouteNextHop` – The IP address of the next hop of this route. (In the case of a route bound to an interface that is realized via a broadcast media, the value of this field is the agent's IP address on that interface.) (netaddress)

`ipRouteType` – The type of route. Note that the values direct (3) and indirect (4) refer to the notion of direct and indirect routing in the IP architecture. (enum)

Setting this object to the value invalid (2) has the effect of invalidating the corresponding entry in the ipRouteTable object. That is, it effectively dissociates the destination identified with said entry from the route identified with said entry. It is an implementation-specific matter as to whether the agent removes an invalidated entry from the table. Accordingly, management stations must be prepared to receive tabular information from agents that corresponds to entries not currently in use. Proper interpretation of such entries requires examination of the relevant ipRouteType object.

`ipRouteProto` – The routing mechanism through which this route was learned. Inclusion of values for gateway routing protocols is not intended to imply that hosts should support those protocols. (enum)

`ipRouteAge` – The number of seconds since this route was last updated or otherwise determined to be correct. Note that no semantics of "too old" can be implied except through knowledge of the routing protocol by which the route was learned. (int) Returns a fixed value of 0.

`ipRouteMask` – Indicate the mask to be logical-ANDed with the destination address before being compared to the value in the ipRouteDest field. For those systems that do not support arbitrary subnet masks, an agent constructs the value of the ipRouteMask by determining whether the value of the correspondent ipRouteDest field belongs to a class-A, B, or C network, and then using one of:

Mask	Network
255.0.0.0	class-A
255.255.0.0	class-B
255.255.255.0	class-C

If the value of the ipRouteDest is 0.0.0.0 (a default route), then the mask value is also 0.0.0.0. It should be noted that all IP routing subsystems implicitly use this mechanism. (netaddress)

`ipRouteMetric5` – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route's ipRouteProto value. If this metric is not used, its value should be set to –1. (int) Returns a fixed value of –1.

`ipRouteInfo` – A reference to MIB definitions specific to the particular routing protocol responsible for this route, as determined by the value specified in the route's ipRouteProto value. If this information is not present, its value should be set to the OBJECT IDENTIFIER { 0 0 }, which is a syntactically valid object identifier. Any conformant implementation of ASN.1 and BER must be able to generate and recognize this value. (objectid)

ipNetToMediaTable

The `ipNetToMediaTable` is the IP Address Translation table used for mapping from IP addresses to physical addresses.

`ipNetToMediaIfIndex` – The interface on which this entry's equivalence is effective. The interface identified by a particular value of this index is the same interface as identified by the same value of ifIndex. (int)

`ipNetToMediaPhysAddress` – The media-dependent physical address. (octet[128])

`ipNetToMediaNetAddress` – The IpAddress corresponding to the media- dependent physical address. (netaddress)

`ipNetToMediaType` – The type of mapping. (enum) Returns a fixed value of (3)dynamic. Setting this object to the value invalid(2) has the effect of invalidating the corresponding entry in the ipNetToMediaTable. That is, it effectively dissociates the interface identified with said entry from the mapping identified with said entry. It is an implementation-specific matter as to whether the agent removes an invalidated entry from the table. Accordingly, management stations must be prepared to receive tabular information from agents that corresponds to entries not currently in use. Proper interpretation of such entries requires examination of the relevant ipNetToMediaType object.

icmp The `icmp` group reports statistics about the ICMP group.

`icmpInMsgs` – The total number of ICMP messages that the entity received. Note that this counter includes all those counted by icmpInErrors. (counter)

`icmpInErrors` – The number of ICMP messages that the entity received but determined as having ICMP-specific errors (bad ICMP checksums, bad length, and the like.). (counter)

`icmpInDestUnreachs` – The number of ICMP Destination Unreachable messages received. (counter)

`icmpInTimeExcds` – The number of ICMP Time Exceeded messages received. (counter)

`icmpInParmProbs` – The number of ICMP Parameter Problem messages received. (counter)

`icmpInSrcQuenchs` – The number of ICMP Source Quench messages received. (counter)

`icmpInRedirects` – The number of ICMP Redirect messages received. (counter)

`icmpInEchos` – The number of ICMP Echo (request) messages received. (counter)

`icmpInEchoReps` – The number of ICMP Echo Reply messages received. (counter)

`icmpInTimestamps` – The number of ICMP Timestamp (request) messages received. (counter)

`icmpInTimestampReps` – The number of ICMP Timestamp Reply messages received. (counter)

`icmpInAddrMasks` – The number of ICMP Address Mask Request messages received. (counter)

`icmpInAddrMaskReps` – The number of ICMP Address Mask Reply messages received. (counter)

`icmpOutMsgs` – The total number of ICMP messages that this entity attempted to send. Note that this counter includes all those counted by icmpOutErrors. (counter)

`icmpOutErrors` – The number of ICMP messages that this entity did not send due to problems discovered within ICMP, such as a lack of buffers. This value should not include errors discovered outside the ICMP layer, such as the inability of IP to route the resultant datagram. In some implementations there may be no types of errors that contribute to this counter's value. (counter)

`icmpOutDestUnreachs` – The number of ICMP Destination Unreachable messages sent. (counter)

`icmpOutTimeExcds` – The number of ICMP Time Exceeded messages sent. (counter)

`icmpOutParmProbs` – The number of ICMP Parameter Problem messages sent. (counter)

`icmpOutSrcQuenchs` – The number of ICMP Source Quench messages sent. (counter)

`icmpOutRedirects` – The number of ICMP Redirect messages sent. For a host, this object will always be zero, since hosts do not send redirects. (counter)

`icmpOutEchos` – The number of ICMP Echo (request) messages sent. (counter)

`icmpOutEchoReps` – The number of ICMP Echo Reply messages sent. (counter)

`icmpOutTimestamps` – The number of ICMP Timestamp (request) messages sent. (counter)

`icmpOutTimestampReps` – The number of ICMP Timestamp Reply messages sent. (counter)

`icmpOutAddrMasks` – The number of ICMP Address Mask Request messages sent. (counter)

`icmpOutAddrMaskReps` – The number of ICMP Address Mask Reply messages sent. (counter)

tcp The `tcp` group reports statistics about the TCP group.

`tcpRtoAlgorithm` – The algorithm used to determine the timeout value used for retransmitting unacknowledged octets. (enum)

`tcpRtoMin` – The minimum value permitted by a TCP implementation for the retransmission timeout, measured in milliseconds. More refined semantics for objects of this type depend upon the algorithm used to determine the retransmission timeout. In particular, when the timeout algorithm is rsre(3), an object of this type has the semantics of the LBOUND quantity described in RFC 793. (int)

`tcpRtoMax` – The maximum value permitted by a TCP implementation for the retransmission timeout, measured in milliseconds. More refined semantics for objects of this type depend upon the algorithm used to determine the retransmission timeout. In particular, when the timeout algorithm is rsre(3), an object of this type has the semantics of the UBOUND quantity described in RFC 793. (int)

`tcpMaxConn` – The limit on the total number of TCP connections that the entity can support. In entities where the maximum number of connections is dynamic, this object should contain the value –1. (int)

`tcpActiveOpens` – The number of times that TCP connections have made a direct transition to the SYN-SENT state from the CLOSED state. (counter)

`tcpPassiveOpens` – The number of times that TCP connections have made a direct transition to the SYN-RCVD state from the LISTEN state. (counter)

`tcpAttemptFails` – The number of times that TCP connections have made a direct transition to the CLOSED state from either the SYN-SENT state or the SYN-RCVD state, plus the number of times TCP connections have made a direct transition to the LISTEN state from the SYN-RCVD state. (counter)

`tcpEstabResets` – The number of times TCP connections have made a direct transition to the CLOSED state from either the ESTABLISHED state or the CLOSE-WAIT state. (counter)

`tcpCurrEstab` – The number of TCP connections for which the current state is either ESTABLISHED or CLOSE-WAIT. (gauge)

`tcpInSegs` – The total number of segments received, including those received in error. This count includes segments received on currently established connections. (counter)

`tcpOutSegs` – The total number of segments sent, including those on current connections but excluding those containing only retransmitted octets. (counter)

`tcpRetransSegs` – The total number of segments retransmitted - that is, the number of TCP segments transmitted containing one or more previously transmitted octets. (counter)

`tcpInErrs` – The total number of segments received in error (for example, bad TCP checksums). (counter)

`tcpOutRsts` – The number of TCP segments sent containing the RST flag. (counter)

tcpConnTable The `tcpConnTable` is a table containing TCP connection-specific information.

`tcpConnState` – The state of this TCP connection. (enum)

The only value that may be set by a management station is deleteTCB(12). Accordingly, it is appropriate for an agent to return a "badValue" response if a management station attempts to set this object to any other value.

If a management station sets this object to the value deleteTCB(12), then this has the effect of deleting the TCB (as defined in RFC 793) of the corresponding connection on the managed node. This results in immediate termination of the connection.

As an implementation-specific option, an RST segment may be sent from the managed node to the other TCP endpoint. (Note, however, that RST segments are not sent reliably.)

`tcpConnLocalAddress` – The local IP address for this TCP connection. For a connection in the listen state that is willing to accept connections for any IP interface associated with the node, the value 0.0.0.0 is used. (netaddress)

`tcpConnLocalPort` – The local port number for this TCP connection. (int)

`tcpConnRemAddress` – The remote IP address for this TCP connection. (netaddress)

`tcpConnRemPort` – The remote port number for this TCP connection. (int)

upd The `udp` group reports statistics about the UDP group.

`udpInDatagrams` – The total number of UDP datagrams delivered to UDP users. (counter) Returns a fixed value of 0.

`udpNoPorts` – The total number of received UDP datagrams for which there was no application at the destination port. (counter) Returns a fixed value of 0.

`udpInErrors` – The number of received UDP datagrams that could not be delivered for reasons other than the lack of an application at the destination port. (counter)

`udpOutDatagrams` – The total number of UDP datagrams sent from this entity. (counter) Returns a fixed value of 0.

udpTable The `udpTable` is a table containing UDP listener information.

`udpLocalAddress` – The local IP address for this UDP listener. For a UDP listener that is willing to accept datagrams for any IP interface associated with the node, the value 0.0.0.0 is used. (netaddress)

`udpLocalPort` – The local port number for this UDP listener. (int)

snmp The `snmp` group reports statistics about the SNMP group.

`snmpInPkts` – The total number of Messages delivered to the SNMP entity from the transport service. (counter)

`snmpOutPkts` – The total number of SNMP Messages passed from the SNMP protocol entity to the transport service. (counter)

`snmpInBadVersions` – The total number of SNMP Messages delivered to the SNMP protocol entity that were for an unsupported SNMP version. (counter)

`snmpInBadCommunityNames` – The total number of SNMP Messages delivered to the SNMP protocol entity that used a SNMP community name not known to said entity. (counter)

`snmpInBadCommunityUses` – The total number of SNMP Messages delivered to the SNMP protocol entity, which represented an SNMP operation not allowed by the SNMP community named in the Message. (counter)

`snmpInASNParseErrs` – The total number of ASN.1 or BER errors encountered by the SNMP protocol entity when decoding received SNMP Messages. (counter)

`snmpInTooBigs` – The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “tooBig.” (counter)

`snmpInNoSuchNames` – The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “noSuchName.” (counter)

`snmpInBadValues` – The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “badValue.” (counter)

`snmpInReadOnlys` – The total number valid SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is "readOnly." It should be noted that it is a protocol error to generate an SNMP PDU that contains the value "readOnly" in the error-status field. This object is provided as a means of detecting incorrect implementations of the SNMP. (counter)

`snmpInGenErrs` – The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is "genErr." (counter)

`snmpInTotalReqVars` – The total number of MIB objects successfully retrieved by the SNMP protocol entity as the result of receiving valid SNMP Get-Request and Get-Next PDUs. (counter)

`snmpInTotalSetVars` – The total number of MIB objects successfully altered by the SNMP protocol entity as the result of receiving valid SNMP Set-Request PDUs. (counter)

`snmpInGetRequests` – The total number of SNMP Get-Request PDUs accepted and processed by the SNMP protocol entity. (counter)

`snmpInGetNexts` – The total number of SNMP Get-Next PDUs accepted and processed by the SNMP protocol entity. (counter)

`snmpInSetRequests` – The total number of SNMP Set-Request PDUs accepted and processed by the SNMP protocol entity. (counter)

`snmpInGetResponses` – The total number of SNMP Get-Response PDUs accepted and processed by the SNMP protocol entity. (counter)

`snmpInTraps` – The total number of SNMP Trap PDUs accepted and processed by the SNMP protocol entity. (counter)

`snmpOutTooBigs` – The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status field is "tooBig." (counter)

`snmpOutNoSuchNames` – The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status is "noSuchName." (counter)

`snmpOutBadValues` – The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status field is "badValue." (counter)

`snmpOutGenErrs` – The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status field is "genErr." (counter)

`snmpOutGetRequests` – The total number of SNMP Get-Request PDUs which have been generated by the SNMP protocol entity. (counter)

`snmpOutGetNexts` – The total number of SNMP Get-Next PDUs generated by the SNMP protocol entity. (counter)

`snmpOutSetRequests` – The total number of SNMP Set-Request PDUs generated by the SNMP protocol entity. (counter)

`snmpOutGetResponses` – The total number of SNMP Get-Response PDUs generated by the SNMP protocol entity. (counter)

`snmpOutTraps` – The total number of SNMP Trap PDUs generated by the SNMP protocol entity. (counter)

`snmpEnableAuthenTraps` – Indicates whether the SNMP agent process is permitted to generate authentication-failure traps. The value of this object overrides any configuration information. As such, it provides a means whereby all authentication-failure traps may be disabled. (enum)

Note that this object must be stored in non-volatile memory, so that it remains constant between reinitializations of the network management system.

The following are Sun-specific group and table definitions.

sunSystem The `sunSystem` group reports general system information.

`agentDescr` – The SNMP agent's description of itself. (string[255])

`hostID` – The unique Sun hardware identifier. The value returned is four byte binary string. (octet[4])

`motd` – The first line of `/etc/motd`. (string[255])

`unixTime` – The UNIX system time. Measured in seconds since January 1, 1970 GMT. (counter)

sunProcessTable The `sunProcessTable` table reports UNIX process table information.

`psProcessID` – The process identifier for this process. (int)

`psParentProcessID` – The process identifier of this process's parent. (int)

`psProcessSize` – The combined size of the data and stack segments (in kilobytes.) (int)

`psProcessCpuTime` – The CPU time (including both user and system time) consumed so far. (int)

`psProcessState` – The run-state of the process. (octet[4])

R	Runnable
T	Stopped
P	In page wait

D	Non-interruptable wait
S	Sleeping (less than 20 seconds)
I	Idle (more than 20 seconds)
Z	Zombie

`psProcessWaitChannel` – Reason process is waiting. (octet[16])

`psProcessTTY` – Terminal, if any, controlling this process. (octet[16])

`psProcessUserName` – Name of the user associated with this process. (octet[16])

`psProcessUserID` – Numeric form of the name of the user associated with this process. (int)

`psProcessName` – Command name used to invoke this process. (octet[64])

`psProcessStatus` – Setting this variable will cause a signal of the set value to be sent to the process. (int)

sunHostPerf The `sunHostPerf` group reports hostperf information.

`rsUserProcessTime` – Total number of timeticks used by user processes since the last system boot. (counter)

`rsNiceModeTime` – Total number of timeticks used by "nice" mode since the last system boot. (counter)

`rsSystemProcessTime` – Total number of timeticks used by system processes since the last system boot. (counter)

`rsIdleModeTime` – Total number of timeticks in idle mode since the last system boot. (counter)

`rsDiskXfer1` – Total number of disk transfers since the last boot for the first of four configured disks. (counter)

`rsDiskXfer2` – Total number of disk transfers since the last boot for the second of four configured disks. (counter)

`rsDiskXfer3` – Total number of disk transfers since the last boot for the third of four configured disks. (counter)

`rsDiskXfer4` – Total number of disk transfers since the last boot for the fourth of four configured disks. (counter)

`rsVPagesIn` – Number of pages read in from disk. (counter)

`rsVPagesOut` – Number of pages written to disk. (counter)

`rsVSwapIn` – Number of pages swapped in. (counter)

`rsVSwapOut` – Number of pages swapped out. (counter)

`rsVIntr` – Number of device interrupts. (counter)

`rsIfInPackets` – Number of input packets. (counter)

`rsIfOutPackets` – Number of output packets. (counter)

`rsIfInErrors` – Number of input errors. (counter)

`rsIfOutErrors` – Number of output errors. (counter)

`rsIfCollisions` – Number of output collisions. (counter)

Files

`/etc/snmp/conf/snmpd.conf`	configuration information
`/etc/snmp/conf/mibiisa.acl`	access control file
`/var/snmp/mib/sun.mib`	standard SNMP MIBII file

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmibii
Interface Stability	Obsolete

See Also `inetd(1M)`, `select(3C)`, `recvfrom(3SOCKET)`, `sendto(3SOCKET)`, `attributes(5)`, `gld(7D)`,

Diagnostics

`cannot dispatch request`	The proxy cannot dispatch the request. The rest of the message indicates the cause of the failure.
`select(3C) failed`	A `select(3C)` call failed. The rest of the message indicates the cause of the failure.
`sendto(3SOCKET) failed`	A `sendto(3SOCKET)` call failed. The rest of the message indicates the cause of the failure.
`recvfrom(3SOCKET) failed`	A `recvfrom(3SOCKET)` call failed. The rest of the message indicates the cause of the failure.

`no response from system`	The SNMP agent on the target system does not respond to SNMP requests. This error might indicate that the SNMP agent is not running on the target system, the target system is down, or the network containing the target system is unreachable.
`response too big`	The agent could not fit the results of an operation into a single SNMP message. Split large groups or tables into smaller entities.
`missing attribute`	An attribute is missing from the requested group.
`bad attribute type`	An object attribute type received from the SNMP agent that does not match the attribute type specified by the proxy agent schema. The rest of the message indicates the expected type and received type.
`cannot get sysUpTime`	The proxy agent cannot get the variable *sysUpTime* from the SNMP agent.
`sysUpTime type bad`	The variable *sysUpTime* received from the SNMP agent has the wrong data type.
`unknown SNMP error`	An unknown SNMP error was received.
`bad variable value`	The requested specified an incorrect syntax or value for a set operation.
`variable is read only`	The SNMP agent did not perform the set request because a variable to set may not be written.
`general error`	A general error was received.
`cannot make request PDU`	An error occurred building a request PDU.
`cannot make request varbind list`	An error occurred building a request variable binding list.

`cannot parse response PDU`	An error occurred parsing a response PDU.
`request ID - response ID mismatch`	The response ID does not match the request ID.
`string contains non-displayable characters`	A displayable string contains non-displayable characters.
`cannot open schema file`	An error occurred opening the proxy agent schema file.
`cannot parse schema file`	The proxy agent couldn't parse the proxy agent schema file.
`cannot open host file`	An error occurred opening the file associated with the *na.snmp.hostfile* keyword in `/etc/snmp/conf/snmpd.conf`
`cannot parse host file`	The proxy agent was unable to parse the file associated with the *na.snmp.hostfile* keyword in `/etc/snmp/conf/snm.conf`.
`attribute unavailable for set operations`	The set could not be completed because the attribute was not available for set operations.

Bugs The `mibiisa` utility returns the wrong interface speed for the SBUS FDDI interface (for example, “bf0”).

The `mibiisa` utility does not return a MAC address for the SBUS FDDI interface (for example, “bf0”).

Process names retrieved from `mibiisa` contain a leading blank space.

When you change attribute values in the system group with an SNMP set request, the change is effective only as long as `mibiisa` is running. `mibiisa` does not save the changes to `/etc/snmp/conf/snmpd.conf`.

Name mipagent – Mobile IP agent

Synopsis

```
/usr/lib/inet/mipagent
```

Description The `mipagent` utility implements the Mobile IP home agent and foreign agent functionality described in *RFC 2002, IP Mobility Support*. The term "mobility agent" is used to refer to the home agent and foreign agent functionality collectively. `mipagent` responds to Mobile IP registration and deregistration requests and router discovery solicitation messages from a mobile node. Besides responding to external messages, the `mipagent` utility also tasks on a periodic basis, such as aging the mobility bindings and visitor entries and sending agent advertisements. The mobility agent can also handle direct delivery style reverse tunneling as specified in *RFC 2344, Reverse Tunneling for Mobile IP*. Limited private address support for mobile nodes is also available. In addition, separate IPsec policies for registration requests, replies, and tunnel traffic can be configured to protect the datagrams associated with these between two mobility agents.

Run the `mipagent` daemon as root using the start-up script, which has the following syntax:

```
example# /etc/init.d/mipagent [start|stop]
```

`/etc/inet/mipagent.conf` must be present before you start-up the `mipagent` daemon. See `mipagent.conf(4)`. At start up, `mipagent` reads the configuration information from `/etc/inet/mipagent.conf`. The `mipagent` daemon records a continuous log of its activities by means of `syslog()`. See `syslog(3C)`. You can use the *LogVerbosity* parameter in `/etc/inet/mipagent.conf` to control the verbosity level of the log.

The `mipagent` daemon can be terminated either by the script:

```
example# /etc/init.d/mipagent stop
```

or by the `kill` command.

Periodically while running, or if terminated or shutdown, the `mipagent` daemon stores the following internal state information in `/var/inet/mipagent_state`:

- a list of the mobile nodes supported as home agents;
- their current care-of addresses; and
- the remaining registration lifetimes.

If the `mipagent` utility is terminated for maintenance and restarted, `mipagent_state` is used to recreate as much of the mobility agent's internal state as possible. This minimizes service disruption for mobile nodes that may be visiting other networks. If `mipagent_state` exists, it is read immediately after `mipagent.conf` when `mipagent` is restarted. The format of `mipagent_state` is undocumented since it is likely to change and programs other than `mipagent` should not use it for any purpose. A separate utility program `mipagentstat` is provided for monitoring `mipagent`.

Exit Status The following exit values are returned:

`0` The daemon started successfully.

`-1` The daemon failed to start.

Files

`/etc/inet/mipagent.conf`	Configuration file for Mobile IP mobility agent.
`/var/inet/mipagent_state`	File where private state information from `mipagent` is stored.
`/etc/init.d/mipagent [start|stop]`	`mipagent` start-up script.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmipu

See Also `mipagentstat(1M)`, `mipagentconfig(1M)`, `syslog(3C)`, `mipagent.conf(4)`, `attributes(5)`

Montenegro, G., editor.*RFC 2344, Reverse Tunneling for Mobile IP*. Network Working Group. May 1998.

Perkins, C. *RFC 2002, IP Mobility Support*. Network Working Group. October 1996.

Diagnostics The `mipagent` utility exits with an error if the configuration file, `mipagent.conf`, cannot be read successfully. Upon receiving a `SIGTERM` or `SIGINT` signal, `mipagent` cleans its internal state, including any changes to the routing and ARP tables, and exits.

Notes The foreign agent adds host– specific local routes to its routing table for visiting mobile nodes after they are successfully registered. If a visiting mobile node departs without sending a de-registration message through the foreign agent, these routing entries persist until the mobile node's previous registration expires. Any packets that arrive at the foreign agent for the departed mobile node during this time, for example because the foreign agent is also a router for the foreign network, will be lost. System administrators can configure foreign agents to accept only short registration lifetimes. This will automatically restrict the maximum duration for which a departed mobile node will be temporarily unreachable.

Home and foreign agents dynamically add and delete IPsec policies configured with a mobility agent peer. Those pertaining to the tunnel are only added when the tunnel is plumbed. At this time, IPsec tunnel policies must be identical in the forward and reverse direction. IPsec policies pertaining to permiting registration requests on the home agent are added to the IPsec policy file at init time as it must be ready to receive these at any time. Otherwise, IPsec policies pertaining to registration request and reply messages with a mobility agent peer are added as soon as they are needed, and are not removed until all mobile nodes are no longer registered with the mobility agent peer, at which point the tunnels are torn down.

Name mipagentconfig – configure Mobility IP Agent

Synopsis

```
/sbin/mipagentconfig [-f configfile] command dest
     [parameters]...
```

Description The `mipagentconfig` utility is used to configure the Mobility IP Agent. `mipagentconfig` allows the user to change settings. The mipagentconfig user can also add and delete mobility clients, Pools, and SPIs in the mobility agent configuration file.

Options The following options are supported:

`-f` *configfile* Use the specified configuration file instead of the system default, `/etc/inet/mipagent.conf`.

Operands The *command* operand, as well as the parameters for each command are described below. See `mipagent.conf(4)` for the default values of the configuration operands that are described here.

`add` This command adds advertisement parameters, security parameters, SPIs, or addresses to the configuration file, based on the destination *dest*.

`add Address` *ipAddress attr_value*
Add the specified *ipAddress* with the specified `SPI`. To add an NAI address, you must specify the `Pool`.

`add adv` *device*
Enable home and foreign agent functionality on the specified interface.

`add adv` *device* `AdvLifetime` *seconds*
Add `AdvLifetime` to the specified device.

`add adv` *device* `RegLifetime` *seconds*
Add `RegLifetime` to the specified device.

`add adv` *device* `AdvFrequency` *seconds*
Add `AdvFrequency` to the specified device.

`add adv` *device* `AdvInitCount` *count*
Add initial unsolicited advertisement count. *count* should be a small integer.

`add adv` *device* `AdvLimitUnsolicited yes | no`
Enable limited or unlimited unsolicited advertisements for foreign agent. Accepted values are:

`yes` Limit unsolicited advertisement to `AdvInitCount` initial advertisements.

`no` Do not limit unsolicited advertisement. The advertisement should take place periodically at the frquency specified by `AdvFrequency`.

`add adv` *device* `HomeAgent yes | no`
Add the `HomeAgent` flag to the specified device.

`add adv` *device* `ForeignAgent yes` | `no`
Add the `ForeignAgent` flag to the specified device.

`add adv` *device* `PrefixLengthExt yes` | `no`
Add the `PrefixLengthExt` flag to the specified device.

`add adv` *device* `NAIExt yes` | `no`
Add the `NAIExt` flag to the specified device.

`add adv` *device* `Challenge yes` | `no`
Add the `Challenge` flag to the specified device.

`add adv` *device* `ReverseTunnel no` | `neither fa ha yes` | `both`
Add the level of `ReverseTunnel` support that is indicated to the specified device. Possible values include:

`no` Do not support `ReverseTunnel` as either a foreign agent or a home agent on this device. Does not advertise reverse tunneling nor accept a registration requesting reverse tunnel support on this device.

`neither` Do not support `ReverseTunnel` as either a foreign agent or a home agent on this device. Do not advertise reverse tunneling or accept a registration that requests reverse tunnel support on this device.

`fa` When the foreign agent processes a registration request received on this device, check to see if the mobile node requests that a reverse tunnel be set up to its home agent. If so, perform the necessary encapsulation of datagrams to the mobile node's home agent as described in *RFC 3024*. This means that a mobile node must see the agent advertising reverse tunnel support, so the reverse tunnel bit is advertised in the agent advertisement on this device.

`ha` When the home agent processes a registration request received on this device, check to see if the mobile node requests that a reverse tunnel be set up from its care-of address. If so, perform the necessary decapsulation as described in *RFC 3024*. This does not mean the home agent is advertising support of reverse tunneling on this device. Mobile nodes are only interested in the advertisement flags if mobile nodes are going to use foreign agent services. Moreover, reverse tunnels by definition originate at the care-of address. HA support is therefore only of interest to the owner of the care-of address.

`yes` Whenever the mobility agent is processing a registration request received on this device, check to see if the mobile node is

requesting that a reverse tunnel be set up. If so, apply *RFC 3024* as appropriate, either as an encapsulating foreign agent, or as a decapsulating home agent, depending on how this mobility agent is servicing the specific mobile node. As a result, the mobility agent advertises reverse tunnel support on this device.

`both` Whenever the mobility agent is processing a registration request received on this device, check to see if the mobile node is requesting that a reverse tunnel be set up. If so, apply *RFC 3024* as appropriate, either as an encapsulating foreign agent, or a decapsulating home agent, depending on how this mobility agent services the specific mobile node. As a result, the mobility agent advertises reverse tunnel support on this device.

`add adv` *device* `ReverseTunnelRequired no` | `neither fa ha yes` | `both yes` | `both`
Add the requirement that the `ReverseTunnel` flag be set in any registration request received on the indicated device. Possible values include:

`no` Reverse tunneling is not required by the `mipagent` on this device.

`neither` Reverse tunneling is not required by the `mipagent` on this device.

`fa` The `ReverseTunnel` flag is required to be set in registration requests received by the foreign agent on this device.

`ha` The `ReverseTunnel` flag is required to be set in registration requests received by the home agent on this device.

`yes` The `ReverseTunnel` flag is required to be set in all registration requests received by either home and or foreign agents on this device.

`both` The `ReverseTunnel` flag is required to be set in all registration requests received by either home and or foreign agents on this device.

`add Pool` *number startAddr length*
Add the specified `Pool` with the specified start addresses and length.

`add SPI` *number replay Key*
Add the specified `SPI` with the given replay type and key. The replay type can have a value of `none` or `timestamps`.

`add HA-FAAuth yes` | `no`
Add the `HA-FAAuth` flag.

`add MN-FAAuth yes` | `no`
Add the `MN-FAAuth` flag.

`add MaxClockSkew` *seconds*
Add the `MaxClockSkew`.

`add KeyDistribution` *type*
Add the `KeyDistribution` type. The only value for `KeyDistribution` that is supported at this time is `file`.

`change` Depending on the destination *dest*, this command will change advertisement parameters, security parameters, SPIs, or addresses in the configuration file. Any of the above destinations are valid.

`delete` Depending on the destination *dest*, this command will delete advertisement parameters, security parameters, SPIs, or addresses from the configuration file. Any destination discussed above is valid.

`get` Display all of the parameters associated with *dest*. Any destination discussed above is valid.

Examples

EXAMPLE 1 Adding an SPI, a Pool, and a Mobile Node and Requiring Reverse Tunneling on a Device to the *configfile*

The following example adds an SPI, a `Pool`, a `mobile node`, and requires reverse tunneling for the foreign agent in the *configfile*. First, the SPI of 250 is added. Then, a Pool of 200 addresses starting at `192.168.168.1` is added. `joe@mobile.com` is added with an SPI of 250 and using Pool 1. Finally, reverse tunneling is required for the foreign agent on device `eri0`.

```
example# mipagentconfig add SPI 250 ReplayMethod none
example# mipagentconfig add SPI 250 Key 00ff00ff00ff
example# mipagentconfig add Pool 1 192.168.168.1 200
example# mipagentconfig add Address joe@mobile.com 250 1
example# mipagentconfig add adv eri0 reversetunnel fa
example# mipagentconfig add adv eri0 reversetunnelrequired fa
```

EXAMPLE 2 Adding Dynamic Interface Mobility Support on PPP Interfaces

The following example adds dynamic interface mobility support on PPP interfaces. Note that in some shells the backslash (\) escape character is required to bypass the expansion of the asterix ("*") and pass the "*" character to `mipagentconfig`. The example also indicates that all the new PPP interfaces offer reverse tunnel service.

```
example# mipagentconfig add adv sppp\* reversetunnel yes
example# mipagentconfig add adv sppp\* AdvLimitUnsolicited yes
example# mipagentconfig add adv sppp\* AdvInitCount 3
example# mipagentconfig add adv sppp\* AdvFrequency 1
```

EXAMPLE 3 Adding IPsec Policies to an Agent-Peer Entry

The following example adds IPsec policies to an existing mobility agent entry, then displays the configuration for the mobility agent peer. The backslash (\) character denotes a line continuation for the formatting of this example.

EXAMPLE 3 Adding IPsec Policies to an Agent-Peer Entry *(Continued)*

```
example# mipagentconfig add Address 192.168.10.1 \
           IPsecRequest apply {auth_algs md5 sa shared}
example# mipagentconfig add Address 192.168.10.1 \
           IPsecReply permit {auth_algs md5}
example# mipagentconfig add Address 192.168.10.1 \
           IPsecTunnel permit {encr_auth_algs md5 encr_algs 3des}
example# mipagentconfig get Address 192.168.10.1

[Address 192.168.10.1]
     Type = agent
     SPI = 137
     IPsecRequest = apply {auth_algs md5 sa shared}
     IPsecReply = permit {auth_algs md5}
     IPsecTunnel = \
     permit {encr_auth_algs md5 encr_algs 3des}
```

EXAMPLE 4 Modifying an SPI

To modify the SPI associated with joe, first, use the command `get` to verify the existing settings, then change the SPI from 250 to 257.

```
example# mipagentconfig get Address joe@mobile.com
Address: joe@mobile.com
SPI:  250
Pool: 1
example# mipagentconfig change Address joe@mobile.com 257 1
```

EXAMPLE 5 Deleting a Pool

Use the following example to delete Pool 3:

```
example# mipagentconfig delete Pool 3
```

EXAMPLE 6 Using the `mipagentconfig` command

Use the following example to delete Pool 3:

```
example# mipagentconfig delete Pool 3
```

Exit Status

The following exit values are returned:

`0`	Successful completion
`non-zero`	An error occurred

Files

`/etc/inet/mipagent.conf`	Configuration file for Mobile IP mobility agent
`/etc/inet/mipagent.conf-sample`	Sample configuration file for mobility agents

`/etc/inet/mipagent.conf.ha-sample`	Sample configuration file for home agent functionality.
`/etc/inet/mipagent.conf.fa-sample`	Sample configuration file for foreign agent functionality.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmipu

See Also `mipagent(1M)`, `mipagent.conf(4)`, `attributes(5)`

Montenegro, G., editor. *RFC 3024, Reverse Tunneling for Mobile IP, revised*. The Internet Society. January, 2001.

Perkins, C. *RFC 2002, IP Mobility Support*. Network Working Group. October 1996.

Name mipagentstat – show Mobile IP Mobility Agent status

Synopsis

```
mipagentstat [-fhp]
```

Description Use the `mipagentstat` utility to display the content of various Mobile-IP related data structures.

Visitor Table (First Form)

The visitor table display lists information for all mobile nodes registered with the foreign agent, one mobile node per line. This list consists of the mobile node's home address or Network Access Identifier (NAI), home agent address, total registration lifetime and the number of seconds remaining before the registration expires.

The following command line shows the output from a foreign agent with two mobile nodes registered:

```
example# mipagentstat -f

Mobile Node     Foreign Agent  Time Granted    Time Remaining     Flags
                               (in secs)       (in secs)
foobar@xyz.com  fa1@tuv.com    600             125
10.1.5.23       123.2.5.12     1000            10                 R
```

An "R" in the flags column indicates a reverse tunnel is present. No reverse tunnel is configured for the mobile node `foobar@xyz.com`. A reverse tunnel is configured from mobile node `10.1.5.23`.

Binding Table (Second Form)

The binding table display lists information for all mobile nodes registered with the home agent, one mobile node per line. This list consists of the mobile node's home address or NAI, foreign agent address, total registration lifetime and the number of seconds remaining before the registration expires.

Use the following command line to show the output from a home agent with two active mobile nodes:

```
example# mipagentstat -h

Mobile Node     Home Agent     Time Granted    Time Remaining     Flags
                               (in secs)       (in secs)
foobar@xyz.com  ha1@xyz.com    600             125
10.1.5.23       10.1.5.1       1000            10                 R
```

An "R" in the flags column indicates a reverse tunnel is present. No reverse tunnel is configured for the mobile node `foobar@xyz.com`. A reverse tunnel is configured for mobile node `10.1.5.23`.

Agent Table (Third Form)

The agent table display lists information for all current mobility agent-peers, that is all mobility agents with which mobile-nodes we are servicing are trying to obtain service.

Provided in this display are the IPsec protection mechanisms being used with registration requests, replies, and tunnels.

Use the following command line to show the output from a home agent with two (foreign) mobility agent peers:

```
example# mipagentstat -hp

Foreign                   ..... Security Association(s).....
Agent                     Requests Replies  FTunnel  RTunnel
-----------------------   -------- -------- -------- --------
fa.eng.example.com        AH,ESP   AH,ESP   AH,ESP   AH,ESP
fa.central.example.com    AH       AH       ESP      ESP
```

Use the following command line to show the output from a home agent with two (foreign) mobility agent peers:

```
example# mipagentstat -fp

Home                      ..... Security Association(s) .....
Agent                     Requests Replies  FTunnel  RTunnel
-----------------------   -------- -------- -------- --------
ha.eng.example.com        AH,ESP   AH,ESP   AH,ESP   AH,ESP
ha.central.example.com
```

Use of the `-p` option without specifying the agent results in both displays described above, that is one display for each agent.

An `AH` in any column indicates the IPsec `AH` mechanism is in place for those datagrams.

An `ESP` in any column indicates the IPsec `ESP` mechanism is in place for those datagrams.

Options The following options are supported:

`-f` Display the list of active mobile nodes in the foreign agent's visitor's list.

`-h` Display the list of active mobile nodes in the home agent's binding table.

`-p` Display the list of mobility agent peers, and the IPsec protection mechanisms currently in use for registration and tunnel traffic.

Exit Status The following exit values are returned:

`0` Successful completion.

`non-zero` An error occurred.

Aboda, B., and Beadles, M. *RFC 2486, The Network Access Identifier*. The Internet Society, 1999.

Name mkbootmedia – create bootable Solaris ISO image

Synopsis

```
/usr/bin/mkbootmedia -v [-l label] media-root iso
```

Description The `mkbootmedia` utility takes *media-root* (the root of an on-disk Solaris install media) as input and creates a bootable Solaris ISO image in the file *iso*, using `mkisofs(8)`. The file can then be burned onto a CD/DVD with utilities such as `cdrw(1)` or `cdrecord(1)`. (Neither `mkisofs(8)` nor `cdrecord(1)` are SunOS man pages.)

Caution – The directory tree *media-root* must contain the file `boot/grub/stage2_eltorito`, which will be written to the media boot sectors. This file will be modified with some boot information, thus it must be writable. If necessary, first save a copy prior to running this utility.

Options The following options are supported:

`-l` *label*
Sets *label* as the label/volume name of the ISO image.

`-v`
Verbose. Multiple `-v` options increase verbosity.

Operands The following operands are supported:

media-root
Top-level directory of an on-disk Solaris install media.

iso
Name of the output file which will contain the resulting ISO image.

Examples **EXAMPLE 1** Creating an ISO Image and Burning a CD/DVD

The following commands create an ISO image from the content of `s10u1` and burn the image to a CD/DVD.

```
# /usr/bin/mkbootmedia s10u1 s10u1.iso
# /usr/bin/cdrw -i s10u1.iso
```

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

`mkisofs(8)`, (`/usr/share/man/man8/mkisofs.8`), in the `SUNWfsman` package (not a SunOS man page)

Name mkdevalloc – Make device_allocate entries

Synopsis

```
/usr/sbin/mkdevalloc
```

Description The `mkdevalloc` command writes to standard out a set of `device_allocate(4)` entries describing the system's frame buffer, audio and removable media devices.

The `mkdevalloc` command is used by the `init.d(4)` scripts to create or update the `/etc/security/device_allocate` file.

Entries are generated based on the device special files found in `/dev`. For the different categories of devices, the `mkdevalloc` command checks for the following files under `/dev`:

```
audio           /dev/audio, /dev/audioctl, /dev/sound/...
tape            /dev/rst*, /dev/nrst*, /dev/rmt/...
floppy          /dev/diskette, /dev/fd*, /dev/rdiskette, /dev/rfd*
removable disk  /dev/sr*, /dev/nsr*, /dev/dsk/c0t?d0s?, /dev/rdsk/c0t?d0s?
frame buffer    /dev/fb
```

All entries set the *device-minimum* and *device-maximum* fields to the hex representations of `ADMIN_LOW` and `ADMIN_HIGH`, respectively. The *device-authorization* field is set to `solaris.device.allocate`, except for the `framebuffer` entry, where it is set to `*`. The *device-name*, *device-type* and *device-clean* fields are set to the following values:

```
                device-name      device-type   device-clean

audio           audio            audio         audio_clean_wrapper
tape            mag_tape_0,1,... st            st_clean
floppy          floppy_0,1,...   fd            disk_clean
removable disk  cdrom_0,1,...    sr            disk_clean
frame buffer    framebuffer      fb            /bin/true
```

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Obsolete

See Also `allocate(1)`, `bsmconv(1M)`, `attributes(5)`

Notes `mkdevalloc` might not be supported in a future release of the Solaris operating system.

Name mkdevmaps – make device_maps entries

Synopsis

```
/usr/sbin/mkdevmaps
```

Description The `mkdevmaps` command writes to standard out a set of `device_maps(4)` entries describing the system's frame buffer, audio, and removable media devices.

The `mkdevmaps` command is used by the `init.d(4)` scripts to create or update the `/etc/security/device_maps` file.

Entries are generated based on the device special files found in `/dev`. For the different categories of devices, the `mkdevmaps` command checks for the following files under `/dev`:

```
audio           /dev/audio, /dev/audioctl, /dev/sound/...
tape            /dev/rst*, /dev/nrst*, /dev/rmt/...
floppy          /dev/diskette, /dev/fd*, /dev/rdiskette, /dev/rfd*
removable disk  /dev/dsk/c0t?d0s?, /dev/rdsk/c0t?d0s?
frame buffer    /dev/fb
```

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Obsolete

See Also `allocate(1)`, `bsmconv(1M)`, `attributes(5)`

Notes `mkdevmaps` might not be supported in a future release of the Solaris operating system.

Name mkfifo – make FIFO special file

Synopsis

```
/usr/bin/mkfifo [-m mode] path...
```

Description The `mkfifo` utility creates the FIFO special files named by its argument list. The arguments are taken sequentially, in the order specified; and each FIFO special file is either created completely or, in the case of an error or signal, not created at all.

If errors are encountered in creating one of the special files, `mkfifo` writes a diagnostic message to the standard error and continues with the remaining arguments, if any.

The `mkfifo` utility calls the library routine `mkfifo(3C)`, with the *path* argument is passed as the *path* argument from the command line, and *mode* is set to the equivalent of `a=rw`, modified by the current value of the file mode creation mask `umask(1)`.

Options The following option is supported:

`-m` *mode* Sets the file permission bits of the newly-created FIFO to the specified *mode* value. The *mode* option-argument will be the same as the *mode* operand defined for the `chmod(1)` command. In <*symbolic*mode> strings, the *op* characters + and – will be interpreted relative to an assumed initial mode of `a=rw`.

Operands The following operand is supported:

file A path name of the FIFO special file to be created.

Usage See `largefile(5)` for the description of the behavior of `mkfifo` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Environment Variables See `environ(5)` for descriptions of the following environment variables that affect the execution of `mkfifo`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

Exit Status The following exit values are returned:

`0` All the specified FIFO special files were created successfully.

`>0` An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
Interface Stability	Standard

See Also `mkfifo(3C)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `standards(5)`

Name mkfile – create a file

Synopsis

```
mkfile [-nv] size [g | k | b | m] filename...
```

Description `mkfile` creates one or more files that are suitable for use as NFS-mounted swap areas, or as local swap areas. When a root user executes `mkfile()`, the sticky bit is set and the file is padded with zeros by default. When non-root users execute `mkfile()`, they must manually set the sticky bit using `chmod(1)`. The default `size` is in bytes, but it can be flagged as gigabytes, kilobytes, blocks, or megabytes, with the `g`, `k`, `b`, or `m` suffixes, respectively.

Options

`-n` Create an empty *filename*. The size is noted, but disk blocks are not allocated until data is written to them. Files created with this option cannot be swapped over local UFS mounts.

`-v` Verbose. Report the names and sizes of created files.

Exit Status The following exit values are returned:

`0` Success.

`>0` An error occurred.

Usage See `largefile(5)` for the description of the behavior of `mkfile` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Committed

See Also `chmod(1)`, `swap(1M)`, `attributes(5)`, `largefile(5)`

Name mkfs – construct a file system

Synopsis

```
mkfs [-F FSType] [generic_options]
     [-o FSType-specific_options] raw_device_file
     [operands]
```

Description The `mkfs` utility constructs a file system on the *raw_device_file* by calling the specific `mkfs` module indicated by `-F` *FSType*.

`Note`: ufs file systems are normally created with the `newfs(1M)` command.

generic_options are independent of file system type. *FSType-specific_options* is a comma-separated list of *keyword=value* pairs (with no intervening spaces), which are *FSType*-specific. *raw_device_file* specifies the disk partition on which to write the file system. It is required and must be the first argument following the *specific_options* (if any). *operands* are *FSType*-specific. See the *FSType*-specific manual page of `mkfs` (for example, `mkfs_ufs(1M)`) for a detailed description.

Options The following are the generic options for `mkfs`:

`-F` Specify the *FSType* to be constructed. If `-F` is not specified, the *FSType* is determined from `/etc/vfstab` by matching the *raw_device_file* with a `vfstab` entry, or by consulting the `/etc/default/fs` file.

`-V` Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided and adding to them information derived from `/etc/vfstab` or `/etc/default/fs`. This option may be used to verify and validate the command line.

`-m` Return the command line which was used to create the file system. The file system must already exist. This option provides a means of determining the command used in constructing the file system.

`-o` Specify *FSType*-specific options. See the manual page for the `mkfs` module specific to the file system type.

Usage See `largefile(5)` for the description of the behavior of `mkfs` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files

`/etc/default/fs` Default file system type. Default values can be set for the following flags in `/etc/default/fs`. For example: `LOCAL=ufs`

- `LOCAL` The default partition for a command if no *FSType* is specified.

`/etc/vfstab` List of default parameters for each file system

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also mkfs_ufs(1M), newfs(1M), vfstab(4), attributes(5), largefile(5)

Manual pages for the *FSType*-specific modules of mkfs.

Notes This command might not be supported for all *FSType*s.

You can use lofiadm to create a file that appears to a mkfs command as a raw device. You can then use a mkfs command to create a file system on that device. See lofiadm(1M) for examples of creating a UFS and a PC (FAT) file system (using mkfs_ufs(1M) and mkfs_pcfs(1M)) on a device created by lofiadm.

Name mkfs_pcfs – construct a FAT file system

Synopsis `mkfs -F pcfs [`*generic_options*`] [-o` *FSType_specific_options*`] `*raw_device_file*

Description The `pcfs`-specific module of `mkfs` constructs a File Allocation Table (FAT) on removable media (diskette, JAZ disk, ZIP disk, PCMCIA card), a hard disk, or a file (see NOTES). FATs are the standard MS-DOS and Windows file system format. Note that you can use `fdformat(1)` to construct a FAT file system only on a diskette or PCMCIA card.

`mkfs` for `pcfs` determines an appropriate FAT size for the medium, then it installs an initial boot sector and an empty FAT. A sector size of 512 bytes is used. `mkfs` for `pcfs` can also install the initial file in the file system (see the `pcfs`-specific `-o i` option). This first file can optionally be marked as read-only, system, and/or hidden.

If you want to construct a FAT with `mkfs` for `pcfs` on a medium that is not formatted, you must first perform a low-level format on the medium with `fdformat(1)` or `format(1M)`. Non-diskette media must also be partitioned with the `fdisk(1M)` utility. Note that all existing data on the diskette or disk partition, if any, is destroyed when a new FAT is constructed.

generic_options are supported by the generic `mkfs` command. See `mkfs(1M)` for a description of these options.

raw_device_file indicates the device on which to write unless the `-o N` option has been specified, or if the `-V` or `-m` generic options are passed from the generic `mkfs` module.

Options See `mkfs(1M)` for the list of supported generic options.

The following options are supported:

`-o` *FSType_specific_options* Specify `pcfs` file system-specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored.

- b=*label* Label the media with volume label. The volume label is restricted to 11 uppercase characters.
- B=*filename* Install *filename* as the boot loader in the file system's boot sector. If you don't specify a boot loader, an MS-DOS boot loader is installed. The MS-DOS boot loader requires specific MS-DOS system files to make the diskette bootable. See `NOTES` for more information.
- fat=*n* The size of a FAT entry. Currently, 12, 16, and 32 are valid values. The default is 12 for diskettes, 16 for larger media.

h	Mark the first file installed as a hidden file. The `-i` option must also be specified.
hidden=*n*	Set the number of hidden sectors to *n*. This is the number of sectors on the physical disk preceding the start of the volume (which is the boot sector itself). This defaults to 0 for diskettes or a computed valued (based on the fdisk table) for disks. This option may be used only in conjunction with the `nofdisk` option.
i=*filename*	Install *filename* as the initial file in the new file system. The initial file's contents are guaranteed to occupy consecutive clusters at the start of the files area. When creating bootable media, a boot program should be specified as the initial file.
nofdisk	Do not attempt to find an `fdisk` table on the medium. Instead rely on the `size` option for determining the partition size. By default, the created FAT is 16 bits and begins at the first sector of the device. This origination sector can be modified with the hidden option (`-h`).
nsect=*n*	The number of sectors per track on the disk. If not specified, the value is determined by using a `dkio(7I)` ioctl to get the disk geometry, or (for diskette) from the results of an `FDIOGCHAR` ioctl.
ntrack=*n*	The number of tracks per cylinder on the disk. If not specified, the value is determined by using a `dkio(7I)` ioctl to get the disk geometry, or (for diskette) from the results of an `FDIOGCHAR` ioctl.
N	No execution mode. Print normal output, but do not actually write the file system to the medium. This is most useful when used in conjunction with the verbose option.
r	Mark the first file installed as read-only. The `-i` option must also be specified.
reserve=*n*	Set the number of reserved sectors to *n*. This is the number of sectors in the volume,

preceding the start of the first FAT, including the boot sector. The value should always be at least 1, and the default value is exactly 1.

s	Mark the first file installed as a system file. The `-i` option must also be specified.
size=*n*	The number of sectors in the file system. If not specified, the value is determined from the size of the partition given in the fdisk table or (for diskette) by way of computation using the `FDIOGCHAR` ioctl.
spc=*n*	The size of the allocation unit for space within the file system, expressed as a number of sectors. The default value depends on the FAT entry size and the size of the file system.
v	Verbose output. Describe, in detail, operations being performed.

Files *raw_device_file* The device on which to build the FAT. The device name for a diskette must be specified as `/dev/rdiskette0` for the first diskette drive, or `/dev/rdiskette1` for a second diskette drive. For non-diskette media, a disk device name must be qualified with a suffix to indicate the proper partition. For example, in the name `/dev/rdsk/c0t0d0p0:c`, the `:c` suffix indicates that the first partition on the disk should receive the new FAT.

For a file, *raw_device_file* is the block device name returned by `lofiadm(1M)`.

Examples The media in these examples must be formatted before running `mkfs` for `pcfs`. See DESCRIPTION for more details.

EXAMPLE 1 Creating a FAT File System on a Diskette

The following command creates a FAT file system on a diskette:

```
mkfs -F pcfs /dev/rdiskette
```

EXAMPLE 2 Creating a FAT File System on a Disk

The following command creates a FAT file system on the second fdisk partition of a disk attached to an x86 based system:

```
mkfs -F pcfs /dev/rdsk/c0d0p0:d
```

EXAMPLE 3 Creating a FAT File System on a ZIP Disk

The following command creates a FAT file system on a ZIP disk located on a SPARC based system:

```
mkfs -F pcfs /dev/rdsk/c0t4d0s2:c
```

EXAMPLE 4 Creating a FAT File System on a JAZ Disk

The following command creates a FAT file system on a JAZ disk located on a SPARC based system and overrides the sectors/track and tracks/cylinder values obtained from the device's controller:

```
mkfs -F pcfs -o nsect=32,ntrack=64 /dev/rdsk/c0t3d0s2:c
```

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
Interface Stability	Stable

See Also

`fdformat(1)`, `fdisk(1M)`, `format(1M)`, `lofiadm(1M)`, `mkfs(1M)`, `attributes(5)`, `fd(7D)`, `dkio(7I)`, `fdio(7I)`

Notes

The default MS-DOS boot loader, which is installed by default if `-o B` is not specified, requires specific MS-DOS system files to make the diskette bootable. These MS-DOS files are not installed when you format a diskette with `mkfs` for `pcfs`, which makes a diskette formatted this way not bootable. Trying to boot from it on an x86 based system will result in the following message:

```
Non-System disk or disk error
Replace and strike any key when ready
```

You must format a diskette with the DOS `format` command to install the specific MS-DOS system files required by the default boot loader.

You can use `lofiadm` to create a file that appears to a `mkfs` command (for example, `mkfs_pcfs` or `mkfs_ufs`) as a raw device. You can then use a `mkfs` command to create a file system on that device. See `lofiadm(1M)` for examples of creating a UFS and a PC (FAT) file system on a device created by `lofiadm`.

Name mkfs_udfs – construct a udfs file system

Synopsis

```
mkfs -F udfs [generic_options] [-o specific_options] raw_device_file
     [size]
```

Description This is the universal disk format file system (udfs) -specific module of the `mkfs` command. `mkfs` constructs a `udfs` file system with a root directory.

Options See `mkfs`(1M) for the list of supported *generic_options*.

The following options are supported:

`-o` *specific_options* Specify a `udfs`-specific option. Specify `udfs` file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored.

The following *specific_options* are available:

N — Print the file system parameters without actually creating the file system.

label=*string* — Specify the label to be written into the volume header structures. Specify *string* as the name of the label. If *string* is not specified, a default *string* is generated in the form of `*NoLabel*`.

Operands The following operands are supported:

raw_device_file Specify the disk partition on which to write.

size Specify the number of 512-byte blocks in the file system.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWudf

See Also `fsck`(1M),`mkfs`(1M), `attributes(5)`

Diagnostics

`not currently a valid file system`

The specified device does not contain a valid `udfs` file system.

`Invalid size: larger than the partition size`

Number of blocks given as parameter to create the file system is larger than the size of the device specified.

`is mounted can't mkfs`

Device is in use, cannot create file system when the device is in use.

```
preposterous size
```

Negative size parameter provided is invalid.

```
sector size must be between 512, 8192 bytes
```

Sector size given is not in the valid range.

```
Volume integrity sequence descriptors too long
File set descriptor too long.
```

Not enough space to create volume integrity sequence or file set descriptor.

```
mkfs: argument out of range
```

One of the arguments is out of range.

```
mkfs: bad numeric arg
```

One of the arguments is potentially a bad numeric.

Notes You can use `lofiadm` to create a file that appears to a `mkfs` command (for example, `mkfs_pcfs` or `mkfs_ufs`) as a raw device. You can then use a `mkfs` command to create a file system on that device. See `lofiadm(1M)` for examples of creating a UFS and a PC (FAT) file system on a device created by `lofiadm`.

Name mkfs_ufs – construct a UFS file system

Synopsis

```
mkfs -F ufs [generic_options] [-o FSType_specific_options] raw_device_file
     [size]
```

Description The UFS-specific module of `mkfs` builds a UFS file system with a root directory and a `lost+found` directory (see `fsck`(1M)).

The UFS-specific `mkfs` is rarely run directly. Use the `newfs`(1M) command instead.

raw_device_file indicates the disk partition on which to create the new file system. If the `-o N`, `-V`, or `-m` options are specified, the *raw_device_file* is not actually modified. *size* specifies the number of disk sectors in the file system, where a disk sector is usually 512 bytes. This argument must follow the *raw_device_file* argument and is required (even with `-o N`), unless the `-V` or `-m` generic options are specified.

generic_options are supported by the generic `mkfs` command. See `mkfs`(1M) for a description of these options.

Options The following generic options are supported:

`-m` Print the command line that was used to create the existing file system.

`-V` Print the current `mkfs` command line.

Options The following UFS-specific options are supported:

`-o` Use one or more of the following values separated by commas (with no intervening spaces) to specify UFS-specific options:

`apc=`*n* The number of alternate sectors per cylinder to reserve for bad block replacement for SCSI devices only. The default is `0`.

This option is not applicable for disks with EFI labels and is ignored.

`bsize=`*n* The logical block size of the file system in bytes, either `4096` or `8192`. The default is `8192`. The sun4u architecture does not support the `4096` block size.

`calcbinsb` Sends to stdout a binary (machine-readable) version of the superblock that would be used to create a file system with the specified configuration parameters.

`calcsb` Sends to stdout a human-readable version of the superblock that would be used to create a file system with the specified configuration parameters.

`cgsize=`*n* The number of cylinders per cylinder group, ranging from `16` to `256`. The default is calculated by dividing the number of sectors in the file system by the number of sectors in a gigabyte. Then, the result is multiplied by `32`. The default value is always between `16` and `256`.

The per-cylinder-group meta data must fit in a space no larger than what is available in one logical file system block. If too large a `cgsize` is requested, it is changed by the minimum amount necessary.

`fragsize=`*n* The smallest amount of disk space in bytes that can be allocated to a file. *fragsize* must be a power of 2 divisor of *bsize*, where:

bsize / *fragsize* is 1, 2, 4, or 8.

This means that if the logical block size is `4096`, legal values for *fragsize* are `512`, `1024`, `2048`, and `4096`. When the logical block size is `8192`, legal values are `1024`, `2048`, `4096`, and `8192`. The default value is `1024`.

For file systems greater than 1 terabyte or for file systems created with the `mtb=y` option, *fragsize* is forced to match block size (*bsize*).

`free=`*n* The minimum percentage of free space to maintain in the file system between 0% and 99%, inclusively. This space is off-limits to users. Once the file system is filled to this threshold, only the superuser can continue writing to the file system.

The default is ((64 Mbytes/partition size) * 100), rounded down to the nearest integer and limited between 1% and 10%, inclusively.

This parameter can be subsequently changed using the `tunefs(1M)` command.

`gap=`*n* Rotational delay. This option is obsolete in the Solaris 10 release. The value is always set to `0`, regardless of the input value.

`maxcontig=`*n* The maximum number of logical blocks, belonging to one file, that are allocated contiguously. The default is calculated as follows:

`maxcontig =` *disk drive maximum transfer size / disk block size*

If the disk drive's maximum transfer size cannot be determined, the default value for `maxcontig` is calculated from kernel parameters as follows:

If `maxphys` is less than `ufs_maxmaxphys`, which is typically 1 Mbyte, then `maxcontig` is set to `maxphys`. Otherwise, `maxcontig` is set to `ufs_maxmaxphys`.

You can set `maxcontig` to any positive integer value.

The actual value will be the lesser of what has been specified and what the hardware supports.

You can subsequently change this parameter by using tunefs(1M).

`mtb=y` Set the parameters of the file system to allow eventual growth to over a terabyte in total file system size. This option sets *fragsize* to be the same as *bsize*, and sets *nbpi* to 1 Mbyte, unless the `-i` option is used to make it even larger. If you explicitly set the *fragsize* or *nbpi* parameters to values that are incompatible with this option, the user-supplied value of *fragsize* or *nbpi* is ignored.

`N` Print out the file system parameters that would be used to create the file system without actually creating the file system.

`nbpi=`*n* The number of bytes per inode, which specifies the density of inodes in the file system. The number is divided into the total size of the file system to determine the number of inodes to create.

This value should reflect the expected average size of files in the file system. If fewer inodes are desired, a larger number should be used. To create more inodes, a smaller number should be given. The default is `2048`.

The number of inodes can increase if the file system is expanded with the `growfs` command.

`nrpos=`*n* The number of different rotational positions in which to divide a cylinder group. The default is `8`.

This option is not applicable for disks with EFI labels and is ignored.

`nsect=`*n* The number of sectors per track on the disk. The default is `32`.

`ntrack=`*n* The number of tracks per cylinder on the disk. The default is `16`.

This option is not applicable for disks with EFI labels and is ignored.

`opt=`*s* | *t* The file system can either be instructed to try to minimize the *time* spent allocating blocks, or to try to minimize the *space* fragmentation on the disk. The default is *time*.

This parameter can be subsequently changed with the tunefs(1M) command.

`rps=`*n* The rotational speed of the disk, in revolutions per second. The default is `60`.

Note that you specify *rps* for `mkfs` and *rpm* for `newfs`.

This option is not applicable for disks with EFI labels and is ignored.

Alternatively, parameters can be entered as a list of space-separated values (without keywords) whose meaning is positional. In this case, the `-o` option is omitted and the list follows the size operand. This is the way `newfs` passes the parameters to `mkfs`.

Operands The following operands are supported:

raw_device_file The disk partition on which to write.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `fsck(1M)`, `mkfs(1M)`, `newfs(1M)`, `tunefs(1M)`, `dir_ufs(4)`, `attributes(5)`, `ufs(7FS)`

Diagnostics The following error message typically occurs with very high density disks. On such disks, the file system structure cannot encode the proper disk layout information. However, such disks have enough onboard intelligence to make up for any layout deficiencies, so there is no actual impact on performance. The warning that performance might be impaired can be safely ignored.

```
Warning: insufficient space in super block for
rotational layout tables with nsect sblock.fs_nsect
and ntrak sblock.fs_ntrak. (File system performance may be impaired.)
```

The following error message occurs when the disk geometry results in a situation where the last truncated cylinder group cannot contain the correct number of data blocks. Some disk space is wasted.

```
Warning: inode blocks/cyl group (grp) >= data blocks (num) in last cylinder
```

If there is only one cylinder group and if the above condition holds true, `mkfs` fails with the following error:

```
File system creation failed. There is only one cylinder group and that is
not even big enough to hold the inodes.
```

The following error message occurs when the best calculated file system layout is unable to include the last few sectors in the last cylinder group. This is due to the interaction between how much space is used for various pieces of meta data and the total blocks available in a cylinder group. Modifying `nbpi` and `cpg` might reduce this number, but it is rarely worth the effort.

```
Warning: num sector(s) in last cylinder group unallocated
```

Notes You can use `lofiadm` to create a file that appears to the `mkfs` command (for example, `mkfs_pcfs` or `mkfs_ufs`) as a raw device. You can then use the `mkfs` command to create a file system on that device. See `lofiadm(1M)` for examples of creating a UFS and a PC (FAT) file system on a device created by `lofiadm`.

Both the block and character devices, such as devices in `/dev/dsk` and `/dev/rdsk`, must be available prior to running the `mkfs` command.

Name mknod – make a special file

Synopsis

```
mknod name b major minor
mknod name c major minor
mknod name p
```

Description `mknod` makes a directory entry for a special file.

Options The following options are supported:

`b` Create a block-type special file.

`c` Create a character-type special file.

`p` Create a FIFO (named pipe).

Operands The following operands are supported:

major The *major* device number.

minor The *minor* device number; can be either decimal or octal. The assignment of major device numbers is specific to each system. You must be the super-user to use this form of the command.

name A special file to be created.

Usage See `largefile(5)` for the description of the behavior of `mknod` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `ftp(1)`, `in.ftpd(1M)`, `mknod(2)`, `symlink(2)`, `attributes(5)`, `largefile(5)`

Notes If `mknod(2)` is used to create a device, the major and minor device numbers are always interpreted by the kernel running on that machine.

With the advent of physical device naming, it would be preferable to create a symbolic link to the physical name of the device (in the `/devices` subtree) rather than using `mknod`.

Name mkpwdict – maintain password-strength checking database

Synopsis

```
/usr/sbin/mkpwdict [-s dict1,... ,dictN]
     [-d destination-path]
```

Description The `mkpwdict` command adds words to the dictionary-lookup database used by `pam_authtok_check(5)` and `passwd(1)`.

Files containing words to be added to the database can be specified on the command-line using the `-s` flag. These source files should have a single word per line, much like `/usr/share/lib/dict/words`.

If `-s` is omitted, `mkpwdict` will use the value of `DICTIONLIST` specified in `/etc/default/passwd` (see `passwd(1)`).

The database is created in the directory specified by the `-d` option. If this option is omitted, `mkpwdict` uses the value of `DICTIONDBDIR` specified in `/etc/default/passwd` (see `passwd(1)`). The default location is `/var/passwd`.

Options The following options are supported:

`-s` Specifies a comma-separated list of files containing words to be added to the dictionary-lookup database.

`-d` Specifies the target location of the dictionary-database.

Files

`/etc/default/passwd`	See `passwd(1)`.
`/var/passwd`	default destination directory

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Evolving

See Also `passwd(1)`, `attributes(5)`, `pam_authtok_check(5)`

Name modinfo – display information about loaded kernel modules

Synopsis

```
/usr/sbin/modinfo [-c] [-w] [-i module-id]
```

Description The `modinfo` utility displays information about the loaded modules. The format of the information is as follows:

Id Loadaddr Size Info Rev Module Name

where *Id* is the module ID, *Loadaddr* is the starting text address in hexadecimal, *Size* is the size of text, data, and bss in hexadecimal bytes, *Info* is module specific information, *Rev* is the revision of the loadable modules system, and *Module Name* is the filename and description of the module.

The module specific information is the block and character major numbers for drivers, the system call number for system calls, and unspecified for other module types.

Options The following options are supported:

`-c` Display the number of instances of the module loaded and the module's current state.

`-i` *module-id* Display information about this module only.

`-w` Do not truncate module information at `80` characters.

Examples **EXAMPLE 1** Displaying the Status of a Module

The following example displays the status of module 2:

```
example% modinfo -i 2
Id   Loadaddr   Size Info Rev Module Name
 2    ff08e000   1734   -   1  swapgeneric (root and swap configuration)
```

EXAMPLE 2 Displaying the Status of Kernel Modules

The following example displays the status of some kernel modules:

```
example% modinfo
Id Loadaddr   Size Info Rev Module Name
 2  ff08e000   1734   -   1  swapgeneric
 4  ff07a000   3bc0   -   1  specfs (filesystem for specfs)
 6  ff07dbc0   2918   -   1  TS (time sharing sched class)
 7  ff0804d8    49c   -   1  TS_DPTBL (Time sharing dispatch table)
 8  ff04a000  24a30   2   1  ufs (filesystem for ufs)
 9  ff080978   c640 226   1  rpcmod (RPC syscall)
 9  ff080978   c640   -   1  rpcmod (rpc interface str mod)
10  ff08cfb8  2031c   -   1  ip (IP Streams module)
10  ff08cfb8  2031c   2   1  ip (IP Streams device)
```

EXAMPLE 3 Using the -c Option

Using the `modinfo` command with the -c option displays the number of instances of the module loaded and the module's current state.

```
example% modinfo -c
Id    Loadcnt Module Name                          State
  1          0 krtld                          UNLOADED/UNINSTALLED
  2          0 genunix                        UNLOADED/UNINSTALLED
  3          0 platmod                        UNLOADED/UNINSTALLED
  4          0 SUNW,UltraSPARC-IIi            UNLOADED/UNINSTALLED
  5          0 cl_bootstrap                   UNLOADED/UNINSTALLED
  6          1 specfs                         LOADED/INSTALLED
  7          1 swapgeneric                    UNLOADED/UNINSTALLED
  8          1 TS                             LOADED/INSTALLED
  9          1 TS_DPTBL                       LOADED/INSTALLED
 10          1 ufs                            LOADED/INSTALLED
 11          1 fssnap_if                      LOADED/INSTALLED
```

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Evolving

See Also

`modload(1M)`, `modunload(1M)`, `attributes(5)`

Name modload – load a kernel module

Synopsis

```
modload [-p] [-e exec_file] filename
```

Description The `modload` command loads the loadable module *filename* into the running system.

filename is an object file produced by `ld -r`. If *filename* is an absolute pathname then the file specified by that absolute path is loaded. If *filename* does not begin with a slash (`/`), then the path to load *filename* is relative to the current directory unless the `-p` option is specified.

The kernel's `modpath` variable can be set using the `/etc/system` file. The default value of the kernel's `modpath` variable is set to the path where the operating system was loaded. Typically this is `/kernel /usr/kernel`.

For example, the following command looks for `./drv/foo`:

```
example# modload drv/foo
```

The following command looks for `/kernel/drv/foo` and then `/usr/kernel/drv/foo`:

```
example# modload -p drv/foo
```

Options The following options are supported:

`-e` *exec_file* — Specify the name of a shell script or executable image file that is executed after the module is successfully loaded. The first argument passed is the module ID (in decimal). The other argument is module specific. The module specific information is: the block and character major numbers for drivers, the system call number for system calls, or, for other module types, the index into the appropriate kernel table. See `modinfo(1M)`

`-p` — Use the kernel's internal modpath variable as the search path for the module.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `ld(1)`, `add_drv(1M)`, `kernel(1M)`, `modinfo(1M)`, `modunload(1M)`, `system(4)`, `attributes(5)`, `modldrv(9S)`, `modlinkage(9S)`, `modlstrmod(9S)`, `module_info(9S)`

Writing Device Drivers

Notes Use `add_drv(1M)` to add device drivers, not `modload`. See *Writing Device Drivers* for procedures on adding device drivers.

Name modunload – unload a module

Synopsis

```
modunload -i module_id [-e exec_file]
```

Description `modunload` unloads a loadable module from the running system. The *module_id* is the ID of the module as shown by `modinfo(1M)`. If `ID` is `0`, all modules that were autoloaded which are unloadable, are unloaded. Modules loaded by `modload(1M)` are not affected.

Options The following options are supported:

`-e` *exec_file* Specify the name of a shell script or executable image file to be executed before the module is unloaded. The first argument passed is the module id (in decimal). There are two additional arguments that are module specific. For loadable drivers, the second argument is the driver major number. For loadable system calls, the second argument is the system call number. For loadable exec classes, the second argument is the index into the `execsw` table. For loadable filesystems, the second argument is the index into the `vfssw` table. For loadable streams modules, the second argument is the index into the `fmodsw` table. For loadable scheduling classes, the second argument is the index into the class array. Minus one is passed for an argument that does not apply.

`-i` *module_id* Specify the module to be unloaded.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `modinfo(1M)`, `modload(1M)`, `update_drv(1M)`, `attributes(5)`

Notes The `modunload` command is often used on driver modules to force the system to reread the associated driver configuration file. While this works in the current Solaris release, it is not the supported way to reread the configuration file and is not guaranteed to work in future releases. The supported way for rereading driver configuration file is through the `update_drv(1M)` command.

Name mofcomp – compile MOF files into CIM classes

Synopsis

```
/usr/sadm/bin/mofcomp [-c cimom_hostname ] [-h]
     [-j filename] [-n namespace] [-o dirname]
     [-p password ] [-CIQ] [-u username] [-v ] [-version]
     [-x] file
```

Description The `mofcomp` utility is executed during installation to compile managed object format (MOF) files that describe the Common Information Model (CIM) and Solaris Schemas into the CIM Object Manager Repository, a central storage area for management data. The CIM Schema is a collection of class definitions used to represent managed objects that occur in every management environment. The Solaris Schema is a collection of class definitions that extend the CIM Schema and represent managed objects in a typical Solaris operating environment.

The `mofcomp` utility must be run as root or as a user with write access to the namespace in which you are compiling.

MOF is a language for defining CIM classes and instances. MOF files are ASCII text files that use the MOF language to describe CIM objects. A CIM object is a computer representation or model of a managed resource, such as a printer, disk drive, or CPU.

Many sites store information about managed resources in MOF files. Because MOF can be converted to Java, Java applications that can run on any system with a Java Virtual Machine can interpret and exchange this information. You can also use the `mofcomp` utility to compile MOF files at any time after installation.

Options The following options are supported:

`-c` *cimom_hostname* — Specify a remote system running the CIM Object Manager.

`-C` — Run the compiler set with the class option, which updates a class if it exists, and returns an error if the class does not exist. If you do not specify this option, the compiler adds a CIM class to the connected namespace, and returns an error if the class already exists.

`-h` — List the arguments to the `mofcomp` utility.

`-I` — Run the compiler set with the instance option, which updates an instance if it exists, and returns an error if the instance does not exist. If you do not specify this option, the compiler adds a CIM instance to the connected namespace, and returns an error if the instance already exists.

`-j` *filename* — Generate Java Beans and Java Interfaces to manage the CIM instances related to the CIM classes in the MOF being compiled.

The contents of *filename* are:

`PACKAGE=`*Java package name*
`IMPORTS=`*import1*:...:*importN*

`<EXCEPTIONS=`*exception1*`:...:`*exceptionN*

`PACKAGE` is a valid Java package name to include in all generated Java source. `IMPORTS` is an optional colon separated list of valid Java classes to be imported in all generated Java source. `EXCEPTIONS` is an optional colon separated list of valid Java exceptions to be thrown by the methods in all generated Java source.

`-n` *namespace*
: Requests that the compiler load the MOF file into the namespace specified as *namespace*. The default namespace (`root\cimv2`) is used unless this switch is used or a `#pragma` *namespace* ("`namespace`") statement appears in the MOF file. If both the `-n` *namespace* switch and the `#pragma` *namespace* construct are used, all namespaces are created, but the objects are created only in the `#pragma namespaces`.

`-o` *dirname*
: Run compiler in standalone mode, without the CIM Object Manager. Specify dirname as the directory in which the compiler output is to be stored. In this mode, the CIM Object Manager need not be running.

`-p` *password*
: Specify a password for connecting to the CIM Object Manager. Use this option for compilations that require privileged access to the CIM Object Manager. If you specify both `-p` and `-u`, you must type the password on the command line, which can pose a security risk. A more secure way to specify a password is to specify `-u` but not `-p`, so that the compiler will prompt for the password.

`-Q`
: Run the compiler set with the qualifier types option, which updates a qualifier type if it exists, and returns an error if the qualifier type does not exist. If you do not specify this option, the compiler adds a CIM qualifier type to the connected namespace, and returns an error if the qualifier type already exists.

`-u` *username*
: Specify user name for connecting to the CIM Object Manager. Use this option for compilations that require privileged access to the CIM Object Manager. If you specify both `-p` and `-u`, you must type the password on the command line, which can pose a security risk. A more secure way to specify a password is to specify `-u` but not `-p`, so that the compiler will prompt for the password.

`-v`
: Run the compiler in verbose mode, which displays compiler messages.

`-version`
: Display the version of the MOF compiler.

`-x`
: Generate XML documents for the CIM classes defined in the input MOF file.

Operands The following operands are supported:

file The pathname of the file to be compiled.

Exit Status The `mofcomp` utility exits with `0` upon success and a positive integer upon failure.

Files MOF files are installed in `/usr/sadm/mof`.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWwbcor

See Also `init.wbem(1M)`, `mofreg(1M)`, `wbemadmin(1M)`, `wbemlogviewer(1M)`, `attributes(5)`, `wbem(5)`

Name mofreg – register MOF classes with WBEM services

Synopsis

```
/usr/sadm/bin/mofreg -r tag file

/usr/sadm/bin/mofreg -s

/usr/sadm/bin/mofreg -u tag [file]
```

Description The `mofreg` command is used by package and patch install scripts, or by any applications that wish to register managed object format (MOF) classes with Sun The Web-Based Enterprise Management (WBEM) services.

The WBEM services daemon (Common Information Model or CIM object manager) processes at start up the files that are specified by `mofreg` commands. Files are processed in the order that the individual `mofreg` commands are executed.

As an alternative to using the `mofreg` command, MOFs can be registered or unregistered by manipulating directories in `/var/sadm/wbem/logr`. Instead of running the `mofreg -r tag file` version fo the command you can create a directory named `tag` under `/var/sadm/wbem/logr/preReg` and copy `file` to the `tag` directory.

Similarly, instead of running the `mofreg -u tag [file]` command, you can create a directory named `tag` under `/var/sadm/wbem/logr/preUnreg` and copy the optional `file` to the `tag` directory.

The entries are processed in increasing order of last modification time of the `tag` directories. If you issue `mofreg` commands in rapid succession, the timestamps might be the same. If you have a situation where the timestamp order is critical, you can place appropriate sleeps between the successive registration or unregistration operations. As with the `mofreg` command, processing is done at next restart or by using the `-s` option.

This alternative mechanism is typically used in package install scripts which do not have access to `/usr`, and therefore do not have access to the `mofreg` command. This case arises when packages are installed for diskless clients.

Options The following options are supported:

`-r` *tag file* The *file* argument is the actual MOF registration file. Its form is identical to the MOF syntax as defined by the Distributed Management Task Force (DMTF). The only difference is the addition of the following 3 new pseudo-pragmas, which are variations of the namespace pragma. The name of file cannot end in `.unreg`.

```
#pragma namespace("__create")
#pragma namespace("__delete")
#pragma namespace("__modify")
```

These three pragmas are used specify if the elements following the pragmas should be created, deleted, or modified by the CIM object manager. The `__delete` pragma can currently only be applied for a `mofreg -u` command.

The *tag* argument is a unique string that specifies the identity of the registry action. This tag can be set to the package name or the patch number if the `mofreg` script is being invoked through packages/patches, though any tag can be specified.

Errors and warnings that are encountered when the CIM object manager handles the `mofreg` script are logged. Processing of the `mofreg` script stops at the first error. Specific warnings include:

```
Element already defined - the element already exists and
cannot be created.

Element not found - the element does not exist and
cannot be modified.
```

The error conditions are:

```
Key modification - A class cannot be modified if its keys
are being changed.

Other mod compilation errors.
```

`-s` Forces the CIM object manager to immediately process outstanding registry requests, instead of at the next restart. This currently requires Java.

`-u` *tag* [*file*] Undoes the operations performed during `mof` registry.

The *tag* argument must correspond to the value set during the original `mofreg` invocation. If no `mofreg` was done with the original *tag*, the command does not succeed.

If required, an *unreg* file can be specified. If no *unreg* file is specified, the CIM object manager automatically undoes the actions of the registry. Any class created by the registry process is removed and any classes modified by the registry revert to the old state.

The `mofreg` command does not take care of cases where packages and patches make conflicting changes to classes. This should be taken care of by the standard patch and package conflict resolution.

Exit Status The following exit values are returned:

`0` Successful completion.

`1` An error occurred. The reason for error is displayed.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWwbcou

Name monitor – SPARC system PROM monitor

Synopsis

```
STOP–A

BREAK

initial system power-on

exit from a client program, e.g., the Operating System
```

Description The CPU board of a workstation contains one or more EPROMs or EEPROMs. The program which executes from the PROMs is referred to as "the monitor". Among other things, the monitor performs system initialization at power-on and provides a user interface.

Monitor Prompt The monitor of earlier workstations was known as the `SunMON` monitor and displayed the > for its prompt. See the `SunMON MONITOR USAGE` section for further details.

Existing workstations use a monitor which is known as the OpenBoot monitor. The OpenBoot monitor typically displays `ok` as its prompt, but it may also display the > prompt under certain circumstances.

If the `'auto-boot?'` NVRAM parameter is set to `'false'` when the workstation is powered on, the system does not attempt to boot and the monitor issues its prompt. If `'auto-boot'` is set to `'true'`, the system initiates the boot sequence. The boot sequence can be aborted by simultaneously pressing two keys on the system's keyboard: L1 and A (on older keyboards), or Stop and A (on newer keyboards). Either a lower case `a` or an upper case `A` works for the keyboard abort sequence. If a console has been attached by way of one of the system's serial ports then the abort sequence can be accomplished by sending a BREAK. See `tip(1)`.

When the NVRAM `'security-mode'` parameter has been turned on, or when the value of the `'sunmon-compat?'` parameter is true, then the OpenBoot monitor displays the message: `Type b (boot), c (continue), or n (new command mode)`

and the > prompt appears.

Openboot Prom Usage Some of the more useful commands that can be issued from OpenBoot's `ok` prompt are described here. Refer to the *OpenBoot 2.x Command Reference Manual* book for a complete list of commands.

Help Help for various functional areas of the OpenBoot monitor can be obtained by typing `help`. The help listing provides a number of other key words which can then be used in the help command to provide further details.

NVRAM Parameters Each workstation contains one or more NVRAM devices which contains unique system ID information, as well as a set of user-configurable parameters. The NVRAM parameters allow the user a certain level of flexibility in configuring the system to act in a given manner under a specific set of circumstances.

See `eeprom(1M)` for a description of the parameters and information regarding setting the parameters from the OS level.

The following commands can be used at the OpenBoot monitor to access the NVRAM parameters.

`printenv`	Used to list the NVRAM parameters, along with their default values and current values.
`setenv` *pn pv*	Used to set or modify a parameter. The *pn* represents the parameter name, and *pv* represents the parameter value.
`set-default` *pn*	Used to set an individual parameter back to its default value.
`set-defaults`	Used to reset all parameters to their default values. (Note that `'set-defaults'` only affects parameters that have assigned default values.)

Security Parameters

Newer OpenBoot monitors contain user interfaces that support the storage and listing of keys for later use by client programs.

`list-security-keys`	Lists the names of keys currently stored on a machine.
`set-security-key` *keyname* [*keydata*]	Stores key data *keydata* in a key named *keyname*. Actual key data can be up to 32 bytes in length. The maximum length of *keyname* is 64 bytes, which allows for the hex-formatted ASCII used to present the key data. If *keydata* is not present, *keyname* and its corresponding data is deleted.

Hardware Checks and Diagnostics

The following commands are available for testing or checking the system's hardware. If the `'diag-switch?'` NVRAM parameter is set to true when the system is powered on, then a Power-On Self Test (POST) diagnostic is run, if present, sending its results messages to the system's serial port A. Not all of the commands shown are available on all workstations.

`test-all`	Run the diagnostic tests on each device which has provided a self-test.
`test floppy`	Run diagnostics on the system's floppy device.
`test /memory`	Run the main memory tests. If the NVRAM parameter `'diag-switch?'` is set to true, then all of main memory is tested. If the parameter is false then only the amount of memory specified in the `'selftest-#megs'` NVRAM parameter is tested.
`test net`	Test the network connection for the on-board network controller.
`watch-net`	Monitor the network attached to the on-board net controller.
`watch-net-all`	Monitor the network attached to the on-board net controller, as well as the network controllers installed in SBus slots.
`watch-clock`	Test the system's clock function.

System Information

The following commands are available for displaying information about the system. Not all commands are available on all workstations.

`banner`	Display the power-on banner.
`.enet-addr`	Display the system's Ethernet address.
`.idprom`	Display the formatted contents of the IDPROM.
`module-info`	Display information about the system's processor(s).
`probe-scsi`	Identify the devices attached to the on-board SCSI controller.
`probe-scsi-all`	Identify the devices attached to the on-board SCSI controller as well as those devices which are attached to SBus SCSI controllers.
`show-disks`	Display a list of the device paths for installed SCSI disk controllers.
`show-displays`	Display a list of the device paths for installed display devices.
`show-nets`	Display a list of the device paths for installed Ethernet controllers.
`show-sbus`	Display list of installed SBus devices.
`show-tapes`	Display a list of the device paths for installed SCSI tape controllers.
`show-ttys`	Display a list of the device paths for tty devices.
`.traps`	Display a list of the SPARC trap types.
`.version`	Display the version and date of the OpenBoot PROM.

Emergency Commands

These commands must be typed from the keyboard, they do not work from a console which is attached by way of the serial ports. With the exception of the Stop-A command, these commands are issued by pressing and holding down the indicated keys on the keyboard immediately after the system has been powered on. The keys must be held down until the monitor has checked their status. The Stop-A command can be issued at any time after the console display begins, and the keys do not need to be held down once they've been pressed. The Stop-D, Stop-F and Stop-N commands are not allowed when one of the security modes has been set. Not all commands are available on all workstations.

Stop (L1)	Bypass the Power-On Self Test (POST). This is only effective if the system has been placed into the diagnostic mode.
Stop-A (L1-A)	Abort the current operation and return to the monitor's default prompt.
Stop-D (L1-D)	Set the system's `'diag-switch?'` NVRAM parameter to `'true'`, which places the system in diagnostic mode. POST diagnostics, if present, are run, and the messages are displayed by way of the system's serial port A.
Stop-F (L1-F)	Enter the OpenBoot monitor before the monitor has probed the system for devices. Issue the `'fexit'` command to continue with system initialization.

Stop-N (L1-N) Causes the NVRAM parameters to be reset to their default values. Note that not all parameters have default values.

Line Editor Commands

The following commands can be used while the monitor is displaying the `ok` prompt. Not all of these editing commands are available on all workstations.

CTRL-A	Place the cursor at the start of line.
CTRL-B	Move the cursor backward one character.
ESC-B	Move the cursor backward one word.
CTRL-D	Erase the character that the cursor is currently highlighting.
ESC-D	Erase the portion of word from the cursor's present position to the end of the word.
CTRL-E	Place the cursor at the end of line.
CTRL-F	Move the cursor forward one character.
ESC-F	Move the cursor forward one word.
CTRL-H	Erase the character preceding the cursor (also use Delete or Back Space)
ESC-H	Erase the portion of the word which precedes the cursor (use also CTRL-W)
CTRL-K	Erase from the cursor's present position to the end of the line.
CTRL-L	Show the command history list.
CTRL-N	Recall the next command from the command history list
CTRL-P	Recall a previous command from the command history list.
CTRL-Q	Quote the next character (used to type a control character).
CTRL-R	Retype the current line.
CTRL-U	Erase from the cursor's present position to the beginning of the line.
CTRL-Y	Insert the contents of the memory buffer into the line, in front (to the left) of the cursor.

nvramrc

The `nvramrc` is an area of the system's NVRAM where users may store Forth programs. The programs which are stored in the `nvramrc` are executed each time the system is reset, provided that the `'use-nvramrc?'` NVRAM parameter has been set to `'true'`. Refer to the *OpenBoot 2.x Command Reference Manual*book for information on how to edit and use the `nvramrc`.

Restricted Monitor

The command `'old-mode'` is used to move OpenBoot into a restricted monitor mode, causing the > prompt to be displayed. Only three commands are allowed while in the restricted monitor; the `'go'` command (to resume a program which was interrupted with the

Stop-A command), the `'n'` command (to return to the normal OpenBoot monitor), and boot commands. The restricted monitor's boot commands approximate the older `SunMON` monitor's boot command syntax. If a `'security-mode'` has been turned on then the restricted monitor becomes the default monitor environment. The restricted monitor may also become the default environment if the `'sunmon-compat?'` NVRAM parameter is set to true. Not all workstations have the `'sunmon-compat?'` parameter.

SunMON Prom Usage

The following commands are available systems with older `SunMON`-based PROM:

`+|–`
Increment or decrement the current address and display the contents of the new location.

`^C` *source destination n*
(caret-C) Copy, byte-by-byte, a block of length *n* from the `source` address to the *destination* address.

`^I` *program*
(caret-I) Display the compilation date and location of *program*.

`^T` *virtual_address*
(caret-T) Display the physical address to which *virtual_address* is mapped.

`b` [`!`] [*device* [`(`*c*`,`*u*`,`*p* `)`]] [*pathname*] [*arguments_list*]

`b[?]`
Reset appropriate parts of the system and bootstrap a program. A '`!`' (preceding the *device* argument) prevents the system reset from occurring. Programs can be loaded from various devices (such as a disk, tape, or Ethernet). '`b`' with no arguments causes a default boot, either from a disk, or from an Ethernet controller. '`b?`' displays all boot devices and their *device*s.

device one of

`le`	Lance Ethernet
`ie`	Intel Ethernet
`sd`	SCSI disk, CDROM
`st`	SCSI 1/4" or 1/2" tape
`fd`	Diskette
`id`	IPI disk
`mt`	Tape Master 9-track 1/2" tape
`xd`	Xylogics 7053 disk
`xt`	Xylogics 1/2" tape
`xy`	Xylogics 440/450 disk

c A controller number (`0` if only one controller),

u A unit number (`0` if only one driver), and

p A partition.

pathname A pathname for a program such as `/stand/diag`.

arguments_list A list of up to seven arguments to pass to the program being booted.

`c` [*virtual_address*]
Resume execution of a program. When given, *virtual_address* is the address at which execution resumes. The default is the current PC. Registers are restored to the values shown by the `d`, and `r` commands.

`d` [*window_number*]
Display (dump) the state of the processor. The processor state is observable only after:

- An unexpected trap was encountered.
- A user program dropped into the monitor (by calling *abortent*).
- The user manually entered the monitor by typing L1–A or BREAK.

The display consists of the following:

- The special registers: PSR, PC, nPC, TBR, WIM, and Y
- Eight global registers
- 24 window registers (8 *in*, 8 *local*, and 8 *out*), corresponding to one of the 7 available windows. If a Floating-Point Unit is on board, its status register along with 32 floating-point registers are also shown.

window_number Display the indicated *window_number*, which can be any value between `0` and `6`, inclusive. If no window is specified and the PSR's current window pointer contains a valid window number, registers from the window that was active just prior to entry into the monitor are displayed. Otherwise, registers from window 0 are displayed.

`e` [*virtual_address*] [*action*] . . .
Open the 16-bit word at *virtual_address* (default zero). The address is interpreted in the address space defined by the `s` command. See the `a` command for a description of *action*.

`f` *virtual_address1 virtual_address2 pattern* [*size*]
Fill the bytes, words, or long words from *virtual_address1* (lower) to *virtual_address2* (higher) with the constant, *pattern*. The `size` argument can take one of the following values:

`b` byte format (the default)

`w` word format

`l` long word format

For example, the following command fills the address block from `0x1000` to `0x2000` with the word pattern, `0xABCD`:

```
f 1000 2000 ABCD W
```

`g` [*vector*] [*argument*]
`g` [*virtual_address*] [*argument*]
Goto (jump to) a predetermined or default routine (first form), or to a user-specified routine (second form). The value of *argument* is passed to the routine. If the *vector* or *virtual_address* argument is omitted, the value in the PC is used as the address to jump to.

To set up a predetermined routine to jump to, a user program must, prior to executing the monitor's `g` command, set the variable `*romp->v_vector_cmd` to be equal to the virtual address of the desired routine. Predetermined routines need not necessarily return control to the monitor.

The default routine, defined by the monitor, prints the user-supplied *vector* according to the format supplied in *argument*. This format can be one of:

`%x` hexadecimal

`%d` decimal

`g0`
Force a panic and produce a crash dump when the monitor is running as a result of the system being interrupted,

`g4`
(Sun-4 systems only) Force a kernel stack trace when the monitor is running as a result of the system being interrupted,

`h`
Display the help menu for monitor commands and their descriptions. To return to the monitor's basic command level, press ESCAPE or `q` before pressing RETURN.

`i` [*cache_data_offset*] [*action*] . . .
Modify cache data RAM command. Display and/or modify one or more of the cache data addresses. See the `a` command for a description of *action*.

`j` [*cache_tag_offset*] [*action*] . . .
Modify cache tag RAM command. Display and/or modify the contents of one or more of the cache tag addresses. See the `a` command for a description of *action*.

`k` [*reset_level*]
Reset the system, where *reset_level* is:

`0` Reset VMEbus, interrupt registers, video monitor (Sun-4 systems). This is the default.

`1` Software reset.

2 Power-on reset. Resets and clears the memory. Runs the EPROM-based diagnostic self test, which can take several minutes, depending upon how much memory is being tested.

`kb`
Display the system banner.

`l` [*virtual_address*] [*action*] . . .
Open the long word (32 bit) at memory address *virtual_address* (default zero). The address is interpreted in the address space defined by the `s` command (below). See the `a` command for a description of *action*.

`m` [*virtual_address*] [*action*] . . .
Open the segment map entry that maps *virtual_address* (default zero). The address is interpreted in the address space defined by the `s` command. See the `a` command for a description of *action*.

`ne`

`ni`
Disable, enable, or invalidate the cache, respectively.

`o` [*virtual_address*] [action*]* . . .
Open the byte location specified by *virtual_address* (default zero). The address is interpreted in the address space defined by the `s` command. See the `a` command for a description of *action*.

`p` [*virtual_address*] [*action*]. . .
Open the page map entry that maps *virtual_address* (default zero) in the address space defined by the `s` command. See the `a` command for a description of *action*.

`q` [*eeprom_offset*] [*action*]. . .
Open the EEPROM *eeprom_offset* (default zero) in the EEPROM address space. All addresses are referenced from the beginning or base of the EEPROM in physical address space, and a limit check is performed to insure that no address beyond the EEPROM physical space is accessed. This command is used to display or modify configuration parameters, such as: the amount of memory to test during self test, whether to display a standard or custom banner, if a serial port (A or B) is to be the system console, etc. See the `a` command for a description of *action*.

`r` [*register_number*]
`r` [*register_type*]
`r` [*w window_number*]
Display and/or modify one or more of the IU or FPU registers. A hexadecimal *register_number* can be one of:

`0x00`–`0x0f`	window(0,i0)–window(0,i7), window(0,i0)—window(0,i7)
`0x16`–`0x1f`	window(1,i0)–window(1,i7), window(1,i0)—window(1,i7)

`0x20–0x2f`	window(2,i0)–window(2,i7), window(2,i0)—window(2,i7)
`0x30–0x3f`	window(3,i0)–window(3,i7), window(3,i0)—window(3,i7)
`0x40–0x4f`	window(4,i0)–window(4,i7), window(4,i0)—window(4,i7)
`0x50–0x5f`	window(5,i0)–window(5,i7), window(5,i0)—window(5,i7)
`0x60–0x6f`	window(6,i0)–window(6,i7), window(6,i0)—window(6,i7)
`0x70–0x77`	`g0, g1, g2, g3, g4, g5, g6, g7`
`0x78–0x7d`	PSR, PC, nPC, WIM, TBR, Y.
`0x7e–0x9e`	FSR, f0–f31

Register numbers can only be displayed after an unexpected trap, a user program has entered the monitor using the *abortent* function, or the user has entered the monitor by manually typing L1–A or BREAK.

If a *register_type* is given, the first register of the indicated type is displayed. *register_type* can be one of:

`f`	floating-point
`g`	global
`s`	special

If `w` and a *window_number* (`0`—`6`) are given, the first *in*-register within the indicated window is displayed. If *window_number* is omitted, the window that was active just prior to entering the monitor is used. If the PSR's current window pointer is invalid, window 0 is used.

`s [`*asi*`])`

Set or display the Address Space Identifier. With no argument, `s` displays the current Address Space Identifier. The *asi* value can be one of:

`0x2`	control space
`0x3`	segment table
`0x4`	Page table
`0x8`	user instruction
`0x9`	supervisor instruction
`0xa`	user data
`0xb`	supervisor data
`0xc`	flush segment

`0xd` flush page

`0xe` flush context

`0xf` cache data

`u` [`echo`]

`u` [*port*] [*options*] [*baud_rate*]

`u` [`u`] [*virtual_address*]
With no arguments, display the current I/O device characteristics including: current input device, current output device, baud rates for serial ports A and B, an input-to-output echo indicator, and virtual addresses of mapped UART devices. With arguments, set or configure the current I/O device. With the `u` argument (`uu. . .`), set the I/O device to be the *virtual_address* of a UART device currently mapped.

`echo` Can be either `e` to enable input to be echoed to the output device, or `ne`, to indicate that input is not echoed.

port Assign the indicated *port* to be the current I/O device. *port* can be one of:

`a` serial port A

`b` serial port B

`k` the workstation keyboard

`s` the workstation screen

baud_rate Any legal baud rate.

options can be any combination of:

`i` input

`o` output

`u` UART

`e` echo input to output

`ne` do not echo input

`r` reset indicated serial port (`a` and `b` ports only)

If either `a` or `b` is supplied, and no *options* are given, the serial port is assigned for both input and output. If `k` is supplied with no options, it is assigned for input only. If `s` is supplied with no options, it is assigned for output only.

`v` *virtual_address1 virtual_address2* [`size`]
Display the contents of *virtual_address1* (lower) *virtual_address2* (higher) in the format specified by `size`:

`b` byte format (the default)

`w` word format

`l` long word format

Enter return to pause for viewing; enter another return character to resume the display. To terminate the display at any time, press the space bar.

For example, the following command displays the contents of virtual address space from address `0x1000` to `0x2000` in word format:

```
v 1000 2000 W
```

`w` [*virtual_address*] [*argument*]
Set the execution vector to a predetermined or default routine. Pass *virtual_address* and *argument* to that routine.

To set up a predetermined routine to jump to, a user program must, prior to executing the monitor's `w` command, set the variable `*romp->v_vector_cmd` to be equal to the virtual address of the desired routine. Predetermined routines need not necessarily return control to the monitor.

The default routine, defined by the monitor, prints the user-supplied *vector* according to the format supplied in *argument*. This format can be one of:

`%x` hexadecimal

`%d` decimal

`x`
Display a menu of extended tests. These diagnostics permit additional testing of such things as the I/O port connectors, video memory, workstation memory and keyboard, and boot device paths.

`y c` *context_number*

`y p|s` *context_number virtual_address*
Flush the indicated context, context page, or context segment.

`c` flush context *context_number*

`p` flush the page beginning at *virtual_address* within context *context_number*

`s` flush the segment beginning at *virtual_address* within context *context_number*

OpenBoot 2.x Command Reference Manual

Name mount, umount – mount or unmount file systems and remote resources

Synopsis

```
mount [-p | -v]

mount [-F FSType] [generic_options] [-o specific_options]
     [-O] special | mount_point

mount [-F FSType] [generic_options] [-o specific_options]
     [-O] special mount_point

mount -a [-F FSType] [-V] [current_options]
     [-o specific_options] [mount_point]...

umount [-f] [-V] [-o specific_options] special | mount_point

umount -a [-f] [-V] [-o specific_options] [mount_point]...
```

Description `mount` attaches a file system to the file system hierarchy at the *mount_point*, which is the pathname of a directory. If *mount_point* has any contents prior to the `mount` operation, these are hidden until the file system is unmounted.

`umount` unmounts a currently mounted file system, which may be specified either as a *mount_point* or as *special*, the device on which the file system resides.

The table of currently mounted file systems can be found by examining the mounted file system information file. This is provided by a file system that is usually mounted on `/etc/mnttab`. The mounted file system information is described in `mnttab(4)`. Mounting a file system adds an entry to the mount table; a `umount` removes an entry from the table.

When invoked with both the *special* and *mount_point* arguments and the `-F` option, `mount` validates all arguments except for *special* and invokes the appropriate *FSType*-specific `mount` module. If invoked with no arguments, `mount` lists all the mounted file systems recorded in the mount table, `/etc/mnttab`. If invoked with a partial argument list (with only one of *special* or *mount_point*, or with both *special* or *mount_point* specified but not *FSType*), `mount` will search `/etc/vfstab` for an entry that will supply the missing arguments. If no entry is found, and the special argument starts with "/", the default local file system type specified in `/etc/default/fs` will be used. Otherwise the default remote file system type will be used. The default remote file system type is determined by the first entry in the `/etc/dfs/fstypes` file. After filling in missing arguments, `mount` will invoke the *FSType*-specific `mount` module.

Only a super-user can mount or unmount file systems using `mount` and `umount`. However, any user can use `mount` to list mounted file systems and resources.

Options

`-F` *FSType*
: Used to specify the *FSType* on which to operate. The *FSType* must be specified or must be determinable from `/etc/vfstab`, or by consulting `/etc/default/fs` or `/etc/dfs/fstypes`.

`-a` [*mount_points*...]
: Perform mount or umount operations in parallel, when possible.

If mount points are not specified, `mount` will mount all file systems whose `/etc/vfstab` "mount at boot" field is "yes". If mount points are specified, then `/etc/vfstab` "mount at boot" field will be ignored.

If mount points are specified, `umount` will only `umount` those mount points. If none is specified, then `umount` will attempt to `unmount` all file systems in `/etc/mnttab`, with the exception of certain system required file systems: `/`, `/usr`, `/var`, `/var/adm`, `/var/run`, `/proc`, `/dev/fd` and `/tmp`.

`-f`
Forcibly unmount a file system.

Without this option, `umount` does not allow a file system to be unmounted if a file on the file system is busy. Using this option can cause data loss for open files; programs which access files after the file system has been unmounted will get an error (`EIO`).

`-p`
Print the list of mounted file systems in the `/etc/vfstab` format. Must be the only option specified. See `BUGS`.

`-v`
Print the list of mounted file systems in verbose format. Must be the only option specified.

`-V`
Echo the complete command line, but do not execute the command. `umount` generates a command line by using the options and arguments provided by the user and adding to them information derived from `/etc/mnttab`. This option should be used to verify and validate the command line.

generic_options
Options that are commonly supported by most *FSType*-specific command modules. The following options are available:

`-m`
Mount the file system without making an entry in `/etc/mnttab`.

`-g`
Globally mount the file system. On a clustered system, this globally mounts the file system on all nodes of the cluster. On a non-clustered system this has no effect.

`-o`
Specify *FSType*-specific options in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the *FSType*-specific module of the command. (See `mount_ufs(1M)`.) When you use `-o` with a file system that has an entry in `/etc/vfstab`, any `mount` options entered for that file system in `/etc/vfstab` are ignored.

The following options are supported:

`devices | nodevices`
Allow or disallow the opening of device-special files. The default is `devices`.

If you use `nosuid` in conjunction with `devices`, the behavior is equivalent to that of `nosuid`.

`exec | noexec`
Allow or disallow executing programs in the file system. Allow or disallow `mmap(2)` with `PROT_EXEC` for files within the file system. The default is `exec`.

`nbmand | nonbmand`
Allow or disallow non-blocking mandatory locking semantics on this file system. Non-blocking mandatory locking is disallowed by default.

If the file system is mounted with the `nbmand` option, then applications can use the `fcntl(2)` interface to place non-blocking mandatory locks on files and the system enforces those semantics. If you enable this option, it can cause standards conformant applications to see unexpected errors.

Do not use the `nbmand` option with `/`, `/var` and `/usr`.

You should not use the `remount` option to change the `nbmand` disposition of the file system. The `nbmand` option is mutually exclusive of the global option. See `-g`.

`ro | rw`
Specify read-only or read-write. The default is `rw`.

`setuid | nosetuid`
Allow or disallow `setuid` or `setgid` execution. The default is `setuid`.

If you specify `setuid` in conjunction with `nosuid`, the behavior is the same as `nosuid`.

`nosuid` is equivalent to `nosetuid` and `nodevices`. When `suid` or `nosuid` is combined with `setuid` or `nosetuid` and `devices` or `nodevices`, the most restrictive options take effect.

This option is highly recommended whenever the file system is shared by way of NFS with the `root=` option. Without it, NFS clients could add `setuid` programs to the server or create devices that could open security holes.

`suid | nosuid`
Allow or disallow `setuid` or `setgid` execution. The default is `suid`. This option also allows or disallows opening any device-special entries that appear within the filesystem.

`nosuid` is equivalent to `nosetuid` and `nodevices`. When `suid` or `nosuid` is combined with `setuid` or `nosetuid` and `devices` or `nodevices`, the most restrictive options take effect.

This option is highly recommended whenever the file system is shared using NFS with the `root=`*option*, because, without it, NFS clients could add `setuid` programs to the server, or create devices that could open security holes.

`-O`
Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error "device busy".

`-r`
Mount the file system read-only.

Usage See `largefile(5)` for the description of the behavior of `mount` and `umount` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files `/etc/mnttab`
Table of mounted file systems.

`/etc/default/fs`
Default local file system type. Default values can be set for the following flags in `/etc/default/fs`. For example: `LOCAL=ufs`

`LOCAL:`
The default partition for a command if no *FSType* is specified.

`/etc/vfstab`
List of default parameters for each file system.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `mount_cachefs(1M)`, `mount_hsfs(1M)`, `mount_nfs(1M)`, `mount_pcfs(1M)`, `mount_tmpfs(1M)`, `mount_ufs(1M)`, `mountall(1M)`, `umountall(1M)`, `fcntl(2)`, `mmap(2)`, `mnttab(4)`, `vfstab(4)`, `attributes(5)`, `largefile(5)`, `lofs(7FS)`, `pcfs(7FS)`

Notes If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

Bugs The `mount -p` output is incorrect for `cachefs`.

Name mountall, umountall – mount, unmount multiple file systems

Synopsis

```
mountall [-F FSType] [-l | -r] [file_system_table]

umountall [-k] [-s] [-F FSType] [-l | -r] [-n]  [-Z]

umountall [-k] [-s] [-h host] [-n] [-Z]
```

Description `mountall` is used to mount file systems specified in a file system table. The file system table must be in `vfstab(4)` format. If no *file_system_table* is specified, `/etc/vfstab` is used. If – is specified as *file_system_table*, `mountall` reads the file system table from the standard input. `mountall` mounts only those file systems with the `mount at boot` field set to `yes` in the *file_system_table*.

For each file system in the file system table, the following logic is executed: if there exists a file`/usr/lib/fs/`*FSType*`/fsckall`, where *FSType* is the type of the file system, save that file system in a list to be passed later, and all at once, as arguments to the `/usr/lib/fs/`*FSType*`/fsckall` script. The `/usr/lib/fs/`*FSType*`/fsckall` script checks all of the file systems in its argument list to determine whether they can be safely mounted. If no `/usr/lib/fs/`*FSType*`/fsckall` script exists for the *FSType* of the file system, the file system is individually checked using `fsck(1M)`. If the file system does not appear mountable, it is fixed using `fsck` before the mount is attempted. File systems with a – entry in the `fsckdev` field are mounted without first being checked.

`umountall` causes all mounted file systems in the current zone except `root`, `/usr`, `/var`, `/var/adm`, `/var/run`, `/proc`, and `/dev/fd` to be unmounted. If the *FSType* is specified, `mountall` and `umountall` limit their actions to the *FSType* specified. There is no guarantee that `umountall` unmounts *busy* file systems, even if the `-k` option is specified.

Options The following options are supported:

`-F` Specify the *FSType* of the file system to be mounted or unmounted.

`-h` *host* Unmount all file systems listed in `/etc/mnttab` that are remote-mounted from host.

`-k` Use the `fuser -k` *mount-point* command. See the `fuser(1M)` for details. The `-k` option sends the `SIGKILL` signal to each process using the file. As this option spawns kills for each process, the kill messages might not show up immediately. There is no guarantee that `umountall` unmounts *busy* file systems, even if the `-k` option is specified.

`-l` Limit the action to local file systems.

`-n` List the actions that would be performed for the specified options, but do not actually execute these actions. Repeating the command without the `-n` option executes the listed actions, assuming that the `/etc/mnttab` file has not changed in the interval prior to repeating the command.

`-r` Limit the action to remote file system types.

`-s` Do not perform the `umount` operation in parallel.

`-Z` Apply the action(s) only to the file systems mounted in non-global zones. By default, `umountall` unmounts only file systems mounted in the current zone. Option `-Z` is ignored if used in a non-global zone.

Files `/etc/mnttab`
Mounted file system table

`/etc/vfstab`
Table of file system defaults

`/usr/lib/fs/`*FSType*`/fsckall`
Script called by `mountall` to perform the file system check of all file systems of type *FSType*

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Committed
Output Stability	Uncommitted

See Also `fsck(1M)`, `fuser(1M)`, `mount(1M)`, `mnttab(4)`, `vfstab(4)`, `attributes(5)`

Diagnostics No messages are printed if the file systems are mountable and clean.

Error and warning messages come from `fsck(1M)` and `mount(1M)`.

Notes At this time, NFS is the only remote file system supported by the `-l`, `-r`, and `-h` options.

Name mount_cachefs – mount CacheFS file systems

Synopsis

```
mount -F cachefs [generic_options] -o backfstype=file_system_type
      [specific_options]
      [-O] special mount_point
```

Description The CacheFS-specific version of the `mount` command mounts a cached file system; if necessary, it NFS-mounts its back file system. It also provides a number of CacheFS-specific options for controlling the caching process. For more information regarding back file systems, refer to the *System Administration Guide: Basic Administration*.

`mount_cachefs` cannot be used with replicated NFS mounts. `mount_cachefs` creates a pass through when used with an NFS version 4 mount. No caching is performed.

Options To mount a CacheFS file system, use the generic `mount` command with the `-F` option followed by the argument `cachefs`.

See `mount(1M)` for a list of supported *generic_options*.

`-o` *specific_options* Specify CacheFS file system specific options in a comma-separated list with no intervening spaces.

`acdirmax=`*n* Specifies that cached attributes are held for no more than *n* seconds after directory update. After *n* seconds, all directory information is purged from the cache. The default value is `30` seconds.

`acdirmin=`*n* Specifies that cached attributes are held for at least *n* seconds after directory update. After *n* seconds, CacheFS checks to see if the directory modification time on the back file system has changed. If it has, all information about the directory is purged from the cache and new data is retrieved from the back file system. The default value is `30` seconds.

`acregmax=`*n* Specifies that cached attributes are held for no more than *n* seconds after file modification. After *n* seconds, all file information is purged from the cache. The default value is `30` seconds.

`acregmin=`*n*	Specifies that cached attributes are held for at least *n* seconds after file modification. After *n* seconds, CacheFS checks to see if the file modification time on the back file system has changed. If it has, all information about the file is purged from the cache and new data is retrieved from the back file system. The default value is `30` seconds.
`actimeo=`*n*	Sets `acregmin`, `acregmax`, `acdirmin`, and `acdirmax` to *n*.
`backfstype=`*file_system_type*	The file system type of the back file system (can be `nfs` or `hsfs`).
`backpath=`*path*	Specifies where the back file system is already mounted. If this argument is not supplied, CacheFS determines a mount point for the back file system. The back file system must be read-only.
`cachedir=`*directory*	The name of the cache directory.
`cacheid=`*ID*	*ID* is a string specifying a particular instance of a cache. If you do not specify a cache ID, CacheFS will construct one.
`demandconst`	Verifies cache consistency only when explicitly requested, rather than the periodic checking that is done by default. A consistency check is requested by using the `-s` option of the `cfsadmin(1M)` command. This option is useful for back file systems that change infrequently, for example, `/usr/openwin`. `demandconst` and `noconst` are mutually exclusive.
`local-access`	Causes the front file system to interpret the mode bits used for access checking instead of having the back file system verify access

permissions. Do not use this argument with secure NFS.

`noconst` — Disables cache consistency checking. By default, periodic consistency checking is enabled. Specify `noconst` only when you know that the back file system will not be modified. Trying to perform cache consistency check using `cfsadmin -s` will result in error. `demandconst` and `noconst` are mutually exclusive.

`write-around` | `non-shared` — Write modes for CacheFS. The `write-around` mode (the default) handles writes the same as NFS does; that is, writes are made to the back file system, and the affected file is purged from the cache. You can use the `non-shared` mode when you are sure that no one else will be writing to the cached file system. In this mode, all writes are made to both the front and the back file system, and the file remains in the cache.

`-O` — Overlay mount. Allows the filesystem to be mounted over an existing mount point, making the underlying filesystem inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, mount will fail with the error: `mount -F cachefs: mount failed Device busy`.

Examples

EXAMPLE 1 CacheFS-mounting a File System

The following example CacheFS-mounts the file system `server1:/user2`, which is already NFS-mounted on `/usr/abc` as `/xyz`.

```
example# mount -F cachefs -o backfstype=nfs,backpath=/usr/abc,
     cachedir=/cache1 server1:/user2 /xyz
```

The lines similar to the following appear in the `/etc/mnttab` file after the `mount` command is executed:

```
server1:/user2   /usr/abc        nfs
/usr/abc         /cache1/xyz    cachefs     backfstype=nfs
```

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `cfsadmin`(1M), `fsck_cachefs`(1M), `mount`(1M), `attributes`(5) *System Administration Guide: Basic Administration*

Bugs The output for the *generic_option* `-p` output is incorrect for `cachefs`.

Name mountd – server for NFS mount requests and NFS access checks

Synopsis

```
/usr/lib/nfs/mountd [-v] [-r]
```

Description `mountd` is an RPC server that answers requests for NFS access information and file system mount requests. It reads the file `/etc/dfs/sharetab` to determine which file systems are available for mounting by which remote machines. See `sharetab(4)`. `nfsd` running on the local server will contact `mountd` the first time an NFS client tries to access the file system to determine whether the client should get read-write, read-only, or no access. This access can be dependent on the security mode used in the remoted procedure call from the client. See `share_nfs(1M)`.

The command also provides information as to what file systems are mounted by which clients. This information can be printed using the `showmount(1M)` command.

The `mountd` daemon is automatically invoked by `share(1M)`.

Only super user can run the `mountd` daemon.

Options The options shown below are supported for NVSv2/v3 clients. They are not supported for Solaris NFSv4 clients.

`-r` Reject mount requests from clients. Clients that have file systems mounted will not be affected.

`-v` Run the command in verbose mode. Each time `mountd` determines what access a client should get, it will log the result to the console, as well as how it got that result.

Files `/etc/dfs/sharetab` shared file system table

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnfssu

See Also `nfsd(1M)`, `share(1M)`, `share_nfs(1M)`, `showmount(1M)`, `nfs(4)`, `sharetab(4)`, `attributes(5)`

Notes Since `mountd` must be running for `nfsd` to function properly, `mountd` is automatically started by the `svc:/network/nfs/server` service. See `nfs(4)`.

Some routines that compare hostnames use case-sensitive string comparisons; some do not. If an incoming request fails, verify that the case of the hostname in the file to be parsed matches the case of the hostname called for, and attempt the request again.

Name mount_hsfs – mount hsfs file systems

Synopsis

```
mount -F hsfs [generic_options]
     [-o FSType-specific_options] [-O ] special | mount_point

mount -F hsfs [generic_options]
     [-o FSType-specific_options] [-O] special  mount_point
```

Description `mount` attaches a High Sierra file system (hsfs) to the file system hierarchy at the *mount_point*, which is the pathname of a directory. If *mount_point* has any contents prior to the `mount` operation, these are hidden until the file system is unmounted.

If `mount` is invoked with *special* or *mount_point* as the only arguments, `mount` will search `/etc/vfstab` to fill in the missing arguments, including the *FSType-specific_options*; see `mount(1M)` for more details.

If the file system being mounted contains `Rock Ridge` extensions, by default they will be used, enabling support of features not normally available under High Sierra file systems such as symbolic links, and special files.

Options

generic_options — See `mount(1M)` for the list of supported options.

`-o` — Specify `hsfs` file system specific options. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available:

`global` | `noglobal` — If `global` is specified and supported on the file system, and the system in question is part of a cluster, the file system will be globally visible on all nodes of the cluster. If `noglobal` is specified, the mount will not be globally visible. The default behavior is `noglobal`.

`ro` — Mount the file system read-only. This option is required.

`nrr` — `no Rock Ridge`: if `Rock Ridge` extensions are present in the file system, ignore them; interpret it as a regular High Sierra file system.

`notraildot` — File names on High Sierra file systems consist of a proper name and an extension separated by a '.' (dot) character. By default, the separating dot is always considered part of the file's name for all file access operations, even if there is no extension present. Specifying `notraildot` makes it optional to specify the trailing dot to access a file whose name lacks an extension.

Exceptions: This option is effective only on file systems for which `Rock Ridge` extensions are not active, either because they are not present on the CD-ROM, or they are explicitly ignored via the `nrr` option. If `Rock Ridge` extensions are active, `hsfs` quietly ignores this option.

`nomaplcase` — File names on High Sierra cdroms with no `Rock Ridge` extensions present should be uppercase characters only. By default, `hsfs` maps file names read from a `non-Rock Ridge` disk to all lowercase characters. `nomaplcase` turns off this mapping. The exceptions for `notraildot` discused above apply to `nomaplcase`.

`-O` — Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error `device busy`.

Files

`/etc/mnttab` table of mounted file systems

`/etc/vfstab` list of default parameters for each file system

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also

`mount(1M)`, `mountall(1M)`, `mount(2)`, `mnttab(4)`, `vfstab(4)`, `attributes(5)`

Notes

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

Name mount_nfs – mount remote NFS resources

Synopsis

```
mount [-F nfs] [generic_options] [-o specific_options] [-O] resource

mount [-F nfs] [generic_options] [-o specific_options] [-O] mount_point

mount [-F nfs] [generic_options] [-o specific_options]
     [-O] resource mount_point
```

Description The `mount` utility attaches a named *resource* to the file system hierarchy at the pathname location *mount_point*, which must already exist. If *mount_point* has any contents prior to the `mount` operation, the contents remain hidden until the *resource* is once again unmounted.

`mount_nfs` starts the `lockd(1M)` and `statd(1M)` daemons if they are not already running.

If the resource is listed in the `/etc/vfstab` file, the command line can specify either *resource* or *mount_point*, and `mount` consults `/etc/vfstab` for more information. If the `-F` option is omitted, `mount` takes the file system type from `/etc/vfstab`.

If the resource is not listed in the `/etc/vfstab` file, then the command line must specify both the *resource* and the *mount_point*.

host can be an IPv4 or IPv6 address string. As IPv6 addresses already contain colons, enclose *host* in a pair of square brackets when specifying an IPv6 address string. Otherwise the first occurrence of a colon can be interpreted as the separator between the host name and path, for example, `[1080::8:800:200C:417A]:tmp/file`. See `inet(7P)` and `inet6(7P)`.

host:*pathname*
: Where *host* is the name of the NFS server host, and *pathname* is the path name of the directory on the server being mounted. The path name is interpreted according to the server's path name parsing rules and is not necessarily slash-separated, though on most servers, this is the case.

nfs://*host*[:*port*]/*pathname*
: This is an NFS URL and follows the standard convention for NFS URLs as described in *NFS URL Scheme*, RFC 2224. See the discussion of URL's and the public option under `NFS FILE SYSTEMS` for a more detailed discussion.

host:*pathname* *nfs*://*host*[:*port*]/*pathname*
: *host*:*pathname* is a comma-separated list of *host*:*pathname*.

  See the discussion of replicated file systems and failover under `NFS FILE SYSTEMS` for a more detailed discussion.

hostlist pathname
: *hostlist* is a comma-separated list of hosts.

  See the discussion of replicated file systems and failover under `NFS FILE SYSTEMS` for a more detailed discussion.

The mount command maintains a table of mounted file systems in /etc/mnttab, described in mnttab(4).

mount_nfs supports both NFSv3 and NFSv4 mounts. The default NFS version is NFSv4.

Options See mount(1M) for the list of supported *generic_options*. See share_nfs(1M) for a description of server options.

-o *specific_options*
Set file system specific options according to a comma-separated list with no intervening spaces.

acdirmax=*n*
Hold cached attributes for no more than *n* seconds after directory update. The default value is 60.

acdirmin=*n*
Hold cached attributes for at least *n* seconds after directory update. The default value is 30.

acregmax=*n*
Hold cached attributes for no more than *n* seconds after file modification. The default value is 60.

acregmin=*n*
Hold cached attributes for at least *n* seconds after file modification. The default value is 3.

actimeo=*n*
Set *min* and *max* times for regular files and directories to *n* seconds. See "File Attributes," below, for a description of the effect of setting this option to 0.

See "Specifying Values for Attribute Cache Duration Options," below, for a description of how acdirmax, acdirmin, acregmax, acregmin, and actimeo are parsed on a mount command line.

bg | fg
If the first attempt fails, retry in the background, or, in the foreground. The default is fg.

forcedirectio | noforcedirectio
If forcedirectio is specified, then for the duration of the mount, forced direct I/O is used. If the filesystem is mounted using forcedirectio, data is transferred directly between client and server, with no buffering on the client. If the filesystem is mounted using noforcedirectio, data is buffered on the client. forcedirectio is a performance option that is of benefit only in large sequential data transfers. The default behavior is noforcedirectio.

grpid
By default, the GID associated with a newly created file obeys the System V semantics; that is, the GID is set to the effective GID of the calling process. This behavior can be

overridden on a per-directory basis by setting the set-GID bit of the parent directory; in this case, the GID of a newly created file is set to the GID of the parent directory (see `open(2)` and `mkdir(2)`). Files created on file systems that are mounted with the `grpid` option obeys BSD semantics independent of whether the set-GID bit of the parent directory is set; that is, the GID is unconditionally inherited from that of the parent directory.

`hard` | `soft`
Continue to retry requests until the server responds (`hard`) or give up and return an error (`soft`). The default value is `hard`. Note that NFSv4 clients do not support soft mounts.

`intr` | `nointr`
Allow (do not allow) keyboard interrupts to kill a process that is hung while waiting for a response on a hard-mounted file system. The default is `intr`, which makes it possible for clients to interrupt applications that can be waiting for a remote mount.

`noac`
Suppress data and attribute caching. The data caching that is suppressed is the write-behind. The local page cache is still maintained, but data copied into it is immediately written to the server.

`nocto`
Do not perform the normal close-to-open consistency. When a file is closed, all modified data associated with the file is flushed to the server and not held on the client. When a file is opened the client sends a request to the server to validate the client's local caches. This behavior ensures a file's consistency across multiple NFS clients. When `-nocto` is in effect, the client does not perform the flush on close and the request for validation, allowing the possiblity of differences among copies of the same file as stored on multiple clients.

This option can be used where it can be guaranteed that accesses to a specified file system are made from only one client and only that client. Under such a condition, the effect of `-nocto` can be a slight performance gain.

`port=`*n*
The server IP port number. The default is `NFS_PORT`. If the `port` option is specified, and if the resource includes one or more NFS URLs, and if any of the URLs include a `port` number, then the `port` number in the option and in the URL must be the same.

`posix`
Request POSIX.1 semantics for the file system. Requires a mount Version 2 `mountd(1M)` on the server. See `standards(5)` for information regarding POSIX.

`proto=`*netid* | `rdma`
By default, the transport protocol that the NFS mount uses is the first available TCP transport supported both by the client and the server. If no TCP transport is found, then it attempts to use a UDP transport, as ordered in the `/etc/netconfig` file.

Use this option to override the default behavior.

`proto` is set to the value of *netid* or `rdma`. *netid* is the value of the `network_id` field entry in the `/etc/netconfig` file.

The UDP protocol is not supported for NFS Version 4. If you specify a UDP protocol with the `proto` option, NFS version 4 is not used.

`public`
The `public` option forces the use of the public file handle when connecting to the NFS server. The resource specified might not have an NFS URL. See the discussion of URLs and the public option under `NFS FILE SYSTEMS` for a more detailed discussion.

`quota` | `noquota`
Enable or prevent `quota(1M)` to check whether the user is over quota on this file system; if the file system has quotas enabled on the server, quotas are still checked for operations on this file system.

`remount`
Remounts a read-only file system as read-write (using the `rw` option). This option cannot be used with other `-o` options, and this option works only on currently mounted read-only file systems.

`retrans=`*n*
Set the number of NFS retransmissions to *n*. The default value is `5`. For connection-oriented transports, this option has no effect because it is assumed that the transport performs retransmissions on behalf of NFS.

`retry=`*n*
The number of times to retry the `mount` operation. The default for the `mount` command is `10000`.

The default for the automounter is `0`, in other words, do not retry. You might find it useful to increase this value on heavily loaded servers, where automounter traffic is dropped, causing unnecessary server not responding errors.

`rsize=`*n*
Set the read buffer size to a maximum of *n* bytes. The default value is `1048576` when using connection-orientated transports with Version 3 or Version 4 of the NFS protocol, and `32768` when using connection-less transports. The default can be negotiated down if the server prefers a smaller transfer size. "`Read`" operations may not necessarily use the maximum buffer size. When using Version 2, the default value is `32768` for all transports.

`sec=`*mode*
Set the security *mode* for NFS transactions. If `sec=` is not specified, then the default action is to use `AUTH_SYS` over NFS Version 2 mounts, or to negotiate a *mode* over NFS Version 3 or Version 4 mounts.

NFS Version 3 mounts negotiate a security mode when the server returns an array of security modes. The client picks the first mode in the array that is supported on the client. In negotiations, an NFS Version 3 client is limited to the security flavors listed in `/etc/nfssec.conf`.

NFS Version 4 mounts negotiate a security mode when the server returns an array of security modes. The client attempts the mount with each security mode, in order, until one is successful.

Only one mode can be specified with the `sec=` option. See `nfssec(5)` for the available *mode* options.

`secure`
This option has been deprecated in favor of the `sec=`*dh* option.

`timeo=`*n*
Set the NFS timeout to *n* tenths of a second. The default value is `11` tenths of a second for connectionless transports, and `600` tenths of a second for connection-oriented transports. This value is ignored for connectionless transports. Such transports might implement their own timeouts, which are outside the control of NFS.

`vers=`*NFS version number*
By default, the version of NFS protocol used between the client and the server is the highest one available on both systems. The default maximum for the client is Version 4. This can be changed by setting the `NFS_CLIENT_VERSMAX` parameter in `/etc/default/nfs` to a valid version (2, 3, or 4). If the NFS server does not support the client's default maximum, the next lowest version attempted until a matching version is found.

`wsize=`*n*
Set the write buffer size to a maximum of *n* bytes. The default value is `1048576` when using connection-orientated transports with Version 3 or Version 4 of the NFS protocol, and `32768` when using connection-less transports. The default can be negotiated down if the server prefers a smaller transfer size. "`Write`" operations may not necessarily use the maximum buffer size. When using Version 2, the default value is `32768` for all transports.

`xattr` | `noxattr`
Allow or disallow the creation and manipulation of extended attributes. The default is `xattr`. See `fsattr(5)` for a description of extended attributes.

`-O`
Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount fails, producing the error "device busy."

Nfs File Systems

Background versus Foreground

File systems mounted with the `bg` option indicate that `mount` is to retry in the background if the server's mount daemon (`mountd(1M)`) does not respond. `mount` retries the request up to the count specified in the `retry=`*n* option. (Note that the default value for `retry` differs between `mount` and `automount`. See the description of `retry`, above.) Once the file system is mounted, each NFS request made in the kernel waits `timeo=`*n* tenths of a second for a response. If no response arrives, the time-out is multiplied by `2` and the request is retransmitted. When the number of retransmissions has reached the number specified in the `retrans=`*n* option, a file system mounted with the `soft` option returns an error on the request; one mounted with the `hard` option prints a warning message and continues to retry the request.

Hard versus Soft

File systems that are mounted read-write or that contain executable files should always be mounted with the `hard` option. Applications using `soft` mounted file systems can incur unexpected I/O errors, file corruption, and unexpected program core dumps. The soft option is not recommended.

Authenticated requests

The server can require authenticated NFS requests from the client. `sec=`*dh* authentication might be required. See `nfssec(5)`.

URLs and the public option

If the `public` option is specified, or if the *resource* includes and NFS URL, `mount` attempts to connect to the server using the public file handle lookup protocol. See *WebNFS Client Specification*, RFC 2054. If the server supports the public file handle, the attempt is successful; `mount` does not need to contact the server's `rpcbind(1M)` and the `mountd(1M)` daemons to get the port number of the `mount` server and the initial file handle of *pathname*, respectively. If the NFS client and server are separated by a firewall that allows all outbound connections through specific ports, such as `NFS_PORT`, then this enables NFS operations through the firewall. The public option and the NFS URL can be specified independently or together. They interact as specified in the following matrix:

	Resource Style	
	host:*pathname*	NFS URL
public option	Force public file handle and fail mount if not supported.	Force public file handle and fail mount if not supported.
	Use Native paths.	Use Canonical paths.
default	Use MOUNT protocol.	Try public file handle with Canonical paths. Fall back to MOUNT protocol if not supported.

A Native path is a path name that is interpreted according to conventions used on the native operating system of the NFS server. A Canonical path is a path name that is interpreted according to the URL rules. See *Uniform Resource Locators (URL)*, RFC 1738. See Examples for uses of Native and Canonical paths.

Replicated file systems and failover

resource can list multiple read–only file systems to be used to provide data. These file systems should contain equivalent directory structures and identical files. It is also recommended that they be created by a utility such as `rdist(1)`. The file systems can be specified either with a comma–separated list of *host:/pathname* entries and/or NFS URL entries, or with a comma –separated list of hosts, if all file system names are the same. If multiple file systems are named and the first server in the list is down, failover uses the next alternate server to access files. If the read–only option is not chosen, replication is disabled. File access, for NFS Versions 2 and 3, is blocked on the original if NFS locks are active for that file.

File Attributes

To improve NFS read performance, files and file attributes are cached. File modification times get updated whenever a write occurs. However, file access times can be temporarily out-of-date until the cache gets refreshed.

The attribute cache retains file attributes on the client. Attributes for a file are assigned a time to be flushed. If the file is modified before the flush time, then the flush time is extended by the time since the last modification (under the assumption that files that changed recently are likely to change soon). There is a minimum and maximum flush time extension for regular files and for directories. Setting `actimeo=`*n* sets flush time to *n* seconds for both regular files and directories.

Setting `actimeo=0` disables attribute caching on the client. This means that every reference to attributes is satisfied directly from the server though file data is still cached. While this guarantees that the client always has the latest file attributes from the server, it has an adverse effect on performance through additional latency, network load, and server load.

Setting the `noac` option also disables attribute caching, but has the further effect of disabling client write caching. While this guarantees that data written by an application is written directly to a server, where it can be viewed immediately by other clients, it has a significant adverse effect on client write performance. Data written into memory-mapped file pages (`mmap(2)`) are not written directly to this server.

Specifying Values for Attribute Cache Duration Options

The attribute cache duration options are `acdirmax`, `acdirmin`, `acregmax`, `acregmin`, and `actimeo`, as described under OPTIONS. A value specified for `actimeo` sets the values of all attribute cache duration options except for any of these options specified following `actimeo` on a `mount` command line. For example, consider the following command:

```
example# mount -o acdirmax=10,actimeo=1000 server:/path /localpath
```

Because `actimeo` is the last duration option in the command line, its value (`1000`) becomes the setting for all of the duration options, including `acdirmax`. Now consider:

```
example# mount -o actimeo=1000,acdirmax=10 server:/path /localpath
```

Because the `acdirmax` option follows `actimeo` on the command line, it is assigned the value specified (`10`). The remaining duration options are set to the value of `actimeo` (`1000`).

Examples

EXAMPLE 1 Mounting an NFS File System

To mount an NFS file system:

```
example# mount serv:/usr/src /usr/src
```

EXAMPLE 2 Mounting An NFS File System Read-Only With No suid Privileges

To mount an NFS file system read-only with no suid privileges:

```
example# mount -r -o nosuid serv:/usr/src /usr/src
```

EXAMPLE 3 Mounting An NFS File System Over Version 2, with the UDP Transport

To mount an NFS file system over Version 2, with the UDP transport:

```
example# mount -o vers=2,proto=udp serv:/usr/src /usr/src
```

EXAMPLE 4 Mounting an NFS File System Using An NFS URL

To mount an NFS file system using an NFS URL (a canonical path):

```
example# mount nfs://serv/usr/man /usr/man
```

EXAMPLE 5 Mounting An NFS File System Forcing Use Of The Public File Handle

To mount an NFS file system and force the use of the public file handle and an NFS URL (a canonical path) that has a non 7–bit ASCII escape sequence:

```
example# mount -o public nfs://serv/usr/%A0abc /mnt/test
```

EXAMPLE 6 Mounting an NFS File System Using a Native Path

To mount an NFS file system using a native path (where the server uses colons (":") as the component separator) and the public file handle:

```
example# mount -o public serv:C:doc:new /usr/doc
```

EXAMPLE 7 Mounting a Replicated Set of NFS File Systems with the Same Pathnames

To mount a replicated set of NFS file systems with the same pathnames:

```
example# mount serv—a,serv—b,serv—c:/usr/man /usr/man
```

EXAMPLE 8 Mounting a Replicated Set of NFS File Systems with Different Pathnames

To mount a replicated set of NFS file systems with different pathnames:

```
example# mount serv—x:/usr/man,serv—y:/var/man,nfs://serv-z/man /usr/man
```

Files

`/etc/mnttab`
table of mounted file systems

`/etc/dfs/fstypes`
default distributed file system type

`/etc/vfstab`
table of automatically mounted resources

Attributes

See `attributes(5)` for descriptions of the following attributes:

Callaghan, Brent, *WebNFS Client Specification*, RFC 2054, October 1996.

Callaghan, Brent, *NFS URL Scheme*, RFC 2224, October 1997.

Berners-Lee, Masinter & McCahill , *Uniform Resource Locators (URL)*, RFC 1738, December 1994.

Notes

An NFS server should not attempt to mount its own file systems. See `lofs(7FS)`.

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on *the directory to which the symbolic link refers,* rather than being mounted on top of the symbolic link itself.

SunOS 4.x used the `biod` maintenance procedure to perform parallel read-ahead and write-behind on NFS clients. SunOS 5.x made `biod` obsolete with multi-threaded processing, which transparently performs parallel read-ahead and write-behind.

Since the root (`/`) file system is mounted read-only by the kernel during the boot process, only the `remount` option (and options that can be used in conjunction with `remount`) affect the root (`/`) entry in the `/etc/vfstab` file.

`mount_cachefs` cannot be used with replicated NFS mounts or any NFS Version 4 mount.

Name mount_pcfs – mount pcfs file systems

Synopsis

```
mount -F pcfs [generic_options]
     [-o FSType-specific_options] special | mount_point

mount -F pcfs [generic_options]
     [-o FSType-specific_options] special mount_point
```

Description `mount` attaches an MS-DOS file system (`pcfs`) to the file system hierarchy at the *mount_point*, which is the pathname of a directory. If *mount_point* has any contents prior to the `mount` operation, these are hidden until the file system is unmounted.

If `mount` is invoked with *special* or *mount_point* as the only arguments, `mount` will search `/etc/vfstab` to fill in the missing arguments, including the *FSType-specific_options*; see `mount(1M)` for more details.

The *special* argument can be one of two special device file types:

- A floppy disk, such as `/dev/diskette0` or `/dev/diskette1`.
- A DOS logical drive on a hard disk expressed as *device-name*:*logical-drive* , where *device-name* specifies the special block device-file for the whole disk and *logical-drive* is either a drive letter (c through z) or a drive number (1 through 24). Examples are `/dev/dsk/c0t0d0p0:`*c* and `/dev/dsk/c0t0d0p0:`*1*.

The *special* device file type must have a formatted MS-DOS file system with either a 12-bit, 16-bit, or 32-bit File Allocation Table.

Options *generic_options*

See `mount(1M)` for the list of supported options.

`-o`

Specify `pcfs` file system-specific options. The following options are supported:

`foldcase` | `nofoldcase`

Force uppercase characters in filenames to lowercase when reading them from the filesystem. This is for compatibility with the previous behavior of `pcfs`. The default is `nofoldcase`.

`hidden` | `nohidden`

Allow or disallow listing of files with hidden or system bits set. Option `hidden` is the default. When `nohidden` is effect, hidden and system files are neither visible nor accessible. Note that PCFS in previous releases of the Solaris operating system used the `nohidden` option as the default.

`atime` | `noatime`

Enable or disable write access timestamps on DOS-formatted media. Default for fixed disks is `atime`, while for removable media `noatime` is used. The latter default is so that writes to flash-based media (“memory sticks”) can be minimized, to prolong lifetime.

`timezone=`*timezone*
Timestamps on DOS-formatted media are recorded in the local time of the recording system. This can cause confusion when accessing removable media in which the recording and receiving system use different time zones. Use this option to force media timestamps to be interpreted for a specific time zone. The `mount_pcfs` command converts the given time zone name into a numerical offset that is passed to the `pcfs` kernel module, using the same rules as described in `environ(5)` for the `TZ` environment variable. By default, the `timezone` value is taken from the `TZ` environment variable.

Notes

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

Name mount_tmpfs – mount tmpfs file systems

Synopsis `mount [-F tmpfs] [-o` *specific_options*`] [-O]` *special mount_point*

Description `tmpfs` is a memory based file system which uses kernel resources relating to the VM system and page cache as a file system.

`mount` attaches a `tmpfs` file system to the file system hierarchy at the pathname location *mount_point*, which must already exist. If *mount_point* has any contents prior to the `mount` operation, these remain hidden until the file system is once again unmounted. The attributes (mode, owner, and group) of the root of the `tmpfs` filesystem are inherited from the underlying *mount_point*, provided that those attributes are determinable. If not, the root's attributes are set to their default values.

The *special* argument is usually specified as `swap` but is in fact disregarded and assumed to be the virtual memory resources within the system.

Options

`-o` *specific_options* Specify `tmpfs` file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available:

size=*sz* The *sz* argument controls the size of this particular `tmpfs` file system. If the argument is has a 'k' suffix, the number will be interpreted as a number of kilobytes. An 'm' suffix will be interpreted as a number of megabytes. No suffix is interpreted as bytes. In all cases, the actual size of the file system is the number of bytes specified, rounded up to the physical pagesize of the system.

`xattr` | `noxattr` Allow or disallow the creation and manipulation of extended attributes. The default is `xattr`. See `fsattr(5)` for a description of extended attributes.

`-O` Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error`device busy`.

Notes If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

Name mount_udfs – mount a udfs file system

Synopsis

```
mount -F udfs [generic_options] [-o specific_options] [-O] special mount_point

mount -F udfs [generic_options] [-o specific_options] [-O] special | mount_point
```

Description The `mount` utility attaches a `udfs` file system to the file system hierarchy at the *mount_point*, which is the pathname of a directory. If *mount_point* has any contents prior to the mount operation, these are hidden until the file system is unmounted.

If mount is invoked with either *special* or *mount_point* as the only arguments, `mount` searches `/etc/vfstab` to fill in the missing arguments, including the *specific_options*. See `mount(1M)`.

If *special* and *mount_point* are specified without any *specific_options*, the default is `rw`.

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

Options See `mount`(1M) for the list of supported *generic_options*.

The following options are supported:

`-o` *specific_options* Specify `udfs` file system specific options in a comma-separated list with no intervening spaces. The following *specific_options* are available:

- m — Mount the file system without making an entry in `/etc/mnttab`.
- remount — Remount the file system as read-write. The option is used in conjunction with the `rw` option.

  A file system mounted read-only can be remounted as read-write. This option fails if the file system is not currently mounted.

`-O` Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount fails, producing the error `device busy`.

Diagnostics

not super user	The command is run by a non-root user. Run as root.
no such device	The device name specified does not exist.
not a directory	The specified mount point is not a directory.
is not an udfs file system	The device specified does not contain a udf 1.50 file system or the udfs file system module is not available.
is already mounted	The specified device is already in use.
not a block device	The device specified is not a block device. Use block device to mount.
write-protected	The device is read-only.
is corrupted. needs checking	The file system is in an inconsistent state. Run `fsck`.

Notes Copy-protected files can be stored on DVD-ROM media using Universal Disk Format (UDF). Reading these copy-protected files is not possible as this involves an authentication process. Unless an authentication process between the host and the drive is completed, reading these copy-protected files after mounting and before the authentication process, returns an error.

Name mount_ufs – mount ufs file systems

Synopsis

```
mount -F ufs [generic_options] [-o specific_options]
     [-O] special | mount_point

mount -F ufs [generic_options] [-o specific_options]
     [-O] special mount_point
```

Description The `mount` utility attaches a `ufs` file system to the file system hierarchy at the *mount_point*, which is the pathname of a directory. If *mount_point* has any contents prior to the `mount` operation, these are hidden until the file system is unmounted.

The `ufs` file system supports direct mounting of files containing the file system as well as block devices. See `mount(1M)` and `lofiadm(1M)`.

If `mount` is invoked with *special* or *mount_point* as the only arguments, `mount` will search `/etc/vfstab` to fill in the missing arguments, including the *specific_options*. See `mount(1M)`.

If *special* and *mount_point* are specified without any *specific_options*, the default is `rw`.

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

Options See `mount(1M)` for the list of supported *generic_options*.

The following options are supported:

`-o` *specific_options*
Specify `ufs` file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available:

`dfratime` | `nodfratime`
By default, writing access time updates to the disk may be deferred (`dfratime`) for the file system until the disk is accessed for a reason other than updating access times. `nodfratime` disables this behavior.

If power management is enabled on the system, do not set `nodfratime` unless `noatime` is also set. If you set `nodfratime` without setting `noatime`, the disk is spun up every time a file within a file system on the disk is accessed - even if the file is not modified.

`forcedirectio` | `noforcedirectio`
If `forcedirectio` is specified and supported by the file system, then for the duration of the mount, forced direct I/O will be used. If the filesystem is mounted using `forcedirectio`, data is transferred directly between user address space and the disk. If the filesystem is mounted using `noforcedirectio`, data is buffered in kernel address

space when data is transferred between user address space and the disk. `forcedirectio` is a performance option that is of benefit only in large sequential data transfers. The default behavior is `noforcedirectio`.

`global` | `noglobal`
If `global` is specified and supported on the file system, and the system in question is part of a cluster, the file system will be globally visible on all nodes of the cluster. If `noglobal` is specified, the mount will not be globally visible. The default behavior is `noglobal`.

`intr` | `nointr`
Allow (do not allow) keyboard interrupts to kill a process that is waiting for an operation on a locked file system. The default is `intr`.

`largefiles` | `nolargefiles`
If `nolargefiles` is specified and supported by the file system, then for the duration of the mount it is guaranteed that all regular files in the file system have a size that will fit in the smallest object of type `off_t` supported by the system performing the mount. The mount will fail if there are any files in the file system not meeting this criterion. If `largefiles` is specified, there is no such guarantee. The default behavior is `largefiles`.

If `nolargefiles` is specified, `mount` will fail for `ufs` if the file system to be mounted has contained a large file (a file whose size is greater than or equal to 2 Gbyte) since the last invocation of `fsck` on the file system. The large file need not be present in the file system at the time of the mount for the mount to fail; it could have been created previously and destroyed. Invoking `fsck` (see `fsck_ufs(1M)`) on the file system will reset the file system state if no large files are present. After invoking `fsck`, a successful mount of the file system with `nolargefiles` specified indicates the absence of large files in the file system; an unsuccessful mount attempt indicates the presence of at least one large file.

`logging` | `nologging`
If `logging` is specified, then logging is enabled for the duration of the mounted file system. Logging is the process of storing transactions (changes that make up a complete UFS operation) in a log before the transactions are applied to the file system. Once a transaction is stored, the transaction can be applied to the file system later. This prevents file systems from becoming inconsistent, therefore reducing the possibility that `fsck` might run. And, if `fsck` is bypassed, logging generally reduces the time required to reboot a system.

The default behavior is `logging` for all UFS file systems.

The log is allocated from free blocks in the file system, and is sized approximately 1 Mbyte per 1 Gbyte of file system, up to a maximum of 256 Mbytes. The log size may be larger (up to a maximum of 512 Mbytes) dependent upon the number of cylinder groups present in the file system.

Logging is enabled on any UFS file system, including root (`/`), except under the following conditions:

- When logging is specifically disabled.
- If there is insufficient file system space for the log. In this case, the following message is displayed and file system is still mounted:

```
# mount /dev/dsk/c0t4d0s0 /mnt
  /mnt: No space left on device
  Could not enable logging for /mnt on  /dev/dsk/c0t4d0s0.
```

The log created by UFS logging is continually flushed as it fills up. The log is totally flushed when the file system is unmounted or as a result of the `lockfs -f` command.

`m`
Mount the file system without making an entry in `/etc/mnttab`.

`noatime`
By default, the file system is mounted with normal access time (`atime`) recording. If `noatime` is specified, the file system will ignore access time updates on files, except when they coincide with updates to the `ctime` or `mtime`. See `stat(2)`. This option reduces disk activity on file systems where access times are unimportant (for example, a Usenet news spool).

`noatime` turns off access time recording regardless of `dfratime` or `nodfratime`.

The POSIX standard requires that access times be marked on files. `-noatime` ignores them unless the file is also modified.

`nosec`
By default, Access Control Lists (ACLs) are supported on a mounted UFS file system. Use this option to disallow the setting or any modification of an ACL on a file within a mounted UFS file system. See `getfacl(1)` for background on ACLs.

`onerror` = *action*
This option specifies the action that UFS should take to recover from an internal inconsistency on a file system. Specify *action* as `panic`, `lock`, or `umount`. These values cause a forced system shutdown, a file system lock to be applied to the file system, or the file system to be forcibly unmounted, respectively. The default is `panic`.

`quota`
Quotas are turned on for the file system.

`remount`
Remounts a file system with a new set of options. All options not explicitly set with `remount` revert to their default values.

`rq`
Read-write with quotas turned on. Equivalent to `rw, quota`.

`xattr` | `noxattr`
Allow or disallow the creation and manipulation of extended attributes. The default is `xattr`. See `fsattr(5)` for a description of extended attributes.

`-O`
Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error "device busy".

Examples

EXAMPLE 1 Turning Off (and On) Logging

The following command turns off logging on an already mounted file system. The subsequent command restores logging.

```
# mount -F ufs -o remount,nologging /export
# (absence of message indicates success)
# mount -F ufs -o remount,logging /export
```

In the preceding commands, the `-F ufs` option is not necessary.

Files

`/etc/mnttab`
table of mounted file systems

`/etc/vfstab`
list of default parameters for each file system

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

See Also

`getfacl(1)`, `fsck(1M)`, `fsck_ufs(1M)`, `lofiadm(1M)`, `mount(1M)`, `mountall(1M)`, `fcntl(2)`, `mount(2)`, `stat(2)`, `mnttab(4)`, `vfstab(4)`, `attributes(5)`, `fsattr(5)`, `largefile(5)`

Notes

Since the root (`/`) file system is mounted read-only by the kernel during the boot process, only the `remount` option (and options that can be used in conjunction with `remount`) affect the root (`/`) entry in the `/etc/vfstab` file.

Name mount_xmemfs – mount xmemfs file systems

Synopsis

```
mount -F xmemfs [generic_options] -o[largebsize,]size=sz
     [-O] special mount_point
```

Interface Level `xmemfs` is obsolete. Users requiring large physical memory should migrate to 64-bit platform support.

Description `xmemfs` is an extended memory file system which provides file system semantics to manage and access large amounts of physical memory which can exceed 4 GB in size.

`mount` attaches a `xmemfs` file system to the file system hierarchy at the pathname location `mount_point`, which must already exist. If `mount_point` has any contents prior to the mount operation, these remain hidden until the file system is once again unmounted. The attributes (`mode`, `owner`, and `group`) of the root of the `xmemfs` filesystem are inherited from the underlying `mount_point`, provided that those attributes are determinable. If not, the root's attributes are set to their default values.

The special argument is not currently used by `xmemfs` but a placeholder, (such as `xmem`), needs to be specified nevertheless.

Options See `mount(1M)` for the list of supported *generic_options*.

`-o`*specific_options* Specify `xmemfs` file system specific options in a comma-separated list with *no intervening spaces*. If invalid options are specified, a warning message is printed and the invalid options are ignored.

The `size=`*sz specific option* is required.

The following options are available:

size=*sz* The *sz* argument specifies the desired size of this particular `xmemfs` file system. If the *sz* argument has a `k` suffix, the number is interpreted as kilobytes. An `m` suffix is interpreted as megabytes and `g` is interpreted as gigabytes. A *sz* specified with no suffix is interpreted as bytes.

In all cases, the actual size of the file system is the number of bytes specified, rounded up to the physical `pagesize` of the system or to the large page size if `largebsize` is specified.

This *specific_option* is required.

largebsize If `largebsize` is specified, `xmemfs` uses the large memory page size as the file system block size. On `IA32`, the large memory page size with `mmu36` which supports PAE (Physical Address Extension) is 2 MB. The large memory

page size without `mmu36/PAE` is 4 MB. If there is no large page support, the file system block size is `PAGESIZE`.

`-O` Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount fails, producing the error `device busy`.

Files `/etc/mnttab` table of mounted file systems

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Architecture	i386
Interface Stability	Obsolete

See Also `mount(1M)`, `mount(2)`, `mkdir(2)`, `open(2)`, `umount(2)`, `mnttab(4)`, `attributes(5)`,`xmemfs(7FS)`

Notes If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

The only file types allowed on xmemfs are directories and regular files. The execution of object files resident in `xmemfs` is not supported. Execution is prevented by not allowing users to set execute permissions on regular files.

Support for `xmemfs` may be removed in a future release of Solaris.

Name mpathadm – multipath discovery and administration

Synopsis `mpathadm` *subcommand direct-object* `[`*options*`] [`*operand*`]`

Description The `mpathadm` command enables multipathing discovery and management. The `mpathadm` command is implemented as a set of subcommands, many with their own options, that are described in the section for that subcommand. Options not associated with a particular subcommand are described under OPTIONS. The `mpathadm` subcommands operate on a *direct-object*. These are described in this section for each subcommand. The *direct-objects*, *initiator-port*, *target-port*, and*logical-unit* in the subcommands are consistent with SCSI standard definitions.

The `mpathadm` command supports the following subcommands, which are described in detail in subsections that follow.

`list`	Display a list of discovered instances for a given object.
`show`	Display information about a given object instance.
`modify`	Modify properties of an object.
`enable`	Enable an object.
`disable`	Disable an object.
`failover`	Cause target port group failover for a logical-unit.
`override`	Set a path to be used over other paths on a logical-unit.

The `mpathadm` subcommands operate on a *direct-object*. These are described in this section for each subcommand.

list Subcommand The syntax for the `list` subcommand is:

```
# mpathadm list direct-object [operands...]
```

The `list` subcommand displays data for following direct-objects:

`mpath-support` [*mpath-support-name*, ...]
List the multipathing support that can be administered by this CLI. This presents itself in the form of a library name registered through the MPAPI framework. If no mpath-support name *mpath-support-name* is specified, all registered multipathing support libraries will be displayed.

`initiator-port` [*initiator-port-name*, ...]
List the initiator ports that are discovered on this system. If no *initiator-port-name* is specified, all discovered initiator ports are displayed.

{`logical-unit` | `lu`} [*options*] [*logical-unit-name*, ...]
List the information on multipath logical units. If no *logical-unit-name* is specified, all discovered logical-units will be displayed.

Options for `list logical-unit` are as follows:

`-n`, `--name` *name*	Return the logical unit name that is associated with the given name string. This name can be extracted from the output of the `mpathadm show lu` command.
`-t`, `--target-port` *target-port-name*	Return the list of logical units names that are associated with the given *target-port-name*.

`show` Subcommand The syntax for the `show` subcommand is:

```
# mpathadm show direct-object [operands...]
```

The `show` subcommand displays detailed information for following the direct-objects:

`mpath-support` [*mpath-support-name*, ...]
Show the detailed information on the given *mpath-support-name* if the name exists. If the given *mpath-support-name* supports only a limited set of device products, the list of device products will be listed as part of the output.

`initiator-port` *initiator-port-name*[,*initiator-port-name*, ...]
Show the detailed information for the given *initiator-port-name*.

{`logical-unit` | `lu`} [*logical-unit-name*, ...]
Display the detailed information on multipath logical unit(s), including path and target port group information. Note that the name property in the logical unit information represents the identifier for this LUN, derived from the hardware, and used by this system. If the name is derived from SCSI Inquiry Vital Product Data (VPD) page 83h, the name type property represents an associated identifier type defined by the SCSI standards.

`modify` Subcommand The syntax for the `modify` subcommand is:

```
# mpathadm modify direct-object [options] [operands...]
```

The `modify` subcommand modifies characteristics of the following direct-objects:

`mpath-support` [*options*] *mpath-support-name*, ...
Configuration management of an *mpath-support*. Options to modify mpath-support are as follows:

Set auto failback. Applicable only when mpath-support provides auto failback support.

Set auto probing. Applicable only when mpath-support provides auto probing support.

Change the default load balance type. The `loadbalance` type is one of the

supported types listed in the `show mpath-support` output.

{`logical-unit` | `lu`} [*options*] *logical-unit-name*, ... — Configuration management of a logical unit. Options to modify `logical-unit` are as follows:

Set auto failback. Applicable only when `mpath-support` provides auto failback support

Set auto probing. Applicable only when `mpath-support` provides auto probing support.

Set load balance type for the logical unit. Applicable only when load balance configuration is supported at the logical unit level.

`enable` Subcommand

The syntax for the `enable` subcommand is:

```
# mpathadm disable [options]
```

The `enable` subcommand supports the following direct-objects to be enabled:

`path -i` *initiator-port-name* `-t` *target-port-name* `-l` *logical-unit-name* — The path that consists of the specified initiator port, target port, and logical unit will be enabled.

`disable` Subcommand

The syntax for the `disable` subcommand is:

```
# mpathadm disable [options]
```

The `disable` subcommand supports the following direct-objects to be disabled:

`path -i` *initiator-port-name* `-t` *target-port-name* `-l` *logical-unit-name* — The path that consists of the specified initiator port, target port, and logical unit will be disabled.

`failover` Subcommand

The syntax for the `failover` subcommand is:

```
# mpathadm failover direct-object [operand]
```

The `failover` subcommand supports failover for the following direct-objects:

{`logical-unit` | `lu`} *logical-unit-name* — The target port group will failover when the given logical-unit is asymmetric and supports explicit

state change. The currently active target port group will be changed to the standby state and the standby target port group will be active.

`override` Subcommand

The syntax for the `override` subcommand is:

```
# mpathadm override [options]
```

The `override` subcommand controls whether or not the following direct-objects override another:

path {`-i` *initiator-port-name* `-t` *target-port-name* | `-c`} `-l` *logical-unit-name*

Cause a path that consists of the specified initiator port, target port, and logical unit to override other paths on the logical unit. Once a path overrides other paths, the mpath-support uses only that path regardless of any other path selection configuration. The `-c` option cancels the setting. The path that consists of the specified initiator port, target port, and logical unit will be disabled.

Options for override path are as follows:

`-i`, `--initiator-port` *initiator-port-name*	Represent the initiator port element of a path. Options `-t` and `-l` must also be included.
`-t`, `--target-port` *target-port-name*	Represent the target port element of a path. Options `-i` and `-l` must also be included.
`-l`, `--logical-unit` *logical-unit*	Represent the logical unit element of a path. Options `-i` and `-t` must also be included.
`-c`, `--cancel`	Cancels overriding setting for the given logical unit. Option `-l` must also be included.

Options The following options are supported:

`-V`, `--version`	Display the version information.
`-?`, `--help`	Display context help. Can be used following an `mpathadm` command with no arguments, following a subcommand, or following a subcommand direct-object combination. Responds with help information appropriate for your entry. For example, if you enter: **`# mpathadm add mpath-support-help`** ... `mpathadm` responds with a display of the options available for that combination of subcommand and direct-object.

Examples

EXAMPLE 1 Obtaining a List of Multipathing Support

The following command uses the `list` subcommand to list all currently registered `mpath-support` libraries.

```
# mpathadm list mpath-support
mpath-support: libmpscsi_vhci.so
```

EXAMPLE 2 Displaying the Properties of a Particular Multipathing Support

The following command uses the `show` subcommand to display the properties for a currently registered `mpath-support` library.

```
# mpathadm show mpath-support libmpscsi_vhci.so
mpath-support:    libmpscsi_vhci.so
       Vendor:  Sun Microsystems
       Driver Name:  scsi_vhci
       Default Load Balance:  round-robin
       Supported Load Balance Types:
              round-robin
          logical-block
Allows To Activate Target Port Group Access:  yes
Allows Path Override:  no
Supported Auto Failback Config:     1
Auto Failback:    on
Failback Polling Rate (current/max):  0/0
Supported Auto Probing Config:    0
Auto Probing:  NA
Probing Polling Rate (current/max):  NA/NA
Supported Devices:
       Vendor:     SUN
       Product:  T300
       Revision:
       Supported Load Balance Types:
              round-robin
       Vendor:     SUN
       Product:  T4
       Revision:
       Supported Load Balance Types:
              round-robin
```

EXAMPLE 3 Obtaining a List of Initiator Ports Discovered Through the `mpath-support` Libraries

The following command uses the `list initiator-port` subcommand to display a list of initiator ports discovered by the currently registered `mpath-support` libraries.

```
# mpathadm list initiator-port
Initiator-Port: iqn.1986-03.com.sun:01:080020b7ac2b.437a3b3e,4000002a0000
Initiator-Port: 2000000173018713
Initiator-Port: 2000000173818713
```

EXAMPLE 4 Displaying the Properties of a Particular Initiator Port

The following command uses the `show initiator-port` subcommand to display the properties of a particular initiator port discovered using the `list initiator-port` subcommand in an example above.

```
# mpathadm show initiator-port 2000000173018713
initiator-port:     2000000173018713
        Transport Type:     Fibre Channel
        OS device File:     devices/pci@1f,4000/pci@2/SUNW,qlca@5/fp@0,0:fc
```

EXAMPLE 5 Displaying the Properties of a Particular Logical Unit

The following command uses the `show logical-unit` subcommand to display the properties of the logical unit with the specified name.

```
# mpathadm show lu /dev/rdsk/c4t60003BA27D2120004204AC2B000DAB00d0s2
Logical Unit: /dev/rdsk/c4t60003BA27D2120004204AC2B000DAB00d0s2
           mpath-support libmpscsi_vhci.so
           Vendor: SUN
           Product: T4
           Revision: 0301
    Name Type: SCSI Inquiry VPD Page 83 type 3
    Name: 60003ba27d2120004204ac2b000dab00
    Asymmetric: yes
    Current Load Balance: round-robin
    Logical Unit Group ID: NA
    Aauto Failback: on
    Auto Probing: NA

Paths:
    Initiator Port Name: 2000000173818713
    Target Port Name: 20030003ba27d212
    Override Path: NA
    Path State: OK
    Disabled: no

    Initiator Port Name: 2000000173018713
    Target Port Name: 20030003ba27d095
    Override Path: NA
    Path State: OK
    Disabled: no

Target Port Group:
    ID: 2
    Explicit Failover: yes
    Access State: standby
    Target Ports:
            Name: 20030003ba27d212
```

EXAMPLE 5 Displaying the Properties of a Particular Logical Unit *(Continued)*

```
          Relative ID: 0

    ID: 5
    Explicit Failover: yes
    Access State: active
    Target Ports
           Name: 20030003ba27d095
          Relative ID: 0
```

EXAMPLE 6 Enabling a Path

The following command uses the `enable path` subcommand to enable the path with the specified initiator port, target port, and logical unit.

```
# mpathadm enable path -i 2000000173018713 -t 20030003ba27d095     \
-l /dev/rdsk/c4t60003BA27D2120004204AC2B000DAB00d0s2
```

EXAMPLE 7 Modifying `mpath-support` To Turn On `autofailback`

```
# mpathadm modify mpath-support -a on libmpscsi_vhci.so
```

Attributes

Name mpstat – report per-processor or per-processor-set statistics

Synopsis

```
/usr/bin/mpstat [-aq] [-p | -P set] [interval [count]]
```

Description The `mpstat` command reports processor statistics in tabular form. Each row of the table represents the activity of one processor. The first table summarizes all activity since boot. Each subsequent table summarizes activity for the preceding interval. All values are rates listed as events per second unless otherwise noted.

During execution of the kernel status command, the `state` of the kernel can change. If relevant, a state change message is included in the `mpstat` output, in one of the following forms:

```
<<processor 3 moved from pset: -1 to: 1>>
<<pset destroyed: 1>>
<<pset created: 1>>
<<processors added: 1, 3>>
<<processors removed: 1, 3>>
```

The `mpstat` command reports the following information:

`CPU` or `SET`	Without the `-a` option, `mpstat` reports `CPU` statistics for a processor ID. With the `-a` option, `mpstat` reports `SET` statistics for a processor set ID.
`minf`	minor faults
`mjf`	major faults
`xcal`	inter-processor cross-calls
`intr`	interrupts
`ithr`	interrupts as threads (not counting clock interrupt)
`csw`	context switches
`icsw`	involuntary context switches
`migr`	thread migrations (to another processor)
`smtx`	spins on mutexes (lock not acquired on first try)
`srw`	spins on readers/writer locks (lock not acquired on first try)
`syscl`	system calls
`usr`	percent user time
`sys`	percent system time
`wt`	the I/O wait time is no longer calculated as a percentage of CPU time, and this statistic will always return zero.
`idl`	percent idle time

`sze`	number of processors in the requested processor set
`set`	processor set membership of each CPU

Options The following options are supported:

`-a`	Aggregate output by processor set. Sort the output by set. The default output is sorted by CPU number.
`-p`	Report processor set membership of each CPU. Sort the output by set. The default output is sorted by CPU number.
`-P` *set*	Display only those processors in the specified *set*.
`-q`	Suppress messages related to state changes.
interval	Report once each *interval* seconds.
count	Only print *count* reports.

Examples **EXAMPLE 1** Using `mpstat` to Generate User and System Operation Statistics

The following command generates processor statistics over a five–second interval in two reports. The command shows the processor set membership of each CPU. The default output is sorted by CPU number, aggregated by *processor set*, for user (`usr`) and system (`sys`) operations.

```
example% mpstat -ap 5 2

SET minf mjf xcal intr ithr csw icsw migr smtx srw syscl usr sys wt idl sze
  0    6   0  355  291  190  22    0    0    0   0    43   0   2  0  43   1
  1   24  17  534  207  200  70    1    0    2   0   600   4   1  0  84   2
  2   19   7  353  325  318  44    0    0    5   0   345   1   1  0  94   3
  3   36   2  149  237  236  14    0    0    4   0    97   0   0  0  98   2
SET minf mjf xcal intr ithr csw icsw migr smtx srw syscl usr sys wt idl sze
  0    1   0  720  405  304  55    0    0   18   0    12   0  15  0  81   1
  1    0  69 1955  230  200 313   33    4   41   9  7086  34  10  0  19   2
  2    0  46  685  314  300 203   11    0   54   1  5287  36   6  0  28   3
  3    0   0   14  386  384   0    0    0    0   0     0   0   0  0 100   2
```

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	See below.

Invocation is evolving. Human readable output is unstable.

See Also sar(1), iostat(1M), sar(1M), vmstat(1M), attributes(5)

Notes The sum of CPU utilization might vary slightly from 100 due to rounding errors in the production of a percentage figure.

The total time used for CPU processing is the sum of `usr` and `sys` output values, reported for user and system operations. The `idl` value reports the time that the CPU is idle for any reason other than pending disk I/O operations.

Run the `iostat` command with the `-x` option to report I/O service times in `svc_t` output. The `iostat` utility also reports the same `wt`, user (`us`), and system (`sy`) statistics. See iostat(1M) for more information.

When executing in a `zone` and if the pools facility is active, `mpstat`(1M) will only provide information for those processors which are a member of the processor set of the pool to which the `zone` is bound.

Name msgid – generate message IDs

Synopsis `/usr/sbin/msgid`

Description The `msgid` utility generates message IDs.

A message ID is a numeric identifier that uniquely identifies a message. Although the probability of two distinct messages having the same ID is high, this can be greatly reduced with the appropriate priority or facility.level designator (see `syslogd(1M)`). Specifically, the message ID is a hash signature on the message's unexpanded format string, generated by `STRLOG_MAKE_MSGID()` as defined in `<sys/strlog.h>`.

`syslogd(1M)` is a simple filter that takes strings as input and produces those same strings, preceded by their message IDs, as output. Every message logged by `syslogd`(1M) includes the message ID. The message ID is intended to serve as a small, language-independent identifier.

Examples **EXAMPLE 1** Using the msgid command to generate a message ID

The following example uses the `msgid` command to generate a message ID for the `echo` command.

```
example# echo hello | msgid205790 hello
```

EXAMPLE 2 Using the msgid command to generate a message catalog

The following example uses the `msgid` command to enumerate all of the messages in the binary `ufs`, to generate a message catalog.

```
example# strings /kernel/fs/ufs | msgid

137713 free:
    freeing free frag, dev:0x%lx, blk:%ld, cg:%d, ino:%lu, fs:%s
567420 ialloccg: block not in mapfs = %s
845546 alloc: %s: file system full
...
```

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `syslogd(1M)`, `attributes(5)`, `log(7D)`

Name mvdir – move a directory

Synopsis `/usr/sbin/mvdir` *dirname name*

Description `mvdir` moves directories within a file system. `dirname` must be a directory. If *name* does not exist, it will be created as a directory. If *name* does exist, and is a directory, `dirname` will be created as *name/dirname*. `dirname` and *name* may not be on the same path; that is, one may not be subordinate to the other. For example:

```
example% mvdir x/y x/z
```

is legal, but

```
example% mvdir x/y x/y/z
```

is not.

Operands

`dirname` The name of the directory that is to be moved to another directory in the filesystem.

name The name of the directory into which `dirname` is to be moved. If *name* does not exist, it will be created. It may not be on the same path as `dirname`.

Usage See `largefile(5)` for the description of the behavior of `mvdir` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Exit Status

`0` Successful operation.

`>0` Operation failed.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `mkdir(1)`, `mv(1)`, `attributes(5)`, `largefile(5)`

Name named, in.named – Internet domain name server

Synopsis

```
named [-fgsVv] [-c config-file] [-d debug-level] [-m flag]
      [-n #cpus] [-p port] [-S #max-socks] [-t directory]
      [-u user] [-x cache-file] [-4 | -6]
```

Description The `named` utility is a Domain Name System (DNS) server, part of the BIND 9 distribution from ISC. For more information on the DNS, see RFCs 1033, 1034, and 1035.

When invoked without arguments, `named` reads the default configuration file `/etc/named.conf`, reads any initial data, and listens for queries.

`in.named` is a link to `named`.

Options The following options are supported:

`-4`
Use only IPv4 transport. By default, both IPv4 and IPv6 transports can be used. Options `-4` and `-6` are mutually exclusive.

`-6`
Use only IPv6 transport. By default, both IPv4 and IPv6 transports can be used. Options `-4` and `-6` are mutually exclusive.

`-c` *config-file*
Use *config-file* as the configuration file instead of the default `/etc/named.conf`. To ensure that reloading the configuration file continues to work after the server has changed its working directory due to to a possible *directory* option in the configuration file, *config-file* should be an absolute pathname.

`-d` *debug-level*
Set the daemon's debug level to *debug-level*. Debugging traces from `named` become more verbose as the debug level increases.

`-f`
Run the server in the foreground (that is, do not run as a daemon).

`-g`
Run the server in the foreground and force all logging to `stderr`.

`-m` *flag*
Turn on memory usage debugging flags. Possible flags are `usage`, `trace`, and `record`, `size`, and `mctx`. These correspond to the `ISC_MEM_DEBUG`*XXXX* flags described in `<isc/mem.h>`.

`-n` *#cpus*
Create *#cpus* worker threads to take advantage of multiple CPUs. If not specified, `named` will try to determine the number of CPUs present and create one thread per CPU. If it is unable to determine the number of CPUs, a single worker thread will be created.

`-p` *port*
Listen for queries on port *port*. If not specified, the default is port 53.

`-S` *#max-socks*
Allow `named` to use up to *#max-socks* sockets.

This option should be unnecessary for the vast majority of users. The use of this option could even be harmful, because the specified value might exceed the limitation of the underlying system API. It therefore should be set only when the default configuration causes exhaustion of file descriptors and the operational environment is known to support the specified number of sockets. Note also that the actual maximum number is normally a little smaller than the specified value because `named` reserves some file descriptors for its internal use.

`-s`
Write memory usage statistics to *stdout* on exit.

This option is mainly of interest to BIND 9 developers and might be removed or changed in a future release.

`-t` *directory*
Change the root directory using `chroot(2)` to *directory* after processing the command line arguments, but before reading the configuration file.

This option should be used in conjunction with the `-u` option, as chrooting a process running as root does not enhance security on most systems; the way `chroot()` is defined allows a process with root privileges to escape a `chroot` jail.

`-u` *user*
Set the real user ID using `setuid(2)` to *user* after completing privileged operations, such as creating sockets that listen on privileged ports.

`-V`
Report the version number and build options, and exit.

`-v`
Report the version number and exit.

`-x` *cache-file*
Load data from *cache-file* into the cache of the default view.

Do not use this option. It is of interest only to BIND 9 developers and might be removed or changed in a future release.

Extended Description

This section describes additional attributes of `named`.

SMF Properties

When starting named from the service management facility, `smf(5)`, `named` configuration is read from the service configuration repository. Use `svcprop(1)` to list the properties and `svccfg(1M)` to make changes.

The following application configuration properties are available to administrators:

`options/`*server*
Specifies the server executable to be used instead of the default server, `/usr/sbin/named`.

`options/`*configuration_file*
Specifies the configuration file to be used instead of the default, `/etc/named.conf`. A directory option might be specified in the configuration file. To ensure that reloading the configuration file continues to work in such a situation, *configuration_file* should be specified as an absolute pathname. This pathname should not include the *chroot_dir* pathname. This property is the equivalent of the `-c` option.

`options/`*ip_interfaces*
Specifies over which IP transport, IPv4 or IPv6, BIND will transmit. Possible values are `IPv4` or `IPv6`. Any other setting assumes `all`, the default. This property is the equivalent of command line option `-4` or `-6`

`options/`*listen_on_port*
Specifies the default UDP and TCP port to be used for listening to DNS requests. This property is the equivalent of the command line option `-p` *port*.

`options/`*debug_level*
Specifies the default debug level. The default is 0, which means no debugging. The higher the number the more verbose debug information becomes. Equivalent of the command line option `-d` *debug_level*.

`options/`*threads*
Specifies the number of CPU worker threads to create. The default of 0 causes `named` to try and determine the number of CPUs present and create one thread per CPU. Equivalent of command line option `-n` *#cpus*.

`options/`*chroot_dir*
Specifies the directory to be used as the root directory after processing SMF properties and the command line arguments but before reading the configuration file. Use this property when using a `chroot(2)` environment. Synonymous to command line option `-t` *pathname*.

When using `chroot(2)`, `named` is unable to disable itself when receiving `rndc(1M)` `stop` or `halt` commands. Instead, you must use the `svcadm(1M)` `disable` command.

In the event of a configuration error originating in one of the above SMF application options, `named` displays a message providing information about the error and the parameters that need correcting. The process then exits with exit code `SMF_EXIT_ERR_CONFIG`.

At startup, in the event of an error other than a configuration error, `named` exits with exit code `SMF_EXIT_ERR_FATAL`. Both of this code and `SMF_EXIT_ERR_CONFIG` cause the start method, `smf_method(5)`, to place the service in the maintenance state, which can be observed with the `svcs(1)` command `svcs -x`.

In addition to the properties listed above, the following property can be used to invoke `named` as a user other than root:

`start/`*user*
Specifies the identity of the user that is invoking `named`. See `smf_method(5)` and `chroot(2)`. Note that the user must have `solaris.smf.manage.bind` authorization. Without this role the `named` will be unable to manage its SMF FMRI and `named` will automatically be restarted by the SMF after an `rndc(1M)` `stop` or `halt` command. See `EXAMPLES` for a sequence of commands that establishes the correct authorization.

SIGNALS In routine operation, signals should not be used to control the nameserver; `rndc(1M)` should be used instead.

`SIGHUP`
Force a reload of the server.

`SIGINT`, `SIGTERM`
Shut down the server.

The result of sending any other signals to the server is undefined.

Configuration The `named` configuration file is too complex to describe in detail here. A list of configuration options is provided in the `named.conf` man page shipped with the BIND 9 distribution. A complete description is provided in the *BIND 9 Administrator Reference Manual*.

Examples

EXAMPLE 1 Configuring `named` to Transmit Only over IPv4 Networks

The following command sequence configures `named` such that it will transmit only over IPv4 networks.

```
# svccfg -s svc:network/dns/server:default setprop \
> options/ip_interfaces=IPv4
# svcadm refresh svc:network/dns/server:default
#
```

EXAMPLE 2 Listing Current Configuration File and Setting an Alternative File

The following sequence of commands lists the current `named` configuration file and sets an alternative file.

```
# svcprop -p options/configuration_file dns/server:default
/etc/named.conf
# svccfg -s dns/server:default setprop \
> options/configuration_file=/var/named/named.conf
# svcadm refresh dns/server:default
# svcprop -p options/configuration_file dns/server:default
/var/named/named.conf
```

EXAMPLE 3 Establishing Appropriate Authorization for `named`

To have `named` start with the `solaris.smf.manage.bind` authorization, perform the steps shown below.

Add the user `dnsadmin` to the `solaris.smf.manage.bind` role:

EXAMPLE 3 Establishing Appropriate Authorization for named *(Continued)*

```
# usermod -A solaris.smf.manage.bind dnsadmin
Observe effect of command:
# tail -1 /etc/user_attr
dnsadmin::::type=normal;auths=solaris.smf.manage.bind
```

Modify the service properties:

```
# svccfg
svc:> select svc:/network/dns/server:default
svc:/network/dns/server:default> setprop start/user = dnsadmin
svc:/network/dns/server:default> setprop start/group = dnsadmin
svc:/network/dns/server:default> exit
# svcadm refresh svc:/network/dns/server:default
# svcadm restart svc:/network/dns/server:default
```

Because only root has write access to create the default process-ID file, `/var/run/named/named.pid`, named must be configured to use an alternative path for the user `dnsadmin`. Here is an example of how to accomplish this:

```
# mkdir /var/named/tmp
# chown dnsadmin /var/named/tmp
```

Shown below is what you must add to `named.conf` to make use of the directory created above.

```
# head /etc/named.conf
options {
directory "/var/named";
pid-file "/var/named/tmp/named.pid";
};
```

Files

`/etc/named.conf`
default configuration file

`/var/run/named/named.pid`
default process-ID file

The `named.conf` man page shipped with the BIND 9 distribution

Name named-checkconf – named configuration file syntax checking tool

Synopsis

```
named-checkconf [-hjvz] [-t directory] filename
```

Description The `named-checkconf` utility checks the syntax, but not the semantics, of a specified configuration file.

Options The following options are supported:

`-h`
Display the usage summary and exit.

`-j`
When loading a zonefile, read the journal if it exists.

`-t` *directory*
Change the root directory to *directory* so that include directives in the configuration file are processed as if run by a named configuration whose root directory has been similarly changed.

`-v`
Print the version of the `named-checkconf` program and exit.

`-z`
Perform a test load of the master zones found in `named.conf`.

Operands The following operands are supported:

filename
The name of the configuration file to be checked. If not specified, it defaults to `/etc/named.conf`.

Exit Status

`0`
No errors were detected.

`1`
An error was detected.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/dns/bind
Interface Stability	Volatile

Name named-checkzone, named-compilezone – zone file validity checking or converting tool

Synopsis

```
named-checkzone [-Ddhjqv] [-c class] [-F format] [-f format]
     [-i mode] [-k mode] [-M mode] [-m mode] [-n mode]
     [-o filename] [-S mode] [-s style] [-t directory]
     [-W mode] [-w directory] zonename filename

named-compilezone [-Ddjqv] [-C mode] [-c class] [-F format]
     [-f format] [-i mode] [-k mode] [-m mode] [-n mode]
     [-o filename] [-s style] [-t directory]
     [-W mode] [-w directory] zonename filename
```

Description The `named-checkzone` utility checks the syntax and integrity of a zone file. It performs the same checks as `named(1M)` does when loading a zone. The `named-checkzone` utility is useful for checking zone files before configuring them into a name server.

`named-compilezone` is similar to `named-checkzone`, differing in that it always dumps the zone contents to a specified file in a specified format. Additionally, it applies stricter check levels by default, since the dump output will be used as an actual zone file loaded by `named(1M)`. Unless manually specified otherwise, the check levels must be at least as strict as those specified in the `named` configuration file.

Options For either or both utilities, the following options are supported:

`-c` *class*
Specify the class of the zone. If not specified, "IN" is assumed.

`-D`
Dump zone file in canonical format.

`-d`
Enable debugging.

`-F` *format*
Specify the format of the output file specified. Possible formats are `text` (default) and `raw`. For `named-checkzone`, this does not cause any effects unless it dumps the zone contents.

`-f` *format*
Specify the format of the zone file. Possible formats are `text` (default) and `raw`.

`-h`
Display usage message for `named-checkzone`.

`-i` *mode*
Perform post-load zone integrity checks. Possible modes are `full` (default), `full-sibling`, `local`, `local-sibling`, and `none`.

Mode `full` checks that MX records refer to the A or AAAA record (both in-zone and out-of-zone hostnames). Mode `local` checks only MX records that refer to in-zone hostnames.

Mode `full` checks that SRV records refer to the A or AAAA record (both in-zone and out-of-zone hostnames). Mode `local` checks only SRV records that refer to in-zone hostnames.

Mode `full` checks that delegation NS records refer to A or AAAA record (both in-zone and out-of-zone hostnames). It also checks that glue address records in the zone match those advertised by the child. Mode `local` checks only NS records that refer to in-zone hostnames or check that some required glue exists, that is, when the nameserver is in a child zone.

Mode `full-sibling` and `local-sibling` disable sibling glue checks, but are otherwise the same as `full` and `local`, respectively.

Mode `none` disables the checks.

`-k` *mode*
Perform "check-name" checks with the specified failure mode. Possible modes are `fail` (default for `named-compilezone`), `warn` (default for `named-checkzone`) and `ignore`.

`-j`
Read the journal, if it exists, when loading the zone file.

`-M` *mode*
Check if an MX record refers to a `CNAME`. Possible modes are `fail`, `warn` (default) and `ignore`.

`-m` *mode*
Specify whether MX records should be checked to see if they are addresses. Possible modes are `fail`, `warn` (default) and `ignore`.

`-n` *mode*
Specify whether NS records should be checked to see if they are addresses. Possible modes are `fail` (default for `named-compilezone`), `warn` (default for `named-checkzone`) and `ignore`.

`-o` *filename*
Write zone output to *filename*. If filename is `-` (a hyphen), then write to standard out. The hyphen mandatory for `named-compilezone`

`-q`
Run in quiet mode, reporting only the exit status.

`-S` *mode*
Check if a SRV record refers to a `CNAME`. Possible modes are `fail`, `warn` (default) and `ignore`.

`-s` *style*
Specify the style of the dumped zone file. Possible styles are `full` (default) and `relative`. The `full` format is most suitable for processing automatically by a separate script. The `relative` format is more human-readable and is thus suitable for editing by hand. For

`named-checkzone` this option does not cause any effects unless it dumps the zone contents. It also has no effect if the output format is not text.

`-t` *directory*
`chroot` to directory so that include directives in the configuration file are processed as if run by a similarly `chrooted` `named`.

`-v`
Print the version of the `named-checkzone` program and exit.

`-W` *mode*
Specify whether to check for non-terminal wildcards. Non-terminal wildcards are almost always the result of a failure to understand the wildcard matching algorithm (RFC 1034). Possible modes are `warn` (default) and `ignore`.

`-w` *directory*
`chdir` to *directory* so that relative filenames in master file `$INCLUDE` directives work. This is similar to the directory clause in `named.conf`.

Operands The following operands are supported:

filename
The name of the zone file.

zonename
The domain name of the zone being checked.

Exit Status

`0`
No errors were detected.

`1`
An error was detected.

Attributes See `attributes(5)` for descriptions of the following attributes:

See the BIND 9 *Administrator's Reference Manual*. As of the date of publication of this man page, this document is available at `https://www.isc.org/software/bind/documentation`.

Name ncaconfd – Solaris Network Cache and Accelerator (NCA) configuration daemon

Synopsis `/usr/lib/inet/ncaconfd [-al ]` *interface1* `[`*interface2* `...]`

Description Use the `ncaconfd` utility to set up NCA on a system. At boot time, the `ncakmod` initialization script reads in `nca.if(4)` to determine on which interface(s) NCA should run. `ncaconfd` then sets up the interface.

`ncaconfd` also operates as a daemon if the `nca_active` key is set to enabled in `ncakmod.conf(4)` file. In this case, `ncaconfd` will continue as a daemon after all the NCA interfaces have been set up, listening for routing changes. The changes are then passed to NCA to control which interface NCA should use to make active outgoing TCP connnections.

Options The following options are supported:

`-a` Enable active connections.

`-l` Enable logging.

Files `/etc/nca/ncakmod.conf`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWncau
Interface Stability	Evolving

See Also `nca(1)`, `ncakmod(1)`, `nca.if(4)`, `ncakmod.conf(4)`, `attributes(5)`

Name ncheck – generate a list of path names versus i-numbers

Synopsis

```
ncheck [-F FSType] [-V] [generic_options]
     [-o FSType-specific_options] [special]...
```

Description `ncheck` with no options generates a path-name versus i-number list of all files on *special*. If *special* is not specified on the command line the list is generated for all *special*s in `/etc/vfstab` which have a numeric `fsckpass`. *special* is the raw device on which the file system exists.

Options

`-F` Specify the *FSType* on which to operate. The *FSType* should either be specified here or be determinable from `/etc/vfstab` by finding an entry in the table that has a numeric `fsckpass` field and an `fsckdev` that matches *special*.

`-V` Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from `/etc/vfstab`. This option may be used to verify and validate the command line.

generic_options Options that are commonly supported by most FSType-specific command modules. The following options are available:

- `-i` *i-list* Limit the report to the files on the *i-list* that follows. The *i-list* must be separated by commas with no intervening spaces.
- `-a` Print the names "." and ". ." which are ordinarily suppressed.
- `-s` Report only special files and files with set-user-ID mode. This option may be used to detect violations of security policy.

`-o` Specify *FSType-specific_options* in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the FSType-specific module of the command.

Usage See `largefile(5)` for the description of the behavior of `ncheck` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files `/etc/vfstab` list of default parameters for each file system

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `vfstab(4)`, `attributes(5)`, `largefile(5)` Manual pages for the FSType-specific modules of `ncheck`

Notes This command may not be supported for all *FSTypes*.

Name ncheck_ufs – generate pathnames versus i-numbers for ufs file systems

Synopsis

```
ncheck -F ufs [generic_options] [-o m] [special]...
```

Description `ncheck -F ufs` generates a pathname versus i-number list of files for the `ufs` file system residing on *special*. Names of directory files are followed by '`/.`'.

Options See `ncheck(1M)` for the list of *generic_options* supported.

`-o` Specify `ufs` file system specific options. The available option is:

`m` Print mode information.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `ff(1M)`, `ncheck(1M)`, `attributes(5)`

Diagnostics When the file system structure is improper, '`??`' denotes the "parent" of a parentless file and a pathname beginning with '`. . .`' denotes a loop.

Name ndd – get and set driver configuration parameters

Synopsis `ndd [-set] driver parameter [value]`

Description `ndd` gets and sets selected configuration parameters in some kernel drivers. Currently, `ndd` only supports the drivers that implement the TCP/IP Internet protocol family. Each driver chooses which parameters to make visible using `ndd`. Since these parameters are usually tightly coupled to the implementation, they are likely to change from release to release. Some parameters may be read-only.

If the `-set` option is omitted, `ndd` queries the named *driver*, retrieves the value associated with the specified *parameter*, and prints it. If the `-set` option is given, `ndd` passes *value*, which must be specified, down to the named *driver* which assigns it to the named *parameter*.

By convention, drivers that support `ndd` also support a special read-only *parameter* named "?" which can be used to list the parameters supported by the driver.

Examples **EXAMPLE 1** Getting Parameters Supported By The TCP Driver

To see which parameters are supported by the TCP driver, use the following command:

```
example% ndd /dev/tcp \?
```

The parameter name "?" may need to be escaped with a backslash to prevent its being interpreted as a shell meta character.

The following command sets the value of the parameter *ip_forwarding* in the dual stack IP driver to zero. This disables IPv4 packet forwarding.

```
example% ndd -set /dev/ip ip_forwarding 0
```

Similarly, in order to disable IPv6 packet forwarding, the value of parameter *ip6_forwarding*

```
example% ndd -set /dev/ip ip6_forwarding 0
```

To view the current IPv4 forwarding table, use the following command:

```
example% ndd /dev/ip ipv4_ire_status
```

To view the current IPv6 forwarding table, use the following command:

```
example% ndd /dev/ip ipv6_ire_status
```

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also nca(1), ioctl(2), attributes(5), arp(7P), ip(7P), ip6(7P), tcp(7P), udp(7P)

Notes The parameters supported by each driver may change from release to release. Like programs that read `/dev/kmem`, user programs or shell scripts that execute `ndd` should be prepared for parameter names to change.

The `ioctl()` command that `ndd` uses to communicate with drivers is likely to change in a future release. User programs should avoid making dependencies on it.

The meanings of many `ndd` parameters make sense only if you understand how the driver is implemented.

Name netservices – enable or disable network services

Synopsis

```
netservices open

netservices limited
```

Description The `netservices` command uses the Solaris service management facility, `smf(5)`, to control services that accept over the network from remote clients.

When `netservices` is invoked with the `limited` command-line argument, all network services except the secure shell daemon, sshd(1M), are either disabled or constrained to respond to local requests only.

Invoking netservices with the `open` command-line argument enables a large set of network services, as in previous releases of Solaris.

To customize the configuration set enabled by `netservices`, use `svcadm(1M)` to enable or disable individual services. Use `svccfg(1M)` to set properties that determine whether a service accepts input from remote clients. See the man pages for individual services for the names of service instances and their properties.

Note that the `netservices` command has an interface stability of Obsolete.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Obsolete

See Also `svcadm(1M)`, `svccfg(1M)`, `sshd(1M)`, `attributes(5)`, `smf(5)`

Name netstat – show network status

Synopsis

```
netstat [-anvR] [-f address_family] [-P protocol]

netstat -g [-nv] [-f address_family]

netstat -p [-n] [-f address_family]

netstat -s [-f address_family] [-P protocol]
     [interval [count]]

netstat -m [-v] [interval [count]]

netstat -i [-I interface] [-an] [-f address_family]
     [interval [count]]

netstat -r [-anvR] [-f address_family | filter]

netstat -M [-ns] [-f address_family]

netstat -D [-I interface] [-f address_family]
```

Description The `netstat` command displays the contents of certain network-related data structures in various formats, depending on the options you select.

The `netstat` command has the several forms shown in the SYNOPSIS section, above, listed as follows:

- The first form of the command (with no required arguments) displays a list of active sockets for each protocol.
- The second, third, and fourth forms (`-g`, `-p`, and `-s` options) display information from various network data structures.
- The fifth form (`-m` option) displays STREAMS memory statistics.
- The sixth form (`-i` option) shows the state of the interfaces.
- The seventh form (`-r` option) displays the routing table.
- The eighth form (`-M` option) displays the multicast routing table.
- The ninth form (`-D` option) displays the state of DHCP on one or all interfaces.

These forms are described in greater detail below.

With no arguments (the first form), `netstat` displays connected sockets for `PF_INET`, `PF_INET6`, and `PF_UNIX`, unless modified otherwise by the `-f` option.

Options `-a`

Show the state of all sockets, all routing table entries, or all interfaces, both physical and logical. Normally, listener sockets used by server processes are not shown. Under most conditions, only interface, host, network, and default routes are shown and only the status of physical interfaces is shown.

`-f` *address_family*
Limit all displays to those of the specified *address_family*. The value of *address_family* can be one of the following:

`inet` For the `AF_INET` address family showing IPv4 information.

`inet6` For the `AF_INET6` address family showing IPv6 information.

`unix` For the `AF_UNIX` address family.

`-f` *filter*
With `-r` only, limit the display of routes to those matching the specified filter. A filter rule consists of a *keyword*:*value* pair. The known keywords and the value syntax are:

`af:{inet|inet6|unix|`*number*`}`	Selects an address family. This is identical to `-f` *address_family* and both syntaxes are supported.
`{inif|outif}:{`*name*`|`*ifIndex*`|any|none}`	Selects an input or output interface. You can specify the interface by name (such as `hme0`) or by `ifIndex` number (for example, `2`). If `any` is used, the filter matches all routes having a specified interface (anything other than null). If `none` is used, the filter matches all routes having a null interface. Note that you can view the index number (*ifIndex*) for an interface with the `-a` option of `ifconfig(1M)`.
`{src|dst}:{`*ip-address*`[/`*mask*`]|any|none}`	Selects a source or destination IP address. If specified with a mask length, then any routes with matching or longer (more specific) masks are selected. If `any` is used, then all but addresses but 0 are selected. If `none` is used, then address 0 is selected.
`flags:[+ -]?[ABDGHLMSU]+`	Selects routes tagged with the specified flags. By default, the flags as specified must be set in order to match. With a leading `+`, the flags specified must be set but others are ignored. With a leading `-`, the flags specified must not be set and others are permitted.

You can specify multiple instances of `-f` to specify multiple filters. For example:

```
% netstat -nr -f outif:hme0 -f outif:hme1 -f dst:10.0.0.0/8
```

The preceding command displays routes within network 10.0.0.0/8, with mask length 8 or greater, and an output interface of either `hme0` or `hme1`, and excludes all other routes.

`-g`
Show the multicast group memberships for all interfaces. If the `-v` option is included, source-specific membership information is also displayed. See DISPLAYS, below.

`-i`
Show the state of the interfaces that are used for IP traffic. Normally this shows statistics for the physical interfaces. When combined with the `-a` option, this will also report information for the logical interfaces. See `ifconfig(1M)`.

`-m`
Show the STREAMS memory statistics.

`-n`
Show network addresses as numbers. `netstat` normally displays addresses as symbols. This option may be used with any of the display formats.

`-p`
Show the net to media tables. See DISPLAYS, below.

`-r`
Show the routing tables. Normally, only interface, host, network, and default routes are shown, but when this option is combined with the `-a` option, all routes will be displayed, including cache.

`-s`
Show per-protocol statistics. When used with the `-M` option, show multicast routing statistics instead. When used with the `-a` option, per-interface statistics will be displayed, when available, in addition to statistics global to the system. See DISPLAYS, below.

`-v`
Verbose. Show additional information for the sockets, STREAMS memory statistics, routing table, and multicast group memberships.

`-I` *interface*
Show the state of a particular interface. *interface* can be any valid interface such as `hme0` or `eri0`. Normally, the status and statistics for physical interfaces are displayed. When this option is combined with the `-a` option, information for the logical interfaces is also reported.

`-M`
Show the multicast routing tables. When used with the `-s` option, show multicast routing statistics instead.

`-P` *protocol*
Limit display of statistics or state of all sockets to those applicable to *protocol*. The protocol can be one of `ip`, `ipv6`, `icmp`, `icmpv6`, `icmp`, `icmpv6`, `igmp`, `udp`, `tcp`, `rawip`. `rawip` can also be specified as `raw`. The command accepts protocol options only as all lowercase.

`-D`
Show the status of DHCP configured interfaces.

`-R`

This modifier displays extended security attributes for sockets and routing table entries. The `-R` modifier is available only if the system is configured with the Solaris Trusted Extensions feature.

With `-r` only, this option displays the routing entries' gateway security attributes. See `route(1M)` for more information on security attributes.

When displaying socket information using the first form of the commmand, this option displays additional information for Multi-Level Port(MLP) sockets. This includes:

- The label for the peer if the the socket is connected.
- The following flags can be appended to the socket's "State" output:

  `P` The socket is a MLP on zone-private IP addresses.

  `S` The socket is a MLP on IP addresses shared between zones.

Operands

interval Display statistics accumulated since last display every *interval* seconds, repeating forever, unless *count* is specified. When invoked with *interval*, the first row of netstat output shows statistics accumulated since last reboot.

The following options support *interval*: `-i`, `-m`, `-s` and `-Ms`. Some values are configuration parameters and are just redisplayed at each interval.

count Display interface statistics the number of times specified by *count*, at the interval specified by *interval*.

Displays

Active Sockets (First Form)

The display for each active socket shows the local and remote address, the send and receive queue sizes (in bytes), the send and receive windows (in bytes), and the internal state of the protocol.

The symbolic format normally used to display socket addresses is either:

`hostname.`*port*

when the name of the host is specified, or

network`.`*port*

if a socket address specifies a network but no specific host.

The numeric host address or network number associated with the socket is used to look up the corresponding symbolic hostname or network name in the *hosts* or *networks* database.

If the network or hostname for an address is not known, or if the `-n` option is specified, the numerical network address is shown. Unspecified, or "wildcard", addresses and ports appear as an asterisk (`*`). For more information regarding the Internet naming conventions, refer to `inet(7P)` and `inet6(7P)`.

For SCTP sockets, because an endpoint can be represented by multiple addresses, the verbose option (`-v`) displays the list of all the local and remote addresses.

TCP Sockets The possible state values for TCP sockets are as follows:

`BOUND`	Bound, ready to connect or listen.
`CLOSED`	Closed. The socket is not being used.
`CLOSING`	Closed, then remote shutdown; awaiting acknowledgment.
`CLOSE_WAIT`	Remote shutdown; waiting for the socket to close.
`ESTABLISHED`	Connection has been established.
`FIN_WAIT_1`	Socket closed; shutting down connection.
`FIN_WAIT_2`	Socket closed; waiting for shutdown from remote.
`IDLE`	Idle, opened but not bound.
`LAST_ACK`	Remote shutdown, then closed; awaiting acknowledgment.
`LISTEN`	Listening for incoming connections.
`SYN_RECEIVED`	Initial synchronization of the connection under way.
`SYN_SENT`	Actively trying to establish connection.
`TIME_WAIT`	Wait after close for remote shutdown retransmission.

SCTP Sockets The possible state values for SCTP sockets are as follows:

`CLOSED`	Closed. The socket is not being used.
`LISTEN`	Listening for incoming associations.
`ESTABLISHED`	Association has been established.
`COOKIE_WAIT`	`INIT` has been sent to the peer, awaiting acknowledgment.
`COOKIE_ECHOED`	State cookie from the INIT-ACK has been sent to the peer, awaiting acknowledgement.
`SHUTDOWN_PENDING`	`SHUTDOWN` has been received from the upper layer, awaiting acknowledgement of all outstanding `DATA` from the peer.

SHUTDOWN_SENT	All outstanding data has been acknowledged in the SHUTDOWN_SENT state. SHUTDOWN has been sent to the peer, awaiting acknowledgement.
SHUTDOWN_RECEIVED	SHUTDOWN has been received from the peer, awaiting acknowledgement of all outstanding DATA.
SHUTDOWN_ACK_SENT	All outstanding data has been acknowledged in the SHUTDOWN_RECEIVED state. SHUTDOWN_ACK has been sent to the peer.

Network Data Structures (Second Through Fifth Forms)

The form of the display depends upon which of the `-g`, `-m`, `-p`, or `-s` options you select.

`-g` Displays the list of multicast group membership.

`-m` Displays the memory usage, for example, STREAMS mblks.

`-p` Displays the net to media mapping table. For IPv4, the address resolution table is displayed. See `arp(1M)`. For IPv6, the neighbor cache is displayed.

`-s` Displays the statistics for the various protocol layers.

The statistics use the MIB specified variables. The defined values for `ipForwarding` are:

forwarding(1)	Acting as a gateway.
not-forwarding(2)	Not acting as a gateway.

The IPv6 and ICMPv6 protocol layers maintain per-interface statistics. If the `-a` option is specified with the `-s` option, then the per-interface statistics as well as the total sums are displayed. Otherwise, just the sum of the statistics are shown.

For the second, third, and fourth forms of the command, you must specify at least `-g`, `-p`, or `-s`. You can specify any combination of these options. You can also specify `-m` (the fifth form) with any set of the `-g`, `-p`, and `-s` options. If you specify more than one of these options, `netstat` displays the information for each one of them.

Interface Status (Sixth Form)

The interface status display lists information for all current interfaces, one interface per line. If an interface is specified using the `-I` option, it displays information for only the specified interface.

The list consists of the interface name, `mtu` (maximum transmission unit, or maximum packet size)(see `ifconfig(1M)`), the network to which the interface is attached, addresses for each interface, and counter associated with the interface. The counters show the number of input packets, input errors, output packets, output errors, and collisions, respectively. For Point-to-Point interfaces, the Net/Dest field is the name or address on the other side of the link.

If the `-a` option is specified with either the `-i` option or the `-I` option, then the output includes names of the physical interface(s), counts for input packets and output packets for each logical interface, plus additional information.

If the `-n` option is specified, the list displays the IP address instead of the interface name.

If an optional *interval* is specified, the output will be continually displayed in *interval* seconds until interrupted by the user or until *count* is reached. See OPERANDS.

The physical interface is specified using the `-I` option. When used with the *interval* operand, output for the `-I` option has the following format:

```
input    eri0          output        input          (Total)   output
packets  errs  packets errs  colls   packets  errs  packets  errs   colls
227681   0     659471  1     502     261331   0     99597    1      502
10       0     0       0     0       10       0     0        0      0
8        0     0       0     0       8        0     0        0      0
10       0     2       0     0       10       0     2        0      0
```

If the input interface is not specified, the first interface of address family `inet` or `inet6` will be displayed.

Routing Table (Seventh Form)

The routing table display lists the available routes and the status of each. Each route consists of a destination host or network, and a gateway to use in forwarding packets. The *flags* column shows the status of the route. These flags are as follows:

`U` Indicates route is up.

`G` Route is to a gateway.

`H` Route is to a host and not a network.

`M` Redundant route established with the `-multirt` option.

`S` Route was established using the `-setsrc` option.

`D` Route was created dynamically by a redirect.

If the `-a` option is specified, there will be routing entries with the following flags:

`A` Combined routing and address resolution entries.

`B` Broadcast addresses.

`L` Local addresses for the host.

Interface routes are created for each interface attached to the local host; the gateway field for such entries shows the address of the outgoing interface.

The `use` column displays the number of packets sent using a combined routing and address resolution (`A`) or a broadcast (`B`) route. For a local (`L`) route, this count is the number of packets

received, and for all other routes it is the number of times the routing entry has been used to create a new combined route and address resolution entry.

The *interface* entry indicates the network interface utilized for the route.

Multicast Routing Tables (Eighth Form)

The multicast routing table consists of the virtual interface table and the actual routing table.

DHCP Interface Information (Ninth Form)

The DHCP interface information consists of the interface name, its current state, lease information, packet counts, and a list of flags.

The states correlate with the specifications set forth in *RFC 2131*.

Lease information includes:

- when the lease began;
- when lease renewal will begin; and
- when the lease will expire.

The flags currently defined include:

`BOOTP` The interface has a lease obtained through `BOOTP` (IPv4 only).

`BUSY` The interface is busy with a DHCP transaction.

`PRIMARY` The interface is the primary interface. See `dhcpinfo(1)` and `ifconfig(1M)`.

`FAILED` The interface is in failure state and must be manually restarted.

Packet counts are maintained for the number of packets sent, the number of packets received, and the number of lease offers declined by the DHCP client. All three counters are initialized to zero and then incremented while obtaining a lease. The counters are reset when the period of lease renewal begins for the interface. Thus, the counters represent either the number of packets sent, received, and declined while obtaining the current lease, or the number of packets sent, received, and declined while attempting to obtain a future lease.

Droms, R., *RFC 2131, Dynamic Host Configuration Protocol*, Network Working Group, March 1997.

Droms, R. *RFC 3315, Dynamic Host Configuration Protocol for IPv6 (DHCPv6)*. Cisco Systems. July 2003.

Notes When displaying interface information, `netstat` honors the `DEFAULT_IP` setting in `/etc/default/inet_type`. If it is set to `IP_VERSION4`, then `netstat` will omit information relating to IPv6 interfaces, statistics, connections, routes and the like.

However, you can override the `DEFAULT_IP` setting in `/etc/default/inet_type` on the command-line. For example, if you have used the command-line to explicitly request IPv6 information by using the `inet6` address family or one of the IPv6 protocols, it will override the `DEFAULT_IP` setting.

If you need to examine network status information following a kernel crash, use the `mdb(1)` utility on the `savecore(1M)` output.

The `netstat` utility obtains TCP statistics from the system by opening `/dev/tcp` and issuing queries. Because of this, `netstat` might display an extra, unused connection in `IDLE` state when reporting connection status.

Previous versions of `netstat` had undocumented methods for reporting kernel statistics published using the `kstat(7D)` facility. This functionality has been removed. Use `kstat(1M)` instead.

`netstat` restricts its output to information that is relevant to the zone in which `netstat` runs. (This is true for both shared-IP and exclusive-IP zones.)

Name netstrategy – return network configuration information

Synopsis

```
/sbin/netstrategy
```

Description The `netstrategy` command determines the network configuration strategy in use on a system and returns information in a form that is easily consumable by a script. The command returns three tokens:

<root filesystem type> <primary interface> <network config strategy>

These tokens are described as follows:

<root filesystem type>
Type of filesystem that contains the bootable kernel, as would be specified in the *fstype* column of the `mnttab(4)`.

<primary interface>
Name of the primary network interface. For a diskless machine, this is the interface used to load the kernel.

<network config strategy>
The means by which a system obtains its IP address for booting. This can be one of `rarp`, `dhcp`, or `none`.

The `netstrategy` command is not intended for use on a command line.

Options The `netstrategy` command has no options.

Exit Status

`0` Success.

`!=0` An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsr
Interface Stability	Evolving

See Also `ifconfig(1M)`, `mnttab(4)`, `attributes(5)`

Name newaliases – rebuild the data base for the mail aliases file

Synopsis

```
newaliases
```

Description `newaliases` rebuilds the random access data base for the mail aliases file `/etc/mail/aliases`.

`newaliases` accepts all the flags that `sendmail(1M)` accepts. However, most of these flags have no effect, except for the `-C` option and three of the `Processing Options` that can be set from a configuration file with the `-o` option:

`-C` */path/to/alt/config/file*	Use alternate configuration file.
`-oA`*file*	Specify possible alias files.
`-oL`*n*	Set the default log level to *n*. Defaults to `9`.
`-on`	Validate the RHS of aliases when rebuilding the `aliases(4)` database.

`newaliases` runs in verbose mode (`-v` option) automatically.

Examples **EXAMPLE 1** Running the `newaliases` Command

The following command runs `newaliases` on an alias file different from the `/etc/mail/aliases` default in `sendmail(1M)`:

```
example% newaliases -oA/path/to/alternate/alias/file
```

Exit Status `newaliases` returns an exit status describing what it did. The codes are defined in `/usr/include/sysexits.h`.

`EX_OK`	Successful completion on all addresses.
`EX_NOUSER`	User name not recognized.
`EX_UNAVAILABLE`	Catchall. Necessary resources were not available.
`EX_SYNTAX`	Syntax error in address.
`EX_SOFTWARE`	Internal software error, including bad arguments.
`EX_OSERR`	Temporary operating system error, such as “cannot fork”.
`EX_NOHOST`	Host name not recognized.
`EX_TEMPFAIL`	Message could not be sent immediately, but was queued.

Files

`/etc/aliases`	Symbolic link to `/etc/mail/aliases`
`/etc/mail/aliases.pag`	
`/etc/mail/aliases.dir`	`ndbm` files maintained by `newaliases`
`/etc/mail/aliases.db`	Berkeley DataBase file maintained by newaliases

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsndmu

See Also sendmail(1M), aliases(4), attributes(5)

Name newfs – construct a UFS file system

Synopsis `newfs [-NSBTv] [`*mkfs-options*`] `*raw-device*

Description `newfs` is a "friendly" front-end to the `mkfs(1M)` program for making UFS file systems on disk partitions. `newfs` calculates the appropriate parameters to use and calls `mkfs`.

If run interactively (that is, standard input is a tty), `newfs` prompts for confirmation before making the file system.

If the `-N` option is not specified and the inodes of the device are not randomized, `newfs` calls `fsirand(1M)`.

You must be super-user or have appropriate write privileges to use this command, except when creating a UFS file system on a *diskette*. See `EXAMPLES`.

Creating a Multiterabyte UFS File System

Keep the following limitations in mind when creating a multiterabyte UFS file system:

- *nbpi* is set to 1 Mbyte unless you specifically set it higher. You cannot set *nbpi* lower than 1 Mbyte on a multiterabyte UFS file system.
- *fragsize* is set equal to *bsize*.

Options The following options are supported:

`-N` Print out the file system parameters that would be used to create the file system without actually creating the file system. `fsirand(1M)` is not called here.

`-S` Sends to stdout a human-readable version of the superblock that would be used to create a filesystem with the specified configuration parameters.

`-B` Sends to stdout a binary (machine-readable) version of the superblock that would be used to create a filesystem with the specified configuration parameters.

`-T` Set the parameters of the file system to allow eventual growth to over a terabyte in total file system size. This option sets *fragsize* to be the same as *bsize*, and sets *nbpi* to 1 Mbyte, unless the `-i` option is used to make it even larger. If you use the `-f` or `-i` options to specify a *fragsize* or *nbpi* that is incompatible with this option, the user-supplied value of *fragsize* or *nbpi* is ignored.

`-v` Verbose. `newfs` prints out its actions, including the parameters passed to `mkfs`.

mkfs-options Options that override the default parameters are:

`-a` *apc* The number of alternate sectors per cylinder to reserve for bad block replacement for SCSI devices only. The default is `0`.

This option is not applicable for disks with EFI labels and is ignored.

`-b` *bsize*
: The logical block size of the file system in bytes, either 4096 or 8192. The default is `8192`. The sun4u architecture does not support the `4096` block size.

`-c` *cgsize*
: The number of cylinders per cylinder group, ranging from `16` to `256`. The default is calculated by dividing the number of sectors in the file system by the number of sectors in a gigabyte. Then, the result is multiplied by `32`. The default value is always between `16` and `256`.

  `mkfs` can override this value. See `mkfs_ufs(1M)` for details.

  This option is not applicable for disks with EFI labels and is ignored.

`-C` *maxcontig*
: The maximum number of logical blocks, belonging to one file, that are allocated contiguously. The default is calculated as follows:

  `maxcontig =` *disk drive maximum transfer size / disk block size*

  If the disk drive's maximum transfer size cannot be determined, the default value for `maxcontig` is calculated from kernel parameters as follows:

  If `maxphys` is less than `ufs_maxmaxphys`, which is typically 1 Mbyte, then `maxcontig` is set to `maxphys`. Otherwise, `maxcontig` is set to `ufs_maxmaxphys`.

  You can set `maxcontig` to any positive integer value.

  The actual value will be the lesser of what has been specified and what the hardware supports.

  You can subsequently change this parameter by using `tunefs(1M)`.

`-d` *gap*
: Rotational delay. This option is obsolete in the Solaris 10 release. The value is always set to `0`, regardless of the input value.

`-f` *fragsize*
: The smallest amount of disk space in bytes that can be allocated to a file. *fragsize* must be a power of 2 divisor of *bsize*, where:

bsize / *fragsize* is 1, 2, 4, or 8.

This means that if the logical block size is `4096`, legal values for *fragsize* are `512`, `1024`, `2048`, and `4096`. When the logical block size is `8192`, legal values are `1024`, `2048`, `4096`, and `8192`. The default value is `1024`.

For file systems greater than 1 terabyte or for file systems created with the `-T` option, *fragsize* is forced to match block size (*bsize*).

`-i` *nbpi*

The number of bytes per inode, which specifies the density of inodes in the file system. The number is divided into the total size of the file system to determine the number of inodes to create.

This value should reflect the expected average size of files in the file system. If fewer inodes are desired, a larger number should be used. To create more inodes, a smaller number should be given. The default for *nbpi* is as follows:

```
Disk size                Density

Less than 1GB            2048
Less than 2GB            4096
Less than 3GB            6144
3GB to 1 Tbyte           8192
Greater than 1 Tbyte
   or created with -T    1048576
```

The number of inodes can increase if the file system is expanded with the `growfs` command.

`-m` *free*

The minimum percentage of free space to maintain in the file system, between 0% and 99%, inclusively. This space is off-limits to users. Once the file system is filled to this threshold, only the super-user can continue writing to the file system.

The default is ((64 Mbytes/partition size) * 100), rounded down to the nearest integer and limited between 1% and 10%, inclusively.

This parameter can be subsequently changed using the `tunefs(1M)` command.

`-n` *nrpos*	The number of different rotational positions in which to divide a cylinder group. The default is `8`. This option is not applicable for disks with EFI labels and is ignored.
`-o` *space* | *time*	The file system can either be instructed to try to minimize the *time* spent allocating blocks, or to try to minimize the *space* fragmentation on the disk. The default is *time*. This parameter can subsequently be changed with the `tunefs(1M)` command.
`-r` *rpm*	The rotational speed of the disk in revolutions per minute. The default is driver- or device-specific. Note that you specify *rpm* for `newfs` and *rps* for `mkfs`. This option is not applicable for disks with EFI labels and is ignored.
`-s` *size*	The size of the file system in sectors. The default is to use the entire partition.
`-t` *ntrack*	The number of tracks per cylinder on the disk. The default is taken from the disk label. This option is not applicable for disks with EFI labels and is ignored.

Operands The following operands are supported:

raw-device	The name of a raw special device residing in the `/dev` directory (for example, `/dev/rdsk/c0t0d0s6`) on which to create the file system.

Usage See `largefile(5)` for the description of the behavior of `newfs` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples **EXAMPLE 1** Displaying the Parameters for the Raw Special Device

The following example verbosely displays the parameters for the raw special device, `c0t0d0s6`. It does not actually create a new file system:

```
example# newfs -Nv /dev/rdsk/c0t0d0s6
mkfs -F ufs -o N /dev/rdsk/c0t0d0s6 1112940 54 15 8192 1024 16 10 60
2048 t 0 –1 8 /dev/rdsk/c0t0d0s6: 1112940 sectors in
1374 cylinders of 15 tracks, 54 sectors 569.8MB in 86 cyl
groups (16 c/g, 6.64MB/g, 3072 i/g) super-block backups
(for fsck -b #) at:
```

EXAMPLE 1 Displaying the Parameters for the Raw Special Device *(Continued)*

```
32, 13056, 26080, 39104, 52128, 65152, 78176, 91200, 104224, . . .
```

EXAMPLE 2 Creating a UFS File System

The following example creates a UFS file system on a diskette that is managed by Volume Manager.

```
example% newfs /vol/dev/aliases/floppy0
newfs: construct a new file system /vol/dev/aliases/floppy0: (y/n)? y
/vol/dev/aliases/floppy0: 2880 sectors in 80 cylinders of 2 tracks,
18 sectors 1.4MB in 5 cyl groups (16 c/g, 0.28MB/g, 128 i/g)
super-block backups (for fsck -F ufs -o b=#) at:
32, 640, 1184, 1792, 2336, . . .
```

EXAMPLE 3 Creating a UFS File System That Will Eventually Be Grown to a Multiterabyte UFS File System

The following example creates a UFS file system that will eventually be grown to a multiterabyte UFS file system.

This command creates a 800-Gbyte file system on the volume, `/dev/md/rdsk/d99`.

```
# newfs -T /dev/md/rdsk/d99
newfs: construct a new file system /dev/md/rdsk/d99: (y/n)? y
   /dev/md/rdsk/d99: 1677754368 sectors in 45512 cylinders of
   144 tracks, 256 sectors
   819216.0MB in 1821 cyl groups (25 c/g, 450.00MB/g, 448 i/g) . . .
```

Then, if you increase the volume size for this file system, you can use the `growfs` command to expand the file system. The file system is grown to 1.2 terabytes in this example:

```
# growfs -v /dev/md/rdsk/d99
/usr/lib/fs/ufs/mkfs -G /dev/md/rdsk/d99 2516631552 /dev/md/rdsk/d99:
   2516631552 sectors in 68268 cylinders of 144 tracks, 256  sectors
   1228824.0MB in 2731 cyl groups (25 c/g, 450.00MB/g, 448 i/g). . .
```

Exit Status

The following exit values are returned:

`0` The operation was successful.

`1`, `10` Usage error or internal error. A message is output to `STDERR` explaining the error.

Other exit values may be returned by `mkfs(1M)`, which is called by `newfs`.

Attributes

Diagnostics

`newfs: No such file or directory`	The device specified does not exist, or a disk partition was not specified.
special`: cannot open`	You must write access to the device to use this command.

Name newkey – create a new Diffie-Hellman key pair in the publickey database

Synopsis

```
newkey -h hostname [-s nisplus | nis | files | ldap]

newkey -u username [-s nisplus | nis | files | ldap]
```

Description `newkey` establishes new public keys for users and machines on the network. These keys are needed when using secure RPC or secure NFS service.

`newkey` prompts for a password for the given *username* or `hostname` and then creates a new public/secret Diffie-Hellman 192 bit key pair for the user or host. The secret key is encrypted with the given password. The key pair can be stored in the `/etc/publickey` file, the NIS `publickey` map, or the NIS+ `cred.org_dir` table.

`newkey` consults the `publickey` entry in the name service switch configuration file (see `nsswitch.conf(4)`) to determine which naming service is used to store the secure RPC keys. If the `publickey` entry specifies a unique name service, `newkey` will add the key in the specified name service. However, if there are multiple name services listed, `newkey` cannot decide which source to update and will display an error message. The user is required to specify the source explicitly with the `-s` option.

In the case of NIS, `newkey` should be run by the superuser on the master NIS server for that domain. In the case of NIS+, `newkey` should be run by the superuser on a machine which has permission to update the `cred.org_dir` table of the new user/host domain.

In the case of NIS+, `nisaddcred(1M)` should be used to add new keys. `newkey` cannot be used to create keys other than 192-bit Diffie-Hellman.

In the case of LDAP, `newkey` should be run by the superuser on a machine that also recognizes the directory manager's bind distinguished name (DN) and password to perform an LDAP update for the host.

Options

`-h` *hostname* — Create a new public/secret key pair for the privileged user at the given `hostname`. Prompts for a password for the given `hostname`.

`-u` *username* — Create a new public/secret key pair for the given *username*. Prompts for a password for the given *username*.

`-s nisplus`
`-s nis`
`-s files`
`-s ldap` — Update the database in the specified source: `nisplus` (for NIS+), `nis` (for NIS), `files`, or `ldap` (LDAP). Other sources may be available in the future.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also chkey(1), keylogin(1), nisaddcred(1M), nisclient(1M), nsswitch.conf(4), publickey(4), attributes(5)

Notes NIS+ might not be supported in future releases of the Solaris operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

Name nfs4cbd – NFS Version 4 callback daemon

Synopsis

```
/usr/lib/nfs/nfs4cbd
```

Description The `nfs4cbd` daemon manages communication endpoints for the NFS Version 4 protocol callback program. `nfs4cbd` runs on the NFS Version 4 client and creates a listener port for each transport over which callbacks can be sent.

The `nfs4cbd` daemon is provided for the exclusive use of the NFS version 4 client.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnfscu

See Also `svcs(1)`, `mount_nfs(1M)`, `svcadm(1M)`, `attributes(5)`, `smf(5)`

Notes The `nfs4cbd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/nfs/cbd
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

If it is disabled, it will be enabled by `mount_nfs(1M)` and `automountd(1M)` on the first NFSv4 mount, unless its `application/auto_enable` property is set to `false`.

This daemon might not exist in a future release of Solaris.

Name nfsd – NFS daemon

Synopsis

```
/usr/lib/nfs/nfsd [-a] [-c #_conn] [-l listen_backlog]
     [-p protocol] [-t device] [nservers]
```

Description `nfsd` is the daemon that handles client file system requests. Only users with `{PRIV_SYS_NFS}` and sufficient privileges to write to `/var/run` can run this daemon.

The `nfsd` daemon is automatically invoked using `share(1M)` with the `-a` option.

By default, `nfsd` starts over the TCP and UDP transports for versions 2 and 3. By default, it starts over the TCP for version 4. You can change this with the `-p` option.

A previously invoked `nfsd` daemon started with or without options must be stopped before invoking another `nfsd` command.

Administrators wanting to change startup parameters for nfsd should, as root, make changes in the `/etc/default/nfs` file. See `nfs(4)`.

Options The following options are supported:

`-a` Start a NFS daemon over all available connectionless and connection-oriented transports, including UDP and TCP. Equivalent of setting the `NFSD_PROTOCOL` parameter to `ALL` in the `nfs` file.

`-c` *#_conn* This sets the maximum number of connections allowed to the NFS server over connection-oriented transports. By default, the number of connections is unlimited. Equivalent of the `NFSD_MAX_CONNECTIONS` parameter in the `nfs` file.

`-l` Set connection queue length for the NFS TCP over a connection-oriented transport. The default value is 32 entries. Equivalent of the `NFSD_LISTEN_BACKLOG` parameter in the `nfs` file.

`-p` *protocol* Start a NFS daemon over the specified protocol. Equivalent of the `NFSD_PROTOCOL` parameter in the `nfs` file.

`-t` *device* Start a NFS daemon for the transport specified by the given device. Equivalent of the `NFSD_DEVICE` parameter in the `nfs` file.

Operands The following operands are supported:

nservers This sets the maximum number of concurrent NFS requests that the server can handle. This concurrency is achieved by up to *nservers* threads created as needed in the kernel. *nservers* should be based on the load expected on this server. 16 is the usual number of *nservers*. If *nservers* is not specified, the maximum number of concurrent NFS requests will default to 1. Equivalent of the `NFSD_SERVERS` parameter in the `nfs` file.

Usage If the NFS_PORTMON variable is set in /etc/system, then clients are required to use privileged ports (ports < IPPORT_RESERVED) to get NFS services. This variable is equal to zero by default. This variable has been moved from the "nfs" module to the "nfssrv" module. To set the variable, edit the /etc/system file and add this entry:

```
set nfssrv:nfs_portmon = 1
```

Exit Status

0	Daemon started successfully.
1	Daemon failed to start.

Files

.nfs*XXX*	Client machine pointer to an open-but-unlinked file.
/etc/default/nfs	Contains startup parameters for nfsd.
/etc/system	System configuration information file.
/var/nfs/v4_state /var/nfs/v4_oldstate	Directories used by the server to manage client state information. These directories should not be removed.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnfssu

See Also ps(1), svcs(1), mountd(1M), share(1M), svcadm(1M), nfs(4), sharetab(4), system(4), attributes(5), smf(5)

System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)

Notes Manually starting and restarting nfsd is not recommended. If it is necessary to do so, use svcadm to enable or disable the nfs service (svc:/network/nfs/server). If it is disabled, it will be enabled by share_nfs(1M), unless its application/auto_enable property is set to false. See the *System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)*, and svcadm(1M) for more information.

The nfsd service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/network/nfs/server
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

If nfsd is killed with SIGTERM, it will not be restarted by the service management facility. Instead, nfsd can be restarted by other signals, such as SIGINT.

Name nfslogd – nfs logging daemon

Synopsis `/usr/lib/nfs/nfslogd`

Description The `nfslogd` daemon provides operational logging to the Solaris NFS server. It is the `nfslogd` daemon's job to generate the activity log by analyzing the RPC operations processed by the NFS server. The log will only be generated for file systems exported with logging enabled. This is specified at file system export time by means of the `share_nfs(1M)` command.

NFS server logging is not supported on Solaris machines that are using NFS Version 4.

Each record in the log file includes a time stamp, the IP address (or hostname if it can be resolved) of the client system, the file or directory name the operation was performed on, and the type of operation. In the basic format, the operation can either be an input (i) or output (o) operation. The basic format of the NFS server log is compatible with the log format generated by the Washington University FTPd daemon. The log format can be extended to include directory modification operations, such as `mkdir`, `rmdir`, and `remove`. The extended format is not compatible with the Washington University FTPd daemon format. See `nfslog.conf(4)` for details.

The NFS server logging mechanism is divided in two phases. The first phase is performed by the NFS kernel module, which records raw RPC requests and their results in work buffers backed by permanent storage. The location of the work buffers is specified in the `/etc/nfs/nfslog.conf` file. Refer to `nfslog.conf(4)` for more information. The second phase involves the `nfslogd` user-level daemon, which periodically reads the work buffers, interprets the raw RPC information, groups related RPC operations into single transaction records, and generates the output log. The `nfslogd` daemon then sleeps waiting for more information to be logged to the work buffers. The amount of time that the daemon sleeps can be configured by modifying the `IDLE_TIME` parameter in `/etc/default/nfslogd`. The work buffers are intended for internal consumption of the `nfslogd` daemon.

NFS operations use file handles as arguments instead of path names. For this reason the `nfslogd` daemon needs to maintain a database of file handle to path mappings in order to log the path name associated with an operation instead of the corresponding file handle. A file handle entry is added to the database when a client performs a lookup or other NFS operation that returns a file handle to the client.

Once an NFS client obtains a file handle from a server, it can hold on to it for an indefinite time, and later use it as an argument for an NFS operation on the file or directory. The NFS client can use the file handle even after the server reboots. Because the database needs to survive server reboots, it is backed by permanent storage. The location of the database is specified by the *fhtable* parameter in the `/etc/nfs/nfslog.conf` file. This database is intended for the internal use of the `nfslogd` daemon.

In order to keep the size of the file handle mapping database manageable, `nfslogd` prunes the database periodically. It removes file handle entries that have not been accessed in more than a specified amount of time. The `PRUNE_TIMEOUT` configurable parameter in

/etc/default/nfslogd specifies the interval length between successive runs of the pruning process. A file handle record will be removed if it has not been used since the last time the pruning process was executed. Pruning of the database can effectively be disabled by setting the PRUNE_TIMEOUT as high as INT_MAX.

When pruning is enabled, there is always a risk that a client may have held on to a file handle longer than the PRUNE_TIMEOUT and perform an NFS operation on the file handle after the matching record in the mapping database had been removed. In such case, the pathname for the file handle will not be resolved, and the log will include the file handle instead of the pathname.

There are various configurable parameters that affect the behavior of the nfslogd daemon. These parameters are found in /etc/default/nfslogd and are described below:

UMASK	Sets the file mode for the log files, work buffer files and file handle mapping database.
MIN_PROCESSING_SIZE	Specifies the minimum size, in bytes, that the buffer file must reach before processing the work information and writing to the log file. The value of MIN_PROCESSING_SIZE must be between 1 and ulimit.
IDLE_TIME	Specifies the amount of time, in seconds, the daemon should sleep while waiting for more information to be placed in the buffer file. IDLE_TIME also determines how often the configuration file will be reread. The value of IDLE_TIME must be between 1 and INT_MAX.
MAX_LOGS_PRESERVE	The nfslogd periodically cycles its logs. MAX_LOGS_PRESERVE specifies the maximum number of log files to save. When MAX_LOGS_PRESERVE is reached, the oldest files will be overwritten as new log files are created. These files will be saved with a numbered extension, beginning with filename.0. The oldest file will have the highest numbered extension up to the value configured for MAX_LOGS_PRESERVE. The value of MAX_LOGS_PRESERVE must be between 1 and INT_MAX.
CYCLE_FREQUENCY	Specifies how often, in hours, the log files are cycled. CYCLE_FREQUENCY is used to insure that the log files do not get too large. The value of CYCLE_FREQUENCY must be between 1 and INT_MAX.
MAPPING_UPDATE_INTERVAL	Specifies the time interval, in seconds, between updates of the records in the file handle to path mapping tables. Instead of updating the atime of a record each time that record is accessed, it is only updated if it has aged based on this

parameter. The record access time is used by the pruning routine to determine whether the record should be removed from the database. The value of this parameter must be between 1 and `INT_MAX`.

`PRUNE_TIMEOUT` Specifies when a database record times out, in hours. If the time that elapsed since the record was last accessed is greater than `PRUNE_TIMEOUT` then the record can be pruned from the database. The default value for `PRUNE_TIMEOUT` is 168 hours (7 days). The value of `PRUNE_TIMEOUT` must be between 1 and `INT_MAX`.

Exit Status The following exit values are returned:

`0` Daemon started successfully.

`1` Daemon failed to start.

Files `/etc/nfs/nfslogtab`

`/etc/nfs/nfslog.conf`

`/etc/default/nfslogd`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnfssu

See Also `share_nfs(1M)`, `nfslog.conf(4)`, `attributes(5)`

Name nfsmapid – NFS user and group id mapping daemon

Synopsis

```
/usr/lib/nfs/nfsmapid
```

Description The `nfsmapid` daemon maps to and from NFS version 4 `owner` and `owner_group` identification attributes and local UID and GID numbers used by both the NFS version 4 client and server.

`nfsmapid` uses the `passwd` and `group` entries in the `/etc/nsswitch.conf` file to direct how it performs the mappings.

The `nfsmapid` daemon has no external, customer-accessible interfaces. You can, however, administratively configure `nfsmapid` in one of the following ways:

- Specify the `NFSMAPID_DOMAIN` parameter in `nfs(4)`
- Specify the `_nfsv4idmapdomain` DNS resource record.

Please refer to the *System Administration Guide: Network Services* for further details.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnfscu

See Also `svcs(1)`, `automountd(1M)`, `groupdel(1M)`, `groupmod(1M)`, `mount_nfs(1M)`, `passmgmt(1M)`, `svcadm(1M)`, `share_nfs(1M)`, `userdel(1M)`, `usermod(1M)`, `nfs(4)`, `attributes(5)`, `smf(5)`

System Administration Guide: Network Services

Notes The `nfsmapid` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/nfs/mapid
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

If it is disabled, it will be enabled by `mount_nfs(1M)`, `share_nfs(1M)`, and `automountd(1M)`, unless its `application/auto_enable` property is set to `false`.

`nfsmapid` caches a user's UID and GID. If a user subsequently changes a UID or GID, using one of the utilities listed below, the `nfsmapid` cache becomes stale. At this point, any NFS operation that gets or set attributes will result in the exchange of this stale information. To resolve this situation, restart `nfsmapid`, as follows:

```
# svcadm restart svc:/network/nfs/mapid:default
```

The utilities that allow you to change UID and GID are:

- usermod(1M)
- userdel(1M)
- groupmod(1M)
- groupdel(1M)
- passmgmt(1M)

The nfsmapid daemon might not exist in a future release of Solaris.

Name nfsstat – NFS statistics

Synopsis

```
nfsstat [-cnrsza] [-v version] [interval [count]]

nfsstat -m [pathname]...
```

Description `nfsstat` displays statistical information about the NFS and RPC (Remote Procedure Call), interfaces to the kernel. It can also be used to reinitialize this information. If no options are given the default is as follows:

```
nfsstat -csnra
```

The default displays everything, but reinitializes nothing.

Options

`-a` Display `NFS_ACL` information.

`-c` Display client information. Only the client side NFS, RPC, and NFS_ACL information is printed. Can be combined with the `-n`, `-r`, and `-a` options to print client side NFS, RPC, and NFS_ACL information only.

`-m` [*pathname...*] Display statistics for each NFS mounted file system. If *pathname* is not specified, displays statistics for all NFS mounted file systems. If *pathname* is specified, displays statistics for the NFS mounted file systems indicated by *pathname*.

This includes the server name and address, mount flags, current read and write sizes, the retransmission count, the attribute cache timeout values, failover information, and the timers used for dynamic retransmission. The dynamic retransmission timers are displayed only where dynamic retransmission is in use. By default, NFS mounts over the TCP protocols and NFS Version 3 mounts over either TCP or UDP do not use dynamic retransmission.

If you specify the `-m` option, this is the only option that `nfsstat` uses. If you specify other options with `-m`, you receive an error message alerting that the `-m` flag cannot be combined with other options.

`-n` Display NFS information. NFS information for both the client and server side are printed. Can be combined with the `-c` and `-s` options to print client or server NFS information only.

`-r` Display RPC information.

`-s` Display server information.

`-v` *version* Specify which NFS version for which to print statistics. When followed by the optional *version* argument, (`2`|`3`|`4`), specifies statistics for that version. By default, prints statistics for all versions.

`-z` Zero (reinitialize) statistics. This option is for use by the super user only, and can be combined with any of the above options to zero particular sets of statistics after printing them.

Operands The following operands are supported:

count Display only count reports

interval Report once each interval seconds.

pathname Specify the pathname of a file in an NFS mounted file system for which statistics are to be displayed.

Displays The server RPC display includes the following fields:

`calls` The total number of RPC calls received.

`badcalls` The total number of calls rejected by the RPC layer (the sum of `badlen` and `xdrcall` as defined below).

`nullrecv` The number of times an RPC call was not available when it was thought to be received.

`badlen` The number of RPC calls with a length shorter than a minimum-sized RPC call.

`xdrcall` The number of RPC calls whose header could not be XDR decoded.

`dupchecks` The number of RPC calls that looked up in the duplicate request cache.

`dupreqs` The number of RPC calls that were found to be duplicates.

The server NFS display shows the number of NFS calls received (`calls`) and rejected (`badcalls`), and the counts and percentages for the various calls that were made.

The server NFS_ACL display shows the counts and percentages for the various calls that were made.

The client RPC display includes the following fields:

`calls` The total number of RPC calls made.

`badcalls` The total number of calls rejected by the RPC layer.

`badxids` The number of times a reply from a server was received which did not correspond to any outstanding call.

`timeouts` The number of times a call timed out while waiting for a reply from the server.

`newcreds` The number of times authentication information had to be refreshed.

`badverfs` The number of times the call failed due to a bad verifier in the response.

`timers`	The number of times the calculated time-out value was greater than or equal to the minimum specified time-out value for a call.
`cantconn`	The number of times the call failed due to a failure to make a connection to the server.
`nomem`	The number of times the call failed due to a failure to allocate memory.
`interrupts`	The number of times the call was interrupted by a signal before completing.
`retrans`	The number of times a call had to be retransmitted due to a timeout while waiting for a reply from the server. Applicable only to RPC over connection-less transports.
`cantsend`	The number of times a client was unable to send an RPC request over a connectionless transport when it tried to do so.

The client NFS display shows the number of calls sent and rejected, as well as the number of times a `CLIENT` handle was received (`clgets`), the number of times the `CLIENT` handle cache had no unused entries (`cltoomany`), as well as a count of the various calls and their respective percentages.

The client NFS_ACL display shows the counts and percentages for the various calls that were made.

The `-m` option includes information about mount flags set by mount options, mount flags internal to the system, and other mount information. See `mount_nfs(1M)`.

The following mount flags are set by mount options:

`sec`	`sec` has one of the following values:	
	`none`	No authentication.
	`sys`	UNIX-style authentication (UID, GID).
	`short`	Short hand UNIX–style authentication.
	`dh`	`des`–style authentication (encrypted timestamps).
	`krb5`	`kerberos v5`–style authentication.
	`krb5i`	`kerberos v5`–style authentication with integrity.
	`krb5p`	`kerberos v5`–style authentication with privacy.
`hard`	Hard mount.	
`soft`	Soft mount.	
`intr`	Interrupts allowed on hard mount.	
`nointr`	No interrupts allowed on hard mount.	

`noac`	Client is not caching attributes.
`rsize`	Read buffer size in bytes.
`wsize`	Write buffer size in bytes.
`retrans`	NFS retransmissions.
`timeo`	Initial NFS timeout, in tenths of a second.
`nocto`	No close-to-open consistency.
`llock`	Local locking being used (no lock manager).
`grpid`	System V group id inheritance.
`rpctimesync`	RPC time sync.

The following mount flags are internal to the system:

`printed`	"Not responding" message printed.
`down`	Server is down.
`dynamic`	Dynamic transfer size adjustment.
`link`	Server supports links.
`symlink`	Server supports symbolic links.
`readdir`	Use `readdir` instead of `readdirplus`.
`acl`	Server supports NFS_ACL.

The following flags relate to additional mount information:

`vers`	NFS version.
`proto`	Protocol.

The `-m` option also provides attribute cache timeout values. The following fields in `-m` ouput provide timeout values for attribute cache:

`acregmin`	Minimum seconds to hold cached file attributes.
`acregmax`	Maximum seconds to hold cached file attributes.
`acdirmin`	Minimum seconds to hold cached directory attributes.
`acdirmax`	Maximum seconds to hold cached directory attributes.

The following fields in `-m` output provide failover information:

`noresponse`	How many times servers have failed to respond.
`failover`	How many times a new server has been selected.

`remap` How many times files have been re-evaluated to the new server.

`currserver` Which server is currently providing NFS service. See the *System Administration Guide: IP Services* for additional details.

The fields in `-m` output shown below provide information on dynamic retransmissions. These items are displayed only where dynamic retransmission is in use.

`srtt` The value for the smoothed round-trip time, in milliseconds.

`dev` Estimated deviation, in milliseconds.

`cur` Current backed-off retransmission value, in milliseconds.

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnfscu

Name nisaddcred – create NIS+ credentials

Synopsis

```
nisaddcred [-p principal] [-P nis_principal]
     [-l login_password] auth_type [domain_name]

nisaddcred -r [nis_principal] [domain_name]
```

Description The `nisaddcred` command is used to create security credentials for NIS+ principals. NIS+ credentials serve two purposes. The first is to provide authentication information to various services; the second is to map the authentication service name into a NIS+ principal name.

When the `nisaddcred` command is run, these credentials get created and stored in a table named `cred.org_dir` in the default NIS+ domain. If *domain_name* is specified, the entries are stored in the `cred.org_dir` of the specified domain. The specified domain must either be the one to which you belong, or one in which you are authenticated and authorized to create credentials, that is, a subdomain. Note that the credentials of normal users must be stored in the same domain as their passwords.

It is simpler to add credentials using `nisclient(1M)`, because it obtains the required information itself. `nispopulate(1M)` is used for "bulk" updates and can also be used to add credentials for entries in the `hosts` and the `passwd` NIS+ tables.

NIS+ principal names are used in specifying clients that have access rights to NIS+ objects. For more details, refer to the "Principal Names" subsection of the `NIS+(1)` manual page. See `nischmod(1)`, `nischown(1)`, `nis_objects(3NSL)`, and `nis_groups(3NSL)`. Various other services can also implement access control based on these principal names.

The `cred.org_dir` table is organized as follows:

cname	auth_type	auth_name	public_data	private_data
user1.foo.com.	LOCAL	2990	10,102,44	
user1.foo.com.	DES	unix.2990@foo.com	098...819	3b8...ab2
user1.foo.com.	DHmmm-n	unix.2990@foo.com	248...428	a42...f32

The `cname` column contains a canonical representation of the NIS+ principal name. By convention, this name is the login name of a user, or the host name of a machine, followed by a dot ('.') followed by the fully qualified "home" domain of that principal. For users, the home domain is defined to be the domain where their DES credentials are kept. For hosts, their home domain is defined to be the domain name returned by the `domainname(1M)` command executed on that host.

There are two basic types of *auth_type* entries in the `cred.org_dir` table, those with authentication type LOCAL, and those with authentication type DES, *auth_type*, specified on the command line in upper or lower case, should be either *local* or `des`.

However, the `cred.org_dir` table may also be used to hold data for other values of *auth_type*. Currently, this is limited to the mechanisms listed on the `nisauthconf(1M)` man page, for which the `nisaddcred` *auth_type* argument is the same as the name of the mechanism. These mechanisms use a modified form of Secure RPC, and they are similar to the DES authentication type.

If the *auth_type* is `des`, and other authentication mechanisms are configured with `nisauthconf(1M)`, then credential entries are added or updated for each mechanism configured. To only add or update 1992-bit Diffie Hellman credentials, that is, those with the *auth_type* of DES, use dh192-0 on the command line. If there are no authentication mechanisms configured, using `des` on the command line will only add or update 192-bit Diffie Hellman credentials.

Entries of type LOCAL are used by the NIS+ service to determine the correspondence between fully qualified NIS+ principal names and users identified by UIDs in the domain containing the `cred.org_dir` table. This correspondence is required when associating requests made using the `AUTH_SYS` RPC authentication flavor (see `rpc_clnt_auth(3NSL)`) to a NIS+ principal name. It is also required for mapping a UID in one domain to its fully qualified NIS+ principal name whose home domain may be elsewhere. The principal's credentials for any authentication flavor may then be sought for within the `cred.org_dir` table in the principal's home domain (extracted from the principal name). The same NIS+ principal may have LOCAL credential entries in more than one domain. Only users, and not machines, have LOCAL credentials. In their home domain, users of NIS+ should have both types of credentials.

The *auth_name* associated with the LOCAL type entry is a UID that is valid for the principal in the domain containing the `cred.org_dir` table. This may differ from that in the principal's home domain. The public information stored in *public_data* for this type contains a list of GIDs for groups in which the user is a member. The GIDs also apply to the domain in which the table resides. There is no private data associated with this type. Neither a UID nor a principal name should appear more than once among the LOCAL entries in any one `cred.org_dir` table.

The DES *auth_type* is used for Secure RPC authentication (see `secure_rpc(3NSL)`).

The authentication name associated with the DES *auth_type* is a Secure RPC *netname*. A Secure RPC netname has the form `unix.id@`*domain.com,* where *domain* must be the same as the domain of the principal. For principals that are users the `id` must be the UID of the principal in the principal's home domain. For principals that are hosts, the `id` is the host's name. In Secure RPC, processes running under effective UID 0 (root) are identified with the host principal. Unlike LOCAL, there cannot be more than one DES credential entry for one NIS+ principal in the NIS+ namespace.

The public information in an entry of authentication type DES is the public key for the principal. The private information in this entry is the private key of the principal encrypted by the principal's network password.

User clients of NIS+ should have credentials of both types in their home domain. In addition, a principal must have a LOCAL entry in the `cred.org_dir` table of each domain from which the principal wishes to make authenticated requests. A client of NIS+ that makes a request from a domain in which it does not have a LOCAL entry will be unable to acquire DES credentials. A NIS+ service running at security level 2 or higher will consider such users unauthenticated and assign them the name *nobody* for determining access rights.

This command can only be run by those NIS+ principals who are authorized to add or delete the entries in the `cred` table.

If credentials are being added for the caller itself, `nisaddcred` automatically performs a keylogin for the caller.

You can list the `cred` entries for a particular principal with `nismatch(1)`.

The `cred.org_dir` NIS+ table replaces the maps *publickey.byname* and *netid.byname* used in NIS (YP).

Options The following options are supported:

`-p` *principal* — The name *principal* specifies the name of the principal as defined by the naming rules for that specific mechanism. For example, LOCAL credential names are supplied with this option by including a string specifying a UID. For DES credentials, the name should be a Secure RPC netname of the form `unix.id@`*domain.com,* as described earlier. If the `-p` option is not specified, the *auth_name* field is constructed from the effective UID of the current process and the name of the local domain.

`-P` *nis_principal* — Use the NIS+ principal name *nis_principal*. This option should be used when creating LOCAL or DES credentials for users whose home domain is different than the local machine's default domain.

Whenever the `-P` option is not specified, `nisaddcred` constructs a principal name for the entry as follows. When it is not creating an entry of type LOCAL, `nisaddcred` calls `nis_local_principal`, which looks for an existing LOCAL entry for the effective UID of the current process in the `cred.org_dir` table and uses the associated principal name for the new entry. When creating an entry of authentication type LOCAL, `nisaddcred` constructs a default NIS+ principal name by taking the login name of the effective UID for its own process, and appending to it a dot ('.') followed by the local machine's default domain. If the caller is a superuser, the machine name is used instead of the login name.

`-l` *login_password* — Use the *login_password* specified as the password to encrypt the secret key for the credential entry. This overrides the prompting for a password from the shell. This option is intended for administration

scripts only. Prompting guarantees not only that no one can see your password on the command line using ps(1) but it also checks to make sure you have not made any mistakes. *login_password* does not really have to be the user's password but if it is, it simplifies logging in.

`-r` [*nis_principal*] Remove all credentials associated with the principal *nis_principal* from the `cred.org_dir` table. This option can be used when removing a client or user from the system. If *nis_principal* is not specified the default is to remove credentials for the current *user*. If *domain_name* is not specified, the operation is executed in the default NIS+ domain.

Examples

EXAMPLE 1 Adding the LOCAL and DES Credentials

The following examples illustrate how to add the LOCAL and DES credentials for some user, `user1`, with a UID of `2990`, who is an NIS+ user principal in the `some.domain.com.` NIS+ domain:

```
example% nisaddcred -p 2990 -P user1.some.domain.com. local
```

Note that credentials are always added in the `cred.org_dir` table in the domain where `nisaddcred` is run, unless *domain_name* is specified as the last parameter on the command line. If credentials are being added from the domain server for its clients, then *domain_name* should be specified. The caller should have adequate permissions to create entries in the `cred.org_dir` table.

The system administrator can add a DES credential for the same user, using the following example:

```
example% nisaddcred -p unix.2990@some.domain.com -P user1.some.domain.com. des
```

Please note that DES credentials can be added only after the LOCAL credentials have been added. Also, if the system is configured to use more than one authentication mechanism, credentials will be made for each mechanism configured. See nisauthconf(1M).

Note that the secure RPC netname does not end with a dot ('.') while the NIS+ principal name, specified with the `-P` option, does. This command should be executed from a machine in the same domain as is the user.

The following example shows how to add a machine's DES credentials in the same domain:

```
example% nisaddcred -p unix.foo@some.domain.com -P foo.some.domain.com. des
```

Please note that no LOCAL credentials are needed in this case.

The following example illustrates how to add a NIS+ workstation's principal DES credential:

```
example% nisaddcred -p unix.host1@sub.some.domain.com \
     -P newhost.sub.some.domain.com. des sub.some.domain.com.
```

EXAMPLE 1 Adding the LOCAL and DES Credentials *(Continued)*

This format is particularly useful if you are running this command from a server which is in a higher domain than sub.some.domain.com. Without the last option for domain name, `nisaddcred` would fail because it would attempt to use the default domain of some.domain.com.

The following example illustrates adding DES credentials without being prompted for the root login password:

```
example% nisaddcred -p unix.2990@some.domain.com \
     -P user1.some.domain.com. -l login_password des
```

The following example shows how to add a credential for a user using a specific authentication mechanism that was previously configured with `nisauthconf(1M)`. See `nisauthconf(1M)` for a list of the valid values of *auth_type*:

```
example% nisaddcred -p unix.2990@some.domain.com \
     -P user.1.some.domain.com dh640-0
```

The password should be the same for all the credentials that belong to the user. Otherwise, only the credentials encrypted with the user's password will be used at login, and the user will have to run `chkey(1)` using the `-p` option.

The following example shows how to add a DES credential when other authentication mechanisms are configured on the system:

```
example% nisaddcred -p unix.2990@some.domain.com \
     -P user1.some.domain.com dh192-0
```

Exit Status

The following exit values are returned:

`0` Successful operation.

`1` Operation failed.

Notes NIS+ might not be supported in future releases of the Solaris operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

Name nisaddent – create NIS+ tables from corresponding /etc files or NIS maps

Synopsis

```
/usr/lib/nis/nisaddent [-D defaults] [-Paorv] [-t table] type
     [nisdomain]

/usr/lib/nis/nisaddent [-D defaults] [-Paprmov] -f file
     [-t table] type [nisdomain]

/usr/lib/nis/nisaddent [-D defaults] [-Parmv] [-t table] -y ypdomain
     [-Y map] type [nisdomain]

/usr/lib/nis/nisaddent -d [-AMoq] [-t table] type
     [nisdomain]
```

Description `nisaddent` creates entries in NIS+ tables from their corresponding `/etc` files and NIS maps. This operation is customized for each of the standard tables that are used in the administration of Solaris systems. The `type` argument specifies the type of the data being processed. Legal values for this type are one of `aliases`, `bootparams`, `ethers`, `group`, `hosts`, `ipnodes`, `netid`, `netmasks`, `networks`, `passwd`, `protocols`, `publickey`, `rpc`, `services`, `shadow`, or `timezone` for the standard tables, or `key-value` for a generic two-column (key, value) table. For a site specific table, which is not of `key-value` type, one can use `nistbladm(1)` to administer it.

The NIS+ tables should have already been created by `nistbladm(1)`, `nissetup(1M)`, or `nisserver(1M)`.

It is easier to use `nispopulate(1M)` instead of `nisaddent` to populate the system tables.

By default, `nisaddent` reads from the standard input and adds this data to the NIS+ table associated with the `type` specified on the command line. An alternate NIS+ table may be specified with the `-t` option. For type `key-value`, a table specification is required.

Note that the *data* type can be different than the table name (`-t`). For example, the automounter tables have `key-value` as the table type.

Although, there is a *shadow* data type, there is no corresponding *shadow* table. Both the shadow and the passwd data is stored in the `passwd` table itself.

Files may be processed using the `-f` option, and NIS version 2 (YP) maps may be processed using the `-y` option. The merge option is not available when reading data from standard input.

When a *ypdomain* is specified, the `nisaddent` command takes its input from the `dbm` files for the appropriate NIS map (`mail.aliases`, `bootparams`, `ethers.byaddr`, `group.byname`, `hosts.byaddr`, `hosts.byname`, `ipnodes.byaddr`,`ipnodes.byname`, `netid.byname`, `netmasks.byaddr`, `networks.byname`, `passwd.byname`, `protocols.byname`, `publickey.byname`, `rpc.bynumber`, `services.byname`, or `timezone.byname`). An alternate NIS map may be specified with the `-Y` option. For type `key-value`, a map specification is required. The map must be in the `/var/yp/`*ypdomain* directory on the local machine. Note that *ypdomain* is case sensitive. `ypxfr(1M)` can be used to get the NIS maps.

If a *nisdomain* is specified, `nisaddent` operates on the NIS+ table in that NIS+ domain, otherwise the default domain is used.

In terms of performance, loading up the tables is fastest when done through the dbm files (`-y`).

To accommodate other credential entries used by other authentication mechanisms stored in the `cred.org_dir` table, the `publickey` dump output has been modified to include a special algorithm `type` field. This format is incompatible with older versions of `nisaddent`. To produce dumps that can be read by older versions of `nisaddent`, or to load dumps created by such older versions, use the `-o` option.

Options The following options are supported:

`-a` Add the file or map to the NIS+ table without deleting any existing entries. This option is the default. Note that this mode only propagates additions and modifications, not deletions.

`-A` All data. This option specifies that the data within the table and all of the data in tables in the initial table's concatenation path be returned.

`-d` Dump the NIS+ table to the standard output in the appropriate format for the given `type`. For tables of type `key-value`, use `niscat(1)` instead. To dump the `cred` table, dump the `publickey` and the `netid` types.

`-D` *defaults* This option specifies a different set of defaults to be used during this operation. The *defaults* string is a series of tokens separated by colons. These tokens represent the default values to be used for the generic object properties. All of the legal tokens are described below.

`ttl=time` This token sets the default time to live for objects that are created by this command. The value `time` is specified in the format as defined by the `nischttl(1)` command. The default is 12 hours.

`owner=`*ownername* This token specifies that the NIS+ principal *ownername* should own the created object. The default for this value is the principal who is executing the command.

`group=`*groupname* This token specifies that the group *groupname* should be the group owner for the object that is created. The default is `NULL`.

`access=`*rights* This token specifies the set of access rights that are to be granted for the given object. The value *rights* is specified in the format as defined by the `nischmod(1)` command. The default is

`– – – –rmcdr – – –r – – –`

`-f` *file*	Specify that `file` should be used as the source of input (instead of the standard input).
`-m`	Merge the file or map with the NIS+ table. This is the most efficient way to bring an NIS+ table up to date with a file or NIS map when there are only a small number of changes. This option adds entries that are not already in the database, modifies entries that already exist (if changed), and deletes any entries that are not in the source. Use the `-m` option whenever the database is large and replicated, and the map being loaded differs only in a few entries. This option reduces the number of update messages that have to be sent to the replicas. Also see the `-r` option.
`-M`	Master server only. This option specifies that lookups should be sent to the master server. This guarantees that the most up-to-date information is seen at the possible expense that the master server may be busy, or that it may be made busy by this operation.
`-o`	Use strictly conforming `publickey` files. Dumps will not add the algorithm `type` field used by additional authentication mechanisms that might be configured using `nisauthconf(1M)`. 192-bit keys that are dumped using this option can be read by previous versions of `nisaddent`. However, the algorithm field will be lost and assumed to be "0" when read. Use the `-o` option when reading `publickey` files from previous versions of `nisaddent` to avoid warnings about the missing algorithm field.
`-p`	Process the password field when loading password information from a file. By default, the password field is ignored because it is usually not valid (the actual password appears in a shadow file).
`-P`	Follow concatenation path. This option specifies that lookups should follow the concatenation path of a table if the initial search is unsuccessful.
`-q`	Dump tables in "quick" mode. The default method for dumping tables processes each entry individually. For some tables, for example, hosts, multiple entries must be combined into a single line, so extra requests to the server must be made. In "quick" mode, all of the entries for a table are retrieved in one call to the server, so the table can be dumped more quickly. However, for large tables, there is a chance that the process will run out of virtual memory and the table will not be dumped.
`-r`	Replace the file or map in the existing NIS+ table by first deleting any existing entries, and then add the entries from the source (`/etc` files, or NIS+ maps). This option has the same effect as the `-m` option. The use of this option is *strongly* discouraged due to its adverse impact on performance, unless there are a large number of changes.

`-t` *table* Specify that *table* should be the NIS+ table for this operation. This should be a relative name as compared to your default domain or the `domainname` if it has been specified.

`-v` Verbose.

`-y` *ypdomain* Use the `dbm` files for the appropriate NIS map, from the NIS domain *ypdomain*, as the source of input. The files are expected to be on the local machine in the `/var/yp/`*ypdomain* directory. If the machine is not an NIS server, use `ypxfr(1M)` to get a copy of the `dbm` files for the appropriate map.

`-Y` *map* Use the `dbm` files for *map* as the source of input.

Examples

EXAMPLE 1 Using `nisaddent`

This example adds the contents of `/etc/passwd` to the `passwd.org_dir` table:

```
example% cat /etc/passwd | nisaddent passwd
```

The next example adds the shadow information. Note that the table type here is "shadow", not "passwd", even though the actual information is stored in the `passwd` table:

```
example% cat /etc/shadow | nisaddent shadow
```

This example replaces the `hosts.org_dir` table with the contents of `/etc/hosts` (in verbose mode):

```
example% nisaddent -rv -f /etc/hosts hosts
```

This example merges the `passwd` map from `yypdomain` with the `passwd.org_dir.nisdomain` table (in verbose mode). The example assumes that the `/var/yp/myypdomain` directory contains the `yppasswd` map.

```
example% nisaddent -mv -y myypdomain passwd nisdomain
```

This example merges the `auto.master` map from `myypdomain` with the `auto_master.org_dir` table:

```
example% nisaddent -m -y myypdomain -Y auto.master \
     -t auto_master.org_dir key-value
```

This example dumps the `hosts.org_dir` table:

```
example% nisaddent -d hosts
```

This example dumps the `ipnodes.org_dir` table:

```
example% nisaddent -d ipnodes
```

Environment Variables

`NIS_DEFAULTS` This variable contains a default string that will override the NIS+ standard defaults. If the `-D` switch is used, those values will then override both the `NIS_DEFAULTS` variable and the standard defaults. To avoid security

accidents, the access rights in the `NIS_DEFAULTS` variable are ignored for the `passwd` table (but access rights specified with `-D` are used).

`NIS_PATH` If this variable is set, and neither the *nisdomain* nor the *table* are fully qualified, each directory specified in `NIS_PATH` will be searched until the table is found (see `nisdefaults(1)`).

Exit Status The following exit values are returned:

`0` Successful operation.

`1` Failure caused by an error other than parsing.

`2` A parsing error occurred on an entry. A parsing error does not cause termination; the invalid entries are simply skipped.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

See Also `niscat(1)`, `nischmod(1)`, `nischttl(1)`, `nisdefaults(1)`, `nistbladm(1)`, `nisauthconf(1M)`, `nispopulate(1M)`, `nisserver(1M)`, `nissetup(1M)`, `ypxfr(1M)`, `hosts(4)`, `passwd(4)`, `shadow(4)`, `attributes(5)`

Notes NIS+ might not be supported in future releases of the Solaris operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

Name nisauthconf – configure NIS+ security

Synopsis

```
nisauthconf [-v] [mechanism,]...
```

Description `nisauthconf` controls which authentication flavors NIS+ should use when communicating with other NIS+ clients and servers. If the command is not executed, then NIS+ will default to the `AUTH_DES` authentication flavor when running security level 2. See `rpc.nisd(1M)`.

`nisauthconf` takes a list of authentication *mechanism*'s in order of preference. An authentication *mechanism* may use one or more authentication flavors listed below. If `des` is the only specified mechanism, then NIS+ only use `AUTH_DES` with other NIS+ clients and servers. If `des` is the first mechanism, then other authentication *mechanism*'s after `des` will be ignored by NIS+, except for `nisaddcred(1M)`. After changing the mechanism configuration, the `keyserv(1M)` daemon must be restarted. Note that doing so will remove encryption keys stored by the running `keyserv` process. This means that a `reboot` usually is the safest option when the mechanism configuration has been changed.

The following mechanisms are available:

Authentication *mechanism*	Authentication Flavor
des	`AUTH_DES`
dh640–0	`RPCSEC_GSS` using 640-bit Diffie-Hellman keys
dh1024–0	`RPCSEC_GSS` using 1024-bit Diffie-Hellman keys

If no mechanisms are specified, then a list of currently configured mechanisms is printed.

Options `-v` Displays a verbose table listing the currently configured authentication mechanisms.

Examples

EXAMPLE 1 Configuring a System with only `RPCSEC_GSS` Authentication Flavor

To configure a system to use only the `RPCSEC_GSS` authentication flavor with 640-bit Diffie-Hellman keys, execute the following as root:

```
example# /usr/lib/nis/nisauthconf dh640-0
```

EXAMPLE 2 Configuring a System with both `RPCSEC_GSS` and `AUTH_DES` Authentication Flavors

To configure a system to use both `RPCSEC_GSS` (with 640-bit Diffie-Hellman keys) and `AUTH_DES` authentication flavors:

```
example# /usr/lib/nis/nisauthconf dh640-0 des
```

EXAMPLE 3 Transitioning to Other Authentication Flavors

The following example can be used while adding credentials for a new mechanism before NIS+ is authenticating with the new mechanism:

EXAMPLE 3 Transitioning to Other Authentication Flavors *(Continued)*

```
example# /usr/lib/nis/nisauthconf des dh640-0
```

Note that except for nisaddcred(1M), NIS+ will not use mechanisms that follow 'des.'

Exit Status The following exit values are returned:

0 Successful completion.

1 An error occurred.

Files

/etc/rpcsec/nisplussec.conf	NIS+ authentication configuration file. This file may change or be removed in future versions of Solaris.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

See Also NIS+(1), keyserv(1M), nisaddcred(1M), rpc.nisd(1M), attributes(5)

Notes A NIS+ client of a server that is configured for either dh640–0 or dh1024–0 must run Solaris 7 or later, even if the server is also configured with des.

NIS+ might not be supported in future releases of the Solaris operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

Name nisbackup – backup NIS+ directories

Synopsis

```
nisbackup [-v] backup-dir directory...

nisbackup [-v] -a backup-dir
```

Description `nisbackup` backs up a NIS+ directory object on a NIS+ master server. Updates to the NIS+ database will be temporarily disabled while `nisbackup` is running. The *backup-dir* is a UNIX directory that must exist prior to running `nisbackup`. The `nisbackup` command can be used to backup an individual NIS+ directory object or all (`-a`) of the NIS+ directory objects served by a master server. The NIS+ directory objects being backed up will be placed into subdirectories under the *backup-dir* directory. These subdirectories are named according to the NIS+ directory object they contain. `nisbackup` operates on individual NIS+ directory objects (for example, `org_dir.wiz.com`). This allows an administrator to selectively backup specific directories.

The `rpc.nisd(1M)` process must be running on the master server with a stable NIS+ database for `nisbackup` to complete. `nisbackup` will not attempt to correct any corruption in the NIS+ database, so it is important that backups be done regularly as part of the NIS+ administration.

The first synopsis is used to backup a single NIS+ directory object or a list of NIS+ directory objects. The objects can be partially qualified or fully qualified. The machine on which the command is executing must be the master for the NIS+ directory objects specified.

The second synopsis will backup all of the NIS+ directory objects that are served by this master. The `-a` option is the recommended method of backing up a master server, since it will backup all NIS+ directory objects that are served by this master. If this server is a master server for more than one domain, the backup will include NIS+ directories that belong to all of the domains served. Individual NIS+ directory objects can be selected for restoring from a *backup-dir* created with the `-a` option. See `nisrestore(1M)`.

The `-a` option only includes directory objects for which this server is the master. It is possible, but not recommended, to configure a master server as a replica for other domains. The objects belonging to those replicated domains will not be backed up with the `-a` option. The backup of replicated objects must be run on the master server for those objects.

Do not use the same *backup-dir* to backup different master servers. Each master server must have its own *backup-dir*.

`nisbackup` will set the `rpc.nisd(1M)` to read only mode, which will disable updates to the NIS+ database. This is neccessary to ensure the consistency of the backup. For this reason, `nisbackup` should not be run while large numbers of updates are being applied to the NIS+ database. Update utilities such as `nisaddent(1M)` should not be run simultaneously with `nisbackup`.

Options

`-a` Creates a backup of all NIS+ directory objects for which this server is a master.

`-v` Verbose option. Additional output will be produced and sent to `syslog(3C)` upon execution of the command (see `syslog.conf(4)`).

Operands

backup-dir The directory into which the subdirectories containing the backed up objects are placed. This must be created prior to running `nisbackup`.

directory The NIS+ directory object(s) being backed up.

Examples

EXAMPLE 1 Backup of the `org_dir` NIS+ directory object of the domain `foo.com` on a master server to a directory named `/backup`

To backup the `org_dir` NIS+ directory object of the domain `foo.com` on a master server to a directory named `/backup`:

```
master_server# nisbackup /backup org_dir.foo.com.
```

EXAMPLE 2 Backup of the entire NIS+ domain `foo.com` to a directory named `/backup`

To backup the entire NIS+ domain `foo.com` to a directory named `/backup`:

```
master_server# nisbackup /backup foo.com. \
              org_dir.foo.com. groups_dir.foo.com. \
              ctx_dir.foo.com.
```

EXAMPLE 3 Backup of an entire NIS+ database to a backup directory named `/backup`

To backup an entire NIS+ database to a backup directory named `/backup`:

```
master_server# nisbackup -a /backup
```

Exit Status

`0` Successful completion.

`1` An error occurred.

Files

/backup-dir/backup_list	This ascii file contains a list of all the objects contained in this *backup-dir* directory.
/backup-dir/directory-object	A subdirectory that is created in the *backup-dir* that contains the NIS+ directory-object backup.
/backup-dir/directory-object`/data`	A subdirectory that contains the data files that are part of the NIS+ directory-object backup.
/backup-dir/directory-object`/last.upd`	This data file contains timestamp information about the directory-object.
/backup-dir/directory-object`/data.dict`	A NIS+ data dictionary for all of the objects contained in the NIS+ directory-object backup.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

See Also NIS+(1), nisdefaults(1), nisrm(1), nisrestore(1M), rpc.nisd(1M), syslog(3C), nisfiles(4), syslog.conf(4), attributes(5)

Notes NIS+ might not be supported in future releases of the Solaris operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

Name nis_cachemgr – NIS+ utility to cache location information about NIS+ servers

Synopsis

```
/usr/sbin/nis_cachemgr [-i] [-v]
```

Description The `nis_cachemgr` daemon maintains a cache of NIS+ directory objects and active servers for domains. It is responsible for locating servers for a domain on behalf of client processes. This improves performance because only one process has to search for servers. The cache contains location information necessary to contact the NIS+ servers. This includes transport addresses, information neeeded to authenticate the server, and a time to live field which gives a hint on how long the directory object can be cached. The cache helps to improve the performance of the clients that are traversing the NIS+ name space. `nis_cachemgr` should be running on all the machines that are using NIS+. However, it is not required that the `nis_cachemgr` program be running in order for NIS+ requests to be serviced.

The cache maintained by this program is shared by all the processes that access NIS+ on a machine. The cache is maintained in a file that is memory mapped by all the processes. See `mmap(2)`. On start up, `nis_cachemgr` initializes the cache from the cold start file and preserves unexpired entries that already exist in the cache file. See `nisinit(1M)`. Thus, the cache survives machine reboots.

The `nis_cachemgr` program is normally started from a system startup script. `nisshowcache(1M)` can be used to look at the cached objects and active servers.

The `nisprefadm(1M)` command can be used to control which NIS+ servers the `nis_cachemgr` program will try to select.

The `nis_cachemgr` program makes NIS+ requests under the NIS+ principal name of the host on which it runs. Before running `nis_cachemgr`, security credentials for the host should be added to the `cred.org_dir` table in the host's domain using `nisaddcred(1M)`. Credentials of type DES will be needed if the NIS+ service is operating at security level 2 (see `rpc.nisd(1M)`). See the Diagnostics section, below. Additionally, a "`keylogin -r` " should be done on the machine.

`svc:/network/rpc/keyserv:default` is required for NIS+ operation. See `NOTES`.

Options

`-i` Force `nis_cachemgr` to ignore the previous cache file and reinitialize the cache from just the cold start file. By default, the cache manager initializes itself from both the cold start file and the old cache file, thereby maintaining the entries in the cache across machine reboots.

`-v` This flag sets verbose mode. In this mode, the `nis_cachemgr` program logs not only errors and warnings, but also additional status messages. The additional messages are logged using `syslog(3C)` with a priority of `LOG_INFO`.

Files

`/var/nis/NIS_SHARED_DIRCACHE`	the shared cache file
`/var/nis/NIS_COLD_START`	the coldstart file

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also keylogin(1), svcs(1), nisaddcred(1M), nisinit(1M), nisprefadm(1M), nisshowcache(1M), rpc.nisd(1M), svcadm(1M), mmap(2), rpc(3NSL), syslog(3C), nisfiles(4), attributes(5), smf(5)

Diagnostics The nis_cachemgr daemon logs error messages and warnings using syslog(3C). Error messages are logged to the DAEMON facility with a priority of LOG_ERR . Warning messages are logged with a priority of LOG_WARNING. Additional status messages can be obtained using the -v option.

Notes NIS+ might not be supported in future releases of the Solaris operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

The nis_cachemgr service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/network/rpc/nisplus:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name nisclient – initialize NIS+ credentials for NIS+ principals

Synopsis

```
/usr/lib/nis/nisclient -c [-x] [-o] [-v]
     [-l <network_password>] [-d <NIS+_domain>] client_name...

/usr/lib/nis/nisclient -i [-x] [-v] -h <NIS+_server_host>
     [-a <NIS+_server_addr>]
     [-k <key_domain>] [-d <NIS+_domain>] [-S 0 | 2]

/usr/lib/nis/nisclient -u [-x] [-v]

/usr/lib/nis/nisclient -r [-x]
```

Description The nisclient shell script can be used to:

- create NIS+ credentials for hosts and users
- initialize NIS+ hosts and users
- restore the network service environment

NIS+ credentials are used to provide authentication information of NIS+ clients to NIS+ service.

Use the first synopsis (`-c` option) to create individual NIS+ credentials for hosts or users. You must be logged in as a NIS+ principal in the domain for which you are creating the new credentials. You must also have write permission to the local "cred" table. The *client_name* argument accepts any valid host or user name in the NIS+ domain (for example, the *client_name* must exist in the hosts or passwd table). `nisclient` verifies each *client_name* against both the `host` and `passwd` tables, then adds the proper NIS+ credentials for hosts or users. Note that if you are creating NIS+ credentials outside of your local domain, the host or user must exist in the `host` or `passwd` tables in both the local and remote domains.

By default, `nisclient` will not overwrite existing entries in the credential table for the hosts and users specified. To overwrite, use the `-o` option. After the credentials have been created, `nisclient` will print the command that must be executed on the client machine to initialize the host or the user. The `-c` option requires a network password for the client which is used to encrypt the secret key for the client. You can either specify it on the command line with the `-l` option or the script will prompt you for it. You can change this network password later with `passwd(1)` or `chkey(1)`.

`nisclient -c` is not intended to be used to create NIS+ credentials for all users and hosts which are defined in the passwd and hosts tables. To define credentials for all users and hosts, use `nispopulate(1M)`.

Use the second synopsis (`-i` option) to initialize a NIS+ client machine. The `-i` option can be used to convert machines to use NIS+ or to change the machine's domainname. You must be logged in as super-user on the machine that is to become a NIS+ client. Your administrator must have already created the NIS+ credential for this host by using `nisclient -c` or `nispopulate -C`. You will need the network password your administrator created. `nisclient` will prompt you for the network password to decrypt your secret key and then for this

machine's root login password to generate a new set of secret/public keys. If the NIS+ credential was created by your administrator using `nisclient -c`, then you can simply use the initialization command that was printed by the `nisclient` script to initialize this host instead of typing it manually.

To initialize an unauthenticated NIS+ client machine, use the `-i` option with `-S` *0*. With these options, the `nisclient -i` option will not ask for any passwords.

During the client initialization process, files that are being modified are backed up as *files*`.no_nisplus`. The files that are usually modified during a client initialization are: `/etc/defaultdomain`, `/etc/nsswitch.conf`, `/etc/inet/hosts`, and, if it exists, `/var/nis/NIS_COLD_START`. Notice that a file will not be saved if a backup file already exists.

The `-i` option does not set up a NIS+ client to resolve hostnames using DNS. Please refer to the DNS documentation for information on setting up DNS. (See `resolv.conf(4)`).

It is not necessary to initialize either NIS+ root master servers or machines that were installed as NIS+ clients using `suninstall(1M)`.

Use the third synopsis (`-u` option) to initialize a NIS+ user. You must be logged in as the user on a NIS+ client machine in the domain where your NIS+ credentials have been created. Your administrator should have already created the NIS+ credential for your username using `nisclient -c` or `nispopulate(1M)`. You will need the network password your administrator used to create the NIS+ credential for your username. `nisclient` will prompt you for this network password to decrypt your secret key and then for your login password to generate a new set of secret/public keys.

Use the fourth synopsis (`-r` option) to restore the network service environment to whatever you were using before `nisclient -i` was executed. You must be logged in as super-user on the machine that is to be restored. The restore will only work if the machine was initialized with `nisclient -i` because it uses the backup files created by the `-i` option.

Reboot the machine after initializing a machine or restoring the network service.

Options The following options are supported:

`-a` <*NIS+_server_addr*>	Specifies the IP address for the NIS+ server. This option is used *only* with the `-i` option.
`-c`	Adds `DES` credentials for NIS+ principals.
`-d` <*NIS+_domain*>	Specifies the NIS+ domain where the credential should be created when used in conjunction with the `-c` option. It specifies the name for the new NIS+ domain when used in conjunction with the `-i` option. The default is your current domainname.
`-h` <*NIS+_server_host*>	Specifies the NIS+ server's hostname. This option is used *only* with the `-i` option.

`-i`	Initializes a NIS+ client machine.
`-l` <*network_password*>	Specifies the network password for the clients. This option is used *only* with the `-c` option. If this option is not specified, the script will prompt you for the network password.
`-k` <*key_domain*>	This option specifies the domain where root's credentials are stored. If a domain is not specified, then the system default domain is assumed.
`-o`	Overwrites existing credential entries. The default is not to overwrite. This is used *only* with the `-c` option.
`-r`	Restores the network service environment.
`-S` *0*|*2*	Specifies the authentication level for the NIS+ client. Level `0` is for unauthenticated clients and level `2` is for authenticated (`DES`) clients. The default is to set up with level `2` authentication. This is used *only* with the `-i` option. `nisclient` always uses level `2` authentication (`DES`) for both `-c` and `-u` options. There is no need to run `nisclient` with `-u` and `-c` for level `0` authentication. To configure authentication mechanisms other than DES at security level 2, use `nisauthconf(1M)` before running `nisclient`.
`-u`	Initializes a NIS+ user.
`-v`	Runs the script in verbose mode.
`-x`	Turns the "echo" mode on. The script just prints the commands that it would have executed. Notice that the commands are not actually executed. The default is off.

Examples

EXAMPLE 1 Adding the DES Credential in the Local Domain

To add the `DES` credential for host `sunws` and user `fred` in the local domain:

```
example% /usr/lib/nis/nisclient -c sunws fred
```

EXAMPLE 2 Adding the DES Credential in a Specified Domain

To add the `DES` credential for host `sunws` and user `fred` in domain `xyz.example.com.`:

```
example% /usr/lib/nis/nisclient -c -d xyz.example.com. sunws fred
```

EXAMPLE 3 Initializing the Host in a Specific Domain

To initialize host `sunws` as a NIS+ client in domain `xyz.example.com.` where `nisplus_server` is a server for the domain `xyz.example.com.`:

```
example# /usr/lib/nis/nisclient -i -h nisplus_server -d xyz.example.com
```

EXAMPLE 3 Initializing the Host in a Specific Domain *(Continued)*

The script will prompt you for the IP address of `nisplus_server` if the server is not found in the `/etc/hosts` file. The `-d` option is needed only if your current domain name is different from the new domain name.

EXAMPLE 4 Initializing the Host as an Unauthenticated Client in a Specific Domain

To initialize host `sunws` as an unauthenticated NIS+ client in domain `xyz.example.com.` where `nisplus_server` is a server for the domain `xyz.example.com`:

```
example# /usr/lib/nis/nisclient -i -S 0 \
   -h nisplus_server -d xyz.example.com. -a 172.16.44.1
```

EXAMPLE 5 Initializing the User as a NIS+ principal

To initialize user `fred` as a NIS+ principal, log in as user `fred` on a NIS+ client machine.

```
example% /usr/lib/nis/nisclient -u
```

Files

`/var/nis/NIS_COLD_START`	This file contains a list of servers, their transport addresses, and their Secure RPC public keys that serve the machines default domain.
`/etc/defaultdomain`	The system default domainname.
`/etc/nsswitch.conf`	Configuration file for the name-service switch.
`/etc/inet/hosts`	Local host name database.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

See Also `chkey(1)`, `keylogin(1)`, `NIS+(1)`, `passwd(1)`, `keyserv(1M)`, `nisaddcred(1M)`, `nisauthconf(1M)`, `nisinit(1M)`, `nispopulate(1M)`, `suninstall(1M)`, `nsswitch.conf(4)`, `resolv.conf(4)`, `attributes(5)`

Notes NIS+ might not be supported in future releases of the Solaris operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

Name nisinit – NIS+ client and server initialization utility

Synopsis

```
nisinit -r

nisinit -p Y | D | N parent_domain host...

nisinit -c [-k <key_domain>] -H host | -B | -C coldstart
```

Description `nisinit` initializes a machine to be a NIS+ client or an NIS+ root master server. It may be easier to use `nisclient(1M)` or `nisserver(1M)` to accomplish this same task.

Options

`-r`

Initialize the machine to be a NIS+ root server. This option creates the file `/var/nis/data/root.object` and initialize it to contain information about this machine. It uses the `sysinfo(2)` system call to retrieve the name of the default domain.

To initialize the machine as an NIS+ root server, it is advisable to use the "`-r`" option of `nisserver(1M)`, instead of using "`nisinit -r`".

`-p Y | D | N` *parent_domain host . . .*

This option is used on a root server to initialize a `/var/nis/data/parent.object` to make this domain a part of the namespace above it. Only root servers can have parent objects. A parent object describes the namespace "above" the NIS+ root. If this is an isolated domain, this option should not be used. The argument to this option tells the command what type of name server is serving the domain above the NIS+ domain. When clients attempt to resolve a name that is outside of the NIS+ namespace, this object is returned with the error `NIS_FOREIGNNS` indicating that a name space boundary has been reached. It is up to the client to continue the name resolution process.

The parameter *parent_domain* is the name of the parent domain in a syntax that is native to that type of domain. The list of host names that follow the domain parameter are the names of hosts that serve the parent domain. If there is more than one server for a parent domain, the first host specified should be the master server for that domain.

`Y` Specifies that the parent directory is a NIS version 2 domain.

`D` Specifies that the parent directory is a DNS domain.

`N` Specifies that the parent directory is another NIS+ domain. This option is useful for connecting a pre-existing NIS+ subtree into the global namespace.

Note that in the current implementation, the NIS+ clients do not take advantage of the `-p` feature. Also, since the parent object is currently not replicated on root replica servers, it is recommended that this option not be used.

`-c` Initializes the machine to be a NIS+ client. There are three initialization options available: initialize by coldstart, initialize by hostname, and initialize by broadcast. The most secure mechanism is to initialize from a trusted coldstart file. The second option is to initialize using a hostname that you specify as a trusted host. The third method is to initialize by broadcast and it is the least secure method.

`-C` *coldstart* Causes the file *coldstart* to be used as a prototype coldstart file when initializing a NIS+ client. This coldstart file can be copied from a machine that is already a client of the NIS+ namespace. For maximum security, an administrator can encrypt and encode (with `uuencode(1C)`) the coldstart file and mail it to an administrator bringing up a new machine. The new administrator would then decode (with `uudecode`), decrypt, and then use this file with the `nisinit` command to initialize the machine as an NIS+ client. If the coldstart file is from another client in the same domain, the `nisinit` command may be safely skipped and the file copied into

the `/var/nis` directory as `/var/nis/NIS_COLD_START`.

`-H` *hostname*
: Specifies that the host `hostname` should be contacted as a trusted NIS+ server. The `nisinit` command will iterate over each transport in the `NETPATH` environment variable and attempt to contact `rpcbind(1M)` on that machine. This hostname *must* be reachable from the client without the name service running. For IP networks this means that there must be an entry in `/etc/hosts` for this host when `nisinit` is invoked.

`-B`
: Specifies that the `nisinit` command should use an IP broadcast to locate a NIS+ server on the local subnet. Any machine that is running the NIS+ service may answer. No guarantees are made that the server that answers is a server of the organization's namespace. If this option is used, it is advisable to check with your system administrator that the server and domain served are valid. The binding information can be dumped to the standard output using the `nisshowcache(1M)` command.

Note that `nisinit -c` will just enable navigation of the NIS+ name space from this client. To make NIS+ your name service, modify the file `/etc/nsswitch.conf` to reflect that. See `nsswitch.conf(4)` for more details.

`-k` <*key_domain*>
: This option specifies the domain where root's credentials are stored. If it is not specified, then the system default domain is assumed. This domain name is used to create the

/var/nis/NIS_COLD_START file.

Return Values `nisinit` returns `0` on success and `1` on failure.

Examples

EXAMPLE 1 Initializing the Machine as an NIS+ Client using the Host *freddy* as a Trusted Server

This example initializes the machine as an NIS+ client using the host *freddy* as a trusted server.

```
example# nisinit -cH freddy
```

EXAMPLE 2 Setting up a Client using a Trusted Coldstart File

This example sets up a client using a trusted coldstart file.

```
example# nisinit -cC /tmp/colddata
```

EXAMPLE 3 Setting up a Client Using an IP Broadcast

This example sets up a client using an IP broadcast.

```
example# nisinit -cB
```

EXAMPLE 4 Setting up a Root Server

This example sets up a root server.

```
example# nisinit -r
```

Environment Variables

`NETPATH` This environment variable may be set to the transports to try when contacting the NIS+ server (see `netconfig(4)`). The client library will only attempt to contact the server using connection oriented transports.

Files

`/var/nis/NIS_COLD_START`	This file contains a list of servers, their transport addresses, and their Secure RPC public keys that serve the machine's default domain.
`/var/nis/data/root.object`	This file describes the root object of the NIS+ namespace. It is a standard XDR-encoded NIS+ directory object that can be modified by authorized clients using the `nis_modify()` interface.
`/var/nis/data/parent.object`	This file describes the namespace that is logically above the NIS+ namespace. The most common type of parent object is a DNS object. This object contains contact information for a server of that domain.
`/etc/hosts`	Internet host table.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

See Also NIS+(1), uuencode(1C), nisclient(1M), nisserver(1M), nisshowcache(1M), sysinfo(2), hosts(4), netconfig(4), nisfiles(4), attributes(5)

Notes NIS+ might not be supported in future releases of the Solaris operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

Name nisldapmaptest – test NIS+ and LDAP mapping configuration files

Synopsis

```
nisldapmaptest [-s | -r | -d] [-l | -t object] [-v] [-i]
     [-o] [-m conffile] [-x attr=val...] [ col=val]...
```

Description Use the `nisldapmaptest` utility to test NIS+ to LDAP mapping configuration files. See `NIS+LDAPmapping(4)`. The `nisldapmaptest` utility uses much of the same internal interface as the `rpc.nisd(1M)` does to read, add, modify, or delete LDAP data, as specified by the column name and value operand pairs. `nisldapmaptest` does not read or modify any of the `rpc.nisd(1M)` database files.

See Notes for details on important differences between the ways that `nisldapmaptest` and `rpc.nisd(1M)` operate on LDAP data.

Options The `nisldapmaptest` utility supports the following options:

`-d` Delete data in LDAP.

`-i` Ignore failures when obtaining information from the NIS+ server. This enables `nisldapmaptest` to work to some extent, even if the NIS+ server is unreachable, or if the system is not a NIS+ client. However, NIS+ lookups are still attempted, so there may be NIS+ error messages.

In this mode, `nisldapmaptest` also tries to guess things such as NIS+ object types and derives table column information from the mapping rules in the configuration files. Avoid using the `-i` option to add, modify, or delete, until you have determined that the `nisldapmaptest`'s guesses are adequate for your needs.

`-l` Parse the configuration file into internal data structures, and then print out the configuration per those structures. Note that the printed data is not in configuration file format.

Either `-l` or `-t` must be specified. If both are present, `-l` is ignored.

`-m` *conffile* Specify the name of the `NIS+LDAPmapping(4)` configuration file. The default directory is `/var/nis` , and the default mapping file is `NIS+LDAPmapping`.

`-o` For NIS+ tables, work on the NIS+ object itself, specified by means of the `-t` option, not on the table entries.

`-r` Replace or add data in LDAP.

`-s` Search for data in LDAP. This is the default.

`-t` *object* Specify the NIS+ object on which to operate. If the object name is not fully qualified, that is, it does not end in a dot, the value of the `nisplusLDAPbaseDomain` attribute is appended.

`-v` Set the verbose flag. This flag produces extra diagnostic information.

`-x attr=val...` Specify mapping attribute and value pairs to override those obtained by means of the configuration file. Although any attributes defined on `NIS+LDAPmapping(4)` or `rpc.nisd(4)` can be specified, the ones that control `rpc.nisd(1M)` operation have no effect on `nisldapmaptest`.

Operands The following operands are supported:

`col=val...` NIS+ column and value pairs used to specify which entries should be looked up, added, modified, or deleted. For additions and modifications, use `col=val` to specify the new values.

Examples

EXAMPLE 1 Searching for a User

Use the following example to search for the user `xyzzy` in the LDAP container specified for the `passwd.org_dir` table.

```
example% nisldapmaptest -t passwd.org_dir name=xyzzy
```

EXAMPLE 2 Listing Table Entries

Use the following example to list all entries in the container specified for the `services.org_dir` table.

```
example% nisldapmaptest -t services.org_dir
```

EXAMPLE 3 Listing an Object

Use the following example to list the `services.org_dir` object itself, as it is stored in LDAP.

```
example% nisldapmaptest -o -t services.org_dir
```

EXAMPLE 4 Modifying a Table Entry

Use the following example to modify the membership list of the group `grp`, in the container specified for the `group.org_dir` table, to be `mem1`, `mem2`, and `mem3`.

```
example% nisldapmaptest -r -t group.org_dir name=grp \
     members=mem1,mem2,mem3
```

EXAMPLE 5 Deleting a Table Entry

Use the following example to delete the host called `bad` from the container specified for the `hosts.org_dir` table.

```
example% nisldapmaptest -d -t hosts.org_dir name=bad
```

Exit Status The following exit values are returned:

`0` The requested operation was successful.

`!= 0` An error occurred.

Files `/var/nis/NIS+LDAPmapping.template`

`/etc/default/rpd.nisd`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisr
Interface Stability	Obsolete

See Also `rpc.nisd(1M)`, `NIS+LDAPmapping(4)`, `rpc.nisd(4)`, `attributes(5)`

Notes There are several differences between the ways that `nisldapmaptest` and `rpc.nisd` operate:

1. `nisldapmaptest` obtains information about NIS+ by means of the NIS+ API calls, while `rpc.nisd` looks in its internal database. Thus, if the NIS+ server is not available, `nisldapmaptest` may be unable to determine NIS+ object types or table column information.
2. While `nisldapmaptest` can add, modify, or delete LDAP data, it does not modify any NIS+ data.
3. When operating on table entries, if `nisldapmaptest` is unable to obtain the entry from NIS+, it composes LDAP operations using only the supplied `col=val` operands. Depending on the mapping used, this can result in extra LDAP operations, for example, attempting to obtain a `DN` for add, modify, or delete.
4. The default value for `nisplusLDAPbaseDomain` is the system domain name per `sysinfo(2)` in `nisldapmaptest`, but the internal notion of the domain it serves in `rpc.nisd`. While the two usually are the same, this is not necessarily always the case.
5. When more than one NIS+ entry maps to a single LDAP entry, `nisldapmaptest` may be unable to perform a complete update, unless you make sure that the `col=val` specification picks up all relevant NIS+ entries. For example, if you have the `services.org_dir` NIS+ entries:

```
cname   name    proto   port

x       x       tcp     12345
x       y       tcp     12345
x       z       tcp     12345
```

then specifying `cname=x` will pick up all three entries and create or modify the corresponding LDAP entry to have three `CN` values: `x`, `y`, and `z`. However, specifying `name=x` will match just the first NIS+ entry, and create or modify the LDAP entry to have just one `CN`: `x`.

Name nislog – display the contents of the NIS+ transaction log

Synopsis

```
/usr/sbin/nislog [-h num | -t num] [-v] [directory]...
```

Description `nislog` displays the contents of the NIS+ server transaction log on the standard output. This command can be used to track changes in the namespace. The `/var/nis/trans.log` file contains the transaction log maintained by the NIS+ server. When updates occur, they are logged to this file and then propagated to replicas as log transactions. When the log is checkpointed, updates that have been propagated to the replicas are removed.

The `nislog` command can only be run on an NIS+ server by superuser. It displays the log entries for that server only.

If *directory* is not specified, the entire log is searched. Otherwise, only those logs entries that correspond to the specified directories are displayed.

Options

`-h` *num* Display *num* transactions from the "head" of the log. If the numeric parameter is `0`, only the log header is displayed.

`-t` *num* Display *num* transactions from the "tail" of the log. If the numeric parameter is `0`, only the log header is displayed.

`-v` Verbose mode.

Files

`/var/nis/trans.log` transaction log

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

See Also `NIS+(1)`, `rpc.nisd(1M)`, `nisfiles(4)`, `attributes(5)`

Notes NIS+ might not be supported in future releases of the Solaris operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

Name nisping – send ping to NIS+ servers

Synopsis

```
/usr/lib/nis/nisping [-uf] [-H hostname] [-r | directory]
/usr/lib/nis/nisping -C [-a] [-H hostname] [directory]
```

Description In the first Synopsis line, the `nisping` command sends a "ping" to all replicas of an NIS+ directory. Once a replica receives a ping, it will check with the master server for the directory to get updates. Prior to pinging the replicas, this command attempts to determine the last update "seen" by a replica and the last update logged by the master. If these two timestamps are the same, the ping is not sent. The `-f` (force) option will override this feature.

Under normal circumstances, NIS+ replica servers get the new information from the master NIS+ server within a short time. Therefore, there should not be any need to use `nisping`.

In the second Synopsis line, the `nisping -C` command sends a checkpoint request to the servers. If no *directory* is specified, the home domain, as returned by `nisdefaults(1)`, is checkpointed. If all directories, served by a given server, have to be checkpointed, then use the `-a` option.

On receiving a checkpoint request, the servers would commit all the updates for the given *directory* from the table log files to the database files. This command, if sent to the master server, will also send updates to the replicas if they are out of date. This option is needed because the database log files for NIS+ are not automatically checkpointed. `nisping` should be used at frequent intervals (such as once a day) to checkpoint the NIS+ database log files. This command can be added to the `crontab(1)` file. If the database log files are not checkpointed, their sizes will continue to grow.

If the server specified by the `-H` option does not serve the directory, then no ping is sent.

Per-server and per-directory access restrictions may apply; see `nisopaccess(1)`. `nisping` uses `NIS_CPTIME` and `NIS_PING` (resync (`ping`) of replicas), or `NIS_CHECKPOINT` (for checkpoint). Since the `NIS_PING` operation does not return a status, the `nisping` command is typically unable to indicate success or failure for resyncs.

Options

`-a`	Checkpoint all directories on the server.
`-C`	Send a request to checkpoint, rather than a ping, to each server. The servers schedule to commit all the transactions to stable storage.
`-H` *hostname*	Only the host `hostname` is sent the ping, checked for an update time, or checkpointed.
`-f`	Force a ping, even though the timestamps indicate there is no reason to do so. This option is useful for debugging.
`-r`	This option can be used to update or get status about the root object from the root servers, especially when new root replicas are added or deleted from the list.

If used without `-u` option, `-r` will send a ping request to the servers serving the root domain. When the replicas receive a ping, they will update their root object if needed.

The `-r` option can be used with all other options except with the `-C` option; the root object need not be checkpointed.

`-u` Display the time of the last update; no servers are sent a ping.

Return Values

`−1` No servers were contacted, or the server specified by the `-H` switch could not be contacted.

`0` Success.

`1` Some, but not all, servers were successfully contacted.

Examples

EXAMPLE 1 Using `nisping`

This example pings all replicas of the default domain:

```
example% nisping
```

Note that this example will not ping the `org_dir` and `groups_dir` subdirectories within this domain.

This example pings the server *example* which is a replica of the *org_dir.foo.com.* directory:

```
example% nisping -H example org_dir.foo.com.
```

This example checkpoints all servers of the *org_dir.bar.com.* directory.

```
example% nisping -C org_dir.bar.com.
```

Environment Variables

`NIS_PATH` If this variable is set, and the NIS+ directory name is not fully qualified, each directory specified will be searched until the directory is found.

Attributes

See `attributes(5)` for descriptions of the following attributes:

Name nispopulate – populate the NIS+ tables in a NIS+ domain

Synopsis

```
/usr/lib/nis/nispopulate -Y [-x] [-f] [-n] [-u] [-v]
     [-S 0 | 2] [-l <network_passwd>]
     [-d <NIS+_domain>] -h <NIS_server_host>
     [-a <NIS_server_addr>] -y <NIS_domain>
     [table] ...

/usr/lib/nis/nispopulate -F [-x] [-f] [-u] [-v] [-S 0 | 2]
     [-d <NIS+_domain>] [-l <network_passwd>]
     [-p <directory_path>] [table] ...

/usr/lib/nis/nispopulate -C [-x] [-f] [-v]
     [-d <NIS+_domain>] [-l <network_passwd>]
     [hosts | passwd]
```

Description The `nispopulate` shell script can be used to populate NIS+ tables in a specified domain from their corresponding files or NIS maps. `nispopulate` assumes that the tables have been created either through `nisserver(1M)` or `nissetup(1M)`.

The table argument accepts standard names that are used in the administration of Solaris systems and non-standard *key-value* type tables. See `nisaddent(1M)` for more information on *key-value* type tables. If the table argument is not specified, `nispopulate` will automatically populate each of the standard tables. These standard (default) tables are: `auto_master`, `auto_home`, `ethers`, `group`, `hosts`, `ipnodes`, `networks`, `passwd`, `protocols`, `services`, `rpc`, `netmasks`, `bootparams`, `netgroup`, `aliases` and `shadow`. Note that the `shadow` table is only used when populating from files. The non-standard tables that `nispopulate` accepts are those of *key-value* type. These tables must first be created manually with the `nistbladm(1)` command.

Use the first synopsis (`-Y`) to populate NIS+ tables from NIS maps. `nispopulate` uses `ypxfr(1M)` to transfer the NIS maps from the NIS servers to the `/var/yp/`*<NIS_domain>* directory on the local machine. Then, it uses these files as the input source. Note that *<NIS_domain>* is case sensitive. Make sure there is enough disk space for that directory.

Use the second synopsis (`-F`) to populate NIS+ tables from local files. `nispopulate` will use those files that match the table name as input sources in the current working directory or in the specified directory.

Note that when populating the `hosts`, `ipnodes`, and `passwd` tables, `nispopulate` will automatically create the NIS+ credentials for all users and `hosts` (`ipnodes`) that are defined in the `hosts`, `ipnodes`, and `passwd` tables, respectively. A network passwd is required to create these credentials. This network password is used to encrypt the secret key for the new users and hosts. This password can be specified using the `-l` option or it will use the default password, `nisplus`. `nispopulate` will not overwrite any existing credential entries in the credential table. Use `nisclient(1M)` to overwrite the entries in the `cred` table. It creates both LOCAL and DES credentials for users, and only DES credentials for hosts. To disable automatic credential creation, specify the "`-S` *0*" option.

The third synopsis (`-C`) is used to populate NIS+ credential table with level 2 authentication (DES) from the `hosts`, `ipnodes` and `passwd` tables of the specified domain. The valid table arguments for this operation are `hosts`, `ipnodes` and `passwd`. If this argument is not specified then it will use `hosts`, `ipnodes` and `passwd` as the input source. If other authentication mechanisms are configured using `nisauthconf(1M)`, the NIS+ credential table will be loaded with credentials for those mechanisms.

If `nispopulate` was earlier used with "`-S` *0*" option, then no credentials were added for the hosts or the users. If later the site decides to add credentials for all users and hosts, then this (`-C`) option can be used to add credentials.

Options

`-a` <*NIS_server_addr*>	Specifies the IP address for the NIS server. This option is only used with the `-Y` option.
`-C`	Populate the NIS+ credential table from `hosts`, `ipnodes`, and `passwd` tables using DES authentication (security level 2). If other authentication mechanisms are configured using `nisauthconf(1M)`, the NIS+ credential table will be populated with credentials for those mechanisms.
`-d` <*NIS+_domain.*>	Specifies the NIS+ domain. The default is the local domain.
`-F`	Populates NIS+ tables from files.
`-f`	Forces the script to populate the NIS+ tables without prompting for confirmation.
`-h` <*NIS_server_host*>	Specifies the NIS server hostname from where the NIS maps are copied from. This is only used with the `-Y` option. This hostname must be present in the NIS+ `hosts` or `ipnodes` table, or in the `/etc/hosts` file. If the hostname is not defined, the script will prompt you for its IP address, or you can use the `-a` option to specify the address manually.
`-l` <*network_passwd*>	Specifies the network password for populating the NIS+ credential table. This is only used when you are populating the `hosts`, `ipnodes`, and `passwd` tables. The default passwd is "nisplus".
`-n`	Does not overwrite local NIS maps in `/var/yp/`<*NISdomain*> directory if they already exist. The default is to overwrite the existing NIS maps in the local `/var/yp/`<*NISdomain*> directory. This is only used with the `-Y` option.
`-p` <*directory_path*>	Specifies the directory where the files are stored. This is only used with the `-F` option. The default is the current working directory.
`-S` *0*|*2*	Specifies the authentication level for the NIS+ clients. Level 0 is for unauthenticated clients and no credentials will be created for users and hosts in the specified domain. Level 2 is for authenticated

(DES) clients and DES credentials will be created for users and hosts in the specified domain. The default is to set up with level 2 authentication (DES). There is no need to run `nispopulate` with `-C` for level 0 authentication. Also, if other authentication mechanisms are configured with `nisauthconf(1M)`, credentials for those mechanisms will also be populated for the NIS+ clients.

`-u` — Updates the NIS+ tables (ie., adds, deletes, modifies) from either files or NIS maps. This option should be used to bring an NIS+ table up to date when there are only a small number of changes. The default is to add to the NIS+ tables without deleting any existing entries. Also, see the `-n` option for updating NIS+ tables from existing maps in the `/var/yp` directory.

`-v` — Runs the script in verbose mode.

`-x` — Turns the "echo" mode on. The script just prints the commands that it would have executed. Note that the commands are not actually executed. The default is off.

`-Y` — Populate the NIS+ tables from NIS maps.

`-y` <*NIS_domain*> — Specifies the NIS domain to copy the NIS maps from. This is only used with the `-Y` option. The default domainname is the same as the local domainname.

Examples

EXAMPLE 1 Using `nispopulate`

To populate all the NIS+ standard tables in the domain *xyz.sun.com.* from NIS maps of the *yp.sun.COM* domain as input source where host *yp_host* is a YP server of *yp.sun.COM*:

```
nis_server# /usr/lib/nis/nispopulate -Y -y yp.sun.COM \
-h yp_host -d xyz.sun.com.
```

To update all of the NIS+ standard tables from the same NIS domain and hosts shown above:

```
nis_server# /usr/lib/nis/nispopulate -Y -u -y yp.sun.COM -h yp_host \
-d xyz.sun.com.
```

To populate the `hosts` table in domain *xyz.sun.com.* from the `hosts` file in the `/var/nis/files` directory and using `somepasswd` as the network password for key encryption:

```
nis_server# /usr/lib/nis/nispopulate -F -p \
 /var/nis/files -l somepasswd hosts
```

To populate the `passwd` table in domain *xyz.sun.com.* from the `passwd` file in the `/var/nis/files` directory without automatically creating the NIS+ credentials:

EXAMPLE 1 Using `nispopulate` *(Continued)*

```
nis_server# /usr/lib/nis/nispopulate -F -p /var/nis/files \
 -d xys.sun.com. -S 0 passwd
```

To populate the credential table in *domain xyz.sun.com.* for all users defined in the passwd table.

```
nis_server# /usr/lib/nis/nispopulate -C -d xys.sun.com. passwd
```

To create and populate a non-standard key-value type NIS+ table, `private`, from the file `/var/nis/files/private`: (nispopulate assumes that the private.org_dirkey-value type table has already been created).

```
nis_server# /usr/bin/nistbladm -D access=og=rmcd,nw=r \
-c private key=S,nogw= value=,nogw= private.org.dir
nis_server# /usr/lib/nis/nispopulate -F -p /var/nis/files private
```

Environment Variables

`nispopulate` normally creates temporary files in the directory `/tmp`. You may specify another directory by setting the environment variable `TMPDIR` to your chosen directory. If `TMPDIR` is not a valid directory, then `nispopulate` will use `/tmp`).

Files

`/etc/inet/hosts`	local database associating names of nodes with IP addresses
`/var/yp`	NIS (YP) domain directory
`/var/nis`	NIS+ domain directory
`/tmp`	

Attributes

See `attributes(5)` for descriptions of the following attributes:

Notes

NIS+ might not be supported in future releases of the Solaris operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

Name nisprefadm – NIS+ utility to set server preferences for NIS+ clients

Synopsis

```
/usr/bin/nisprefadm -a {-L | -G} [-o opt-string]
     [-d domain] [-C client] server...

/usr/bin/nisprefadm -m {-L | -G} [-o opt-string]
     [-d domain] [-C client] oldserver=newserver...

/usr/bin/nisprefadm -r {-L | -G} [-o opt-string]
     [-d domain] [-C client] server...

/usr/bin/nisprefadm -u {-L | -G} [-o opt-string]
     [-d domain] [-C client] server...

/usr/bin/nisprefadm -x {-L | -G} [-d domain] [-C client]

/usr/bin/nisprefadm -l {-L | -G} [-d domain] [-C client]

/usr/bin/nisprefadm -F
```

Description `nisprefadm` defines which servers are to be preferred by NIS+ clients. This information is used by `nis_cachemgr(1M)` to control the order in which it selects which server to use for a particular domain. On a client system, the cache manager first looks for a local preferred server list in `/var/nis`. If it doesn't find one, it looks for an entry with its host name in the NIS+ table. Finally, if it doesn't find it there, it looks for an entry for its subnet.

By default, `nis_cachemgr` puts all servers that are on the same subnet as the client system (that is, local servers) are on the preferred server list. In some cases this default preferred server list is inadequate. For example, if all of the servers for a domain are remote, but some are *closer* than others, the cache manager should try to select the closer one. Because the cache manager has no reliable way to determine the distance to remote servers, `nisprefadm` is used to provide this information.

The preferred server information is stored either globally in a NIS+ table (with the `-G` option) or locally in a file, `/var/nis/client_info` (with the `-L` option). It is preferable to store the information globally so that it can be used by all clients on a subnet. The `nis_cachemgr` process on a client machine reloads the preferred server information periodically, depending on the machine's setup. If the local file is used, the information is reloaded every 12 hours. If the global table is used, the information is reloaded based on the TTL value of the client information table. This TTL value can be changed using `nischttl(1)`. If you want your changes to take effect immediately, use the `nisprefadm -F` command. When changing local information (`-L`), `nisprefadm` automatically forces `nis_cachemgr` to reload the information.

The cache manager assigns weights to all of the servers on the preferred list. By default, local servers (that is, servers on the same subnet) are given a weight of 0. Other servers are given the weight, “infinite”. This can be changed by using the `nisprefadm` command and giving a weight in parentheses after the server name. When selecting a server for a domain, the cache manager first tries to contact the servers with the lowest weight. If it doesn't get a response, it tries the servers with the next lowest weight, and so on. If it fails to get a response from any of the preferred servers, it tries to contact the non-preferred servers.

The use of weights gives fine control over the server selection process, but care must be given to avoid assigning too many different weights. For example, if weights 0, 1, 2, and 3 are used, but all of the servers with weight 0, 1, and 2, are unavailable, then there will be a noticeable delay in selecting a server. This is because the cache manager waits 5 seconds for a response at each weight level before moving on to the next one. As a general rule, one or two weight levels provides a good balance of server selection control and performance.

When specifying a server name, it is not necessary to fully qualify the name. When the cache manager tries to access a domain, it compares the list of servers for the domain with the list of preferred servers. It will find a match if a preferred server name is a prefix of the name of a server for the domain. If a domain is served by two servers with the same prefix, the preferred server name must include enough of the domain name to distinguish the two.

The `nis_cachemgr(1M)` process automatically adds local servers (same subnet as the client) to the preferred server list with a weight of 0. Thus, it is not necessary to specify them, though it does no harm.

If you specify a weight for a server, you probably should quote the parentheses to avoid having the shell interpret them. The following command illustrates this:

```
example% nisprefadm -G -a -C client1 "srv1(2)"
```

In general, `nis_cachemgr` does a fairly good job of selecting servers on its own. Therefore, the use of `nisprefadm` is not usually necessary. Some situations in which it is recommended are:

No local servers, many remote servers	In this case, `nis_cachemgr` needs to choose one of the remote servers. Because it doesn't have information on which is closest, it sends a ping to all of them and then selects the one that responds fastest. This may not always select the best server. If some of the servers are closer to the client than the others, they should be listed as preferred servers so that `nis_cachemgr` will try them first. This reduces the amount of network traffic for selecting a server.
Very remote servers	In some networks there are NIS+ servers that are only reachable through very slow network connections. It is usually best to avoid unnecessary traffic over that connection. If the *pref_type*=`pref_only` option is set along with preferred servers, then only the preferred servers are contacted for domains they serve. The non-preferred servers are not tried at all; even if all of the preferred servers are unavailable. For domains that are not served by any of the preferred servers, the `pref_only` option is ignored.

Options In the SYNOPSIS, when several options are surrounded by braces (that is, by '{' and '}') one of the options must be specified.

`-a` Add the specified servers to the preferred server list.

`-C` *client* Store the preferred server information with the key, *client*. The *client* can be either a hostname or a subnet number. When a hostname is specified, the preferred server information applies to that host only. When a subnet is specified, the preferred server information applies to all clients on that subnet. The cache manager searches for host specific entries first. It only searches for subnet entries if no host entry is found. If this option is not specified, then the hostname of the machine on which the command is run is used.

`-d` *domain* Specify the *domain* to which the command is to apply.

`-F` Tells `nis_cachemgr(1M)` to refresh its preferred server information. The program periodically does this anyway, but this option forces it to do the refresh immediately. When updating the local information, `nis_cachemgr` automatically refreshes the preferred server information.

This option must be executed as `root`.

`-l` List the current preferred server information.

`-L | -G` Store the preferred server information locally in the file, `/var/nis/client_info` (the `-L` option), or globally in a NIS+ table `client.info.org-dir.`*domain* (the `-G` option). If the information is stored locally, then it only applies to the system on which the command is run. If it is stored globally then it can apply to all systems on a subnet (depending on the value of the `-C` option).

The `-L` option must be run as `root`.

`-m` Modify the preferred server list. The server specified by *oldserver* is replaced by *newserver*. This is typically used to change the weight for a server.

`-o` Specify additional options to control server selection. Currently the only valid option is *pref_type*, which can have a value of either `all` (the default) or `pref_only`. If the value is `all`, then the cache manager tries to contact non-preferred servers if all of the preferred servers fail to respond. If `pref_only` is specified, then it won't try non-preferred servers. The only exception to this is when a domain is not served by any of the preferred servers. In this case, the cache manager ignores the option. This is to avoid requiring that preferred servers be defined for every domain.

`-r` Remove the specified servers from the preferred server list.

`-u` Clear the list of preferred servers and then add the specified servers to the preferred server list.

`-x` Remove the preferred server information completely.

Return Values `nisprefadm` returns the following values:

`0` On success.

`1` On failure.

Examples **EXAMPLE 1** Using `nisprefadm`

This command sets the preferred server list for the system on which it is run:

```
example% nisprefadm -L -a srv1 srv2
```

The information is stored in a file, `/var/nis/client_info`, so it will only affect this one system.

The following command has the same effect, but the information is stored in a NIS+ table in the default domain.

```
example% nisprefadm -G -a srv1 srv2
```

As a system administrator, you might want to set the preferred server information for a client system other than the one you are running the command on. The following command sets the preferred server information for a client system named *client1*:

```
example% nisprefadm -G -a -C client1 srv1 srv2
```

It is common for all client systems on a subnet to use the same set of preferred servers. The following command sets a preferred server list that applies to all clients on subnet, 192.85.18.0:

```
example% nisprefadm -G -a -C 192.85.18.0 srv1 srv2
```

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `nischttl(1)`, `nis_cachemgr(1M)`, `attributes(5)`

Notes NIS+ might not be supported in future releases of the Solaris Operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

Name nisrestore – restore NIS+ directory backup

Synopsis

```
nisrestore [-fv] backup-dir directory...

nisrestore [-fv] -a backup-dir

nisrestore -t backup-dir
```

Description `nisrestore` restores an existing backup of a NIS+ directory object that was created using `nisbackup(1M)`. The *backup-dir* is the UNIX directory that contains the NIS+ backup on the server being restored. The `nisrestore` command can be used to restore a NIS+ directory object or a complete NIS+ database. It also can be used as an "out of band" fast replication for a new replica server being initialized. The `rpc.nisd(1M)` daemon must be stopped before running `nisrestore`.

The first synopsis is used to restore a single directory object or a specified list of directory objects. The directory can be partially qualified or fully qualified. The server being restored will be verified against the list of servers serving the directory. If this server is not configured to serve this object, `nisrestore` will exit with an error. The `-f` option will override this check and force the operation.

The second synopsis will restore all of the directory objects contained in the *backup-dir*. Again, the server will be validated against the serving list for each of the directory objects in the *backup-dir*. If one of the objects in the *backup-dir* are not served by this server, `nisrestore` will exit with an error. The `-f` option will override this check and force the operation.

The `-a` option will attempt to restore all NIS+ objects contained in the *backup-dir*. If any of these objects are not served by the server, `nisrestore` will exit with an error. If the *backup-dir* contains objects that are not served by the server, `nisrestore` must be executed without the `-a` option and the specific directory objects listed.

The `-f` option will disable verification of the server being configured to serve the objects being restored. This option should be used with care, as data could be inadvertently restored to a server that doesn't serve the restored data. This option is required in the case of restoring a single server domain (master server only) or if the other NIS+ servers are unavailable for NIS+ lookups.

The combination of options `-f` and `-a` should be used with caution, as no validation of the server serving the restored objects will be done.

New replicas can be quickly added to a namespace with the `nisrestore` command. The steps are as follows.

Configure the new replica on the master server (see `nisserver(1M)`):

```
master# nisserver -R -h replica
```

Temporarily stop the `rpc.nisd` server process on the new replica server:

```
replica# svcadm disable -t network/rpc/nisplus:default
```

Create a backup of the NIS+ database on the master, which will include the new replica information. See nisbackup(1M). The /backup will need to be exported to the new replica. See share_nfs(1M).

```
master# nisbackup -a /backup
```

Restore the backup of the NIS+ database on the new replica. Use the -f option if nisrestore is unable to lookup the NIS+ objects being restored. The backup should be available through nfs or similar means. See share_nfs(1M).

```
replica# nisrestore -f -a //nfs-mnt/backup
```

Restart the rpc.nisd(1M) process on the new replica, and the server will immediately be available for service:

```
replica# svcadm enable network/rpc/nisplus:default
```

Options The following options are supported:

-a Restores all directory objects included in the *backup-dir* partition.

-f Forces the restoration of a directory without the validation of the server in the directory object's serving list.

-t Lists all directory objects contained in *backup-dir*.

-v Verbose option. Additional output will be produced upon execution of the command.

Operands The following options are supported:

backup-dir The UNIX directory that contains the data files for the NIS+ directory objects to be restored.

directory The NIS+ directory object(s) to be restored. This can be a fully or partially qualified name.

Examples **EXAMPLE 1** Restoring the Directory Object on a Replica Server from a Local UFS Partition

To restore the org_dir directory object of the domain foo.com on a replica server from a local ufs partition named /var/backup:

```
replica_server# nisrestore /var/backup org_dir.foo.com.
```

EXAMPLE 2 Forcing the Restore of a Backed up NIS+ Namespace to a Replica Server From the Backup Partition

To force the restore of an entire backed up NIS+ namespace to a replica server from the backup partition named /var/backup:

```
replica_server# nisrestore -f -a /var/backup
```

EXAMPLE 3 Restoring the Subdomain on a Master Server From a Backup that Includes Other Directory Objects

To restore the subdomain `sub.foo.com` on a master server, from a backup that includes other directory objects:

```
master_server# nisrestore /var/backup sub.foo.com. \
 org_dir.sub.foo.com. groups_dir.sub.foo.com.
```

Exit Status

`0` Successful completion.

`1` An error occurred.

Files

/backup-dir`/backup_list`	This ASCII file contains a list of all the objects contained in this *backup-dir* directory. This information can be displayed with the `-t` option.
/backup-dir/directory-object	A subdirectory that is created in the *backup-dir* which contains the directory-object backup.
/backup-dir/directory-object`/data`	A subdirectory that contains the data files that are part of the directory-object backup.
/backup-dir/directory-object`/last.upd`	This data file contains timestamp information about the directory-object.
/backup-dir/directory-object`/data.dict`	A NIS+ data dictionary for all of the objects contained in this directory-object backup.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

`svcs(1)`, `NIS+(1)`, `nisdefaults(1)`, `nisbackup(1M)`, `nisserver(1M)`, `rpc.nisd(1M)`, `share_nfs(1M)`, `svcadm(1M)`, `nisfiles(4)`, `attributes(5)`, `smf(5)`

Notes

NIS+ might not be supported in future releases of the Solaris Operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

The NIS+ service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/rpc/nisplus:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

Name nisserver – set up NIS+ servers

Synopsis

```
/usr/lib/nis/nisserver -r [-x] [-f] [-v] [-Y]
     [-d NIS+_domain] [-g NIS+_groupname]
     [-l network_passwd]

/usr/lib/nis/nisserver -M [-x] [-f] [-v] [-Y] -d NIS+_domain
     [-g NIS+_groupname]
     [-h NIS+_server_host]

/usr/lib/nis/nisserver -R [-x] [-f] [-v] [-Y]
     [-d NIS+_domain] [-h NIS+_server_host]
```

Description The `nisserver` shell script can be used to set up a root master, non-root master, and replica NIS+ server with level 2 security (DES). If other authentication mechanisms are configured with `nisauthconf(1M)`, `nisserver` will set up a NIS+ server using those mechanisms. `nisauthconf(1M)` should be used before `nisserver`.

When setting up a new domain, this script creates the NIS+ directories (including `groups_dir` and `org_dir`) and system table objects for the domain specified. It does not populate the tables. `nispopulate(1M)` must be used to populate the tables.

Options

`-d` *NIS+_domain*	Specifies the name for the NIS+ domain. The default is your local domain.
`-f`	Forces the NIS+ server setup without prompting for confirmation.
`-g` *NIS+_groupname*	Specifies the NIS+ group name for the new domain. This option is not valid with `-R` option. The default group is admin.<domain>.
`-h` *NIS+_server_host*	Specifies the hostname for the NIS+ server. It must be a valid host in the local domain. Use a fully qualified hostname (for example, *hostx.xyz.sun.com.*) to specify a host outside of your local domain. This option is *only* used for setting up non-root master or replica servers. The default for non-root master server setup is to use the same list of servers as the parent domain. The default for replica server setup is the local hostname.
`-l` *network_password*	Specifies the network password with which to create the credentials for the root master server. This option is *only* used for master root server setup (`-r` option). If this option is not specified, the script prompts you for the login password.
`-M`	Sets up the specified host as a master server. Make sure that `rpc.nisd(1M)` is running on the new master server before this command is executed.
`-R`	Sets up the specified host as a replica server. Make sure that `rpc.nisd` is running on the new replica server.

`-r`	Sets up the server as a root master server. Use the `-R` option to set up a root replica server.
`-v`	Runs the script in verbose mode.
`-x`	Turns the echo mode on. The script just prints the commands that it would have executed. Note that the commands are not actually executed. The default is off.
`-Y`	Sets up a NIS+ server with NIS-compatibility mode. The default is to set up the server without NIS-compatibility mode.

Usage Use the first synopsis of the command (`-r`) to set up a root master server. To run the command, you must be logged in as super-user on the server machine.

Use the second synopsis of the command (`-M`) to set up a non-root master server for the specified domain. To run the command, you must be logged in as a NIS+ principal on a NIS+ machine and have write permission to the parent directory of the domain that you are setting up. The new non-root master server machine must already be an NIS+ client (see `nisclient(1M)`) and have the `rpc.nisd(1M)` daemon running.

Use the third synopsis of the command (`-R`) to set up a replica server for both root and non-root domains. To run the command, you must be logged in as a NIS+ principal on a NIS+ machine and have write permission to the parent directory of the domain that you are replicating. The new non-root replica server machine must already be an NIS+ client and have the `rpc.nisd` daemon running.

Examples **EXAMPLE 1** Setting up Servers

To set up a root master server for domain `sun.com.`:

```
root_server# /usr/lib/nis/nisserver -r -d sun.com.
```

For the following examples make sure that the new servers are NIS+ clients and that `rpc.nisd` is running on these hosts before executing `nisserver`. To set up a replica server for the `sun.com.` domain on host *sunreplica*:

```
root_server# /usr/lib/nis/nisserver -R -d sun.com. -h sunrep
```

To set up a non-root master server for domain *xyz.sun.com.* on host *sunxyz* with the NIS+ groupname as *admin-mgr.xyz.sun.com.*:

```
root_server# /usr/lib/nis/nisserver -M -d xyz.sun.com. -h sunxyz \
-g admin-mgr.xyz.sun.com.
```

To set up a non-root replica server for domain *xyz.sun.com.* on host *sunabc*:

```
sunxyz# /usr/lib/nis/nisserver -R -d xyz.sun.com. -h sunabc
```

Notes NIS+ might not be supported in future releases of the Solaris Operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

Name nissetup – initialize a NIS+ domain

Synopsis

```
/usr/lib/nis/nissetup [-Y] [domain]
```

Description `nissetup` is a shell script that sets up a NIS+ domain to service clients that wish to store system administration information in a domain named *domain*. This domain should already exist prior to executing this command. See `nismkdir(1)` and `nisinit(1M)`.

A NIS+ domain consists of a NIS+ directory and its subdirectories: `org_dir` and `groups_dir`. `org_dir` stores system administration information and `groups_dir` stores information for group access control.

`nissetup` creates the subdirectories `org_dir` and `groups_dir` in *domain*. Both subdirectories will be replicated on the same servers as the parent domain. After the subdirectories are created, `nissetup` creates the default tables that NIS+ serves. These are `auto_master`, `auto_home`, `bootparams`, `cred`, `ethers`, `group`, `hosts`, `mail_aliases`, `netmasks`, `networks`, `passwd`, `protocols`, `rpc`, `services`, and `timezone`. The `nissetup` script uses the `nistbladm(1)` command to create these tables. The script can be easily customized to add site specific tables that are created at setup time.

This command is normally executed just once per domain.

While this command creates the default tables, it does not initialize them with data. This is accomplished with the `nisaddent(1M)` command.

It is easier to use the `nisserver(1M)` script to create subdirectories and the default tables.

Options

`-Y` Specify that the domain will be served as both a NIS+ domain as well as an NIS domain using the backward compatibility flag. This will set up the domain to be less secure by making all the system tables readable by unauthenticated clients as well.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

See Also `NIS+(1)`, `nismkdir(1)`, `nistbladm(1)`, `nisaddent(1M)`, `nisinit(1M)` `nisserver(1M)`, `attributes(5)`

Notes NIS+ might not be supported in future releases of the Solaris Operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

Name nisshowcache – NIS+ utility to print out the contents of the shared cache file

Synopsis

```
/usr/lib/nis/nisshowcache [-v]
```

Description `nisshowcache` prints out the contents of the per-machine NIS+ directory cache that is shared by all processes accessing NIS+ on the machine. By default, `nisshowcache` only prints out the directory names in the cache along with the list of active servers. The shared cache is maintained by `nis_cachemgr(1M)`.

Options

`-v` Verbose mode. Print out the contents of each directory object, including the information on the server name and its universal addresses.

Files `/var/nis/NIS_SHARED_DIRCACHE`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `nis_cachemgr(1M)`, `syslogd(1M)`, `nisfiles(4)`, `attributes(5)`

Diagnostics Error messages are sent to the `syslogd(1M)` daemon.

Notes NIS+ might not be supported in future releases of the Solaris Operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

Name nisstat – report NIS+ server statistics

Synopsis `/usr/lib/nis/nisstat [-H` *host*`] [`*directory*`]`

Description The `nisstat` command queries a NIS+ server for various statistics about its operations. These statistics may vary between implementations and from release to release. Not all statistics are available from all servers. If you request a statistic from a server that does not support that statistic, it is never a fatal error. The message "unknown statistic" is returned.

By default, statistics are fetched from the server(s) of the NIS+ directory for the default domain. If *directory* is specified, servers for that directory are queried.

Supported statistics for this release are as follows:

root server	This reports whether the server is a root server.
NIS compat mode	This reports whether the server is running in NIS compat mode.
DNS forwarding in NIS mode	This reports whether the server in NIS compat mode will forward host lookup calls to DNS.
security level	This reports the security level of this server.
serves directories	This lists the directories served by this server.
Operations	This statistic returns results in the form: `OP=`*opname*`:C=`*calls*`:E=`*errors*`:T=`*micros* Where *opname* is replaced by the RPC procedure name or operation, *calls* is the number of calls to this procedure that have been made since the server started running. *errors* is the number of errors that have occurred while processing a call, and *micros* is the average time in microseconds to complete the last 16 calls.
Directory Cache	This statistic reports the number of calls to the internal directory object cache, the number of hits on that cache, the number of misses, and the hit rate percentage.
Group Cache	This statistic reports the number of calls to the internal NIS+ group object cache, the number of hits on that cache, the number of misses, and the hit rate percentage.
Static Storage	This statistic reports the number of bytes the server has allocated for its static storage buffers.
Dynamic Storage	This statistic reports the amount of heap the server process is currently using.
Uptime	This statistic reports the time since the service has been running.

Per-server and per-directory access restrictions may apply. See `nisopaccess(1)`. `nisstat` uses `NIS_STATUS`.

Options

`-H` *host* Normally all servers for the directory are queried. With this option, only the machine named *host* is queried. If the named machine does not serve the directory, no statistics are returned.

Environment Variables

`NIS_PATH` If this variable is set, and the NIS+ directory name is not fully qualified, each directory specified will be searched until the directory is found. See `nisdefaults(1)`.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

See Also

`nisdefaults(1)`, `nisopaccess(1)`, `attributes(5)`

Notes

NIS+ might not be supported in future releases of the Solaris Operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

Name nisupdkeys – update the public keys in a NIS+ directory object

Synopsis

```
/usr/lib/nis/nisupdkeys [-a | -C] [-H host] [directory]

/usr/lib/nis/nisupdkeys -s [-a | -C] -H host
```

Description This command updates the public keys in an NIS+ directory object. When the public key(s) for a NIS+ server are changed, `nisupdkeys` reads a directory object and attempts to get the public key data for each server of that directory. These keys are placed in the directory object and the object is then modified to reflect the new keys. If *directory* is present, the directory object for that directory is updated. Otherwise the directory object for the default domain is updated. The new key must be propagated to all directory objects that reference that server.

On the other hand, `nisupdkeys -s` gets a list of all the directories served by *host* and updates those directory objects. This assumes that the caller has adequate permission to change all the associated directory objects. The list of directories being served by a given server can also be obtained by `nisstat(1M)`. Before you do this operation, make sure that the new address/public key has been propagated to all replicas. If multiple authentication mechanisms are configured using `nisauthconf(1M)`, then the keys for those mechanisms will also be updated or cleared.

The user executing this command must have modify access to the directory object for it to succeed. The existing directory object can be displayed with the `niscat(1)` command using the `-o` option.

This command does not update the directory objects stored in the `NIS_COLD_START` file on the NIS+ clients.

If a server is also the root master server, then `nisupdkeys -s` cannot be used to update the root directory.

Options

`-a` Update the universal addresses of the NIS+ servers in the directory object. Currently, this only works for the TCP/IP family of transports. This option should be used when the IP address of the server is changed. The server's new address is resolved using `getipnodebyname(3SOCKET)` on this machine. The `/etc/nsswitch.conf` file must point to the correct source for *ipnodes* and *hosts* for this resolution to work.

`-C` Specify to clear rather than set the public key(s). Communication with a server that has no public key(s) does not require the use of secure RPC.

`-H` *host* Limit key changes only to the server named *host*. If the hostname is not a fully qualified NIS+ name, then it is assumed to be a host in the default domain. If the named host does not serve the directory, no action is taken.

`-s` Update all the NIS+ directory objects served by the specified server. This assumes that the caller has adequate access rights to change all the associated directory objects. If the NIS+ principal making this call does not have adequate permissions to update the directory objects, those particular updates will fail and the caller will

be notified. If the `rpc.nisd` on *host* cannot return the list of servers it serves, the command will print an error message. The caller would then have to invoke `nisupdkeys` multiple times (as in the first synopsis), once per NIS+ directory that it serves.

Examples

EXAMPLE 1 Using `nisupdkeys`

The following example updates the keys for servers of the *foo.bar.* domain.

```
example% nisupdkeys foo.bar.
```

This example updates the key(s) for host *fred* that serves the *foo.bar.* domain.

```
example% nisupdkeys -H fred foo.bar.
```

This example clears the public key(s) for host *wilma* in the *foo.bar.* directory.

```
example% nisupdkeys -CH wilma foo.bar.
```

This example updates the public key(s) in all directory objects that are served by the host *wilma*.

```
example% nisupdkeys -s -H wilma
```

Attributes

Notes

NIS+ might not be supported in future releases of the Solaris Operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

Name nlsadmin – network listener service administration

Synopsis

```
/usr/sbin/nlsadmin -x

/usr/sbin/nlsadmin [options] net_spec

/usr/sbin/nlsadmin [options] -N port_monitor_tag

/usr/sbin/nlsadmin -V

/usr/sbin/nlsadmin -c cmd | -o streamname [-p modules]
     [-A address | -D] [-R prognum : versnum]
```

Description `nlsadmin` is the administrative command for the network listener process(es) on a machine. Each network has at least one instance of the network listener process associated with it; each instance (and thus, each network) is configured separately. The listener process "listens" to the network for service requests, accepts requests when they arrive, and invokes servers in response to those service requests. The network listener process may be used with any network (more precisely, with any connection-oriented transport provider) that conforms to the transport provider specification.

`nlsadmin` can establish a listener process for a given network, configure the specific attributes of that listener, and start and kill the listener process for that network. `nlsadmin` can also report on the listener processes on a machine, either individually (per network) or collectively.

net_spec represents a particular listener process. Specifically, *net_spec* is the relative path name of the entry under `/dev` for a given network (that is, a transport provider). *address* is a transport address on which to listen and is interpreted using a syntax that allows for a variety of address formats. By default, *address* is interpreted as the symbolic ASCII representation of the transport address. An *address* preceded by `\x` will let you enter an address in hexadecimal notation. Note that *address* must appear as a single word to the shell, thus it must be quoted if it contains any blanks.

Changes to the list of services provided by the listener or the addresses of those services are put into effect immediately.

Options `nlsadmin` may be used with the following combinations of options and arguments:

`-x`	Report the status of all of the listener processes installed on this machine.
net_spec	Print the status of the listener process for *net_spec* .
`-q` *net_spec*	Query the status of the listener process for the specified network, and reflects the result of that query in its exit code. If a listener process is active, `nlsadmin` will exit with a status of `0`; if no process is active, the exit code will be `1`; the exit code will be greater than `1` in case of error.

`-v` *net_spec*	Print a verbose report on the servers associated with *net_spec,* giving the service code, status, command, and comment for each. It also specifies the `uid` the server will run as and the list of modules to be pushed, if any, before the server is started.
`-z` *service_code net_spec*	Print a report on the server associated with *net_spec* that has service code *service_code,* giving the same information as in the `-v` option.
`-q -z` *service_code net_spec*	Query the status of the service with service code *service_code* on network *net_spec,* and exits with a status of `0` if that service is enabled, `1` if that service is disabled, and greater than `1` in case of error.
`-l` *address net_spec*	Change or set the transport address on which the listener listens (the general listener service). This address can be used by remote processes to access the servers available through this listener (see the `-a` option, below). If *address* is just a dash (" – "), `nlsadmin` reports the address currently configured, instead of changing it. A change of address takes effect immediately.
`-t` *address net_spec*	Change or set the address on which the listener listens for requests for terminal service but is otherwise similar to the `-l` option above. A terminal service address should not be defined unless the appropriate remote login software is available; if such software is available, it must be configured as service code 1 (see the `-a` option, below).
`-i` *net_spec*	Initialize an instance of the listener for the network specified by *net_spec;* that is, create and initialize the files required by the listener as well as starting that instance of the listener. Note that a particular instance of the listener should be initialized only once. The listener must be initialized before assigning addresses or services.
`-a` *service_code*	[`-p` *modules*] [`-w` *name*] `-c` *cmd* `-y` *comment net_spec* Add a new service to the list of services available through the indicated listener. *service_code* is the code for the service, *cmd* is the command to be invoked in response to that service code, comprised of the full path name of the server and its arguments, and *comment* is a brief (free-form) description of the service for use in various reports. Note that *cmd* must appear as a single word to the shell; if arguments are required,

the *cmd* and its arguments must be enclosed in quotation marks. The *comment* must also appear as a single word to the shell. When a service is added, it is initially enabled (see the `-e` and `-d` options, below).

Service codes are alphanumeric strings, and are administered by AT&T. The numeric service codes 0 through 100 are reserved for internal use by the listener. Service code 0 is assigned to the nlps server, which is the service invoked on the general listening address. In particular, code 1 is assigned to the remote login service, which is the service automatically invoked for connections to the terminal login address.

If the `-p` option is specified, then *modules* will be interpreted as a list of STREAMS modules for the listener to push before starting the service being added. The modules are pushed in the order they are specified. *modules* should be a comma-separated list of modules, with no white space included.

If the `-w` option is specified, then *name* is interpreted as the user name from `/etc/passwd` that the listener should look up. From the user name, the listener obtains the user ID, the group ID(s), and the home directory for use by the server. If `-w` is not specified, the default is to use the user name `listen`.

A service must explicitly be added to the listener for each network on which that service is to be available. This operation will normally be performed only when the service is installed on a machine, or when populating the list of services for a new network.

`-r` *service_code net_spec*

Remove the entry for the *service_code* from that listener's list of services. This is normally done only in conjunction with the de-installation of a service from a machine.

`-e` *service_code net_spec*
`-d` *service_code net_spec*

Enable or disable (respectively) the service indicated by *service_code* for the specified network. The service must previously have been added to the listener for that network (see the `-a` option, above). Disabling a service will cause subsequent service requests for that service to be denied, but the processes from any prior service requests that are still running will continue unaffected.

`-s` *net_spec*
`-k` *net_spec*
: Start and kill (respectively) the listener process for the indicated network. These operations are normally performed as part of the system startup and shutdown procedures. Before a listener can be started for a particular network, it must first have been initialized (see the `-i` option, above). When a listener is killed, processes that are still running as a result of prior service requests will continue unaffected.

Under the Service Access Facility, it is possible to have multiple instances of the listener on a single *net_spec*. In any of the above commands, the option `-N` *port_monitor_tag* may be used in place of the *net_spec* argument. This argument specifies the tag by which an instance of the listener is identified by the Service Access Facility. If the `-N` option is not specified (that is, the *net_spec* is specified in the invocation), then it will be assumed that the last component of the *net_spec* represents the tag of the listener for which the operation is destined. In other words, it is assumed that there is at least one listener on a designated *net_spec*, and that its tag is identical to the last component of the *net_spec*. This listener may be thought of as the primary, or default, listener for a particular *net_spec*.

`nlsadmin` is also used in conjunction with the Service Access Facility commands. In that capacity, the following combinations of options can be used:

`-V`
: Write the current version number of the listener's administrative file to the standard output. It is used as part of the `sacadm` command line when `sacadm` adds a port monitor to the system.

`-c` *cmd* | `-o` *streamname* [`-p` *modules*] [`-A` *address* | `-D`] [`-R` *prognum* : *versnum*]
: Format the port monitor-specific information to be used as an argument to `pmadm(1M)`

  The `-c` option specifies the full path name of the server and its arguments. *cmd* must appear as a single word to the shell, and its arguments must therefore be surrounded by quotes.

  The `-o` option specifies the full path name of a FIFO or named stream through which a standing server is actually receiving the connection.

  If the `-p` option is specified, then *modules* will be interpreted as a list of STREAMS modules for the listener to push before starting the service being added. The modules are pushed in the order in which they are specified. *modules* must be a comma-separated list, with no white space included.

  If the `-A` option is specified, then *address* will be interpreted as the server's private address. The listener will monitor this address on behalf of the service and will dispatch all calls arriving on this address directly to the designated service. This option may not be used in conjunction with the `-D` option.

If the `-D` option is specified, then the service is assigned a private address dynamically, that is, the listener will have the transport provider select the address each time the listener begins listening on behalf of this service. For RPC services, this option will be often be used in conjunction with the `-R` option to register the dynamically assigned address with the rpcbinder. This option may not be used in conjunction with the `-A` option.

When the `-R` option is specified, the service is an RPC service whose address, program number, and version number should be registered with the rpcbinder for this transport provider. This registration is performed each time the listener begins listening on behalf of the service. *prognum* and *versnum* are the program number and version number, respectively, of the RPC service.

`nlsadmin` may be invoked by any user to generate reports; all operations that affect a listener's status or configuration may only be run by a super-user.

The options specific to the Service Access Facility may not be used together with any other options.

Errors If successful, `nlsadmin` exits with a status of 0. If `nlsadmin` fails for any reason, it exits with a status greater than or equal to 2. See `-q` option for a return status of 1.

Attributes See `attributes(5)` for descriptions of the following attributes:

System Administration Guide: Basic Administration

Notes Dynamically assigned addresses are not displayed in reports as statically assigned addresses are.

Name nscd – name service cache daemon

Synopsis

```
/usr/sbin/nscd  [-f configuration-file] [-g] [-e cachename, yes
 |  no] [-i cachename]
```

Description The nscd daemon is a process that provides a cache for most name service requests. The default *configuration-file* /etc/nscd.conf determines the behavior of the cache daemon. See nscd.conf(4).

nscd provides caching for the passwd(4), group(4), hosts(4), ipnodes(4), exec_attr(4), prof_attr(4), user_attr(4), ethers(4), rpc(4), protocols(4), networks(4), bootparams(4), audit_user(4), auth_attr(4), services(4), netmasks(4), printers(4), project(4) databases through standard libc interfaces, such as gethostbyname(3NSL), getipnodebyname(3SOCKET), gethostbyaddr(3NSL), and others. Each cache has a separate time-to-live for its data; modifying the local database (/etc/hosts, /etc/resolv.conf, and so forth) causes that cache to become invalidated upon the next call to nscd. The shadow file is specifically not cached. getspnam(3C) calls remain uncached as a result.

nscd also acts as its own administration tool. If an instance of nscd is already running, commands are passed to the running version transparently.

When running with per-user lookups enabled (see nscd.conf(4)), nscd forks one and only one child process (that is, a per-user nscd) on behalf of the user making the request. The per-user nscd will use the credentials of the user to open a per-user connection to the name repository configured for the per-user style of lookups. The lookup will be performed in the child process. The results are cached in the process and are available only to the same user. The caches are managed exactly the same as the main nscd daemon manages its own caches. Subsequent requests from the user will be handled by that per-user nscd until it terminates. The per-user nscd uses a configurable inactivity time-to-live (TTL) value and terminates itself after the inactivity TTL expires.

The maximum number of per-user nscds that can be created by the main nscd is configurable (see nscd.conf(4)). After the maximum number of them are created, the main nscd will use an LRU algorithm to terminate less active child nscds as needed.

The main nscd daemon creates, monitors, and manages all the child nscds. It creates a user's own nscd upon receiving the user's first per-user lookup. When the nscd daemon is started, if per-user lookups are enabled, it checks to ensure all conditions are met before getting ready to create a per-user nscd. When the daemon is stopped, it terminates all the per-user nscds under its control.

Per-user nscds use the same configuration as the main nscd. They read and use the same default configuration file or the one specified with the -f command line option. Once the configuration is read, the per-user nscd will use it for its entire lifetime.

Options Several of the options described below require a *cachename* specification. Supported values for *cachename* are: `passwd`, `group`, `hosts`, `ipnodes`, `exec_attr`, `prof_attr`, `user_attr`, `ethers`, `rpc`, `protocols`, `networks`, `bootparams`, `audit_user`, `auth_attr`, `services`, `netmasks`, `printers`, and `project`.

`-f` *configuration-file*
Causes `nscd` to read its configuration data from the specified file.

`-g`
Prints current configuration and statistics to standard output. This is the only option executable by non-root users.

`-e` *cachename*`, yes|no`
Enables or disables the specified cache.

`-i` *cachename*
Invalidate the specified cache.

Examples **EXAMPLE 1** Stopping and restarting the `nscd` daemon.

```
example# svcadm disable system/name-service-cache

example# svcadm enable system/name-service-cache
```

Files `/etc/nscd.conf` Determines athe behavior of the cache daemon

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `svcs(1)`, `svcadm(1M)`, `getspnam(3C)`, `gethostbyname(3NSL)`, `getipnodebyname(3SOCKET)`, `audit_user(4)`, `auth_attr(4)`, `bootparams(4)`, `ethers(4)`, `exec_attr(4)`, `group(4)`, `hosts(4)`, `netmasks(4)`, `networks(4)`, `nscd.conf(4)`, `nsswitch.conf(4)`, `passwd(4)`, `printers(4)`, `prof_attr(4)`, `project(4)`, `protocols(4)`, `rpc(4)`, `services(4)`, `user_attr(4)`, `attributes(5)`

Notes The output from the `-g` option to `nscd` is subject to change. Do not rely upon it as a programming interface.

The `nscd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/system/name-service-cache
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

Name nslookup – query Internet name servers interactively

Synopsis

```
nslookup [-option] [name | -] [server]
```

Description The `nslookup` utility is a program to query Internet domain name servers. It has two modes: interactive and non-interactive. Interactive mode allows the user to query name servers for information about various hosts and domains or to print a list of hosts in a domain. Non-interactive mode is used to print just the name and requested information for a host or domain.

Parameters Interactive mode is entered in the following cases:

1. No arguments are given (the default name server is used).
2. The first argument is a hyphen (-) and the second argument is the host name or Internet address of a name server.

Non-interactive mode is used when the name or Internet address of the host to be looked up is given as the first argument. The optional second argument specifies the host name or address of a name server.

Options can also be specified on the command line if they precede the arguments and are prefixed with a hyphen. For example, to change the default query type to host information, and the initial timeout to 10 seconds, type:

```
nslookup -query=hinfo  -timeout=10
```

Interactive Commands

`host` [*server*]
Look up information for host using the current default server or using server, if specified. If host is an Internet address and the query type is A or PTR, the name of the host is returned. If host is a name and does not have a trailing period, the search list is used to qualify the name. To look up a host not in the current domain, append a period to the name.

`server` *domain*
`lserver` *domain*
Change the default server to *domain*; `lserver` uses the initial server to look up information about *domain*, while `server` uses the current default server. If an authoritative answer can't be found, the names of servers that might have the answer are returned.

`root`
Not implemented.

`finger`
Not implemented.

`ls`
Not implemented.

`view`
Not implemented.

`help`
Not implemented.

`?`
Not implemented.

`exit`
Exits the program.

`set` *keyword*[=*value*]
This command is used to change state information that affects the lookups. Valid keywords are:

`all`
Prints the current values of the frequently used options to `set`. Information about the current default server and host is also printed.

`class=`*value*
Change the query class to one of:

`IN`
the Internet class

`CH`
the Chaos class

`HS`
the Hesiod class

`ANY`
wildcard

The class specifies the protocol group of the information.

(Default = `IN`; abbreviation = `cl`)

`[no]debug`
Turn on or off the display of the full response packet and any intermediate response packets when searching.

(Default = `nodebug`; abbreviation = `[no]deb`)

`[no]d2`
Turn debugging mode on or off. This displays more about what `nslookup` is doing.

(Default = `nod2`)

`domain=`*name*
Sets the search list to *name*.

`[no]search`
If the lookup request contains at least one period but doesn't end with a trailing period, append the domain names in the domain search list to the request until an answer is received.

(Default = `search`)

`port=`*value*
Change the default TCP/UDP name server port to *value*.

(Default = `53`; abbreviation = `po`)

`querytype=`*value*
`type=`*value*
Change the top of the information query.

(Default = `A`; abbreviations = `q`, `ty`)

`[no]recurse`
Tell the name server to query other servers if it does not have the information. (Default = `recurse`; abbreviation = `[no]rec`)

`retry=`*number*
Set the number of retries to number.

`timeout=`*number*
Change the initial timeout interval for waiting for a reply to number seconds.

`[no]vc`
Always use a virtual circuit when sending requests to the server.

(Default = `novc`)

`[no]fail`
Try the next nameserver if a nameserver responds with `SERVFAIL` or a referral (`nofail`) or terminate query (`fail`) on such a response.

(Default = `nofail`)

Files `/etc/resolv.conf`
resolver configuration file

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	network/dns/bind
Interface Stability	Volatile

See Also dig(1M), host(1M), named(1M), attributes(5)

See the BIND 9 *Administrator's Reference Manual*. As of the date of publication of this man page, this document is available at https://www.isc.org/software/bind/documentation.

Notes BIND 9 nslookup is deprecated and not as full featured as its BIND 8 version. For more features and functionality refer to dig(1M).

nslookup and dig(1M) now report "Not Implemented" as NOTIMP rather than NOTIMPL. This will have impact on scripts that are looking for NOTIMPL.

Name nsupdate – Dynamic DNS update utility

Synopsis

```
nsupdate [-dv] [-y keyname:secret | -k keyfile] [-t timeout]
     [-u udptimeout] [-r udpretries] [filename]
```

Description The `nsupdate` utility submits Dynamic DNS Update requests as defined in RFC 2136 to a name server. This utility allows resource records to be added or removed from a zone without manually editing the zone file. A single update request can contain requests to add or remove more than one resource record.

Zones that are under dynamic control with `nsupdate` or a DHCP server should not be edited by hand. Manual edits could conflict with dynamic updates and cause data to be lost.

The resource records that are dynamically added or removed with `nsupdate` must be in the same zone. Requests are sent to the zone's master servers identified by the `MNAME` field of the zone's SOA record.

Transaction signatures can be used to authenticate the Dynamic DNS updates using the TSIG resource record type described in RFC 2845. The signatures rely on a shared secret that should only be known to `nsupdate` and the name server. Currently, the only supported encryption algorithm for TSIG is HMAC-MD5, which is defined in RFC 2104. Once other algorithms are defined for TSIG, applications will need to ensure that they select the appropriate algorithm as well as the key when authenticating each other. For instance, suitable `key` and `server` statements would be added to `/etc/named.conf` so that the name server can associate the appropriate secret key and algorithm with the IP address of the client application that will be using TSIG authentication. The `nsupdate` utility does not read `/etc/named.conf`.

The `nsupdate` utility uses the `-y` or `-k` option to provide the shared secret needed to generate a TSIG record for authenticating Dynamic DNS update requests. These options are mutually exclusive. See OPTIONS.

Options The following options are supported:

`-d` Operate in debug mode. This provides tracing information about the update requests that are made and the replies received from the name server.

`-k` *keyfile* Read the shared secret from the file *keyfile*, whose name is of the form `K{`*name*`}.+157.+{`*random*`}.private`. For historical reasons, the file `K{`*name*`}.+157.+{`*random*`}.key` must also be present.

`-r` *udpretries* Set the number of UDP retries. The default is 3 seconds. If *udpretries* is set to zero, only one update request is made.

`-t` *timeout* Set *timeout* interval in seconds before update is aborted. The default is 300 seconds. A setting of zero disables the timeout.

`-u` *udptimeout* Set interval in seconds between UDP retires, the default is 3 seconds. A setting of zero causes the interval to be calculated based on the timeout (`-t`) and the number of UDP retries (`-r`).

`-v` Use a TCP connection. Using a TCP connection could be preferable when a batch of update requests is made. By default, `nsupdate` uses UDP to send update requests to the name server.

`-y` *keyname*:*secret* Generate a signature from *keyname*:*secret*, where*keyname* is the name of the key and *secret* is the base64 encoded shared secret.

Use of the `-y` option is discouraged because the shared secret is supplied as a command line argument in clear text and could be visible in the output from `ps(1)` or in a history file maintained by the user's shell.

Input Format The `nsupdate` utility reads input from *filename* or the standard input. Each command is supplied on exactly one line of input. Some commands are for administrative purposes. The others are either update instructions or prerequisite checks on the contents of the zone. These checks set conditions that some name or set of resource records (RRset) either exists or is absent from the zone. These conditions must be met if the entire update request is to succeed. Updates will be rejected if the tests for the prerequisite conditions fail.

Every update request consists of zero or more prerequisites and zero or more updates. This condition allows a suitably authenticated update request to proceed if some specified resource records are present or missing from the zone. A blank input line (or the `send` command) causes the accumulated commands to be sent as one Dynamic DNS update request to the name server.

The command formats and their meaning are as follows:

`server` *servername* [*port*]
Send all dynamic update requests to the name server *servername*. When no `server` statement is provided, `nsupdate` sends updates to the master server of the correct zone. The `MNAME` field of that zone's SOA record identifies the master server for that zone. The *port* argument is the port number on *servername* where the dynamic update requests get sent. If no port number is specified, the default DNS port number of 53 is used.

`local` *address* [*port*]
Send all dynamic update requests using the local *address*. When no `local` statement is provided, `nsupdate` sends updates using an address and port chosen by the system. The *port* argument can also be used to make requests come from a specific port. If no port number is specified, the system assigns one.

`zone` *zonename*
Specify that all updates are to be made to the zone *zonename*. If no `zone` statement is provided, `nsupdate` attempts to determine the correct zone to update based on the rest of the input.

`class` *classname*
Specify the default class. If no class is specified the default class is IN.

`key` *name secret*
Specify that all updates are to be TSIG signed using the *name secret* pair. The `key` command overrides any key specified on the command line with `-y` or `-k`.

`prereq nxdomain` *domain-name*
Require that no resource record of any type exists withthe name *domain-name*.

`prereq yxdomain` *domain-name*
Require that *domain-name* exists (has as at least one resource record, of any type).

`prereq nxrrset` *domain-name* [*class*] *type*
Require that no resource record exists of the specified *type*, *class* and *domain-name*. If *class* is omitted, IN (internet) is assumed.

`prereq yxrrset` *domain-name* [*class*] *type*
Require that a resource record of the specified *type*, *class* and *domain-name* must exist. If *class* is omitted, IN (internet) is assumed.

`prereq yxrrset` *domain-name* [*class*] *type data...*
The *data* from each set of prerequisites of this form sharing a common *type*, *class*, and *domain-name* are combined to form a set of RRs. This set of RRs must exactly match the set of RRs existing in the zone at the given *type*, *class*, and *domain-name*. The *data* are written in the standard text representation of the resource record's RDATA.

`update delete` *domain-name* [*ttl*] [*class*] [*type* [*data...*]]
Delete any resource records named *domain-name*. If *type* and *data* are provided, only matching resource records are removed. The internet class is assumed if *class* is not supplied. The *ttl* is ignored, and is only provided for compatibility.

`update add` *domain-name ttl* [*class*] *type data...*
Add a new resource record with the specified *ttl*, *class* and *data*.

`show`
Display the current message, containing all of the prerequisites and updates specified since the last send.

`send`
Sens the current message. This is equivalent to entering a blank line.

Lines beginning with a semicolon are comments and are ignored.

Examples

EXAMPLE 1 Insert and delete resource records from the zone.

The examples below show how `nsupdate` could be used to insert and delete resource records from the `example.com` zone. Notice that the input in each example contains a trailing blank line so that a group of commands are sent as one dynamic update request to the master name server for `example.com`.

```
# nsupdate
> update delete oldhost.example.com A
```

EXAMPLE 1 Insert and delete resource records from the zone. *(Continued)*

```
> update add newhost.example.com 86400 A 172.16.1.1
> send
```

Any A records for `oldhost.example.com` are deleted. An A record for `newhost.example.com` with IP address 172.16.1.1 is added. The newly-added record has a 1 day TTL (86400 seconds).

```
# nsupdate
> prereq nxdomain nickname.example.com
> update add nickname.example.com 86400 CNAME somehost.example.com
> send
```

The prerequisite condition gets the name server to check that there are no resource records of any type for `nickname.example.com`. If there are, the update request fails. If this name does not exist, a `CNAME` for it is added. This action ensures that when the `CNAME` is added, it cannot conflict with the long-standing rule in RFC 1034 that a name must not exist as any other record type if it exists as a `CNAME`. (The rule has been updated for DNSSEC in RFC 2535 to allow `CNAME`s to have `SIG`, `KEY`, and `NXT` records.)

Files

`/etc/resolv.conf`	used to identify default name server
`K{`*name*`}.+157.+{`*random*`}.key`	base-64 encoding of HMAC-MD5 key created by `dnssec-keygen`(1M).
`K{`*name*`}.+157.+{`*random*`}.private`	base-64 encoding of HMAC-MD5 key created by `dnssec-keygen(1M)`

Bugs The TSIG key is redundantly stored in two separate files. This is a consequence of `nsupdate` using the DST library for its cryptographic operations and could change in future releases.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbind
Interface Stability	External

RFC 2136, *RFC 3007*, *RFC 2104*, *RFC 2845*, *RFC 1034*, *RFC 2535*, *RFC 2931*

Notes Source for BIND9 is available in the `SUNWbind9S` package.

Name ntpdate – set the date and time by way of NTP

Synopsis

```
/usr/sbin/ntpdate [-bBdoqsuv] [-a key#] [-e authdelay]
     [-k keyfile] [-m] [-o version] [-p samples]
     [-t timeout] [-w] server...
```

Description The `ntpdate` utility sets the local date and time. To determine the correct time, it polls the Network Time Protocol (NTP) servers on the hosts given as arguments. This utility must be run as root on the local host. It obtains a number of samples from each of the servers and applies the standard NTP clock filter and selection algorithms to select the best of these.

The reliability and precision of `ntpdate` improve dramatically with a greater number of servers. While a single server may be used, better performance and greater resistance to inaccuracy on the part of any one server can be obtained by providing at least three or four servers, if not more.

The `ntpdate` utility makes time adjustments in one of two ways. If it determines that your clock is off by more than 0.5 seconds it simply steps the time by calling `gettimeofday(3C)`. If the error is less than 0.5 seconds, by default, it slews the clock's time with the offset, by way of a call to `adjtime(2)`. The latter technique is less disruptive and more accurate when the offset is small; it works quite well when `ntpdate` is run by `cron` every hour or two. The adjustment made in the latter case is actually 50% larger than the measured offset. This adjustment tends to keep a badly drifting clock more accurate, at some expense to stability. This tradeoff is usually advantageous. At boot time, however, it is usually better to step the time. This can be forced in all cases by specifying the `-b` option on the command line.

The `ntpdate` utility declines to set the date if an NTP server daemon like `xntpd(1M)` is running on the same host. It can be run on a regular basis from `cron(1M)` as an alternative to running a daemon. Doing so once every one to two hours results in precise enough timekeeping to avoid stepping the clock.

Options The following options are supported:

`-a` *key#* Authenticate transactions, using the key number, *key#*.

`-b` Step the time by calling `gettimeofday(3C)`.

`-B` Force the time to always be slewed using the `adjtime(2)` system call, even if the measured offset is greater than +-128 ms. The default is to step the time using `settimeofday(3C)` if the offset is greater than +-128 ms. If this option is used and the offset is much greater than +-128 ms, it can take a long time (hours) to slew the clock to the correct value. During this time the host should not be used to synchronize clients.

`-d` Display what will be done without actually doing it. Information useful for general debugging is also printed.

`-e` *authdelay* Specify an authentication processing delay, *authdelay* in seconds. See `xntpd(1M)` for details. This number is usually small enough to be negligible for purposes of `ntpdate`. However, specifying a value may improve timekeeping on very slow CPU's.

`-k` *keyfile* Read keys from the file *keyfile* instead of the default file, `/etc/inet/ntp.keys`. *keyfile* should be in the format described in `xntpd(1M)`.

`-m` Join multicast group specified in *server* and synchronize to multicast NTP packets. The standard NTP group is 224.0.1.1.

`-o` *version* Force the program to poll as a version 1 or version 2 implementation. By default `ntpdate` claims to be an NTP version 3 implementation in its outgoing packets. However, some older software declines to respond to version 3 queries. This option can be used in these cases.

`-p` *samples* Set the number of samples `ntpdate` acquires from each server. *samples* can be between 1 and 8 inclusive. The default is 4.

`-q` Query only. Do not set the clock.

`-s` Log actions by way of the `syslog(3C)` facility rather than to the standard output — a useful option when running the program from `cron(1M)`.

`-t` *timeout* Set the time `ntpdate` spends, waiting for a response. *timeout* is rounded to a multiple of 0.2 seconds. The default is 1 second, a value suitable for polling across a LAN.

`-u` Use an unprivileged port to send the packets from. This option is useful when you are behind a firewall that blocks incoming traffic to privileged ports, and you want to synchronize with hosts beyond the firewall. The `-d` option always uses unprivileged ports.

`-v` Be verbose. This option causes `ntpdate`'s version identification string to be logged.

`-w` Wait until able to synchronize with a server. When the `-w` option is used together with `-m`, `ntpdate` waits until able to join the group and synchronize.

Files `/etc/inet/ntp.keys` Contains the encryption keys used by `ntpdate`.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWntpu

See Also cron(1M), xntpd(1M), adjtime(2), gettimeofday(3C), settimeofday(3C)syslog(3C), attributes(5)

Notes The technique of compensating for clock oscillator errors to improve accuracy is inadequate. However, to further improve accuracy would require the program to save *state* from previous runs.

Name ntpq – standard Network Time Protocol query program

Synopsis `/usr/sbin/ntpq [-inp] [-c` *command*`] [`*host*`] [...]`

Description `ntpq` queries NTP servers which implement the recommended NTP mode 6 control message format, about current state. It can also request changes in that state. The program can be run in interactive mode; or it can be controlled using command line arguments. Requests to read and write arbitrary variables can be assembled, with raw and pretty-`printed` output options available. By sending multiple queries to the server, `ntpq` can also obtain and print a list of peers in a common format.

If one or more request options are included on the command line, `ntpq` sends each of the requests to NTP servers running on each of the hosts given as command line arguments. By default, `ntpq` sends its requests to `localhost`, if hosts are not included on the command line. If no request options are given, `ntpq` attempts to read commands from the standard input and execute them on the NTP server running on the first host given on the command line. Again, `ntpq` defaults to `localhost` if no other host is specified.

`ntpq` uses NTP mode 6 packets to communicate with an NTP server. Thus, it can be used to query any compatible server on the network that permits queries. Since NTP is a UDP protocol, this communication will be somewhat unreliable, especially over large distances. `ntpq` makes one attempt to retransmit requests; requests timeout if the remote host is not heard from within a suitable period.

Options Command line options are described below. Specifying a command line option other than `-i` or `-n` causes the specified query (queries) to be sent, immediately to the indicated host(s). Otherwise, `ntpq` attempts to read interactive format commands from standard input.

`-c` Interpret the next argument as an interactive format command and add it to the list of commands to be executed on the specified host(s). Multiple `-c` options may be given.

`-i` Operate in interactive mode; write prompts to standard output and read commands from standard input.

`-n` Output all host addresses in dotted-quad numeric format rather than converting them to canonical host names.

`-p` Print a list of the peers known to the server as well as a summary of their state. This is equivalent to the `peers` interactive command. See `USAGE` below.

Usage Interactive format commands consist of a keyword followed by up to four arguments. Only enough characters of the full keyword to uniquely identify the command need be typed. Normally, the output of a command is sent to standard output; but this output may be written to a file by appending a '>', followed by a file name, to the command line.

Interactive Commands A number of interactive format commands are executed entirely within the `ntpq` program itself. They do not result in NTP mode 6 requests being sent to a server. If no request options are included on the command line, and if the standard input is a terminal device, `ntpq` prompts for these commands. The interactive commands are described below:

`? [`*command_keyword* `]`	A '?' by itself prints a list of all the command keywords known to the current version of `ntpq`. A '?' followed by a command keyword prints function and usage information about the command.
`timeout`*milliseconds*	Specifies a time out period for responses to server queries. The default is about 5000 milliseconds. Since `ntpq` retries each query once after a time out, the total waiting time for a time out is twice the time out value that is set.
`delay`*milliseconds*	Specifies a time interval to be added to timestamps included in requests which require authentication. This command is used to enable (unreliable) server reconfiguration over long delay network paths or between machines whose clocks are unsynchronized. Currently, the server does not require time stamps in authenticated requests. Thus, this command may be obsolete.
`host`*hostname*	Set the name of the host to which future queries are to be sent. *Hostname* may be either a host name or a numeric address.
`keyid` #	Specify of a key number to be used to authenticate configuration requests. This number must correspond to a key number the server has been configured to use for this purpose.
`passwd`	Allow the user to specify a password at the command line. This will be used to authenticate configuration requests. If an authenticating key has been specified (see `keyid` above), this password must correspond to this key. `ntpq` does not echo the password as it is typed.
`hostnames yes | no`	If "yes" is specified, host names are printed in information displays. If "no" is given, numeric addresses are printed instead. The default is "yes" unless modified using the command line `-n` switch.
`raw`	Print all output from query commands exactly as it is received from the remote server. The only formatting/filtering done on the data is to transform non-ASCII data into printable form.
`cooked`	Causes output from query commands to be "cooked". The values of variables recognized by the server are reformatted,

so that they can be more easily read. Variables which `ntpq` thinks should have a decodable value, but do not, are marked with a trailing '?'.

`ntpversion[ 1 | 2 | 3 ]` Sets the NTP version number which `ntpq` claims in packets (defaults is 3). Note that mode 6 control messages (and modes, for that matter) did not exist in NTP version 1. There appear to be no servers left which demand version 1.

`authenticate[ yes | no ]` The command `authenticate yes` instructs `ntpq` to send authentication with all requests it makes. Normally `ntpq` does not authenticate requests unless they are write requests. Authenticated requests cause some servers to handle requests slightly differently, and can occasionally cause a slowed response if you turn authentication on before doing a peer display. `addvars` *variable_name*[=*value*] [,. . .] `rmvars` *variable_name* [,. . .] `clearvars`

The data carried by NTP mode 6 messages consists of a list of items of the form

variable_name=*value*

where the "=*value*" is ignored, and can be omitted, in requests to the server to read variables. `ntpq` maintains an internal list in which data to be included in control messages can be assembled, and sent. This is accomplished with the `readlist` and `writelist` commands described below. The `addvars` command allows variables and their optional values to be added to the list. If more than one variable is to be added, the list should be comma-separated, and it should not contain white space. The `rmvars` command can be used to remove individual variables from the list; the `clearlist` command removes all variables from the list.

`debug[ more | less | off ]` Turns internal query program debugging on and off.

`quit` Exit `ntpq`.

Control Message Commands Each peer known to an NTP server has a 16 bit integer *association identifier* assigned to it. NTP control messages which carry peer variables must identify the peer that the values correspond to, by including its association ID. An association ID of 0 is special. It indicates the variables are system variables, whose names are drawn from a separate name space.

Control message commands send one or more NTP mode 6 messages to the server, and cause the data returned to be printed in some format. Most commands currently implemented send a single message and expect a single response. The current exceptions are the `peers` `mreadlist` and `mreadvar` commands. The `peers` command sends a preprogrammed series of messages to obtain the data it needs. The `mreadlist` and `mreadvar` commands, iterate over a range of associations.

Control message commands are described below:

`associations`
Obtains and prints a list of association identifiers and peer statuses for in-spec peers of the server being queried. The list is printed in columns. The first of these is an index that numbers the associations from 1, for internal use. The second column contains the actual association identifier returned by the server and the third the status word for the peer. This is followed by a number of columns containing data decoded from the status word. Note that the data returned by the `associations` command is cached internally in `ntpq`. The index is then of use when dealing with "dumb" servers which use association identifiers that are hard for humans to type. For any subsequent commands which require an association identifier as an argument, the identifier can be specified by using the form, *&index*. Here *index* is taken from the previous list.

`lassociations`
Obtains and prints a list of association identifiers and peer statuses for all associations for which the server is maintaining *state*. This command differs from the `associations` command only for servers which retain *state* for out-of-spec client associations. Such associations are normally omitted from the display when the `associations` command is used, but are included in the output of `lassociations`.

`passociations`
Prints association data concerning in-spec peers from the internally cached list of associations. This command performs identically to the `associations` command except that it displays the internally stored data rather than making a new query.

`lpassociations`
Print data for all associations, including out-of-spec client associations, from the internally cached list of associations. This command differs from `passociations` only when dealing with servers which retain *state* for out-of-spec client associations.

`pstatus`*assocID*
Sends a read status request to the server for the given association. The names and values of the peer variables returned will be printed. Note that the status word from the header is displayed preceding the variables, both in hexadecimal and in pigeon English.

`readvar` [*assoc*] [*variable_name*[=*value*] [,. . .]]
Requests that the values of the specified variables be returned by the server by sending a read variables request. If the association ID is omitted or is given as zero the variables are system variables, otherwise they are peer variables and the values returned will be those of

the corresponding peer. Omitting the variable list will send a request with no data which should induce the server to return a default display.

`rv` [*assocID*] [*variable_name*[=*value*] [,. . .]]
An easy-to-type short form for the `readvar` command.

`writevar` *assocID variable_name*=*value* [,. . .]
Like the `readvar` request, except the specified variables are written instead of read.

`readlist` [*assocID*]
Requests that the values of the variables in the internal variable list be returned by the server. If the association ID is omitted or is 0 the variables are assumed to be system variables. Otherwise they are treated as peer variables. If the internal variable list is empty a request is sent without data, which should induce the remote server to return a default display.

`rl` [*assocID*]
An easy-to-type short form of the `readlist` command.

`writelist` [*assocID*]
Like the `readlist` request, except the internal list variables are written instead of read.

`mreadvar` *assocID assocID* [*variable_name*[=*value*] [,. . .]]
Like the `readvar` command except the query is done for each of a range of (nonzero) association IDs. This range is determined from the association list cached by the most recent `associations` command.

`mrv` *assocID assocID* [*variable_name*[=*value*] [,. . .]]
An easy-to-type short form of the `mreadvar` command.

`mreadlist`*assocID assocID*
Like the `readlist` command except the query is done for each of a range of (nonzero) association IDs. This range is determined from the association list cached by the most recent `associations` command.

`mrl`*assocID assocID*
An easy-to-type short form of the `mreadlist` command.

`clockvar` [*assocID*] [*variable_name*[=*value*] [,. . .]]
Requests that a list of the server's clock variables be sent. Servers which have a radio clock or other external synchronization respond positively to this. If the association identifier is omitted or zero the request is for the variables of the “system clock”. This request generally gets a positive response from all servers with a clock. Some servers may treat clocks as pseudo-peers and, hence, can possibly have more than one clock connected at once. For these servers, referencing the appropriate peer association ID shows the variables of a particular clock. Omitting the variable list causes the server to return a default variable display.

`cv` [*assocID*] [*variable_name*[=*value*] [,. . .]]
An easy-to-type short form of the `clockvar` command.

`peers`
Obtains a list of in-spec peers of the server, along with a summary of each peer's state. Summary information includes:

- The address of the remote peer
- The reference ID (0.0.0.0 if the ref ID is unknown)
- The stratum of the remote peer
- The type of the peer (local, unicast, multicast or broadcast) when the last packet was received
- The polling interval in seconds
- The reachability register, in octal
- The current estimated delay offset and dispersion of the peer, all in milliseconds.

The character in the left margin indicates the fate of this peer in the clock selection process. The codes mean:

`SPACE`	Discarded due to high stratum and/or failed sanity checks.
`x`	Designated falsticker by the intersection algorithm.
`.`	Culled from the end of the candidate list.
–	Discarded by the clustering algorithm.
`+`	Included in the final selection set.
`#`	Selected for synchronization; but distance exceeds maximum.
`*`	Selected for synchronization.
`o`	Selected for synchronization, pps signal in use.

Since the `peers` command depends on the ability to parse the values in the responses it gets, it may fail to work from time to time with servers which poorly control the data formats.

The contents of the host field may be given in one of four forms. It may be a host name, an IP address, a reference clock implementation name with its parameter or, `REFCLK`(*implementation number*, *parameter*). On "hostnames no" only IP–addresses will be displayed.

`lpeers`
Like `peers`, except a summary of all associations for which the server is maintaining state is printed. This can produce a much longer list of peers from inadequate servers.

`opeers`
An old form of the `peers` command with the reference ID replaced by the local interface address.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWntpu

See Also attributes(5)

Bugs The peers command is non-atomic. It may occasionally result in spurious error messages about invalid associations occurring and terminating the command.

The timeout value is a fixed constant. As a result, it often waits a long time to timeout, since the fixed value assumes sort of a worst case. The program should improve the time out estimate as it sends queries to a particular host; but it does not.

Name ntptrace – trace a chain of NTP hosts back to their master time source

Synopsis

```
/usr/sbin/ntptrace [-vdn] [-r retries] [-t timeout]
     [server]
```

Description `ntptrace` determines where a given Network Time Protocol (NTP) server gets its time from, and follows the chain of NTP servers back to their master time source. If given no arguments, it starts with *localhost*.

Options The following options are supported:

`-d` Turns on some debugging output.

`-n` Turns off the printing of host names; instead, host IP addresses are given. This may be necessary if a nameserver is down.

`-r` *retries* Sets the number of retransmission attempts for each host.

`-t` *timeout* Sets the retransmission timeout (in seconds); default = 2.

`-v` Prints verbose information about the NTP servers.

Examples **EXAMPLE 1** Sample Output From the `ntptrace` Command

The following example shows the output from the `ntptrace` command:

```
% ntptrace

localhost: stratum 4, offset 0.0019529, synch distance 0.144135
server2.bozo.com: stratum 2, offset 0.0124263, synch distance 0.115784
usndh.edu: stratum 1, offset 0.0019298, synch distance 0.011993, refid 'WWVB'
```

On each line, the fields are (left to right):

- The server's host name
- The server's stratum
- The time offset between that server and the local host (as measured by `ntptrace`; this is why it is not always zero for *localhost*)
- The host's synchronization distance
- The reference clock `ID` (only for stratum-1 servers)

All times are given in seconds. Synchronization distance is a measure of the goodness of the clock's time.

Bugs This program makes no attempt to improve accuracy by doing multiple samples.

Name obpsym – Kernel Symbolic Debugging for OpenBoot Firmware

Synopsis

```
modload -p misc/obpsym
```

Description `obpsym` is a kernel module that installs OpenBoot callback handlers that provide kernel symbol information to OpenBoot. OpenBoot firmware user interface commands use the callbacks to convert numeric *addresses* to kernel symbol names for display purposes, and to convert kernel symbol names to numeric *literals* allowing symbolic names to be used as input arguments to user interface commands.

Once `obpsym` is installed, kernel symbolic names may be used anywhere at the OpenBoot firmware's user interface command prompt in place of a literal (numeric) string. For example, if `obpsym` is installed, the OpenBoot firmware commands `ctrace` and `dis` typically display symbolic names and offsets in the form *modname:symbolname + offset*. User interface Commands such as `dis` can be given a kernel symbolic name such as `ufs:ufs_mount` instead of a numeric address.

Placing the command

```
forceload: misc/obpsym
```

into the `system(4)` file forces the kernel module `misc/obpsym` to be loaded and activates the kernel callbacks during the kernel startup sequence.

`obpsym` may be useful as a kernel debugger in situations where other kernel debuggers are not useful. For example, on SPARC machines, if `obpsym` is loaded, you may be able to use the OpenBoot firmware's `ctrace` command to display symbolic names in the stack backtrace after a watchdog reset.

Kernel Symbolic Name Syntax The syntax for a kernel symbolic name is:

[*module-name* `:`] *symbol-name*

Where *module-name* is the name of the kernel module that the symbol *symbol-name* appears in. A `NULL` module name is taken as "all modules, in no particular order" by `obpsym`. The module name `unix` is equivalent to a `NULL` module name, so that conflicts with words defined in the firmware's vocabulary can be avoided.

Typically, OpenBoot firmware reads a word from the input stream and looks the word up in its internal *vocabulary* before checking if the word is a *literal*. Thus, kernel symbols, such as `reset` may be given as `unix:reset` to avoid the unexpected side effect of the firmware finding and executing a matching word in its vocabulary.

OpenBoot 2.x Command Reference Manual

Warnings Some OpenBoot firmware user interface commands may use system resources incompatibly with the way they are used by the Unix kernel. These commands and the use of this feature as a kernel debugger may cause interactions that the Unix kernel is not prepared to deal with. If this occurs, the Unix kernel and/or the OpenBoot firmware user interface commands may react unpredictably and may panic the system, or may hang or may cause other unpredictable results. For these reasons, the use of this feature is only minimally supported and recommended to be used only as a kernel debugger of "last resort".

If a breakpoint or watchpoint is triggered while the console frame buffer is powered off, the system can crash and be left in a state from which it is difficult to recover. If one of these is triggered while the monitor is powered off, you will not be able to see the debugger output.

Notes *platform-name* can be found using the `-i` option of uname(1)

`obpsym` is supported only on architectures that support OpenBoot firmware.

On some systems, OpenBoot must be completely RAM resident so the `obpsym` symbol callback support can be added to the firmware, if the firmware doesn't include support for the symbol callbacks. On these systems, `obpsym` may complain that it requires that "you must use ramforth to use this module".

See the *OpenBoot 2.x Command Reference Manual* for details on how to use the *ramforth* command, how to place the command into *nvramrc*, and how to set *use-nvramrc?* to `true`. On systems with version 1.x OpenBoot firmware, *nvramrc* doesn't exist, and the *ramforth* command must be typed manually after each reset, in order to use this module.

Once installed, the symbol table callbacks can be disabled by using the following OpenBoot firmware command:

```
0 0 set-symbol-lookup
```

Name ocfserv – OCF server

Synopsis

```
ocfserv [-D] [-p path]
```

Description The OCF server, `ocfserv`, is a per-host daemon that acts as the central point of communications with all smartcards connected to the host. Applications that need to use a smartcard can do so by using the APIs in `libsmartcard.so` or `smartcard.jar`. The internal implementation of these APIs communicates with `ocfserv` to perform the requested function.

`inetd(1M)` automatically starts the `ocfserv` command when it is needed. Once started, `ocfserv` runs forever. If `ocfserv` is killed or crashes, it restarts automatically if necessary.

Because `ocfserv` is run automatically, there really is not a reason to run it manually. You must have root privileges to execute this utility.

Options The following options are supported:

`-D` Run `ocfserv` in debug mode.

`-p` *path* Specify property file name.

Exit Status The following exit values are returned:

`0` Successful completion.

>`0` An error occurred.

Files `/etc/smartcard/opencard.properties` File where server stores properties

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWocf

See Also `svcs(1)`, `inetd(1M)`, `inetadm(1M)`, `smartcard(1M)`, `svcadm(1M)`, `attributes(5)smartcard(5)`, `smf(5)`

Notes The `ocfserv` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/rpc/ocfserv
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. Responsibility for initiating and restarting this service is delegated to `inetd(1M)`. Use `inetadm(1M)` to make configuration changes and to view configuration information for this service. The service's status can be queried using the `svcs(1)` command.

Name oplhpd – Hot plug daemon for SPARC Enterprise Server line

Synopsis

```
/usr/platform/SUNW,SPARC-Enterprise/lib/sparcv9/lib/oplhpd
```

Description The hot plug daemon for SPARC Enterprise Servers is a daemon process that runs on the SUNW,SPARC-Enterprise family of servers. The daemon is started by the service management facility (see smf(5)) and communicates with the service processor when hot plug PCI cassettes change their dynamic reconfiguration state.

The service FMRI for `oplhpd` is:

```
svc:/platform/sun4u/oplhpd:default
```

A domain supports only one running `oplhpd` process at a time.

Errors OPLHPD uses syslog(3C) to report status and error messages. All of the messages are logged with the LOG_DAEMON facility.

Error messages are logged with the LOG_ERR and LOG_NOTICE priorities, and informational messages are logged with the LOG_DEBUG priority. The default entries in the `/etc/syslog.conf` file log all of the OPLHPD error messages to the `/var/adm/messages` `log`.

Name parse_dynamic_clustertoc – parse clustertoc file based on dynamic entries

Synopsis

cdrom/export/exec/sparc.Solaris_2.x/sbin/install.d/parse_dynamic_clustertoc

cdrom/export/exec/i386.Solaris_2.x/sbin/install.d/parse_dynamic_clustertoc

Description This script parses the clustertoc file before the suninstall(1M) process is run. parse_dynamic_clustertoc is called by a modified sysconfig script on the install CD. When parse_dynamic_clustertoc runs, it reads the clustertoc and when it encounters SUNW_CSRMBRIFF lines, it either checks the platform using the script's builtin function, or calls an external script. The script exits with a 0 if the cluster entry is included, otherwise it will be ignored. If the cluster entry is to be included, the SUNW_CSRMBRIFF =(*test test_arg*) *cluster* line is converted to SUNW_CSRMEMBER =*cluster*.

Examples **EXAMPLE 1** Checking For an SX Framebuffer

The following is an example of a simple external test to check for an SX Framebuffer. The entry in the clustertoc file is shown and following that is the script that must be placed in the install.d/dynamic_test directory.

```
SUNW_CSRMBRIFF=(smcc.dctoc sx)SUNWCsx
#! /bin/sh
#
# Likewise, this file is expected to live under $(TESTDIR).
#
case "$1"
in
        sx)     prtconf -p  | grep 'SUNW,sx' 1> /dev/null;;
esac
```

Files *cdrom*/Solaris_2.x/locale/C/.clustertoc.dynamic
Dynamic version of the clustertoc file

cdrom/export/exec/sparc.Solaris_2.x/sbin/install.d/dynamic_test
Directory that contains any additional tests

cdrom/export/exec/i386.Solaris_2.x/sbin/install.d/dynamic_test
Directory that contains any additional tests

See Also suninstall(1M), clustertoc(4), attributes(5)

Name passmgmt – password files management

Synopsis

```
passmgmt -a options name
passmgmt -m options name
passmgmt -d name
```

Description The `passmgmt` command updates information in the password files. This command works with both `/etc/passwd` and `/etc/shadow`.

`passmgmt -a` adds an entry for user *name* to the password files. This command does not create any directory for the new user and the new login remains locked (with the string `*LK*` in the password field) until the `passwd(1)` command is executed to set the password.

`passmgmt -m` modifies the entry for user *name* in the password files. The name field in the `/etc/shadow` entry and all the fields (except the password field) in the `/etc/passwd` entry can be modified by this command. Only fields entered on the command line will be modified.

`passmgmt -d` deletes the entry for user *name* from the password files. It will not remove any files that the user owns on the system; they must be removed manually.

`passmgmt` can be used only by the super-user.

Options

`-c` *comment*	A short description of the login, enclosed in quotes. It is limited to a maximum of 128 characters and defaults to an empty field.
`-e` *expire*	Specify the expiration date for a login. After this date, no user will be able to access this login. The expire option argument is a date entered using one of the date formats included in the template file `/etc/datemsk`. See `getdate(3C)`.
`-f` *inactive*	The maximum number of days allowed between uses of a login ID before that ID is declared invalid. Normal values are positive integers. A value of `0` defeats the status. Changing the password reactivates an account for the inactivity period.
`-g` *gid*	GID of *name*. This number must range from 0 to the maximum non-negative value for the system. The default is 1.
`-h` *homedir*	Home directory of *name*. It is limited to a maximum of 256 characters and defaults to `/usr/`*name*.
`-K` *key=value*	Set a *key=value* pair. See `user_attr(4)`, `auth_attr(4)`, and `prof_attr(4)`. The valid *key=value* pairs are defined in `user_attr(4)`, but the "type" key is subject to the `usermod(1M)` and `rolemod(1M)` restrictions. Multiple *key=value* pairs may be added with multiple `-K` options.

`-k` *skel_dir* — A directory that contains skeleton information (such as `.profile`) that can be copied into a new user's home directory. This directory must already exist. The system provides the `/etc/skel` directory that can be used for this purpose.

`-l` *logname* — This option changes the *name* to *logname*. It is used only with the `-m` option. The total size of each login entry is limited to a maximum of 511 bytes in each of the password files.

`-o` — This option allows a UID to be non-unique. It is used only with the `-u` option.

`-s` *shell* — Login shell for *name*. It should be the full pathname of the program that will be executed when the user logs in. The maximum size of *shell* is 256 characters. The default is for this field to be empty and to be interpreted as `/usr/bin/sh`.

`-u` *uid* — UID of the *name*. This number must range from 0 to the maximum non-negative value for the system. It defaults to the next available UID greater than 99. Without the `-o` option, it enforces the uniqueness of a UID.

Files

```
/etc/passwd
/etc/shadow
/etc/opasswd
/etc/oshadow
```

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Evolving

See Also `passwd(1)`, `rolemod(1M)`, `useradd(1M)`, `userdel(1M)`, `usermod(1M)`, `auth_attr(4)`, `passwd(4)`, `prof_attr(4)`, `shadow(4)`, `user_attr(4)`, `attributes(5)`

Exit Status The `passmgmt` command exits with one of the following values:

`0` Success.

`1` Permission denied.

`2` Invalid command syntax. Usage message of the `passmgmt` command is displayed.

`3` Invalid argument provided to option.

`4` UID in use.

`5` Inconsistent password files (for example, *name* is in the `/etc/passwd` file and not in the `/etc/shadow` file, or vice versa).

6 Unexpected failure. Password files unchanged.

7 Unexpected failure. Password file(s) missing.

8 Password file(s) busy. Try again later.

9 *name* does not exist (if `-m` or `-d` is specified), already exists (if `-a` is specified), or `logname` already exists (if `-m -l` is specified).

Notes Do not use a colon (`:`) or RETURN as part of an argument. It is interpreted as a field separator in the password file. The `passmgmt` command will be removed in a future release. Its functionality has been replaced and enhanced by `useradd`, `userdel`, and `usermod`. These commands are currently available.

This command only modifies password definitions in the local `/etc/passwd` and `/etc/shadow` files. If a network nameservice such as NIS or NIS+ is being used to supplement the local files with additional entries, `passmgmt` cannot change information supplied by the network nameservice.

Name patchadd – apply a patch package to a system running the Solaris operating system

Synopsis

```
patchadd [-dun] [-G] [-B backout_dir] [-k keystore]
     [-P passwd] [-t] [-x proxy] {patch} |
     {-M patch_location [patch_list]} [-C net_install_image |
     -R client_root_path | -S service]

patchadd -p
     [-C net_install_image | -R client_root_path | -S service]
```

Description `patchadd` applies a patch package to a system running the Solaris 2.*x* operating environment or later Solaris environments (such as Solaris 10) that are compatible with Solaris 2.*x*. This patch installation utility cannot be used to apply Solaris 1 patches. `patchadd` must be run as root.

The `patchadd` command has the following forms:

- The first form of `patchadd` installs one or more patches to a system, client, service, or to the miniroot of a Net Install Image.
- The second form of `patchadd` displays installed patches on the client, service, or to the miniroot of a Net Install Image.

Starting with version 10 of the Solaris operating system, `patchadd` performs validity and dependency checking among a collection of patches that you specify with the `-M` source specifier. See the description of `-M` under OPERANDS, below.

With respect to `zones(5)`, when invoked in the global zone, by default, `patchadd` patches all appropriate packages in all zones. Patching behavior on system with `zones` installed varies according to the following factors:

- use of the `-G` option (described below)
- setting of the `SUNW_PKG_ALLZONES` variable in the `pkginfo` file (see `pkginfo(4)`)
- type of zone, global or local (non-global) in `patchadd` which is invoked

The interaction of the factors above is specified in "Interaction of `-G` and `pkginfo` Variable in Zones," below.

When you add patches to packages on a Solaris system with zones installed, you will see numerous zones-related messages, the frequency and content of which depend on whether you invoke `patchadd` in a global or local zone, the setting of `SUNW_PKG_ALLZONES`, and the use of the `-G` option.

Note that if you apply a patch that modifies objects in the boot archive, you will need to run the `bootadm` command shown below. This is true whether the patch is installed individually or as part of a cluster, using `install_cluster` and specifying an alternate root.

```
# bootadm update_archive -R /altroot
```

If you do not enter the preceding command, you will need to boot twice to build a clean boot archive.

The *patch*, `-M`, `-C`, `-R`, and `-S` arguments shown in the SYNOPSIS are described under OPERANDS, following OPTIONS.

Options The following options are supported:

`-B` *backout_dir*
Saves backout data to a directory other than the package database. Specify *backout_dir* as an absolute path name.

`-d`
Does not back up the files to be patched. *The patch cannot be removed.*

`-G`
Add patch(es) to packages in the current zone only. When used in the global zone, the patch is added to packages in the global zone only and is not propagated to packages in any existing or yet-to-be-created non-global zone. When used in a non-global zone, the patch is added to packages in the non-global zone only. See "Interaction of `-G` and `pkginfo` Variable in Zones,", below.

`-k` *keystore*
Use *keystore* as the location to get trusted certificate authority certificates when verifying digital signatures found in each patch. If no keystore is specified, then the default keystore locations are searched for valid trusted certificates. See `KEY STORE LOCATIONS` in `pkgadd(1M)` for more information.

`-n`
Tells `patchadd` to ignore the signature and not to validate it. This should be used only when the content of the patch is known and trusted, and is primarily included to allow `patchadd` to apply a patch on systems without the ability to verify the patch signature, such as Solaris 8.

`-p`
In the second form, displays a list of the patches currently applied.

`-P` *passwd*
Password to use to decrypt the keystore specified with `-k`, if required. See `PASS PHRASE ARGUMENTS` in `pkgadd(1M)` for more information about the format of this option's argument.

`-t`
Maintains the `patchadd` return codes from the Solaris release prior to Solaris 10. On a system with `zones(5)` installed, a return code of 0 indicates success. Any other return code indicates failure.

`-u`
Turns off validation against other required or incompatible patches. Use extreme caution when using this option. Its use can precipitate unanticipated bad consequences.

`-x` *proxy*
Specify a HTTP[S] proxy to use when downloading packages The format of proxy is *host*:*port*, where *host* is the hostname of the HTTP[S] proxy, and *port* is the port number associated with the proxy. This switch overrides all other methods of specifying a proxy. See ENVIRONMENT VARIABLES in `pkgadd(1M)` for more information on alternate methods of specifying a default proxy.

Operands The following operands are supported:

Sources `patchadd` must be supplied a source for retrieving the patch. Specify sources using the syntax shown below.

patch
The absolute path name to *patch_id* or a URI pointing to a signed patch. `/var/sadm/spool/patch/104945-02` is an example of a *patch*. `https://syrinx.eng:8887/patches/104945-02` is an example of a URI pointing to a signed patch.

`-M` *patch_location* [*patch_list*]
Specifies the patches to be installed by directory location or URL and, optionally, the name of a file containing a patch list.

When using a directory as the *patch_location*, specify that directory as an absolute path name. Specify a URL as the server and path name that contains the spooled patches. The optional *patch_list* is the name of the file at a specified location containing the patches to be installed.

`-M` *patch_location patch_id* [*patch_id...*]
Specifies the patches to be installed by directory location or URL, and patch number.

To use the directory location or URL and the patch number, specify *patch_location* as the absolute path name of the directory that contains spooled patches. Specify a URL as the server and path name that contains the spooled patches. Specify *patch_id* as the patch number of a given patch. `104945-02` is an example of a *patch_id*. `104945-02` is also an example of a patchid in `104945-02.jar`.

Note that `patchadd` does not require a list of patches. Among a collection of patches—residing in a directory, specified in a list, or entered on a command line—`patchadd` performs validity and dependency checking. Specifically, the command does the following:

- Determines whether a patch is applicable for a system. For example, if the package to be patched is not installed, `patchadd` does not attempt to add the patch.
- Establishes dependencies among valid patches and orders the installation of patches accordingly.

With the "Zones Parallel Patching" feature, patches can be applied to zones in parallel. After a patch is installed successfully in the global zone, the patch installation software will start a number of processes whose task is to apply patches to zones. The number of processes to be started would be determined by the `num_proc` parameter in the configuration file `/etc/patch/pdo.conf`.

The number of processes to be started is determined in the following order:

1. The value of the `num_proc` parameter. Setting this to 1 retains the current behavior of the patch system.
2. The number of online CPUs in the system.

The upper bound is the number of configured Solaris zones.

Most users will find the easiest way to specify a source for `patchadd` is to specify only a *patch_location* containing a set of patches.

Destinations

By default, `patchadd` applies a patch to the specified destination. If no destination is specified, then the current system (the one with its root filesystem mounted at `/`) is assumed to be the destination for the patch. You can specify a destination in the following ways:

`-C` *net_install_image*
Patches the files located on the miniroot on a Net Install Image created by `setup_install_server`. Specify *net_install_image* as the absolute path name to a Solaris 8 or compatible version boot directory. See `EXAMPLES`.

You should use the `-C` option only to install patches that are recommended for installation to the miniroot. Patches that are recommended for installation to the miniroot usually include install-related patches such as package commands, and Sun install and patch installation tools. If you apply too many patches to the miniroot it can grow too large to fit into memory during a net installation of Solaris. Use the `-B` option and the `-C` option together so the miniroot does not get too large. See `-B`, above.

Note that in the current release and in certain versions of Solaris 10, the miniroot is compressed. To determine whether the miniroot is compressed on your system, look for a file called `sparc.miniroot` or `x86.miniroot` under `/boot`, on the boot medium. Before you can patch a compressed miniroot, you must perform certains steps. See "Patching a Compressed Miniroot" below.

`-R` *client_root_path*
Locates all patch files generated by `patchadd` under the directory *client_root_path*. *client_root_path* is the directory that contains the bootable root of a client from the server's perspective. Specify *client_root_path* as the absolute path name to the beginning of the directory tree under which all patch files generated by `patchadd` are to be located. `-R` cannot be specified with the `-S` option. See `NOTES`.

Note – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.

`-S` *service*
Specifies an alternate service (for example, `Solaris_8`). This service is part of the server and client model, and can only be used from the server's console. Servers can contain shared `/usr` file systems that are created by `smosservice(1M)`. These service areas can then be made available to the clients they serve. `-S` cannot be specified with the `-R` option. See `NOTES`.

Patching a Compressed Miniroot

The Solaris operating system uses a compressed miniroot. The compressed miniroot was adopted first in Solaris for x86 and then in Solaris for SPARC over the course of Solaris 10 update releases. See below for an easy way to determine whether your Solaris system uses a compressed miniroot.

To patch a system with a compressed miniroot (full or partial), you must unpack and then repack the miniroot before and after running `patchadd` with the `-C` destination specifier. Use the procedure shown below and accompanying example commands.

1. Unpack the compressed miniroot:

```
# /boot/solaris/bin/root_archive unpackmedia \
/export/home/altuser/testdir /export/home/altuser/mr
```

2. Run `patchadd` with `-C` to patch the miniroot:

```
# patchadd -C /export/home/altuser/mr \
/var/sadm/spool/104945-02
```

3. Repack the miniroot:

```
# /boot/solaris/bin/root_archive packmedia \
/export/home/altuser/testdir /export/home/altuser/mr
```

At this point, you can use `setup_install_server(1M)` to install the patched miniroot on an install server. See `root_archive(1M)` for a description of that command.

To determine whether a Solaris image uses a compressed miniroot, check for the presence of either an `x86.miniroot` or `sparc.miniroot` file under `/boot` on the boot medium.

Interaction of `-G` and `pkginfo` Variable in Zones

The following list specifies the interaction between the `-G` option and the `SUNW_PKG_ALLZONES` variable (see `pkginfo(4)`) when adding a patch in global and local (non-global) zones.

global zone, `-G` specified
If *any* packages have `SUNW_PKG_ALLZONES` set to true: Error; nothing changes.

If *no* packages have `SUNW_PKG_ALLZONES` set to true: Apply patch to package(s) in global zone only.

global zone, `-G` not specified
If *any* packages have `SUNW_PKG_ALLZONES` set to true: Apply patch to appropriate package(s) in all zones.

If *no* packages have `SUNW_PKG_ALLZONES` set to true: Apply patch to appropriate package(s) in all zones.

local zone, `-G` specified or not specified
If *any* packages have `SUNW_PKG_ALLZONES` set to true: Error; nothing changes.

If *no* packages have `SUNW_PKG_ALLZONES` set to true: Apply patch package(s) in local zone only.

Keystore Locations See the section KEYSTORE LOCATIONS in the `pkgadd(1M)` man page for details.

Keystore And Certificate Formats See the section KEYSTORE AND CERTIFICATE FORMATS in the `pkgadd(1M)` man page for details.

Examples The examples in this section are all relative to the `/usr/sbin` directory.

EXAMPLE 1 Installing a Patch to a Standalone Machine

The following example installs a patch to a standalone machine:

```
example# patchadd /var/sadm/spool/104945-02
```

EXAMPLE 2 Installing a Patch to a Client From the Server's Console

The following example installs a patch to a client from the server's console:

```
example# patchadd -R /export/root/client1  /var/sadm/spool/104945-02
```

EXAMPLE 3 Installing a Patch to a Service From the Server's Console

The following example installs a patch to a service from the server's console:

```
example# patchadd -S Solaris_8 /var/sadm/spool/104945-02
```

EXAMPLE 4 Installing Multiple Patches in a Single Invocation

The following example installs multiple patches in a single `patchadd` invocation:

```
example# patchadd -M /var/sadm/spool 104945-02 104946-02 102345-02
```

EXAMPLE 5 Installing Multiple Patches Specifying List of Patches to Install

The following example installs multiple patches specifying a file with the list of patches to install:

```
example# patchadd -M /var/sadm/spool patchlist
```

EXAMPLE 6 Installing Multiple Patches to a Client and Saving the Backout Data

The following example installs multiple patches to a client and saves the backout data to a directory other than the default:

```
example# patchadd -M /var/sadm/spool -R /export/root/client1 \
     -B /export/backoutrepository 104945-02 104946-02 102345-02
```

EXAMPLE 7 Installing a Patch to a Solaris 8 or Compatible Version Net Install Image

The following example installs a patch to a Solaris 8 or compatible version Net Install Image:

```
example# patchadd -C /export/Solaris_8/Tools/Boot \
    /var/sadm/spool/104945-02
```

EXAMPLE 8 Installing a Patch to a Compressed Miniroot

The following example installs a patch to a compressed miniroot, such as one finds on a Solaris x86 machine that supports GRUB–style booting. This example assumes that `/export/Solaris_11/Tools/Boot` contains the unpacked miniroot. After applying the patch, the miniroot needs to be repacked

```
example# patchadd -C /export/Solaris_11/Tools/Boot \
/var/sadm/spool/104945-02
```

See "Patching a Compressed Miniroot," above, for information on Solaris versions that use a compressed miniroot.

EXAMPLE 9 Installing a Patch to an Uncompressed Miniroot

The following example installs a patch to a miniroot on a Solaris machine that does not have a compressed miniroot.

```
example# patchadd -C /export/Solaris_9/Tools/Boot \
/var/sadm/spool/104945-02
```

See "Patching a Compressed Miniroot," above, for information on Solaris versions that use a compressed miniroot.

EXAMPLE 10 Displaying the Patches Installed on a Client

The following example displays the patches installed on a client:

```
example# patchadd -R /export/root/client1 -p
```

Note the caveat on the use of the `-R` option in the description of that option, above.

EXAMPLE 11 Installing a Digitally Signed Set of Patches

The following example installs multiple patches, some of which have been signed, using the supplied keystore, password, and HTTP proxy.

```
example# patchadd -k /etc/mycerts -P pass:abcd -x webcache.eng:8080 \
-M http://www.sun.com/solaris/patches/latest 101223-02 102323-02
```

Files One configuration file of note:

`/etc/patch/pdo.conf` Patch configuration file. Can be used to configure "Zones Parallel Patching" feature.

Exit Status The following exit values are returned:

`0`
Successful completion.

`>0`
An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWswmt, SUNWcsu
Interface Stability	Evolving

See Also `cpio(1)`, `pkginfo(1)`, `patchrm(1M)`, `pkgadd(1M)`, `pkgadm(1M)`, `pkgchk(1M)`, `pkgrm(1M)`, `setup_install_server(1M)`, `smpatch(1M)`, `showrev(1M)`, `pdo.conf(4)`, `pkginfo(4)`, `attributes(5)`, `grub(5)`, `zones(5)`

Diagnostics The following messages might help in determining some of the most common problems associated with installing a patch.

Patch Installation errors Message

```
The prepatch script exited with return code retcode.
patchadd is terminating.
```

Explanation and Recommended Action
The prepatch script supplied with the patch exited with a return code other than `0`. Run a script trace of the prepatch script and find out why the prepatch had a bad return code. Add the `-x` option to the first line of the prepatch script to fix the problem and run `patchadd` again.

Message

```
The signature on patch patch_id was unable to be verified.
patchadd is terminating.
```

Explanation and Recommended Action
The digital signature on a patch was unable to be verified given the keystore in use and the signature on the patch. Check the keystore to make sure it has the requisite trust anchor(s) required to validate the signature on the package and that the package has not been tampered with.

Message

```
The postpatch script exited with return code retcode.
Backing out patch.
```

Explanation and Recommended Action

The postpatch script provided with the patch exited with an error code other than `0`. This script is mostly used to cleanup files (that is, when a package is known to have ownership or permission problems) attributes that do not correspond to the patch package's objects. After the user has noted all validation errors and taken the appropriate action for each one, the user should re-run `patchadd` using the `-u` (unconditional) option. This time, the patch installation will ignore validation errors and install the patch anyway.

Message

```
Insufficient space in /var/sadm/patch to save old files.
(For 2.4 systems and previous)
```

Explanation and Recommended Action

There is insufficient space in the `/var/sadm/patch` directory to save old files. The user has three options for handling this problem: Use the `-B` option while invoking `patchadd`. This option will direct `patchadd` to: save the backout data to the user specified file system, generate additional disk space by deleting unneeded files, or override the saving of the old files by using the `-d` (do not save) option when running `patchadd`.

If the user elects not to save the old versions of the files to be patched, `patchrm` *cannot* be used. One way to regain space on a system is to remove the save area for previously applied patches. Once the user has decided that it is unlikely that a patch will be backed out, the user can remove the files that were saved by `patchadd`. The following commands should be executed to remove the saved files for `patch`*patch_id*:

```
cd /var/sadm/patch/patch_id
rm -r save/*
rm .oldfilessaved
```

After these commands have been executed, `patch` *patch_id* can no longer be backed out.

Message

```
Insufficient space in /var/sadm/pkg/PKG/save to save old files.
(For 2.5 systems and later)
```

Explanation and Recommended Action

There is insufficient space in the `/var/sadm/pkg/PKG/save` directory to save old files. The user has three options for handling this problem: (1) Use the `-B` option while invoking `patchadd`. This option will direct `patchadd` to save the backout data to the user specified file system. (See synopsis above.) (2) Generate additional disk space by deleting unneeded files, or (3) override the saving of the old files by using the `-d` (do not save)

option when running `patchadd`. However, if the user elects not to save the old versions of the files to be patched, `patchrm` *cannot* be used. One way to regain space on a system is to remove the save area for previously applied patches. Once the user has decided that it is unlikely that a patch will be backed out, the user can remove the files that were saved by `patchadd`. The following commands should be executed to remove the saved files for patch *patch_id*:

```
cd /var/sadm/pkg/pkgabbrev/save
rm -r patch_id
```

After these commands have been executed, `patch` *patch_id* can no longer be backed out.

Message

```
Save of old files failed.
(For 2.4 systems and previous)
```

Explanation and Recommended Action

Before applying the patch, the patch installation script uses `cpio` to save the old versions of the files to be patched. This error message means that the `cpio` failed. The output of the `cpio` would have been preceded this message. The user should take the appropriate action to correct the `cpio` failure. A common reason for failure will be insufficient disk space to save the old versions of the files. The user has two options for handling insufficient disk space: (1) generate additional disk space by deleting unneeded files, or (2) override the saving of the old files by using the `-d` option when running `patchadd`. However if the user elects not to save the old versions of the files to be patched, the patch *cannot* be backed out.

Message

```
Pkgadd of pkgname package failed with error code code.
See /tmp/log.patch_id for reason for failure.
```

Explanation and Recommended Action

The installation of one of the patch packages failed. `patchadd` will backout the patch to leave the system in its pre-patched state. See the log file for the reason for failure. Correct the problem and reapply the patch.

Message

```
Pkgadd of pkgname package failed with error code code.
Will not backout patch...patch re-installation.
Warning: The system may be in an unstable state!
See /tmp/log.patch_id for reason for failure.
```

Explanation and Recommended Action

The installation of one of the patch packages failed. `patchadd` will *not* backout the patch. You may manually backout the patch using `patchrm`, then re-apply the entire patch. Look in the log file for the reason `pkgadd` failed. Correct the problem and re-apply the patch.

Message

```
patchadd is unable to find the INST_RELEASE file. This file
must be present for patchadd to function correctly.
```

Explanation and Recommended Action

The `INST_RELEASE` file is missing from the system. This file is created during either initial installation or during an update.

Message

```
A previous installation of patch patch_id was invoked
that saved files that were to be patched. Since files
were saved, you must run this instance of patchadd
without the -d option.
```

Explanation and Recommended Action

If a patch was previously installed without using the `-d` option, then the re-installation attempt must also be invoked without the `-d` option. Execute `patchadd` without the `-d` option.

Message

```
A previous installation of patch patch_id was invoked
with the -d option. (i.e. Do not save files that would
be patched) Therefore, this invocation of patchadd
must also be run with the -d option.
```

Explanation and Recommended Action

If a patch was previously installed using the `-d` option, then the re-installation attempt must also be invoked with the `-d` option. Execute `patchadd` with the `-d'` option.

Message

```
Illegal character found during parsing. Read the man page
for pdo config file.
```

Explanation and Recommended Action

The `/etc/patch/pdo.conf` follows a specific layout. Each entry in this file should conform to this layout. See `pdo.conf(4)`.

Diagnostic Reference

The patch installation messages listed below are not necessarily considered errors, as indicated in the explanations given. These messages are, however, recorded in the patch installation log for diagnostic reference.

Message

```
Package not patched:
PKG=SUNxxxx
Original package not installed
```

Explanation and Recommended Action

One of the components of the patch would have patched a package that is not installed on your system. This is not necessarily an error. A patch may fix a related bug for several packages.

For example, suppose a patch fixes a bug in both the online-backup and `fddi` packages. If you had online-backup installed but didn't have `fddi` installed, you would get the message :

```
Package not patched:
PKG=SUNWbf
Original package not installed
```

This message only indicates an error if you thought the package was installed on your system. If this is the case, take the necessary action to install the package, backout the patch (if it installed other packages) and re-install the patch.

Message

```
Package not patched:
PKG=SUNxxx
ARCH=xxxxxxx
VERSION=xxxxxxx
Architecture mismatch
```

Explanation and Recommended Action

One of the components of the patch would have patched a package for an architecture different from your system. This is not necessarily an error. Any patch to one of the architecture-specific packages might contain one element for each of the possible architectures. For example, assume you are running on a `sun4u`. If you were to install a patch to package `SUNWcar`, you would see the following (or similar) messages:

```
Package not patched:
PKG=SUNWcar
ARCH=sparc.sun4c
VERSION=11.5.0,REV=2.0.18
Architecture mismatch

Package not patched:
PKG=SUNWcar
ARCH=sparc.sun4u
VERSION=11.5.0,REV=2.0.18
Architecture mismatch

Package not patched:
PKG=SUNWcar
ARCH=sparc.sun4e
VERSION=11.5.0,REV=2.0.18

Package not patched:
```

```
PKG=SUNWcar
ARCH=sparc.sun4
VERSION=11.5.0,REV=2.0.18
Architecture mismatch
```

These messages indicate an error condition only if `patchadd` does not correctly recognize your architecture.

Message

```
Package not patched:
PKG=SUNxxxx
ARCH=xxxx
VERSION=xxxxxxx
Version mismatch
```

Explanation and Recommended Action

The version of software to which the patch is applied is not installed on your system. For example, if you were running Solaris 8, and you tried to install a patch against Solaris 9, you would see the following (or similar) message:

```
Package not patched:
PKG=SUNWcsu
ARCH=sparc
VERSION=10.0.2
Version mismatch
```

This message does not necessarily indicate an error. If the version mismatch was for a package you needed patched, either get the correct patch version or install the correct package version. Then backout the patch (if necessary) and reapply.

Message

```
Re-installing Patch.
```

Explanation and Recommended Action

The patch has already been applied, but there is at least one package in the patch that could be added. For example, if you applied a patch that had both Openwindows and Answerbook components, but your system did not have Answerbook installed, the Answerbook parts of the patch would not have been applied. If, at a later time, you `pkgadd` Answerbook, you could re-apply the patch, and the Answerbook components of the patch would be applied to the system.

Message

```
patchadd Interrupted.
patchadd is terminating.
```

Explanation and Recommended Action

`patchadd` was interrupted during execution (usually through pressing CTRL-c). `patchadd` will clean up its working files and exit.

Message

```
patchadd Interrupted.
Backing out Patch...
```

Explanation and Recommended Action

`patchadd` was interrupted during execution (usually through pressing CTRL-c). `patchadd` will clean up its working files, backout the patch, and exit.

Message

```
Warning: Cannot open configuration file %s for reading. Using
default serial patching behavior
```

Explanation and Recommended Action

The `/etc/patch/pdo.conf` file is missing from the system. This file is typically created during an initial install or update or by applying the patch for the "Zones Parallel Patching" feature. If the file is not present, the default, one-at-time behavior of adding or removing patches from a zoned system would ensue.

Notes To successfully install a patch to a client or server, `patchadd` must be issued twice, once with the `-R` option and once with the `-S` option. This guarantees that the patch is installed to both the `/usr` and `root` partitions. This is necessary if there are both `/usr` and `root` packages in the patch.

`pkgadd` is invoked by `patchadd` and executes the installation scripts in the *pkg*`/install` directory. The `checkinstall` script is executed with its ownership set to user `install`, if there is no user `install` then `pkgadd` executes the `checkinstall` script as noaccess. The SVR4 ABI states that the `checkinstall` shall only be used as an information gathering script. If the permissions for the `checkinstall` script are changed to something other than the initial settings, `pkgadd` may not be able to open the file for reading, thus causing the patch installation to abort with the following error:

```
pkgadd: ERROR: checkinstall script did not complete successfully.
```

The permission for the `checkinstall` script should not be changed. Contents of log file for a successfull installation: `patchadd` redirects `pkgadd`'s output to the patch installation log file. For a successfull installation, `pkgadd` will produce the following message that gets inserted into the log file:

```
This appears to be an attempt to install the same architecture
and version of a package which is already installed. This
installation will attempt to overwrite this package.
This message does not indicate a failure, it represents the
correct behavior by pkgadd when a patch installs correctly.
```

This message does not indicate a failure, it represents the correct behavior by `pkgadd` when a patch installs correctly.

On client server machines the patch package is *not* applied to existing clients or to the client root template space. Therefore, when appropriate, *all client machines will need the patch applied directly using this same patchadd method on the client.* See instructions above for applying patches to a client. A bug affecting a package utility (for example, `pkgadd`, `pkgrm`, `pkgchk`) could affect the reliability of `patchadd` or `patchrm`, which use package utilities to install and backout the patch package. It is recommended that any patch that fixes package utility problems be reviewed and, if necessary, applied before other patches are applied. Existing patches are:

Solaris 2.5.1 Sparc Platform Edition:
104578

Solaris 2.5.1 Intel Platform Edition:
104579

Solaris 2.6 Sparc Platform Edition:
106292

Solaris 2.6 Intel Platform Edition:
106293

Warnings Certain patches are classified as "deferred activation" patches (sometimes with initial capitals, as "Deferred Activation" patches). Under conditions indicated below, such patches require special treatment. A patch's `README` file specifies whether that patch is of the deferred activation variety. (Search on "Deferred Activation" in the `README` file.)

If you are installing or removing a patch that uses deferred activation patching, you must check on the following:

- On a system running zones, all non-global zones must be in a halted state for adding or removing a patch.
- Deferred activation patching requires the loopback file system (`lofs`) in order to complete safely. Systems running Sun Cluster 3.1 or Sun Cluster 3.2 are likely to have `lofs` turned off because of restrictions on HA-NFS functionality when `lofs` is enabled. Therefore, before a deferred activation patch is installed or removed, you must re-enable the loopback file system by commenting out the following line in the `/etc/system` file:

  ```
  exclude:lofs
  ```

  Then, reboot your system and install or remove the patch. After you have completed the patch operation, uncomment the line cited above, then reboot to resume normal operation.

Name patchrm – remove a Solaris patch package and restore previously saved files

Synopsis

```
patchrm [-f] [-G] [-B backout_dir]
     [-C net_install_image | -R client_root_path | -S service]
     [-t] patch_id
```

Description `patchrm` removes a patch package and restores previously saved files to a system running the Solaris 2.x operating environment or later Solaris environments (such as Solaris 8) that are compatible with Solaris 2.x. `patchrm` cannot be used with Solaris 1 patches. `patchrm` must be run as root.

With respect to `zones(5)`, when invoked in the global zone, by default, `patchrm` patches all appropriate packages in all zones. Patch removal behavior in a `zones` environment varies according to the following factors:

- use of the `-G` option (described below)
- setting of the `SUNW_PKG_ALLZONES` variable in the `pkginfo` file (see `pkginfo(4)`).
- type of zone, global or local (non-global) in `patchrm` which is invoked

The interaction of the factors above is specified in "Interaction of `-G` and `pkginfo` Variable in Zones," below.

When you remove patches from packages on a Solaris system with zones installed, you will see numerous zones-related messages, the frequency and content of which depend on whether you invoke `patchrm` in a global or local zone, the setting of `SUNW_PKG_ALLZONES`, and the use of the `-G` option.

With the "Zones Parallel Patching" feature, patches can be removed from zones in parallel. Using this feature, patches are removed from all zones first and, once they are removed from all zones, removed from the global zone. For this removal to occur, the patch removal software starts a number of processes whose task is to remove patches from zones. The number of processes to be started would be determined by the `num_proc` parameter in the configuration file `/etc/patch/pdo.conf`.

The number of processes to be started is determined in the following order:

1. The value of the `num_proc` parameter. Setting this to 1 retains the current behavior of the patch system.
2. The number of online CPUs in the system.

The upper bound is the number of configured Solaris zones.

Options The following options are supported:

`-B` *backout_dir*
Removes a patch whose backout data has been saved to a directory other than the package database. This option is only needed if the original backout directory, supplied to the `patchadd` command at installation time, has been moved. Specify *backout_dir* as an absolute path name.

`-C` *net_install_image*
Removes the patched files located on the mini root on a Net Install Image created by `setup_install_server`. Specify *net_install_image* as the absolute path name to a Solaris 2.6 or compatible version boot directory. See `EXAMPLES`.

`-f`
Forces the patch removal regardless of whether the patch was superseded by another patch.

`-G`
Remove patch(es) to packages in the current zone only. When used in the global zone, the patch is removed from packages in the global zone only and is not removed from packages in any existing non-global zone. When used in a non-global zone, the patch is removed from packages in the non-global zone only. See "Interaction of `-G` and `pkginfo` Variable in Zones,", below.

`-R` *client_root_path*
Locates all patch files generated by `patchrm` under the directory *client_root_path*. *client_root_path* is the directory that contains the bootable root of a client from the server's perspective. Specify *client_root_path* as the absolute path name to the beginning of the directory tree under which all patch files generated from `patchrm` will be located. `-R` cannot be specified with the `-S` option.

Note – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.

`-S` *service*
Specifies an alternate service (for example, Solaris_2.3). This service is part of the server and client model, and can only be used from the server's console. Servers can contain shared `/usr` file systems that are created by `smosservice(1M)`. These service areas can then be made available to the clients they serve. `-S` cannot be specified with the `-R` option.

`-t`
Maintains the `patchrm` return codes from the Solaris release prior to Solaris 10. On a system with `zones(5)` installed, a return code of 0 indicates success. Any other return code indicates failure.

Interaction of `-G` and `pkginfo` Variable in Zones

The following list specifies the interaction between the `-G` option and the `SUNW_PKG_ALLZONES` variable (see `pkginfo(4)`) when removing a patch in global and local (non-global) zones.

global zone, `-G` specified
If *any* packages have `SUNW_PKG_ALLZONES` set to true: Error; nothing changes.

If *no* packages have `SUNW_PKG_ALLZONES` set to true: Remove patch from package(s) in global zone only.

global zone, `-G` not specified
If *any* packages have `SUNW_PKG_ALLZONES` set to true: Remove patch from appropriate package(s) in all zones.

If *no* packages have `SUNW_PKG_ALLZONES` set to true: Remove patch from appropriate package(s) in all zones.

local zone, `-G` specified or not specified
If *any* packages have `SUNW_PKG_ALLZONES` set to true: Error; nothing changes.

If *no* packages have `SUNW_PKG_ALLZONES` set to true: Remove patch from package(s) in local zone only.

Operands

The following operands are supported:

patch_id
The patch number of a given patch. `104945-02` is an example of a *patch_id*.

Examples

The examples in this section assume that patch `104945-02` has been installed to the system prior to removal. All of the examples are relative to the `/usr/sbin` directory.

EXAMPLE 1 Removing a Patch From a Stand-alone System

The following example removes a patch from a standalone system:

```
example# patchrm 104945-02
```

EXAMPLE 2 Removing a Patch From a Client's System From the Server's Console

The following example removes a patch from a client's system from the server's console:

```
example# patchrm -R /export/root/client1 104945-02
```

Note the caveat on the use of the `-R` option in the description of that option, above.

EXAMPLE 3 Removing a Patch From a Server's Service Area

The following example removes a patch from a server's service area:

```
example# patchrm -S Solaris_2.3 104945-02
```

EXAMPLE 4 Removing a Patch From a Net Install Image

The following example removes a patch from a Net Install Image:

```
example# patchrm -C /export/Solaris_2.6/Tools/Boot 104945-02
```

Files

One configuration file of note:

`/etc/patch/pdo.conf` Patch configuration file. Can be used to configure “Zones Parallel Patching” feature.

Exit Status The following exit values are returned:

`0`
Successful completion.

`>0`
An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWswmt, SUNWcsu

See Also `cpio(1)`, `pkginfo(1)`, `patchadd(1M)`, `pkgadd(1M)`, `pkgchk(1M)`, `pkgrm(1M)`, `showrev(1M)`, `pdo.conf(4)`, `pkginfo(4)`, `attributes(5)`, `zones(5)`

Diagnostics The following messages may help in determining some of the most common problems associated with backing out a patch.

Message

```
prebackout patch exited with return code code.
patchrm exiting.
```

Explanation and Recommended Action
The prebackout script supplied with the patch exited with a return code other than `0`. Generate a script trace of the prebackout script to determine why the prebackout script failed. Add the `-x` option to the first line of the prepatch script to fix the problem and run `patchadd` again.

Message

```
postbackout patch exited with return code code.
patchrm exiting.
```

Explanation and Recommended Action
The postbackout script supplied with the patch exited with a return code other than `0`. Look at the postbackout script to determine why it failed. Add the `-x` option to the first line of the prepatch script to fix the problem, and, if necessary, *re-exececute the postbackout script only*.

Message

```
Only one service may be defined.
```

Explanation and Recommended Action
You have attempted to specify more than one service from which to backout a patch. Different services must have their patches backed out with different invocations of `patchrm`.

Message

```
The -S and -R arguments are mutually exclusive.
```

Explanation and Recommended Action

You have specified both a non-native service and a *client_root_path* from which to backout a patch. These two arguments are mutually exclusive. If backing out a patch from a non-native `usr` partition, the `-S` option should be used. If backing out a patch from a client's root partition (either native or non-native), the `-R` option should be used.

Message

```
The service service cannot be found on this system
```

Explanation and Recommended Action

You have specified a non-native service from which to backout a patch, but the specified service is not installed on your system. Correctly specify the service when backing out the patch.

Message

```
Only one client_root_path may be defined.
```

Explanation and Recommended Action

You have specified more than one *client_root_path* using the `-R` option. The `-R` option may be used only once per invocation of `patchrm`.

Message

```
The dir directory cannot be found on this system.
```

Explanation and Recommended Action

You have specified a directory using the `-R` option which is either not mounted, or does not exist on your system. Verify the directory name and re-backout the patch.

Message

```
Patch patch_id has not been successfully installed to this system.
```

Explanation and Recommended Action

You have attempted to backout a patch that is not installed on this system. If you must restore previous versions of patched files, you may have to restore the original files from the initial installation CD.

Message

```
Patch patch_id has not been successfully applied to this system.
Will remove directory dir.
```

Explanation and Recommended Action

You have attempted to back out a patch that is not applied to this system. While the patch has not been applied, a residual `/var/sadm/patch/`*patch_id* (perhaps from an unsuccessful `patchadd`) directory still exists. The patch cannot be backed out. If you

must restore old versions of the patched files, you may have to restore them from the initial installation CD.

Message

```
This patch was obsoleted by patch patch_id.
Patches must be backed out in the reverse order in
which they were installed. Patch backout aborted.
```

Explanation and Recommended Action

You are attempting to backout patches out of order. Patches should never be backed-out out of sequence. This could undermine the integrity of the more current patch.

Message

```
Patch patch_id is required to be installed by an already
installed patch_id.
It cannot be backed out until the required patch is backed out first.
```

Explanation and Recommended Action

Backout the patch that is required to be installed then backout the desired patch.

Message

```
The installation of patch patch_id was interrupted.
```

Explanation and Recommended Action

A previous installation was interrupted. The interrupted patch needs to be installed before backing out the desired patch.

Message

```
Patch patch_id was installed without backing up the original
files. It cannot be backed out.
```

Explanation and Recommended Action

Either the `-d` option of `patchadd` was set when the patch was applied, or the save area of the patch was deleted to regain space. As a result, the original files are not saved and `patchrm` cannot be used. The original files can only be recovered from the original installation CD.

Message

```
pkgadd of pkgname package failed return code code.
See /var/sadm/patch/patch_id/log for reason for failure.
```

Explanation and Recommended Action

The installation of one of patch packages failed. See the log file for the reason for failure. Correct the problem and run the backout script again.

Message

```
Restore of old files failed.
```

Explanation and Recommended Action
The backout script uses the `cpio` command to restore the previous versions of the files that were patched. The output of the cpio command should have preceded this message. The user should take the appropriate action to correct the `cpio` failure. This is for Solaris 2.4 or previous versions.

Message

```
Illegal character found during parsing. Read the man page
for pdo config file.
```

Explanation and Recommended Action
The `/etc/patch/pdo.conf` follows a specific layout. Each entry in this file should conform to this layout. See `pdo.conf(4)`.

Message

```
Warning: Cannot open configuration file %s for reading. Using
default serial patching behavior
```

Explanation and Recommended Action
The `/etc/patch/pdo.conf` file is missing from the system. This file is typically created during an initial install or update or by applying the patch for the "Zones Parallel Patching" feature. If the file is not present, the default, one-at-time behavior of adding or removing patches from a zoned system would ensue.

Notes On client server machines the patch package is *not* removed from existing clients or from client root template space. Therefore, when appropriate, *all client machines will need the patch removed directly using this same patchrm method on the client.* A bug affecting a package utility (for example, `pkgadd`, `pkgrm`, `pkgchk`) could affect the reliability of `patchadd` or `patchrm` which use package utilities to install and backout the patch package. It is recommended that any patch that fixes package utility problems be reviewed and, if necessary, applied before other patches are applied. Existing patches are:

Solaris 2.1:
patch 100901

Solaris 2.2:
101122

Solaris 2.3:
10133

Solaris 2.4 Sparc Platform Edition:
102039

Solaris 2.4 Intel Platform Edition:
102041

Solaris 2.5.1 Sparc Platform Edition:
104578

Solaris 2.51 Intel Platform Edition:
104579

Solaris 2.6 Sparc Platform Edition:
106292

Solaris 2.6 Intel Platform Edition:
106293

Warnings Certain patches are classified as "deferred activation" patches (sometimes with initial capitals, as "Deferred Activation" patches). Under conditions indicated below, such patches require special treatment. A patch's `README` file specifies whether that patch is of the deferred activation variety. (Search on "Deferred Activation" in the `README` file.)

If you are installing or removing a patch that uses deferred activation patching, you must check on the following:

- On a system running zones, all non-global zones must be in a halted state for adding or removing a patch.
- Deferred activation patching requires the loopback file system (`lofs`) in order to complete safely. Systems running Sun Cluster 3.1 or Sun Cluster 3.2 are likely to have `lofs` turned off because of restrictions on HA-NFS functionality when `lofs` is enabled. Therefore, before a deferred activation patch is installed or removed, you must re-enable the loopback file system by commenting out the following line in the `/etc/system` file:

  ```
  exclude:lofs
  ```

  Then, reboot your system and install or remove the patch. After you have completed the patch operation, uncomment the line cited above, then reboot to resume normal operation.

Name pbind – control and query bindings of processes or LWPs

Synopsis

```
pbind -b processor_id pid [/lwpid]...

pbind [-q] [pid [/lwpid]]...

pbind -Q [processor_id]...

pbind -u pid [/lwpid]...

pbind -U [processor_id]...
```

Description `pbind` controls and queries bindings of processes and LWPs (lightweight processes) to processors. `pbind` can also remove processor bindings that were previously established.

When an LWP is bound to a processor, it will be executed only by that processor except when the LWP requires a resource that is provided only by another processor. The binding is not exclusive, that is, the processor is free to execute other LWPs as well.

Bindings are inherited, so new LWPs and processes created by a bound LWP will have the same binding. Binding an interactive shell to a processor, for example, binds all commands executed by the shell.

Superusers may bind or unbind any process or LWP, while other users can bind or unbind any process or LWP for which they have permission to signal, that is, any process that has the same effective user ID as the user.

Options The following options are supported:

`-b` *processor_id*
: Binds all or a subset of the LWPs of the specified processes to the processor *processor_id*. Specify *processor_id* as the processor ID of the processor to be controlled or queried. *processor_id* must be present and on-line. Use the `psrinfo` command to determine whether or not *processor_id* is present and on-line. See `psrinfo(1M)`.

`-q`
: Displays the bindings of the specified processes or of all processes. If a process is composed of multiple LWPs which have different bindings and the LWPs are not explicitly specified, the bindings of only one of the bound LWPs will be displayed. The bindings of a subset of LWPs can be displayed by appending "/lwpids" to the process IDs. Multiple LWPs may be selected using "-" and "," delimiters. See EXAMPLES.

`-Q`
: Displays the LWPs bound to the specified list of processors, or all LWPs with processor bindings. For processes composed of multiple LWPs, the bindings of individual LWPs will be displayed.

`-u`
: Removes the bindings of all or a subset of the LWPs of the specified processes, allowing them to be executed on any on-line processor.

`-U`
Removes the bindings of all LWPs bound to the specified list of processors, or to any processor if no argument is specified.

Operands The following operands are supported:

pid
The process ID of the process to be controlled or queried.

lwpid
The set of LWP IDs of the specified process to be controlled or queried. The syntax for selecting LWP IDs is as follows:

```
2,3,4-8       LWP IDs 2, 3, and 4 through 8
-4            LWPs whose IDs are 4 or below
4-            LWPs whose IDs are 4 or above
```

processor_id
The processor ID of the processor to be controlled or queried.

Examples **EXAMPLE 1** Binding Processes

The following example binds processes 204 and 223 to processor 2:

```
example% pbind -b 2 204 223
process id 204: was 2, now 2
process id 223: was 3, now 2
```

EXAMPLE 2 Unbinding a Process

The following example unbinds process 204:

```
example% pbind -u 204
```

EXAMPLE 3 Querying Bindings

The following example queries bindings. It demonstrates that process 1 is bound to processor 0, process 149 has at least one LWP bound to CPU3, and process 101 has no bound LWPs.

```
example% pbind -q 1 149 101
process id 1: 0
process id 149: 3
process id 101: not bound
```

EXAMPLE 4 Querying LWP Bindings

The following example queries bindings of LWPs. It demonstrates that LWP 1 of process 149 is bound to CPU3, and LWP 2 of process 149 is not bound.

```
example% pbind -q 149/1-2
lwp id 149/1: 3
lwp id 149/2: not bound
```

EXAMPLE 5 Querying LWP Bindings for Processor 2:

The following example queries all LWPs bound to processor 2:

```
example% pbind -Q 2
lwp id 149/4: 2
lwp id 149/5: 2
```

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

Exit Status

The following exit values are returned:

`0`
Successful completion.

`>0`
An error occurred.

See Also

`psradm(1M)`, `psrinfo(1M)`, `psrset(1M)`, `processor_bind(2)`, `processor_info(2)`, `sysconf(3C)`, `attributes(5)`

Diagnostics

`pbind: cannot query pid 31: No such process`
The process specified did not exist or has exited.

`pbind: cannot bind pid 31: Not owner`
The user does not have permission to bind the process.

`pbind: cannot bind pid 31: Invalid argument`
The specified processor is not on-line.

Name pcmciad – PCMCIA user daemon

Synopsis

```
/usr/lib/pcmciad
```

Description The PCMCIA user daemon provides user-level services for the PCMCIA nexus driver and PCMCIA card client drivers. There are no user-configurable options for this daemon.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpcmcu

See Also pcmcia(7D), attributes(5)

Diagnostics

```
pcmciad: can't open /dev/pem: No such file or directory
```

The user daemon could not communicate with the PCMCIA event management driver.

Name pfinstall – tests installation profiles

Synopsis

```
/usr/sbin/install.d/pfinstall -D | -d disk_config
     [-c CDpath] profile
```

Description After you create a profile, you can use the `pfinstall` command to test the profile and see if it does what you want before using it to install or upgrade a system. `pfinstall` enables you to test a profile against:

- The system's disk configuration where `pfinstall` is being run.
- Other disks by using a disk configuration file that represents a structure of a disk. See `NOTES` on how to create a disk configuration file.

To successfully and accurately test a profile for a particular Solaris release, you must test a profile within the Solaris environment of the same release. For example, if you want to test a profile for Solaris 2.10, you have to run the `pfinstall` command on a system running Solaris 2.10.

So, on a system running Solaris 2.10, you can test Solaris 2.10 initial installation profiles. However, if you want to test a Solaris 2.10 upgrade profile on a system running a previous version of Solaris, or if you don't have a Solaris 2.10 system installed yet to test Solaris 2.10 initial installation profiles, you have to boot a system from a Solaris 2.10 CD image and temporarily create a Solaris 2.10 install environment. Then, you can run `pfinstall` in the Solaris 2.10 install environment to test your profiles.

To create a temporary Solaris operating system install environment, boot a system from a Solaris CD image (just as you would to install), answer any system identification questions, choose the Solaris Interactive Installation program, and exit out of the first screen that is presented. Then, from the shell, you can execute the `pfinstall` command.

Options The following options are supported:

`-c` *CDpath* — The path to the Solaris installation image. This is required if the image is not mounted on `/cdrom`. (For example, use this option if you copied the installation image to disk or mounted the CD-ROM on a directory other than `/cdrom`.) When testing a profile on an x86 machine, the miniroot needs to be unpacked before using `-c` option. See EXAMPLES, below, for the procedure to unpack the miniroot.

`-d` *disk_config* — `pfinstall` uses a disk configuration file, *disk_config*, to test the profile. See `NOTES` on how to create a disk configuration file. You must specify either this option or the `-D` option to test the profile (see `WARNINGS`). This option cannot be used with an upgrade profile (`install_type upgrade`). You must always test an upgrade profile against a system's disk configuration (`-D` option).

`-D` — `pfinstall` uses the system's disk configuration to test the profile. You must specify either this option or the `-d` option to test the profile (see `WARNINGS`).

Operands The following operands are supported:

profile The file name of the profile to test. If *profile* is not in the directory where `pfinstall` is being run, you must specify the path.

Examples **EXAMPLE 1** Testing an Upgrade Profile

The following example tests an upgrade profile, `upgrade.prof`, on a system with a previous version of the Solaris software installed.

1. Boot the system to be upgraded from the Solaris image chosen for the upgrade, just as you would to install. The image can be located in the system's local CD-ROM or on an install server.
2. Answer the system configuration questions, if prompted.
3. If you are presented with a choice of installation options, choose the Solaris Interactive Installation program.
4. Exit from the first screen of the Solaris Interactive Installation program.

   After the Solaris Interactive Installation program exits, a shell prompt is displayed.
5. Create a temporary mount point:

   ```
   example# mkdir /tmp/mnt
   ```
6. Mount the directory that contains the profile(s) you want to test.

   If you want to mount a remote NFS file system (for systems on the network), enter:

   ```
   example# mount -F nfs server_name:path /tmp/mnt
   ```

   If you want to mount a UFS-formatted diskette, enter:

   ```
   example# mount -F ufs /dev/diskette /tmp/mnt
   ```

   If you want to mount a PCFS-formatted diskette, enter:

   ```
   example# mount -F pcfs /dev/diskette /tmp/mnt
   ```
7. Change directory to `/tmp/mnt` where the profile resides:

   ```
   example# cd /tmp/mnt
   ```
8. Test the `upgrade.prof` profile:

   ```
   example# /usr/sbin/install.d/pfinstall -D upgrade.prof
   ```

EXAMPLE 2 Testing the `basic.prof` Profile on an x86 Machine (Includes Unpacking miniroot)

The following example tests the `basic.prof` profile against the disk configuration on a Solaris 8 system where `pfinstall` is being run. The path to the Solaris CD image is specified because Volume Management is being used.

```
example# /usr/sbin/install.d/pfinstall -D -c /cdrom/cdrom0/s0 basic.prof
```

EXAMPLE 2 Testing the `basic.prof` Profile on an x86 Machine (Includes Unpacking miniroot) *(Continued)*

When testing a profile on an x86 machine, before using `pfinstall` with `-c` option, use the following procedure to unpack the miniroot:

1. Uncompress the miniroot archive into a temporary file. The miniroot archive is under `/cdrom/cdrom0/s0`.

   ```
   # /usr/bin/gzcat /cdrom/cdrom0/boot/x86.miniroot > \
   /tmp/x86_miniroot_gz
   ```

2. Create the miniroot device using `lofiadm(1M)`:

   ```
   /usr/sbin/lofiadm -a /tmp/x86_miniroot_gz
   /dev/lofi/1
   ```

3. Mount the miniroot under miniroot directory using the `lofi` device returned by `lofiadm` in the previous step:

   ```
   # /usr/sbin/mount -F ufs /dev/lofi/1 \
   /cdrom/cdrom0/Solaris_10/Tools/Boot
   ```

4. Now run `pfinstall` with `-D` option:

   ```
   # /usr/sbin/install.d/pfinstall -D -c /cdrom/cdrom0/ jumpstart.profile
   ```

5. After `pfinstall` testing is completed, unmount the `lofi` device:

   ```
   # /usr/sbin/umount /dev/lofi/1
   ```

6. Delete the `lofi` device:

   ```
   # /usr/sbin/lofiadm -d /tmp/x86_miniroot_gz
   ```

EXAMPLE 3 Testing the `basic.prof` Profile Against Disk Config File

The following example tests the `basic.prof` profile against the `535_test` disk configuration file. This example uses a Solaris CD image located in the `/export/install` directory, and `pfinstall` is being run on a Solaris 2.6 system.

```
example# /usr/sbin/install.d/pfinstall -d 535_test \
     -c /export/install basic.prof
```

Exit Status

`0` Successful (system rebooted).

`1` Successful (system not rebooted).

`2` An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWinst

See Also fdisk(1M), lofiadm(1M), prtvtoc(1M), attributes(5)

Solaris 10 Installation Guide: Basic Installations

Warnings If the -d or -D option is not specified, pfinstall may perform an actual installation on the system by using the specified profile, and the data on the system may be overwritten.

Notes You have to test a profile on a system with the same platform type for which the profile was created.

SPARC To create a disk configuration file (-d option) for a SPARC based system:

1. Locate a SPARC based system with a disk that you want to test.
2. Create a disk configuration file by redirecting the output of the prtvtoc(1M) command to a file.

   ```
   example# prtvtoc /dev/rdsk/c0t3d0s2 > 535_disk
   ```

3. (Optional.) Concatenate disk configuration files into a single file to test a profile against multiple disks. The target numbers in the disk device names must be unique.

   ```
   example# cat 535_disk 1G_disk > mult_disks
   ```

x86 To create a disk configuration file (-d option) for an x86 based system:

1. Locate an x86 based system with a disk that you want to test.
2. Create part of the disk configuration file by saving the output of the fdisk(1M) command to a file:

   ```
   example# fdisk -R -W 535_disk /dev/rdsk/c0t3d0p0
   ```

3. Append the output of the prtvtoc(1M) command to the disk configuration file.

   ```
   example# prtvtoc /dev/rdsk/c0t3d0s2 >> 535_disk
   ```

4. (Optional.) Concatenate disk configuration files into a single file to test a profile against multiple disks. The target numbers in the disk device names must be unique.

   ```
   example# cat 535_disk 1G_disk > mult_disks
   ```

To test a profile with a specific system memory size, set SYS_MEMSIZE to the specific memory size (in Mbytes) before running pfinstall:

```
example# SYS_MEMSIZE=memory_size

example# export SYS_MEMSIZE
```

Name pgxconfig, GFXconfig, TSIgfxp_config – configure the PGX32 (Raptor GFX) Graphics Accelerator

Synopsis

```
/usr/sbin/pgxconfig [-dev device-filename]
     [-res video-mode [try | noconfirm | nocheck]]
     [-file machine | system] [-depth 8 | 24]
     [-24only true | false] [-cachedpixmap true | false]
     [-defaults]

/usr/sbin/pgxconfig [-propt] [-prconf]

/usr/sbin/pgxconfig [-help] [-res ?]

/usr/sbin/pgxconfig [-i]
```

Description The `pgxconfig` utility configures the PGX32 (Raptor GFX) Graphics Accelerator and some of the X11 window system defaults for PGX32 (Raptor GFX). A previous version of this utility was named `GFXconfig`.

The first form of `pgxconfig` shown in the synopsis above stores the specified options in the OWconfig file. These options are used to initialize the PGX32 (Raptor GFX) device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots.

The second, third, and fourth forms, which invoke only the `-prconf`, `-propt`, `-help`, and `-res ?` options, do not update the OWconfig file. For the third form all other options are ignored.

The `-i` option starts `pgxconfig` in interactive mode.

Options may be specified for only one PGX32 (Raptor GFX) device at a time.

Only PGX32 (Raptor GFX)-specific options can be specified through `pgxconfig`. The normal window system options for specifying default depth, default visual class and so forth are still specified as device modifiers on the `openwin` command line. See the `Xsun`(1) manual page available with the SUNWxwman package.

The user can also specify the OWconfig file that is to be updated. By default, the machine-specific file in the `/usr/openwin` directory tree is updated. The `-file` option can be used to specify an alternate file to use. For example, the system-global OWconfig file in the `/etc/openwin` directory tree can be updated instead.

Both of these standard OWconfig files can only be written by root.

Options The following options are supported:

`-cachedpixmap` true | false
: When set to `false`, it forces the PGX32 (Raptor GFX) device to use 24–bit only when running OpenWindows. The default value is `true`.

Certain applications make use of a cached pixmap when writing to the display device. Such a technique can cause garbled output and can cause the X server to crash. If you experience such behavior, try setting the `-cachedpixmap` option to `false`.

`-defaults` — Reset all option values to their default values.

`-depth` 8 | 24 — Sets the screen depth to 8 or 24 bits per pixel. 24 bits per pixel enables TrueColor graphics in the window system.

`-dev` *device-filename* — Specify the PGX32 (Raptor GFX) special file. The default is `/dev/fbs/gfxp0`, or `/dev/fbs/raptor0` if applicable.

`-file machine| system` — Specifies which `OWconfig` file to update. If *machine* is specified, the machine-specific `OWconfig` file in the `/etc/openwin` directory tree is updated. If *system* is specified, the global `OWconfig` file in the `/usr/openwin` directory tree is updated. If the specified file does not exist, it is created. This option has no effect unless other options are specified. The default is *machine*.

`-help` — Print a list of the `pgxconfig` command line options, along with a brief explanation of each.

`-i` — Start `pgxconfig` in interactive mode.

`-prconf` — Print the PGX32 (Raptor GFX) hardware configuration. Thie following is a typical display:

```
--- Hardware Configuration for /dev/fbs/gfxp0 ---
DAC: version 0x0
Type:
Board:
PROM: version 0x0
PROM Information:
RAM:
EDID Data:
Monitor Sense ID:
```

```
Card possible resolutions:  640x480x60, 800x600x75, 1024x768x60
               1024x768x70, 1024x768x75, 1280x1024x75, 1280x1024x76
               1280x1024x60, 1152x900x66, 1152x900x76, 1280x1024x67
               960x680x112S, 960x680x108S, 640x480x60i, 768x575x50i,
               1280x800x76, 1440x900x76, 1600x1000x66, 1600x1000x76,
               vga, svga, 1152, 1280, stereo, ntsc, pal
Monitor possible resolutions:  720x400x70, 720x400x88, 640x480x60
               640x480x67, 640x480x72, 640x480x75, 800x600x56,
               800x600x60, 800x600x72, 800x600x75, 832x624x75,
               1024x768x87, 1024x768x60, 1024x768x70, 1024x768x75,
               1280x1024x75, 1280x1024x76, 1152x900x66, 1152x900x76,
               1280x1024x67, 960x680x112S, vga, svga, 1152, 1280
               stereo
Current resolution setting: 1280x1024x76
Possible depths: 8, 24, 8+24
Current depth: 8
```

`-propt`

Print the current values of all PGX32 (Raptor GFX) options in the `OWconfig` file specified by the `-file` option for the device specified by the `-dev` option. Print the values of options as they would be in the `OWconfig` file after the call to `pgxconfig` would have completed. The following is a typical display:

```
--- OpenWindows Configuration for /dev/fbs/gfxp0 ---
OWconfig: machine
Video Mode: not set
Depth: 8+24
```

`-res` *video-mode* [`try` | `noconfirm` | `nocheck`]

Specify the built-in video mode used to drive the monitor connected to the specified PGX32 (Raptor GFX) device.

The format for *video-mode* can be one of the following:

*width*x*height*x*rate*

The *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh. As a convenience, `-res`

also accepts formats with @ prepended to the refresh rate rather than `x`. For example: 1280x1024@76. The list can be obtained by running `pgxconfig` with the `-res ?` option (the third form shown in the command synopsis above). Note that not all resolutions are supported by both the video board and by the monitor. The `pgxconfig` utility will not permit you to set a resolution not supported by the board unless the `noconfirm` or `nocheck` option is specified. It will also request confirmation before setting a resolution not supported by the monitor if the `nocheck` option is not specified.

Symbolic names

For convenience, the video modes listed below have symbolic names defined. Rather than the form *width*x*height*x*rate*, the symbolic name may be supplied as the argument to

`-res`. If the symbolic name is `none`, the screen resolution will be the video mode that is currently programmed in the device when the window system is run.

`svga`	1024x768x60
`1152`	1152x900x76
`1280`	1280x1024x76
`vga`	640x480x60
`none`	default console resolution

The `-res` option also accepts additional, optional arguments immediately following the video mode specification. Any or all of these may be present.

`noconfirm` Using the `-res` option, the user could put the system into an unusable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this occurring, the default behavior of `pgxconfig` is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. The `noconfirm` option instructs `pgxconfig` to bypass this confirmation and to

program the requested video mode anyway. This option is useful when `pgxconfig` is being run from a shell script.

`nocheck` — If present, normal error checking based on the monitor sense code is suspended. The video mode specified by the user will be accepted regardless of whether it is appropriate for the currently attached monitor. (This option is useful if a different monitor is to be connected to the PGX32 (Raptor GFX) device). Use of this option implies `noconfirm` as well.

`try` — This option allows the user to test the specified resolution before committing it. It displays a pattern on the screen with the specified resolution. If the test pattern appears correctly, the user may answer "y" to the query. The other permissable answer is "n".

This sub-option should not be used with `pgxconfig` while the configured device is being used (for example, while running the window system) as unpredictable results may occur. To run `pgxconfig` with the `try` sub-option, the window system should be brought down first.

`-res ?`	Print the list of possible resolutions supported by the PGX32 and the monitor.
`-24only`	Force the PGX32 (Raptor GFX) device to use 24 bit only when running Openwindows.

Defaults For a given invocation of `pgxconfig`, if an option does not appear on the command line, the corresponding OWconfig option is not updated; it retains its previous value, except for `-depth` and `-24only`.

A default value is used if a PGX32 (Raptor GFX) option has not been specified with `pgxconfig` when the window system is run. The option defaults are as follows:

`-dev` `/dev/fbs/gfxp0`

`-file` `system`

`-res` none

The default of none for the `-res` option indicates that when the window system is run, the screen resolution will be the video mode that is currently programmed in the device.

Examples **EXAMPLE 1** Switching the Resolution on the Monitor Type

The following example switches the monitor type to the resolution of `1280` x `1024` at `76` Hz:

```
example# /usr/sbin/pgxconfig -res 1280x1024x76
```

Files

`/dev/fbs/gfxp0`	device special file
`/usr/openwin/server/etc/OWconfig`	system configuration file
`/etc/openwin/server/etc/OWconfig`	machine configuration file

See Also *PGX32 Installation Manual*

Name picld – PICL daemon

Synopsis `/usr/lib/picl/picld`

Description The Platform Information and Control Library (PICL) provides a mechanism to publish platform-specific information for clients to access in a platform-independent way. `picld` maintains and controls access to the PICL information from clients and plug-in modules. The daemon is started in both single-user and multi-user boot mode.

Upon startup, the PICL daemon loads and initializes the plug-in modules. These modules use the `libpicltree(3PICLTREE)` interface to create nodes and properties in the PICL tree to publish platform configuration information. After the plug-in modules are initialized, the daemon opens the PICL daemon door to service client requests to access information in the PICL tree.

PICL Tree The PICL tree is the repository of all the nodes and properties created by the plug-in modules to represent the platform configuration. Every node in the PICL tree is an instance of a well-defined PICL class. The name of the base PICL class is `picl`, which defines a basic set of properties that all nodes in the tree must possess. Two of those properties are `name` and `_class`, where `name` contains the name of the node, and the `_class` contains the PICL class name of the node. Certain nodes in the PICL tree have well-known names. For example, the name of the root node of the PICL tree is `/` and the name of the root node of the sub-tree containing platform device nodes is `platform`.

PICL plug–in Modules The PICL plug-in modules are shared objects that publish platform-specific data in the PICL tree. They are located in well-known directories so that the daemon can locate and load them.

Plug-in modules are located in one of the following plug-in directories depending on the plaform-specific nature of the data that they collect and publish:

```
/usr/platform/‘uname -i‘/lib/picl/plugins
/usr/platform/‘uname -m‘/lib/picl/plugins
```

A plug-in module can specify its dependency on another plug-in module using the `-l` or `-R` linker option. The plug-ins are loaded by the daemon using `dlopen(3C)` according to the specified dependencies. Each plug-in module must define a `.init` section, which is executed when the plug-in module is loaded, to register themselves with the daemon. See `picld_plugin_register(3PICLTREE)` for additional information on plug-in registration.

The plug-in modules use the `libpicltree(3PICLTREE)` interface to publish nodes and properties in the PICL tree so that clients can access them.

When the PICL daemon invokes the initialization routine of the plug-in module, the plug-in collects the platform information and creates nodes and/or properties to represent the configuration in the PICL tree. A plug-in can create additional threads to monitor the platform configuration and update the PICL tree with any changes. This enables a PICL plug-in to operate as a daemon within the PICL framework.

An environmental monitor is an example of a plug-in module that uses a thread to monitor the temperatures and fan speeds of the platform, then publishes the environmental information in the PICL tree so clients can access them.

Clients use the libpicl(3PICL) interface to send requests to picld for accessing the PICL tree.

Exit Status picld does not return an exit status.

Files

/var/run/picld_door	PICL daemon door
/usr/lib/picl/picld	PICL daemon

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpiclu

See Also svcs(1), svcadm(1M), dlopen(3C), libpicl(3PICL), libpicltree(3PICLTREE), picld_log(3PICLTREE), picld_plugin_register(3PICLTREE), attributes(5), smf(5)

Notes The picld service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/system/picl
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name ping – send ICMP (ICMP6) ECHO_REQUEST packets to network hosts

Synopsis

```
/usr/sbin/ping  host [timeout]

/usr/sbin/ping  -s [-l |  -U] [-adlLnrRv] [-A addr_family]
 [-c traffic_class] [-g gateway  [-g  gateway...]] [-F flow_label]
 [-I interval] [-i interface] [-P tos] [-p port] [-t ttl]
 host [data_size] [npackets]
```

Description The utility `ping` utilizes the ICMP (ICMP6 in IPv6) protocol's `ECHO_REQUEST` datagram to elicit an ICMP (ICMP6) `ECHO_RESPONSE` from the specified *host* or network *gateway*. If *host* responds, `ping` will print:

```
host is alive
```

on the standard output and exit. Otherwise, after *timeout* seconds, it will write:

```
no answer from host
```

The default value of *timeout* is `20` seconds.

When you specify the s flag, sends one datagram per second (adjust with `-I`) and prints one line of output for every `ECHO_RESPONSE` that it receives. `ping` produces no output if there is no response. In this second form, `ping` computes round trip times and packet loss statistics; it displays a summary of this information upon termination or timeout. The default *data_size* is `56` bytes, or you can specify a size with the *data_size* command-line argument. If you specify the optional *npackets*, `ping` sends `ping` requests until it either sends *npackets* requests or receives *npackets* replies.

When using `ping` for fault isolation, first `ping` the local host to verify that the local network interface is running.

Options The following options are supported:

`-A` *addr_family*

Specify the address family of the target host. *addr_family* can be either `inet` or `inet6`. Address family determines which protocol to use. For an argument of `inet`, IPv4 is used. For `inet6`, IPv6 is used.

By default, if the name of a host is provided, not the literal IP address, and a valid IPv6 address exists in the name service database, `ping` will use this address. Otherwise, if the name service database contains an IPv4 address, it will try the IPv4 address.

Specify the address family `inet` or `inet6` to override the default behavior. If the argument specified is `inet`, `ping` will use the IPv4 address associated with the host name. If none

exists, `ping` will state that the host is unknown and exit. It does not try to determine if an IPv6 address exists in the name service database.

If the specified argument is `inet6`, `ping` uses the IPv6 address that is associated with the host name. If none exists, `ping` states that the host is unknown and exits.

`-F` *flow_label*
: Specify the flow label of probe packets. The value must be an integer in the range from 0 to 1048575. This option is valid only on IPv6.

`-I` *interval*
: Turn on the statistics mode and specify the interval between successive transmissions. The default is one second. See the discussion of the `-s` option.

`-L`
: Turn off loopback of multicast packets. Normally, members are in the host group on the outgoing interface, a copy of the multicast packets will be delivered to the local machine.

`-P` *tos*
: Set the type of service (*tos*) in probe packets to the specified value. The default is zero. The value must be an integer in the range from 0 to 255. Gateways also in the path can route the probe packet differently, depending upon the value of *tos* that is set in the probe packet. This option is valid only on IPv4.

`-R`
: Record route. Sets the IPv4 record route option, which stores the route of the packet inside the IPv4 header. The contents of the record route are only printed if the `-v` and `-s` options are given. They are only set on return packets if the target host preserves the record route option across echos, or the `-l` option is given. This option is valid only on IPv4.

`-U`
: Send UDP packets instead of ICMP (ICMP6) packets. `ping` sends UDP packets to consecutive ports expecting to receive back ICMP (ICMP6) `PORT_UNREACHABLE` from the target host.

`-a`
: `ping` all addresses, both IPv4 and IPv6, of the multihomed destination. The output appears as if `ping` has been run once for each IP address of the destination. If this option is used together with `-A`, `ping` probes only the addresses that are of the specified address family. When used with the `-s` option and *npackets* is not specified, `ping` continuously probes the destination addresses in a round robin fashion. If *npackets* is

specified, `ping` sends *npackets* number of probes to each IP address of the destination and then exits.

`-c` *traffic_class*
: Specify the traffic class of probe packets. The value must be an integer in the range from 0 to 255. Gateways along the path can route the probe packet differently, depending upon the value of *traffic_class* set in the probe packet. This option is valid only on IPv6.

`-d`
: Set the `SO_DEBUG` socket option.

`-g` *gateway*
: Specify a loose source route gateway so that the probe packet goes through the specified host along the path to the target host. The maximum number of gateways is 8 for IPv4 and 127 for IPv6. Note that some factors such as the link MTU can further limit the number of gateways for IPv6.

`-i` *interface_address*
: Specify the outgoing interface address to use for multicast packets for IPv4 and both multicast and unicast packets for IPv6. The default interface address for multicast packets is determined from the (unicast) routing tables. *interface_address* can be a literal IP address, for example, `10.123.100.99`, or an interface name, for example, `eri0`, or an interface index, for example `2`.

`-l`
: Use to send the probe packet to the given host and back again using loose source routing. Usually specified with the `-R` option. If any gateways are specified using `-g`, they are visited twice, both to and from the destination. This option is ignored if the `-U` option is used.

`-n`
: Show network addresses as numbers. `ping` normally does a reverse name lookup on the IP addresses it extracts from the packets received. The `-n` option blocks the reverse lookup, so `ping` prints IP addresses instead of host names.

`-p` *port*
: Set the base UDP *port* number used in probes. This option is used with the `-U` option. The default base *port* number is 33434. The `ping` utility starts setting the destination port number of UDP packets to this base and increments it by one at each probe.

`-r`
: Bypass the normal routing tables and send directly to a host on an attached network. If the host is not on a directly attached network, an error is returned. This option can be used to `ping` a local host through an interface that has been dropped by the router daemon. See `in.routed(1M)`.

`-s`	Send one datagram per second and collect statistics.
`-t` *ttl*	Specify the IPv4 time to live, or IPv6 hop limit, for unicast and multicast packets. The default time to live (hop limit) for unicast packets can be set with the `ndd` module, `/dev/icmp`, using the `icmp_ipv4_ttl` variable for IPv4 and the `icmp_ipv6_hoplimit` variable for IPv6. The default time to live (hop limit) for multicast is one hop. See `EXAMPLES`. For further information, see`ndd(1M)`.
`-v`	Verbose output. List any ICMP (ICMP6) packets, other than replies from the target host.

Operands *host* The network host

Examples **EXAMPLE 1** Using `ping` With IPv6

This example shows `ping` sending probe packets to all the IPv6 addresses of the host `xyz`, one at a time. It sends an ICMP6 `ECHO_REQUEST` every second until the user interrupts it.

```
istanbul% ping -s -A inet6 -a xyz
PING xyz: 56 data bytes
64 bytes from xyz (4::114:a00:20ff:ab3d:83ed): icmp_seq=0. time=0.479 ms
64 bytes from xyz (fec0::114:a00:20ff:ab3d:83ed): icmp_seq=1. time=0.843 ms
64 bytes from xyz (4::114:a00:20ff:ab3d:83ed): icmp_seq=2. time=0.516 ms
64 bytes from xyz (fec0::114:a00:20ff:ab3d:83ed): icmp_seq=3. time=4.94 ms
64 bytes from xyz (4::114:a00:20ff:ab3d:83ed): icmp_seq=4. time=0.485 ms
64 bytes from xyz (fec0::114:a00:20ff:ab3d:83ed): icmp_seq=5. time=2.20 ms
^C
----xyz PING Statistics----
6 packets transmitted, 6 packets received, 0% packet loss
round-trip (ms)  min/avg/stddev = 0.479/1.58/4.94/1.8
```

EXAMPLE 2 Using `ndd` to Set the `icmp_ipv6_hoplimit`

This example shows the `ndd` module, `/dev/icmp`, used to set the `icmp_ipv6_hoplimit`.

```
# ndd -set /dev/icmp icmp_ipv6_hoplimit 100
```

Exit Status The following exit values are returned:

`0`	Successful operation; the machine is alive.
non-zero	An error has occurred. Either a malformed argument has been specified, or the machine was not alive.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Name pkg2du – convert driver packages to Driver Update format

Synopsis

```
/usr/bin/pkg2du [-f] [-v] [-d dir] [-o iso] [-l label]
     [-r release] pkg [pkg ...]
```

Description The `/usr/bin/pkg2du` utility takes one or more packages as input and converts them to Driver Update (DU) format. If the `-d` option is specified, the resulting DU directory tree is placed in the directory *dir*. If the `-o` option is specified, a Solaris ISO image of the DU directory tree is written in the file *iso*. The ISO image can be burned onto CD/DVD using `cdrw(1)` or `cdrecord(1)` (not a SunOS man page) and used during Solaris installation.

At least one of the `-d` and `-o` options must be specified. If both are specified, then both an ISO image and a directory tree are generated.

Options The following options are supported:

`-d` *dir*
Directory where the DU directory should be created.

`-o` *iso*
Create a Solaris ISO image of the DU directory.

`-f`
If *dir*`/DU` or *iso* exists, remove it without asking first.

`-l` *label*
Label/volume name of the ISO image (if `-o` option is specified).

`-r` *release*
Solaris release number to use. It takes the form of the return from `uname -r` command, for example, `5.10`. If unspecified, the release number of the currently running Solaris is used.

`-v`
Verbose. Multiple `-v` options increase verbosity.

Operands The following operands are supported:

pkg [*pkg*...]
One or more packages to be converted to DU format.

Examples **EXAMPLE 1** Creating a DU CD/DVD

The following commands create a DU CD or DVD containing packages `SUNWfoo` and `SUNWbar`.

```
# /usr/bin/pkg2du -r 5.10 -o my.iso SUNWfoo SUNWbar
# /usr/bin/cdrw -i my.iso
```

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Committed

See Also cdrw(1), mkbootmedia(1M), attributes(5)

mkisofs(8), (/usr/share/man/man8/mkisofs.8), in the SUNWfsman package (not a SunOS man page)

Name pkgadd – transfer software packages to the system

Synopsis

```
pkgadd [-nv] [-a admin] [-G] [-x proxy]
     [ [-M] -R root_path] [-r response] [-k keystore]
     [-P passwd] [-V fs_file]
     [-d device | -d datastream pkginst | all]
     [pkginst | -Y category [,category]...]

pkgadd -s [-d device | -d datastream pkginst | all]
     [pkginst | -Y category [,category]...]
```

Description `pkgadd` transfers the contents of a software package from the distribution medium or directory to install it onto the system. Used without the `-d` *device* source specifier, `pkgadd` looks in the default spool directory (`/var/spool/pkg`) for the package. Used with the `-s` option, it writes the package to a spool directory instead of installing it.

The `pkgadd` utility requires an amount of temporary space the size of the package that is being installed. `pkgadd` determines which temporary directory to use by checking for the existance of the `$TMPDIR` environment variable. If `$TMPDIR` is not defined, `pkgadd` uses `P_tmpdir` from `stdio.h`. `P_tmpdir` has a default of `/var/tmp/`.

Certain unbundled and third-party packages are no longer entirely compatible with the latest version of `pkgadd`. These packages require user interaction throughout the installation and not just at the very beginning, or require that their request scripts be run as the root user.

To install these older packages (released prior to Solaris 2.4), set the following environment variable: `NONABI_SCRIPTS=TRUE`

As long as this environment variable is set, `pkgadd` permits keyboard interaction throughout the installation and package request scripts are run as `root`.

If you have package request scripts that require running as user `root` (instead of `noaccess` [the default] or user `install`), use the `rscript_alt` parameter in the `admin(4)` file to make an appropriate selection. See `admin(4)`.

Note that, in Solaris 8 and Solaris 9, the default user when running a request script was either `root` or `nobody`, depending on the operating system's patch level. In the current release, the default user is `noaccess`.

When running `pkgadd` in the global zone (see `zones(5)`), a package that contains a request script (see `pkgask(1M)`) is added only to the global zone. The package is not propagated to any current or yet-to-be-installed non-global zone. This behavior mimics the effect of the `-G` option, described below.

Package commands are `largefile(5)`-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, `pkgadd`, `pkgtrans(1)` and other package commands can process a datastream of up to 4 GB.

The `-d`, `-Y`, and *pkginst* arguments shown in the SYNOPSIS are described under OPERANDS, following OPTIONS.

Options The supported options are described as follows. The `-d` *device* source specifier is described under OPERANDS, below.

`-a` *admin*
Define an installation administration file, *admin*, to be used in place of the default administration file. The token `none` overrides the use of any *admin* file, and thus forces interaction with the user. Unless a full path name is given, `pkgadd` first looks in the current working directory for the administration file. If the specified administration file is not in the current working directory, `pkgadd` looks in the `/var/sadm/install/admin` directory for the administration file.

`-G`
Add package(s) in the current zone only. When used in the global zone, the package is added to the global zone only and is not propagated to any existing or yet-to-be-created non-global zone. When used in a non-global zone, the package(s) are added to the non-global zone only.

This option causes package installation to fail if, in the `pkginfo` file for a package, `SUNW_PKG_ALLZONES` is set to true. See `pkginfo(4)`.

`-k` *keystore*
Use *keystore* as the location from which to get trusted certificate authority certificates when verifying digital signatures found in packages. If no keystore is specified, then the default keystore locations are searched for valid trusted certificates. See `KEYSTORE LOCATIONS` for more information.

`-M`
Instruct `pkgadd` not to use the `$`*root_path*`/etc/vfstab` file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.

`-n`
Installation occurs in non-interactive mode. Suppress output of the list of installed files. The default mode is interactive.

`-P` *passwd*
Password to use to decrypt keystore specified with `-k`, if required. See `PASS PHRASE ARGUMENTS` for more information about the format of this option's argument.

`-r` *response*
Identify a file or directory which contains output from a previous `pkgask(1M)` session. This file supplies the interaction responses that would be requested by the package in interactive mode. *response* must be a full pathname.

`-R` *root_path*
Define the full path name of a directory to use as the *root_path*. All files, including package system information files, are relocated to a directory tree starting in the specified *root_path*. The *root_path* may be specified when installing to a client from a server (for example, `/export/root/client1`).

Note – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.

`-s` *spool*
Write the package into the directory *spool* instead of installing it.

`-v`
Trace all of the scripts that get executed by `pkgadd`, located in the *pkginst*`/install` directory. This option is used for debugging the procedural and non-procedural scripts.

`-V` *fs_file*
Specify an alternative *fs_file* to map the client's file systems. For example, used in situations where the $*root_path*`/etc/vfstab` file is non-existent or unreliable.

`-x` *proxy*
Specify a HTTP[S] proxy to use when downloading packages The format of proxy is *host*:*port*, where *host* is the hostname of the HTTP[S] proxy, and *port* is the port number associated with the proxy. This switch overrides all other methods of specifying a proxy. See ENVIRONMENT VARIABLES for more information on alternate methods of specifying a default proxy.

When executed without options or operands, `pkgadd` uses `/var/spool/pkg` (the default spool directory).

Operands The following operands are supported:

Sources By default, pkgadd looks in the `/var/spool/pkg` directory when searching for instances of a package to install or spool. Optionally, the source for the package instances to be installed or spooled can be specified using:

`-d` *device*
`-d` *datastream pkgname*,... | `all`
Install or copy a package from *device*. *device* can be any of the following:

- A full path name to a directory or the identifiers for tape, floppy disk, or removable disk (for example, `/var/tmp` or `/floppy/`*floppy_name*).
- A device alias (for example, `/floppy/floppy0`).
- A datastream created by `pkgtrans` (see `pkgtrans(1)`).
- A URL pointing to a datastream created by `pkgtrans`. The supported Universal Resource Identifiers (URIs) are `http:` and `https:`.

The second form of the `-d` specifier, above, indicates the syntax you use when specifying a datastream. In this case you must specify either a comma-separated list of package names or the keyword `all`.

Instances By default, `pkgadd` searches the specified source, and presents an interactive menu allowing the user to select which package instances found on the source are to be installed. As an alternative, the package instances to be installed can be specified using:

pkginst
The package instance or list of instances to be installed. The token `all` may be used to refer to all packages available on the source medium. The format *pkginst*`.*` can be used to indicate all instances of a package.

The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, the asterisk must be surrounded by single quotes (`'`) or preceded by a backslash (\).

`-Y` *category*[,*category*...]
Install packages based on the value of the `CATEGORY` parameter stored in the package's `pkginfo(4)` file. All packages on the source medium whose `CATEGORY` matches one of the specified categories will be selected for installation or spooling.

Keystore Locations Package and patch tools such as `pkgadd` or `patchadd` use a set of trusted certificates to perform signature validation on any signatures found within the packages or patches. If there are no signatures included in the packages or patches then signature validation is skipped. The certificates can come from a variety of locations. If `-k` *keystore* is specified, and *keystore* is a directory, then *keystore* is assumed to be the base directory of the certificates to be used. If *keystore* is a file, then the file itself is assumed to have all required keys and certificates. When `-k` is not specified, then `/var/sadm/security` is used as the base directory.

Within the specified base directory, the store locations to be searched are different based on the application doing the searching and the type of store being searched for. The following directories are searched in the specified order:

1. <*store_dir*>/<*app_name*>/<*store_type*>
2. <*store_dir*>/<*store_type*>

Where <*store_dir*> is the directory specified by `-k`, <*app_name*> is the name of the application doing the searching, and <*store_type*> is one of `keystore` (for private keys), `certstore` (for untrusted public key certificates), or `truststore` (for trusted certificate authority certificates).

For example, when `pkgadd` is run with `-k /export/certs`, then the following locations are successively searched to find the trust store:

1. /export/certs/pkgadd/truststore
2. /export/certs/truststore

This searching order enables administrators to have a single location for most applications, and special certificate locations for certain applications.

Keystore And Certificate Formats

The packaging and patching utilities, such as `pkgtrans` and `patchadd`, require access to a set of keys and certificates in order to sign, and optionally verify, packages and patches.

The keystore files found by following the search pattern specified in `KEYSTORE LOCATIONS` must each be a self-contained PKCS#12-format file.

When signing a package with `pkgtrans`, if a `certstore` has more than one public key certificate, then each public key must have a `friendlyName` attribute in order to be identifiable and selectable with the `-a` option when signing packages or patches. In addition, the public key certificate selected with `-a` and found in the `certstore` must have an associated private key in the keystore.

Several browsers and utilities can be used to export and import certificates and keys into a PKCS#12 keystore. For example, a trusted certificate can be exported from Mozilla, and then imported into a PKCS#12 keystore for use with `pkgadd` with the OpenSSL Toolkit.

Pass Phrase Arguments

`pkgtrans` and `pkgadd` accept password arguments, typically using `-p` to specify the password. These allow the password to be obtained from a variety of sources. Both of these options take a single argument whose format is described below. If no password argument is given and a password is required then the user is prompted to enter one: this will typically be read from the current terminal with echoing turned off.

`pass:`*password*
: The actual password is *password*. Because the password is visible to utilities such as `ps` this form should only be used where security is not important.

`env:`*var*
: Obtain the password from the environment variable *var*. Because the environment of other processes is visible on certain platforms this option should be used with caution.

`file:`*pathname*
: The first line contained within *pathname* is the password. *pathname* need not refer to a regular file: it could, for example, refer to a device or named pipe. For example, to read the password from standard input, use `file:/dev/stdin`.

`console`
: Read the password from `/dev/tty`.

Examples

EXAMPLE 1 Installing a Package from a Solaris DVD

The following example installs a package from a Solaris DVD. You are prompted for the name of the package you want to install.

```
example# pkgadd -d /cdrom/cdrom0/s0/Solaris_10/Product
```

EXAMPLE 2 Installing a Set of Packages from a Datastream

The example command shown below installs all of the packages in the datastream specified by the `-d` source specifier. Prior to this command, this datastream must have been created with the `pkgtrans(1)` command.

EXAMPLE 2 Installing a Set of Packages from a Datastream *(Continued)*

```
example# pkgadd -d /var/tmp/datastream all
```

The keyword `all` specifies that all of the packages found in the designated datastream will be installed.

Exit Status

`0`
Successful completion

`1`
Fatal error.

`2`
Warning.

`3`
Interruption.

`4`
Administration.

`5`
Administration. Interaction is required. Do not use `pkgadd -n`.

`10`
Reboot after installation of all packages.

`20`
Reboot after installation of this package.

Environment Variables

`HTTPPROXY`
Specifies an HTTP proxy host. Overrides administration file setting, and `http_proxy` environment variable.

`HTTPPROXYPORT`
Specifies the port to use when contacting the host specified by `HTTPPROXY`. Ignored if `HTTPPROXY` is not set.

`http_proxy`
URL format for specifying proxy host and port. Overrides administration file setting.

Files

`/var/sadm/install/logs/`
Location where `pkgadd` logs an instance of software installation.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpkgcmdsu

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Evolving

Application Packaging Developer's Guide

`http://www.openssl.org`

Notes When transferring a package to a spool directory, the `-r`, `-n`, and `-a` options cannot be used.

The `-r` option can be used to indicate a directory name as well as a filename. The directory can contain numerous response files, each sharing the name of the package with which it should be associated. This would be used, for example, when adding multiple interactive packages with one invocation of `pkgadd`. In this situation, each package would need a response file. If you create response files with the same name as the package (for example, `pkinst1` and `pkinst2`), then name the directory in which these files reside after the `-r`.

The `-n` option causes the installation to halt if any interaction is needed to complete it.

If the default *admin* file is too restrictive, the administration file may need to be modified to allow for total non-interaction during a package installation. See admin(4) for details.

If a package stream is specified with `-d`, and a digital signature is found in that stream, the default behavior is to attempt to validate the certificate and signature found. This behavior can be overridden with `admin` file settings. See admin(4) for more information.

Name pkgadm – manage packaging and patching system

Synopsis

```
pkgadm addcert [-ty] [-a app] [-k keystore] [-e keyfile]
     [-f format] [-n name] [-P passarg]
     [-p import_passarg] [-R rootpath] certfile

pkgadm removecert [-a app] [-k keystore] -n name
     [-P passarg] [-R rootpath]

pkgadm listcert [-a app] [-f format] [-k keystore] -n name
     [-P passarg] [-o outfile] [-R rootpath]

pkgadm dbstatus [-R rootpath]

pkgadm sync [-R rootpath] [-q]

pkgadm -V

pkgadm -?
```

Description The `pkgadm` utility is used for managing the packaging and patching system. It has several subcommands that perform various operations relating to packaging. The `pkgadm` command includes subcommands for managing certificates and keys used.

Managing Keys and Certificates

`pkgadm` maintains the packaging-system-wide keystore in `/var/sadm/security`, and individual user's certificates in `~/.pkg/security`. The following subcommands operate on the package keystore database:

`addcert`
: Add (import) a certificate into the database, with optional trust. Once added, trusted certificates can be used to verify signed packages and patches. Non-trusted user certificates and their associated keys can be used to sign packages and patches. Added user certificates are *not* used to build certificate chains during certificate verification.

`removecert`
: Removes a user certificate/private key pair, or a trusted certificate authority certificate from the keystore. Once removed, the certificate and keys cannot be used.

`listcert`
: Print details of one or more certificates in the keystore.

`sync`
: Writes the contents file and rolls the contents log file. With use of the `-q` option, forces the contents file server to quit.

Internal Install Database

The Solaris operating system relies upon enhanced System V revision 4 (SVr4) packages as the basis for its software installation and revision management. The package maintenance software stores information about installed packages in an internal database. The `pkgadm` subcomand `dbstatus` is used to determine how the package internal database is implemented. The `dbstatus` command returns a string that indicates the type of internal database in use. In

the current implementation, the `dbstatus` command always returns the string `text`, which indicates that the `contents(4)` package database is inuse. Future releases of Solaris might supply alternative database implementations.

Options The following options are supported:

`-a` *app*
If this option is used, then the command only affects the keystore associated with a particular application. Otherwise, the global keystore is affected.

`-e` *keyfile*
When adding a non-trusted certificate/key combination, this option can be used to specify the file that contains the private key. If this option is not used, the private key must be in the same file as the certificate being added.

`-f` *format*
When adding certificates, this specifies the format to expect certificates and private keys in. Possible values when adding are:

`pem`
Certificate and any private key uses PEM encoding.

`der`
Certificate and any private key uses DER encoding.

When printing certificates, this specifies the output format used when printing. Acceptable values for format are:

`pem`
Output each certificate using PEM encoding.

`der`
Output each certificate using DER encoding.

`text`
Output each certificate in human-readable format.

`-k` *keystore*
Overrides the default location used when accessing the keystore.

`-n` *name*
Identifies the entity in the store on which you want to operate. When adding a user certificate, or removing certificates, this name is required. The name is associated with the certificate/key combination, and when adding, can be used later to reference the entity. When printing certificates, if no alias is supplied, then all keystore entities are printed.

`-o` *outfile*
Output the result of the command to *outfile*. Only used when examining (printing) certificates from the key store. Standard out is the default.

`-P` *passarg*
Password retrieval method to use to decrypt keystore specified with `-k`, if required. See `PASS PHRASE ARGUMENTS` in `pkgadd(1M)` for more information about the format of this option's argument. `console` is the default.

`-p` *import_passarg*
This option's argument is identical to `-P`, but is used for supplying the password used to decrypt the certificate and/or private key being added. `console` is the default.

`-q`
(Applies to `sync` subcommand.) Shuts down the contents file cache daemon.

`-R` *rootpath*
Defines the full name of a directory to use as the root (`/`) path. The default user location of the certificate operations is `${HOME}/.pkg`. If the `-R` option is supplied, the certificates and keys will be stored under <*altroot*>`/var/sadm/security`. Note that this operation fails if the user does not have sufficient permissions to access this directory. The `listcert` command requires read permission, while `addcert` and `removecert` require both read and write permission.

Note – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.

`-t`
Indicates the certificate being added is a trusted CA certificate. The details of the certificate (including the Subject Name, Validity Dates, and Fingerprints) are printed and the user is asked to verify the data. This verification step can be skipped with `-y`. When importing a trusted certificate, a private key should not be supplied, and will be rejected if supplied. Once a certificate is trusted, it can be used as a trust anchor when verifying future untrusted certificates.

`-V`
Print version associated with packaging tools.

`-y`
When adding a trusted certificate, the details of the certificate (Subject name, Issuer name, Validity dates, Fingerprints) are shown to the user and the user is asked to verify the correctness before proceeding. With `-y`, this additional verification step is skipped.

`-?`
Print help message.

Operands The following operand is supported:

`certfile`
File containing the certificate and optional private key, used when adding a trust anchor or certificate/key combination. Certificates must be encoded using PEM or binary DER.

Keystore Aliases All keystore entries (user cert/key and trusted certificate entries) are accessed via unique aliases. Aliases are case-sensitive.

An alias is specified when you add an entity to a keystore using the `addcert` or `trustcert` subcommand. If an alias is not supplied for a trust anchor, the trust anchor's Common Name is used as the alias. An alias is required when adding a signing certificate or chain certificate. Subsequent `pkgcert` or other package tool commands must use this same alias to refer to the entity.

Keystore Passwords See the `pkgadd(1M)` man page for a description of the passwords supplied to the `pkgadm` utility.

Examples

EXAMPLE 1 Adding a Trust Anchor

The following example adds a well-known and trusted certificate to be used when verifying signatures on packages.

```
example% pkgadm addcert -t /tmp/certfile.pem
```

EXAMPLE 2 Adding a Signing Certificate

The following example adds a signing certificate and associated private key, each of which is in a separate file, which can then be used to sign packages.

```
example% pkgadm addcert -a pkgtrans -e /tmp/keyfile.pem \
/tmp/certfile.pem
```

EXAMPLE 3 Printing Certificates

The following example prints all certificates in the root keystore.

```
example% pkgadm listcert
```

Exit Status

`0`
successful completion

`non-zero`
fatal error

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpkgcmdsu
Interface Stability	Evolving

See Also `pkginfo(1)`, `pkgmk(1)`, `pkgparam(1)`, `pkgproto(1)`, `pkgtrans(1)`, `svcs(1)`, `installf(1M)`, `pkgadd(1M)`, `pkgask(1M)`, `pkgrm(1M)`, `removef(1M)`, `svcadm(1M)`, `admin(4)`, `contents(4)`, `exec_attr(4)`, `pkginfo(4)`, `attributes(5)`, `rbac(5)`, `smf(5)`

Application Packaging Developer's Guide

Notes The service for `pkgadm` is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/system/pkgserv
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

Name pkgask – stores answers to a request script

Synopsis

```
pkgask [-d device] [-R root_path] -r response pkginst...
```

Description `pkgask` allows the administrator to store answers to an interactive package (one with a `request` script, that is, a user-created file that must be named `request`). Invoking this command generates a response file that is then used as input at installation time. The use of this response file prevents any interaction from occurring during installation since the file already contains all of the information the package needs.

Options The following options are supported

`-d` *device* Run the request script for a package on *device*. *device* can be a directory pathname or the identifiers for tape, floppy disk or removable disk (for example, `/var/tmp`, `/dev/diskette`, and `/dev/dsk/c1d0s0`). The default device is the installation spool directory.

`-R` *root_path* Define the full path name of a directory to use as the *root_path*. All files, including package system information files, are relocated to a directory tree starting in the specified *root_path*.

Note – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.

`-r` *response* Identify a file or directory which should be created to contain the responses to interaction with the package. The name must be a full pathname. The file, or directory of files, can later be used as input to the `pkgadd(1M)` command.

Operands The following operands are supported:

pkginst Specify the package instance, or list of instances for which `request` scripts will be created. The token `all` may be used to refer to all packages available on the source medium.

Exit Status

`0` Successful completion.

`>0` An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `pkginfo(1)`, `pkgmk(1)`, `pkgparam(1)`, `pkgproto(1)`, `pkgtrans(1)`, `installf(1M)`, `pkgadd(1M)`, `pkgchk(1M)`, `pkgrm(1M)`, `removef(1M)`, `admin(4)`,`attributes(5)`

Application Packaging Developer's Guide

Notes The `-r` option can be used to indicate a directory name as well as a filename. The directory name is used to create numerous response files, each sharing the name of the package with which it should be associated. This would be used, for example, when you will be adding multiple interactive packages with one invocation of `pkgadd(1M)`. Each package would need a response file. To create multiple response files with the same name as the package instance, name the directory in which the files should be created and supply multiple instance names with the `pkgask` command. When installing the packages, you will be able to identify this directory to the `pkgadd(1M)` command.

If the default `admin` file is too restrictive, the administration file may need to be modified to allow for total non-interaction during a package installation. See`admin(4)` for details.

Name pkgchk – check package installation accuracy

Synopsis

```
pkgchk [-l | -acfnqvx] [-i file | -]
     [-p path... | -P partial-path...] [-R root_path]
     [ [-m pkgmap [-e envfile]] | pkginst... | -Y category,category...]

pkgchk -d device [-l | -fv] [-i file | -] [-M] [-p path]...
     [-V fs_file]
     [pkginst... | -Y category[,category...]]
```

Description `pkgchk` checks the accuracy of installed files or, by using the `-l` option, displays information about package files. `pkgchk` checks the integrity of directory structures and files. Discrepancies are written to standard error along with a detailed explanation of the problem.

The first synopsis defined above is used to list or check the contents and/or attributes of objects that are currently installed on the system, or in the indicated `pkgmap`. Package names may be listed on the command line, or by default, the entire contents of a machine will be checked.

The second synopsis is used to list or check the contents of a package which has been spooled on the specified device, but not installed. Note that attributes cannot be checked for spooled packages.

Options The following options are supported:

`-a`
Audit the file attributes only and do not check file contents. Default is to check both.

`-c`
Audit the file contents only and do not check file attributes. Default is to check both.

`-d` *device*
Specify the device on which a spooled package resides. *device* can be a directory path name or the identifiers for tape, floppy disk, or removable disk (for example, `/var/tmp` or `/dev/diskette`).

`-e` *envfile*
Request that the package information file named as *envfile* be used to resolve parameters noted in the specified `pkgmap` file.

`-f`
Correct file attributes if possible. If used with the `-x` option, this option removes hidden files. When `pkgchk` is invoked with this option, it creates directories, named pipes, links, and special devices if they do not already exist. If the `-d` option calls out an uninstalled package, the `-f` option will only take effect if the package is in directory (not stream) format. All file attributes will be set to agree with the entries in the `pkgmap` file except that setuid, setgid, and sticky bits will not be set in the mode.

`-i` *file* | –
Read a list of path names from *file* or from stdin (–) and compare this list against the installation software database or the indicated `pkgmap` file. Path names that are not contained in *file* or stdin are not checked.

`-l`
List information on the selected files that make up a package. This option is not compatible with the `-a`, `-c`, `-f`, `-g`, and `-v` options.

`-m pkgmap`
Check the package against the package map file, `pkgmap`.

`-M`
Instruct `pkgchk` not to use the `$`*root_path*`/etc/vfstab` file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.

`-n`
Do not check volatile or editable files' contents. This should be used for most post-installation checking.

`-p` *path*
Check the accuracy only of the path name or path names listed. *path* can be one or more path names separated by commas (or by whitespace, if the list is quoted).

To specify a *path* that includes a comma, you must use the `-i` option, described above. See EXAMPLES.

`-P` *partial-path*
Check the accuracy of only the partial path name or path names listed. *partial-path* can be one or more partial path names separated by commas (or by whitespace, if the list is quoted). This option can be used instead of `-p` and is not compatible with the other option. This option matches any path name that contains the string contained in the partial path. See the note about paths that contain commas in the description of `-p`.

`-q`
Quiet mode. Do not give messages about missing files.

`-R` *root_path*
Define the full name of a directory to use as the *root_path*. All files, including package system information files, are relocated to a directory tree starting in the specified *root_path*. The *root_path* may be specified when installing to a client from a server (for example, `/export/root/client1`).

Note – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.

`-v`
Verbose mode. Files are listed as processed.

`-V` *fs_file*
Specify an alternative *fs_file* to map the client's file systems. For example, used in situations where the `$`*root_path*`/etc/vfstab` file is non-existent or unreliable.

`-x`
Search exclusive directories, looking for files which exist that are not in the installation software database or the indicated `pkgmap` file.

`-Y` *category*
Check packages based on the value of the `CATEGORY` parameter stored in the installed or spooled package's `pkginfo(4)` file.

Operands *pkginst*
The package instance or instances to be checked. The format *pkginst*`.*` can be used to check all instances of a package. The default is to display all information about all installed packages.

The asterisk character (`*`) is a special character to some shells and may need to be escaped. In the C-Shell, an asterisk must be surrounded by single quotes (`'`) or preceded by a backslash (\);

partial-path
A portion of a path, such as a file or directory name.

Examples **EXAMPLE 1** Using `pkgchk` for Displaying Package Installation Information

The following example displays package installation information for `/usr/bin/ls`:

```
example% pkgchk -l -p /usr/bin/ls
```

EXAMPLE 2 Checking on Java Font Properties

The following example displays package installation information for all Java font properties installed on the system.

```
example% pkgchk -l -P font.properties
```

EXAMPLE 3 Specifying a Path That Contains a Comma

Assume you want to specify the path:

```
/platform/SUNW,Netra-T12/lib
```

List this path in a file. Here is one way in which you can do that:

```
example% echo "/platform/SUNW,Netra-T12/lib" > /tmp/p
```

You can then enter:

EXAMPLE 3 Specifying a Path That Contains a Comma *(Continued)*

```
example% pkgchk -i /tmp/p -l
Pathname: /platform/SUNW,Netra-T12/lib
Type: directory
Expected mode: 0755
Expected owner: root
Expected group: bin
Referenced by the following packages:
        SUNWcar
Current status: installed
```

Exit Status

`0`
Successful completion.

`>0`
An error occurred.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also

`pkginfo(1)`, `pkgtrans(1)`, `pkgadd(1M)`, `pkgask(1M)`, `pkgrm(1M)`, `pkginfo(4)`, `attributes(5)`, `largefile(5)`

Application Packaging Developer's Guide

Notes

Package commands are `largefile(5)`-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, `pkgadd(1M)`, `pkgtrans(1)` and other package commands can process a datastream of up to 4 GB.

Name pkgcond – determine type and capability of target

Synopsis `/usr/bin/pkgcond [-nv]` *condition*

Description The `pkgcond` command allows you to determine the type of target being operated on (global zone, non-global zone, diskless client, and so forth) and the capabilities available for that type of client (can add a driver, path is writable, and so forth). The `pkgcond` command is intended to be invoked from package and patch scripts, but can also be used in situations that mimic the context of these scripts. See `NOTES` for further guidance.

`pkgcond` has one mandatory argument, a condition. The command tests whether the condition is true for the specified path. The condition can be one of the following:

- `can_add_driver` [*path*]
- `can_remove_driver` [*path*]
- `can_update_driver` [*path*]
- `is_alternative_root` [*path*]
- `is_boot_environment` [*path*]
- `is_diskless_client` [*path*]
- `is_global_zone` [*path*]
- `is_mounted_miniroot` [*path*]
- `is_netinstall_image` [*path*]
- `is_nonglobal_zone` [*path*]
- `is_path_writable` *path*
- `is_running_system` [*path*]
- `is_sparse_root_nonglobal_zone` [*path*]
- `is_what` [*path*]
- `is_whole_root_nonglobal_zone` [*path*]

The *path* argument usually denotes the root of the global zone or non-global zone, or alternate root. If path is optional and not specified, the default is `/`.

The behavior of the `is_what` condition is somewhat special, because it displays results of all other conditions to standard output.

Options The following options are supported:

`-n`
Negate return status (`0` becomes `1` and `1` becomes `0`). It negates results in the case of `is_what` condition.

`-v`
Verbose mode. Displays detailed data about intermediate checks performed.

Examples **EXAMPLE 1** Listing All Available Information

The following command lists all available information about the current running system, in a user-friendly way.

```
example# pkgcond -n is_what
```

EXAMPLE 2 Determining if Target is an Alternate Root

The following command determines whether an alternate boot environment exists under `/altroot_mount`.

```
example# pkgcond is_alternative_root /altroot_mount
```

Exit Status

`0`
Condition is true unless `-n` was specified.

`1`
Condition is false unless `-n` was specified.

`2`
Command line usage error.

`3`
Command failed to perform the test due to a fatal error.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs
Interface Stability	Uncommitted

See Also

`pkgtrans(1)`, `pkgadd(1M)`, `pkgask(1M)`, `pkgchk(1M)`, `pkgrm(1M)`, `pkginfo(4)`, `attributes(5)`

Notes

Supported usage of `pkgcond` is subject to the following constraints:

1. Do not use `pkgcond` outside of the Solaris marketing release in which it is provided (for example, do not use Solaris 10 `pkgcond` against a Solaris 9 target).
2. Restrict use of the optional path argument according to the following rules:
   - The command `pkgcond` *condition* `$ROOTDIR` can be used in patch level scripts.
   - The command `pkgcond` *condition* `$PKG_INSTALL_ROOT` can be used in package level scripts.
   - A command of the form `pkgcond` *condition without* the optional path argument can be used in any context.

Use of `pkgcond` with an arbitrary path argument is *not* recommended or supported, as the results returned might not be accurate.

Name pkgrm – remove a package from the system

Synopsis

```
pkgrm [-nv] [-a admin] [ [-A | -M] -R root_path]
     [-V fs_file]
     [pkginst... | -Y category[,category...]]

pkgrm -s spool
     [pkginst... | -Y category[,category...]]
```

Description `pkgrm` will remove a previously installed or partially installed package from the system. A check is made to determine if any other packages depend on the one being removed. If a dependency exists, the action taken is defined in the `admin` file.

The default state for the command is in interactive mode, meaning that prompt messages are given during processing to allow the administrator to confirm the actions being taken. Non-interactive mode can be requested with the `-n` option.

The `-s` option can be used to specify the directory from which spooled packages should be removed.

Certain unbundled and third-party packages are no longer entirely compatible with the latest version of `pkgrm`. These packages require user interaction throughout the removal and not just at the very beginning.

To remove these older packages (released prior to Solaris 2.4), set the following environment variable:`NONABI_SCRIPTS=TRUE` `pkgrm` permits keyboard interaction throughout the removal as long as this environment variable is set.

Options The following options are supported:

`-a` *admin*
: Use the installation administration file, `admin`, in place of the default `admin` file. `pkgrm` first looks in the current working directory for the administration file. If the specified administration file is not in the current working directory, `pkgrm` looks in the `/var/sadm/install/admin` directory for the administration file.

`-A`
: Remove the package files from the client's file system, absolutely. If a file is shared with other packages, the default behavior is to not remove the file from the client's file system.

`-M`
: Instruct `pkgrm` not to use the $*root_path*`/etc/vfstab` file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.

`-n`
: Non-interactive mode. If there is a need for interaction, the command will exit.

Use of this option requires that at least one package instance be named upon invocation of the command. Certain conditions must exist for a package to be removed non-interactively or a non-restrictive `admin` file needs to be used.

`-R` *root_path*
Defines the full path name of a directory to use as the *root_path*. All files, including package system information files, are relocated to a directory tree starting in the specified *root_path*.

Note – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.

`-s` *spool*
Remove the specified package(s) from the directory *spool*. The default directory for spooled packages is `/var/sadm/pkg`.

`-v`
Trace all of the scripts that get executed by `pkgrm`, located in the *pkginst*`/install` directory. This option is used for debugging the procedural and non-procedural scripts.

`-V` *fs_file*
Specify an alternative *fs_file* to map the client's file systems. Used in situations where the $*root_path*`/etc/vfstab` file is non-existent or unreliable.

`-Y` *category*
Remove packages based on the value of the `CATEGORY` parameter stored in the installed or spooled package's `pkginfo(4)` file. No package with the `CATEGORY` value of `system` can removed from the file system with this option.

Operands The following operand is supported:

pkginst
Specifies the package to be removed. The format *pkginst*`.*` can be used to remove all instances of a package.

The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, "*" must be surrounded by single quotes (') or preceded by a backslash (\).

Examples **EXAMPLE 1** Removing All Instances of `SUNWjunk` from `client1`

The following example removes all instances of `SUNWjunk` from `client1`:

```
example% pkgrm -R /export/root/client1 SUNWjunk*
```

Note the caveat on the use of the `-R` option in the description of that option, above.

Exit Status The following exit values are returned:

`0`
Successful completion.

`1`
Fatal error.

`2`
Warning.

`3`
Interruption.

`4`
Administration.

`10`
Reboot after removal of all packages.

`20`
Reboot after removal of this package.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `pkginfo(1)`, `pkgmk(1)`, `pkgparam(1)`, `pkgproto(1)`, `pkgtrans(1)`, `installf(1M)`, `pkgadd(1M)`, `pkgask(1M)`, `pkgchk(1M)`, `removef(1M)`, `admin(4)`, `pkginfo(4)`, `attributes(5)`, `largefile(5)`

Application Packaging Developer's Guide

Notes Package commands are `largefile(5)`-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, `pkgadd(1M)`, `pkgtrans(1)` and other package commands can process a datastream of up to 4 GB.

Name plockstat – report user-level lock statistics

Synopsis

```
plockstat [-vACHV] [-n count] [-s depth] [-e secs]
     [-x arg [=val]] command [arg]...

plockstat [-vACHV] [-n count] [-s depth] [-e secs]
     [-x arg [=val]] -p pid
```

Description The `plockstat` utility gathers and displays user-level locking statistics. By default, `plockstat` monitors all lock contention events, gathers frequency and timing data about those events, and displays the data in decreasing frequency order, so that the most common events appear first.

`plockstat` gathers data until the specified command completes or the process specified with the `-p` option completes.

`plockstat` relies on DTrace to instrument a running process or a command it invokes to trace events of interest. This imposes a small but measurable performance overhead on the processes being observed. Users must have the `dtrace_proc` privilege and have permission to observe a particular process with `plockstat`. Refer to the *Solaris Dynamic Tracing Guide* for more information about DTrace security features.

Options The following options are supported:

`-A`	Watch all lock events. This option is equivalent to `-CH`.
`-C`	Watch contention events.
`-H`	Watch hold events.
`-e` *secs*	Exit after the number of seconds specified have elapsed.
`-n` *count*	Display only the specified number of entries for each output category.
`-s` *depth*	Record a stack trace rather than just the calling function.
`-p` *pid*	Specify a process ID from which `plockstat` is to gather data.
`-v`	Print out a message to indicate that tracing has started.
`-x` *arg*[=*val*]	Enable or modify a DTrace runtime option or D compiler option. The list of options is found in the *Solaris Dynamic Tracing Guide*. Boolean options are enabled by specifying their name. Options with values are set by separating the option name and value with an equals sign (=).
`-V`	Print the Dtrace commands used to gather the data. The output can then be used directly with the `dtrace(1M)` command.

Operands The following operands are supported:

arg	A string to be passed as an argument to *command*.
command	The name of a utility to be invoked.

count A positive integer value.

pid A process identifier for a process to be monitored.

secs Duration specified as a positive integer number of seconds.

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdtrc
Interface Stability	See below.

The command-line syntax is Evolving. The human-readable output is Unstable.

Solaris Dynamic Tracing Guide

Name pmadm – port monitor administration

Synopsis

```
pmadm -a [-p pmtag | -t type] -s svctag -i id -m pmspecific -v ver
     [-f xu]
     [-y comment] [-z  script]

pmadm -r -p pmtag -s svctag

pmadm -e -p pmtag -s svctag

pmadm -d -p pmtag -s svctag

pmadm -l [-t type | -p pmtag] [-s svctag]

pmadm -L [-t type | -p pmtag] [-s svctag]

pmadm -g -p pmtag -s svctag [-z script]

pmadm -g -s svctag -t type -z script
```

Description `pmadm` is the administrative command for the lower level of the Service Access Facility hierarchy, that is, for service administration. A port may have only one service associated with it although the same service may be available through more than one port. In order to uniquely identify an instance of a service, the `pmadm` command must identify both the port monitor or port monitors through which the service is available (`-p` or `-t`) and the service (`-s`). See Options.

`pmadm` performs the following functions:

- adds or removes a service
- enables or disables a service
- installs or replaces a per-service configuration script
- prints requested service information

Any user on the system may invoke `pmadm` to request service status (`-l` or `-L`) or to print per-service configuration scripts (`-g` without the `-z` option). `pmadm` with other options may be executed only by a privileged user.

Options The following options are supported:

`-a` Add a service. `pmadm` adds an entry for the new service to the port monitor's administrative file. Because of the complexity of the options and arguments that follow the `-a` option, it may be convenient to use a command script or the menu system to add services.

`-d` Disable a service. Add `x` to the flag field in the entry for the service *svctag* in the port monitor's administrative file. This is the entry used by port monitor *pmtag*. See the `-f` option, below, for a description of the flags available.

`-e` Enable a service. Remove `x` from the flag field in the entry for the service *svctag* in the port monitor administrative file. This is the entry used by port monitor *pmtag*. See the `-f` option, below, for a description of the flags available.

`-f xu` The `-f` option specifies one or both of the following two flags which are then included in the flag field of the entry for the new service in the port monitor's administrative file. If the `-f` option is not included, no flags are set and the default conditions prevail. By default, a new service is enabled and no `utmpx` entry is created for it. An `-f` option without a following argument is illegal.

- `x` Do not enable the service *svctag* available through port monitor *pmtag*.
- `u` Create a `utmpx` entry for service *svctag* available through port monitor *pmtag*.

`-g` Print, install, or replace a per-service configuration script. The `-g` option with a `-p` option and a `-s` option prints the per-service configuration script for service *svctag* available through port monitor *pmtag*. The `-g` option with a `-p` option, a `-s` option, and a `-z` option installs the per-service configuration script contained in the file `script` as the per-service configuration script for service *svctag* available through port monitor *pmtag*. The `-g` option with a `- s` option, a `-t` option, and a `-z` option installs the file `script` as the per-service configuration script for service *svctag* available through any port monitor of type `type`. Other combinations of options with `-g` are invalid.

`-i` *id* `id` is the identity that is to be assigned to service *svctag* when it is started. `id` must be an entry in `/etc/passwd`.

`-l` The `-l` option requests service information. Used by itself and with the options described below, it provides a filter for extracting information in several different groupings.

`-l`	By itself, the `-l` option lists all services on the system.
`-l -p` *pmtag*	Lists all services available through port monitor *pmtag*.
`-l -s` *svctag*	Lists all services with tag *svctag*.
`-l -p` *pmtag*`-s`*svctag*	Lists service *svctag*.
`-l -t` *type*	Lists all services available through port monitors of type `type`.
`-l -t` *type*`-s`*svctag*	Lists all services with tag *svctag* available through a port monitor of type `type`.

Other combinations of options with `-l` are invalid.

`-L` The `-L` option is identical to the `-l` option except that output is printed in a condensed format.

`-m` *pmspecific* *pmspecific* is the port monitor-specific portion of the port monitor administrative file entry for the service.

`-p` *pmtag* Specifies the tag associated with the port monitor through which a service (specified as `-s` *svctag*) is available.

`-r` Remove a service. When `pmadm` removes a service, the entry for the service is removed from the port monitor's administrative file.

`-s` *svctag* Specifies the service tag associated with a given service. The service tag is assigned by the system administrator and is part of the entry for the service in the port monitor's administrative file.

`-t` *type* Specifies the port monitor type.

`-v` *ver* Specifies the version number of the port monitor administrative file. The version number may be given as

`-v 'pmspec -V`

where *pmspec* is the special administrative command for port monitor *pmtag*. This special command is `ttyadm` for `ttymon` and `nlsadmin` for `listen`. The version stamp of the port monitor is known by the command and is returned when *pmspec* is invoked with a `-V` option.

`-y` *comment* Associate *comment* with the service entry in the port monitor administrative file.

`-z` *script* Used with the `-g` option to specify the name of the file that contains the per-service configuration script. Modifying a configuration script is a three-step procedure. First a copy of the existing script is made (`-g` alone). Then the copy is edited. Finally, the copy is put in place over the existing script (`-g` with `-z`).

Options that request information write the requested information to the standard output. A request for information using the `-l` option prints column headers and aligns the information under the appropriate headings. In this format, a missing field is indicated by a hyphen. A request for information in the condensed format using the `-L` option prints the information in colon-separated fields; missing fields are indicated by two successive colons. # is the comment character.

Examples

EXAMPLE 1 Adding a Service to a Port Monitor with the Tag `pmtag`

The following command adds a service to a port monitor with tag `pmtag` and gives the service the tag `svctag`. The port monitor-specific information is generated by `specpm`. The service defined by `svctag` will be invoked with identity `root`.

```
pmadm -a -p pmtag -s svctag -i root -m ‘specpm -a arg1 -b arg2‘-v ‘specpm -V‘
```

EXAMPLE 2 Adding a Service with Service Tab `svctag`

The following command adds a service with service tag `svctag`, identity `guest`, and port monitor-specific information generated by `specpm` to all port monitors of type `type`:

```
pmadm -a -s svctag -i guest -t type -m ‘specpm -a arg1 -b arg2‘-v ‘specpm -V‘
```

EXAMPLE 3 Removing a Service

The following command removes the service `svctag` from port monitor `pmtag`:

```
pmadm -r -p pmtag -s svctag
```

EXAMPLE 4 Enabling a Service

The following command enables the service `svctag` available through port monitor `pmtag`:

```
pmadm -e -p pmtag -s svctag
```

EXAMPLE 5 Disabling a Service

The following command disables the service `svctag` available through port monitor `pmtag`:

```
pmadm -d -p pmtag -s svctag
```

EXAMPLE 6 Listing Status Information

The following command lists status information for all services:

```
pmadm -l
```

EXAMPLE 7 Listing Status Information

The following command lists status information for all services available through the port monitor with tag `ports`:

```
pmadm -l -p ports
```

EXAMPLE 8 Listing Status Information in Condensed Format

The following command lists the status information for all services available through the port monitor with tag `ports` in condensed format:

```
pmadm -L -p ports
```

EXAMPLE 9 Listing Status Information for All Services

List status information for all services available through port monitors of type `listen`:

```
pmadm -l -t listen
```

EXAMPLE 10 Printing the per-service Configuration

The following command prints the per-service configuration script associated with the service `svctag` available through port monitor `pmtag`:

```
pmadm -g -p pmtag -s svctag
```

Exit Status

The following exit values are returned:

`0` Successful operation.

`>0` Operation failed.

Files

`/etc/saf/`*pmtag*`/_config`

`/etc/saf/`*pmtag*`/`*svctag*

`/var/saf/`*pmtag*`/*`

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

`sac(1M)`, `sacadm(1M)`, `doconfig(3NSL)`, `attributes(5)`

Name pmconfig – Configure the Power Management system

Synopsis

```
/usr/sbin/pmconfig [-r]
```

Description The `pmconfig` utility sets the Power Management and suspend-resume configuration. User has permission to change Power Management configuration using `pmconfig` only if he is allowed to do so according to `PMCHANGEPERM` keyword of `/etc/default/power`. User has permission to change the suspend-resume configuration using `pmconfig` only if he is allowed to do so according to the `CPRCHANGEPERM` keyword of `/etc/default/power`. See FILES section below for a description of the `PMCHANGEPERM` and `CPRCHANGEPERM` keywords of `/etc/default/power`.

Based on user permissions, `pmconfig` first resets the Power Management and/or suspend-resume state back to its default and then reads the new Power Management and/or suspend-resume configuration from `/etc/power.conf` and issues the commands to activiate the new configuration. The `pmconfig` utility is run at system boot. This utility can also be run from the command line after manual changes have been made to the `/etc/power.conf` file. For editing changes made to the `/etc/power.conf` file to take effect, users must run `pmconfig`.

The preferred interface for changing Power Management and suspend-resume configuration is `dtpower`(1M).

Options The following options are supported:

`-r` Reset Power Management and suspend-resume state to default and exit. User must have both Power Management and suspend-resume configuration permission for this option.

Exit Status The following exit values are returned:

`0` Upon successful completion

`>0` An error occurred

Files

`/etc/power.conf`	System Power Management configuration file
`/etc/default/power`	File that controls permissions for system's Power Management and suspend-resume features. The `PMCHANGEPERM` keyboard controls the Power Management configuration permissions, while the `CPRCHANGEPERM` keyword controls the suspend-resume configuration permissions.

Allowed values are:

`all`	Any user can change the configuration.
`-`	No one except super-user can change the configuration.

`<user1, user2,...>`	A user in this user list or a super-user can change the configuration. The user list is a space and/or comma (,) separated list. You must enclose the list in < and > characters.
`console-owner`	A user who owns the system console device node or a super-user can change the configuration.

The default values are `PMCHANGEPERM=console-owner` and `CPRCHANGEPERM=console-owner`.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpmu
Interface stability	Unstable

See Also `svcs(1)`, `powerd(1M)`, `power.conf(4)`, `svcadm(1M)`, `attributes(5)`, `smf(5)`, `cpr(7)`, `pm(7D)`

Using Power Management

Notes The `pmconfig` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/system/power:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

Diagnostics If the program cannot open the configuration file, it prints an error message to standard error. If the program encounters a syntax error in the configuration file, it prints an error message and the line number of the error in the configuration file. It then skips the rest of the information on that line and processes the next line. Any configuration information already processed on the line containing the error is used. If user does not have permission to change Power Management and/or suspend-resume configuration, and configuration file has entries for which user doesn't have permission, it process the entries for which user has permissions and prints error on rest.

Name pntadm – DHCP network table management utility

Synopsis

```
pntadm -C [-r resource] [-p path] [-u uninterpreted] network

pntadm -A name_IP_address [-c comment] [-e mm/dd/yyyy]
     [-f num | keywords] [-h client_hostname]
     [-i [-a] client_ID] [-m [-y] macro] [-s server]
     [-r resource] [-p path] [-u uninterpreted] network

pntadm -M name_IP_address [-c comment] [-e mm/dd/yyyy]
     [-f num | keywords] [-h client_hostname]
     [-i [-a] client ID] [-m [-y] macro]
     [-n new_client_IP_address] [-s server] [-r resource]
     [-p path] [-u uninterpreted] network

pntadm -D name_IP_address [-y] [-r resource] [-p path]
     [-u uninterpreted] network

pntadm -P [-v] [-x] [-r resource] [-p path]
     [-u uninterpreted] network

pntadm -R [-r resource] [-p path] [-u uninterpreted] network

pntadm -L [-r resource] [-p path] [-u uninterpreted]

pntadm -B [-v] [batchfile]
```

Description The `pntadm` command is used to manage the Dynamic Host Configuration Protocol (DHCP) network tables. It is used to add and remove networks under DHCP management, and add, delete, or modify IP address records within network tables, or to view tables. For a description of the format of DHCP network tables, see `dhcp_network(4)`.

`pntadm` can be run as root or by other users assigned to the DHCP Management profile. See `rbac(5)` and `user_attr(4)`.

If the networks you want to add are subnetted, you need to update the `netmasks(4)` table.

One of the following options (function flags) must be specified with the `pntadm` command: `-A`, `-B`, `-C`, `-D`, `-L`, `-M`, `-P`, or `-R`.

Options The following options are supported:

`-A` *name_IP_address* Add a client entry with hostname or client IP address, *name_IP_address*, to the named DHCP network table.

The following sub-options are optional:

`-c` *comment*	Comment text. The default is `NULL`.
`-e` *mm/dd/yyyy*	Absolute lease. The default is `0`.
`-f` *num* | *keywords*	Flag value. The default is `00`.

The flag (`-f`) option can be specified either as a single number denoting the intended flag value, or as a series of the following keywords, combined using the plus (+) symbol:

`DYNAMIC` or `00`	Server manager's assignment.
`PERMANENT` or `01`	Lease on entry is permanent.
`MANUAL` or `02`	Administrator managed assignment.
`UNUSABLE` or `04`	Entry is not valid.
`BOOTP` or `08`	Entry reserved for `BOOTP` clients.

For a more detailed description of the flag values, see `dhcp_network(4)`.

`-h` *client_hostname*

Client hostname. The default is NULL.

When the `-h` option is used in this mode, the *client_hostname* is added to the hosts table within the resource used for storing host names (files, NIS+ or DNS). The command will fail if this *client_hostname* is already present in the hosts table.

`-i` *client_ID* [`-a`]

Client identifier [`-a`]. The default is `00`.

The `-i` option modified with `-a` specifies that the client identifier is in ASCII format, and thus needs to be converted to hexadecimal format before insertion into the table.

`-m` *macro* [`-y`]

Macro name. Default is UNKNOWN.

The `-m` option modified with `-y` verifies the existence of the named macro in the `dhcptab` table before adding the entry.

`-s` *server*

Server IP or name. Default is system name (`uname -n`).

`-B`

Activate batch mode. `pntadm` will read from the specified file or from standard input a series of `pntadm` commands and execute them within the same process. Processing many `pntadm` commands using this method is much faster than running an executable batchfile itself. Batch mode is recommended for using `pntadm` in scripts.

The following sub-option is optional:

`-v` Display commands to standard output as they are processed.

`-C`

Create the DHCP network table for the network specified by *network*. See Operands. For details, see `dhcp_network(4)` and `networks(4)`.

`-D` *name_IP_address*

Delete the specified client entry with hostname or client IP address, *name_IP_address*, in the named DHCP network table. (See `dhcp_network(4)`.)

The following sub-option is optional:

`-y` Remove associated host table entry. The `-y` option requests that all hostnames associated with the IP address in the hosts table in the resource be removed.

`-L`

List the DHCP network tables presently configured, one per line, on standard output. If none are found, no output is printed and an exit status of `0` is returned.

`-M` *name_IP_address*

Modify the specified client entry with hostname or client IP address, *name_IP_address*, in the named DHCP network table. See `dhcp_network(4)`. The default for the sub-options is what they currently are set to.

The following sub-options are optional.

`-c` *comment*	New comment text.
`-e` *mm/dd/yy*	New absolute lease expiration date. Time defaults to 12:00 AM of the day specified.
`-f` *num* | *keyboard*	New flag value, see explanation following the description of the `-A` option.
`-h` *host_name*	New client hostname.

The `-h` option allows you to change the current *hostname* associated with the IP address or to add a new *hostname* to the hosts table if an entry associated with this IP address does not exist.

`-i` *client_ID* — New client identifier [`-a`].

`-m` *macro* [`-y`] — Macro name defined in `dhcptab`.

`-n` *new_client_IP_address* — New IP address.

`-s` *server* — New server IP or name.

For more detailed description of the sub-options and flag values, see `dhcp_network(4)`.

`-P` — Display the named DHCP network table.

The following sub-options are optional:

`-v` Display lease time in full verbose format and resolve IP addresses for the clients and server to hostnames.

`-x` Display lease time in raw format.

These flag codes are used with the `-P` sub-options:

`-v`	`-x`	Description
D	00	DYNAMIC
P	01	PERMANENT
M	02	MANUAL
U	04	UNUSABLE
B	08	BOOTP

See `dhcp_network(4)` for information on these sub-options and associated flag codes.

`-p` *path* — Override the `dhcpsvc.conf(4)` configuration value for data store resource path, *path* See `dhcpsvc.conf(4)`

`-R` — Remove the named DHCP network table. See `dhcp_network(4)`.

`-r` *data_store_resource* — Override the `/etc/inet/dhcpsvc.conf` configuration value for `RESOURCE=` with the *data_store_resource* specified. See the

dhcpsvc.conf(4) man page for more details on resource type, and the *Solaris DHCP Service Developer's Guide* for more information about adding support for other data stores.

`-u` uninterpreted — Data which will be ignored by `pntadm`, but passed to the currently configured public module to be interpreted by the data store. This might be used for a database account name or other authentication or authorization parameters required by a particular data store.

Operands The following operand is supported:

network — The network address or network name which corresponds to the `dhcp network` table. See dhcp_network(4).

Examples

EXAMPLE 1 Creating a Table for the `10.0.0.0` DHCP Network

The following command creates a table for the `10.0.0.0` (subnetted to class C) DHCP network table. Note that if you have an alias for this network in your networks(4) table, you can use that value rather than the dotted Internet Address notation.

```
example# pntadm -C 10.0.0.0
```

EXAMPLE 2 Adding an Entry to the `10.0.0.0` Table

The following command adds an entry to the `10.0.0.0` table in the `files` resource in the `/var/mydhcp` directory:

```
example# pntadm -r SUNWfiles -p /var/mydhcp -A 10.0.0.1 10.0.0.0
```

EXAMPLE 3 Modifying the `10.0.0.1` Entry of the `10.0.0.0` Table

The following command modifies the `10.0.0.1` entry of the `10.0.0.0` table, changing the macro name to `Green`, setting the flags field to `MANUAL` and `PERMANENT`:

```
example# pntadm -M 10.0.0.1 -m Green -f 'PERMANENT+MANUAL' 10.0.0.0
```

EXAMPLE 4 Changing the `10.0.0.1` Entry to `10.0.0.2`

The following command changes the `10.0.0.1` entry to `10.0.0.2`, making an entry in the hosts(4) table called `myclient`:

```
example# pntadm -M 10.0.0.1 -n 10.0.0.2 -h myclient 10.0.0.0
```

EXAMPLE 5 Setting the Client ID as ASCII

The following command sets the client ID as ASCII `aruba.foo.com` for the `myclient` entry:

```
example# pntadm -M myclient -i 'aruba.foo.com' -a 10.0.0.0
```

EXAMPLE 6 Deleting the `myclient` Entry from the `10.0.0.0` Table

The following command deletes the `myclient` (`10.0.0.2`) entry from the `10.0.0.0` table:

```
example# pntadm -D myclient 10.0.0.0
```

EXAMPLE 7 Removing the Named DHCP Network Table

The following command removes the named DHCP network table in the NIS+ directory specified:

```
example# pntadm -r SUNWnisplus -p Test.Nis.Plus. -R 10.0.0.0
```

EXAMPLE 8 Listing the Configured DHCP Network Tables

The following command lists the configured DHCP network tables:

```
example# pntadm -L
192.168.0.0
10.0.0.0
```

EXAMPLE 9 Executing `pntadm` Commands in Batch Mode

The following command runs a series of `pntadm` commands contained in a batch file:

```
example# pntadm -B addclients
```

Exit Status

`0` Successful completion.

1 Object already exists.

2 Object does not exist.

3 Non-critical error.

4 Critical error.

Files

`/etc/inet/dhcpsvc.conf`

`/etc/inet/hosts`

Name pooladm – activate and deactivate the resource pools facility

Synopsis

```
/usr/sbin/pooladm [-n] [-s] [-c] [filename] | -x

/usr/sbin/pooladm [-d | -e]
```

Description The `pooladm` command provides administrative operations on pools and sets. `pooladm` reads the specified filename and attempts to activate the pool configuration contained in it.

Before updating the current pool run-time configuration, `pooladm` validates the configuration for correctness.

Without options, `pooladm` prints out the current running pools configuration.

Options The following options are supported:

`-c` Instantiate the configuration at the given location. If a filename is not specified, it defaults to `/etc/pooladm.conf`.

`-d` Disable the pools facility so that pools can no longer be manipulated.

`-e` Enable the pools facility so that pools can be manipulated.

`-n` Validate the configuration without actually updating the current active configuration. Checks that there are no syntactic errors and that the configuration can be instantiated on the current system. No validation of application specific properties is performed.

`-s` Update the specified location with the details of the current dynamic configuration.

This option requires update permission for the configuration that you are going to update. If you use this option with the `-c` option, the dynamic configuration is updated before the static location.

`-x` Remove the currently active pool configuration. Destroy all defined resources, and return all formerly partitioned components to their default resources.

Operands The following operands are supported:

filename Use the configuration contained within this file.

Examples **EXAMPLE 1** Instantiating a Configuration

The following command instantiates the configuration contained at `/home/admin/newconfig`:

```
example# /usr/sbin/pooladm -c /home/admin/newconfig
```

EXAMPLE 2 Validating the Configuration Without Instantiating It

The following command attempts to instantiate the configuration contained at `/home/admin/newconfig`. It displays any error conditions that it encounters, but does not actually modify the active configuration.

EXAMPLE 2 Validating the Configuration Without Instantiating It *(Continued)*

```
example# /usr/sbin/pooladm -n -c /home/admin/newconfig
```

EXAMPLE 3 Removing the Current Configuration

The following command removes the current pool configuration:

```
example# /usr/sbin/pooladm -x
```

EXAMPLE 4 Enabling the Pools Facility

The following command enables the pool facility:

```
example# /usr/sbin/pooladm -e
```

EXAMPLE 5 Enabling the Pools Facility Using SMF

The following command enables the pool facility through use of the Service Management Facility. See `smf(5)`.

```
example# /usr/sbin/svcadm enable svc:/system/pools:default
```

EXAMPLE 6 Saving the Active Configuration to a Specified Location

The following command saves the active configuration to `/tmp/state.backup`:

```
example# /usr/sbin/pooladm -s /tmp/state.backup
```

Files `/etc/pooladm.conf` Configuration file for `pooladm`.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpool
Interface Stability	See below.

The invocation is Evolving. The output is Unstable.

See Also `poolcfg(1M)`, `poolbind(1M)`, `psrset(1M)`, `svcadm(1M)`, `pset_destroy(2)`, `libpool(3LIB)`, `attributes(5)`, `smf(5)`

System Administration Guide: Solaris Containers-Resource Management and Solaris Zones

Notes Resource bindings that are not presented in the form of a binding to a partitionable resource, such as the scheduling class, are not necessarily modified in a `pooladm -x` operation.

The pools facility is not active by default when Solaris starts. `pooladm -e` explicitly activates the pools facility. The behavior of certain APIs related to processor partitioning and process binding are modified when pools is active. See `libpool(3LIB)`.

You cannot enable the pools facility on a system where processor sets have been created. Use the `psrset(1M)` command or `pset_destroy(2)` to destroy processor sets manually before you enable the pools facility.

Because the Resource Pools facility is an `smf(5)` service, it can also be enabled and disabled using the standard SMF interfaces.

Name poolbind – bind processes, tasks, or projects or query binding of processes to resource pools

Synopsis

```
/usr/sbin/poolbind  -p poolname [-i idtype] id...

/usr/sbin/poolbind  -q pid...

/usr/sbin/poolbind  -Q pid...
```

Description The `poolbind` command allows an authorized user to bind zones, projects, tasks, and processes to pools. It can also allow a user to query a process to determine which pool the process is bound to.

Options The following options are supported:

`-i` *idtype*
: This option, together with the *idlist* arguments, specifies one or more processes to which the poolbind command is to apply. The interpretation of *idlist* depends on the value of *idtype*. The valid *idtype* arguments and corresponding interpretations of *idlist* are as follows:

  pid
  : *idlist* is a list of process IDs. Binds the specified processes to the specified pool. This is the default behavior if no idtype is specified.

  taskid
  : *idlist* is a list of task IDs. Bind all processes within the list of task IDs to the specified pool.

  projid
  : *idlist* is a list of project IDs. Bind all processes within the list of projects to the specified pool. Each project ID can be specified as either a project name or a numerical project ID. See `project(4)`.

  zoneid
  : *idlist* is a list of zone IDs. Bind all processes within the list of zones to the specified pool. Each zone ID can be specified as either a zone name or a numerical zone ID. See `zones(5)`.

`-p` *poolname*
: Specifies the name of a pool to which the specified zone, project, tasks, or processes are to be bound.

`-q` *pid ...*
: Queries the pool bindings for a given list of process IDs. If the collection of resources associated with the process does not correspond to any currently existing pool, or if there are multiple pools with the set of resources that the process is bound to, the query fails for that particular process ID.

`-Q` *pid ...*
: Queries the resource bindings for a given list of process IDs. The resource bindings are each reported on a separate line.

Examples

EXAMPLE 1 Binding All Processes

The following command binds all processes in projects 5 and 7 to the pool `web_app`:

```
example# /usr/sbin/poolbind -p web_app -i projid 5 7
```

EXAMPLE 2 Binding the Running Shell

The following command binds the running shell to the pool `web_app`:

```
 example# /usr/sbin/poolbind -p web_app $$
```

EXAMPLE 3 Querying the Pool Bindings

The following command queries the bindings to verify that the shell is bound to the given pool:

```
example# /usr/sbin/poolbind -q $$
```

EXAMPLE 4 Querying the Resource Bindings

The following command queries the bindings to verify that the shell is bound to the given resources:

```
example# /usr/sbin/poolbind -Q $$
```

Exit Status

The following exit values are returned:

`0` Successful completion.

`1` Requested operation could not be completed.

`2` Invalid command line options were specified.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpool
Interface Stability	See below.

The invocation is Evolving. The output is Unstable.

System Administration Guide: Solaris Containers-Resource Management and Solaris Zones

Name poolcfg – create and modify resource pool configuration files

Synopsis

```
/usr/sbin/poolcfg -c command [-d | [filename]]
/usr/sbin/poolcfg -f command_file [-d | [filename]]
/usr/sbin/poolcfg -h
```

Description The `poolcfg` utility provides configuration operations on pools and sets. These operations are performed upon an existing configuration and take the form of modifications to the specified configuration file. If you use the `-d` option, the modifications occur to the kernel state. Actual activation of the resulting configuration is achieved by way of the `pooladm(1M)` utility.

Pools configuration files are structured files that must have been constructed using `poolcfg` itself or `libpool(3LIB)` directly.

An invocation of `poolcfg` with the pool dynamic location and write permission will hang if the dynamic location has already been opened for writing.

The configurations which are created by this utility can be used by `pooladm` to instantiate the configuration upon a target host.

Options The following options are supported:

`-c` *command*	Specify *command* as an editing command. See `USAGE`.
`-d`	Operate directly on the kernel state. No *filename* is allowed.
`-f` *command_file*	Take the commands from *command_file*. *command_file* consists of editing commands, one per line.
`-h`	Display extended information about the syntax of editing commands.

Usage

Scripts A script consists of editing commands, one per line, of the following:

info [*entity-name*]
Display configuration (or specified portion) in human readable form to standard output. If no entity is specified, system information is displayed. Therefore, `poolcfg -c 'info' afile` is an equivalent invocation to `poolcfg -c 'info system name' afile`.

create *entity-name* [*property-list*]
Make an entity of the specified type and name.

destroy *entity-name*
Remove the specified entity.

modify *entity-name* [*property-list*]
Change the listed properties on the named entity.

associate *pool-name* [*resource-list*]
Connect one or more resources to a pool, or replace one or more existing connections.

transfer to [*resourcetype*] *name*[*component-list*]
Transfer one or more discrete components to a resource .

transfer [*quantity*] from [*resourcetype*] [*src*] to [*tgt*]
Transfer a resource quantity from *src* to *tgt*.

transfer [*quantity*] to [*resourcetype*] [*tgt*] from [*src*]
Transfer a resource quantity to *tgt* from *src*.

discover
Create a system entity, with one pool entity and resources to match current system configuration. All discovered resources of each resource type are recorded in the file, with the single pool referring to the default resource for each resource type.

This command is a NO-OP when `poolcfg` operates directly on the kernel. See the `-d` option.

You should avoid use of this command. The preferred method for creating a configuration is to export the dynamic configuration using `pooladm(1M)` with the `-s` option.

rename *entity-name* to *new-name*
Change the name of an entity on the system to its new name.

Property Lists The property list is specified by:

```
( proptype name = value [ ; proptype name = value ]* )
```

where the last definition in the sequence for a given proptype, name pair is the one that holds. For property deletion, use ~ `proptype name`.

Resource Lists A resource list is specified by:

```
( resourcetype name [ ; resourcetype name ]* )
```

where the last specification in the sequence for a resource is the one that holds. There is no deletion syntax for resource lists.

Component Lists A component list is specified by:

```
( componenttype name [ ; componenttype name ]* )
```

where the last specification in the sequence for a component is the one that holds. There is no deletion syntax for component lists.

Recognized Entities

system	Machine level entity
pool	Named collection of resource associations

Resource Types

pset	Processor set resource

Property Types

boolean	Takes one of two values true or false.
int	A 64–bit signed integer value.
uint	A 64–bit unsigned integer value.
string	Strings are delimited by quotes ("), and support the character escape sequences defined in `formats(5)`.
float	Scientific notation is not supported.

Examples

EXAMPLE 1 Writing a poolcfg Script

The following `poolcfg` script creates a pool named `Accounting`, and a processor set, `small-1`. The processor set is created first, then the pool is created and associated with the set.

```
create pset small-1 ( uint pset.min = 1 ; uint pset.max = 4)
create pool Accounting
associate pool Accounting ( pset small-1 )
```

EXAMPLE 2 Reporting on `pool_0`

The following command reports on `pool_0` to standard output in human readable form:

```
 # poolcfg -c 'info pool pool_0' /etc/pooladm.conf
```

EXAMPLE 3 Destroying pool_0 and Its Associations

The following command destroys `pool_0` and associations, but not the formerly associated resources:

```
# poolcfg -c 'destroy pool pool_0' /etc/pooladm.conf
```

EXAMPLE 4 Displaying the Current Configuration

The following command displays the current configuration:

```
$ poolcfg -c 'info' /etc/pooladm.conf
system example_system
               int system.version 1
               boolean system.bind-default true
               string system.comment Discovered by libpool

               pool pool_default
                    boolean pool.default true
                    boolean pool.active true
                    int pool.importance 5
                    string pool.comment
                    string.pool.scheduler FSS
                    pset pset_default

               pset pset_default
```

EXAMPLE 4 Displaying the Current Configuration *(Continued)*

```
int pset.sys_id -1
string pset.units population
boolean pset.default true
uint pset.max 4294967295
uint pset.min 1
string pset.comment
boolean pset.escapable false
uint pset.load 0
uint pset.size 2

cpu
     int cpu.sys_id 0
     string cpu.comment

cpu
     int cpu.sys_id 2
     string cpu.comment
```

EXAMPLE 5 Moving cpu with ID 2 to Processor Set pset1 in the Kernel

The following command moves `cpu` with ID `2` to processor set `pset1` in the kernel:

```
# poolcfg -dc 'transfer to pset pset1 ( cpu 2 )'
```

EXAMPLE 6 Moving 2 cpus from Processor Set pset1 to Processor Set pset2 in the Kernel

The following command moves 2 `cpus` from processor set `pset1` to processor set `pset2` in the kernel:

```
# poolcfg -dc 'transfer 2 from pset pset1 to pset2'
```

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpool
Interface Stability	See below.

The invocation is Committed. The output is Uncommitted.

System Administration Guide: Solaris Containers-Resource Management and Solaris Zones

Name poold – automated resource pools partitioning daemon

Synopsis `poold [-l level]`

Description `poold` provides automated resource partitioning facilities. Normally, `poold` is active on the system whenever the pools facility is active. `poold` starts and stops when the `pool_set_status(3POOL)` function activates or deactivates the pools facility. `poold` starts when you activate pools and stops when you deactivate pools. If you manually stop `poold` by using a utility such as `kill(1)`, you can invoke it manually.

`poold`'s configuration details are held in a `libpool(3LIB)` configuration and you can access all customizable behavior from this configuration.

`poold` periodically examines the load on the system and decides whether intervention is required to maintain optimal system performance with respect to resource consumption. `poold` also responds to externally initiated (with respect to `poold`) changes of either resource configuration or objectives.

If intervention is required, `poold` attempts to reallocate the available resources to ensure that performance objectives are satisfied. If it is not possible for `poold` to meet performance objectives with the available resources, then a message is written to the log. `poold` allocates scarce resources according to the objectives configured by the administrator. The system administrator must determine which resource pools are most deserving of scarce resource and indicate this through the importance of resource pools and objectives.

Options The following options are supported:

`-l` *level* Specify the vebosity level for logging information.

Specify *level* as `ALERT`, `CRIT`, `ERR`, `WARNING`, `NOTICE`, `INFO`, and `DEBUG`. If *level* is not supplied, then the default logging level is `INFO`.

`ALERT`	A condition that should be corrected immediately, such as a corrupted system database.
`CRIT`	Critical conditions, such as hard device errors.
`ERR`	Errors.
`WARNING`	Warning messages.
`NOTICE`	Conditions that are not error conditions, but that may require special handling.
`INFO`	Informational messages.
`DEBUG`	Messages that contain information normally of use only when debugging a program.

When invoked manually, with the `-l` option, all log output is directed to standard error.

Examples

EXAMPLE 1 Modifying the Default Logging Level

The following command modifies the default logging level to ERR:

```
# /usr/lib/pool/poold -l ERR
```

Attributes

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpool
Interface Stability	See below.

The invocation is Evolving. The output is Unstable.

System Administration Guide: Solaris Containers-Resource Management and Solaris Zones

Name poolstat – report active pool statistics

Synopsis

```
poolstat [-p pool-list] [-r rset-list] [interval [count]]

poolstat [-p pool-list] [-o format -r rset-list]
     [interval [count]]
```

Description The `poolstat` utility iteratively examines all active pools on the system. It reports statistics based on the selected output mode. `poolstat` provides options to examine only specified pools and report resource set-specific statistics.

Without options, `poolstat` examines all pools, reports basic statistics for their resource sets, and exits.

DISPLAY FORMATS In default output format, `poolstat` outputs a header line and a line for each pool. The line begins with the pool ID and its name, followed by a column of statistical data for the processor set attached to the pool.

The columns are defined as follows:

`id` Pool ID.

`pool` Pool name.

`rid` Resource set id.

`rset` Resource set name.

`type` Resource set type.

`min` Minimum resource set size.

`max` Maximum resource set size.

`size` Current resource set size.

`used` The measure of how much of the resource set is currently is use. This is calculated as the percentage utilization of the resource set multiplied by its size. If resource set has been reconfigured during last sampling interval, this value might be not reported (`-`).

`load` The absolute representation of the load that is put on the resource set. For the definition of this property see `libpool(3LIB)`.

Options The following options are supported:

`-o` *format* Report statistics according to the format specification given in format. See `DISPLAY FORMATS`.

The `-o` option accepts lists as arguments. Items in a list can be either separated by commas or enclosed in quotes and separated by commas or spaces.

You can specify multiple `-o` options. The format specification is interpreted as the whitespace separated concatenation of all the format option arguments.

The `-o` option must be used in conjunction with the `-r` option.

`-p` *pool-list* Report only pools whose names are in the given list. If the -r option is also used, this option selects only resource sets which belong to pools in the given list. Statistics for pools or resource sets are reported in the same order in which pool names are listed on the pool-list. Pool can be specified by name or by ID.

The `-p` option accepts lists as arguments. Items in a *pool-list* can only be separated by spaces.

`-r` *rset-list* Report resource set statistics. If the *rset-list* argument is "`all`", then all possible resource set types are selected.

The `-r` option accepts lists as arguments. Items in a list can be either separated by commas or enclosed in quotes and separated by commas or spaces.

The following resource set types are supported:

`all` All resource set types

`pset` Processor set

Operands The following operands are supported:

count The number of times that the statistics are repeated. By default, poolstat reports statistics only once.

If neither interval nor count are specified, statistics are reported once. If interval is specified and count is not, statistics are reported indefinitely.

interval The sampling interval in seconds.

If neither interval nor count are specified, statistics are reported once. If interval is specified and count is not, statistics are reported indefinitely.

Examples **EXAMPLE 1** Using `poolstat`

The following example shows the default output from the `poolstat` utility:

```
% poolstat
                          pset
  id pool           size used load
   0 pool_default      4  3.6  6.2
   1 pool_admin        4  3.3  8.4
```

EXAMPLE 2 Reporting Resource Set Statistics

The following example reports resource set statistics.

```
% poolstat -r pset
```

EXAMPLE 2 Reporting Resource Set Statistics *(Continued)*

```
  id pool           type rid rset          min  max size used load
  0 pool_default    pset  -1 pset_default    1  65K    2  1.2  8.3
  1 pool_admin      pset   1 pset_admin      1    1    1  0.4  5.2
  2 pool_other      pset  -1 pset_default    1  65K    2  1.2  8.3
```

Resource sets attached to multiple pools, as `pset_default` in the example above, are listed multiple times, once for each pool.

EXAMPLE 3 Restricting the Output to the List of Pools

The following example restricts the output to the list of pools

```
% poolstat -p pool_default
                     pset
 id pool         size used load
 0 pool_default    8  5.3 10.3

% poolstat -p 'pool_admin pool_default'
                       pset
  id pool         size used load
  1 pool_admin      6  4.3  5.3
  0 pool_default    2  1.9  2.0

% poolstat -r all -p 'pool_admin pool_default'
  id pool            type rid rset          min  max size used load
  1 pool_admin      pset   1 pset_admin      1    1    1  0.9  2.3
  2 pool_default    pset  -1 pset_default    1  65K    2  2.0  2.0
```

EXAMPLE 4 Customizing Output

The following example customizes output:

```
% poolstat -r -o pool,rset,size,load
  pool            rset          size load
  pool_default    pset_default     4  4.5
  pool_admin      pset_admin       4  2.1
```

Exit Status

The following exit values are returned:

`0` Successful completion.

1 An error occurred.

2 Invalid command line options were specified.

System Administration Guide: Solaris Containers-Resource Management and Solaris Zones

Notes The system ids associated with resources can change after the system reboots or the resource configuration is altered.

Name ports – creates /dev entries and inittab entries for serial lines

Synopsis `/usr/sbin/ports [-r` *rootdir*`]`

Description `devfsadm(1M)` is now the preferred command for `/dev` and `/devices` and should be used instead of `ports`.

The `ports` command creates symbolic links in the `/dev/term` and `/dev/cua` directories to the serial-port character device files in `/devices` and adds new entries in `/etc/inittab` for non-system ports found. System-board ports are given single lower-case letters for names (such as `a` and `b`) while other ports are named numerically.

`ports` searches the kernel device tree to find the serial devices attached to the system. It also checks `/dev/term` and `/dev/cua` to see what symbolic links to serial devices already exist. `ports` then performs the following:

1. Assigns new numbers (or letters for system-board ports) to ports that are attached to the system but do not have `/dev/term` and `/dev/cua` entries. The numbers or letters assigned are the lowest-unused numbers or letters.
2. Removes dangling links: links from `/dev/term` and `/dev/cua` pointing to no-longer-existing ports.
3. Creates new `/dev/term` and `/dev/cua` links for new serial devices.
4. Invokes `sacadm(1M)` to make new port monitor entries for the new devices. This is not done automatically for on-board ports; on workstations these ports are often not used for dial-in sessions, so a port-monitor for one of these ports must be created explicitly.

If the configuration has not changed, ports exits without doing anything.

Notice to Driver Writers

`ports` considers devices with a node type of `DDI_NT_SERIAL`, `DDI_NT_SERIAL_MB`, `DDI_NT_SERIAL_DO`, or `DDI_NT_SERIAL_MB_DO` to be serial port devices. Devices with one of these node types must create minor device names that obey the following conventions when calling `ddi_create_minor_node(9F)`.

- The minor name for non-system port devices (`DDI_NT_SERIAL`) consists of an ASCII numeric string, where the first port on the device is named `0`, the second named `1`, the third named `2`, up to the number of ports provided by the device.
- The minor name for non-system dialout devices (`DDI_NT_SERIAL_DO`) is the ASCII numeric port name, concatenated with `,cu`. For example, the minor name for the first dialout port on the serial board is `0,cu`.
- The minor name for system-board port devices (`DDI_NT_SERIAL_MB`) consists of a string containing a single ASCII lowercase character, where the first port on the device is named `a`, the second is named `b`, the third is named `c`, for all ports on the device (or up through port `z`).
- The minor name for system-board dialout devices (`DDI_NT_SERIAL_MB_DO`) consists of the lowercase character port name, concatenated with `,cu`. For example, the minor name for the first dialout port on the on-board serial device is `a,cu`.

To prevent `disks` from attempting to automatically generate links for a device, drivers must specify a private node type and refrain from using one of the above node types when calling `ddi_create_minor_node(9F)`.

Options The following options are supported:

`-r` *rootdir* Causes `ports` to presume that the `/dev/term`, `/dev/cua`, and `/devices` directories are found under *rootdir*, not directly under `/`. If this argument is specified, `sacadm(1M)` is not invoked, since it would update terminal administration files under `/etc` without regard to the *rootdir*.

Examples **EXAMPLE 1** Creating the Serial and Dialout Minor Device Nodes

The following example creates the serial and dialout minor device nodes from the `xkserial` driver's `attach(9E)` function:

```
/*
* Create the minor number by combining the instance number
* with the port number.
*/ #define XKNUMPORTS           8
#define XKMINORNUM(i, p)     ((i) << 4 | (p))
#define XKMINORNUM_DO(i, p)  ((i) << 4 | (p) | 0x80)
int
xkserialattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
   int instance, portnum;
   char name[8];
       /* other stuff in attach... */
   instance = ddi_get_instance(dip);
   for (portnum = 0; portnum < XKNUMPORTS; portnum++) {
       /*
        * create the serial port device
        */
        sprintf(name, "%d", portnum);
        ddi_create_minor_node(dip, name, S_IFCHR,
           XKMINORNUM(instance, portnum), DDI_NT_SERIAL, 0);

        /*
         * create the dialout device
         */
         sprintf(name,"%d,cu", portnum);
         ddi_create_minor_node(dip, name, S_IFCHR,
             XKMINORNUM_DO(instance, portnum), DDI_NT_SERIAL_DO, 0);
     }
}
```

EXAMPLE 2 Installing the `xkserial` Port Driver on a Sun Fire 4800

The following example installs the `xkserial` port driver on a Sun Fire 4800 (with the driver controlling the fictional XKSerial 8 port serial board), with these special files in `/devices`:

```
# ls -l /devices/ssm@0,0/pci@18,700000/pci@1/xkserial@f,800000/
crw-r-----   1 root sys   32,  16 Aug 29 00:02 xkserial@2000:0
crw-r-----   1 root sys   32, 144 Aug 29 00:02 xkserial@2000:0,cu
crw-r-----   1 root sys   32,  17 Aug 29 00:02 xkserial@2000:1
crw-r-----   1 root sys   32, 145 Aug 29 00:02 xkserial@2000:1,cu
crw-r-----   1 root sys   32,  18 Aug 29 00:02 xkserial@2000:2
crw-r-----   1 root sys   32, 146 Aug 29 00:02 xkserial@2000:2,cu
crw-r-----   1 root sys   32,  19 Aug 29 00:02 xkserial@2000:3
crw-r-----   1 root sys   32, 147 Aug 29 00:02 xkserial@2000:3,cu
crw-r-----   1 root sys   32,  20 Aug 29 00:02 xkserial@2000:4
crw-r-----   1 root sys   32, 148 Aug 29 00:02 xkserial@2000:4,cu
crw-r-----   1 root sys   32,  21 Aug 29 00:02 xkserial@2000:5
crw-r-----   1 root sys   32, 149 Aug 29 00:02 xkserial@2000:5,cu
crw-r-----   1 root sys   32,  22 Aug 29 00:02 xkserial@2000:6
crw-r-----   1 root sys   32, 150 Aug 29 00:02 xkserial@2000:6,cu
crw-r-----   1 root sys   32,  23 Aug 29 00:02 xkserial@2000:7
crw-r-----   1 root sys   32, 151 Aug 29 00:02 xkserial@2000:7,cu
```

`/dev/term` contain symbolic links to the serial port device nodes in `/devices`

```
# ls -l /dev/term
/dev/term/0 -> ../../devices/[....]/xkserial@2000:0
/dev/term/1 -> ../../devices/[....]/xkserial@2000:1
/dev/term/2 -> ../../devices/[....]/xkserial@2000:2
/dev/term/3 -> ../../devices/[....]/xkserial@2000:3
/dev/term/4 -> ../../devices/[....]/xkserial@2000:4
/dev/term/5 -> ../../devices/[....]/xkserial@2000:5
/dev/term/6 -> ../../devices/[....]/xkserial@2000:6
/dev/term/7 -> ../../devices/[....]/xkserial@2000:7
```

and `/dev/cua` contain symbolic links to the dialout port device nodes in `/devices`

```
# ls -l /dev/cua

/dev/cua/0 -> ../../devices/[....]/xkserial@2000:0,cu
/dev/cua/1 -> ../../devices/[....]/xkserial@2000:1,cu
/dev/cua/2 -> ../../devices/[....]/xkserial@2000:2,cu
/dev/cua/3 -> ../../devices/[....]/xkserial@2000:3,cu
/dev/cua/4 -> ../../devices/[....]/xkserial@2000:4,cu
/dev/cua/5 -> ../../devices/[....]/xkserial@2000:5,cu
/dev/cua/6 -> ../../devices/[....]/xkserial@2000:6,cu
/dev/cua/7 -> ../../devices/[....]/xkserial@2000:7,cu
```

Writing Device Drivers

Name powerd – power manager daemon

Synopsis

```
/usr/lib/power/powerd [-n]
```

Description The `powerd` daemon is started by `pmconfig(1M)` to monitor system activity and perform an automatic shutdown using the suspend-resume feature. When the system is suspended, complete current state is saved on the disk before power is removed. On reboot, the system automatically starts a resume operation and the system is restored to the same state it was in immediately prior to suspend.

Immediately prior to system shutdown, the daemon notifies `syslogd(1M)` of the shutdown, which broadcasts a notification.

Options The following option is supported:

`-n` No broadcast mode. The daemon silently shuts down the system without notifying `syslogd(1M)`.

Files `/etc/power.conf` Power Management configuration information file

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpmu

Using Power Management

Name ppdmgr – utility for managing PPD files

Synopsis

```
ppdmgr -a ppd_filename_path [-L label] [-R ppd_repository_name] [-w]

ppdmgr -r [-L label] [-R ppd_repository_name]

ppdmgr -u [-L label] [-R ppd_repository_name]
```

Description The PPD File Manager adds PPD files to the print system's PPD file repositories. When changes in the PPD file repositories are made by the utility, they are reflected in the Solaris Print Manager (see `printmgr(1M)`) GUI printer driver field when adding or modifying local attached or network attached printers.

Multiple PPD file repositories may be available. PPD files that are supplied with the system are available in the "`system`" repository. PPD files that are supplied by third party vendors may be available in the "`vendor`" repository. PPD files that are supplied by system administrators may be available in the "`admin`" repository, and PPD files that are added using this utility are available in the "user" repository. When this utility is used to update or rebuild printer information reflected in the `printmgr(1M)`, the special reserved repository name "`all`" can be used to specify all of the available PPD file repositories.

PPD files are grouped under a user-provided "label" within the print system's PPD file repository to allow easier selection of a printer driver through the `printmgr` GUI. The special reserved label name "`all`" can be used to specify all of the available labels in a PPD file repository. The results are undefined if a label name contains characters that are not in the portable filename character set or if a label name starts with a hyphen (-). A label name may not contain a semi-colon (:).

Options The following subcommand are supported:

`-a` *ppd_file_path*
: Adds a copy of *ppd_file_path* to the system under the specified label in the specified repository, where *ppd_file_path* is the full path and file name to the PPD file. The utility accepts a valid PPD file with either a `.ppd` or `.ppd.gz` (gzipped) extension.

`-L` *label*
: Specifies a label to group PPD files under. When specified with the `-a` option, the default label is "`user`". When specified with the `-r` or `-u` option, the default label is "`all`". The following are reserved labels:

`caches`	may never be specified
`ppdcache`	may never be specified
`manufaliases`	may never be specified
`all`	applies the specified action to all labels in a repository, and may only be specified with the `-r` or `-u` option.
`SUNW*`	anything starting with `SUNW` is reserved and should not be specified with the `-a` option.

`-R` *repository_name*
Specifies the name of a PPD file repository representing one of the PPD file installation locations. Possible repository names include: "`user`", "`admin`", "`vendor`", "`system`", and "`all`".

The repository name "`all`" signifies all of the possible repository names. The default repository name is "`user`". Only the "`user`" or "`admin`" repository may be specified with the `-a` option.

`-r`
Rebuilds the cache information for the specified label in the specified repository.

`-u`
Updates the cache information for the specified label in the specified repository.

`-w`
Write the full path of the added PPD file. This option is only valid with the `-a` option. Otherwise, this option is ignored.

Examples

EXAMPLE 1 Adding a copy of a PPD file to the repository

The following commands add a copy of a PPD file to the "`user`" repository under the "`user`" label:

```
# ppdmgr -a /net/somesystem/ppdfiles/ppdfile.ppd
```

or

```
# ppdmgr -a /net/somesystem/ppdfiles/ppdfile.ppd -L user
```

The following command adds a copy of a PPD file to the "`user`" repository under the "`Photo`" label and write the full path of the added copy to standard output:

```
# ppdmgr -a /net/somesystem/ppdfiles/ppdfile.ppd -L "Photo" -w
```

EXAMPLE 2 Updating the cache for the PPD files

The following commands update the cache for the PPD files under the "`all`" labels in the "`user`" repository:

```
 # ppdmgr -u
```

or

```
 # ppdmgr -u -R user -L all
```

The following command updates the cache for the PPD files under the "photo" label in the "`user`" repository:

```
 # ppdmgr -u -R user -L Photo
```

EXAMPLE 3 Rebuilding the cache for the PPD files

The following command rebuilds the cache for the PPD files under the "Photo" label in the "user" repository:

```
# ppdmgr -r -R user -L Photo
```

Exit Status

The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Name pppd – point to point protocol daemon

Synopsis `pppd [`*tty_name*`] [`*speed*`] [`*options*`]`

Description The point-to-point protocol (PPP) provides a method for transmitting datagrams over serial point-to-point links. PPP is composed of three components: a facility for encapsulating datagrams over serial links, an extensible link control protocol (LCP), and a family of network control protocols (NCP) for establishing and configuring different network-layer protocols.

The encapsulation scheme is provided by driver code in the kernel. `pppd` provides the basic LCP authentication support and several NCPs for establishing and configuring the Internet Protocol (referred to as the IP Control Protocol or "IPCP") and IPv6 (IPV6CP).

Options The following sections discuss the `pppd` options:

Options Files Options are taken from files and the command line. `pppd` reads options from the files `/etc/ppp/options`, `$HOME/.ppprc` and `/etc/ppp/options.`*ttyname* (in that order) before processing the options on the command line. (Command-line options are scanned for the terminal name before the `options.`*ttyname* file is read.) To form the name of the `options.`*ttyname* file, the initial `/dev/` is removed from the terminal name, and any remaining forward slash characters (/) are replaced with dots. For example, with serial device `/dev/cua/a`, option file `/etc/ppp/options.cua.a` is read.

An options file is parsed into a series of words that are delimited by whitespace. Whitespace can be included in a word by enclosing the word in double-quotes ("). A backslash (\) quotes the succeeding character. A hash (#) starts a comment, which continues until the end of the line. There is no restriction on using the `file` or `call` options within an options file.

Frequently Used Options

`<tty_name>` Communicate over the named device. The string `/dev/` is prepended if necessary. If no device name is given, or if the name of the terminal connected to the standard input is given, `pppd` uses that terminal and does not fork to put itself in the background. A value for this option from a privileged source cannot be overridden by a non-privileged user.

`<speed>` Set the baud rate to `<speed>` (a decimal number). The default is to leave the baud rate unchanged. This option is normally needed for dial-out only.

`asyncmap` <*map*> Set the `async` character map to <*map*>. The map describes which control characters cannot be successfully received over the serial line. `pppd` asks the peer to send these characters as a 2-byte escape sequence. The argument is a 32 bit hex number, with each bit representing a character to escape. Bit 0 (00000001) represents the character 0x00; bit 31 (80000000) represents the character 0x1f or ^_. If multiple `asyncmap` options are given, the values are `ORed` together. If no `asyncmap` option is given, `pppd` attempts to negotiate a value of 0. If the

peer agrees, this disables escaping of the standard control characters. Use the `default-asyncmap` option to disable negotiation and escape all control characters.

`auth` — Require the peer to authenticate itself before allowing network packets to be sent or received. This option is the default if the system has a default route. If the `auth` or the `noauth` option is not specified, `pppd` allows the peer to use only those IP addresses to which the system does not already have a route.

`call` *name* — Read options from the file `/etc/ppp/peers/`*name*. This file may contain privileged options, including `noauth`, even if `pppd` is not being run by root. The *name* string may not begin with a slash ("/") or include consecutive periods (`".."`) as a pathname component.

`callback` *number* — Request a callback to the given telephone number using Microsoft CBCP.

`connect` *script* — Use the executable or shell command specified by *script* to set up the serial line. This script would typically use the `chat(1M)` program to dial the modem and start the remote `PPP` session. A value for this option originating from a privileged source cannot be overridden by a non-privileged user.

`crtscts` — Use hardware flow control, that is, RTS/CTS, to control the flow of data on the serial port. If the `crtscts`, `nocrtscts`, `cdtrcts` or `nocdtrcts` option is not provided, the hardware flow control setting for the serial port is left unchanged. Some serial ports lack a true RTS output and use this mode to implement unidirectional flow control. The serial port suspends transmission when requested by the modem by means of CTS but cannot request the modem to stop sending to the computer. This mode allows the use of DTR as a modem control line.

`defaultroute` — Add a default route to the system routing tables when IPCP negotiation successfully completes, using the peer as the gateway. This entry is removed when the `PPP` connection is broken. This option is privileged if the `nodefaultroute` option is specified.

`disconnect` *script* — Run the executable or shell command specified by *script* after `pppd` terminates the link. Typically, this script is used to command the modem to hang up if hardware modem control signals are not available. `disconnect` is not run if the modem has already hung up. A value for this option originating from a privileged source cannot be overridden by a non-privileged user.

`escape` *xx,yy,...* — Specifies that certain characters be escaped on transmission regardless of whether the peer requests them to be escaped with its `async` control

character map. The characters to be escaped are specified as a list of hex numbers separated by commas. Note that almost any character can be specified for the `escape` option, unlike the `asyncmap` option which allows only control characters to be specified. Characters that cannot be escaped are those containing hex values 0x20 through 0x3f and 0x5e.

`file` *name* — Read options from file *name*. If this option is used on the command line or in `$HOME/.pppprc`, the file must be readable by the user invoking `pppd`. See Options Files for a list of files that `pppd` always reads, regardless of the use of this option.

`init` *script* — Run the executable or shell command specified by *script* to initialize the serial line. This script would typically use the `chat(1M)` program to configure the modem to enable auto-answer. A value for this option from a privileged source cannot be overridden by a non-privileged user.

`lock` — Directs `pppd` to create a UUCP-style lock file for the serial device to ensure exclusive access to the device.

`mru` *n* — Set the Maximum Receive Unit (MRU) value to *n*. `pppd` asks the peer to send packets of no more than *n* bytes. Minimum MRU value is 128. Default MRU value is 1500. A value of 296 is recommended for slow links (40 bytes for TCP/IP header + 256 bytes of data). For IPv6, MRU must be at least 1280.

`mtu` *n* — Set the Maximum Transmit Unit (MTU) value to *n*. Unless the peer requests a smaller value via MRU negotiation, `pppd` requests the kernel networking code to send data packets of no more than *n* bytes through the PPP network interface. For IPv6, MTU must be at least 1280.

`passive` — Enables the "passive" option in the LCP. With this option, `pppd` attempts to initiate a connection; if no reply is received from the peer, `pppd` waits passively for a valid LCP packet instead of exiting, as it would without this option.

Options `<local_IP_address>:<remote_IP_address>`

Set the local and/or remote interface IP addresses. Either one may be omitted, but the colon is required. The IP addresses are specified with a host name or in decimal dot notation, for example: `:10.1.2.3`. The default local address is the first IP address of the system unless the `noipdefault` option is provided. The remote address is obtained from the peer if not specified in any option. Thus, in simple cases, this option is not required. If a local and/or remote IP address is specified with this option, `pppd` will not accept a different value from the peer in the IPCP negotiation unless the `ipcp-accept-local` and/or `ipcp-accept-remote` options are given, respectively.

`allow-fcs` *fcs-type*
Set allowable FCS type(s) for data sent to the peer. The *fcs-type* is a comma-separated list of "crc16", "crc32", "null", or integers. By default, all known types are allowed. If this option is specified and the peer requests a type not listed, a LCP Configure-Nak is sent to request only the listed types.

`allow-ip` *address(es)*
Allow peers to use the given IP address or subnet without authenticating themselves. The parameter is parsed in the same manner as each element of the list of allowed IP addresses is parsed in the secrets files. See the Authentication section more more details.

`bsdcomp` *nr,nt*
Request that the peer compress packets that it sends using the BSD-Compress scheme, with a maximum code size of *nr* bits, and agree to compress packets sent to the peer with a maximum code size of *nt* bits. If *nt* is not specified, it defaults to the value given for *nr*. Values in the range 9 to 15 may be used for *nr* and *nt*; larger values provide better compression but consume more kernel memory for compression dictionaries. Alternatively, a value of 0 for *nr* or *nt* disables compression in the corresponding direction. Use `nobsdcomp` or `bsdcomp 0` to disable BSD-Compress compression entirely. If this option is read from a privileged source, a nonprivileged user may not specify a code size larger than the value from the privileged source.

`cdtrcts`
Use a non-standard hardware flow control such as DTR/CTS to control the flow of data on the serial port. If the `crtscts`, `nocrtscts`, `cdtrcts` or `nocdtrcts` option is not specified, the hardware flow control setting for the serial port is left unchanged. Some serial ports lack a true RTS output. Such serial ports use this mode to implement true bi-directional flow control. Note that this flow control mode does not permit using DTR as a modem control line.

`chap-interval` *n*
If this option is given, `pppd` will rechallenge the peer every *n* seconds.

`chap-max-challenge` *n*
Set the maximum number of CHAP challenge transmissions to *n* (default 10).

`chap-restart` *n*
Set the CHAP restart interval (retransmission timeout for challenges) to *n* seconds. The default is 3.

`connect-delay` *n*
Wait for up to *n* milliseconds after the connect script finishes for a valid PPP packet from the peer. When the wait period elapses or when a valid PPP packet is received from the peer, `pppd` begins negotiation by sending its first LCP packet. The default value is 1000 (1 second). A wait period applies only if the `connect` or `pty` option is used.

`datarate` *n*
Set maximum data rate to *n* (in bytes per second) when using the `pty`, `notty`, `record`, or `socket` options.

`debug`
Enables connection debugging facilities. If this option is given, `pppd` logs the contents of all control packets sent or received in a readable form. The packets are logged through syslog with facility `daemon` and level `debug`. This information can be directed to a file by configuring `/etc/syslog.conf` appropriately.

`default-asyncmap`
Disable `asyncmap` negotiation, forcing all control characters to be escaped for both the transmit and the receive direction.

`default-fcs`
Disable FCS Alternatives negotiation entirely. By default, no FCS Alternatives option is sent to the peer, but the option is accepted. If this option is specified by the peer, then LCP Configure-Reject is sent.

`default-mru`
Disable MRU [Maximum Receive Unit] negotiation. With this option, `pppd` uses the default MRU value of 1500 bytes for the transmit and receive directions.

`deflate` *nr,nt,e*
Request that the peer compress packets that it sends, using the `deflate` scheme, with a maximum window size of *2**nr* bytes, and agree to compress packets sent to the peer with a maximum window size of *2**nt* bytes and effort level of *e* (1 to 9). If *nt* is not specified, it defaults to the value given for *nr*. If *e* is not specified, it defaults to 6. Values in the range 9 to 15 may be used for *nr* and *nt*; larger values provide better compression but consume more kernel memory for compression dictionaries. (Value 8 is not permitted due to a zlib bug.) Alternatively, a value of 0 for *nr* or *nt* disables compression in the corresponding direction. Use `nodeflate` or `deflate 0` to disable `deflate` compression entirely. (Note: `pppd` requests deflate compression in preference to BSD-Compress if the peer can do either.) If this option is read from a privileged source, a nonprivileged user may not specify a code size larger than the value from the privileged source.

`demand`
Initiate the link only on demand, that is, when data traffic is present. With this option, the remote IP address must be specified by the user on the command line or in an options file. `pppd` initially configures and enables the interface for IP traffic without connecting to the peer. When traffic is available, `pppd` connects to the peer and performs negotiation, authentication and other actions. When completed, `pppd` passes data packets across the link. The `demand` option implies the `persist` option. If this behavior is not desired, use the `nopersist` option after the `demand` option. The `idle` and `holdoff` options can be used in conjunction with the `demand` option.

`domain` *d*
Append the domain name *d* to the local host name for authentication purposes. For example, if `gethostname()` returns the name `porsche`, but the fully qualified domain name is `porsche.Quotron.COM`, you could specify `domain Quotron.COM`. With this configuration, `pppd` uses the name `porsche.Quotron.COM` for accessing secrets in the secrets file and as the default name when authenticating to the peer. This option is privileged.

`endpoint` *endpoint-value*
Set the endpoint discriminator (normally used for RFC 1990 Multilink PPP operation). The *endpoint-value* consists of a class identifier and a class-dependent value. The class identifier is one of "null," "local," "IP," "MAC," "magic," "phone," or a decimal integer. If present, the class-dependent value is separated from the identifier by a colon (":") or period (".") . This value may be a standard dotted-decimal IP address for class "IP," an optionally colon-or-dot separated hex Ethernet address for class "MAC" (must have 6 numbers), or an arbitrary string of bytes specified in hex with optional colon or dot separators between bytes. Although this option is available, this implementation does not support multilink.

`fcs` *fcs-type*
Set FCS type(s) desired for data sent by the peer. The *fcs-type* is a comma-separated list of `crc16`, `crc32`, `null`, or integers. By default, an FCS Alternatives option is not specified, and the medium-dependent FCS type is used. If this option is specified and the peer sends an LCP Configure-Nak, only the listed types are used. If none are in common, the FCS Alternatives option is omitted from the next LCP Configure-Request to drop back to the default.

`hide-password`
When logging the contents of PAP packets, this option causes `pppd` to exclude the password string from the log. This is the default.

`holdoff` *n*
Specifies how many seconds to wait before re-initiating the link after it terminates. This option is effective only if the `persist` or `demand` option is used. The holdoff period is not applied if the link is terminated because it was idle.

`ident` *string*
Set the LCP Identification string. The default value is a version string similar to that displayed by the `--version` option.

`idle` *n*
Specifies that `pppd` must disconnect if the link is idle for *n* seconds. The link is idle when no data packets (i.e. IP packets) are being sent or received. Do not use this option with the `persist` option but without the `demand` option.

`ipcp-accept-local`
With this option, `pppd` accepts the peer's idea of the local IP address, even if the local IP address is specified in an option.

`ipcp-accept-remote`
With this option, `pppd` accepts the peer's idea of its remote IP address, even if the remote IP address is specified in an option.

`ipcp-max-configure` *n*
Set the maximum number of IPCP Configure-Request transmissions to *n* (default 10).

`ipcp-max-failure` *n*
Set the maximum number of IPCP Configure-NAKs sent before sending Configure-Rejects instead to *n* (default 10).

`ipcp-max-terminate` *n*
Set the maximum number of IPCP terminate-request transmissions to *n* (default 3).

`ipcp-restart` *n*
Set the IPCP restart interval (retransmission timeout) to *n* seconds (default 3).

`ipparam` *string*
Provides an extra parameter to the ip-up and ip-down scripts. When this option is given, the *string* supplied is given as the sixth parameter to those scripts. See the Scripts section.

`ipv6` <*local_interface_identifier*>,<*remote_interface_identifier*>
Set the local and/or remote 64-bit interface identifier. Either one may be omitted. The identifier must be specified in standard ASCII notation of IPv6 addresses (for example: `::dead:beef`). If the `ipv6cp-use-ipaddr` option is given, the local and remote identifiers are derived from the respective IPv4 addresses (see above). The `ipv6cp-use-persistent` option can be used instead of the `ipv6 <local>,<remote>` option.

`ipv6cp-accept-local`
Accept peer's interface identifier for the local link identifier.

`ipv6cp-max-configure` *n*
Set the maximum number of IPv6CP Configure-Request transmissions to *n* (default 10).

`ipv6cp-max-failure` *n*
Set the maximum number of IPv6CP Configure-NAKs sent before sending Configure-Rejects instead to *n* (default 10).

`ipv6cp-max-terminate` *n*
Set the maximum number of IPv6CP terminate-request transmissions to *n* (default 3).

`ipv6cp-restart` *n*
Set the IPv6CP restart interval (retransmission timeout) to *n* seconds (default 3).

`ipv6cp-use-ipaddr`
If either the local or remote IPv6 address is unspecified, use the corresponding configured IPv4 address as a default interface identifier. (This option uses the configured addresses, not the negotiated addresses. Do not use it with `ipcp-accept-local` if the local IPv6 identifier is unspecified or with `ipcp-accept-remote` if the remote IPv6 identifier is unspecified.)

`ipv6cp-use-persistent`
Use uniquely-available persistent value for link local address.

`kdebug` *n*
Enable debugging code in the kernel-level PPP driver. Argument *n* is the sum of the following values: `1` to enable general debug messages, `2` to request that contents of received

packets be printed, and 4 to request contents of transmitted packets be printed. Messages printed by the kernel are logged by `syslogd(1M)` to a file directed in the `/etc/syslog.conf` configuration file. Do not use the `kdebug` option to debug failed links. Use the `debug` option instead.

`lcp-echo-failure` *n*
If this option is given, `pppd` presumes the peer to be dead if *n* LCP Echo-Requests are sent without receiving a valid LCP Echo-Reply. If this happens, `pppd` terminates the connection. This option requires a non-zero value for the `lcp-echo-interval` parameter. This option enables `pppd` to terminate after the physical connection is broken (for example, if the modem has hung up) in situations where no hardware modem control lines are available.

`lcp-echo-interval` *n*
If this option is given, `pppd` sends an LCP Echo-Request frame to the peer every *n* seconds. Normally the peer responds to the Echo-Request by sending an Echo-Reply. This option can be used with the `lcp-echo-failure` option to detect that the peer is no longer connected.

`lcp-max-configure` *n*
Set the maximum number of LCP Configure-Request transmissions to *n* (default 10).

`lcp-max-failure` *n*
Set the maximum number of LCP Configure-NAKs sent before starting to send Configure-Rejects instead to *n* (default 10).

`lcp-max-terminate` *n*
Set the maximum number of LCP Terminate-Request transmissions to *n* (default 3).

`lcp-restart` *n*
Set the LCP restart interval (retransmission timeout) to *n* seconds (default 3).

`linkname` *name*
Sets the logical name of the link to *name*. `pppd` creates a file named `ppp-`*name*`.pid` in `/var/run` containing its process ID. This is useful in determining which instance of `pppd` is responsible for the link to a given peer system. This is a privileged option.

`local`
Do not use modem control lines. With this option, `pppd` ignores the state of the CD (Carrier Detect) signal from the modem and does not change the state of the DTR (Data Terminal Ready) signal.

`logfd` *n*
Send log messages to file descriptor *n*. `pppd` sends log messages to (at most) one file or file descriptor (as well as sending the log messages to syslog), so this option and the `logfile` option are mutually exclusive. By default `pppd` sends log messages to `stdout` (file descriptor 1) unless the serial port is open on stdout.

`logfile` *filename*
Append log messages to the file *filename* (and send the log messages to syslog). The file is opened in append mode with the privileges of the user who invoked `pppd`.

`login`
Use the system password database for authenticating the peer using PAP, and record the user in the system `wtmp` file. Note that the peer must have an entry in the `/etc/ppp/pap-secrets` file and the system password database to be allowed access.

`maxconnect` *n*
Terminate the connection after it has been available for network traffic for *n* seconds (that is, *n* seconds after the first network control protocol starts). An LCP Time-Remaining message is sent when the first NCP starts, and again when 5, 2, and 0.5 minutes are remaining.

`maxfail` *n*
Terminate after *n* consecutive failed connection attempts. A value of 0 means no limit. The default value is 10.

`modem`
Use the modem control lines. This option is the default. With this option, `pppd` waits for the CD (Carrier Detect) signal from the modem to be asserted when opening the serial device (unless a connect script is specified), and drops the DTR (Data Terminal Ready) signal briefly when the connection is terminated and before executing the connect script.

`ms-dns` <*addr*>
If `pppd` is acting as a server for Microsoft Windows clients, this option allows `pppd` to supply one or two DNS (Domain Name Server) addresses to the clients. The first instance of this option specifies the primary DNS address; the second instance (if given) specifies the secondary DNS address. If the first instance specifies a name that resolves to multiple IP addresses, then the first two addresses are used. (This option is present in some older versions of `pppd` under the name `dns-addr`.)

`ms-lanman`
If `pppd` connects as a client to a Microsoft server and uses MS-CHAPv1 for authentication, this option selects the LAN Manager password style instead of Microsoft NT.

`ms-wins` <*addr*>
If `pppd` acts as a server for Microsoft Windows or Samba clients, this option allows `pppd` to supply one or two WINS (Windows Internet Name Services) server addresses to the clients. The first instance of this option specifies the primary WINS address; the second instance (if given) specifies the secondary WINS address. As with `ms-dns`, if the name specified resolves to multiple IP addresses, then the first two will be taken as primary and secondary.

`name` *name*
Set the name of the local system for authentication purposes to *name*. This is a privileged option. With this option, `pppd` uses lines in the secrets files that have *name* as the second field to look for a secret to use in authenticating the peer. In addition, unless overridden with the `user` option, *name* is used as the name to send to the peer when authenticating the local system. (Note that `pppd` does not append the domain name to *name*.)

`no-accm-test`
Disable use of `asyncmap` (ACCM) checking using LCP Echo-Request messages. If the `lcp-echo-failure` is used on an asynchronous line, `pppd` includes all control characters in the first *n* LCP Echo-Request messages. If the `asyncmap` is set incorrectly, the link drops rather than continue operation with random failures. This option disables that feature.

`noaccomp`
Disable HDLC Address/Control compression in both directions (send and receive).

`noauth`
Do not require the peer to authenticate itself. This option is privileged.

`nobsdcomp`
Disables BSD-Compress compression; `pppd` will not request or agree to compress packets using the BSD-Compress scheme. This option is not necessary if `noccp` is specified.

`noccp`
Disable CCP (Compression Control Protocol) negotiation. This option should only be required if the peer has bugs or becomes confused by requests from `pppd` for CCP negotiation. If CCP is disabled, then BSD and deflate compression do not need to be separately disabled.

`nocrtscts`
Disable hardware flow control (i.e. RTS/CTS) on the serial port. If the `crtscts`, `nocrtscts`, `cdtrcts` or `nocdtrcts` options are not given, the hardware flow control setting for the serial port is left unchanged.

`nocdtrcts`
This option is a synonym for `nocrtscts`. Either option will disable both forms of hardware flow control.

`nodefaultroute`
Disable the `defaultroute` option. You can prevent non-root users from creating default routes with `pppd` by placing this option in the `/etc/ppp/options` file.

`nodeflate`
Disables deflate compression; `pppd` will not request or agree to compress packets using the deflate scheme. This option is not necessary if `noccp` is specified.

`nodeflatedraft`
Do not use Internet Draft (incorrectly assigned) algorithm number for deflate compression. This option is not necessary if `noccp` is specified.

`nodetach`
Do not detach from the controlling terminal. Without this option, `pppd` forks to become a background process if a serial device other than the terminal on the standard input is specified.

`noendpoint`
Do not send or accept the Multilink Endpoint Discriminator option.

`noident`
Disable use of LCP Identification. LCP Identification messages will not be sent to the peer, but received messages will be logged. (Specify this option twice to completely disable LCP Identification. In this case, `pppd` sends LCP Code-Reject in response to received LCP Identification messages.)

`noip`
Disable IPCP negotiation and IP communication. Use this option only if the peer has bugs or becomes confused by requests from `pppd` for IPCP negotiation.

`noipv6`
Disable IPv6CP negotiation and IPv6 communication. IPv6 is not enabled by default.

`noipdefault`
Disables the default behavior when no local IP address is specified, which is to determine (if possible) the local IP address from the hostname. With this option, the peer must supply the local IP address during IPCP negotiation (unless it specified explicitly on the command line or in an options file).

`nolog`
Do not send log messages to a file or file descriptor. This option cancels the `logfd` and `logfile` options. `nologfd` acts as an alias for this option.

`nomagic`
Disable magic number negotiation. With this option, `pppd` cannot detect a looped-back line. Use this option only if the peer has bugs. Do not use this option to work around the "Serial line is looped back" error message.

`nopam`
This privileged option disables use of pluggable authentication modules. If this option is specified, `pppd` reverts to standard authentication mechanisms. The default is not to use PAM.

`nopcomp`
Disable protocol field compression negotiation in the receive and the transmit direction.

`nopersist`
Exit once a connection has been made and terminated. This is the default unless the `persist` or `demand` option is specified.

`noplink`
Cause `pppd` to use I_LINK instead of I_PLINK. This is the default. When I_LINK is used, the system cleans up terminated interfaces (even when SIGKILL is used) but does not allow `ifconfig(1M)` to unplumb PPP streams or insert or remove modules dynamically. Use the `plink` option if `ifconfig(1M)` modinsert, modremove or unplumb support is needed.

`nopredictor1`
Do not accept or agree to Predictor-1 compression. (This option is accepted for compatibility. The implementation does not support Predictor-1 compression.)

`noproxyarp`
Disable the `proxyarp` option. If you want to prevent users from creating proxy ARP entries with `pppd`, place this option in the `/etc/ppp/options` file.

`notty`
Normally, `pppd` requires a terminal device. With this option, `pppd` allocates itself a pseudo-tty master/slave pair and uses the slave as its terminal device. `pppd` creates a child process to act as a character shunt to transfer characters between the pseudo-tty master and its standard input and output. Thus, `pppd` transmits characters on its standard output and receives characters on its standard input even if they are not terminal devices. This option increases the latency and CPU overhead of transferring data over the ppp interface as all of the characters sent and received must flow through the character shunt process. An explicit device name may not be given if this option is used.

`novj`
Disable Van Jacobson style TCP/IP header compression in both the transmit and the receive direction.

`novjccomp`
Disable the connection-ID compression option in Van Jacobson style TCP/IP header compression. With this option, `pppd` does not omit the connection-ID byte from Van Jacobson compressed TCP/IP headers, nor does it ask the peer to do so. This option is unnecessary if `novj` is specified.

`pam`
This privileged option enables use of PAM. If this is specified, `pppd` uses the `pam(3PAM)` framework for user authentication with a service name of "ppp" if the `login` option and PAP authentication are used. The default is not to use PAM.

`papcrypt`
Indicates that `pppd` should not accept a password which, before encryption, is identical to the secret from the `/etc/ppp/pap-secrets` file. Use this option if the secrets in the `pap-secrets` file are in `crypt(3C)` format.

`pap-max-authreq` *n*
Set the maximum number of PAP authenticate-request transmissions to *n* (default 10).

`pap-restart` *n*
Set the PAP restart interval (retransmission timeout) to *n* seconds (default 3).

`pap-timeout` *n*
Set the maximum time that `pppd` waits for the peer to authenticate itself with PAP to *n* seconds (0= no limit). The default is 30 seconds.

`password` *string*
Password string for authentication to the peer.

`persist`
Do not exit after a connection is terminated; instead try to reopen the connection.

`plink`
Cause `pppd` to use I_PLINK instead of I_LINK. The default is to use I_LINK, which cleans up terminated interface (even if SIGKILL is used), but does not allow `ifconfig(1M)` to unplumb PPP streams or insert or remove modules dynamically. Use this option if `ifconfig(1M)` modinsert/modremove/unplumb support is needed. See also the `plumbed` option.

`plugin` *filename*
Load the shared library object file *filename* as a plugin. This is a privileged option. Unless the filename specifies an explicit path, `/etc/ppp/plugins` and `/usr/lib/inet/ppp` will be searched for the object to load in that order.

`plumbed`
This option indicates that `pppd` should find a plumbed interface and use that for the session. If IPv4 addresses or IPv6 interface IDs or link MTU are otherwise unspecified, they are copied from the interface selected. This mode mimics some of the functionality of the older `aspppd` implementation and may be helpful when `pppd` is used with external applications that use `ifconfig(1M)`.

`pppmux` *timer*
Enable PPP Multiplexing option negotiation and set transmit multiplexing timeout to *timer* microseconds.

`privgroup` *group-name*
Allows members of group *group-name* to use privileged options. This is a privileged option. Because there is no guarantee that members of *group-name* cannot use `pppd` to become root themselves, you should be careful using this option. Consider it equivalent to putting the members of *group-name* in the `root` or `sys` group.

`proxyarp`
Add an entry to the system's Address Resolution Protocol (ARP) table with the IP address of the peer and the Ethernet address of this system. When you use this option, the peer appears to other systems to be on the local Ethernet. The remote address on the PPP link must be in the same subnet as assigned to an Ethernet interface.

`pty` *script*
Specifies that the command *script*, and not a specific terminal device is used for serial communication. `pppd` allocates itself a pseudo-tty master/slave pair and uses the slave as its terminal device. *script* runs in a child process with the pseudo-tty master as its standard input and output. An explicit device name may not be given if this option is used. (Note: if the `record` option is used in conjunction with the `pty` option, the child process will have pipes on its standard input and output.)

`receive-all`
With this option, `pppd` accepts all control characters from the peer, including those marked in the receive `asyncmap`. Without this option, `pppd` discards those characters as specified in *RFC 1662*. This option should be used only if the peer has bugs, as is often found with dial-back implementations.

`record` *filename*
Directs `pppd` to record all characters sent and received to a file named *filename*. *filename* is opened in append mode, using the user's user-ID and permissions. Because this option uses a pseudo-tty and a process to transfer characters between the pseudo-tty and the real serial device, it increases the latency and CPU overhead of transferring data over the PPP interface. Characters are stored in a tagged format with timestamps that can be displayed in readable form using the `pppdump`(1M) program. This option is generally used when debugging the kernel portion of `pppd` (especially CCP compression algorithms) and not for debugging link configuration problems. See the `debug` option.

`remotename` *name*
Set the assumed name of the remote system for authentication purposes to *name*. Microsoft WindowsNT does not provide a system name in its CHAP Challenge messages, and this option is often used to work around this problem.

`refuse-chap`
With this option, `pppd` will not agree to authenticate itself to the peer using standard Challenge Handshake Authentication Protocol (CHAP). (MS-CHAP is not affected.)

`refuse-mschap`
Do not agree to authenticate to peer with MS-CHAPv1. If this option is specified, requests for MS-CHAPv1 authentication from the peer are declined with LCP Configure-Nak. That option does not disable any other form of CHAP.

`refuse-mschapv2`
Do not agree to authenticate to peer with MS-CHAPv2. If specified, this option requests that MS-CHAPv2 authentication from the peer be declined with LCP Configure-Nak. That option does not disable any other form of CHAP.

`refuse-pap`
With this option, `pppd` will not agree to authenticate itself to the peer using Password Authentication Protocol (PAP).

`require-chap`
Require the peer to authenticate itself using standard CHAP authentication. MS-CHAP is not affected.

`require-mschap`
Require the peer to authenticate itself using MS-CHAPv1 authentication.

`require-mschapv2`
Require the peer to authenticate itself using MS-CHAPv2 authentication.

`require-pap`
Require the peer to authenticate itself using PAP authentication.

`show-password`
When logging contents of PAP packets, this option causes `pppd` to show the password string in the log message.

`silent`
With this option, `pppd` will not transmit LCP packets to initiate a connection until a valid LCP packet is received from the peer. This is like the "passive" option with older versions of `pppd` and is retained for compatibility, but the current `passive` option is preferred.

`small-accm-test`
When checking the `asyncmap` (ACCM) setting, `pppd` uses all 256 possible values by default. See `no-accm-test`. This option restricts the test so that only the 32 values affected by standard ACCM negotiation are tested. This option is useful on very slow links.

`socket` *host*:*port*
Connect to given host and port using TCP and run PPP over this connection.

`sync`
Use synchronous HDLC serial encoding instead of asynchronous. The device used by `pppd` with this option must have sync support. Currently supports `zs`, `se`, and `hsi` drivers.

`unit` *n*
Set PPP interface unit number to *n*, if possible.

`updetach`
With this option, `pppd` detaches from its controlling terminal after establishing the PPP connection. When this is specified, messages sent to `stderr` by the connect script, usually `chat(1M)`, and debugging messages from the debug option are directed to `pppd`'s standard output.

`usehostname`
Enforce the use of the hostname with domain name appended, if given, as the name of the local system for authentication purposes. This overrides the `name` option. Because the `name` option is privileged, this option is normally not needed.

`usepeerdns`
Ask the peer for up to two DNS server addresses. Addresses supplied by the peer, if any, are passed to the `/etc/ppp/ip-up` script in the environment variables DNS1 and DNS2. In addition, `pppd` creates an `/etc/ppp/resolv.conf` file containing one or two nameserver lines with the address(es) supplied by the peer.

`user` *name*
Sets the name used for authenticating the local system to the peer to *name*.

`vj-max-slots` *n*
Sets the number of connection slots to be used by the Van Jacobson TCP/IP header compression and decompression code to *n*, which must be between 2 and 16 (inclusive).

`welcome` *script*
Run the executable or shell command specified by *script* before initiating PPP negotiation, after the connect script, if any, has completed. A value for this option from a privileged source cannot be overridden by a non-privileged user.

`xonxoff`
Use software flow control, that is, XON/XOFF, to control the flow of data on the serial port.

Obsolete Options

The following options are obsolete:

`+ua` *name* Read a PAP user name and password from the file *name*. This file must have two lines for name and password. Name and password are sent to the peer when the peer requests PAP authentication.

`+ipv6` Enable IPv6 and IPv6CP without specifying interface identifiers.

`--version` Show version number and exit.

`--help` Show brief help message and exit.

Extended Description

The following sections discuss miscellaneous features of `pppd`:

Security

`pppd` allows system administrators to provide legitimate users with PPP access to a server machine without fear of compromising the security of the server or the network it runs on. Access control is provided by restricting IP addresses the peer may use based on its authenticated identity (if any), and through restrictions on options a non-privileged user may use. Options that permit potentially insecure configurations are privileged. Privileged options are accepted only in files that are under the control of the system administrator or when `pppd` is being run by root.

By default, `pppd` allows an unauthenticated peer to use a given IP address only if the system does not already have a route to that IP address. For example, a system with a permanent connection to the wider Internet will normally have a default route, meaning all peers must authenticate themselves to set up a connection. On such a system, the `auth` option is the default. Conversely, a system with a PPP link that comprises the only connection to the Internet probably does not possess a default route, so the peer can use virtually any IP address without authenticating itself.

Security-sensitive options are privileged and cannot be accessed by a non-privileged user running `pppd`, either on the command line, in the user's `$HOME/.pprc` file, or in an options file read using the `file` option. Privileged options may be used in `/etc/ppp/options` file or in an options file read using the `call` option. If `pppd` is run by the root user, privileged options can be used without restriction. If the `/etc/ppp/options` file does not exist, then only root may invoke `pppd`. The `/etc/ppp/options` file must be created (but may be empty) to allow ordinary non-root users to access `pppd`.

When opening the device, `pppd` uses the invoking user's user ID or the root UID (that is, 0), depending if the device name was specified by the user or the system administrator. If the device name comes from a privileged source, that is, `/etc/ppp/options` or an options file read using the `call` option, `pppd` uses full root privileges when opening the device. Thus, by creating an appropriate file under `/etc/ppp/peers`, the system administrator can allow users

to establish a PPP connection via a device that they would not normally have access to. Otherwise pppd uses the invoking user's real UID when opening the device.

Authentication

During the authentication process, one peer convinces the other of its identity by sending its name and some secret information to the other. During authentication, the first peer becomes the "client" and the second becomes the "server." Authentication names can (but are not required to) correspond to the peer's Internet hostnames.

pppd supports four authentication protocols: the Password Authentication Protocol (PAP) and three forms of the Challenge Handshake Authentication Protocol (CHAP). With the PAP protocol, the client sends its name and a cleartext password to the server to authenticate itself. With CHAP, the server initiates the authentication exchange by sending a challenge to the client who must respond with its name and a hash value derived from the shared secret and the challenge.

The PPP protocol is symmetrical, meaning that each peer may be required to authenticate itself to the other. Different authentication protocols and names can be used for each exchange.

By default, pppd authenticates if requested and does not require authentication from the peer. However, pppd does not authenticate itself with a specific protocol if it has no secrets that can do so.

pppd stores authentication secrets in the /etc/ppp/pap-secrets (for PAP), and /etc/ppp/chap-secrets (for CHAP) files. Both files use the same format. pppd uses secrets files to authenticate itself to other systems and to authenticate other systems to itself.

Secrets files contain one secret per line. Secrets are specific to a particular combination of client and server and can only be used by that client to authenticate itself to that server. Each line in a secrets file has a minimum of three fields that contain the client and server names followed by the secret. Often, these three fields are followed by IP addresses that are used by clients to connect to a server.

A secrets file is parsed into words, with client name, server name and secrets fields allocated one word each. Embedded spaces or other special characters within a word must be quoted or escaped. Case is significant in all three fields.

A secret beginning with an at sign (“@”) is followed by the name of a file containing the secret. An asterisk (*) as the client or server name matches any name. When choosing a match, pppd selects the one with the fewest wildcards. Succeeding words on a line are interpreted by pppd as acceptable IP addresses for that client. IP Addresses are disallowed if they appear in lines that contain only three words or lines whose first word begins with a hyphen (“-”). To allow any address, use "*". An address starting with an exclamation point (”!”) indicates that the specified address is not acceptable. An address may be followed by "/" and a number *n* to indicate a whole subnet (all addresses that have the same value in the most significant *n* bits).

In this form, the address may be followed by a plus sign ("+") to indicate that one address from the subnet is authorized, based on the ppp network interface unit number in use. In this case, the host part of the address is set to the unit number, plus one.

When authenticating the peer, `pppd` chooses a secret with the peer's name in the first field of the secrets file and the name of the local system in the second field. The local system name defaults to the hostname, with the domain name appended if the `domain` option is used. The default can be overridden with the `name` option unless the `usehostname` option is used.

When authenticating to the peer, `pppd` first determines the name it will use to identify itself to the peer. This name is specified with the `user` option. If the `user` option is not used, the name defaults to the host name of the local system. `pppd` then selects a secret from the secrets file by searching for an entry with a local name in the first field and the peer's name in the second field. `pppd` will know the name of the peer if standard CHAP authentication is used because the peer will have sent it in the Challenge packet. However, if MS-CHAP or PAP is being used, `pppd` must determine the peer's name from the options specified by the user. The user can specify the peer's name directly with the `remotename` option. Otherwise, if the remote IP address was specified by a name, rather than in numeric form, that name will be used as the peer's name. If that fails, `pppd` uses the null string as the peer's name.

When authenticating the peer with PAP, the supplied password is compared with data in the secrets file. If the password and secret do not match, the password is encrypted using `crypt()` and checked against the secret again. If the `papcrypt` option is given, the first unencrypted comparison is omitted for better security, and entries must thus be in encrypted `crypt(3C)` form.

If the `login` option is specified, the username and password are also checked against the system password database. This allows you to set up the `pap-secrets` file to enable PPP access only to certain users, and to restrict the set of IP addresses available to users. Typically, when using the `login` option, the secret in `/etc/ppp/pap-secrets` would be "", which matches any password supplied by the peer. This makes having the same secret in two places unnecessary. When `login` is used, the `pam` option enables access control through `pam(3PAM)`.

Authentication must be completed before IPCP (or other network protocol) can be started. If the peer is required to authenticate itself and fails, `pppd` closes LCP and terminates the link. If IPCP negotiates an unacceptable IP address for the remote host, IPCP is closed. IP packets are sent or received only when IPCP is open.

To allow hosts that cannot authenticate themselves to connect and use one of a restricted set of IP addresses, add a line to the `pap-secrets` file specifying the empty string for the client name and secret.

Additional `pppd` options for a given peer may be specified by placing them at the end of the secrets entry, separated by two dashes (––). For example

```
peername servername secret ip-address -- novj
```

Routing When IPCP negotiation is complete, pppd informs the kernel of the local and remote IP addresses for the PPP interface and creates a host route to the remote end of the link that enables peers to exchange IP packets. Communication with other machines generally requires further modification to routing tables and/or Address Resolution Protocol (ARP) tables. In most cases the defaultroute and/or proxyarp options are sufficient for this, but further intervention may be necessary. If further intervention is required, use the /etc/ppp/ip-up script or a routing protocol daemon.

To add a default route through the remote host, use the defaultroute option. This option is typically used for "client" systems; that is, end-nodes that use the PPP link for access to the general Internet.

In some cases it is desirable to use proxy ARP, for example on a server machine connected to a LAN, to allow other hosts to communicate with the remote host. proxyarp instructs pppd to look for a network interface on the same subnet as the remote host. That is, an interface supporting broadcast and ARP that is not a point-to-point or loopback interface and that is currently up. If found, pppd creates a permanent, published ARP entry with the IP address of the remote host and the hardware address of the network interface.

When the demand option is used, the interface IP addresses are already set at the time when IPCP comes up. If pppd cannot negotiate the same addresses it used to configure the interface, it changes the interface IP addresses to the negotiated addresses. This may disrupt existing connections. Using demand dialing with peers that perform dynamic IP address assignment is not recommended.

Scripts pppd invokes scripts at various stages during processing that are used to perform site-specific ancillary processing. These scripts may be shell scripts or executable programs. pppd does not wait for the scripts to finish. The scripts are executed as root (with the real and effective user-id set to 0), enabling them to update routing tables, run privileged daemons, or perform other tasks. Be sure that the contents of these scripts do not compromise your system's security. pppd runs the scripts with standard input, output and error redirected to /dev/null, and with an environment that is empty except for some environment variables that give information about the link. The pppd environment variables are:

DEVICE	Name of the serial tty device.
IFNAME	Name of the network interface.
IPLOCAL	IP address for the link's local end. This is set only when IPCP has started.
IPREMOTE	IP address for the link's remote end. This is set only when IPCP has started.
PEERNAME	Authenticated name of the peer. This is set only if the peer authenticates itself.
SPEED	Baud rate of the tty device.
ORIG_UID	Real user-id of user who invoked pppd.

PPPLOGNAME Username of the real user-id who invoked pppd. This is always set.

pppd also sets the following variables for the ip-down and auth-down scripts:

CONNECT_TIME Number of seconds between the start of PPP negotiation and connection termination.

BYTES_SENT Number of bytes sent at the level of the serial port during the connection.

BYTES_RCVD Number of bytes received at the level of the serial port during the connection.

LINKNAME Logical name of the link, set with the linkname option.

If they exist, pppd invokes the following scripts. It is not an error if they do not exist.

/etc/ppp/auth-up Program or script executed after the remote system successfully authenticates itself. It is executed with five command-line arguments: interface-name peer-name user-name tty-device speed. Note that this script is not executed if the peer does not authenticate itself, for example, when the noauth option is used.

/etc/ppp/auth-down Program or script executed when the link goes down if /etc/ppp/auth-up was previously executed. It is executed in the same manner with the same parameters as /etc/ppp/auth-up.

/etc/ppp/ip-up A program or script that is executed when the link is available for sending and receiving IP packets (that is, IPCP has come up). It is executed with six command-line arguments: interface-name tty-device speed local-IP-address remote-IP-address ipparam.

/etc/ppp/ip-down A program or script which is executed when the link is no longer available for sending and receiving IP packets. This script can be used for undoing the effects of the /etc/ppp/ip-up script. It is invoked in the same manner and with the same parameters as the ip-up script.

/etc/ppp/ipv6-up Similar to /etc/ppp/ip-up, except that it is executed when the link is available for sending and receiving IPv6 packets. Executed with six command-line arguments: interface-name tty-device speed local-link-local-address remote-link-local-address ipparam.

/etc/ppp/ipv6-down Similar to /etc/ppp/ip-down, but executed when IPv6 packets can no longer be transmitted on the link. Executed with the same parameters as the ipv6-up script.

Examples

EXAMPLE 1 Using the auth Option

The following examples assume that the /etc/ppp/options file contains the auth option.

EXAMPLE 1 Using the auth Option *(Continued)*

pppd is commonly used to dial out to an ISP. You can do this using the "pppd call isp" command where the /etc/ppp/peers/isp file is set up to contain a line similar to the following:

```
cua/a 19200 crtscts connect '/usr/bin/chat -f /etc/ppp/chat-isp' noauth
```

For this example, chat(1M) is used to dial the ISP's modem and process any login sequence required. The /etc/ppp/chat-isp file is used by chat and could contain the following:

```
ABORT "NO CARRIER"
ABORT "NO DIALTONE"
ABORT "ERROR"
ABORT "NO ANSWER"
ABORT "BUSY"
ABORT "Username/Password Incorrect"
"" "at"
OK "at&f&d2&c1"
OK "atdt2468135"
"name:" "^Umyuserid"
"word:" "\qmypassword"
"ispts" "\q^Uppp"
"~-^Uppp-~"
```

See the chat(1M) man page for details of chat scripts.

EXAMPLE 2 Using pppd with proxyarp

pppd can also provide a dial-in ppp service for users. If the users already have login accounts, the simplest way to set up the ppp service is to let the users log in to their accounts and run pppd as shown in the following example:

```
example% pppd proxyarp
```

EXAMPLE 3 Providing a User with Access to PPP Facilities

To provide a user with access to the PPP facilities, allocate an IP address for the user's machine, create an entry in /etc/ppp/pap-secrets or /etc/ppp/chap-secrets. This enables the user's machine to authenticate itself. For example, to enable user "Joe" using machine "joespc" to dial in to machine "server" and use the IP address "joespc.my.net," add the following entry to the /etc/ppp/pap-secrets or /etc/ppp/chap-secrets files:

```
joespc    server    "joe's secret"    joespc.my.net
```

Alternatively, you can create another username, for example "ppp," whose login shell is /usr/bin/pppd and whose home directory is /etc/ppp. If you run pppd this way, add the options to the /etc/ppp/.ppprc file.

EXAMPLE 3 Providing a User with Access to PPP Facilities *(Continued)*

If your serial connection is complex, it may be useful to escape such control characters as XON (^Q) and XOFF (^S), using `asyncmap a0000`. If the path includes a telnet, escape ^] (`asyncmap 200a0000`). If the path includes a `rlogin` command, add `escape ff` option to the options, because `rlogin` removes the window-size-change sequence [0xff, 0xff, 0x73, 0x73, followed by any 8 bytes] from the stream.

Exit Status The `pppd` exit status indicates errors or specifies why a link was terminated. Exit status values are:

`0` `pppd` has detached or the connection was successfully established and terminated at the peer's request.

`1` An immediately fatal error occurred. For example, an essential system call failed.

`2` An error was detected in the options given. For example, two mutually exclusive options were used, or `/etc/ppp/options` is missing and the user is not root.

`3` `pppd` is not `setuid-root` and the invoking user is not root.

`4` The kernel does not support PPP. For example, the PPP kernel driver is not included or cannot be loaded.

`5` `pppd` terminated because it was sent a SIGINT, SIGTERM or SIGHUP signal.

`6` The serial port could not be locked.

`7` The serial port could not be opened.

`8` The connect script failed and returned a non-zero exit status.

`9` The command specified as the argument to the `pty` option could not be run.

`10` The PPP negotiation failed because no network protocols were able to run.

`11` The peer system failed or refused to authenticate itself.

`12` The link was established successfully, but terminated because it was idle.

`13` The link was established successfully, but terminated because the connect time limit was reached.

`14` Callback was negotiated and an incoming call should arrive shortly.

`15` The link was terminated because the peer is not responding to echo requests.

`16` The link was terminated by the modem hanging up.

`17` The PPP negotiation failed because serial loopback was detected.

`18` The init script failed because a non-zero exit status was returned.

`19` Authentication to the peer failed.

Files

`/var/run/spppn.pid`	Process-ID for `pppd` process on PPP interface unit *n*.
`/var/run/ppp-`*name*`.pid`	Process-ID for `pppd` process for logical link name (see the `linkname` option).
`/etc/ppp/pap-secrets`	Usernames, passwords and IP addresses for PAP authentication. This file should be owned by root and not readable or writable by any other user, otherwise `pppd` will log a warning.
`/etc/ppp/chap-secrets`	Names, secrets and IP addresses for all forms of CHAP authentication. The `/etc/ppp/pap-secrets` file should be owned by `root` should not readable or writable by any other user, otherwise, `pppd` will log a warning.
`/etc/ppp/options`	System default options for `pppd`, read before user default options or command-line options.
`$HOME/.ppprc`	User default options, read before `/etc/ppp/options.`*ttyname*.
`/etc/ppp/options.`*ttyname*	System default options for the serial port in use; read after `$HOME/.ppprc`. The *ttyname* component of this filename is formed when the initial `/dev/` is stripped from the port name (if present), and slashes (if any) are converted to dots.
`/etc/ppp/peers`	Directory with options files that may contain privileged options, even if `pppd` was invoked by a user other than `root`. The system administrator can create options files in this directory to permit non-privileged users to dial out without requiring the peer to authenticate, but only to certain trusted peers.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpppdu

Simpson, W. *RFC 1662, HDLC-like Framing* . Network Working Group. July 1994.

Notes These signals affect `pppd` behavior:

`SIGINT, SIGTERM`	Terminate the link, restore the serial device settings and exit.
`SIGHUP`	Terminate the link, restore the serial device settings and close the serial device. If the `persist` or `demand` option is specified, `pppd` attempts to reopen the serial device and start another connection after the holdoff period. Otherwise `pppd` exits. If received during the holdoff period, `SIGHUP` causes `pppd` to end the holdoff period immediately.
`SIGUSR1`	Toggles the state of the `debug` option and prints link status information to the log.
`SIGUSR2`	Causes `pppd` to renegotiate compression. This is useful to re-enable compression after it has been disabled as a result of a fatal decompression error. (Fatal decompression errors generally indicate a bug in an implementation.)

Diagnostics Messages are sent to the syslog daemon using facility `LOG_DAEMON`. To see error and debug messages, edit the `/etc/syslog.conf` file to direct the messages to the desired output device or file, or use the `updetach` or `logfile` options.

The `debug` option causes the contents of all LCP, PAP, CHAP or IPCP control packets sent or received to be logged. This is useful if PPP negotiation does not succeed or if authentication fails.

Debugging can also be enabled or disabled by sending a `SIGUSR1` signal, which acts as a toggle to the `pppd` process.

Name pppoec – PPPoE chat utility

Synopsis

```
pppoec [-omillisecs] [-smillisecs] [-v] device
     [service [ [except]server... [only]]]

pppoec [-omillisecs] [-v] -i [device]
```

Description The `pppoec` utility implements the client-side negotiation of PPPoE. It is intended to be used with the `pppd(1M)` `connect` option, in the same manner as the `chat(1M)` utility is used for asynchronous dial-up PPP.

When given with the `-i` flag, `pppoec` sends out a broadcast query on the given interface named by the *device* parameter. You can specify no other arguments in this mode. All responding PPPoE servers and the offered services are displayed on standard output.

Otherwise, when given without the `-i` flag, `pppoec` does the full PPPoE client-side negotiation. The *device* parameter is the intended Ethernet interface, and must already be plumbed with `sppptun(1M)`. The optional *service* parameter specifies a particular service desired; other offered services will be ignored. The optional *server* parameter specifies a specific server desired. You can specify *server* as an Ethernet address in the usual x:x:x:x:x:x format (with "*" in any of the six byte positions interpreted to mean "any"), or as a symbolic name resolved through `/etc/ethers` (or NIS), or as a PPPoE access concentrator name. The sense of the match (true or false) can be inverted by specifying the keyword `except` before this string. This parameter can be specified more than once, and the first match is taken.

If you specify the *server* parameter, then the selected servers become "preferred." If no preferred server responds, then the first responding server is used instead. To exclude non-matching servers entirely, append the keyword `only`.

Options The following options are supported:

`-i` Sends out broadcast query over interface specified by *device*.

`-o` Sets the initial wait time in milliseconds for PADO from the server before PADI is retried. The default is 500 milliseconds for normal operation, or 3000 milliseconds (3 seconds) for inquiry (`-i`) mode.

`-s` Sets the initial wait time in milliseconds for PADS from the server before PADR is retried. The default is 2000 milliseconds (2 seconds).

`-v` Displays verbose progress messages, including all PPPoE messages sent, and all state machine transitions.

You normally do not need to adjust the parameters set with `-o` and `-s`. They are provided for coping with unusually slow servers.

Operands The following operands are supported:

device plumbed Ethernet interface

server preferred server or, if you specify `only`, the specified server

service desired service; other available services are ignored

Examples

EXAMPLE 1 Connecting to Any Service on `hme0`

The following command enables you to connect to any PPPoE service on `hme0`:

```
# /usr/bin/pppd sppptun plugin pppoe.so \
connect "/usr/lib/inet/pppoec hme0" debug
```

Often, a command such as the preceding is specified in an `/etc/ppp/peers` file instead. For example, enter the following in `/etc/ppp/peers/myisp`:

```
sppptun
plugin pppoe.so
connect "/usr/lib/inet/pppoec hme0"
debug
```

To invoke the PPP connection described in the file, enter:

```
% /usr/bin/pppd call myisp
```

Note that, because the `/etc/ppp/peers` files are considered privileged by `pppd`, you need not be root to invoke the preceding command.

EXAMPLE 2 Connecting to a Particular Service

A more complex example: on `hme0`, connect to only the `internet` service offered by PPPoE servers with access concentrator name `isp`, but not to any Ethernet addresses starting with `40:0:1a`.

```
# /usr/lib/inet/pppoec hme0 internet except 40:0:1a:*:*:* isp only
```

Note that the `except 40:0:1a:*:*:*` filter must come before `isp`, because the filters are first-match.

Exit Status

The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Files

`/usr/lib/inet/pppoec`	executable command
`/dev/sppptun`	Solaris PPP tunneling device driver.
`/etc/ppp/connect-errors`	usual location of error output (see DIAGNOSTICS, below)

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpppdt

See Also pppd(1M), sppptun(1M), pppoed(1M), sppptun(7M)

RFC 2516, Method for Transmitting PPP Over Ethernet (PPPoE), Mamakos et al, February 1999

Diagnostics Error messages are written to standard error, which is normally redirected by pppd to /etc/ppp/connect-errors. The errors can also be redirected to pppd's standard output by using the updetach option.

If you specify the -v, verbose progress messages are displayed, including all PPPoE messages sent, and all state machine transitions. Specifying the updetach or nodetach pppd option is helpful when using verbose mode.

Name pppoed – PPPoE server daemon

Synopsis `ppoed [`*options*`]`

Description The `pppoed` daemon implements the server-side negotiation of PPPoE. When a client requests service from this daemon, a copy of `pppd(1M)` is invoked to handle the actual PPP communication.

At startup, options are read from the command line and the `/etc/ppp/pppoe` file. After these options have been read, options in the per-device `/etc/ppp/pppoe.`*device* files are read, using the device names specified on the command line or in `/etc/ppp/pppoe`. Device names are not permitted in the per-device files. It is not an error if any of these files are absent; missing files are ignored.

Options are reread in the same order on `SIGHUP`. Except for the possibility of short delays due to the processing time, `SIGHUP` does not interfere with any client operations. Current status, including options read, is dumped to `/tmp/pppoed.`*pid* on `SIGINT`.

The options are used to set up a list of services to be offered to PPPoE clients on the broadcast domains (Ethernet subnets) specified by the named devices. Option parsing is always in one of two modes, either global mode or service mode. The initial mode at the beginning of each file (and the command line) is global mode. Options specified in global mode serve as default values for subsequently defined services. Service mode is entered by the `service` *name* option. In this mode, the named option is defined. Options that appear in this mode override any global mode definitions for the current service.

The option parsing follows standard shell tokenizing rules, using whitespace to delimit tokens, quotes to enclose strings that can contain whitespace, and escape sequences for special characters. Environment variables are substituted using familiar `$VAR` and `${VAR}` syntax and set using `NEWVAR=`*string*. Variables are both usable in subsequent options and provided to the `pppd(1M)` processes spawned for each client, but they are interpreted as they are encountered during option processing. Thus, all set variables are seen by all processes spawned; position in the configuration files has no effect on this.

Options The `pppoed` daemon supports the following options:

`client [except]` *client-list* This option restricts the clients that may receive the service. If the `except` keyword is given, then the clients on the list cannot access the service, but others can. If this keyword is not given, then only the listed clients can access the service.

This option can be specified more than once for a given service. For a given client, first match among all listed options encountered specifies the handling. If it matches an option with `except` specified, then access is denied. Otherwise, it is granted. The `client` list within a service is prepended to any list specified in the global context.

If no `client` options are given or if all options are specified with `except`, then all clients are permitted by default. If any `client` options without `except` are specified, then no clients are permitted by default.

The *client-list* is a comma-separated list of client identifiers. The match is made if any client on the list matches; thus, these are logically "ORed" together. Each client identifier can be either a symbolic name (resolved through `/etc/ethers` or NIS, as defined by `/etc/nsswitch.conf`) or a hexadecimal Ethernet address in the format `x:x:x:x:x:x`. In the latter case, any byte of the address can be "*", which matches any value in that position. For example, `40:0:1a:*:*:*` matches Ethernet adapters from the manufacturer assigned block `40:0:1a`.

`debug`

Increase debug logging detail level by one. The detail levels are 0 (no logging), 1 (errors only; the default), 2 (warnings), 3 (informational messages), and 4 (debug messages). Log messages are written by default to `syslog(3C)` using facility *daemon* (see the `log` option below). When specified on the command line or in the global context of the `/etc/ppp/pppoe` file, this option also sets the daemon's default (non-service-related) detail level.

`device` *device-list*

Specify the devices on which the service is available. The *device-list* is a comma-separated list of logical device names (without the leading `/dev/`), such as `hme0`. This option is ignored if encountered in the per-device `/etc/ppp/pppoe.`*device* files.

`extra` *string*

Specifies extra options to `pppd(1M)`. It defaults to "`plugin pppoe.so directtty`" and usually does not need to be overridden.

`file` *path*

Suspends parsing of the current file, returns to global mode, and reads options from *path*. This file must be present and readable; if it is not, an error is logged. When the end of that file is reached, processing returns to the current file and the mode is reset to global again.

The global mode options specified in files read by this command use the options set in the current file's global mode; this condition extends to any file included by those files. All files read are parsed as though the command line had specified this option, and thus inherit the command line's global modes.

This option can be used to revert to global mode at any point in an option file by specifying `file /dev/null`.

`group` *name*
: Specifies the group ID (symbolic or numeric) under which `pppd` is executed. If `pppoed` is not run as root, this option is ignored.

`log` *path*
: Specifies an alternate debug logging file. Debug messages are sent to this file instead of `syslog`. The special name `syslog` is recognized to switch logging back to `syslog`. When specified on the command line or in the global context of the `/etc/ppp/pppoe` file, this option also sets the daemon's default (non-service-related) log file.

`nodebug`
: Set debug logging detail level to 0 (no logging). When specified on the command line or in the global context of the `/etc/ppp/pppoe` file, this option also sets the daemon's default (non-service-related) detail level.

`nowildcard`
: Specifies that the current service should not be included in response to clients requesting "any" service. The client must ask for this service by name. When specified on the command line or in the global context of the `/etc/ppp/pppoe` file, this option causes `pppoed` to ignore all wildcard service requests.

`path` *path*
: Specifies the path to the `pppd` executable. Defaults to `/usr/bin/pppd`.

`pppd` *string*
: Passes command-line arguments to `pppd`. It can be used to set the IP addresses or configure security for the session. The default value is the empty string.

`server` *string*
: Specifies the PPPoE Access Concentrator name to be sent to the client. It defaults to "Solaris PPPoE".

`service` *name*
: Closes any service being defined and begins definition of a new service. The same service name can be used without conflict on multiple devices. If the same service name is used on a single device, then the last definition encountered during parsing overrides all previous definitions.

`user` *name*
: Specifies the user ID, symbolic or numeric, under which `pppd` is executed. If `pppoed` is not run as root, this option is ignored.

`wildcard`
: Specifies that the service should be included in responses to client queries that request "any" service, which is done by requesting a service name of length zero. When specified on the command line or in the global context of the

/etc/ppp/pppoe file, this option causes pppoed to ignore all wildcard service requests. This is the default.

Examples

EXAMPLE 1 Configuring for Particular Services

In the /etc/ppp/pppoe file:

```
service internet
    device $DEV
    pppd "proxyarp 192.168.1.1:"
service debugging
    device hme0,$DEV
    pppd "debug proxyarp 192.168.1.1:"
```

You then invoke the daemon with:

```
example% /usr/lib/inet/pppoed DEV=eri0
```

The lines in /etc/ppp/pppoe and the preceding command result in offering services "internet" and "debugging" (and responding to wildcard queries) on interface eri0, and offering only service "debugging" on interface hme0.

Signals

The pppoed daemon responds to the following signals:

SIGHUP — Causes pppoed to reparse the original command line and all configuration files, and close and reopen any log files.

SIGINT — Causes a snapshot of the state of the pppoed daemon to be written to /tmp/pppoed.*pid* (where *pid* is the decimal process ID of the daemon).

Files

/usr/lib/inet/pppoed	executable command
/dev/sppptun	Solaris PPP tunneling device driver
/etc/ppp/pppoe	main configuration option file
/etc/ppp/pppoe.*device*	per–device configuration option file
/etc/ppp/pppoe-errors	location of output from pppd's stderr
/etc/ppp/pppoe.if	list of Ethernet interfaces to be plumbed at boot time
/tmp/pppoed.*pid*	ASCII text file containing dumped pppoed state information

Attributes

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpppdt

See Also pppd(1M), pppoec(1M), sppptun(1M), sppptun(7M)

Mamakos, L., et al. *RFC 2516, A Method for Transmitting PPP Over Ethernet (PPPoE)*. Network Working Group. February 1999

Notes Because `pppd` is installed setuid root, this daemon need not be run as root. However, if it is not run as root, the `user` and `group` options are ignored.

The Ethernet interfaces to be used must be plumbed for PPPoE using the sppptun(1M) utility before services can be offered.

The daemon operate runs even if there are no services to offer. If you want to modify a configuration, it is not necessary to terminate the daemon. Simply use `pkill -HUP pppoed` after updating the configuration files.

The PPPoE protocol is far from perfect. Because it runs directly over Ethernet, there is no possibility of security and the MTU is limited to 1492 (violating RFC 1661's default value of 1500). It is also not possible to run the client and the server of a given session on a single machine with a single Ethernet interface for testing purposes. The client and server portions of a single session must be run on separate Ethernet interfaces with different MAC addresses.

Name pppstats – print PPP statistics

Synopsis

```
pppstats [-a] [-v] [-r] [-z] [-c <count>] [-w <secs>]
     [interface]
```

Description The `pppstats` utility reports PPP-related statistics at regular intervals for the specified PPP interface. If the interface is unspecified, `pppstats` defaults to `sppp0`. The display is split horizontally into input and output sections containing columns of statistics describing the properties and volume of packets received and transmitted by the interface.

Options The `pppstats` options are:

`-a` Display absolute values rather than deltas. With this option, all reports show statistics for the time elapsed since the link was initiated. Without this option, the second and subsequent reports show statistics for the time since the last report.

`-c` *count* Repeat the display *count* times. If this option is not specified, the default repeat count is 1 if the `-w` option is not specified, otherwise infinity.

`-r` Display additional statistics summarizing the compression ratio achieved by the packet compression algorithm in use.

`-v` Display additional statistics relating to the performance of the Van Jacobson TCP header compression algorithm.

`-w` *wait* Pause *wait* seconds between each display. If this option is not specified, the default interval is five seconds.

`-z` Instead of the standard display, show statistics indicating the performance of the packet compression algorithm in use.

Extended Description The following fields are printed on the input side when the `-z` option is not used:

`IN` Total number of bytes received by this interface.

`PACK` Total number of packets received by this interface.

`VJCOMP` Number of header-compressed TCP packets received by this interface.

`VJUNC` Number of header-uncompressed TCP packets received by this interface. Not reported when the `-r` option is specified.

`VJERR` Number of corrupted or bogus header-compressed TCP packets received by this interface. Not reported when the `-r` option is specified.

`VJTOSS` Number of VJ header-compressed TCP packets dropped on reception by this interface because of preceding errors. Only reported when the `-v` option is specified.

`NON-VJ` Total number of non-TCP packets received by this interface. Only reported when the `-v` option is specified.

RATIO Compression ratio achieved for received packets by the packet compression scheme in use, defined as the uncompressed size divided by the compressed size. Only reported when the -r option is specified.

UBYTE Total number of bytes received, after decompression of compressed packets. Only reported when the -r option is specified.

The following fields are printed on the output side:

OUT Total number of bytes transmitted from this interface.

PACK Total number of packets transmitted from this interface.

VJCOMP Number of TCP packets transmitted from this interface with VJ-compressed TCP headers.

VJUNC Number of TCP packets transmitted from this interface with VJ-uncompressed TCP headers. Not reported when the -r option is specified.

NON-VJ Total number of non-TCP packets transmitted from this interface. Not reported when the -r option is specified.

VJSRCH Number of searches for the cached header entry for a VJ header compressed TCP packet. Only reported when the -v option is specified.

VJMISS Number of failed searches for the cached header entry for a VJ header compressed TCP packet. Only reported when the -v option is specified.

RATIO Compression ratio achieved for transmitted packets by the packet compression scheme in use, defined as the size before compression divided by the compressed size. Only reported when the -r option is specified.

UBYTE Total number of bytes to be transmitted before packet compression is applied. Only reported when the -r option is specified.

When the -z option is specified, pppstats displays the following fields relating to the packet compression algorithm currently in use. If packet compression is not in use, these fields display zeroes. The fields displayed on the input side are:

COMPRESSED BYTE Number of bytes of compressed packets received.

COMPRESSED PACK Number of compressed packets received.

INCOMPRESSIBLE BYTE Number of bytes of incompressible packets (that is, those which were transmitted in uncompressed form) received.

INCOMPRESSIBLE PACK Number of incompressible packets received.

COMP RATIO Recent compression ratio for incoming packets, defined as the uncompressed size divided by the compressed size (including both compressible and incompressible packets).

The fields displayed on the output side are:

`COMPRESSED BYTE`	Number of bytes of compressed packets transmitted.
`COMPRESSED PACK`	Number of compressed packets transmitted.
`INCOMPRESSIBLE BYTE`	Number of bytes of incompressible packets received; that is, those that were transmitted by the peer in uncompressed form.
`INCOMPRESSIBLE PACK`	Number of incompressible packets transmitted.
`COMP RATIO`	Recent compression ratio for outgoing packets.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Interface Stability	Evolving

See Also `pppd(1M)`, `attributes(5)`

Name pprosetup – setup program for Patch Manager

Synopsis

```
/usr/sbin/pprosetup [-a admin-email-addr] [-b backout-dir]
     [-c config-name] [-C] [-d patch-dir]
     [ [-D | -M day-of-month | -W day-of-week] [-s hh:mm]]
     [-h] [-H] [-i [none | patch-property-list]] [-L]
     [-p [none | standard]] [-P patch-source-url]
     [-q sequester-dir] [-u user-name]
     [-U proxy-user-name] [-x [host:port]]
```

Description **Note –** This command is deprecated. Use the `smpatch set`, `smpatch unset`, and `smpatch get` commands instead. See the `smpatch(1M)` man page.

Use the `pprosetup` command, as superuser, to configure your patch management environment by doing the following:

- Scheduling the patch operations
- Setting a patch policy
- Specifying patch directories
- Specifying the hardware on the system
- Specifying alternate configurations

Scheduling the Patch Operations

Schedule the automatic synchronization of patches with Sun's patch base. This scheduling makes the `pprosvc` command run in *automatic mode*. This mode is set up by using the `cron` interface. Use the `-C`, `-D`, `-M`, `-s`, and `-W` options to perform the scheduling tasks.

If you do not want to schedule patch operations, you can run the `pprosvc` and `smpatch` commands in *manual mode*, which means running the tool from the command line.

Note that midnight is represented as 00:00.

Note – The `smpatch` command does not directly support this mechanism for scheduling patch operations. You can set up a schedule by using `cron` to run `smpatch` in local mode. See the `smpatch(1M)` man page.

Setting a Patch Policy

Patches are classified as being standard or nonstandard. A *standard patch* can be applied by `pprosvc` in automatic mode. Such a patch is associated with the `standard` patch property. A *nonstandard patch* is one that has one of the following characteristics:

- A patch that is associated with the `rebootafter`, `rebootimmediate`, `reconfigafter`, `reconfigimmediate`, or `singleuser` properties. This nonstandard patch can be applied by running the `pprosvc` command or the `smpatch` command in manual mode.
- A patch that is associated with the `interactive` property. Such a patch cannot be applied by using the `smpatch` command.

Use `pprosetup` to schedule patch operations to run in *automatic mode*. Patches are applied based on the policy, which you can set by running `pprosetup`.

Use `pprosetup -p` to specify the types of patches to apply in automatic mode. You can set a policy to apply no patches (`none`) or standard patches (`standard`).

Use `pprosetup -i` to specify the types of patches to apply in *manual* mode. Such patches might include those that require a reboot and those that must be applied while the system is in single-user mode. Specify the types of patches that can be applied by using the following command:

```
# pprosetup -i patch-property-list
```

patch-property-list is a colon-separated list of one or more of the following patch properties:

`interactive`	A patch that cannot be applied by running the usual patch management tools (`pprosvc`, `smpatch`, or `patchadd`). Before this patch is applied, the user must perform special actions. Such actions might include checking the serial number of a disk drive, stopping a critical daemon, or reading the patch's README file.
`rebootafter`	The effects of this patch are not visible until after the system is rebooted.
`rebootimmediate`	When this patch is applied, the system becomes unstable until the system is rebooted. An unstable system is one in which the behavior is unpredictable and data might be lost.
`reconfigafter`	The effects of this patch are not visible until after a reconfiguration reboot (`boot -r`). See the `boot(1M)` man page.
`reconfigimmediate`	When this patch is applied, the system becomes unstable until the system gets a reconfiguration reboot (`boot -r`). An unstable system is one in which the behavior is unpredictable and data might be lost.
`singleuser`	Do not apply this patch while the system is in multiuser mode. You must apply this patch on a quiet system with no network traffic and with extremely restricted I/O activity.
`standard`	This patch can be applied while the system is in multiuser mode. The effects of the patch are visible as soon as it is applied unless the application being patched is running while the patch is applied. In this case, the effects of the patch are visible after the affected application is restarted.

Note – The `smpatch` command only supports the patch policy for manual mode.

Specifying Patch Directories

Use the following options to specify the directories in which to store patch-related data:

- Use the `-b` option to specify the directory in which to store backout data. During a patch backout operation, the data is retrieved from this directory to restore the system to its state prior to applying the patch.
- Use the `-d` option to specify the download directory in which to store patches that are downloaded from the Sun patch server. This directory is also the location from which patches are applied.

- Use the `-q` option to specify the directory in which to store patches that cannot be applied automatically. Such patches are called *sequestered patches*.

  Note – The sequester directory is not used by the `smpatch` command.

Specifying the Hardware on the System

Use the `-H` option to run a program that helps you determine the hardware that is attached to the host system, such as firmware, disk array systems, and tape storage systems.

Use this option to select the hardware that applies to this system. Select the sequence number of the specific hardware. A confirmation page lists the selections.

Save the specified hardware configuration information to a file. Then, the system responds by performing the appropriate actions.

Note – The `smpatch` command does not support this feature for specifying hardware on your system.

Specifying Alternate Configurations

The `pprosetup` command uses a configuration file to specify the collection of patches with which to perform patch operations. By default, all of the patches from the Sun patch server are available for patch operations.

The `-c` option enables you to specify an alternate configuration.

Sun currently provides one alternate configuration, which is called the `recommended` configuration. This configuration includes only those patches that have been declared significant. Such patches include security patches and patches that address known performance and availability problems.

You can use the `-c recommended` option when you schedule patch operations. For example, the following command schedules monthly patch operations that use the `recommended` configuration:

```
# pprosetup -c recommended -M 15 -s 23:30
```

To cancel a schedule that uses the `recommended` configuration, type:

```
# pprosetup -c recommended -C
```

You are permitted to modify the `recommended` configuration by using the `-c` option. See EXAMPLES.

Note – The `smpatch` command does not support this feature for specifying alternate configurations.

Options The following options are supported:

`-a` *admin-email-addr* Is the email address of the patch administrator. Email notification is sent to describe the patches downloaded, the

patches applied, and any error events that occurred when running the `pprosvc -i -n` command.

Note – This option does not affect the `smpatch` command.

`-b` *backout-dir*

Stores backout data in the specified directory.

The backout data is used whenever you use the `patchrm` command to remove a patch that has already been applied to your system. The data is used to restore a system to the state it was in before you applied a particular patch. Since backout data might be quite large, store the data in a large partition that holds large transitory data. Such a partition might be `/var`.

If you do not specify the `-b` option, the backout data is stored in the default locations used by `patchadd`. These locations are the `save` directories of the packages that were modified by the patch. For example, if a patch modifies the `SUNWcsr` package, the backout data for that package is stored in the `/var/sadm/pkg/SUNWcsr/save` directory.

To specify the backout directory, use the `smpatch set` command to set the `patchpro.backout.directory` parameter.

Note – The root file system of any non-global zones must not be referenced with the `-b` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.

`-C`

Clears the existing patch service schedule.

Note – This feature is not supported by the `smpatch` command.

`-c` *config-name*

Uses the *config-name* configuration for patch operations. When this option is included in any `pprosetup` command, the entire command applies to the specified configuration.

Note – This feature is not supported by the `smpatch` command.

`-d` *patch-dir*

Is the directory in which to download the patches that are appropriate for this host system. This directory is also the

location from which patches are applied. By default, the download directory is `/var/sadm/spool`.

Note – To specify the download directory, use the `smpatch set` command to set the `patchpro.download.directory` parameter.

`-D` Schedules the automatic analysis, download, and optional application of patches on a daily basis. This option is equivalent to executing the `pprosvc -i -n` command on a daily basis. See the `crontab(1)` man page.

The policy defined by the `-p` option determines whether no patches (`pprosetup -p none`) are applied or whether standard patches (`pprosetup -p standard`) are applied. By default, no patches are applied.

This option is mutually exclusive with the `-M` option and the `-W` option.

Note – This feature is not supported by the `smpatch` command.

`-h` Displays information about command-line options.

`-H` Establishes a dialog with the user to determine what hardware is attached to the host system.

Note – This feature is not supported by the `smpatch` command.

`-i` [`none` | *patch-property-list*] Specifies the policy for applying patches in manual mode.

No patches are applied when `none` is specified. *patch-property-list* is a colon-separated list of one or more of the following patch properties: `interactive`, `rebootafter`, `rebootimmediate`, `reconfigafter`, `reconfigimmediate`, `singleuser`, and `standard`. See Setting a Patch Policy.

Note – To specify the patch policy, use the `smpatch set` command to set the `patchpro.install.types` parameter.

`-L` Displays the configuration parameter settings of your patch management environment.

This option is mutually exclusive with the other options.

Note – To view the configuration parameter settings, use the `smpatch get` command.

`-M` *day-of-month*

Schedules the automatic analysis, download, and optional application of patches on a monthly basis.

The policy defined by the `-p` option determines whether no patches (`pprosetup -p none`) are applied or whether standard patches (`pprosetup -p standard`) are applied. By default, no patches are applied.

day-of-month is a numerical value from 1-28, which represents the day of the month. Note that the values 29, 30, and 31 are invalid. See the `crontab(1)` man page.

This option is mutually exclusive with the `-D` option and the `-W` option.

Note – This feature is not supported by the `smpatch` command.

`-p` [`none` | `standard`]

Specifies the policy for applying patches in automatic mode.

No patches are applied when `none`, the default, is specified.

When `standard` is specified, only standard patches are applied.

Note – This feature is not supported by the `smpatch` command.

`-P` *patch-source-url*

Is the URL that points to the collection of patches. The default is the Sun patch server, which has the following URL:

`https://updateserver.sun.com/solaris/`

Note – To specify the URL that points to the collection of patches, use the `smpatch set` command to set the `patchpro.patch.source` parameter.

`-q` *sequester-dir*

Is the directory in which patches are moved if they cannot be automatically applied. By default, the sequester directory is `/var/sadm/spool/patchproSequester`.

Note – The sequester directory is not used by the `smpatch` command.

`-s` *hh*`:`*mm*

Optionally sets the time of day to perform patch operations, which by default, is midnight local time.

hh is a value from 00-23, which specifies the hour. *mm* is a value from 00-59, which specifies the minute.

Use this option with the `-D`, `-M`, and `-W` options.

Note – This feature is not supported by the `smpatch` command.

`-u` *user-name*

Is the user name with which to obtain contract patches from Sun.

Store the corresponding SunSpectrum user's password in the `lib/.sunsolvepw` file. If PatchPro is installed in the default location, this file is in the `/opt/SUNWppro` directory.

Keep the password safe by setting the owner, group, and permissions to `root`, `sys`, and `0600`, respectively.

Note – This file method of supplying passwords is no longer supported.

Note – To specify this user, use the `smpatch set` command to set the `patchpro.sun.user` parameter. Also, specify this user's password by setting the `patchpro.sun.passwd` parameter.

`-U` *proxy-user-name*

Is the user name required for authentication of the web proxy, if applicable.

Store the corresponding user's password in the `lib/.proxypw` file. If PatchPro is installed in the default location, this file is in the `/opt/SUNWppro` directory.

Keep the password safe by setting the owner, group, and permissions to `root`, `sys`, and `0600`, respectively.

Note – This file method of supplying passwords is no longer supported.

Note – To specify this user, use the `smpatch set` command to set the `patchpro.proxy.user` parameter. Also, specify this user's password by setting the `patchpro.proxy.passwd` parameter.

`-W` *day-of-week*

Schedules the automatic analysis, download, and optional application of patches on a weekly basis.

day-of-week is a numerical value from 0-6, which represents the day of the week. 0 represents Sunday. See the `crontab(1)` man page.

The policy defined by the `-p` option determines whether no patches (`pprosetup -p none`) are applied or whether standard patches (`pprosetup -p standard`) are applied. By default, no patches are applied.

This option is mutually exclusive with the `-D` option and the `-M` option.

Note – This feature is not supported by the `smpatch` command.

`-x` [*host*`:`*port*]

Specifies the web proxy. If your system is behind a firewall, use this option to specify your web proxy. Get the name of the web proxy and its port from your system administrator or network administrator.

Note – To specify the web proxy host name and port, use the `smpatch set` command to set the `patchpro.proxy.host` and `patchpro.proxy.port` parameters, respectively.

Examples

EXAMPLE 1 Scheduling Daily Patch Operations in Automatic Mode

```
# pprosetup -D
```

Schedules `smpatch update` to run in automatic mode daily at midnight local time.

EXAMPLE 2 Scheduling Weekly Patch Operations in Automatic Mode

```
# pprosetup -W 0 -s 00:45
```

Schedules `smpatch update` to run in automatic mode every Sunday at 12:45 a.m. local time.

EXAMPLE 3 Scheduling Monthly Patch Operations in Automatic Mode

```
# pprosetup -M 15 -s 02:30
```

Schedules `smpatch update` to run in automatic mode on the 15th day of every month at 2:30 a.m. local time.

EXAMPLE 4 Canceling Scheduled Jobs

```
# pprosetup -C
```

Cancels the scheduled jobs that use the default configuration.

EXAMPLE 5 Specifying the Patch Policy for Manual Mode

```
# pprosetup -i standard:singleuser:reconfigafter:rebootafter
```

Specifies the policy for applying patches in manual mode. This policy permits you to apply the following types of patches to your system in manual mode:

- Standard patches
- Patches that must be applied in single-user mode
- Patches that require that the system undergo a reconfiguration reboot after they have been applied
- Patches that require that the system undergo a reboot after they have been applied

EXAMPLE 6 Specifying the Patch Policy for Automatic Mode

```
# pprosetup -p none
```

Specifies that no patches are automatically applied.

```
# pprosetup -p standard
```

Specifies that *only* standard patches can be downloaded and applied.

EXAMPLE 7 Specifying an Alternate Download Directory

```
# pprosetup -d /export/home/patches
```

Specifies that patches are downloaded to the `/export/home/patches` directory.

EXAMPLE 8 Specifying an Alternate Sequester Directory

```
# pprosetup -q /export/home/patches/sequester
```

Specifies that sequestered patches are stored in the `/export/home/patches/sequester` directory.

EXAMPLE 9 Identifying the Hardware on Your System

```
# pprosetup -H
```

Enables a patch analysis to determine whether your system needs specific patches based on your hardware configuration. This command only helps you identify hardware products from Sun Network Storage.

EXAMPLE 10 Configuring Your System to Obtain Contract Patches

```
# pprosetup -u myuser
# echo mypasswd > /opt/SUNWppro/lib/.sunsolvepw
```

Enables your contract user, `myuser`, to obtain the contract patches.

Ensure that the contract user's password is safe by setting the owner, group, and permissions of the `.sunsolvepw` file to `root`, `sys`, and `0600`, respectively.

EXAMPLE 11 Specifying a Web Proxy

```
# pprosetup -x webaccess.corp.net.com:8080
```

Specifies the host name, `webaccess.corp.net.com`, and port, `8080`, of the web proxy to use.

EXAMPLE 12 Scheduling Daily Patch Operations to Use the `recommended` Configuration

```
# pprosetup -c recommended -D -s 23:00
```

Schedules a daily patch analysis that uses the `recommended` configuration. You can use the alternate configuration in conjunction with or in place of a full analysis.

```
# pprosetup -c recommended -C
```

Cancels this job that uses the `recommended` configuration.

EXAMPLE 13 Modifying the `recommended` Configuration

```
# pprosetup -c recommended -a recommended@local
```

Modifies the `recommended` configuration to send email notifications to the `recommended@local` email alias about each scheduled analysis that uses the `recommended` cluster. Any scheduled operation that uses the `recommended` configuration will send notification to the alias you specify.

EXAMPLE 14 Creating a New Configuration

```
# pprosetup -c export -d /export/patches
```

Creates a new configuration named `export` that downloads patches to the `/export/patches` directory. After executing this command, you can schedule patch operations or manually run patch operations that use the `export` configuration by running the `pprosetup` or `pprosvc` commands, respectively.

```
# pprosvc -c export -d
```

Downloads patches to the download directory specified by the `export` configuration.

Attributes

See the `attributes(5)` man page for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpprou
Interface Stability	Obsolete

See Also crontab(1), boot(1M), patchadd(1M), patchrm(1M), pprosvc(1M), smpatch(1M), attributes(5)

Name pprosvc – automation service program for Patch Manager

Synopsis

```
/usr/sbin/pprosvc [-c config-name]
     [-d [-p patch-id [,patch-id]...]] [-h]
     [-i [-n] [-p patch-id [,patch-id]...]] [-l]
```

Description **Note –** This command is deprecated. Use the `smpatch analyze`, `smpatch download`, and `smpatch update` commands instead. See the `smpatch(1M)` man page.

Use the `pprosvc` command to analyze a system to determine the list of appropriate patches, download the patches, and apply them. This command invokes patch operations in response to a user request or at a scheduled time. You must run this command as superuser.

The `pprosvc` command enables you to do the following:

- Analyze the host system for appropriate patches based on an established configuration
- Generate the list of appropriate patches
- Download the patches to your host system from the Sun patch server
- Apply the patches based on a patch policy

Use the `pprosvc -i` command to analyze a system, download the appropriate patches, and apply them. If analysis determines that patches are needed, the `pprosvc` command downloads them and applies them.

Specify other options to automate a subset of the patch management tasks. If you specify the `-d` option, your system is analyzed and the appropriate patches are downloaded to your system. If you specify the `-l` option, your system is analyzed and the appropriate patches are listed.

The list of patches that is generated by the analysis is based on all of the available patches from the Sun patch server. No explicit information about your host system or its network configuration is transmitted to Sun. Only a request for the Sun patch set is transmitted. The patch set is scanned for patches that are appropriate for this host system, the results are displayed, and those patches are optionally downloaded.

The `-d`, `-i`, and `-l` options are mutually exclusive.

Use the `-p` option to specify the patches on which to operate. You can use the `-p` option with the `-d` and `-i` options.

Options The following options are supported:

`-c` *config-name*
: Uses an alternate configuration for the current patch operation. Use the `pprosetup` command to create new configurations.

  A configuration named `recommended` is included. For more information, see "Specifying Alternate Configurations" in the `pprosetup(1M)` man page.

Note – This feature is not supported by the `smpatch` command.

`-d`

Downloads the patches that are appropriate for this host system. The patches are downloaded to the designated download directory.

This option generates a list of appropriate patches, as does the `-l` option. However, instead of just displaying the list of patches, the `-d` option displays and downloads the patches from the Sun patch server. The patches are downloaded using a secure connection, and all patches are authenticated using digital signature technology. Only patches that are signed with a Sun digital signature are stored in your download directory.

Note – Specifying this option is equivalent to running the `smpatch download` command.

`-h`

Displays information about the command-line options.

`-i`

Applies the patches based on the patch policy. This option analyzes your system to generate a list of appropriate patches. If analysis determines that patches are needed, the patches are downloaded and applied. If no patches are permitted to be applied in *automatic* mode (by running `pprosetup -p none`), this option is identical to specifying the `-d` option.

If only standard patches are permitted to be applied in automatic mode (by running `pprosetup -p standard`), all standard patches are applied.

Note – Specifying this option is equivalent to running the `smpatch update` command.

`-l`

Generates a list of the patches that are appropriate for this host system.

Note – Specifying this option is equivalent to running the `smpatch analyze` command.

`-n`

Runs `pprosvc` in *automatic mode*. The command that the `cron` job specifies is `pprosvc -i -n`. To schedule patch operations to run in automatic mode, see the `pprosetup(1M)` man page.

In automatic mode, the patch administrator (specified by the `-a` option) receives email notifications that describe the patches you downloaded and applied, and any error events that occurred.

Do not use this option on the command line.

Standard patches do not require any special actions on the part of the user. Such patches can be applied by using the `patchadd` command (see the `patchadd(1M)` man page) and do not need the host system to reboot for the patch to take effect.

All nonstandard patches are moved to the sequester directory if you use the `-n` option to run in automatic mode. If you run in manual mode, however, nonstandard patches that have properties that match the policy specified by `pprosetup -i` are applied. The rest of the nonstandard patches are moved to the sequester directory. You can apply patches from this directory at a later time. Patches, whether standard or nonstandard, that depend on sequestered patches are not applied under any circumstances. Such patches are placed in the sequester directory.

For any patch that is placed in the sequester directory, refer to the patch's README file to determine how to apply it to your system.

Note – This feature is not supported by the `smpatch` command.

`-p` [*patch-id*[,*patch-id*,...] Designates the specific patches on which to operate. Use this option with the `-d` option or the `-i` option. The list of patch IDs must be separated by commas.

The specified patches are adjusted to use the current versions based on the patch baseline. Patches that are required by the specified patches are added to the complete list of patches to be applied.

Note – Specifying this option is equivalent to specifying the `-i` option to the `smpatch analyze`, `smpatch download`, and `smpatch update` commands.

Examples

EXAMPLE 1 Applying Specific Patches in Manual Mode

```
# pprosvc -i -p 102893-01,106895-09,106527-05
```

Applies patches 102893-01, 106895-09, and 106527-05 to the local system in manual mode.

EXAMPLE 2 Analyzing a System and Downloading Appropriate Patches

```
# pprosvc -i
```

EXAMPLE 2 Analyzing a System and Downloading Appropriate Patches *(Continued)*

Performs an analysis of the current system and downloads the appropriate patches based on all the patches from the Sun patch server. The resulting list of patches can be very long.

EXAMPLE 3 Applying Patches From the Recommended Configuration

```
# pprosvc -c recommended -i
```

Uses the `recommended` configuration to perform an analysis of the current system and downloads the appropriate patches. Standard patches and those needed from the `recommended` configuration are applied to the system based on the established patch policy. For information about setting the patch policy for manual mode, see the description of the `-i` option on the `pprosetup(1M)` man page.

Attributes

See the `attributes(5)` man page for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpprou
Interface Stability	Obsolete

Name praudit – print contents of an audit trail file

Synopsis

```
praudit [-lrsx] [-ddel] [filename]...
```

Description `praudit` reads the listed *filename*s (or standard input, if no *filename* is specified) and interprets the data as audit trail records as defined in `audit.log(4)`. By default, times, user and group IDs (UIDs and GIDs, respectively) are converted to their ASCII representation. Record type and event fields are converted to their ASCII representation. A maximum of 100 audit files can be specified on the command line.

Options The following options are supported:

`-d`*del*
: Use *del* as the field delimiter instead of the default delimiter, which is the comma. If *del* has special meaning for the shell, it must be quoted. The maximum size of a delimiter is three characters. The delimiter is not meaningful and is not used when the `-x` option is specified.

`-l`
: Print one line per record.

`-r`
: Print records in their raw form. Times, UIDs, GIDs, record types, and events are displayed as integers. This option is useful when naming services are offline. The `-r` option and the `-s` option are exclusive. If both are used, a format usage error message is output.

`-s`
: Display records in their short form. Numeric fields' ASCII equivalents are looked up by means of the sources specified in the `/etc/nsswitch.conf` file (see `nsswitch.conf(4)`). All numeric fields are converted to ASCII and then displayed. The short ASCII representations for the record type and event fields are used. This option and the `-r` option are exclusive. If both are used, a format usage error message is output.

`-x`
: Print records in XML form. Tags are included in the output to identify tokens and fields within tokens. Output begins with a valid XML prolog, which includes identification of the DTD which can be used to parse the XML.

Files

`/etc/security/audit_event`
: Audit event definition and class mappings.

`/etc/security/audit_class`
: Audit class definitions.

`/usr/share/lib/xml/dtd`
: Directory containing the verisioned DTD file referenced in XML output, for example, `adt_record.dtd.1`.

`/usr/share/lib/xml/style`
: Directory containing the versioned XSL file referenced in XML output, for example, `adt_record.xsl.1`.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	See below

The command stability is evolving. The output format is unstable.

Notes This functionality is available only if the Solaris Auditing feature has been enabled. See bsmconv(1M) for more information.

Name printmgr – Solaris Print Manager is a graphical user interface for managing printers in a network

Synopsis

```
/usr/sadm/admin/bin/printmgr
```

Description Solaris Print Manager is a Java-based graphical user interface that enables you to manage local and remote printer access. This tool can be used in the following name service environments: LDAP, NIS, NIS+, and files. You must be logged in as superuser to use this tool.

Using Solaris Printer Manager is the preferred method for managing printer access because Solaris Print Manager centralizes printer information when it is used in a name service environment.

Adding printer information to a name service makes access to printers available to all systems on the network and generally makes printer administration easier because all the information about printers is centralized.

Solaris Print Manager may be run on a remote system with the display sent to the local system. See the *System Administration Guide: Printing* for instructions on setting the `DISPLAY` environment variable.

Using Solaris Print Manager to perform printer-related tasks automatically updates the appropriate printer databases. Solaris Print Manager also includes a command-line console that displays the `lp` command line for the add, modify, and delete printer operations. Errors and warnings may also be displayed when Printer Manager operations are performed.

Help is available by clicking the Help button.

Usage Solaris Print Manager enables you to do the following tasks:

Select a Name Service	Select a name service for retrieving or changing printer information.
Add Access to a Printer	Add printer access on a printer client using Solaris Print Manager.
Add an Attached Printer	After physically attaching the printer to a system, use Solaris Print Manager to install a local printer and make it available for printing.
Add a Network Printer	After physically attaching the printer to a system, use Solaris Print Manager to install a local printer and make it available for printing.
Modify Printer Properties	After adding access to a printer or adding an attached or network printer, you can modify certain printer attributes.
Delete a Printer	Delete access to a printer from the print client or delete a printer from the print server or from the name service environment.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWppm

See Also `ldap(1)`, `lpget(1M)`, `lpset(1M)`, `attributes(5)`

System Administration Guide: Printing for information on LDAP server replication.

Although users can use the LDAP command line utilities `ldapadd(1)` and `ldapmodify(1)`to update printer entries in the directory, the preferred method is to use `lpset`. Otherwise, if the `lpadd` and `lpmodify` utilities are used, the administrator must ensure that the `printer-name` attribute value is unique within the `ou=printers` container on the LDAP server. If the value is not unique, the result of modifications done using `lpset` or the Solaris Print Manager, `printmgr` may be unpredictable.

Name privatepw – administer FTP Server enhanced group access file

Synopsis

```
privatepw [-c] [-f ftpgroups] [-g real_group_name] accessgroup

privatepw -d [-f ftpgroups] accessgroup

privatepw -l [-f ftpgroups]

privatepw -V
```

Description The `privatepw` utility is an administrative tool to add, delete and list enhanced access group information in the `ftpgroups` file. See `ftpgroups(4)`.

When `privatepw` is used without options, the help usage message is displayed. The `privatepw` utility prompts for a password when adding an enhanced access group entry or modifiying an existing one.

Options The following options are supported by the `privatepw` utility:

`-c`	Create a new `ftpgroups` file for the specified *accessgroup*.
`-d`	Delete information about the specified *accessgroup* from the `ftpgroups` file.
`-f` *ftpgroups*	Use the specifed `ftpgroups` file for all updates.
`-g` *group*	Set the real system group to the *group* specified. *group* is a valid group name returned by `getgrnam(3C)`. If the real system group is not supplied with the `-g` option when adding an ehanced access group entry, the `privatepw` utility prompts for it.
`-l`	List the contents of the `ftpgroups` file.
`-V`	Display program copyright and version information, then terminate.

Operands The following operands are supported:

accessgroup	The name of the enhanced access group to create or update It consists of an arbitrary string of alphanumeric and punctuation characters. See `ftpgroups(4)`.

Exit Status The following exit values are returned:

`0`	Successful completion.
`>0`	An error occurred.

Files

```
/etc/ftpd/ftpgroups

/etc/group
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWftpu
Interface Stability	External

See Also in.ftpd(1M), getgrnam(3C), ftpgroups(4), attributes(5)

Name prodreg – Solaris Product Registry administration

Synopsis

```
prodreg [--help] | [subcommand operand ...]
```

Description The `prodreg` utility browses, unregisters, and uninstalls components in the Solaris Product Registry.

Some installers make use of the `libwsreg(3LIB)` interface to register information. The Solaris Product Registry contains information about this installed software.

The database associated with the Solaris Product Registry is relative to the root of the installed file system. Normally, this is the root of the file system (`/`). Sometimes, an alternate root, with a different Solaris Product Registry install database is used, as during live upgrade installation. See `live_upgrade(5)`.

The Registry database informs installers about installed software. The Registry and the `prodreg` utility do not directly perform installation or deinstallation. `prodreg` supports installers which are executed externally and launched by the `prodreg` utility or other means.

Depending on the subcommand, the `prodreg` command offers equivalent functions from the command line or a GUI viewer. Two versions of the GUI viewer are available. The default is the Java Swing GUI. The other version, the Java awt GUI is provided for environments without Java Swing support.

The only feature which exists in the CLI which is not present in the GUI is the `unregister` subcommand. It is possible for the product registry to become corrupted, if for example, some software is removed manually instead of by means of an uninstaller program. These entries can confuse installers which are run subsequently. The `unregister` subcommand allows stale entries to be removed, even forcefully. Care should be exercised when unregistering software with the recursive or force options so that valid entries in the registry are not removed by mistake.

The `prodreg` command, whether it launches the GUI or the command line interface browser, displays the contents of the registry at that time only. If software is installed or uninstalled subsequent to or concurrent with launching either `prodreg` viewer, the view can be inconsistent with the Solaris Product Registry.

Subcommands You can specify options to the `prodreg` command without specifying a subcommand. If the subcommand is omitted, the `swing` subcommand is assumed.

The following subcommands are supported:

awt — Launch the Java `awt` GUI.

The `awt` subcommand has the following format:

```
awt [-R alt_root | --help]
```

browse

Display the Solaris Product Registry using a command line interface. The text output of this command displays identifying information of any component in the product registry tree, including its ancestors and children. If you repeatedly invoke this subcommand, you can interactively browse the product registry.

The database components are related as a tree. Components may have one or more children. Except for the root, components have one parent. This subcommand displays the ancestors and children for a given component in the Solaris Product Registry database.

Each time the `prodreg browse` subcommand is executed, one component in the Registry is shown, along with its ancestry to the root of the Registry, as well as the component's children. To browse in the `prodreg` GUI, a user selects a node to expand and clicks on it. The analogous activity using the command line interface is to browse on children of nodes successively, which effectively expands a view into the registry.

Start by browsing the root of the Registry with `prodreg browse`. Select components to expand the scope of the browsing activity. Use browse numbers as a convenience during this interactive browsing, but not in scripts. Browse numbers can change from one session to the next or on different systems. This is because browse numbers are generated as they are first used, by a given user on a particular system.

The `browse` subcommand has the following format:

```
browse [-R alt_root] [-u uuid [-i instance | -p location]]
browse [-R alt_root] -n bnum [-i instance | -p location]
browse [-R alt_root] -m name
browse --help
```

This following information is output for each component:

BROWSE # — This is the browse number associated with each component. This number can be used as an argument to either the `prodreg browse` or `info` subcommands as a convenience

+/-/. — The + indicates a component in the tree with children who are not shown. - indicates a component with children of which at least one child is being shown. The . indicates a component which has no children. This field is

arranged so that each space (reading left to right) depicts a successive generation.

UUID — This is the component's unique identifier.

— This is the instance number of the component. Software components can be installed multiple times. The software registry assigns a unique instance to each one.

NAME — Each component in the Solaris Product Registry database has a localized name which is displayed in this field. It is possible that this name may not be unique in the registry since there could be another component that has the same name.

The `browse` subcommand provides four distinct options for viewing the registry database. If multiple instances are associated with the same component, then the output of the subcommand is the ambiguous list. The request must be made unambiguous. The instance or location operands can be used to disambiguate the browse subcommand when used with the `-u` or `-n` options.

- If no operand information is given, the root of the registry tree is displayed, as well as its children. This is the starting point for interactive browsing of the entire registry database.
- If the browse number is given, the component associated is output.
- If the `uuid` is given, the component associated with it is output.
- If the name is given, the component associated with it is output.

info — Display attributes for any component in the Solaris Product Registry by supplying identifying information for the component.

Components in the product registry are associated with attributes. These attributes are composed of a *name* and a single *value* string.

This subcommand outputs attribute information associated with components in the Solaris Product Registry. Individual components in the product registry are specified as for the `browse` subcommand, except that either the *uuid*, *name* or *bnum* must be specified.

If a component requested is ambiguous as it has more than one instance or the name is assigned to more than one component in the registry, the list of possibilities is output, not the attribute information.

The default output of this subcommand is a complete list of each attributes, each on a new line. The attribute name is followed by a colon (`:`) and a SPACE. The attribute value follows, after which a RETURN is appended. Other options include can be specified using `-a` and `-d`.

The `info` subcommand has the following format:

```
info --help
info [-R alt_root] -u uuid [-i instance | -p location]
info [-R alt_root] -n bnum [-i instance | -p location]
info [-R alt_root] -m name [-a attr | -d ]
```

help | `--help` | `-?`

Display help text.

The `help` subcommand has the following format:

```
help | --help | -?
```

swing

Launch the Java Swing GUI. If the Java Swing GUI is not available, this subcommand fails.

The `swing` subcommand has the following format:

```
swing  [-R alt_root | --help]
```

version | `--version` | `-V`

Outputs a current version string.

The `version` subcommand has the following format:

```
version | --version | -V
```

unregister

Unregister an entry in the registry.

Remove a component from the Solaris Product Registry. The component corresponding to the *uuid* specified with the `-u` option must be a single instance. If it is not, the subcommand fails and returns the list of instances with the associated *uuid*. The subcommand must be reissued using either `-p` or `-i` to uniquely determine which component instance to unregister.

The `unregister` subcommand fails if there are components in the registry which depend on the component which is to be unregistered.

The `unregister` subcommand fails if the user does not have write access to the registry. See `wsreg_can_access_registry(3WSREG)`. The `unregister` subcommand fails if the user attempts to unregister a system component, instead of a component registered with the Solaris Product Registry. System components include those which include the attribute `PKG` and certain special Registry nodes including the following:

```
UUID                                   Name
====================================  ============================
root                                   System Registry
a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b  Solaris System Software
8f64eabf-1dd2-11b2-a3f1-0800209a5b6b  Unclassified Software
b96ae9a9-1dd1-11b2-a3f2-0800209a5b6b  System Software Localizations
b1c43601-1dd1-11b2-a3f2-0800209a5b6b  Additional System Software
a8dcab4f-1dd1-11b2-a3f2-0800209a5b6b  Software Localizations
```

Before the `unregister` subcommand with the `-f` option is used, you should carefully review what components depend upon the component which is to be unregistered. The `-r` option is even more dangerous, since all children and software components depending upon the component are also deregistered. You can obtain the list of dependent components for a component with UUID *uuid* using :

```
prodreg info -u uuid -a "Dependent Components"
```

You can obtain a list of required components using:

```
prodreg info -u <uuid> -a "Required Components"
```

The output lists the name, UUID and instance of the component.

The `unregister` subcommand has the following format:

```
unregister [-R alt_root] [-fr] -u uuid [-p location | -i instance]
unregister --help
```

uninstall

Launch an uninstaller program.

Each component in the registry can have an uninstaller associated with it. This subcommand executes this associated installer, if there is one, for a component in the registry given by the `-u` option. If there is no uninstaller associated with the component, the subcommand fails. If the component given by the `-u` option is not unique (as there is more than one instance of the component installed), the subcommand outputs a list of all instances. The subcommand must then be reissued using `-i` or `-p`

to disambiguate the uuid given with the `-u` option. Finally, if the component to uninstall is depended upon by other components, the command fails.

The command may also launch an uninstaller with a `-x` option. No checks for whether this uninstalls a component upon which other components depend in this case.

The `uninstall` command is not executed if the user does not have write access to the registry. See `wsreg_can_access_registry(3WSREG)`.

The `uninstall` command has the following format:

```
uninstall [-R alt_root] [-f] -u uuid -p location
uninstall [-R alt_root] -i instance[arguments ...]
uninstall --help
```

Options The `awt` subcommand supports the following options:

`--help` Display help text, do not launch the viewer.

`-R` *alt_root* Use the specified alternate root to locate the database to display with the GUI viewer.

See OPERANDS for information regarding specification of *alt_root*.

Note – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.

The `browse` subcommand supports the following options:

`-help` Display help text, do not execute the browse subcommand.

`-i` *instance* Output the specified component instance.

`-m` *name* Output the component instances associated with the name.

`-n` *bnum* Output the component instances associated with the browse number.

`-p` *location* Output the component instance installed in the specified location. The install location for a component can be obtained using the 'info' subcommand.

`-R` *alt_root* Use the specified alternate root to locate the database.

Note – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.

`-u` *uuid* Output the component instances associated with the uuid.

The `info` subcommand supports the following options:

`-a` *attr* Output only the attribute whose name is given by the operand 'attr', instead of all attributes of the specified component.

`-d` Output only the attribute whose name is `isDamaged`, instead of all attributes of the specified component. If the value is set to `true`, this attribute indicates that the component in the registry

`--help` Output help text, do not execute the browse subcommand.

`-i` *instance* The instance operand distinguishes among multiple instances of components with the same `uuid` or browse number.

`-m` *name* The name operand indicates one or more components in the registry.

`-n` *bnum* Output the attributes of the component instance associated with the browse number bnum. If there is more than one instance, the command must be disambiguated using the `-i`or `-p` options.

`-p` *location* The install location indicated distinguishes among multiple instances of components with the same uuid or browse number.

`-R` *alt_root* Use the specified alternate root to locate the database.

Note – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.

`-u` *uuid* Output the attributes of the component instance associated with the uuid. If there is more than one instance, the subcommand must be disambiguated using the `-i` or `-p` options.

The `swing` subcommand supports the following options:

`--help` Output help text, do not execute the install subcommand.

`-R` *alt_root* Use the specified alternate root to locate the database.

Note – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global

zone's file system. See zones(5).

The uninstall subcommand supports the following options:

-f — Force the uninstall. A forced subcommand uninstalls all instances of a component, even if there are multiple ambiguous instances of the uuid operand.

--help — Output help text, do not execute the unregister subcommand.

-i *instance* — Disambiguate the *uuid* operand.

-p *location* — Disambiguate the *uuid* operand. *location* corresponds to the where the software component was installed.

-R *alt_root* — Use the specified alternate root to locate the database.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-u *uuid* — Unregister the *uuid* component. If this component has been installed multiple times, the instance to unregister must be indicated unambiguously by using the -i or -p option.

The unregister subcommand supports the following options:

-f — Force the unregistration. A forced subcommand unregisters a component even if there are other components which are dependent on this component.

--help — Output help text, do not execute the unregister subcommand.

-i *instance* — Disambiguate the *uuid* operand.

-p *location* — Disambiguate the uuid operand. The *location* corresponds to the where the software component was installed.

-r — Causes a recursive deregistration of a component as well as that component's children and dependencies.

-R *alt_root* — Use the specified alternate root to locate the database.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-u *uuid* — Unregister component *uuid* of the component to unregister. If this component has been installed multiple times, the instance to unregister must be indicated unambiguously by using the -i or -p option.

Operands The following operands are supported:

alt_root Pathname to a file indicating an alternate root. The Solaris Product Registry database is located relative to the alternate root. If database relative to this location does not exist, it is created.

Note – The root file system of any non-global zones must not be referenced by *alt_root*. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.

attr Name of an attribute. This operand is used only with the `info` subcommand. If *attr* is associated with a component, the attribute name and value is displayed.

bnum The browse number.

Each component in the Solaris Product Registry is associated with a browse number. This number is generated for the convenience of an interactive user. The browse number can change if the system is rebooted or reinstalled. Do not store or use the browse number except to facilitate the `browse` and `info` subcommands. Browse numbers are always output by the `prodreg browse` subcommand. Only these values can be used as input values to the browse or info subcommand.

instance Software can be installed in more than one location. The Solaris Product Registry associates a unique instance number for each. The browse subcommand shows the instance number associated with each component in the registry. The instance operand is used to distinguish between installed, and possibly different, copies of software, when such exist.

location A path to a specific file or directory in the file system. This operand indicates the installed location of registered software. For instance, if software is installed relative to `/usr/local` the value of this operand would be `/usr/local`. The install location is used to installer or to indicate the location of an installer or to disambiguate which instance is intended, of a software component which can have multiple instances.

name Each software component in the Solaris Product Registry is associated with a name. This name is output by the `browse` subcommand. Some subcommands allow the user to input the software by name as an operand as a convenience. These names might not be unique. If the user supplies an ambiguous name, for which more than one components exist, the subcommand outputs a list of possible choices. The name can be localized; depending on the language setting the name can differ.

uuid Each software component in the Solaris Product Registry is associated with a unique identifier. This identifier is a handle which accesses an entry in the registry database. The uuid corresponds to the component irrespective of how many

instances of the component have been installed, and what the localized name of the component is.

Examples

EXAMPLE 1 Using the `prodreg` Command to Browse

Browsing is performed by means of the `prodreg` browse subcommand. Using these requests iteratively, one can peruse the tree, much as one would using a GUI by expanding components which are collections of other components. Browsing using browse numbers for convenience should be done only during this iterative browsing process, since the numbers are generated as a result of the browsing operation.

Evoking the `browse` subcommand without any arguments browses from the top of the registry. The output varies depending on the software installed on a particular system.

```
$ prodreg browse
BROWSE # +/-/.  UUID                                 #  NAME
======== =====  ===================================  =  ============
1        -      root                                 1  System
                                                       Registry
2         +     a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b  1  Solaris 10
                                                       System
                                                       Software
3         +     8f64eabf-1dd2-11b2-a3f1-0800209a5b6b  1  Unclassified
                                                       Software
```

The output of this command lists the browse number, UUID, instance number and name of the root component and its children. The ancestors of a component, each parent up to the root, are also shown. The `+/-/.` column indicates whether the component in the tree is an expanded parent (`-`), a child with children (`+`) or a child without children (`.`).

EXAMPLE 2 Requesting Information About the Components in a Tree

The UUID, name and browse number fields can be used to request browsing information about components in the tree. The next example shows how a component can be browsed by UUID.

```
$ prodreg browse -u a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b
BROWSE #  +/-/.  UUID                                 #  NAME
========  =====  ===================================  =  ===========
1         -      root                                 1  System
                                                       Registry
2          -     a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b  1  Solaris 10
                                                       System
                                                       Software
4           +    b96ae9a9-1dd1-11b2-a3f2-0800209a5b6b  1  System
                                                       Software
                                                       Localizations
5           +    SUNWCall                              1  Entire
```

EXAMPLE 2 Requesting Information About the Components in a Tree *(Continued)*

```
                                                                Distribution
```

EXAMPLE 3 Browsing a Node by Name

The following example shows how a node can be browsed by name.

```
$ prodreg browse -m "System Software Localizations"
BROWSE #  +/-/.  UUID                                 #  NAME
========  =====  ====================================  =  ===========
1         -      root                                  1  System
                                                        Registry
2          -     a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b  1  Solaris 10
                                                        System
                                                        Software

```

EXAMPLE 4 Browsing Iteratively

Additional output has been omitted. As a convenience, the browse number can be used for iterative browsing. This number should not be stored, as it differs depending on which system the `prodreg` command is run on, which user is running the command, and the log in session in which the command is run.

```
$ prodreg browse -n 3

BROWSE #  +/-/.  UUID                                 #  NAME
========  =====  ====================================  =  ===========
1         -      root                                  1  System
                                                        Registry
2          -     a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b  1  Solaris 10
                                                        System
                                                        Software
5           -    SUNWCall                              1  Entire
                                                        Software
```

EXAMPLE 4 Browsing Iteratively *(Continued)*

```
                                                        Distribution
6            .   SUNWrsmo                           1   RSMPI
                                                        Operations
                                                        Registration
                                                        Module
7            +   SUNWCjvx                           1   JavaVM
                                                        (64-bit)
8            .   SUNWrsmx                           1   Remote
                                                        Shared
                                                        Memory
                                                        (64-bit)
9            +   SUNWCacc                           1   System
                                                        Accounting
```

EXAMPLE 5 Browsing Using an Ambiguous Value

If the requested value is ambiguous, the list of ambiguous instances are displayed. In the following example, there are two distinct software components with the same name.

```
$ ./prodreg browse -m JavaVM
The request failed because multiple components correspond to the
criteria given. Use the list of possible components given below,
select one and try again.

BROWSE #  +/-/.  UUID                                #  NAME
========  =====  ==================================  =  ==========
12        .      org.spybeam.javavm                  1  JavaVM
51        .      SUNWCjv                             1  JavaVM
```

Issue one of the following requests again:

```
$ prodreg browse -u SUNWCjv
```

or

```
$ prodreg browse -u org.spybeam.javavm
```

EXAMPLE 6 Browsing Multiple Installations of Software

Another possible ambiguous response arises when a particular software component is installed multiple times. In the example below `Example` software is registered three times.

```
$ prodreg browse -m Example
The request failed because multiple components correspond to the
criteria given. Use the list of possible components given below,
select one and try again.
BROWSE #  +/-/.  UUID                                #  NAME
========  =====  ==================================  =  ==========
```

EXAMPLE 6 Browsing Multiple Installations of Software *(Continued)*

```
7         .      org.spybeam.example                  2  Example
7         .      org.spybeam.example                  3  Example
7         .      org.spybeam.example                  1  Example
The component requested could not be found.
```

EXAMPLE 7 Browsing Using a Particular Instance

The request can be repeated specifying a particular instance to disambiguate it. It is also possible to disambiguate a request with the `-p` option, followed by the install location. In this case, to browse the first instance of the `Example` software, one would use the command:

```
$ prodreg browse -u org.spybeam.example -i 1
```

EXAMPLE 8 Using the `info` Subcommand

The install location, as well as other attributes of a component can be obtained with the info subcommand. The info subcommand accepts the same disambiguating options and returns all the attributes of a component, each on a single line.

```
$ prodreg info -m Example
The request failed because multiple components correspond to the
criteria given. Use the list of possible components given below,
select one and try again.
BROWSE # +/-/. UUID                                 # NAME
======== ===== ==================================== = ===========
7        .     org.spybeam.example                  2 Example
7        .     org.spybeam.example                  3 Example
7        .     org.spybeam.example                  1 Example
The component requested could not be found.
```

This variation of the info subcommand outputs all information associated with instance 1 of the `Example` component. The output from this variation is not displayed

```
$ prodreg info -u org.spybeam.example -i 1
```

EXAMPLE 9 Obtaining Information on the Install Location

You can use the `info` subcommand to obtain the install location and other attributes of a component. The `info` subcommand accepts the same disambiguating options as the `browse` subcommand. It returns all the attributes of a component, each on a single line. You can also request a single attribute.

The following command outputs the value of the install location attribute:

```
$ prodreg info -n 23 -a Location
```

EXAMPLE 10 Idenitifying and Unregistering Damaged Software

Removing installed software without using the associated uninstaller can damage the software in the registry. A damaged component indicates that certain software is installed, when in fact it is not present. A component can be damaged by removing files or packages directly, without running the associated uninstaller. The general rule to follow is: If software has been installed by an installer program, it should be uninstalled using the supplied uninstaller program.

This example shows how to identify and repair damaged software components so that software can be reinstalled.

Browsing for `Examplesoft`, produces the following:

```
$ prodreg browse -m Examplesoft
BROWSE #  +/-/.  UUID                                  #  NAME
========  =====  ====================================  =  ============
1         -      root                                  1  System
                                                          Registry
2          +     a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b  1  Solaris 10
                                                          System
                                                          Software
3          +     8f64eabf-1dd2-11b2-a3f1-0800209a5b6b  1  Unclassified
                                                          Software
4          -     95842091-725a-8501-ef29-0472985982be  1  ExampleSoft
233         .    90209809-9785-b89e-c821-0472985982be  1  Example Doc
234         .    EXSOzzt                               1
235         .    EXSOblob                              1  Example Data
```

The `Examplesoft` child `EXSOzzt`, representing a package component of registered software does not display its name. This is likely to be because the software `Examplesoft` is damaged. Verify this with the following command:

```
$ prodreg info -u 95842091-725a-8501-ef29-0472985982be \
     -i 1 -d
isDamaged=TRUE
```

Since `Damaged` is `TRUE`, some part of `Examplesoft` is damaged. The following command lists the packages which make up `Examplesoft`:

```
$ prodreg info \
     -u 95842091-725a-8501-ef29-0472985982be\
     -i 1 -a PKGS pkgs:
EXSOzzt EXSOblob
```

Use the `pkginfo` command to verify if `EXSO` is installed:

```
$ pkginfo EXSOzzt
ERROR: information for "EXSOzzt" was not found
```

EXAMPLE 10 Idenitifying and Unregistering Damaged Software *(Continued)*

```
$ pkginfo EXSOblob
application EXSOblob       Example Data
```

The output of these commands shows that the package `EXSOzzt` has been removed, probably with the `pkgrm` command. The `Examplesoft` software will probably not function. To repair the software, one should run the uninstaller registered with `Examplesoft`. You probably need to run the uninstaller with root permissions, as it unregisters the software and runs `pkgrm` commands. Both of these operations require root permissions.

```
# prodreg uninstall -u 95842091-725a-8501-ef29-0472985982be -i 1
The install program requested could not be found.
```

Something is wrong, or else you would be able to access uninstall program to uninstall the software. One possibility is that the uninstaller program has been removed manually. It is possible to determine where the uninstaller is located by requesting the `uninstallprogram` attribute:

```
$ prodreg info -m ExampleSoft -a uninstallprogram
uninstallprogram: /usr/bin/java -mx64m -classpath
/var/sadm/prod/org.example.ExampleSoft/987573587 uninstall_ExampleSoft
```

Check to see if there is an uninstaller in the registered location.

```
# ls /var/sadm/prod/org.example.ExampleSoft/987573587
/var/sadm/prod/org.example.ExampleSoft/987573587:
No such file or directory
```

Since there is no uninstaller at the desired location, you have two options. One is to load the uninstaller from back up storage and run it manually. Use the command line stored in the registry:

```
# /usr/bin/java -mmx64m -classpath \
     /var/sadm/prod/org.example.ExampleSoft/987573587 \
     uninstall_ExampleSoft
```

If there is no other possibility, manually unregister the software.

```
# prodreg unregister -u 95842091-725a-8501-ef29-0472985982be -i 1
```

This does not remove the remaining package `EXSOblob`. You must do this manually.

```
# pkgrm EXSOblob
```

EXAMPLE 11 Removing Multiple Components

Component A has children B and C, and C has children D and E, and the you wish to remove all of the components at once. This is useful if the whole hierarchy has to be reinstalled and the uninstaller has been lost or cannot be run

EXAMPLE 11 Removing Multiple Components *(Continued)*

```
$ prodreg browse -u UUID-of-C
BROWSE #  +/-/.  UUID                                 #  NAME
========  =====  ====================================  =  ============
1         -      root                                  1  System
                                                          Registry
2          +     a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b  1  Solaris 10
                                                          System
                                                          Software
3          +     8f64eabf-1dd2-11b2-a3f1-0800209a5b6b  1  Unclassified
                                                          Software
1423       -     UUID-of-A                             1  Example A
1436        .    UUID-of-B                             1  Example B
1437        -    UUID-of-C                             1  Example C
1462         .   UUID-of-D                             1  Example D
1463         .   UUID-of-E                             1  Example E

# prodreg uninstall -u UUID-of-A -i 1
```

The `uninstall` subcommand can fail various ways, for example if the java classes have been removed, if the user has insufficient permissions or if Java software is not present on the system. The recursive unregistration subcommand is very powerful and dangerous. Not only does it unregister every child of a component, it also unregisters every component which depends upon the component to unregister. It is a good idea to view all information about the component to determine if any components will be unintentionally unregistered with UUID-of-A.

```
$ prodreg info -u UUID-of-A
Title: Example A Software
Version: 5.8.0.2001.11.02
Location: /usr
Vendor: Example Vendor
uninstallprogram: /usr/bin/java -mx64m -classpath
/var/sadm/prod/org.example.ExampleA/90820965 uninstall_ExampleA
vendorurl: http://www.example.org
description: Example A Software has many uses
Supported Languages: en

Child Components:
Name                        UUID                                  #
--------------------------  ------------------------------------  -
Example B                   UUID-of-B                             1
Example C                   UUID-of-C                             1

Required Components:
Name                        UUID                                  #
```

EXAMPLE 11 Removing Multiple Components *(Continued)*

```
-------------------------  ----------------------------------  -
Example B                  UUID-of-B                           1
Example C                  UUID-of-C                           1
```

No software depends on Example A, or else an additional field, `Dependent Components` would be shown. To further ensure that there are no surprises, one should examine the dependent components and children of UUID-of-B and UUID-of-C, all the components which depend on UUID-of-B, UUID-of-C and their children, and so on.

If you examine the browse tree, you know the entire list of descendents of UUID-of-A. You can also examine the dependent component attributes of all of Example A's descendents.

```
$ prodreg info -u UUID-of-B -i 1 -a "Dependent Components"
Dependent Components:
Name                        UUID                                #
--------------------------  ----------------------------------  -
Example A                   UUID-of-A                           1

$ prodreg info -u UUID-of-C -i 1 -a "Dependent Components"
Dependent Components:
Name                        UUID                                #
--------------------------  ----------------------------------  -
Example A                   UUID-of-A                           1

$ prodreg info -u UUID-of-D -i 1 -a "Dependent Components"
Dependent Components:
Name                        UUID                                #
--------------------------  ----------------------------------  -
Example C                   UUID-of-C                           1

$ prodreg info -u UUID-of-E -i 1 -a "Dependent Components"
Dependent Components:
Name                        UUID                                #
--------------------------  ----------------------------------  -
Example C                   UUID-of-C                           1
```

A recursive unregistration of Example A only results in unregistering Example A and its descendents, as intended.

```
# prodreg unregister -r -u UUID-of-A -i 1
```

EXAMPLE 12 Reinstalling a Damaged Component

In this example, there is a component, Software ZZZ which is depended upon by other software. Software ZZZ has been damaged and you need to reinstall it. The reinstallation is impossible until Software ZZZ is unregistered.

EXAMPLE 12 Reinstalling a Damaged Component *(Continued)*

First, you check what depends upon Software ZZZ:

```
$ prodreg info -m "Software ZZZ" -a "Dependent Components"
Dependent Components:
Name                         UUID                                  #
---------------------------  ------------------------------------  -
Software Foobar              d9723500-9823-1432-810c-0100e09832ff  1
```

Normally, you would have to uninstall Software Foobar before unregistering Software ZZZ, since Software Foobar depends on Software ZZZ. You decide that it is impossible or unreasonable to reinstall Software Foobar. Performing a recursive unregister of Software ZZZ is not an option as it would unregister Software Foobar as well. Instead you can do a forced unregister of Software ZZZ. The UUID of Software ZZZ is 90843fb1-9874-3a20-9b88-984b32098432.

```
# prodreg unregister -f -u 90843fb1-9874-3a20-9b88-984b32098432 -i 1
```

You can then reinstall Software ZZZ:

```
# /usr/bin/java -cp /usr/installers/org.example.softwarezzz
```

Bugs

The registry can become out of date because of software being manually removed, or removed using `pkgrm(1M)` directly. To avoid damaging the registry, use uninstall programs to remove software which was initially installed using an install program.

Environment Variables

The following environment variable affects the execution of `prodreg`:

`PKG_INSTALL_ROOT` If present, defines the full path name of a directory to use as the system's `PKG_INSTALL_ROOT` path. All product and package information files are then looked for in the directory tree, starting with the specified `PKG_INSTALL_ROOT` path. If not present, the default system path of `/` is used.

Exit Status

The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWwsr2, SUNWwsrv
Interface Stability	Evolving

Application Packaging Developer's Guide

Notes The prodreg GUI and command line interface view both the Solaris Product Registry and the package database. Both look like components in the registry, but some of these cannot be unregistered or uninstalled. Packages do not have an associated uninstaller, so they cannot be uninstalled using the prodreg uninstall subcommand. Solaris packages cannot be unregistered using the prodreg unregister subcommand. Packages are removed using the pkgrm(1M) command, after which time the packages do not appear in the GUI or CLI prodreg viewer.

It is preferable to remove software using the uninstaller associated with the software installed than to remove individual packages using pkgrm(1M), since the uninstaller software takes care of comprehensive removal of all resources associated with the installed software, including unregistering information in Registry and removing the appropriate packages.

The prodreg uninstall subcommand launches an external program. The command line conventions of these programs have to be used to indicate the alternate root for the product registry. Another possibility is to use the PKG_INSTALL_ROOT environment variable for this purpose as the install program is executed in the same environment as prodreg. Uninstall programs are frequently java classes which require Java to be installed. If Java software has been removed or is missing from a Solaris distribution, it is impossible to run java based uninstallers.

Only the prodreg unregister and uninstall subcommands can only be run with root permissions. This is because they modify the product registry in the case of unregister, and remove packages in the case of uninstall. The other operations merely read the registry and can be run with any user permissions. The prodreg uninstall subcommand might require root permissions as well, as installers can execute commands such as pkgadd(1M) or pkgrm(1M) which require root permissions to run.

Attributes associated with components are documented in various places -primarily in the *Application Packaging Developer's Guide*. The attributes associated with the Solaris Product Registry itself are described in the following glossary.

Dependent Components	List of components upon which the component depends.
Location	The location relative to which software was installed.
pkgs	List of packages which correspond to the component. These packages are added with pkgadd after the component is registered. They are removed with pkgrm before the component is unregistered.
Required Components	List of components on which the component depends.
Source	Media from which the install was done.

Supported Languages	List of locales for which there are registered titles.
Title	*Name* given by the `prodreg browse` subcommand. This name can be localized to the locale in which the shell is running.
Unique Name	Name used by previous versions of the Solaris Product Registry. This value is often set to the package name corresponding to a given component in the registry.
Vendor	Vendor who produced the component.
Version	Version string associated with the component.

The Registry can contain components which do not correspond to software actually installed on the system. This can be detected several ways. The easiest is to check using the `info` subcommand if a component is damaged. Another way is to determine where software was installed using the `info` subcommand, and verify it is still there.

Name projadd – administer a new project on the system

Synopsis

```
projadd [-n] [-f filename] [-p projid [-o]] [-c comment]
     [-U user [,user]... ] [-G group [,group]... ]
     [ [-K name [=value [,value]...]...]] project
```

Description `projadd` adds a new project entry to the `/etc/project` file. If the files backend is being used for the project database, the new project is available for use immediately upon the completion of the `projadd` command.

Options The following options are supported:

`-c` *comment*
: Add a project comment. Comments are stored in the project's entry in the `/etc/project` file. Generally, comments contain a short description of the project and are used as the field for the project's full name.

  Specify *comment* as a text string. *comment* cannot contain a colon (`:`) or NEWLINE.

`-f` *filename*
: Specify the project file to modify. If no *filename* is specified, the system project file, `/etc/project`, is modified.

`-G` *group*[,group...]
: Specify a group list for the project.

`-K` *name*[=*value*[,*value*...]
: Specify an attribute list for the project. Multiple `-K` options can be specified to set values on multiple keys, such as:

  `-K` *key1=value1* `-K "`*key2=*`(`*value2a*`),(`*value2b*`)"`

  Resource control attributes use parentheses to specify values for a key. Because many user shells interpret parentheses as special characters, it is best to enclose an argument to `-K` that contains parentheses with double quotes, as shown above and in EXAMPLES, below. See `resource_controls(5)` for a description of the resource controls you can specify for a project.

`-n`
: Syntax check. Check the format of the existing system project file and modifications only. The contents of the existing project file, such as user names, group names, and resources that are specified in the project attributes are not checked.

`-o`
: This option allows the project ID specified by the `-p` option to be non-unique within the project file.

`-p` *projid*
: Set the project ID of the new project.

  Specify *projid* as a non-negative decimal integer below `UID_MAX` as defined in `limits.h`. *projid* defaults to the next available

unique number above the highest number currently assigned. For example, if *projid*s `100`, `105`, and `200` are assigned, the next default *projid* is `201`. *projid*s between `0-99` are reserved by SunOS.

`-U` *user*[,user...] Specify a user list for the project.

Operands The following operands are supported:

project The name of the project to create. The *project* operand is a string consisting of characters from the set of alphabetic characters, numeric characters, underline (_), and hyphen (-). The period ('.') is reserved for projects with special meaning to the operating system. The first character of the project name must be a letter. An error message is displayed if these restrictions are not met.

Examples **EXAMPLE 1** Adding a Project

The following command creates the project `salesaudit` and sets the resource controls specified as arguments to the `-K` option.

```
projadd -p 111 -G sales,finance -c "Auditing Project" \
   -K "rcap.max-rss=10GB" \
   -K "process.max-file-size=(priv,50MB,deny)" \
   -K "task.max-lwps=(priv,100,deny)" salesaudit
```

This command would produce the following entry in `/etc/project`:

```
salesaudit:111:Auditing Project::sales,finance: \
process.max-file-size=(priv,52428800,deny); \
rcap.max-rss=10737418240;task.max-lwps=(priv,100,deny)
```

Note that the preceding would appear as one line in `/etc/project`.

Comparing the `projadd` command and resulting output in `/etc/project`, note the effect of the scaling factor in the resource cap (`rcap.max-rss=10GB`) and the resource control (`process.max-file-size=(priv,50MB,deny)`). Modifiers, such as B, KB, and MB, and scaling factors are specified in `resource_controls(5)`.

Exit Status The following exit values are returned:

`0` Successful completion.

`2` The command syntax was invalid. A usage message for `projadd` is displayed.

`3` An invalid argument was provided to an option.

`4` The *projid* given with the `-p` option is already in use.

`5` The project files contain an error. See `project(4)`.

`6` The project to be added, group, user, or resource does not exist.

9 The project is already in use.

10 Cannot update the `/etc/project` file.

Files `/etc/project` System project file

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
Interface Stability	See below.

Invocation is evolving. Human readable output is unstable.

See Also `projects(1)`, `groupadd(1M)`, `groupdel(1M)`, `groupmod(1M)`, `grpck(1M)`, `projdel(1M)`, `projmod(1M)`, `useradd(1M)`, `userdel(1M)`, `usermod(1M)`, `project(4)`, `attributes(5)`, `resource_controls(5)`

Notes In case of an error, `projadd` prints an error message and exits with a non-zero status.

`projadd` adds a project definition only on the local system. If a network name service such as NIS or LDAP is being used to supplement the local `/etc/project` file with additional entries, `projadd` cannot change information supplied by the network name service.

Name projdel – delete a project from the system

Synopsis

```
projdel [-f filename] project
```

Description The `projdel` utility deletes a project from the system and makes the appropriate changes to the system file.

Options The following options are supported:

`-f` *filename* Specify the project file to modify. If no *filename* is specified, the system project file, `/etc/project`, is modified.

Operands The following operands are supported:

project The name of the project to be deleted.

Exit Status The following exit values are returned:

`0` Successful completion.

`2` The command syntax was invalid. A usage message for `projdel` is displayed.

`3` An invalid argument was provided to an option.

`4` The *projid* given with the `-p` option is already in use.

`5` The project files contain an error. See `project(4)`.

`6` The project to be modified, group, user, or resource does not exist.

`9` The project is already in use.

`10` Cannot update the `/etc/project` file.

Files `/etc/project` System project file

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
Interface stabilty	See below.

Invocation is evolving. Human readable output is unstable.

See Also `projects(1)`, `groupadd(1M)`, `groupdel(1M)`, `groupmod(1M)`, `grpck(1M)`, `logins(1M)`, `projadd(1M)`, `projmod(1M)`, `useradd(1M)`, `userdel(1M)`, `usermod(1M)`, `project(4)`, `attributes(5)`

Diagnostics In case of an error, `projdel` prints an error message and exits with a non-zero status.

Notes `projdel` deletes a project definition only on the local system. If a network name service such as NIS or LDAP is being used to supplement the local `/etc/project` file with additional entries, `projdel` cannot change information supplied by the network name service.

Name projmod – modify a project's information on the system

Synopsis

```
projmod [-n] [-A|-f filename | -]

projmod [-n] [-A|-f filename | -] [-p projid [-o]]
     [-c comment] [-a|-s|-r] [-U user [,user]... ]
     [-G group [,group]... ]
     [ [-K name [=value [,value]...]...]]
     [-l new_projectname] project
```

Description The `projmod` utility modifies a project's definition on the system. `projmod` changes the definition of the specified project and makes the appropriate project-related system file and file system changes.

Options The following options are supported:

`-A`
Apply the project's resource controls, as defined in the system's project database, to the project if it is active.

`-a`
Specify that the users, groups, attributes, or attribute values specified by the `-U`, `-G` or `-K` options should be added to the project, rather than replacing the existing member or attribute list.

`-c` *comment*
Specify *comment* as a text string. Generally, *comment* contains a short description of the project. This information is stored in the project's `/etc/project` entry.

`-f` *filename*
Specify the project file to modify. If no *filename* is specified, the system project file, `/etc/project`, is modified.

`-G` *group* [,*group*...]
Specify a replacement list of member groups of the project. When used in conjunction with the `-a` or `-r` options, this option specifies a list of groups to be added or removed from the project.

`-K` *name*[=*value*[,*value*...]
Specify a replacement list of project attributes for the project. When used in conjunction with the `-a`, `-r`, or `-s` options, this option specifies a list of attribute values to be added, removed, or replaced in the project. Attributes must be delimited by semicolons (`;`). Multiple `-K` options can be specified to set, add, remove, or substitute values on multiple keys, such as:

```
-K key1=value1 -K "key2=(value2a),(value2b)"
```

Resource control attributes use parentheses to specify values for a key. Because many user shells interpret parentheses as special characters, it is best to enclose an argument to `-K` that

contains parentheses with double quotes, as shown above and in EXAMPLES, below. See `resource_controls(5)` for a description of the resource controls you can specify for a project.

`-l` *new_projectname*
Specify the new project name for the project. The *new_projectname* argument is a string consisting of characters from the set of alphabetic characters, numeric characters, period (`.`), underline (_), and hyphen (`-`). The first character should be alphabetic. An error message is written if these restrictions are not met. The project name must also be unique within the project file.

`-n`
Syntax check. Check the format of the existing system project file and modifications only. The contents of the existing project file, such as user names, group names, and resources that are specified in the project attributes are not checked.

`-o`
This option allows the project ID specified by the `-p` option to be non-unique within the project file.

`-p` *projid*
Specify a new project ID for the project. It must be a non-negative decimal integer less than MAXUID as defined in `param.h`. This value must be unique within the project file if the `-o` option is not specified.

`-r`
Specify that the users, groups, attributes, or attribute values specified by the `-U`, `-G` or `-K` options should be removed from the project, rather than replacing the existing member or attribute list.

`-s`
Specify that the list of attributes specified by the `-K` option should have their values replaced. If the attributes do not exist, they are added as if the a option was used. This option has no effect the `-U` or `-G` options.

`-U` *user* [,*user*...]
Specify a replacement list of member users of the project. When used in conjunction with the `-a` or `-r` options, this option specifies a list of users to be added or removed from the project.

Operands The following operands are supported:

project	An existing project name to be modified or displayed.
(none)	If no operand is given, the project file is validated without modifying any project.

Examples

EXAMPLE 1 Using the -K Option for Addition of an Attribute Value

Consider the following `project(4)` entry:

```
salesaudit:111:Auditing Project::sales,finance: \
  process.max-file-size=(priv,52428800,deny); \
  task.max-lwps=(priv,100,deny)
```

The preceding would appear as one line in `/etc/project`. For this and the following examples, the focus is on the attributes field in the `project` entry. That is, the last field, the field following the last semicolon.

The attributes field for the project `salesaudit` lists the following resource control:

```
task.max-lwps=(priv,1000,signal=KILL)
```

The following `projmod` command adds an action clause to the preceding entry:

```
# projmod -a -K "task.max-lwps=(priv,100,deny)" salesaudit
```

...with the resulting attributes field in the entry for `salesaudit`:

```
task.max-lwps=(priv,100,deny),(priv,1000,signal=KILL)
```

EXAMPLE 2 Using the -K Option for the Substitution of an Attribute Value

Assume an attributes field in a `project(4)` entry for the project `salesaudit` that lists the following resource control:

```
task.max-lwps=(priv,100,deny),(priv,1000,signal=KILL)
```

The following `projmod` command substitutes the action clause specified in the command for the action clauses in the preceding entry:

```
# projmod -s -K "task.max-lwps=(priv,500,signal=SIGSTOP)" salesaudit
```

...with the resulting attributes field in the entry for `salesaudit`:

```
task.max-lwps=(priv,500,signal=SIGSTOP)
```

EXAMPLE 3 Using the -K Option for Removal of an Attribute Value

Assume an attributes field in a `project(4)` entry for a project `salesaudit` that lists the following resource control:

```
task.max-lwps=(priv,100,deny),(priv,1000,signal=KILL)
```

The following `projmod` command removes the first action clause from the preceding entry:

```
# projmod -r -K "task.max-lwps=(priv,100,deny)" salesaudit
```

...with the resulting attributes field in the entry for `salesaudit`:

EXAMPLE 3 Using the -K Option for Removal of an Attribute Value *(Continued)*

```
task.max-lwps=(priv,1000,signal=KILL)
```

EXAMPLE 4 Specifying Multiple Attribute Values

Suppose you want to achieve the following resource controls for the project `salesaudit`:

```
task.max-lwps=(priv,100,deny)
process.max-file-size=(priv,50MB,deny)
```

The following `projmod` command adds these resource controls for `salesaudit`:

```
# projmod -a -K "task.max-lwps=(priv,100,deny)" \
-K "process.max-file-size=(priv,50MB,deny)" salesaudit
```

...with the resulting attributes field in the entry for `salesaudit`:

```
task.max-lwps=(priv,100,deny);process.max-file-size=(priv,52428800,deny)
```

In this example, note the effect of the use of the modifier and scaling factor for the resource control `process.max-file-size`. The specification in `projmod`:

```
"process.max-file-size=(priv,50MB,deny)"
```

...becomes, in `/etc/project`:

```
process.max-file-size=(priv,52428800,deny)
```

That is, `50MB` is expanded to `52428800`. The modifiers, such as MB, and scaling factors you can use for resource controls are specified in `resource_controls(5)`.

EXAMPLE 5 Binding a Pool to a Project

The following command sets the `project.pool` attribute for the project `sales`.

```
# projmod -a -K project.pool=salespool sales
```

Exit Status

In case of an error, `projmod` prints an error message and exits with one of the following values:

The following exit values are returned:

`0` Successful completion.

`2` The command syntax was invalid. A usage message for `projmod` is displayed.

`3` An invalid argument was provided to an option.

`4` The *projid* given with the `-p` option is already in use.

`5` The project files contain an error. See `project(4)`.

`6` The project to be modified, group, user, or resource does not exist.

9	The project is already in use.
10	Cannot update the `/etc/project` file.

Files

`/etc/group`	System file containing group definitions
`/etc/project`	System project file
`/etc/passwd`	System password file
`/etc/shadow`	System file containing users' encrypted passwords and related information

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
Interface Stability	See below.

Invocation is committed. Human readable output is uncommitted.

See Also `groupadd(1M)`, `groupdel(1M)`, `groupmod(1M)`, `projadd(1M)`, `projdel(1M)`, `useradd(1M)`, `userdel(1M)`, `usermod(1M)`, `passwd(4)`, `project(4)`, `attributes(5)`, `resource_controls(5)`

Notes The `projmod` utility modifies project definitions only in the local `/etc/project` file. If a network name service such as NIS or LDAP is being used to supplement the local files with additional entries, *projmod* cannot change information supplied by the network name service. However `projmod` verifies the uniqueness of project name and project ID against the external name service.

Name prstat – report active process statistics

Synopsis

```
prstat [-acJLmRtTv] [-C psrsetlist] [-j projlist]
     [-k tasklist] [-n ntop[,nbottom]] [-p pidlist]
     [-P cpulist] [-s key | -S key ] [-u euidlist]
     [-U uidlist] [-z zoneidlist] [-Z] [interval [count]]
```

Description The `prstat` utility iteratively examines all active processes on the system and reports statistics based on the selected output mode and sort order. `prstat` provides options to examine only processes matching specified PIDs, UIDs, zone IDs, CPU IDs, and processor set IDs.

The `-j`, `-k`, `-C`, `-p`, `-P`, `-u`, `-U`, and `-z` options accept lists as arguments. Items in a list can be either separated by commas or enclosed in quotes and separated by commas or spaces.

If you do not specify an option, `prstat` examines all processes and reports statistics sorted by CPU usage.

Options The following options are supported:

`-a`
Report information about processes and users. In this mode `prstat` displays separate reports about processes and users at the same time.

`-c`
Print new reports below previous reports instead of overprinting them.

`-C` *psrsetlist*
Report only processes or lwps that are bound to processor sets in the given list. Each processor set is identified by an integer as reported by `psrset(1M)`. The load averages displayed are the sum of the load averages of the specified processor sets (see `pset_getloadavg(3C)`). Processes with one or more LWPs bound to processor sets in the given list are reported even when the `-L` option is not used.

`-j` *projlist*
Report only processes or lwps whose project ID is in the given list. Each project ID can be specified as either a project name or a numerical project ID. See `project(4)`.

`-J`
Report information about processes and projects. In this mode `prstat` displays separate reports about processes and projects at the same time.

`-k` *tasklist*
Report only processes or lwps whose task ID is in *tasklist*.

`-L`
Report statistics for each light-weight process (LWP). By default, `prstat` reports only the number of LWPs for each process.

`-m`
Report microstate process accounting information. In addition to all fields listed in `-v` mode, this mode also includes the percentage of time the process has spent processing system traps, text page faults, data page faults, waiting for user locks and waiting for CPU (latency time).

`-n` *ntop*[,*nbottom*]
Restrict number of output lines. The *ntop* argument determines how many lines of process or `lwp` statistics are reported, and the *nbottom* argument determines how many lines of user, task, or projects statistics are reported if the `-a`, `-t`, `-T`, or `-J` options are specified. By default, `prstat` displays as many lines of output that fit in a window or terminal. When you specify the `-c` option or direct the output to a file, the default values for `ntop` and `nbottom` are `15` and `5`.

`-p` *pidlist*
Report only processes whose process ID is in the given list.

`-P` *cpulist*
Report only processes or lwps which have most recently executed on a CPU in the given list. Each CPU is identified by an integer as reported by `psrinfo(1M)`.

`-R`
Put `prstat` in the real time scheduling class. When this option is used, `prstat` is given priority over time-sharing and interactive processes. This option is available only for superuser.

`-s` *key*
Sort output lines (that is, processes, `lwps`, or users) by *key* in descending order. Only one *key* can be used as an argument.

There are five possible key values:

cpu
Sort by process CPU usage. This is the default.

pri
Sort by process priority.

rss
Sort by resident set size.

size
Sort by size of process image.

time
Sort by process execution time.

`-S` *key*
Sort output lines by *key* in ascending order. Possible *key* values are the same as for the `-s` option. See `-s`.

`-t`
Report total usage summary for each user. The summary includes the total number of processes or LWPs owned by the user, total size of process images, total resident set size, total cpu time, and percentages of recent cpu time and system memory.

`-T`
Report information about processes and tasks. In this mode `prstat` displays separate reports about processes and tasks at the same time.

`-u` *euidlist*
Report only processes whose effective user ID is in the given list. Each user ID may be specified as either a login name or a numerical user ID.

`-U` *uidlis*t
Report only processes whose real user ID is in the given list. Each user ID may be specified as either a login name or a numerical user ID.

`-v`
Report verbose process usage. This output format includes the percentage of time the process has spent in user mode, in system mode, and sleeping. It also includes the number of voluntary and involuntary context switches, system calls and the number of signals received. Statistics that are not reported are marked with the `-` sign.

`-z` *zoneidlist*
Report only processes or LWPs whose zone ID is in the given list. Each zone ID can be specified as either a zone name or a numerical zone ID. See `zones(5)`.

`-Z`
Report information about processes and zones. In this mode, `prstat` displays separate reports about processes and zones at the same time.

Output The following list defines the column headings and the meanings of a `prstat` report:

PID
The process ID of the process.

USERNAME
The real user (login) name or real user ID.

SWAP
The total virtual memory size of the process, including all mapped files and devices, in kilobytes (`K`), megabytes (`M`), or gigabytes (`G`).

RSS
The resident set size of the process (RSS), in kilobytes (K), megabytes (M), or gigabytes (G). The RSS value is an estimate provided by `proc(4)` that might underestimate the actual resident set size. Users who want to get more accurate usage information for capacity planning should use the `-x` option to `pmap(1)` instead.

STATE
The state of the process:

cpu*N*
Process is running on CPU *N*.

sleep
Sleeping: process is waiting for an event to complete.

wait
Waiting: process is waiting for CPU usage to drop to the CPU-caps enforced limits. See the description of `CPU-caps` in `resource_controls(5)`.

run
Runnable: process in on run queue.

zombie
Zombie state: process terminated and parent not waiting.

stop
Process is stopped.

PRI
The priority of the process. Larger numbers mean higher priority.

NICE
Nice value used in priority computation. Only processes in certain scheduling classes have a nice value.

TIME
The cumulative execution time for the process.

CPU
The percentage of recent CPU time used by the process. If executing in a non-global `zone` and the pools facility is active, the percentage will be that of the processors in the processor set in use by the pool to which the `zone` is bound.

PROCESS
The name of the process (name of executed file).

LWPID
The `lwp` ID of the `lwp` being reported.

NLWP
The number of `lwps` in the process.

With the some options, in addition to a number of the column headings shown above, there are:

NPROC
Number of processes in a specified collection.

MEMORY
Percentage of memory used by a specified collection of processes.

The following columns are displayed when the `-v` or `-m` option is specified

USR
The percentage of time the process has spent in user mode.

SYS
The percentage of time the process has spent in system mode.

TRP
The percentage of time the process has spent in processing system traps.

TFL
The percentage of time the process has spent processing text page faults.

DFL
The percentage of time the process has spent processing data page faults.

LCK
The percentage of time the process has spent waiting for user locks.

SLP
The percentage of time the process has spent sleeping.

LAT
The percentage of time the process has spent waiting for CPU.

VCX
The number of voluntary context switches.

ICX
The number of involuntary context switches.

SCL
The number of system calls.

SIG
The number of signals received.

Under the `-L` option, one line is printed for each `lwp` in the process and some reporting fields show the values for the `lwp`, not the process.

Operands The following operands are supported:

count
Specifies the number of times that the statistics are repeated. By default, `prstat` reports statistics until a termination signal is received.

interval
Specifies the sampling interval in seconds; the default interval is `5` seconds.

Examples

EXAMPLE 1 Reporting the Five Most Active Super-User Processes

The following command reports the five most active super-user processes running on CPU1 and CPU2:

```
example% prstat -u root -n 5 -P 1,2 1 1

PID   USERNAME  SWAP   RSS STATE  PRI  NICE      TIME  CPU PROCESS/LWP
 306   root     3024K 1448K sleep   58    0   0:00.00 0.3% sendmail/1
 102   root     1600K  592K sleep   59    0   0:00.00 0.1% in.rdisc/1
 250   root     1000K  552K sleep   58    0   0:00.00 0.0% utmpd/1
 288   root     1720K 1032K sleep   58    0   0:00.00 0.0% sac/1
   1   root      744K  168K sleep   58    0   0:00.00 0.0% init/1
TOTAL:       25, load averages:  0.05, 0.08, 0.12
```

EXAMPLE 2 Displaying Verbose Process Usage Information

The following command displays verbose process usage information about processes with lowest resident set sizes owned by users root and john.

```
example% prstat -S rss -n 5 -vc -u root,john

See Also

proc(1), psrinfo(1M), psrset(1M), sar(1M), pset_getloadavg(3C), proc(4), project(4), attributes(5), resource_controls(5), zones(5)

Notes The snapshot of system usage displayed by `prstat` is true only for a split-second, and it may not be accurate by the time it is displayed. When the `-m` option is specified, `prstat` tries to turn on microstate accounting for each process; the original state is restored when `prstat` exits. See `proc(4)` for additional information about the microstate accounting facility.

The total memory size reported in the SWAP and RSS columns for groups of processes can sometimes overestimate the actual amount of memory used by processes with shared memory segments.

Name prtconf – print system configuration

Synopsis

```
/usr/sbin/prtconf   [-V] |  [-F] |  [-x] |  [-bpv]
 |  [-acDPv] [dev_path]
```

Description The `prtconf` command prints the system configuration information. The output includes the total amount of memory, and the configuration of system peripherals formatted as a device tree.

If a device path is specified on the command line for those command options that can take a device path, `prtconf` will only display information for that device node.

Options The following options are supported:

`-a` Display all the ancestors device nodes, up to the root node of the device tree, for the device specified on the command line.

`-b` Display the firmware device tree root properties for the purpose of platform identification. These properties are “name”, “compatible”, “banner-name” and “model”.

`-c` Display the device subtree rooted at the device node specified on the command line, that is, display all the children of the device node specified on the command line.

`-D` For each system peripheral in the device tree, displays the name of the device driver used to manage the peripheral.

`-F` A SPARC-only option. Returns the device path name of the console frame buffer, if one exists. If there is no frame buffer, `prtconf` returns a non-zero exit code. This flag must be used by itself. It returns only the name of the console, frame buffer device or a non-zero exit code. For example, if the console frame buffer on a SUNW,Ultra-30 is `ffb`, the command returns: `/SUNW,ffb@1e,0:ffb0`. This option could be used to create a symlink for `/dev/fb` to the actual console device.

`-p` Displays information derived from the device tree provided by the firmware (PROM) on SPARC platforms or the booting system on x86 platforms.The device tree information displayed using this option is a snapshot of the initial configuration and may not accurately reflect reconfiguration events that occur later.

`-P` Includes information about pseudo devices. By default, information regarding pseudo devices is omitted.

`-v` Specifies verbose mode.

`-V` Displays platform-dependent PROM (on SPARC platforms) or booting system (on x86 platforms) version information. This flag must be used by itself. The output is a string. The format of the string is arbitrary and platform-dependent.

`-x` Reports if the firmware on this system is 64-bit ready. Some existing platforms may need a firmware upgrade in order to run the 64-bit kernel. If the operation is not applicable to this platform or the firmware is already 64-bit ready, it exits silently with a return code of zero. If the operation is applicable to this platform and the firmware is not 64-bit ready, it displays a descriptive message on the standard output and exits with a non-zero return code. The hardware platform documentation contains more information about the platforms that may need a firmware upgrade in order to run the 64-bit kernel.

This flag overrides all other flags and must be used by itself.

Operands The following operands are supported:

dev_path The path to a target device minor node, device nexus node, or device link for which device node configuration information is displayed

Exit Status The following exit values are returned:

`0` No error occurred.

`non-zero` With the `-F` option (SPARC only), a non-zero return value means that the output device is not a frame buffer. With the `-x` option, a non-zero return value means that the firmware is not 64–bit ready. In all other cases, a non-zero return value means that an error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
Interface Stability	Unstable

See Also `fuser(1M)`, `modinfo(1M)`, `sysdef(1M)`, `attributes(5)`

Sun Hardware Platform Guide

SPARC Only `openprom(7D)`

Notes The output of the `prtconf` command is highly dependent on the version of the PROM installed in the system. The output will be affected in potentially all circumstances.

The `driver not attached` message means that no driver is currently attached to that instance of the device. In general, drivers are loaded and installed (and attached to hardware instances) on demand, and when needed, and may be uninstalled and unloaded when the device is not in use.

On x86 platforms, the use of `prtconf -vp` provides a subset of information from `prtconf -v`. The value of integer properties from `prtconf -vp` might require byte swapping for correct interpretation.

Name prtdiag – display system diagnostic information

Synopsis

```
/usr/sbin/prtdiag [-v] [-l]
```

Description `prtdiag` displays system configuration and diagnostic information on `sun4u` and `sun4v` systems.

The diagnostic information lists any failed field replaceable units (FRUs) in the system.

The interface, output, and location in the directory hierarchy for `prtdiag` are uncommitted and subject to change in future releases.

`prtdiag` does not display diagnostic information and environmental status when executed on the Sun Enterprise 10000 server. See the `/var/opt/SUNWssp/adm/${SUNW_HOSTNAME}/messages` file on the system service processor (SSP) to obtain such information for this server.

Options The following options are supported:

`-l` Log output. If failures or errors exist in the system, output this information to `syslogd(1M)` only.

`-v` Verbose mode. Displays the time of the most recent AC Power failure, and the most recent hardware fatal error information, and (if applicable) environmental status. The hardware fatal error information is useful to repair and manufacturing for detailed diagnostics of FRUs.

Exit Status The following exit values are returned:

`0` No failures or errors are detected in the system.

`1` Failures or errors are detected in the system.

`2` An internal `prtdiag` error occurred, for example, out of memory.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWkvm
Interface Stability	Unstable*

*The output is unstable.

See Also `modinfo(1M)`, `prtconf(1M)`, `psrinfo(1M)`, `sysdef(1M)`, `syslogd(1M)`, `attributes(5)`, `openprom(7D)`

Notes Not all diagnostic and system information is available on every Solaris platform, and therefore cannot be displayed by `prtdiag`. On those platforms, further information can be obtained from the System Controller.

Name prtdscp – display DSCP IP addresses

Synopsis

```
prtdscp [-v ]

prtdscp [-v ] -h

prtdscp [-v ] -d

prtdscp [-v ] -s
```

Description `prtdscp` displays the IP addresses associated with a Domain to Service Processor Communications Protocol (DSCP) link. If no arguments are specified, `prtdscp` displays the IP addresses on both ends of the DSCP link. The IP address of either the Service Processor or domain side can be displayed separately by the use of the `-s` or `-d` options, respectively.

Options The following options are supported:

`-v` Verbose mode. Print additional details about the program's internal progress to `stderr`.

`-h` Help. Print a brief synopsis of the program's usage and exit. All other command line arguments are ignored.

`-d` Display only the local domain's IP address.

`-s` Display only the remote Service Processor's IP address.

Examples **EXAMPLE 1** Displaying both addresses

The following example displays both the local domain's IP address and the remote SP's IP address:

```
# prtdscp
Domain Address: 192.168.103.2
SP Address: 192.168.103.1
```

EXAMPLE 2 Displaying the local IP address

The following example displays the local domain's IP address:

```
# prtdscp -d
192.168.103.2
```

EXAMPLE 3 Displaying the remote IP address

The following example display the remote SP's IP address:

```
# prtdscp -s
192.168.103.1
```

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Name prtfru – print FRUID-specific information about the FRUs on a system or domain

Synopsis

```
/usr/sbin/prtfru [-d] | [-clx] [container]
```

Description The `prtfru` utility is used to obtain FRUID data from the system or domain. Its output is that of a tree structure echoing the path in the FRU (Field-Replaceable Unit) tree to each container. When a container is found, the data from that container is printed in a tree-like structure as well.

`prtfru` without any arguments will print the FRU hierarchy and all of the FRUID container data. `prtfru` prints to stdout which may be redirected to a file.

Options The following options are supported:

`-c` Prints *only* the containers and their data. This option does not print the FRU tree hierarchy.

`-d` Prints a DTD for the current registry to stdout.

`-l` Prints *only* the FRU tree hierarchy. This option does not print the container data.

`-x` Prints in XML format with a system identifier (SYSTEM) of `prtfrureg.dtd`.

Options `-c` and `-l` can be used together to obtain a list of the containers.

Operands The folowing operand is supported:

container The name of a particular container in the FRU hierarchy, that is, either the name or path/name of a container as displayed in the `-l` option.

Exit Status The following exit values are returned:

`0` All information was found and printed successfully.

`>0` An error has occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWfruid

See Also `fruadm(1M)`, `attributes(5)`

Name prtpicl – print PICL tree

Synopsis

```
/usr/sbin/prtpicl [-c picl_class] [-v]
```

Description The `prtpicl` command prints the PICL tree maintained by the PICL daemon. The output of `prtpicl` includes the name and PICL class of the nodes.

Options The following options are supported:

`-c` *picl_class* Print only the nodes of the named PICL class.

`-v` Print in verbose mode. In verbose mode, `prtpicl` prints a list of properties and values for each node. Verbose mode is disabled by default.

Exit Status The following exit values are returned:

`0` Successful completion.

`non-zero` An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpiclu

See Also `picld(1M)`, `attributes(5)`

Name prtvtoc – report information about a disk geometry and partitioning

Synopsis `prtvtoc [-fhs] [-t` *vfstab*`] [-m` *mnttab*`]` *device*

Description The `prtvtoc` command allows the contents of the label to be viewed. The command can be used only by the super-user.

The *device* name can be the file name of a raw device in the form of `/dev/rdsk/c?t?d?s2` or can be the file name of a block device in the form of `/dev/dsk/c?t?d?s2`.

Options The following options are supported:

`-f` Report on the disk free space, including the starting block address of the free space, number of blocks, and unused partitions.

`-h` Omit the headers from the normal output.

`-m` *mnttab* Use *mnttab* as the list of mounted filesystems, in place of `/etc/mnttab`.

`-s` Omit all headers but the column header from the normal output.

`-t` *vfstab* Use *vfstab* as the list of filesystem defaults, in place of `/etc/vfstab`.

Examples **EXAMPLE 1** Using the `prtvtoc` Command

The following example uses the `prtvtoc` command on a 424-megabyte hard disk:

```
example# prtvtoc /dev/rdsk/c0t3d0s2
* /dev/rdsk/c0t3d0s2 partition map
*
* Dimension:
*     512 bytes/sector
*      80 sectors/track
*       9 tracks/cylinder
*     720 sectors/cylinder
*    2500 cylinders
*    1151 accessible cylinders
*
* Flags:
*   1: unmountable
*  10: read-only
* *                          First    Sector   Last
* Partition   Tag   Flags   Sector   Count    Sector   Mount Directory
     0         2     00          0    76320    76319   /
     1         3     01      76320   132480   208799
     2         5     00          0   828720   828719
     5         6     00     208800   131760   340559   /opt
     6         4     00     340560   447120   787679   /usr
     7         8     00     787680    41040   828719   /export/home
example#
```

EXAMPLE 1 Using the `prtvtoc` Command *(Continued)*

The data in the `Tag` column above indicates the type of partition, as follows:

Name	*Number*
UNASSIGNED	0x00
BOOT	0x01
ROOT	0x02
SWAP	0x03
USR	0x04
BACKUP	0x05
STAND	0x06
VAR	0x07
HOME	0x08
ALTSCTR	0x09
CACHE	0x0a
RESERVED	0x0b

The data in the `Flags` column above indicates how the partition is to be mounted, as follows:

Name	*Number*
MOUNTABLE, READ AND WRITE	0x00
NOT MOUNTABLE	0x01
MOUNTABLE, READ ONLY	0x10

EXAMPLE 2 Using the `prtvtoc` Command with the `-f` Option

The following example uses the `prtvtoc` command with the `-f` option on a 424-megabyte hard disk:

```
example# prtvtoc -f /dev/rdsk/c0t3d0s2
FREE_START=0 FREE_SIZE=0 FREE_COUNT=0 FREE_PART=34
```

EXAMPLE 3 Using the `prtvtoc` Command on a Disk Over One Terabyte

The following example uses uses the `prtvtoc` command on a disk over one terabyte:.

EXAMPLE 3 Using the `prtvtoc` Command on a Disk Over One Terabyte *(Continued)*

```
example# prtvtoc /dev/rdsk/c1t1d0s2
* /dev/rdsk/c1t1d0s2 partition map
*
* Dimensions:
*     512 bytes/sector
* 3187630080 sectors
* 3187630013 accessible sectors
*
* Flags:
*   1: unmountable
*  10: read-only
*
*                          First     Sector    Last
* Partition  Tag  Flags    Sector     Count    Sector  Mount Directory
0      2    00         34    262144    262177
1      3    01     262178    262144    524321
6      4    00     524322 3187089340 3187613661
8     11    00  3187613662     16384 318763004
```

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `devinfo(1M)`, `fmthard(1M)`, `format(1M)`, `mount(1M)`, `attributes(5)`

Warnings The `mount` command does not check the "not mountable" bit.

Name psradm – change processor operational status

Synopsis

```
psradm -f | -i | -n | -s [-v] [-F] processor_id

psradm -a -f | -i | -n | -s [-v] [-F]
```

Description The `psradm` utility changes the operational status of processors. The legal states for the processor are `on-line`, `off-line`, `spare`, `faulted`, and `no-intr`.

An `on-line` processor processes LWPs (lightweight processes) and can be interrupted by I/O devices in the system.

An `off-line` processor does not process any LWPs. Usually, an `off-line` processor is not interruptible by I/O devices in the system. On some processors or under certain conditions, it might not be possible to disable interrupts for an `off-line` processor. Thus, the actual effect of being `off-line` might vary from machine to machine.

A spare processor does not process any LWPs. A spare processor can be brought `on-line`, `off-line` or to `no-intr` by a privileged user of the system or by the kernel in response to changes in the system state.

A faulted processor is identified by the kernel, which monitors the behavior of processors over time. A privileged user can set the state of a faulted processor to be `on-line`, `off-line`, `spare` or `no-intr`, but must use the force option to do so.

A `no-intr` processor processes LWPs but is not interruptible by I/O devices.

A processor can not be taken `off-line` or made `spare` if there are LWPs that are bound to the processor unless the additional `-F` option is used. The `-F` option removes processor bindings of such LWPs before changing the processor's operational status. On some architectures, it might not be possible to take certain processors `off-line` or `spare` if, for example, the system depends on some resource provided by the processor.

At least one processor in the system must be able to process LWPs. At least one processor must also be able to be interrupted. Since an `off-line` or `spare` processor can be interruptible, it is possible to have an operational system with one processor `no-intr` and all other processors `off-line` or `spare` but with one or more accepting interrupts.

If any of the specified processors are powered off, `psradm` might power on one or more processors.

Only users with the `PRIV_SYS_RES_CONFIG` privilege can use the `psradm` utility.

Options The following options are supported:

`-a` Perform the action on all processors, or as many as possible.

`-f` Take the specified processors `off-line`.

`-F` Force the transition to the additional specified state. Required if one or more of the specified processors was in the faulted state. Set the specified processors to faulted, if no other transition option was specified. Forced transitions can only be made to `faulted`, `spare`, or `off-line` states. Administrators are encouraged to use the `-Q` option for `pbind(1M)` to find out which threads will be affected by forced a processor state transition.

`-i` Set the specified processors `no-intr`.

`-n` Bring the specified processors `on-line`.

`-s` Make the specified processors spare.

`-v` Output a message giving the results of each attempted operation.

Operands The following operands are supported:

processor_id The processor ID of the processor to be set `on-line` or `off-line`, `spare`, or `no-intr`.

Specify *processor_id* as an individual processor number (for example, `3`), multiple processor numbers separated by spaces (for example, `1 2 3`), or a range of processor numbers (for example, `1-4`). It is also possible to combine ranges and (individual or multiple) *processor_id*s (for example, `1-3 5 7-8 9`).

Examples **EXAMPLE 1** Setting Processors to `off-line`

The following example sets processors 2 and 3 `off-line`:

```
% psradm -f 2 3
```

EXAMPLE 2 Setting Processors to no-intr

The following example sets processors 1 and 2 `no-intr`:

```
% psradm -i 1 2
```

EXAMPLE 3 Setting Processors to `spare`

The following example sets processors 1 and 2 spare, even if either of the processors was in the faulted state:

```
% psradm -F -s 1 2
```

EXAMPLE 4 Setting All Processors `on-line`

```
% psradm -a -n
```

EXAMPLE 5 Forcing Processors to `off-line`

The following example sets processors 1 and 2 offline, and revokes the processor bindings from the processes bound to them:

```
% psradm -F -f 1 2
```

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Files `/etc/wtmpx` Records logging processor status changes

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `pbind(1M)`, `psrinfo(1M)`, `psrset(1M)`, `p_online(2)`, `processor_bind(2)`, `attributes(5)`

Diagnostics

`psradm: processor 4: Invalid argument`
The specified processor does not exist in the configuration.

`psradm: processor 3: Device busy`
The specified processor could not be taken `off-line` because it either has LWPs bound to it, is the last `on-line` processor in the system, or is needed by the system because it provides some essential service.

`psradm: processor 3: Device busy`
The specified processor could not be set `no-intr` because it is the last interruptible processor in the system, or or it is the only processor in the system that can service interrupts needed by the system.

`psradm: processor 3: Device busy`
The specified processor is powered off, and it cannot be powered on because some platform-specific resource is unavailable.

`psradm: processor 0: Not owner`
The user does not have permission to change processor status.

`psradm: processor 2: Operation not supported`
The specified processor is powered off, and the platform does not support power on of individual processors.

Name psrinfo – displays information about processors

Synopsis

```
psrinfo [-p] [-v] [processor_id]...

psrinfo [-p] -s processor_id
```

Description `psrinfo` displays information about processors. Each physical processor may support multiple virtual processors. Each virtual processor is an entity with its own interrupt ID, capable of executing independent threads.

Without the *processor_id* operand, `psrinfo` displays one line for each configured processor, displaying whether it is on-line, non-interruptible (designated by no-intr), spare, off-line, faulted or powered off, and when that status last changed. Use the processor_id operand to display information about a specific processor. See `OPERANDS`.

Options The following options are supported:

`-s` *processor_id* Silent mode. Displays `1` if the specified processor is fully on-line. Displays `0` if the specified processor is non-interruptible, spare, off-line, faulted or powered off.

Use silent mode when using `psrinfo` in shell scripts.

`-p` Display the number of physical processors in a system.

When combined with the `-v` option, reports additional information about each physical processor.

`-v` Verbose mode. Displays additional information about the specified processors, including: processor type, floating point unit type and clock speed. If any of this information cannot be determined, `psrinfo` displays `unknown`.

When combined with the `-p` option, reports additional information about each physical processor.

Operands The following operands are supported:

processor_id The processor ID of the processor about which information is to be displayed.

Specify *processor_id* as an individual processor number (for example, `3`), multiple processor numbers separated by spaces (for example, `1 2 3`), or a range of processor numbers (for example, `1-4`). It is also possible to combine ranges and (individual or multiple) *processor_id*s (for example, `1-3 5 7-8 9`).

Examples

EXAMPLE 1 Displaying Information About All Configured Processors in Verbose Mode

The following example displays information about all configured processors in verbose mode.

```
psrinfo -v
```

EXAMPLE 2 Determining If a Processor is On-line

The following example uses `psrinfo` in a shell script to determine if a processor is on-line.

```
if [ "`psrinfo -s 3 2> /dev/null`" –eq 1 ]
then
    echo "processor 3 is up"
fi
```

EXAMPLE 3 Displaying Information About the Physical Processors in the System

With no additional arguments, the `-p` option displays a single integer: the number of physical processors in the system:

```
> psrinfo -p
               8
```

`psrinfo` also accepts command line arguments (processor IDs):

```
> psrinfo -p 0 512   # IDs 0 and 512 exist on the
1                    # same physical processor

> psrinfo -p 0 1     # IDs 0 and 1 exist on different
2                    # physical processors
```

In this example, virtual processors `0` and `512` exist on the same physical processor. Virtual processors `0` and `1` do not. This is specific to this example and is and not a general rule.

Exit Status

The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also

`psradm(1M)`, `p_online(2)`, `processor_info(2)`, `attributes(5)`

Diagnostics

`psrinfo: processor 9: Invalid argument` The specified processor does not exist.

Name psrset – creation and management of processor sets

Synopsis

```
psrset -a [-F] processor_set_id processor_id...

psrset -b processor_set_id pid [/lwpid]...

psrset -c [-F] [processor_id]...

psrset -d processor_set_id...

psrset -e processor_set_id command [argument(s)]

psrset -f processor_set_id

psrset [-i] [processor_set_id]...

psrset -n processor_set_id

psrset -p [processor_id]...

psrset [-q] [pid [/lwpid]]...

psrset -Q [processor_set_id]...

psrset -r [-F] processor_id...

psrset -u pid [/lwpid]...

psrset -U [processor_set_id]...
```

Description The `psrset` utility controls the management of processor sets. Processor sets allow the binding of processes or LWPs to groups of processors, rather than just a single processor. Processors assigned to processor sets can run only LWPs that have been bound to that processor set.

This command cannot be used to modify processor disposition when pools are enabled. Use `pooladm(1M)` and `poolcfg(1M)` to modify processor set configuration through the resource pools facility.

Options The following options are supported:

`-a` Assign the specified processors to the specified processor set. With the additional `-F` option, all LWPs bound to the specified processors will be unbound prior to changing processor sets.

This option is restricted to users with the `PRIV_SYS_RES_CONFIG` privilege.

`-b` Bind all or a subset of the LWPs of the specified processes to the specified processor set.

LWPs bound to a processor set are restricted to run only on the processors in that set. Processes can only be bound to non-empty processor sets, that is, processor sets that have had processors assigned to them.

Bindings are inherited, so new LWPs and processes created by a bound LWP have the same binding. Binding an interactive shell to a processor, for example, binds all commands executed by the shell.

This option is restricted to users with the `PRIV_SYS_RES_CONFIG` privilege.

`-c` Create a new processor set and displays the new processor set ID. With the additional `-F` option, all LWPs bound to the specified processors will be unbound prior to assigning them to the processor set being created.

If a list of processors is given, it also attempts to assign those processors to the processor set. If this succeeds, the processors are idle until LWPs are bound to the processor set. This option is restricted to users with the `PRIV_SYS_RES_CONFIG` privilege.

Only a limited number of processor sets can be active (created and not destroyed) at a given time. This limit is always be greater than the number of processors in the system. If the `-c` option is used when the maximum number of processor sets is already active, the command fails.

The following format is used for the first line of output of the `-c` option when the `LC_MESSAGES` locale category specifies the "C" locale. In other locales, the strings `created`, `processor`, and `set` can be replaced with more appropriate strings corresponding to the locale.

`"created processor set %d\n"` *processor set ID*

`-d` Remove the specified processor set, releasing all processors and processes associated with it.

This option is restricted to users with the `PRIV_SYS_RES_CONFIG` privilege.

`-e` Execute a command (with optional arguments) in the specified processor set.

The command process and any child processes are executed only by processors in the processor set.

This option is restricted to users with the `PRIV_SYS_RES_CONFIG` privilege.

`-f` Disables interrupts for all processors within the specified processor set. See `psradm`(1M).

If some processors in the set cannot have their interrupts disabled, the other processors still have their interrupts disabled, and the command reports an error and return non-zero exit status.

This option is restricted to users with the `PRIV_SYS_RES_CONFIG` privilege.

`-F` Forces the specified processor set operation by unbinding all threads bound to the specified processor. Only the `-a` or the `-r` option can be used in combination with this option. Administrators are encouraged to use the `-Q` option for `pbind(1M)` to find out which threads will be affected by such operation.

`-i` Display a list of processors assigned to each named processor set. If no argument is given, a list of all processor sets and the processors assigned to them is displayed. This is also the default operation if the `psrset` command is not given an option.

`-n` Enable interrupts for all processors within the specified processor set. See `psradm(1M)`.

This option is restricted to users with the `PRIV_SYS_RES_CONFIG` privilege.

`-p` Display the processor set assignments for the specified list of processors. If no argument is given, the processor set assignments for all processors in the system is given.

`-q` Display the processor set bindings of the specified processes or of all processes. If a process is composed of multiple LWPs which have different bindings and the LWPs are not explicitly specified, the bindings of only one of the bound LWPs is displayed. The bindings of a subset of LWPs can be displayed by appending "/lwpids" to the process IDs. Multiple LWPs may be selected using "-" and "," delimiters. See EXAMPLES.

`-Q` Display the LWPs bound to the specified list of processor sets, or all LWPs with processor set bindings.

`-r` Remove a list of processors from their current processor sets. Processors that are removed return to the general pool of processors.

Processors with LWPs bound to them using `pbind(1M)` can be assigned to or removed from processor sets using the `-F` option.

This option is restricted to users with the `PRIV_SYS_RES_CONFIG` privilege.

`-u` Remove the processor set bindings of a subset or all the LWPs of the specified processes, allowing them to be executed on any on-line processor if they are not bound to individual processors through `pbind`.

Users with the `PRIV_SYS_RES_CONFIG` privilege can unbind any process or LWP from any active processor set. Other users can unbind processes and LWPs from processor sets that do not have the `PSET_NOESCAPE` attribute set. In addition, the user must have permission to control the affected processes; the real or effective user ID of the user must match the real or saved user ID of the target processes.

`-U` Removes the bindings of all LWPs bound to the specified list of processor sets, or to any processor set if no argument is specified.

Operands The following operands are supported:

pid Specify *pid* as a process ID.

lwpid The set of LWPIDs of the specified process to be controlled or queried. The syntax for selecting LWP IDs is as follows:

```
2,3,4-8       LWP IDs 2, 3, and 4 through 8
-4            LWPs whose IDs are 4 or below
4-            LWPs whose IDs are 4 or above
```

processor_id Specify *processor_id* as an individual processor number (for example, `3`), multiple processor numbers separated by spaces (for example, `1 2 3`), or a range of processor numbers (for example, `1-4`). It is also possible to combine ranges and (individual or multiple) *processor_id*s (for example, `1-3 5 7-8 9`).

processor_set_id Specify *processor_set_id* as a processor set ID.

Exit Status The following exit values are returned:

`0` Successful completion.

non-0 An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Stability Level	Stable

See Also `pbind(1M)`, `pooladm(1M)`, `poolcfg(1M)`, `psradm(1M)`, `psrinfo(1M)`, `processor_bind(2)`, `processor_info(2)`, `pset_bind(2)`, `pset_create(2)`, `pset_info(2)`, `sysconf(3C)`, `libpool(3LIB)`, `attributes(5)`, `privileges(5)`

Diagnostics The following output indicates that the specified process did not exist or has exited:

```
psrset: cannot query pid 31: No such process
```

The following output indicates that the user does not have permission to bind the process:

```
psrset: cannot bind pid 31: Not owner
```

The following output indicates that the user does not have permission to assign the processor:

```
psrset: cannot assign processor 4: Not owner
```

The following output indicates that the specified processor is not on-line, or the specified processor does not exist.

```
psrset: cannot assign processor 8: Invalid argument
```

The following output indicates that an LWP in the specified process is bound to a processor and cannot be bound to a processor set that does not include that processor:

```
psrset: cannot bind pid 67: Device busy
```

The following output indicates that the specified processor could not be added to the processor set. This can be due to bound LWPs on that processor, or because that processor cannot be combined in the same processor set with other processors in that set, or because the processor is the last one in its current processor set:

```
psrset: cannot assign processor 7: Device busy
```

The following output indicates that the specified processor set does not exist:

```
psrset: cannot execute in processor set 8: Invalid argument
```

The following output indicates that the maximum number of processor sets allowed in the system is already active:

```
psrset: cannot create processor set: Not enough space
```

The following output indicates that the pools facility is active.

```
psrset: cannot assign processor 7: Operation not supported
psrset: cannot bind pid 31: Operation not supported
psrset: cannot bind pid 31: Operation not supported
psrset: could not create processor set: Operation not supported
psrset: could not remove processor set 1: Operation not supported
psrset: cannot exec in processor set 1: Operation not supported
psrset: cannot remove processor 7: Operation not supported
psrset: cannot unbind pid 31: Operation not supported
```

Name putdev – edits device table

Synopsis

```
putdev -a alias [attribute=value [...]]

putdev -m device attribute=value [attribute = value [...]]

putdev -d device [attribute [...]]
```

Description `putdev` adds a new device to the device table, modifies an existing device description or removes a device entry from the table. The first synopsis is used to add a device. The second synopsis is used to modify existing entries by adding or changing attributes. If a specified attribute is not defined, this option adds that attribute to the device definition. If a specified attribute is already defined, it modifies the attribute definition. The third synopsis is used to delete either an entire device entry or, if the attribute argument is used, to delete an attribute assignment for a device.

Options The following options are supported:

`-a` Add a device to the device table using the specified attributes. The device must be referenced by its `alias`.

`-d` Remove a device from the device table, when executed without the *attributes* argument. Used with the *attribute* argument, it deletes the given attribute specification for *device* from the table.

`-m` Modify a device entry in the device table. If an entry already exists, it adds any specified attributes that are not defined. It also modifies any attributes which already have a value with the value specified by this command.

Operands The following operands are supported:

alias Designates the alias of the device to be added.

attribute Designates a device attribute to be added, modified, or deleted. Can be any of the device attributes described under `DEVICE ATTRIBUTES` except `alias`. This prevents an accidental modification or deletion of a device's alias from the table.

device Designates the pathname or alias of the device whose attribute is to be added, modified, or removed.

value Designates the value to be assigned to a device's attribute.

Device Attributes The following list shows the standard device attributes, used by applications such as `ufsdump(1M)` and `ufsrestore(1M)`, which can be defined for a device. You are not limited to this list, you can define any attribute you like.

`alias` The unique name by which a device is known. No two devices in the database may share the same alias name. The name is limited in length to 14 characters and should contain only alphanumeric characters and the following special characters if they are escaped with a backslash: underscore (_), dollar sign ($), hyphen (–), and period (.).

`bdevice`	The pathname to the block special device node associated with the device, if any. The associated major/minor combination should be unique within the database and should match that associated with the `cdevice` field, if any. (It is the administrator's responsibility to ensure that these `major/minor` numbers are unique in the database.)
`capacity`	The capacity of the device or of the typical volume, if removable.
`cdevice`	The pathname to the character special device node associated with the device, if any. The associated major/minor combination should be unique within the database and should match that associated with the `bdevice` field, if any. (It is the administrator's responsibility to ensure that these `major/minor` numbers are unique in the database.)
`cyl`	Used by the command specified in the `mkfscmd` attribute.
`desc`	A description of any instance of a volume associated with this device (such as floppy diskette).
`dpartlist`	The list of disk partitions associated with this device. Used only if `type=disk`. The list should contain device aliases, each of which must have `type=dpart`.
`dparttype`	The type of disk partition represented by this device. Used only if `type=dpart`. It should be either `fs` (for file system) or `dp` (for data partition).
`erasecmd`	The command string that, when executed, erases the device.
`fmtcmd`	The command string that, when executed, formats the device.
`fsname`	The file system name on the file system administered on this partition, as supplied to the `/usr/sbin/labelit` command. This attribute is specified only if `type=dpart` and `dparttype=fs`.
`gap`	Used by the command specified in the `mkfscmd` attribute.
`mkfscmd`	The command string that, when executed, places a file system on a previously formatted device.
`mountpt`	The default mount point to use for the device. Used only if the device is mountable. For disk partitions where `type=dpart` and `dparttype=fs`, this attribute should specify the location where the partition is normally mounted.
`nblocks`	The number of blocks in the file system administered on this partition. Used only if `type=dpart` and `dparttype=fs`.
`ninodes`	The number of inodes in the file system administered on this partition. Used only if `type=dpart` and `dparttype=fs`.
`norewind`	The name of the character special device node that allows access to the serial device without rewinding when the device is closed.

`pathname` Defines the pathname to an i-node describing the device (used for non-block or character device pathnames, such as directories).

`type` A token that represents inherent qualities of the device. Standard types include: 9-track, ctape, disk, directory, diskette, dpart, and qtape.

`volname` The volume name on the file system administered on this partition, as supplied to the `/usr/sbin/labelit` command. Used only if `type=dpart` and `dparttype=fs`.

`volume` A text string used to describe any instance of a volume associated with this device. This attribute should not be defined for devices which are not removable.

Exit Status The following exit values are returned:

`0` Successful completion.

`1` Command syntax was incorrect, an invalid option was used, or an internal error occurred.

`2` The device table could not be opened for reading, or a new device table could not be created.

`3` If executed with the `-a` option, indicates that an entry in the device table with the alias `alias` already exits. If executed with the `-m` or `-d` options, indicates that no entry exists for device *device*.

`4` Indicates that `-d` was requested and one or more of the specified attributes were not defined for the device.

Files `/etc/device.tab`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `devattr(1M)`, `putdgrp(1M)`, `ufsdump(1M)`, `ufsrestore(1M)`, `attributes(5)`

System Administration Guide: Basic Administration

Name putdgrp – edits device group table

Synopsis

```
putdgrp [-d] dgroup [device]...
```

Description `putdgrp` modifies the device group table. It performs two kinds of modification. It can modify the table by creating a new device group or removing a device group. It can also change group definitions by adding or removing a device from the group definition.

When the command is invoked with only a *dgroup* specification, the command adds the specified group name to the device group table if it does not already exist. If the `-d` option is also used with only the *dgroup* specification, the command deletes the group from the table.

When the command is invoked with both a *dgroup* and a *device* specification, it adds the given device name(s) to the group definition. When invoked with both arguments and the `-d` option, the command deletes the device name(s) from the group definition.

When the command is invoked with both a *dgroup* and a *device* specification and the device group does not exist, it creates the group and adds the specified devices to that new group.

Options The following options are supported:

`-d` Delete the group or, if used with *device*, delete the device from a group definition.

Operands The following operands are supported:

dgroup Specify a device group name.

device Specify the pathname or alias of the device that is to be added to, or deleted from, the device group.

Exit Status The following exit values are returned:

`0` Successful completion.

`1` Command syntax was incorrect, an invalid option was used, or an internal error occurred.

`2` Device group table could not be opened for reading or a new device group table could not be created.

`3` If executed with the `-d` option, indicates that an entry in the device group table for the device group *dgroup* does not exist and so cannot be deleted. Otherwise, indicates that the device group *dgroup* already exists and cannot be added.

`4` If executed with the `-d` option, indicates that the device group *dgroup* does not have as members one or more of the specified devices. Otherwise, indicates that the device group *dgroup* already has one or more of the specified devices as members.

Examples

EXAMPLE 1 Adding a new device group.

The following example adds a new device group:

```
example#  putdgrp floppies
```

EXAMPLE 2 Adding a device to a device group.

The following example adds a device to a device group:

```
example#  putdgrp floppies diskette2
```

EXAMPLE 3 Deleting a device group.

The following example deletes a device group:

```
example#  putdgrp -d floppies
```

EXAMPLE 4 Deleting a device from a device group.

The following example deletes a device from a device group:

```
example#  putdgrp -d floppies diskette2
```

Files

`/etc/dgroup.tab`

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also

`listdgrp(1M)`, `putdev(1M)`, `attributes(5)`

Name pwck, grpck – password/group file checkers

Synopsis

```
/usr/sbin/pwck [filename]

/usr/sbin/grpck [filename]
```

Description `pwck` scans the password file and notes any inconsistencies. The checks include validation of the number of fields, login name, user ID, group ID, and whether the login directory and the program-to-use-as-shell exist. The default password file is `/etc/passwd`.

`grpck` verifies all entries in the group file. This verification includes a check of the number of fields, group name, group ID, whether any login names belong to more than `NGROUPS_MAX` groups, and that all login names appear in the password file. The default group file is `/etc/group`.

All messages regarding inconsistent entries are placed on the `stderr` stream.

Files `/etc/group`

`/etc/passwd`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `getpwent(3C)`, `group(4)`, `passwd(4)`, `attributes(5)`

Diagnostics Group entries in `/etc/group` with no login names are flagged.

`Group file '`*filename*`' is empty`
The `/etc/passwd` or `/etc/group` file is an empty file.

`cannot open file` *filename*`: No such file or directory`
The `/etc/passwd` or `/etc/group` file does not exist.

Notes If no filename argument is given, `grpck` checks the local group file, `/etc/group`, and also makes sure that all login names encountered in the checked group file are known to the system `getpwent(3C)` routine. This means that the login names may be supplied by a network name service.

Name pwconv – installs and updates /etc/shadow with information from /etc/passwd

Synopsis

```
pwconv
```

Description The `pwconv` command creates and updates `/etc/shadow` with information from `/etc/passwd`.

`pwconv` relies on a special value of 'x' in the password field of `/etc/passwd`. This value of 'x' indicates that the password for the user is already in `/etc/shadow` and should not be modified.

If the `/etc/shadow` file does not exist, this command will create `/etc/shadow` with information from `/etc/passwd`. The command populates `/etc/shadow` with the user's login name, password, and password aging information. If password aging information does not exist in `/etc/passwd` for a given user, none will be added to `/etc/shadow`. However, the last changed information will always be updated.

If the `/etc/shadow` file does exist, the following tasks will be performed:

Entries that are in the `/etc/passwd` file and not in the `/etc/shadow` file will be added to the `/etc/shadow` file.

Entries that are in the `/etc/shadow` file and not in the `/etc/passwd` file will be removed from `/etc/shadow`.

Password attributes (for example, password and aging information) that exist in an `/etc/passwd` entry will be moved to the corresponding entry in `/etc/shadow`.

The `pwconv` command can only be used by the super-user.

Files

`/etc/opasswd`

`/etc/oshadow`

`/etc/passwd`

`/etc/shadow`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `passwd(1)`, `passmgmt(1M)`, `usermod(1M)`, `passwd(4)`, `attributes(5)`

Diagnostics `pwconv` exits with one of the following values:

`0` SUCCESS.

`1` Permission denied.

`2` Invalid command syntax.

3 Unexpected failure. Conversion not done.

4 Unexpected failure. Password file(s) missing.

5 Password file(s) busy. Try again later.

6 Bad entry in `/etc/shadow` file.

Name quot – summarize file system ownership

Synopsis

```
quot [-acfhnv] filesystem...

quot -a [-cfhnv]
```

Description `quot` displays the number of blocks (1024 bytes) in the named *filesystem* (one or more) currently owned by each user. There is a limit of 2048 blocks. Files larger than this will be counted as a 2048 block file, but the total block count will be correct.

Options The following options are supported:

`-a` Generate a report for all mounted file systems.

`-c` Display three columns giving a file size in blocks, the number of files of that size, and a cumulative total of blocks containing files of that size or a smaller size.

`-f` Display three columns giving, for each user, the number of blocks owned, the count of number of files, and the user name. This option is incompatible with the `-c` and `-v` options.

`-h` Estimate the number of blocks in the file. This does not account for files with holes in them.

`-n` Attach names to the list of files read from standard input. `quot -n` cannot be used alone, because it expects data from standard input. For example, the pipeline

```
ncheck myfilesystem | sort +0n | quot -n myfilesystem
```

will produce a list of all files and their owners. This option is incompatible with all other options.

`-v` In addition to the default output, display three columns containing the number of blocks not accessed in the last 30, 60, and 90 days.

Operands *filesystem* mount-point of the filesystem(s) being checked

Usage See `largefile(5)` for the description of the behavior of `quot` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Exit Status

`0` Successful operation.

`32` Error condition (bad or missing argument, bad path, or other error).

Files

`/etc/mnttab` Lists mounted file systems.

`/etc/passwd` Used to obtain user names

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also du(1), mnttab(4), passwd(4), attributes(5), largefile(5)

Notes This command can only be used by the super-user.

Name quota – display a user's ufs or zfs file system disk quota and usage

Synopsis

```
quota [-v] [username]
```

Description `quota` displays users' UFS or ZFS disk usage and limits. Only the super-user may use the optional *username* argument to view the limits of other users.

`quota` without options only display warnings about mounted file systems where usage is over quota. Remotely mounted file systems which do not have quotas turned on are ignored.

username can be the numeric UID of a user.

Options `-v` Display user's quota on all mounted file systems where quotas exist.

Usage See `largefile(5)` for the description of the behavior of `quota` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files `/etc/mnttab` list of currently mounted filesystems

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `edquota(1M)`, `quotaon(1M)`, `quotacheck(1M)`, `repquota(1M)`, `rquotad(1M)`, `attributes(5)`, `largefile(5)`, `zones(5)`

Notes `quota` displays quotas for NFS mounted UFS- or ZFS-based file systems if the `rquotad` daemon is running. See `rquotad(1M)`. In a `zones(5)` environment, `quota` displays quotas only for the zone in which it is invoked.

`quota` can display entries for the same file system multiple times for multiple mount points. For example,

```
# quota -v user1
```

might display identical quota information for `user1` at the mount points `/home/user1`, `/home/user2`, and `/home/user`, if all three mount points are mounted from the same file system with quotas turned on.

Name quotacheck – ufs file system quota consistency checker

Synopsis

```
quotacheck [-fp] [-v] filesystem...

quotacheck -a [-fpv]
```

Description `quotacheck` examines each mounted ufs file system, builds a table of current disk usage, and compares this table against the information stored in the file system's disk quota file. If any inconsistencies are detected, both the quota file and the current system copy of the incorrect quotas are updated.

filesystem is either a file system mount point or the block device on which the file system resides.

`quotacheck` expects each file system to be checked to have a quota file named `quotas` in the root directory. If none is present, `quotacheck` will not check the file system.

`quotacheck` accesses the character special device in calculating the actual disk usage for each user. Thus, the file systems that are checked should be quiescent while `quotacheck` is running.

Options The following options are supported:

`-a` Check the file systems which `/etc/mnttab` indicates are ufs file systems. These file systems must be read-write mounted with disk quotas enabled, and have an `rq` entry in the `mntopts` field in `/etc/vfstab`.

`-f` Force check on file systems with logging enabled. Use in combination with the `-p` option.

`-p` Check quotas of file systems in parallel. For file systems with logging enabled, no check is performed unless the `-f` option is also specified.

`-v` Indicate the calculated disk quotas for each user on a particular file system. `quotacheck` normally reports only those quotas modified.

Usage See `largefile(5)` for the description of the behavior of `quotacheck` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files

`/etc/mnttab` Mounted file systems

`/etc/vfstab` List of default parameters for each file system

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also edquota(1M), quota(1M), quotaon(1M), repquota(1M), attributes(5), largefile(5), quotactl(7I), mount_ufs(1M)

Name quotaon, quotaoff – turn ufs file system quotas on and off

Synopsis

```
quotaon [-v] filesystem...

quotaon -a [-v]

quotaoff [-v] filesystem...

quotaoff -a [-v]
```

Description `quotaon` turns on disk quotas for one or more ufs file systems.

Before a file system may have quotas enabled, a file named `quotas`, owned by root, must exist in the root directory of the file system. See `edquota(1M)` for details on how to modify the contents of this file.

`quotaoff` turns off disk quotas for one or more ufs file systems.

The file systems specified must already be mounted.

These commands update the `mntopts` field of the appropriate entries in `/etc/mnttab` to indicate when quotas are on or off for each file system. If quotas are on, the string `quota` will be added to `mntopts`; if quotas are off, the `quota` string is not present.

filesystem must be either the mount point of a file system, or the block device on which the file system resides.

Options

quotaon

`-a` This option is normally used at boot time to enable quotas. It applies only to those file systems in `/etc/vfstab` which have "rq" in the `mntopts` field, are currently mounted "rw", and have a `quotas` file in the root directory.

`-v` Display a message for each file system after quotas are turned on.

quotaoff

`-a` Force all file systems in `/etc/mnttab` to have their quotas disabled.

`-v` Display a message for each file system affected.

Usage See `largefile(5)` for the description of the behavior of `quotaon` and `quotaoff` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files

`/etc/mnttab` mounted file systems

`/etc/vfstab` list of default parameters for each file system

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

Name raidctl – RAID hardware utility

Synopsis

```
raidctl -C "disks" [-r raid_level] [-z capacity] [-s stripe_size] [-f]
     controller

raidctl -d [-f] volume

raidctl -F filename [-f] controller...

raidctl -a {set | unset} -g disk {volume | controller}

raidctl -p "param=value" [-f] volume

raidctl -c [-f] [-r raid_level] disk1 disk2 [disk3...]

raidctl -l -g disk controller

raidctl -l volume

raidctl -l controller...

raidctl [-l]

raidctl -S [volume | controller]

raidctl -S -g disk controller

raidctl -h
```

Description The `raidctl` utility is a hardware RAID configuration tool that supports different RAID controllers by providing a CLI (command-line interface) to end-users to create, delete or display RAID volume(s). The utility can also used to set properties of a volume, assign hot-spare (HSP) disks to volumes or controllers, and to update firmware/fcode/BIOS for RAID controllers.

The `raidctl` utility requires privileges that are controlled by the underlying file-system permissions. Only privileged users can manipulate the RAID system configuration. If a non-privileged user attempts to run `raidctl`, the command fails with an exit status of 1.

The `raidctl` utility, as described in this man page, defines a broad set of command line options to provide management for full-featured RAID controllers. However, support for a given option depends on two elements:

- the presence of a software driver
- the firmware level of the RAID device

The dependency on a software driver is due to the design of `raidctl`. The utility is built on a common library that enables the insertion of plug-in modules for different drivers. Currently, the Solaris operating system is shipped with a plug-in for the `mpt` driver. This plug-in does not support all of the `raidctl` options. On a given storage device, options might be further limited by the device's firmware level.

The level of support for the various `raidctl` options cannot be determined by `raidctl`. The user must rely on the documentation for his RAID controller or hardware platform.

Currently, `raidctl` Currently, `raidctl` provides some level of support for the following RAID controllers:

- LSI1020 SCSI HBA
- LSI1030 SCSI HBA
- LSI1064 SAS HBA
- LSI1068 SAS HBA

All of the above HBAs are maintained by the `mpt` driver, on X86-32/64 and SPARC platforms.

Options The following options are supported:

`-C` *"disks"* [`-r` *raid_level*] [`-z` *capacity*] [`-s` *stripe_size*] [`-f`] controller
Create a RAID volume using specified disks.

When creating a RAID volume using this option, the identity of the newly created volume is automatically generated and raidctl reports it to the user.

The argument specified by this option contains the elements used to form the volume that will be created. Elements can be either disks or sub-volumes, where disks are separated by space(s) and a sub-volume is a set of disks grouped by parenthesis. All disks should be in `C.ID.L` expression (for example, `0.1.2` represents a physical disk of channel 0, target id 1, and logical unit number 2). The argument must match the RAID level specified by the `-r` option, even if it's omitted. This means the argument can only be:

for RAID 0
At least 2 disks

for RAID 1
Only 2 disks

for RAID 1E
At least 3 disks

for RAID 5
At least 3 disks

for RAID 10
At least 2 sub-volumes, each sub-volume must be formed by 2 disks

for RAID 50
At least 2 sub-volumes, each sub-volume must be formed by at least 3 disks, and the disk amount in each sub-volume should be the same

For example, the expression "0.0.0 0.1.0" means that the 2 specified disks form a RAID volume, which can either be a RAID 0 or a RAID 1 volume. "(0.0.0 0.1.0)(0.2.0 0.3.0)" means that the first 2 disks and the last 2 disks form 2 sub-volumes, and that these 2 sub-volumes form a RAID 10 volume. See the `EXAMPLES` section for more samples.

The `-r` option specifies the RAID level of the volume that will be created. Possible levels are 0, 1, 1E, 5, 10, 50. If this option is omitted, `raidctl` creates a RAID 1 volume by default.

The `-z` option specifies the capacity of the volume that will be created. The unit can be tera-bytes, giga-bytes, or mega-bytes (for example, 2t, 10g, 20m, and so on). If this option is omitted, `raidctl` calculates the maximum capacity of the volume that can be created by the specified disks and uses this value to create the volume.

The `-s` option specifies the stripe size of the volume that will be created. The possible values are 512, 1k, 2k, 4k, 8k, 16k, 32k, 64k, or 128k. If this option is omitted, `raidctl` chooses an appropriate value for the volume (for example, 64k).

In some cases, the creation of a RAID volume may cause data on specified disks to be lost (for instance, on LSI1020, LSI1030, SAS1064, or SAS1068 HBAs), and `raidctl` prompts the user for confirmation about the creation. Use the `-f` option to force the volume creation without prompting the user for confirmation.

The controller argument is used to identify which RAID controller the specified disks belongs. The `-l` option can be used to list the controller's ID number.

`-d` [`-f`] *volume*
Delete the RAID volume specified as volume. The volume is specified in canonical form (for example, `c0t0d0`).

When a volume is deleted, all data is lost. Therefore, unless the `-f` option is specified, `raidctl` prompts the user for confirmation before deleting the volume.

When a RAID 1 volume is deleted from a LSI1020, LSI1030, SAS1064, or SAS1068 HBA, the primary and secondary disks are "split". If the volume was in `SYNCING` state, the primary will contain the data, and the secondary will not. If the volume state was `OPTIMAL`, both disks will contain a complete image of the data.

`-F` *filename* [`-f`] *controller…*
Update the firmware running on the specified controller(s). The `raidctl` utility prompts the user for confirmation of this action, unless the `-f` option is provided.

`-a` {`set` | `unset`} `-g` *disk* {`volume` | `controller`}
If the volume is specified, `raidctl` sets or unsets the disk as a local hot-spare disk dedicated to the volume, depending on the value specified by the `-a` option. If the controller is specified, `raidctl` sets or unsets the disk as a global hot-spare disk.

`-p` *"param=value"* [`-f`] *volume*
Change the property value for a given RAID volume. This option can be used to change cache write policy or to activate a volume. When changing the cache write policy, *param* should be the string `wp` (`SET_WR_POLICY`), and *value* can be either `on` or `off`. When used to activate a volume, *param* should be `state` and *value* should be `activate`.

Changing a RAID volume's property may affect the internal behavior of the RAID controller, so `raidctl` prompts the user for a confirmation before applying the change, unless the `-f` option is specified.

`-c` [`-f`] [`-r` *raid_level*] *disk1 disk2* [*disk3*...]
Create a volume using the specified disks. This is an alternative to the `-C` option with similar functionality. This option is preserved for compatibility reasons, but only works with LSI1020, LSI1030, SAS1064, and SAS1068 HBAs to create RAID 0, RAID 1, or RAID 1E volumes. For other HBAs, the user can only use the `-C` option.

The `-r` option can be used to specify the RAID level of the target volume. If the `-r` option is omitted, `raidctl` will create a RAID 1 volume.

Disks must be specified in Solaris canonical format (for example, c0t0d0).

Creating a RAID 1 volume with this option replaces the contents of disk2 with the contents of disk1.

When the user creates a RAID volume with this option, the RAID volume assumes the identity of disk1. Other disks become invisible and the RAID volume appears as one disk.

Creating a volume with this option is by default interactive. The user must answer a prompt affirmatively to create the volume. Use the `-f` option to force the volume creation without prompting the user for confirmation.

`-l` -g *disk controller*
Display information about the specified disk of the given controller. The output includes the following information:

Disk
Displays the disk in `C.ID.L` expression disk.

Vendor
Displays the vendor ID string.

Product
Displays the product ID string.

Capacity
Displays the total capacity of the disk.

Status
Displays the current status of disk. The status can be either "`GOOD`" (operating normally), "`FAILED`" (non-functional), or "`MISSING`" (disk not present).

HSP
Indicates if the disk has been set as a global hot-spare disk, local hot-spare disk, or a normal one. If it is a local hot-spare disk, all volumes which this disk is assigned to are displayed.

GUID
GUID string for the specified disk. This is an additional datum and might be unavailable in some cases.

`-l` *volume*
Display information about the specified volume. The output includes the following information:

Volume
Displays volume in canonical format.

Sub
Displays sub-volumes, if the specified volume is of RAID 10 or RAID 50 volume.

Disk
Displays all disks that form the specified volume.

Stripe Size
Displays the stripe size of the volume.

Status
Displays the status of the specified volume, or the sub-volumes or disks that form the specified volume. For an inactive volume, the status should be `INACTIVE`; otherwise it can be `OPTIMAL` (operating optimally), `DEGRADED` (operating with reduced functionality), `FAILED` (non-functional), or `SYNC` (disks are syncing). For a disk, the status can be `GOOD`, `FAILED`, or `MISSING`.

Cache
Indicates whether the cache is applied to `I/O` write activities. The cache can be either "`ON`" or "`OFF`".

RAID level
Displays the RAID level. The RAID level can be either 0, 1, 1E, 5, 10, or 50.

`-l` *controller ...*
Display information about the specified controller(s). The output includes the following information:

Controller
Displays the RAID controller's ID number.

Type
Displays the RAID controller's product type.

fw_version
Displays the controller's firmware version.

`[-l]`
List all RAID related objects that the `raidctl` utility can manipulate, including all available RAID controllers, RAID volumes, and physical disks. The `-l` option can be omitted.

The output includes the following information:

Controller
Displays the RAID controller's ID number.

Volume
Displays the logical RAID volume name.

Disk
Displays the RAID disk in `C.ID.L` expression.

`-S` [`volume` | `controller`]
Takes a snapshot of the RAID configuration information including all available RAID devices, RAID controllers, volumes, and disks.

Each line of the output specifies a RAID device and its related information, separated by space(s). All volumes and disks belong to the last specified controller.

The output lists the following information:

Controller
Displays the controller ID number, and the controller type string in double-quotation marks.

Volume
Displays the RAID volume name, number of component disks, the `C.ID.L` expression of the component disks, the RAID level, and the status. The status can be either `OPTIMAL`, `DEGRADED`, `FAILED`, or `SYNCING`.

Disk
Displays the `C.ID.L` expression of the disk, and the status. The status can be either `GOOD`, `FAILED`, or `HSP` (disk has been set as a stand-by disk).

If a volume or a controller is specified, a snapshot is only taken of the information for the specified volume or controller.

`-S` -g *disk controller*
Takes a snapshot of the information for the specified disk.

`-h`
Print out the usage string.

Examples

EXAMPLE 1 Creating the RAID Configuration

The following command creates a RAID 0 volume of 10G on controller 0, and the stripe size will be set to 64k:

```
# raidctl -C "0.0.0 0.2.0" -r 0 -z 10g -s 64k 0
```

The following command creates a RAID 1 volume on controller 2:

```
# raidctl -C "0.0.0 1.1.0" -r 1 2
```

The following command creates a RAID 5 volume on controller 2:

```
# raidctl -C "0.0.0 0.1.0 0.2.0" -r 5 2
```

The following command creates a RAID 10 volume on controller 0:

EXAMPLE 1 Creating the RAID Configuration *(Continued)*

```
# raidctl -C "(0.0.0 0.1.0)(0.2.0 0.3.0)" -r 10 0
```

The following command creates a RAID 50 volume on controller 0:

```
# raidctl -C "(0.0.0 0.1.0 0.2.0)(0.3.0 0.4.0 0.5.0)" -r 50 0
```

EXAMPLE 2 Displaying the RAID Configuration

The following command displays all available controllers, volumes, and disks:

```
# raidctl -l

Controller: 0
Controller: 2
         Volume:c2t0d0
         Disk: 0.0.0
         Disk: 0.1.0
         Disk: 0.2.0
         Disk: 0.3.0(HSP)
```

The following command displays information about controller 2:

```
# raidctl -l 2

Controller      Type            Fw_version
------------------------------------------------------------
c2              LSI 1030        1.03.39.00
```

The following command displays information about the specified volume:

```
# raidctl -l c2t0d0

Volume                  Size    Stripe  Status  Cache   RAID
         Sub                     Size                    Level
                Disk
----------------------------------------------------------------
c2t0d0                 10240M  64K     OPTIMAL ON      RAID5
                0.0.0   5120M           GOOD
                0.1.0   5120M           GOOD
                0.2.0   5120M           GOOD
```

The following command displays information about disk 0.0.0 on controller 0:

```
# raidctl -l -g 0.0.0  0

Disk    Vendor  Product         Firmware Capacity        Status  HSP
-------------------------------------------------------------------
0.0.0   HITACHI H101473SCSUN72G SQ02     68.3G           GOOD    N/A
GUID:2000000cca02536c
```

EXAMPLE 3 Deleting the RAID Configuration

The following command deletes a volume:

```
# raidctl -d c0t0d0
```

EXAMPLE 4 Updating Flash Images on the Controller

The following command updates flash images on the controller 0:

```
# raidctl -F lsi_image.fw 0
```

EXAMPLE 5 Setting or Unsetting a Hot-Spare Disk

The following command sets disk 0.3.0 on controller 2 as a global hot-spare disk:

```
# raidctl -a set -g 0.3.0 2
```

The following command sets disk 0.3.0 on controller 2 as a local hot-spare disk to volume c2t0d0:

```
# raidctl -a set -g 0.3.0 c2t0d0
```

The following command converts disk 0.3.0 on controller 2 from a global hot-spare disk to a normal one:

```
# raidctl -a unset -g 0.3.0 2
```

The following command removes disk 0.3.0 from being a local hot-spare disk from volume c2t0d0:

```
# raidctl -a unset -g 0.3.0 c2t0d0
```

EXAMPLE 6 Setting the Volume's Property

The following command sets the write policy of the volume to "`off`":

```
# raidctl -a set -p "wp=off" c0t0d0
```

EXAMPLE 7 Creating Volumes with the - c Option

The following command creates a RAID 1 volume:

```
# raidctl -c c0t0d0 c0t1d0
```

The following command creates a RAID 0 volume:

```
# raidctl -c -r 0 c0t1d0 c0t2d0 c0t3d0
```

EXAMPLE 8 Taking a Snapshot of the RAID Configuration

The following command takes a snapshot of all RAID devices:

```
# # raidctl -S

1 "LSI 1030"
```

EXAMPLE 8 Taking a Snapshot of the RAID Configuration *(Continued)*

```
c1t1d0 2 0.2.0 0.3.0 1 DEGRADED
0.2.0 GOOD
0.3.0 FAILED
```

The following command takes a snapshot about volume c1t0d0:

```
# raidctl -S c1t0d0

c1t0d0 2 0.0.0 0.1.0 1 OPTIMAL
```

The following command takes a snapshot about disk 0.1.0 on controller 1:

```
# raidctl -S -g 0.1.0 1

0.1.0 GOOD
```

Exit Status

The following exit values are returned:

`0`
: Successful completion.

`1`
: Invalid command line input or permission denied.

`2`
: Request operation failed.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Volatile

See Also

`attributes(5)`, `mpt(7D)`

System Administration Guide: Basic Administration

Warnings

Do not create raid volumes on internal SAS disks if you are going to use the Solaris Multipathing I/O feature (also known as MPxIO). Creating a new raid volume under Solaris Multipathing will give your root device a new GUID which does not match the GUID for the existing devices. This will cause a boot failure since your root device entry in `/etc/vfstab` will not match.

Notes The `-z` option is not supported on systems that use the `mpt` driver and LSI RAID controllers.

Name ramdiskadm – administer ramdisk pseudo device

Synopsis

```
/usr/sbin/ramdiskadm -a name size [g | m | k | b]

/usr/sbin/ramdiskadm -d name

/usr/sbin/ramdiskadm
```

Description The `ramdiskadm` command administers `ramdisk(7D)`, the ramdisk driver. Use `ramdiskadm` to create a new named ramdisk device, delete an existing named ramdisk, or list information about existing ramdisks.

Ramdisks created using `ramdiskadm` are not persistent across reboots.

Options The following options are supported:

`-a` *name size* Create a ramdisk named *name* of size *size* and its corresponding block and character device nodes.

name must be composed only of the characters a-z, A-Z, 0-9, _ (underbar), and - (hyphen), but it must not begin with a hyphen. It must be no more than 32 characters long. Ramdisk names must be unique.

The size can be a decimal number, or, when prefixed with `0x`, a hexadecimal number, and can specify the size in bytes (no suffix), 512-byte blocks (suffix `b`), kilobytes (suffix `k`), megabytes (suffix `m`) or gigabytes (suffix `g`). The size of the ramdisk actually created might be larger than that specified, depending on the hardware implementation.

If the named ramdisk is successfully created, its block device path is printed on standard out.

`-d` *name* Delete an existing ramdisk of the name *name*. This command succeeds only when the named ramdisk is not open. The associated memory is freed and the device nodes are removed.

You can delete only ramdisks created using `ramdiskadm`. It is not possible to delete a ramdisk that was created during the boot process.

Without options, `ramdiskadm` lists any existing ramdisks, their sizes (in decimal), and whether they can be removed by `ramdiskadm` (see the description of the `-d` option, above).

Examples **EXAMPLE 1** Creating a 2MB Ramdisk Named `mydisk`

```
# ramdiskadm -a mydisk 2m
/dev/ramdisk/mydisk
```

EXAMPLE 2 Listing All Ramdisks

```
# ramdiskadm
Block Device                    Size  Removable
/dev/ramdisk/miniroot     134217728    No
/dev/ramdisk/certfs         1048576    No
/dev/ramdisk/mydisk         2097152    Yes
```

Exit Status

`ramdiskadm` returns the following exit values:

`0` Successful completion.

`>0` An error occurred.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsr
Interface Stability	Evolving

See Also

`attributes(5)`, `ramdisk(7D)`

Notes

The abilities of `ramdiskadm` and the privilege level of the person who uses the utility are controlled by the permissions of `/dev/ramdiskctl`. Read access allows query operations, for example, listing device information. Write access is required to do any state-changing operations, for example, creating or deleting ramdisks.

As shipped, `/dev/ramdiskctl` is owned by `root`, in group `sys`, and mode 0644, so all users can do query operations but only root can perform state-changing operations. An administrator can give write access to non-privileged users, allowing them to add or delete ramdisks. However, granting such ability entails considerable risk; such privileges should be given only to a trusted group.

Name rcapadm – configure resource capping daemon

Synopsis

```
rcapadm
```

```
rcapadm [ [-n] -E | -D]
     [-i interval=value,...,interval=value] [-c percent]
     [-z zonename -m maxvalue]
```

Description The `rcapadm` command allows a user with the privileges described below to configure various attributes of the resource capping daemon. If used without arguments, `rcapadm` displays the current status of the resource capping daemon if it has been configured. See `rcapd(1M)` for more information.

In the current release of the Solaris operating environment, `rcapadm` is available to users with all privileges and to users who have the Process Management profile in their list of profiles. The System Administrator role includes the Process Management profile.

Options

`-c` *percent*
: Set the minimum physical memory utilization for memory cap enforcement. Caps will not be enforced until the physical memory available to processes is low. The *percent* value should be in the range 0 to 100. The minimum (and default) value is `0`, which means that memory caps are always enforced.

`-D`
: Disable the resource capping daemon so that it will not be started when the system is booted. Also stop the resource capping daemon now, if the `-n` option is not specified and it is currently running.

`-E`
: Enable the resource capping daemon so that it will be started each time the system is booted. Also start the resource capping daemon now, if the `-n` option is not specified and it is not currently running.

`-i` *interval=value,...,interval=value*
: Set intervals for various periodic operations performed by `rcapd`. All intervals are specified in seconds. You can set the following intervals:

  `scan` — The interval at which `rcapd` scans for new processes. The default scan interval is every 15 seconds. The minimum value is 1 second.

  `sample` — The interval of process resident set size sampling. The default sample interval is every 5 seconds. The minimum value is 1 second.

`report` The interval at which various paging statistics are updated by `rcapd`, in seconds. These statistics can be viewed by using `rcapstat`(1SRM). The default reporting interval is every 5 seconds. When the interval is set to `0`, statistics will not be updated.

Note – Paging refers to the act of relocating portions of memory, called pages, to or from physical memory. `rcapd` pages out the most infrequently used pages.

`config` The reconfiguration interval, in seconds. At each reconfiguration event, `rcapd` checks its configuration file for updates, and scans the project databases for new project caps. The default reconfiguration interval is every 60 seconds. The minimum interval is `0`. When the interval is set to `0`, no periodic reconfiguration occurs, although the running daemon can still be reconfigured by sending it `SIGHUP`.

`-m` *maxvalue* Used in conjunction with the `-z` option. Specifies a value for `rcap.max-rss`, a dynamically-set cap on the usage of physical memory for the zone specified by `-z`. You can apply a scale (`K`, `M`, `G`, `T`) to the value you specify. `K` means kilobyte; `M`, megabyte; `G`, gigabyte; and `T`, terabyte. For example, `100M` is 100 megabytes.

`-n` Do not affect the running state of the resource capping daemon when enabling or disabling it.

`-z` *zonename* Used in conjunction with the `-m` option. Specifies the zone for which you are dynamically specifying a cap on physical memory usage (using `-m`).

Note – To set a persistent cap on memory usage within a zone, use `zonecfg`(1M).

Examples

EXAMPLE 1 Configuring the Resource Capping Daemon with Immediate Enforcement

```
# rcapadm -E -i scan=15,sample=5,report=5,config=60 -c 0
```

EXAMPLE 2 Specifying a Resource Cap for a Zone

The command shown below specifies the maximum amount of memory that can be consumed by a specified zone. Note that this value lasts only until the next reboot. To set a persistent cap, use `zonecfg(1M)`.

```
# rcapadm -z testzone -m 512M
```

Exit Status

The following exit values are returned:

`0` Successful completion. The modifications to the current configuration were valid and made successfully.

`1` An error occurred. A fatal error occurred either in obtaining or modifying the resource capping configuration.

`2` Invalid command-line options were specified.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWrcapu
Interface Stability	Evolving

The `-z` and `-m` options are committed interfaces.

"Physical Memory Control Using the Resource Capping Daemon" in *System Administration Guide: Solaris Containers-Resource Management and Solaris Zones*

Name rcapd – resource cap enforcement daemon

Synopsis

```
rcapd [-d]
```

Description The `rcapd` daemon enforces resource caps on collections of processes. Per-project and per-zone physical memory caps are supported. For information about projects, see `project(4)`. For zones information, see `zones(5)`

When the resident set size (RSS) of a collection of processes exceeds its cap, `rcapd` takes action and reduces the RSS of the collection.

The virtual memory system divides physical memory into segments known as pages. To read data from a file into memory, the virtual memory system reads in individual pages. To reduce resource consumption, the daemon can page out, or relocate, infrequently used pages to an area outside of physical memory.

In the `project` file, caps are defined for projects that have positive values for the following project attribute:

`rcap.max-rss` The total amount of physical memory, in bytes, that is available to the project's member processes

See `project`(4) for a description of project attributes.

For a system with one or more zones, you can dynamically set the `rcap.max-rss` value for a zone with `rcapadm(1M)`. To set a persistent cap on memory usage within a zone, you use `zonecfg(1M)`.

You configure `rcapd` through the use of `rcapadm(1M)`. The daemon can be monitored with `rcapstat(1)`. Configuration changes are incorporated into `rcapd` by sending it `SIGHUP` (see `kill(1)`), or according to the configuration interval (see `rcapadm(1M)`).

Options The following option is supported:

`-d` Enable debug mode. Messages are displayed on the invoking user's terminal.

Examples **EXAMPLE 1** Setting Resident Set Size Cap Attribute

The following line in the `/etc/project` database sets an RSS cap of 1073741824 bytes for a project named `foo`.

```
foo:100::foo,root::rcap.max-rss=10737418240
```

Exit Status The following exit values are returned:

0 Successful completion.

1 An error occurred.

2 Invalid command-line options were specified.

Files `/etc/project` Project database.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWrcapu
Interface Stability	Evolving

See Also `rcapstat`(1), `svcs(1)`, `rcapadm(1M)`, `zonecfg(1M)`, `svcadm(1M)`, `project(4)`, `attributes(5)`, `smf(5)`, `zones(5)`

"Physical Memory Control Using the Resource Capping Daemon" in *System Administration Guide: Solaris Containers-Resource Management and Solaris Zones*

Notes If killed with `SIGKILL`, `rcapd` can leave processes in a stopped state. Use `SIGTERM` to cause `rcapd` to terminate properly.

A collection's RSS can exceed its cap for some time before the cap is enforced, even if sufficient pageable memory is available. This period of time can be reduced by shortening the RSS sampling interval with `rcapadm`.

The `rcapd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/system/rcap:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

Name rctladm – display or modify global state of system resource controls

Synopsis

```
rctladm [-lu] [-e action] [-d action] [name...]
```

Description The `rctladm` command allows the examination and modification of active resource controls on the running system. An instance of a resource control is referred to as an *rctl*. See `setrctl(2)` for a description of an `rctl`; see `resource_controls(5)` for a list of the `rctl`s supported in the current release of the Solaris operating system. Logging of `rctl` violations can be activated or deactivated system-wide and active `rctl`s (and their state) can be listed.

An `rctladm` command without options is the equivalent of an `rctladm` with the `-l` option. See the description of `-l` below.

Options The following options are supported:

`-d` *action*
`-e` *action*
Disable (`-d`) or enable (`-e`) the global action on the specified `rctl`s. If no `rctl` is specified, no action is taken and an error status is returned. You can use the special token `all` with the disable option to deactivate all global actions on a resource control.

You can set the `syslog` action to a specific degree by assigning a severity level. To do this, specify `syslog=`*level*, where *level* is one of the string tokens given as valid severity levels in `syslog(3C)`. You can omit the common `LOG_` prefix on the severity level. Note that not all `rctl`s support the `syslog` action. See `resource_controls(5)`.

`-l`
List information about `rctl`s. The name, global event actions and statuses, and global flags are displayed. If one or more name operands are specified, only those `rctl`s matching the names are displayed.

`-u`
Configure resource controls based on the contents of `/etc/rctladm.conf`. Any name operands are ignored.

Operands The following operands are supported:

name
The name of the `rctl` to operate on. Multiple `rctl` names can be specified. If no names are specified, and the list action has been specified, then all `rctl`s are listed. If the enable or disable action is specified, one or more `rctl` names must be specified.

Examples **EXAMPLE 1** Activating System Logging for Specific Violations

The following command activates system logging of all violations of `task.max-lwps`.

```
# rctladm -e syslog task.max-lwps
#
```

EXAMPLE 2 Examining the Current Status of a Specific Resource

The following command examines the current status of the `task.max-lwps` resource.

```
$ rctladm -l task.max-lwps
task.max-lwps               syslog=DEBUG
$
```

Exit Status

The following exit values are returned:

`0`
Successful completion.

`1`
A fatal error occurred. A message is written to standard error to indicate each resource control for which the operation failed. The operation was successful for any other resource controls specified as operands.

`2`
Invalid command line options were specified.

Files

`/etc/rctladm.conf`
Each time `rctladm` is executed, it updates the contents of `rctladm.conf` with the current configuration.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

See Also

`setrctl(2)`, `getrctl(2)`, `prctl(1)`, `rctlblk_get_global_flags(3C)`, `rctlblk_get_global_action(3C)`, `attributes(5)`, `resource_controls(5)`

Notes

By default, there is no global logging of `rctl` violations.

Name rdate – set system date from a remote host

Synopsis `rdate` *hostname*

Description `rdate` sets the local date and time from the *hostname* given as an argument. You must have the authorization `solaris.system.date` on the local system. Typically, `rdate` is used in a startup script.

`rdate` requests are responded to by the "time" service on the specified host. To enable the "time" service, use the following commands:

```
svcadm enable time:stream
svcadm enable time:dgram
```

Usage The `rdate` command is IPv6–enabled. See `ip6(7P)`.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWrcmdc

See Also `inetd(1M)`, `inetd.conf(4)`, `attributes(5)`, `ip6(7P)`

Name reboot – restart the operating system

Synopsis

```
/usr/sbin/reboot [-dlnq] [boot_arguments]
```

Description The `reboot` utility restarts the kernel. The kernel is loaded into memory by the PROM monitor, which transfers control to the loaded kernel.

Although `reboot` can be run by the super-user at any time, `shutdown(1M)` is normally used first to warn all users logged in of the impending loss of service. See `shutdown(1M)` for details.

The `reboot` utility performs a `sync(1M)` operation on the disks, and then a multi-user reboot is initiated. See `init(1M)` for details. On x86 systems, reboot may also update the boot archive as needed to ensure a successful reboot.

The `reboot` utility normally logs the reboot to the system log daemon, `syslogd(1M)`, and places a shutdown record in the login accounting file `/var/adm/wtmpx`. These actions are inhibited if the `-n` or `-q` options are present.

Normally, the system reboots itself at power-up or after crashes.

Options The following options are supported:

`-d` Force a system crash dump before rebooting. See `dumpadm(1M)` for information on configuring system crash dumps.

`-l` Suppress sending a message to the system log daemon, `syslogd(1M)` about who executed `reboot`.

`-n` Avoid calling `sync(2)` and do not log the reboot to `syslogd(1M)` or to `/var/adm/wtmpx`. The kernel still attempts to sync filesystems prior to reboot, except if the `-d` option is also present. If `-d` is used with `-n`, the kernel does not attempt to sync filesystems.

`-q` Quick. Reboot quickly and ungracefully, without shutting down running processes first.

Operands The following operands are supported:

boot_arguments An optional *boot_arguments* specifies arguments to the `uadmin(2)` function that are passed to the boot program and kernel upon restart. The form and list of arguments is described in the `boot(1M)` and `kernel(1M)` man pages.. If the arguments are specified, whitespace between them is replaced by single spaces unless the whitespace is quoted for the shell. If the *boot_arguments* begin with a hyphen, they must be preceded by the `--` delimiter (two hyphens) to denote the end of the `reboot` argument list.

Examples

EXAMPLE 1 Passing the `-r` and `-v` Arguments to `boot`

In the following example, the delimiter `--` (two hyphens) must be used to separate the options of `reboot` from the arguments of `boot(1M)`.

```
example# reboot -dl -- -rv
```

EXAMPLE 2 Rebooting Using a Specific Disk and Kernel

The following example reboots using a specific disk and kernel.

```
example# reboot disk1 kernel.test/unix
```

Files

`/var/adm/wtmpx` login accounting file

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also

`mdb(1)`, `boot(1M)`, `dumpadm(1M)`, `fsck(1M)`, `halt(1M)`, `init(1M)`, `kernel(1M)`, `shutdown(1M)`, `sync(1M)`, `syslogd(1M)`, `sync(2)`, `uadmin(2)`, `reboot(3C)`, `attributes(5)`

Notes

The `reboot` utility does not execute the scripts in `/etc/rc`*num*`.d` or execute shutdown actions in `inittab(4)`. To ensure a complete shutdown of system services, use `shutdown(1M)` or `init(1M)` to reboot a Solaris system.

Name regadm – Solaris system registration utility

Synopsis

```
regadm auth [-u username] [-p password_file]

regadm register [-q] [-d]

regadm list

regadm clear

regadm set [-n name] [-v value]

regadm status

regadm disable

regadm enable
```

Description The `regadm` utility is used by a privileged system administrator to register products on a given Solaris system with My Oracle Support (MOS), and to manage the background auto-registration service that runs at system boot time. Registered products are extracted from the Service Tag Registry (see `stclient(1M)`) and uploaded to MOS by means of a secure HTTPS connection.

You can use `regadm` to explicitly register products. In addition, an `smf(5)` service runs at boot time that attempts to refresh the registration if the product installation base has changed. This service can be administratively enabled or disabled by means of subcommands of regadm. By default, the service is enabled.

Options The following options are supported:

`-d`
Dry-run mode. Show the registration information that will be transmitted to MOS but do not perform the actual registration. Output is displayed in XML format.

`-p` *password_file*
Used with the authentication subcommand, the `-p` option specifies a file name containing the password associated with the MOS username (the `-u` option). This should be a single-line file and it can be immediately removed after running this command.

`-q`
Quiet mode. Do not show any output during a registration.

`-u` *username*
Used with the authentication subcommand, the `-u` option specifies the MOS user name to be associated with registrations of products on a given system.

Sub-commands The subcommands for `regadm` are as follows:

`auth`
Each system must be authenticated with valid MOS credentials before its products can be registered. A successful authentication is made persistent and thus only needs to be done once.

`clear`
Remove all configured authentication and HTTPS connectivity information. This effectively configures an anonymous registration with no HTTP proxy information.

`disable`
Disable the auto-registration service at system boot time.

`enable`
Enable the auto-registration service at system boot time.

`list`
Displays the current authenticated MOS user name and the network connectivity information needed for HTTPS communication with MOS. If no authentication has yet been done (by means of the `auth` command), the anonymous account will be displayed.

`register`
Registers each product from the Solaris Service Tag registry (see `stclient(1M)`) with MOS, using the current authentication credentials. If no credentials have been supplied, the registration is performed using an anonymous MOS account.

`set`
Configure HTTP proxy information, to be used for HTTPS communication with the MOS backend.

`status`
Report the status (enabled/disabled) of the Solaris auto-registration `smf(5)` service. See the `disable` and `enable` subcommands.

Examples

EXAMPLE 1 Authenticating with MOS Interactively

The following command is used to interactively authenticate this system with MOS. You will be prompted for your support username and password.

```
# regadm auth
```

EXAMPLE 2 Authenticating Non-Interactively

This is similar to the interactive example, but specifies the MOS username and password on the command line.

```
# regadm auth -u "pat.smith@example.com" -p mypassword
```

The file `mypassword` must contain the MOS password.

EXAMPLE 3 Setting HTTP Proxy Information

The following command sequence configures an HTTP proxy and port, used for HTTPS communication with the MOS.

```
# regadm set -n http_proxy -v webcache.example.com
# regadm set -n http_proxy_port -v 8080
```

EXAMPLE 4 Setting HTTP Proxy Authentication Information

Some HTTP proxies require authentication. This example shows the configuring of a username/password for basic RFC 2617 HTTP authentication. Note that a filename containing the password (`mypassword`) is specified, not the actual password itself.

```
# regadm set -n http_proxy_user -v webuser
# regadm set -n http_proxy_user_pw -v mypassword
```

Attributes

Name rem_drv – remove a device driver from the system

Synopsis

```
rem_drv [-b basedir] device_driver
```

Description The `rem_drv` command informs the system that the device driver *device_driver* is no longer valid. If possible, `rem_drv` unloads *device_driver* from memory. `rem_drv` also updates the system driver configuration files.

If `rem_drv` has been executed, the next time the system is rebooted it automatically performs a reconfiguration boot (see `kernel(1M)`).

Options The following options are supported:

`-b` *basedir*
Sets the path to the root directory of the diskless client. Used on the server to execute `rem_drv` for a client. The client machine must be rebooted to unload the driver.

Note – The root file system of any non-global zones must not be referenced with the `-b` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.

`-C`
Remove dangling device attribute nodes bound to the driver being removed. This causes any device ownership or permissions customizations made to any node not to be preserved if the driver is added back. Recommended for use when reprovisioning a machine from one configuration or use to another where past administrative customizations might not be desired.

Examples

EXAMPLE 1 Removing the `sd` Driver

The following example removes the `sd` driver from use:

```
example% rem_drv sd
```

EXAMPLE 2 Removing a Diskless Client

The following example removes the driver from the `sun1` diskless client. The driver is not uninstalled or unloaded until the client machine is rebooted.

```
example% rem_drv -b /export/root/sun1 sd
```

Note the caveat on the use of the `-b` option in the description of that option, above.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also add_drv(1M), kernel(1M), update_drv(1M), attributes(5), zones(5), devfs(7FS)

Name remove_allocatable – remove entries from allocation databases

Synopsis

```
/usr/sbin/remove_allocatable  [-f] -n name

/usr/sbin/remove_allocatable  [-f] [-d] -t dev-type
```

Description `remove_allocatable` removes entries of user allocatable devices from the device allocation mechanism. `remove_allocatable` also removes entries of some non-allocatable devices, such as printers, whose label range is managed by the mechanism.

Options The following options are supported:

`-d` Removes system-supplied default attributes of the device type that is specified with `-t`.

`-f` Force the removal of an entry. `remove_allocatable` exits with an error if this option is not specified when an entry with the specified device name no longer exists.

`-n` *name* Removes the entry for the device *name*.

`-t` *dev-type* Removes devices of type *dev-type*.

Exit Status When successful, `remove_allocatable` returns an exit status of `0` (true). `remove_allocatable` returns a nonzero exit status in the event of an error. The exit codes are as follows:

1 Invocation syntax error

2 Unknown system error

3 Device *name* or *dev-type* not found. This error occurs only when the `-f` option is not specified.

4 Permission denied. User does not have DAC or MAC access to database.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWtsu
Interface Stability	See below.

The invocation is Uncommitted. The options are Uncommitted. The output is Not-an-Interface.

See Also `allocate(1)`, `deallocate(1)`, `add_allocatable(1M)`, `attributes(5)`, `device_clean(5)`

Notes The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

Name removef – remove a file from software database

Synopsis

```
removef [ [-M] -R root_path] [-V fs_file] pkginst path...
removef [ [-M] -R root_path] [-V fs_file] -f pkginst
```

Description `removef` informs the system that the user, or software, intends to remove a pathname. Output from `removef` is the list of input pathnames that may be safely removed (no other packages have a dependency on them).

Options The following options are supported:

`-f`
After all files have been processed, `removef` should be invoked with the `-f` option to indicate that the removal phase is complete.

`-M`
Instruct `removef` not to use the $*root_path*`/etc/vfstab` file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.

`-R` *root_path*
Define the full path name of a directory to use as the *root_path*. All files, including package system information files, are relocated to a directory tree starting in the specified *root_path*. The *root_path* may be specified when installing to a client from a server (for example, `/export/root/client1`).

`removef` inherits the value of the `PKG_INSTALL_ROOT` environment variable. (See ENVIRONMENT VARIABLES, below.) If `PKG_INSTALL_ROOT` is set, such as when the `-R` option is used with `pkgadd(1M)` or `pkgrm(1M)`

Note – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.

`-V` *fs_file*
Specify an alternative *fs_file* to map the client's file systems. For example, used in situations where the $*root_path*`/etc/vfstab` file is non-existent or unreliable.

Operands The following operands are supported:

path
The pathname to be removed.

pkginst
The package instance from which the pathname is being removed.

Examples

EXAMPLE 1 Using `removef`

The following example uses the `removef` command in an optional pre-install script:

```
echo "The following files are no longer part of this package
      and are being removed."
removef $PKGINST /myapp/file1 /myapp/file2 |
while read pathname
do
     echo "$pathname"
     rm -f $pathname
done
removef -f $PKGINST || exit 2
```

Environment Variables

`removef` inherits the value of the following environment variable. This variable is set when `pkgadd(1M)` or `pkgrm(1M)`

`PKG_INSTALL_ROOT`
: If present, defines the full path name of a directory to use as the system's `PKG_INSTALL_ROOT` path. All product and package information files are then looked for in the directory tree, starting with the specified `PKG_INSTALL_ROOT` path. If not present, the default system path of `/` is used.

Exit Status

`0`
: Successful completion.

`>0`
: An error occurred.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also

`pkginfo(1)`, `pkgmk(1)`, `pkgparam(1)`, `pkgproto(1)`, `pkgtrans(1)`, `installf(1M)`, `pkgadd(1M)`, `pkgask(1M)`, `pkgchk(1M)`, `pkgrm(1M)`, `attributes(5)`, `largefile(5)`

Application Packaging Developer's Guide

Notes

Package commands are `largefile(5)`-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, `pkgadd(1M)`, `pkgtrans(1)` and other package commands can process a datastream of up to 4 GB.

Name repquota – summarize quotas for a ufs file system

Synopsis

```
repquota [-v] filesystem...

repquota -a [-v]
```

Description `repquota` prints a summary of the disk usage and quotas for the specified ufs file systems. The current number of files and amount of space (in kilobytes) is printed for each user along with any quotas created with `edquota(1M)`.

The *filesystem* must have the file `quotas` in its root directory.

Only the super-user may view quotas which are not their own.

Options The following options are supported:

`-a` Report on all mounted ufs file systems that have `rq` in the `mntopts` field of the `/etc/vfstab` file.

`-v` Report quotas for all users, even those who do not consume resources.

Usage See `largefile(5)` for the description of the behavior of `repquota` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `edquota(1M)`, `quota(1M)`, `quotacheck(1M)`, `quotaon(1M)`, `attributes(5)`, `largefile(5)`, `quotactl(7I)`

Name re-preinstall – installs the JumpStart software on a system

Synopsis

```
cdrom-mnt-pt/Solaris_XX/Tools/Boot/usr/sbin/install.d/re-preinstall
     [-m Solaris_boot_dir]
     [-k platform_name] target-slice
```

Description `re-preinstall` installs the JumpStart software (preinstall boot image) on a system, so you can power-on the system and have it automatically install the Solaris software (perform a JumpStart installation on the system). When you turn on a re-preinstalled system, the system looks for the JumpStart software on the system's default boot disk. *All* new SPARC systems have the JumpStart software already preinstalled. The *XX* in Solaris_*XX* is the version number of the Solaris release being used.

You can use the `re-preinstall` command in several ways. The most common way is to run `re-preinstall` on a system to install the JumpStart software on its own default boot disk. This is useful if you want to restore a system to its original factory conditions. (See the first procedure described in `EXAMPLES`.)

You can also run `re-preinstall` on a system to install JumpStart software on any attached disk (non-boot disk). After you install the JumpStart software on a disk, you can move the disk to a different system and perform a JumpStart installation on the different system. (See the second procedure described in `EXAMPLES`.)

`re-preinstall` creates a standard file system on the specified *target-slice* (usually slice 0), and `re-preinstall` makes sure there is enough space on the *target-slice* for the JumpStart software. If sufficient space is not available, `re-preinstall` fails with the following message:

`re-preinstall:` *target-slice* `too small` *xx* `Megabytes required`

You can use the `format(1M)` command to create sufficient space on the *target-slice* for the JumpStart software.

Options The following options are supported:

`-k` *platform_name* — Platform name of the system that will use the disk with the JumpStart software. The default is the platform name of the system running `re-preinstall`. (Use the `uname(1)` command (`-i` option) to determine a system's platform name.)

`-m` *Solaris_boot_dir* — Absolute path to the `Solaris_`*XX*`/Tools/Boot` subdirectory of a mounted Solaris CD or a Solaris CD copied to disk that `re-preinstall` uses to install the JumpStart software. The default is root (`/`), which is where the Solaris CD is mounted in single-user mode.

Operands The following operands are supported:

target-slice — Device name of the disk slice where the JumpStart software will be installed (usually slice 0), for example, `c0t3d0s0`.

Examples

EXAMPLE 1 Installing the JumpStart Software on a System's Own Default Boot Disk

The following procedure installs the JumpStart software on a system's own default boot disk:

1. From the `ok` prompt, boot the system from the Solaris media CD or DVD in single-user mode:

   ```
   ok boot cdrom -s
   ```

2. The following command installs the Jumpstart software on the System default boot disk, `c0t0d0s0` on a Solaris system:

   ```
   example# /usr/sbin/install.d/re-preinstall c0t0d0s1
   ```

3. Reboot the slice:

   ```
   example# reboot disk:b
   ```

EXAMPLE 2 Installing the JumpStart Software on a System's Attached (non-boot) Disk

The following procedure installs the JumpStart software on a system's attached (non-boot) disk:

1. Mount the Solaris CD or DVD if `vold(1M)` is not running or CD or DVD is not mounted.
2. Use the `format(1M)` command to determine the target-slice where JumpStart will be installed.
3. Use the `uname(1)` command (`-i` option) to determine the platform name of the system that will use the re-preinstalled disk
4. Run `re-preinstall` with the `-m` *Solaris_boot_dir* option if the Solaris CD or DVD is not mounted on `/cdrom`.

   The following command installs the JumpStart software on the system's attached disk for a system with a Sun4u kernel architecture, and it uses the Solaris CD or DVD mounted with `vold(1M)` on a Solaris system:

   ```
   example#  /cdrom/cdrom/s1/usr/bin/install.d/re-preinstall  -m
             /cdrom/cdrom/s1 -k sun4u c0t2d0s0
   ```

Exit Status

The following exit values are returned:

`0` Successful completion.

`1` An error has occurred.

Attributes

See `attributes(5)` for descriptions of the following attributes:

Solaris 10 Installation Guide: Basic Installations

Name rmmount – removable media mounter for CD-ROM, floppy, Jaz drive, and others

Synopsis

```
/usr/sbin/rmmount [-D]
```

Description The `rmmount` utility is a removable media mounter that is executed by Volume Management whenever a removable medium, such as a CD-ROM or a floppy, is inserted. The Volume Management daemon, `vold(1M)`, manages removable media. `rmmount` can also be called by using `volrmmount(1)`.

Upon insertion of a medium and following invocation of the `volcheck(1)` command, `rmmount` determines what type of file system (if any) is on that medium. If a file system is present, `rmmount` mounts the file system in one of the locations listed below.

For a diskette (floppy):

`/floppy/floppy0`	symbolic link to mounted floppy in local floppy drive
`/floppy/floppy_name`	mounted named floppy
`/floppy/unnamed_floppy`	mounted unnamed floppy

For a CD-ROM or a DVD-ROM:

`/cdrom/cdrom0`	symbolic link to mounted CD-ROM in local CD-ROM drive
`/cdrom/CD-ROM_name`	mounted named CD-ROM
`/cdrom/CD-ROM_name/partition`	mounted named CD-ROM with partitioned file system
`/cdrom/unnamed_cdrom`	mounted unnamed CD-ROM

For a Zip drive:

`/rmdisk/zip0`	symbolic link to mounted Zip medium in local Zip drive
`/rmdisk/`*Zip_name*	mounted named Zip medium
`/rmdisk/`*Zip_name*`/partition`	mounted named Zip medium with partitioned file system
`/rmdisk/unnamed_zip`	mounted unnamed Zip medium

For a Jaz drive:

`/rmdisk/jaz0`	symbolic link to mounted Jaz medium in local Jaz drive
`/rmdisk/`*Jaz_name*	mounted named Jaz medium
`/rmdisk/`*Jaz_name*`/partition`	mounted named Jaz medium with partitioned file system
`/rmdisk/unnamed_Jaz`	mounted unnamed Jaz medium

For a generic “rmdisk” drive:

`/rmdisk/rmdisk0`	symbolic link to mounted removable medium in local removable medium drive
`/rmdisk/`*`rmdisk_name`*	mounted named removable medium
`/rmdisk/`*`rmdisk_name`*`/partition`	mounted named removable medium with partitioned file system
`/rmdisk/unnamed_rmdisk`	mounted unnamed removable medium

If the media is read-only (for example, a CD-ROM or a floppy with write-protect tab set), the file system is mounted read-only.

If a file system is not identified, `rmmount` does not mount a file system. See the *System Administration Guide: Basic Administration* for more information on the location of CD-ROM, floppy, and other media without file systems. Also see `volfs`(7FS).

If a file system type has been determined, it is then checked to see that it is "clean." If the file system is "dirty," `fsck -p` (see `fsck`(1M)) is run in an attempt to clean it. If `fsck` fails, the file system is mounted read-only.

After the mount is complete, "actions" associated with the media type are executed. These actions allow for the notification to other programs that new media are available. These actions are shared objects and are described in the configuration file, `/etc/rmmount.conf`. See `rmmount.conf`(4).

Actions are executed in the order in which they appear in the configuration file. The action function can return either `1` or `0`. If it returns `0`, no further actions will be executed. This allows the function to control which applications are executed.

In order to execute an action, `rmmount` performs a `dlopen`(3C) on the shared object and calls the action function defined within it. The definition of the interface to actions can be found in `/usr/include/rmmount.h`.

File systems mounted by `rmmount` are always mounted with the `nosuid` flag set, thereby disabling setuid programs and access to block or character devices in that file system. Upon ejection, `rmmount` unmounts mounted file systems and executes actions associated with the media type. If a file system is "busy" (that is, it contains the current working directory of a live process), the ejection will fail.

Options

`-D` Turn on the debugging output from the `rmmount` `dprintf` calls.

Files

`/etc/rmmount.conf`	removable media mounter configuration file
`/usr/lib/rmmount/*.so.1`	shared objects used by `rmmount`.

System Administration Guide: Basic Administration

Name rmt – remote magtape protocol module

Synopsis `/usr/sbin/rmt`

Description `rmt` is a program used by the remote dump and restore programs in manipulating a magnetic tape drive through an interprocess communication connection. `rmt` is normally started up with an `rexec(3SOCKET)` or `rcmd(3SOCKET)` call.

The `rmt` program accepts requests that are specific to the manipulation of magnetic tapes, performs the commands, then responds with a status indication. All responses are in ASCII and in one of two forms. Successful commands have responses of:

`A`*number*`\n` where *number* is an ASCII representation of a decimal number.

Unsuccessful commands are responded to with:

`E`*error-number*`\n`*error-message*`\n` where *error-number* is one of the possible error numbers described in `Intro(3)`, and *error-message* is the corresponding error string as printed from a call to `perror(3C)`.

The protocol consists of the following commands:

`S\n` Return the status of the open device, as obtained with a `MTIOCGET` `ioctl` call. If the operation was successful, an "ack" is sent with the size of the status buffer, then the status buffer is sent (in binary).

`C`*device*`\n` Close the currently open device. The *device* specified is ignored.

`I`*operation*`\n`*count*`\n` Perform a `MTIOCOP` `ioctl(2)` command using the specified parameters. The parameters are interpreted as the ASCII representations of the decimal values to place in the *mt_op* and *mt_count* fields of the structure used in the `ioctl` call. When the operation is successful the return value is the *count* parameter.

`L`*offset*`\nwhence\n` Perform an `lseek(2)` operation using the specified parameters. The response value is returned from the `lseek` call.

`O`*device*`\n`*mode*`\n` Open the specified *device* using the indicated *mode*. *device* is a full pathname, and *mode* is an ASCII representation of a decimal number suitable for passing to `open(9E)`. If a device is already open, it is closed before a new open is performed.

`R`*count*`\n` Read *count* bytes of data from the open device. `rmt` performs the requested `read(9E)` and responds with `A`*count-read*`\n` if the read was successful; otherwise an error in standard format is returned. If the read was successful, the data read is sent.

`W`*count*`\n` Write data onto the open device. `rmt` reads *count* bytes from the connection, aborting if a premature EOF is encountered. The

response value is returned from the write(9E) call.

Any other command causes rmt to exit.

Attributes See attributes(5) for descriptions of the following attributes:

Diagnostics All responses are of the form described above.

Bugs Do not use this for a remote file access protocol.

Name rndc – name server control utility

Synopsis

```
rndc [-V] [-b src-addr] [-c config-file] [-k key-file] [-s server]
     [-p port] [-y key_id] command
```

Description The `rndc` utility controls the operation of a name server. It supersedes the `ndc` utility that was provided in previous BIND releases. If `rndc` is invoked with no command line options or arguments, it prints a short summary of the supported commands and the available options and their arguments.

The `rndc` utility communicates with the name server over a TCP connection, sending commands authenticated with digital signatures. The only supported authentication algorithm in the current versions of `rndc` and `named(1M)` is HMAC-MD5, which uses a shared secret on each end of the connection. This algorithm provides TSIG-style authentication for the command request and the name server's response. All commands sent over the channel must be signed by a *key_id* known to the server.

The `rndc` utility reads a configuration file to determine how to contact the name server and decide what algorithm and key it should use.

Options The following options are supported:

`-b` *source-address*
Use *source-address* as the source address for the connection to the server. Multiple instances are permitted to allow setting of both the IPv4 and IPv6 source addresses.

`-c` *config-file*
Use *config-file* as the configuration file instead of the default `/etc/rndc.conf`.

`-k` *key-file*
Use *key-file* as the key file instead of the default, `/etc/rndc.key`. The key in `/etc/rndc.key` is used to authenticate commands sent to the server if the *config-file* does not exist.

`-s` *server*
The *server* argument is the name or address of the server that matches a server statement in the configuration file for `rndc`. If no server is supplied on the command line, the host named by the default-server clause in the options statement of the `rndc` configuration file is used.

`-p` *port*
Send commands to TCP port *port* instead of BIND 9's default control channel port, 953.

`-V`
Enable verbose logging.

`-y` *key_id*
Use the key *key_id* from the configuration file. The *key_id* argument must be known by `named` with the same algorithm and secret string for control message validation to succeed. If no *key_id* is specified, `rndc` will first look for a key clause in the server statement of the

server being used, or if no server statement is present for that host, then the `default-key` clause of the options statement. The configuration file contains shared secrets that are used to send authenticated control commands to name servers. It should therefore not have general read or write access.

For the complete set of commands supported by `rndc`, see the *BIND 9 Administrator Reference Manual* or run `rndc` without arguments to see its help message.

Limitations The `rndc` utility does not support all the commands of the BIND 8 `ndc` utility.

There is no way to provide the shared secret for a *key_id* without using the configuration file.

Several error messages tend toward the cryptic.

Attributes See `attributes(5)` for descriptions of the following attributes:

Name rndc-confgen – rndc key generation tool

Synopsis

```
rndc-confgen [-ah] [-b keysize] [-c keyfile] [-k keyname]
     [-p port] [-r randomfile] [-s address] [-t chrootdir]
     [-u user]
```

Description The `rndc-confgen` utility generates configuration files for `rndc(1M)`. This utility can be used as a convenient alternative to writing by hand the `rndc.conf(4)` file and the corresponding `controls` and `key` statements in `named.conf`. It can also be run with the `-a` option to set up a `rndc.key` file and avoid altogether the need for a `rndc.conf` file and a `controls` statement.

Options The following options are supported:

`-a`
Perform automatic `rndc` configuration. This option creates a file `rndc.key` in `/etc` (or however *sysconfdir* was specified when BIND was built) that is read by both `rndc` and `named(1M)` on startup. The `rndc.key` file defines a default command channel and authentication key allowing `rndc` to communicate with `named` with no further configuration.

Running `rndc-confgen` with `-a` specified allows BIND 9 and `rndc` to be used as drop-in replacements for BIND 8 and `ndc`, with no changes to the existing BIND 8 `named.conf` file.

If a more elaborate configuration than that generated by `rndc-confgen -a` is required, for example if `rndc` is to be used remotely, you should run `rndc-confgen` without the `-a` option and set up `rndc.conf` and `named.conf` files, as directed.

`-b` *keysize*
Specify the size of the authentication key in bits. The *keysize* argument must be between 1 and 512 bits; the default is 128.

`-c` *keyfile*
Used with the `-a` option to specify an alternate location for `rndc.key`.

`-h`
Print a short summary of the options and arguments to `rndc-confgen`.

`-k` *keyname*
Specify the key name of the `rndc` authentication key. The *keyname* argument must be a valid domain name. The default is `rndc-key`.

`-p` *port*
Specify the command channel port where `named` listens for connections from `rndc`. The default is 953.

`-r` *randomfile*
Specify a source of random data for generating the authorization. By default, `/dev/random` is used. The *randomdev* argument specifies the name of a character device or file containing random data to be used instead of the default. The special value `keyboard` indicates that keyboard input should be used.

`-s` *address*
Specify the IP address where `named` listens for command channel connections from `rndc`. The default is the loopback address 127.0.0.1.

`-t` *chrootdir*
Used with the `-a` option to specify a directory where `named` will run after the root directory is changed with `chroot(2)`. An additional copy of the `rndc.key` will be written relative to this directory so that it will be found by the `named` in the new directory.

`-u` *user*
Used with the `-a` option to set the owner of the `rndc.key` file generated. If `-t` is also specified only the file in the chroot area has its owner changed.

Examples

EXAMPLE 1 Create Automatic `rndc` Configuration

The following command creates an automatic `rndc` configuration, so that `rndc` can be used immediately.

```
# rndc-confgen -a
```

EXAMPLE 2 Print a Sample `rndc.conf` File

The following command prints a sample `rndc.conf` file with corresponding `controls` and `key` statements. These statements can subsequently be manually inserted in the file `named.conf`.

```
# rndc-confgen
```

Name roleadd – administer a new role account on the system

Synopsis

```
roleadd [-c comment] [-d dir] [-e expire] [-f inactive]
     [-g group] [-G group [, group...]] [-m [-k skel_dir]]
     [-u uid [-o]] [-s shell]
     [-A authorization [,authorization...]] [-K key=value] role

roleadd -D [-b base_dir] [-e expire] [-f inactive]
     [-g group] [-A authorization [,authorization...]]
     [-P profile [,profile...] [-K key=value]]
```

Description `roleadd` adds a role entry to the `/etc/passwd` and `/etc/shadow` and `/etc/user_attr` files. The `-A` and `-P` options respectively assign authorizations and profiles to the role. Roles cannot be assigned to other roles. The `-K` option adds a *key=value* pair to `/etc/user_attr` for a role. Multiple *key=value* pairs can be added with multiple `-K` options.

`roleadd` also creates supplementary group memberships for the role (`-G` option) and creates the home directory (`-m` option) for the role if requested. The new role account remains locked until the `passwd(1)` command is executed.

Specifying `roleadd -D` with the `-g`, `-b`, `-f`, `-e`, or `-K` option (or any combination of these option) sets the default values for the respective fields. See the `-D` option. Subsequent `roleadd` commands without the `-D` option use these arguments.

The system file entries created with this command have a limit of 512 characters per line. Specifying long arguments to several options can exceed this limit.

The role (`role`) field accepts a string of no more than eight bytes consisting of characters from the set of alphabetic characters, numeric characters, period (`.`), underscore (`_`), and hyphen (`-`). The first character should be alphabetic and the field should contain at least one lower case alphabetic character. A warning message is written if these restrictions are not met. A future Solaris release might refuse to accept role fields that do not meet these requirements.

The `role` field must contain at least one character and must not contain a colon (`:`) or a newline (`\n`).

Options The following options are supported:

`-A` *authorization* — One or more comma separated authorizations defined in `auth_attr(4)`. Only a user or role who has grant rights to the authorization can assign it to an account

`-b` *base_dir* — The default base directory for the system if `-d` *dir* is not specified. *base_dir* is concatenated with the account name to define the home directory. If the `-m` option is not used, *base_dir* must exist.

`-c` *comment* — Any text string. It is generally a short description of the role. This information is stored in the role's `/etc/passwd` entry.

`-d` *dir*
: The home directory of the new role. It defaults to *base_dir*/*account_name*, where *base_dir* is the base directory for new login home directories and *account_name* is the new role name.

`-D`
: Display the default values for *group*, *base_dir*, *skel_dir*, *shell*, *inactive*, *expire* and *key=value* pairs. When used with the `-g`, `-b`, `-f`, or `-K`, options, the `-D` option sets the default values for the specified fields. The default values are:

group	`other` (GID of 1)
base_dir	`/home`
skel_dir	`/etc/skel`
shell	`/bin/pfsh`
inactive	`0`
expire	Null
auths	Null
profiles	Null
key=value (pairs defined in `user_attr(4)`	not present

`-e` *expire*
: Specify the expiration date for a role. After this date, no user is able to access this role. The expire option argument is a date entered using one of the date formats included in the template file `/etc/datemsk`. See `getdate(3C)`.

  If the date format that you choose includes spaces, it must be quoted. For example, you can enter `10/6/90` or `October 6, 1990`. A null value (`""`) defeats the status of the expired date. This option is useful for creating temporary roles.

`-f` *inactive*
: The maximum number of days allowed between uses of a role ID before that ID is declared invalid. Normal values are positive integers. A value of `0` defeats the status.

`-g` *group*
: An existing group's integer ID or character-string name. Without the `-D` option, it defines the new role's primary group membership and defaults to the default group. You can reset this default value by invoking `roleadd -D -g` *group*.

`-G` *group*
: An existing group's integer ID or character-string name. It defines the new role's supplementary group membership. Duplicates between *group* with the `-g` and `-G` options are ignored. No more than `NGROUPS_MAX` groups can be specified.

`-k` *skel_dir* — A directory that contains skeleton information (such as `.profile`) that can be copied into a new role's home directory. This directory must already exist. The system provides the `/etc/skel` directory that can be used for this purpose.

`-K` *key=value* — A *key=value* pair to add to the role's attributes. Multiple `-K` options can be used to add multiple *key=value* pairs. The generic `-K` option with the appropriate key can be used instead of the specific implied key options (`-A` and `-P`). See `user_attr(4)` for a list of valid *key=value* pairs. The "type" key is not a valid key for this option. Keys can not be repeated.

`-m` — Create the new role's home directory if it does not already exist. If the directory already exists, it must have read, write, and execute permissions by *group*, where *group* is the role's primary group.

`-o` — This option allows a UID to be duplicated (non-unique).

`-P` *profile* — One or more comma-separated execution profiles defined in `prof_attr(4)`.

`-s` *shell* — Full pathname of the program used as the user's shell on login. It defaults to an empty field causing the system to use `/bin/pfsh` as the default. The value of *shell* must be a valid executable file.

`-u` *uid* — The UID of the new role. This UID must be a non-negative decimal integer below `MAXUID` as defined in `<sys/param.h>`. The UID defaults to the next available (unique) number above the highest number currently assigned. For example, if UIDs 100, 105, and 200 are assigned, the next default UID number is 201. (UIDs from `0-99` are reserved for possible use in future applications.)

Files

`/etc/datemsk`

`/etc/passwd`

`/etc/shadow`

`/etc/group`

`/etc/skel`

`/usr/include/limits.h`

`/etc/user_attr`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Evolving

See Also passwd(1), pfexec(1), profiles(1), roles(1), users(1B), groupadd(1M), groupdel(1M), groupmod(1M), grpck(1M), logins(1M), pwck(1M), userdel(1M), usermod(1M), getdate(3C), auth_attr(4), passwd(4), prof_attr(4), user_attr(4), attributes(5)

Diagnostics In case of an error, `roleadd` prints an error message and exits with a non-zero status.

The following indicates that `login` specified is already in use:

```
UX: roleadd: ERROR: login is already in use. Choose another.
```

The following indicates that the *uid* specified with the `-u` option is not unique:

```
UX: roleadd: ERROR: uid uid is already in use. Choose another.
```

The following indicates that the *group* specified with the `-g` option is already in use:

```
UX: roleadd: ERROR: group group does not exist. Choose another.
```

The following indicates that the *uid* specified with the `-u` option is in the range of reserved UIDs (from `0-99`):

```
UX: roleadd: WARNING: uid uid is reserved.
```

The following indicates that the *uid* specified with the `-u` option exceeds `MAXUID` as defined in `<sys/param.h>`:

```
UX: roleadd: ERROR: uid uid is too big. Choose another.
```

The following indicates that the `/etc/passwd` or `/etc/shadow` files do not exist:

```
UX: roleadd: ERROR: Cannot update system files - login cannot be created.
```

Notes If a network nameservice such as NIS or NIS+ is being used to supplement the local `/etc/passwd` file with additional entries, `roleadd` cannot change information supplied by the network nameservice.

Name roledel – delete a role's login from the system

Synopsis

```
roledel [-r] role
```

Description The `roledel` utility deletes a role account from the system and makes the appropriate account-related changes to the system file and file system. `roledel` also removes the role from each user's list of assumable roles.

Options The following options are supported:

`-r` Remove the role's home directory from the system. This directory must exist. The files and directories under the home directory will no longer be accessible following successful execution of the command.

Operands The following operands are supported:

role An existing role name to be deleted.

Exit Status The following exit values are returned:

`0` Successful completion.

`2` Invalid command syntax. A usage message for the `roledel` command is displayed.

`6` The account to be removed does not exist.

`8` The account to be removed is in use.

`10` Cannot update the `/etc/group` or `/etc/user_attr` file but the login is removed from the `/etc/passwd` file.

`12` Cannot remove or otherwise modify the home directory.

Files

`/etc/passwd`	system password file
`/etc/shadow`	system file containing roles' encrypted passwords and related information
`/etc/group`	system file containing group definitions
`/etc/user_attr`	system file containing additional role attributes

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `auths(1)`, `passwd(1)`, `profiles(1)`, `roles(1)`, `users(1B)`, `groupadd(1M)`, `groupdel(1M)`, `groupmod(1M)`, `logins(1M)`, `roleadd(1M)`, `rolemod(1M)`, `useradd(1M)`, `userdel(1M)`, `usermod(1M)`, `passwd(4)`, `prof_attr(4)`, `user_attr(4)`, `attributes(5)`

Notes The `roledel` utility only deletes an account definition that is in the local `/etc/group`, `/etc/passwd`, `/etc/shadow`, and `/etc/user_attr` file. file. If a network name service such as NIS or NIS+ is being used to supplement the local `/etc/passwd` file with additional entries, `roledel` cannot change information supplied by the network name service.

Name rolemod – modify a role's login information on the system

Synopsis

```
rolemod [-u uid [-o]] [-g group] [-G group [, group...]]
     [-d dir [-m]] [-s shell] [-c comment] [-l new_name]
     [-f inactive] [-e expire]
     [-A authorization [, authorization]]
     [-P profile [, profile]] [-K key=value] role
```

Description The `rolemod` utility modifies a role's login information on the system. It changes the definition of the specified login and makes the appropriate login-related system file and file system changes.

The system file entries created with this command have a limit of 512 characters per line. Specifying long arguments to several options may exceed this limit.

Options The following options are supported:

`-A` *authorization*
One or more comma separated authorizations as deined in `auth_attr(4)`. Only role with `grant` rights to the `authorization` can assign it to an account. This replaces any existing authorization setting. If no authorization list is specified, the existing setting is removed.

`-c` *comment*
Specify a comment string. *comment* can be any text string. It is generally a short description of the login, and is currently used as the field for the user's full name. This information is stored in the user's `/etc/passwd` entry.

`-d` *dir*
Specify the new home directory of the role. It defaults to *base_dir/login*, where *base_dir* is the base directory for new login home directories, and `login` is the new login.

`-e` *expire*
Specify the expiration date for a role. After this date, no role will be able to access this login. The expire option argument is a date entered using one of the date formats included in the template file `/etc/datemsk`. See `getdate(3C)`.

For example, you may enter `10/6/90` or `October 6, 1990`. A value of "`''` defeats the status of the expired date.

`-f` *inactive*
Specify the maximum number of days allowed between uses of a login ID before that login ID is declared invalid. Normal values are positive integers. A value of `0` defeats the status.

`-g` *group*
Specify an existing group's integer ID or character-string name. It redefines the role's primary group membership.

-G *group*
Specify an existing group's integer ID or character string name. It redefines the role's supplementary group membership. Duplicates between *group* with the -g and -G options are ignored. No more than NGROUPS_UMAX groups may be specified as defined in <param.h>.

-K *key=value*
Replace existing or add to a role's *key=value* pair attributes. Multiple -K options can be used to replace or add multiple *key=value* pairs. However, keys must not be repeated. The generic -K option with the appropriate key may be used instead of the specific implied key options (-A and -P). See user_attr(4) for a list of valid *key=value* pairs.

The keyword type can be specified with the value role or the value normal. When using the value normal, the account changes from a role user to a normal user; using the value role keeps the account a role user.

-l *new_logname*
Specify the new login name for the role. The *new_logname* argument is a string no more than eight bytes consisting of characters from the set of alphabetic characters, numeric characters, period (.), underline (_), and hypen (–). The first character should be alphabetic and the field should contain at least one lower case alphabetic character. A warning message will be written if these restrictions are not met. A future Solaris release may refuse to accept login fields that do not meet these requirements. The *new_logname* argument must contain at least one character and must not contain a colon (:) or NEWLINE (\n).

-m
Move the role's home directory to the new directory specified with the -d option. If the directory already exists, it must have permissions read/write/execute by *group*, where *group* is the role's primary group.

-o
This option allows the specified UID to be duplicated (non-unique).

-P *profile*
One or more comma-separated execution profiles defined in auth_attr(4). This replaces any existing profile setting. If no profile list is specified, the existing setting is removed.

-s *shell*
Specify the full pathname of the program that is used as the role's shell on login. The value of *shell* must be a valid executable file.

-u *uid*
Specify a new UID for the role. It must be a non-negative decimal integer less than MAXUID as defined in <param.h>. The UID associated with the role's home directory is not modified with this option; a role will not have access to their home directory until the UID is manually reassigned using chown(1).

Operands The following operands are supported:

`login`
An existing login name to be modified.

Exit Status In case of an error, `rolemod` prints an error message and exits with one of the following values:

`2`
The command syntax was invalid. A usage message for the `rolemod` command is displayed.

`3`
An invalid argument was provided to an option.

`4`
The *uid* given with the `-u` option is already in use.

`5`
The password files contain an error. `pwconv(1M)` can be used to correct possible errors. See `passwd(4)`.

`6`
The login to be modified does not exist, the *group* does not exist, or the login shell does not exist.

`8`
The login to be modified is in use.

`9`
The *new_logname* is already in use.

`10`
Cannot update the `/etc/group` or `/etc/user_attr` file. Other update requests will be implemented.

`11`
Insufficient space to move the home directory (`-m` option). Other update requests will be implemented.

`12`
Unable to complete the move of the home directory to the new home directory.

Files `/etc/group`
system file containing group definitions

`/etc/datemsk`
system file of date formats

`/etc/passwd`
system password file

`/etc/shadow`
system file containing users' and roles' encrypted passwords and related information

`/etc/user_attr`
system file containing additional user and role attributes

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Evolving

See Also `chown(1)`, `passwd(1)`, `users(1B)`, `groupadd(1M)`, `groupdel(1M)`, `groupmod(1M)`, `logins(1M)`, `pwconv(1M)`, `roleadd(1M)`, `roledel(1M)`, `useradd(1M)`, `userdel(1M)`, `usermod(1M)`, `getdate(3C)`, `auth_attr(4)`, `passwd(4)`, `attributes(5)`

Name root_archive – manage bootable miniroot archives

Synopsis

```
/boot/solaris/bin/root_archive pack archive root

/boot/solaris/bin/root_archive unpack archive root

/boot/solaris/bin/root_archive packmedia solaris_image root

/boot/solaris/bin/root_archive unpackmedia solaris_image root
```

Description The `root_archive` utility is used to manipulate boot archives and the bootable miniroot(s) in a Solaris install image. The utility can pack and unpack boot archives and image miniroots. Both `ufs` and `hsfs` (`iso9660`) format archives can be unpacked, although only `ufs` format is generated when packing.

For normal, boot-related system administration, `bootadm(1M)` is recommended. `root_archive`'s primary purpose is to enable OEMs to add or update a driver or other component on the Solaris install media.

A miniroot and a boot archive is closely associated with the release it is intended to boot. To ensure that the tools and system services used to construct the miniroot match, miniroot manipulation must be performed only on a system running the same release for which the miniroot is intended to install.

Subcommands The `root_archive` command has the following subcommands:

`pack` *archive root* Pack the contents of the root directory into the boot archive *archive*.

`unpack` *archive root* Unpack the contents of the boot archive named *archive* to the directory named *root*.

`packmedia` *solaris_image root* Create and pack the miniroot(s) in *solaris_image* from the contents of the directory named *root*.

`unpackmedia` *solaris_image root* Unpack the contents of the miniroot(s) in *solaris_image* to the directory named *root*.

The contents of a miniroot are constructed to need the requirements of the release. When unpacking a miniroot, all the contents of the miniroot(s) are unpacked. When packing a miniroot, the source directory must contain all the necessary components with which to construct a miniroot. In general, this can only be achieved by first unpacking an existing miniroot.

Examples **EXAMPLE 1** Unpacking the Miniroots in a Solaris x86 Install Image

The following command unpacks the miniroots in a Solaris image to the root directory in `/export/release/latest`.

```
# root_archive unpackmedia \
/export/nv/solarisdvd.nvx_dvd/latest /export/release/latest/root
```

EXAMPLE 1 Unpacking the Miniroots in a Solaris x86 Install Image *(Continued)*

In the preceding, `/export/nv/solarisdvd.nvx_dvd/latest` represents a path to a Solaris x86 install image and `/export/release/latest/root` is a directory that will be purged or created, as necessary.

EXAMPLE 2 Packing the Miniroots in a Solaris x86 Install Image

The following command creates and packs the miniroot(s) in a Solaris image from the contents of the directory `/export/release/latest/root`.

```
# root_archive packmedia \
/export/nv/solarisdvd.nvx_dvd/latest /export/release/latest/root
```

Exit Status

The following exit values are returned:

`0` The command completed successfully.

`1` The command exited due to an error.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs
Interface Stability	Committed

`cpio(1)`, `bootadm(1M)`, `mount(1M)`, `attributes(5)`, `lofi(7D)`

Name route – manually manipulate the routing tables

Synopsis

```
route [-fnvq] sub-command [ [modifiers] args]

route [-fnvq] [-p [-R root-dir]] add | delete [modifiers] destination gateway
     [args]

route [-fnvq] change | get [modifiers] destination
     [gateway [args]]

route [-fn] monitor [modifiers]

route [-fnvq] flush [modifiers]

route -p [-R root-dir] show
```

Description `route` manually manipulates the network routing tables. These tables are normally maintained by the system routing daemon, such as `in.routed(1M)` and `in.ripngd(1M)`.

`route` supports a limited number of general options, but a rich command language. Users can specify an arbitrary request that can be delivered by means of the programmatic interface discussed in `route(7P)`.

`route` uses a routing socket and the new message types `RTM_ADD`, `RTM_DELETE`, `RTM_GET`, and `RTM_CHANGE`. While only superusers can modify routing tables, the `RTM_GET` operation is allowed for non-privileged users.

Options

`-f` Flush the routing tables of all gateway entries. If you use the `-f` option in conjunction with any of the `route` sub-commands, `route` flushes the gateways before performing the sub-command. Specify the table to flush by placing the `inet` or `inet6` modifier immediately after the `-f` option. If unspecified, flushing IPv4 (`inet`) routes is the default.

`-n` Prevent attempts to print host and network names symbolically when reporting actions. This option is useful when name servers are unavailable.

`-p` Make changes to the network route tables persistent across system restarts. The operation is applied to the network routing tables first and, if successful, is then applied to the list of saved routes used at system startup. In determining whether an operation was successful, a failure to add a route that already exists or to delete a route that is not in the routing table is ignored. Particular care should be taken when using host or network names in persistent routes, as network-based name resolution services are not available at the time routes are added at startup.

`-q` Suppress all output.

`-R` *root-dir* Specify an alternate root directory where `route` applies changes. This option is ignored unless used in conjunction with the `-p` option. When `-R` is specified, route changes are applied only to the list of saved routes to be used at startup, *not* to the network routing tables. In addition, certain checks, such as the

existance of network interfaces used with `-ifp`, are skipped. This can be useful from within JumpStart scripts, where the root directory of the system being modified is in a location other than `/`.

`-v` Print additional details in verbose mode.

Subcommands

The following subcommands are supported:

`add` Add a route.

`change` Change aspects of a route (such as its gateway).

`delete` Delete a specific route.

`flush` Remove all gateway entries from the routing table.

`get` Look up and display the route for a destination.

`monitor` Continuously report any changes to the routing information base, routing lookup misses, or suspected network partitionings.

`show` Display the list of routes to be applied at system startup. Can be used only in conjunction with the `-p` option.

The `add` and `delete` sub-commands have the following syntax:

```
route [ -fnvq ] cmd destination gateway [metric/netmask]
```

where *cmd* is `add` or `delete`, *destination* is the destination host or network, and *gateway* is the next-hop intermediary through which packets should be routed. Modifiers described in `OPERANDS` can be placed anywhere on the command line.

The `get` and `change` sub-commands have the following syntax:

```
route [ -fnvq ] cmd destination [gateway [metric/netmask]]
```

where *cmd* is `get` or `change`, *destination* is the destination host or network, and *gateway* is the next-hop intermediary through which packets should be routed. Modifiers described in `OPERANDS` can be placed anywhere on the command line.

The `monitor` sub-command has the following syntax:

```
route monitor [ -inet | -inet6 ]
```

Operands

`route` executes its sub-commands on routes to destinations by way of gateways.

Destinations and Gateways

By default, destination and gateway addresses are interpreted as IPv4 addresses. All symbolic names are tried first as a host name, using `getipnodebyname(3SOCKET)`. If this lookup fails in the AF_INET case, `getnetbyname(3SOCKET)` interprets the name as that of a network.

Including an optional modifier on the command line before the address changes how the `route` sub-command interprets it.

The following modifiers are supported:

`-inet` Force the address to be interpreted as an IPv4 address, that is, under the `AF_INET` address family.

`-inet6` Force the address to be interpreted as an IPv6 address, that is, under the `AF_INET6` address family.

For IPv4 addresses, routes to a particular host are by default distinguished from those to a network by interpreting the Internet address specified as the destination. If the destination has a *local address part* (that is, the portion not covered by the netmask) of `0`, or if the destination is resolved as the symbolic name of a network, then the route is assumed to be to a network; otherwise, it is presumed to be a route to a host.

You can force this selection by using one of the following modifiers:

`-host` Force the destination to be interpreted as a host.

`-net` Force the destination to be interpreted as a network.

For example:

Destination	Destination Equivalent
`128.32`	`-host 128.0.0.32`
`128.32.130`	`-host 128.32.0.130`
`-net 128.32`	`128.32.0.0`
`-net 128.32.130`	`128.32.130.0`

Two modifiers avoid confusion between addresses and keywords (for example., `host` used as a symbolic host name). You can distinguish a *destination* by preceding it with the `-dst` modifier. You can distinguish a gateway address by using the `-gateway` modifier. If the destination is directly reachable by way of an interface requiring no intermediary IP router to act as a gateway, this can be indicated by using the `-interface` or `-iface` modifier.

In the following example, the route does not refer to an external gateway (router), but rather to one of the machine's interfaces. Packets with IP destination addresses matching the destination and mask on such a route are sent out on the interface identified by the gateway address. For interfaces using the ARP protocol, this type of route is used to specify that all matching destinations are local to the physical link. That is, a host could be configured to ARP for all addresses, without regard to the configured interface netmask, by adding a default route using this command. For example:

```
example# route add default hostname -interface
```

where gateway address *hostname* is the name or IP address associated with the network interface over which all matching packets should be sent. On a host with a single network interface, *hostname* is usually the same as the *nodename* returned by the `uname -n` command. See `uname(1)`.

For backward compatibility with older systems, directly reachable routes can also be specified by placing a `0` after the gateway address:

```
example# route add default hostname 0
```

This value was once a route metric, but this metric is no longer used. If the value is specified as `0`, then the destination is directly reachable (equivalent to specifying `-interface`). If it is non-zero but cannot be interpreted as a subnet mask, then a gateway is used (default).

With the `AF_INET` address family or an IPv4 address, a separate subnet mask can be specified. This can be specified in one of the following ways:

- IP address following the gateway address . This is typically specified in *decimal dot* notation as for `inet_addr(3SOCKET)` rather than in symbollic form.
- IP address following the `-netmask` qualifier.
- Slash character and a decimal length appended to the destination address.

If a subnet mask is not specified, the mask used is the subnet mask of the output interface selected by the gateway address, if the classful network of the destination is the same as the classful network of the interface. Otherwise, the classful network mask for the destination address is used.

Each of the following examples creates an IPv4 route to the destination `192.0.2.32` subnet with a subnet mask of `255.255.255.224`:

```
example# route add 192.0.2.32/27 somegateway
example# route add 192.0.2.32 -netmask 255.255.255.224 somegateway
example# route add 192.0.2.32 somegateway 255.255.255.224
```

For IPv6, only the slash format is accepted. The following example creates an IPv6 route to the destination `33fe::` with a netmask of `16` one-bits followed by 112 zero-bits.

```
example# route add -inet6 3ffe::/16 somegateway
```

In cases where the gateway does not uniquely identify the output interface (for example, when several interfaces have the same address), you can use the `-ifp` *ifname* modifier to specify the interface by name. For example, `-ifp lo0` associates the route with the `lo0` interface.

Routing Flags

Routes have associated flags that influence operation of the protocols when sending to destinations matched by the routes. These flags can be set (and in some cases cleared, indicated by ~) by including the following modifiers on the command line:

Modifier	Flag	Description
-interface	~RTF_GATEWAY	Destination is directly reachable
-iface	~RTF_GATEWAY	Alias for interface modifier
-static	RTF_STATIC	Manually added route
-nostatic	~RTF_STATIC	Pretend route was added by kernel or routing daemon
-reject	RTF_REJECT	Emit an ICMP unreachable when matched
-blackhole	RTF_BLACKHOLE	Silently discard packets duing updates
-proto1	RTF_PROTO1	Set protocol specific routing flag #1
-proto2	RTF_PROTO2	Set protocol specific routing flag #2
-private	RTF_PRIVATE	Do not advertise this route
-multirt	RTF_MULTIRT	Creates the specified redundant route
-setsrc	RTF_SETSRC	Assigns the default source address

The optional modifiers `-rtt`, `-rttvar`, `-sendpipe`, `-recvpipe`, `-mtu`, `-hopcount`, `-expire`, and `-ssthresh` provide initial values to quantities maintained in the routing entry by transport level protocols, such as TCP. These can be individually locked either by preceding each modifier to be locked by the `-lock` meta-modifier, or by specifying that all ensuing metrics can be locked by the `-lockrest` meta-modifier.

Some transport layer protocols can support only some of these metrics. The following optional modifiers are supported:

`-expire` Lifetime for the entry. This optional modifier is not currently supported.

`-hopcount` Maximum hop count. This optional modifier is not currently supported.

`-mtu` Maximum MTU in bytes.

`-recvpipe` Receive pipe size in bytes.

`-rtt` Round trip time in microseconds.

`-rttvar` Round trip time variance in microseconds.

`-sendpipe` Send pipe size in bytes.

`-ssthresh` Send pipe size threshold in bytes.

`-secattr` Security attributes of the route. This modifier is available only if the system is configured with the Solaris Trusted Extensions feature.

The `-secattr` modifier has the following format:

`min_sl=`*val*`,max_sl=`*val*`,doi=`*val*`,cipso`

or:

`sl=VAL,doi=VAL,cipso`

In the first form, above, the *val* for `min_sl` and `max_sl` is a sensitivity label in either hex or string form. The *val* for `doi` is a non-negative integer. The route will apply only for packets with the same domain of interpretation as defined by the `doi` value and within the accreditation range defined by the `min_sl` and `max_sl` values. The `cipso` keyword is optional and set by default. Valid `min_sl`, `max_sl` and `doi` keyword/value pairs are mandatory. Note that if *val* contains a space, it must be protected by double quotes.

The second form, above, is equivalent to specifying the first form with the same `VAL` for `min_sl` and `max_sl`. The second form should be used for the `get` command, because `get` uses only a single sensitivity label.

Compatibility The modifiers `host` and `net` are taken to be equivalent to `-host` and `-net`. To specify a symbolic address that matches one of these names, use the `dst` or `gateway` keyword to distinguish it. For example: `-dst host`

The following two flags are also accepted for compatibility with older systems, but have no effect.

Modifier	Flag
`-cloning`	RTF_CLONING
`-xresolve`	RTF_XRESOLVE

The `-ifa hostname` modifier is also accepted, but has no effect.

Files

`/etc/defaultrouter`	List of default routers
`/etc/hosts`	List of host names and net addresses
`/etc/networks`	List of network names and addresses

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `uname(1)`, `in.ripngd(1M)`, `in.routed(1M)`, `netstat(1M)`, `routed(1M)`, `ioctl(2)`, `getipnodebyname(3SOCKET)`, `getnetbyname(3SOCKET)`, `inet_addr(3SOCKET)`, `defaultrouter(4)`, `hosts(4)`, `networks(4)`, `attributes(5)`, `arp(7P)`, `ip(7P)`, `route(7P)`, `routing(7P)`

Diagnostics

`add` [`host` | `network`] *destination*:*gateway* *flags*	The specified route is being added to the tables. The values printed are from the routing table entry supplied in the `ioctl(2)` call. If the gateway address used was not the primary address of the gateway (the first one returned by `getipnodebyname(3SOCKET)`) the gateway address is printed numerically as well as symbolically.
`delete` [`host` | `network`] *destination*:*gateway* *flags* `change` [`host` | `network`] *destination*:*gateway* *flags*	As `add`, but when deleting or changing an entry.
destination `done`	When the `-f` flag is specified, or the `flush` sub-command is used, each routing table entry deleted is indicated with a message of this form.
`Network is unreachable`	An attempt to add a route failed because the gateway listed was not on a directly-connected network. Give the next-hop gateway instead.
`not in table`	A `delete` operation was attempted for an entry that is not in the table.
`entry exists`	An `add` operation was attempted for a route that already exists in the kernel.
`routing table overflow`	An operation was attempted, but the system was unable to allocate memory to create the new entry.
`insufficient privileges`	An attempt to add, delete, change, or flush a route failed because the calling process does not have appropriate privileges.

Notes Specifying that destinations are local (with the `-interface`modifier) assumes that the routers implement `proxy ARP`, meaning that they respond to ARP queries for all reachable destinations. Normally, using either router discovery or RIP is more reliable and scalable than using proxy ARP. See `in.routed(1M)` for information related to RIP.

Combining the all destinations are local route with subnet or network routes can lead to unpredictable results. The search order as it relates to the all destinations are local route are undefined and can vary from release to release.

Name routeadm – IP forwarding and routing configuration

Synopsis

```
routeadm [-p [option]]

routeadm [-R root-dir] [-e option ...] [-d option...]
 [-r option...] [-s var=value]

routeadm [-l fmri]

routeadm [-m fmri key=value [key=value]...]

routeadm [-u]
```

Description The `routeadm` command is used to administer system-wide configuration for IP forwarding and routing. IP forwarding is the passing of IP packets from one network to another; IP routing is the use of a routing protocol to determine routes.

IP forwarding and routing functions are also represented as services within the service management facility (SMF), and can be administered by means of `svcadm(1M)` also, using the following fault management resource identifiers (FMRIs):

```
svc:/network/ipv4-forwarding:default
svc:/network/ipv6-forwarding:default
svc:/network/routing/route:default
svc:/network/routing/ripng:default
```

See EXAMPLES for relevant examples.

In addition to enabling and disabling routing and forwarding, `routeadm` is used to interact with SMF-based routing daemon services. Routing daemon services are identified by the presence of a `routeadm` application property group, which `routeadm` uses in administering the given service. Routing daemon services can also specify properties relating to their operation in the `routing` application property group; these can be modified by means of routeadm -m. If an FMRI for a service without such a property group is specified, an error is issued and the operation is not carried out. If a routing daemon has not been converted to SMF, the `ipv4`*`[or 6]`*`-routing-daemon`, `ipv4`*`[or 6]`*`-routing-daemon-args`, and `ipv4`*`[or 6]`*`-routing-stop-cmd` variables can be used to specify the appropriate daemon for IPv4 or IPv6 routing. `routeadm` will then run that daemon using the `svc:/network/routing/legacy-routing:ipv4`*`[or 6]`* service as appropriate. This conversion process occurs when you issue an enable (`-e`), disable (`-d`) or an update (`-u`) command.

The first usage, in the SYNOPSIS above, reports the current configuration.

Options The following command-line options are supported:

`-p` [*option*]
: Print the configuration in parseable format. If *option* is specified, only the configuration for the specified option or variable is displayed.

`-R` *root-dir*
Specify an alternate root directory where `routeadm` applies changes. This can be useful from within JumpStart scripts, where the root directory of the system being modified is mounted elsewhere.

Note – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.

`-e` *option...*
Enable the specified option. The effect is to prepare the associated services (`svc:/network/ipv4-forwarding:default` in the case of `ipv4-forwarding`) for enabling. By means of the `routing-svcs` variable, the routing daemons are specified to be enabled on subsequent boot or when `routeadm -u` is run.

`-d` *option...*
Disable the specified option. The effect is to prepare the associated services (`svc:/network/ipv4-forwarding:default` in the case of `ipv4-forwarding`) for enabling. By means of the `routing-svcs` variable, the routing daemons are specified to be disabled on subsequent boot or when `routeadm -u` is run.

`-l` *fmri*
List all properties in the routing application property group for the SMF routing daemon service.

`-m` *fmri key=value*
Change property value of property *key* to *value* in routing application property group for the SMF routing daemon service. For multi-valued properties, the property name can be used multiple times in the modify operation, and each associated value will be added.

`-r` *option...*
Revert the specified option to the system default. The system defaults are specified in the description of each *option*.

`-u`
Apply the currently configured options to the running system. These options might include enabling or disabling IP forwarding and launching or killing routing daemons, if any are specified. It does not alter the state of the system for those settings that have been set to default. This option is meant to be used by administrators who do not want to reboot to apply their changes. In addition, this option upgrades non-SMF configurations from the invocations of daemon stop commands, which might include a set of arguments, to a simple enabling of the appropriate service.

`-s` *key=value*
Specify string values for specific variables in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is displayed and the program exits. The following variables can be specified:

`routing-svcs=`*fmrilist*
Specifies the routing daemon services to be enabled. Routing daemon services are determined to be IPv4 or IPv6 (and so enabled or disabled when `routeadm -e/-d ipv4`*(6)*`-routing` is run) on the basis of property values in the `routeadm` application property group. Default: `route:default ripng:default`

`ipv4-routing-daemon=`<*full_path_to_routing_daemon*>
Specifies the routing daemon to be started when `ipv4-routing` is enabled. The routing daemon specified must be an executable binary or shell-script. If the specified program maps to an SMF service, the service will be used, and daemon arguments to the program will be transferred to the properties of the service at enable time. Default: ""

`ipv4-routing-daemon-args=`<*args*>
Specifies the startup arguments to be passed to the `ipv4-routing-daemon` when `ipv4-routing` is enabled. Default: no arguments

`ipv4-routing-stop-cmd=`<*command*>
Specifies the command to be executed to stop the routing daemon when `ipv4-routing` is disabled. <*command*> can be an executable binary or shell-script, or a string that can be parsed by `system`(3C). Default: ""

`ipv6-routing-daemon=`<*full_path_to_routing_daemon*>
Specifies the routing daemon to be started when `ipv6-routing` is enabled. The routing daemon specified must be an executable binary or shell-script. If the specified program maps to an SMF service, the service will be used, and daemon arguments to the program will be transferred to the properties of the service at enable time. Default: ""

`ipv6-routing-daemon-args=`<*args*>
Specifies the startup arguments to be passed to the `ipv6-routing-daemon` when `ipv6-routing` is enabled. Default: ""

`ipv6-routing-stop-cmd=`<*command*>
Specifies the command to be executed to stop the routing daemon when `ipv6-routing` is disabled. <*command*> can be an executable binary or shell-script, or a string that can be parsed by `system`(3C). Default: ""

Multiple `-e`, `-d`, and `-r` options can be specified on the command line. Changes made by `-e`, `-d`, and `-r` are persistent, but are not applied to the running system unless `routeadm` is called later with the `-u` option.

Use the following options as arguments to the `-e`, `-d`, and `-r` options (shown above as *option...*).

`ipv4-forwarding`
Controls the global forwarding configuration for all IPv4 interfaces. The system default is `disabled`. If enabled, IP will forward IPv4 packets to and from interfaces when appropriate. If disabled, IP will not forward IPv4 packets to and from interfaces when appropriate. The SMF service associated with this configuration variable is

svc:/network/routing/ipv4-forwarding. This service will be enabled or disabled as appropriate when routeadm is called with the u option. As an alternative, you can use svcadm(1M). Services that require ipv4-forwarding to be enabled should specify a dependency on this service.

ipv4-routing
Determines whether an IPv4 routing daemon is run. The system default is enabled unless the /etc/defaultrouter file exists (see defaultrouter(4)), in which case the default is disabled. The value of this option reflects the state of all IPv4 routing services, such that if any IPv4 routing service is enabled, ipv4-routing is enabled. This allows users to interact with routing services using svcadm(1M), as well as through routeadm. IPv4 routing services, specified by means of the routing-svcs variable, will be prepared for enable on next boot when the user explicitly enables ipv4-routing. The SMF routing daemon service for in.routed (svc:/network/routing/route:default) is specified by default.

ipv6-forwarding
Controls the global forwarding configuration for all IPv6 interfaces. The system default is disabled. If enabled, IP will forward IPv6 packets to and from interfaces when appropriate. If disabled, IP will not forward IPv6 packets to and from interfaces when appropriate. The SMF service associated with this configuration variable is svc:/network/routing/ipv6-forwarding. This service will be enabled or disabled as appropriate when routeadm is called with the -u option, or svcadm(1M) is used. Services that require ipv6-forwarding to be enabled should specify a dependency on this service.

ipv6-routing
Determines whether an IPv6 routing daemon is run. The system default is disabled. The value of this option reflects the state of all IPv6 routing services, such that, if any IPv6 routing service is enabled, ipv6-routing is enabled. This allows users to interact with routing services via svcadm(1M) as well as through routeadm. IPv6 routing services, specified by means of the routing-svcs variable, will be prepared for enable on next boot when the user explicitly enables ipv6-routing. The SMF routing daemon service for in.ripngd (svc:/network/routing/ripng:default) is specified by default.

The forwarding and routing settings are related but not mutually dependent. For example, a router typically forwards IP packets and uses a routing protocol, but nothing would prevent an administrator from configuring a router that forwards packets and does not use a routing protocol. In that case, the administrator would enable forwarding, disable routing, and populate the router's routing table with static routes.

The forwarding settings are global settings. Each interface also has an IFF_ROUTER forwarding flag that determines whether packets can be forwarded to or from a particular interface. That flag can be independently controlled by means of ifconfig(1M)'s router option. When the global forwarding setting is changed (that is, -u is issued to change the value from enabled to disabled or vice-versa), all interface flags in the system are changed simultaneously to reflect the new global policy. Interfaces configured by means of DHCP automatically have their interface-specific IFF_ROUTER flag cleared.

When a new interface is plumbed by means of `ifconfig`, the value of the interface-specific forwarding flag is set according to the current global forwarding value. Thus, the forwarding value forms the "default" for all new interfaces.

Examples

EXAMPLE 1 Enabling IPv4 Forwarding

IPv4 forwarding is disabled by default. The following command enables IPv4 forwarding:

```
example# routeadm -e ipv4-forwarding
```

EXAMPLE 2 Apply Configured Settings to the Running System

In the previous example, a system setting was changed, but will not take effect until the next reboot unless a command such as the following is used:

```
example# routeadm -u
```

An alternative to the above two steps is to simply enable the equivalent SMF service:

```
example# svcadm enable svc:/network/ipv4-forwarding
```

...or, using the abbreviated FMRI:

```
example# svcadm enable ipv4-forwarding
```

EXAMPLE 3 Making a Setting Revert to its Default

To make the setting changed in the first example revert to its default, enter the following:

```
example# routeadm -r ipv4-forwarding
example# routeadm -u
```

EXAMPLE 4 Starting `in.routed` with the `-q` Flag

Setting the `-q` flag is represented in the SMF service by setting the `quiet_mode` property to true. The following sequence of commands starts `in.routed` with the `-q` flag:

```
example# routeadm -m route:default quiet_mode=true
example# routeadm -e ipv4-routing -u
```

See `in.routed(1M)` for details of property names and how they relate to daemon behavior.

Exit Status

The following exit values are returned:

`0` Successful completion.

`!=0` An error occurred while obtaining or modifying the system configuration.

Name rpcbind – universal addresses to RPC program number mapper

Synopsis

```
rpcbind [-d] [-w]
```

Description `rpcbind` is a server that converts RPC program numbers into universal addresses. It must be running on the host to be able to make RPC calls on a server on that machine.

When an RPC service is started, it tells `rpcbind` the address at which it is listening, and the RPC program numbers it is prepared to serve. When a client wishes to make an RPC call to a given program number, it first contacts `rpcbind` on the server machine to determine the address where RPC requests should be sent.

`rpcbind` should be started before any other RPC service. Normally, standard RPC servers are started by port monitors, so `rpcbind` must be started before port monitors are invoked.

When `rpcbind` is started, it checks that certain name-to-address translation-calls function correctly. If they fail, the network configuration databases can be corrupt. Since RPC services cannot function correctly in this situation, `rpcbind` reports the condition and terminates.

`rpcbind` maintains an open transport end for each transport that it uses for indirect calls. This is the UDP port on most systems.

The `rpcbind` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/rpc/bind
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. `rpcbind` can only be started by the superuser or someone in the Primary Administrator role.

The configuration properties of this service can be modified with `svccfg(1M)`.

The following SMF property is used to allow or disallow access to `rpcbind` by remote clients:

```
config/local_only = true
```

The default value, `true`, shown above, disallows remote access; a value of `false` allows remove access. See EXAMPLES.

The FMRI `svc:network/rpc/bind` property group `config` contains the following property settings:

`enable_tcpwrappers` Specifies that the TCP wrappers facility is used to control access to TCP services. The value `true` enables checking. The default value for `enable_tcpwrappers` is `false`. If the `enable_tcpwrappers` parameter is enabled, then all calls to `rpcbind` originating from non-local addresses are automatically wrapped by the TCP wrappers facility. The `syslog` facility code daemon is used to log

allowed connections (using the `info` severity level) and denied traffic (using the `warning` severity level). See `syslog.conf(4)` for a description of `syslog` codes and severity levels. The stability level of the TCP wrappers facility and its configuration files is External. As the TCP wrappers facility is not controlled by Sun, intrarelease incompatibilities are not uncommon. See `attributes(5)`.

`verbose_logging` Specifies whether the TCP wrappers facility logs all calls orjust the denied calls. The default is `false`. This option has no effect if TCP wrappers are not enabled.

`allow_indirect` Specifies whether `rpcbind` allows indirect calls at all. By default, `rpcbind` allows most indirect calls, except to a number of standard services(`keyserv`, `automount`, `mount`, `nfs`, `rquota`, and selected NIS and `rpcbind` procedures). Setting `allow_indirect` to `false` causes all indirect calls to be dropped. The default is `true`. NIS broadcast clients rely on this functionality on NIS servers.

Options

The following options are supported:

`-d` Run in debug mode. In this mode, `rpcbind` does not fork when it starts. It prints additional information during operation, and aborts on certain errors. With this option, the name-to-address translation consistency checks are shown in detail.

`-w` Do a warm start. If `rpcbind` aborts or terminates on `SIGINT` or `SIGTERM`, it writes the current list of registered services to `/var/run/portmap.file` and `/var/run/rpcbind.file`. Starting `rpcbind` with the `-w` option instructs it to look for these files and start operation with the registrations found in them. This allows `rpcbind` to resume operation without requiring all RPC services to be restarted.

Examples

EXAMPLE 1 Allowing Remote Access

The following sequence of commands allows remote access to `rpcbind`.

```
# svccfg -s svc:/network/rpc/bind setprop config/local_only = false
# svcadm refresh svc:/network/rpc/bind
```

Files

`/var/run/portmap.file` Stores the information for RPC services registered over IP based transports for warm start purposes.

`/var/run/rpcbind.file` Stores the information for all registered RPC services for warm start purposes.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	See below.

TCP wrappers is External.

See Also smf(5), rpcinfo(1M), svcadm(1M), svccfg(1M), rpcbind(3NSL), syslog.conf(4), attributes(5), smf(5)

For information on the TCP wrappers facility, see the `hosts_access(4)` man page, delivered as part of the Solaris operating environment in `/usr/sfw/man` and available in the `SUNWtcpd` package.

Notes Terminating `rpcbind` with `SIGKILL` prevents the warm-start files from being written.

All RPC servers are restarted if the following occurs: `rpcbind` crashes (or is killed with `SIGKILL`) and is unable to to write the warm-start files; `rpcbind` is started without the `-w` option after a graceful termination. Otherwise, the warm start files are not found by `rpcbind`.

Name rpc.bootparamd, bootparamd – boot parameter server

Synopsis

```
/usr/sbin/rpc.bootparamd [-d]
```

Description `rpc.bootparamd` is a server process that provides information from a `bootparams` database to diskless clients at boot time. See `bootparams(4)`

The source for the `bootparams` database is determined by the `nsswitch.conf(4)` file (on the machine running the `rpc.bootparamd` process).

Options The following options are supported:

`-d` Display debugging information.

Files

`/etc/bootparams`	boot parameter data base
`/etc/nsswitch.conf`	configuration file for the name-service switch

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbsu

See Also `svcs(1)`,`svcadm(1M)`, `bootparams(4)`, `nsswitch.conf(4)`, `attributes(5)`, `smf(5)`

Notes A diskless client requires service from at least one `rpc.bootparamd` process running on a server that is on the same IP subnetwork as the diskless client.

Some routines that compare hostnames use case-sensitive string comparisons; some do not. If an incoming request fails, verify that the case of the hostname in the file to be parsed matches the case of the hostname called for, and attempt the request again.

The `rpc.bootparamd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/rpc/bootparams
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

Name rpcinfo – report RPC information

Synopsis

```
rpcinfo [-m | -s] [host]

rpcinfo -p [host]

rpcinfo -T transport host prognum [versnum]

rpcinfo -l [-T transport] host prognum versnum

rpcinfo [-n portnum] -u host prognum [versnum]

rpcinfo [-n portnum] -t host prognum [versnum]

rpcinfo -a serv_address -T transport prognum [versnum]

rpcinfo -b [-T transport] prognum versnum

rpcinfo -d [-T transport] prognum versnum
```

Description `rpcinfo` makes an RPC call to an RPC server and reports what it finds.

In the first synopsis, `rpcinfo` lists all the registered RPC services with `rpcbind` on *host*. If *host* is not specified, the local host is the default. If `-s` is used, the information is displayed in a concise format.

In the second synopsis, `rpcinfo` lists all the RPC services registered with `rpcbind`, version 2. Note that the format of the information is different in the first and the second synopsis. This is because the second synopsis is an older protocol used to collect the information displayed (version 2 of the `rpcbind` protocol).

The third synopsis makes an RPC call to procedure 0 of *prognum* and *versnum* on the specified *host* and reports whether a response was received. *transport* is the transport which has to be used for contacting the given service. The remote address of the service is obtained by making a call to the remote `rpcbind`.

The *prognum* argument is a number that represents an RPC program number (see `rpc(4)`).

If a *versnum* is specified, `rpcinfo` attempts to call that version of the specified *prognum*. Otherwise, `rpcinfo` attempts to find all the registered version numbers for the specified *prognum* by calling version 0, which is presumed not to exist; if it does exist, `rpcinfo` attempts to obtain this information by calling an extremely high version number instead, and attempts to call each registered version. Note that the version number is required for `-b` and `-d` options.

The `EXAMPLES` section describe other ways of using `rpcinfo`.

Options

`-T` *transport* — Specify the transport on which the service is required. If this option is not specified, `rpcinfo` uses the transport specified in the `NETPATH` environment variable, or if that is unset or `NULL`, the transport in the `netconfig(4)` database is used. This is a generic option, and can be used in conjunction with other options as shown in the `SYNOPSIS`.

`-a` *serv_address* Use *serv_address* as the (universal) address for the service on *transport* to `ping` procedure 0 of the specified *prognum* and report whether a response was received. The `-T` option is required with the `-a` option. If *versnum* is not specified, `rpcinfo` tries to ping all available version numbers for that program number. This option avoids calls to remote `rpcbind` to find the address of the service. The *serv_address* is specified in universal address format of the given transport.

`-b` Make an RPC broadcast to procedure 0 of the specified *prognum* and *versnum* and report all hosts that respond. If *transport* is specified, it broadcasts its request only on the specified transport. If broadcasting is not supported by any transport, an error message is printed. Use of broadcasting should be limited because of the potential for adverse effect on other systems.

`-d` Delete registration for the RPC service of the specified *prognum* and *versnum*. If *transport* is specified, unregister the service on only that transport, otherwise unregister the service on all the transports on which it was registered. Only the owner of a service can delete a registration, except the superuser, who can delete any service.

`-l` Display a list of entries with a given *prognum* and *versnum* on the specified *host*. Entries are returned for all transports in the same protocol family as that used to contact the remote `rpcbind`.

`-m` Display a table of statistics of `rpcbind` operations on the given *host*. The table shows statistics for each version of `rpcbind` (versions 2, 3 and 4), giving the number of times each procedure was requested and successfully serviced, the number and type of remote call requests that were made, and information about RPC address lookups that were handled. This is useful for monitoring RPC activities on *host*.

`-n` *portnum* Use *portnum* as the port number for the `-t` and `-u` options instead of the port number given by `rpcbind`. Use of this option avoids a call to the remote `rpcbind` to find out the address of the service. This option is made obsolete by the `-a` option.

`-p` Probe `rpcbind` on *host* using version 2 of the `rpcbind` protocol, and display a list of all registered RPC programs. If *host* is not specified, it defaults to the local host. This option is not useful for IPv6; use `-s` (see below) instead. Note that version 2 of the `rpcbind` protocol was previously known as the portmapper protocol.

`-s` Display a concise list of all registered RPC programs on *host*. If *host* is not specified, it defaults to the local host.

`-t` Make an RPC call to procedure 0 of *prognum* on the specified *host* using TCP, and report whether a response was received. This option is made obsolete by the `-T` option as shown in the third synopsis.

`-u` Make an RPC call to procedure 0 of *prognum* on the specified *host* using UDP, and report whether a response was received. This option is made obsolete by the `-T` option as shown in the third synopsis.

Examples

EXAMPLE 1 RPC services.

To show all of the RPC services registered on the local machine use:

```
example% rpcinfo
```

To show all of the RPC services registered with `rpcbind` on the machine named `klaxon` use:

```
example% rpcinfo klaxon
```

The information displayed by the above commands can be quite lengthy. Use the `-s` option to display a more concise list:

```
example% rpcinfo -s klaxon
```

program	vrsn	netid(s)	service	owner
100000	2,3,4	tcp,udp,ticlts,ticots,ticotsord	rpcbind	superuser
100008	1	ticotsord,ticots,ticlts,udp,tcp	walld	superuser
100002	2,1	ticotsord,ticots,ticlts,udp,tcp	rusersd	superuser
100001	2,3,4	ticotsord,ticots,tcp,ticlts,udp	rstatd	superuser
100012	1	ticotsord,ticots,ticlts,udp,tcp	sprayd	superuser
100007	3	ticotsord,ticots,ticlts,udp,tcp	ypbind	superuser
100029	1	ticotsord,ticots,ticlts	keyserv	superuser
100078	4	ticotsord,ticots,ticlts	-	superuser
100024	1	ticotsord,ticots,ticlts,udp,tcp	status	superuser
100021	2,1	ticotsord,ticots,ticlts,udp,tcp	nlockmgr	superuser
100020	1	ticotsord,ticots,ticlts,udp,tcp	llockmgr	superuser

To show whether the RPC service with program number *prognum* and version *versnum* is registered on the machine named `klaxon` for the transport TCP use:

```
example% rpcinfo -T tcp klaxon prognum versnum
```

To show all RPC services registered with version 2 of the `rpcbind` protocol on the local machine use:

```
example% rpcinfo -p
```

To delete the registration for version 1 of the `walld` (program number `100008`) service for all transports use:

```
example# rpcinfo -d 100008 1
```

or

```
example# rpcinfo -d walld 1
```

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `rpcbind(1M)`, `rpc(3NSL)`, `netconfig(4)`, `rpc(4)`, `attributes(5)`

Name rpc.mdcommd – multi-node disk set services

Synopsis

```
/usr/sbin/rpc.mdcommd
```

Description `rpc.mdcommd` is an `rpc(4)` daemon that functions as a server process. `rpc.mdcommd` manages communication among hosts participating in a multi-node disk set configuration.

`rpc.mdcommd` is invoked by `inetd(1M)`.

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmfu
Stability	Evolving

See Also `svcs(1)`, `inetadm(1M)`, `inetd(1M)`, `metaset(1M)`, `svcadm(1M)`, `rpc(3NSL)`, `rpc(4)`, `services(4)`, `attributes(5)`, `smf(5)`

Solaris Volume Manager Administration Guide

Notes The `rpc.mdcommd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/rpc/mdcomm
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. Responsibility for initiating and restarting this service is delegated to `inetd(1M)`. Use `inetadm(1M)` to make configuration changes and to view configuration information for this service. The service's status can be queried using the `svcs(1)` command.

Name rpc.metad – remote metaset services

Synopsis

```
/usr/sbin/rpc.metad
```

Description `rpc.metad` is an rpc(4) daemon (functioning as a server process) that is used to manage local copies of metadevice diskset information. The `rpc.metad` daemon is controlled by inetadm(1M).

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmdu

See Also svcs(1), inetadm(1M), inetd(1M), metaset(1M), rpc.metamhd(1M), svcadm(1M), rpc(3NSL), services(4), attributes(5), smf(5)

Solaris Volume Manager Administration Guide

Notes The `rpc.metad` service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/network/rpc/meta:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

Name rpc.metamedd – remote mediator services

Synopsis

```
/usr/sbin/rpc.metamedd
```

Description `rpc.metamedd` is an `rpc(4)` server which is used to manage mediator information for use in 2–string HA configurations. The `rpc.metamedd` daemon is controlled by `inetadm(1M)`.

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmdu
Interface Stability	Evolving

See Also `svcs(1)`, `inetadm(1M)`, `inetd(1M)`, `svcadm(1M)`, `rpc(4)`, `services(4)`, `attributes(5)`, `smf(5)`

Sun Cluster documentation, *Solaris Volume Manager Administration Guide*

Notes The `rpc.metamedd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/rpc/metamed:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. Responsibility for initiating and restarting this service is delegated to `inetd(1M)`. Use `inetadm(1M)` to make configuration changes and to view configuration information for this service. The service's status can be queried using the `svcs(1)` command.

Name rpc.metamhd – remote multihost disk services

Synopsis

```
/usr/sbin/rpc.metamhd
```

Description `rpc.metamhd` is an `rpc(4)` daemon (functioning as a server process) that is used to manage multi-hosted disks. The `rpc.metamhd` daemon is controlled by `inetadm(1M)`.

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmdu

See Also `svcs(1)`, `inetadm(1M)`, `inetd(1M)`, `metaset(1M)`, `rpc.metad(1M)`, `svcadm(1M)`, `rpc(3NSL)`, `services(4)`, `attributes(5)`, `smf(5)`

Solaris Volume Manager Administration Guide

Notes The `rpc.metamhd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/rpc/metamh:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. Responsibility for initiating and restarting this service is delegated to `inetd(1M)`. Use `inetadm(1M)` to make configuration changes and to view configuration information for this service. The service's status can be queried using the `svcs(1)` command.

Name rpc.nisd, nisd – NIS+ service daemon

Synopsis

```
/usr/sbin/rpc.nisd [-ACDFhlv] [-Y [-B [-t netid]]]
     [-d dictionary] [-L load] [-S level] [-m mappingfile]
     [-x attribute=value]... [-z number]
```

Description The `rpc.nisd` daemon is an RPC service that implements the NIS+ service. This daemon must be running on all machines that serve a portion of the NIS+ namespace.

`rpc.nisd` is usually started from a system startup script.

The `-B` option causes `rpc.nisd` to start an auxiliary process, `rpc.nisd_resolv`, which provides ypserv compatible DNS forwarding for NIS host requests. `rpc.nisd_resolv` can also be started independently. See `rpc.nisd_resolv(1M)` for more information on using `rpc.nisd_resolv` independently.

The `/etc/default/rpc.nisd` file contains the following default parameter settings. See `FILES`.

`ENABLE_NIS_YP_EMULATION`	Specifies whether the server is put into NIS (YP) compatibility mode. `ENABLE_NIS_YP_EMULATION=YES` is equivalent to the `-Y` command-line option. The default value for `ENABLE_NIS_YP_EMULATION` is `NO`.

Options

`-A`	Authentication verbose mode. The daemon logs all the authentication related activities to `syslogd(1M)` with `LOG_INFO` priority.
`-B`	Provide ypserv compatible DNS forwarding for NIS host requests. The DNS resolving process, `rpc.nisd_resolv`, is started and controlled by `rpc.nisd`. This option requires that the `/etc/resolv.conf` file be setup for communication with a DNS nameserver. The `nslookup` utility can be used to verify communication with a DNS nameserver. See `resolv.conf(4)` and `nslookup(1M)`.
`-C`	Open diagnostic channel on `/dev/console`.
`-D`	Debug mode. Do not fork.
`-d` *dictionary*	Specify an alternate dictionary for the NIS+ database. The primary use of this option is for testing. Note that the string is not interpreted, rather it is simply passed to the `db_initialize` function.>
`-F`	Force the server to do a checkpoint of the database when it starts up. Forced checkpoints may be required when the server is low on disk space. This option removes updates from the transaction log that have propagated to all of the replicas.
`-h`	Print list of options.

`-L` *number*
: Specify the "load" the NIS+ service is allowed to place on the server. The load is specified in terms of the *number* of child processes that the server may spawn. The value of *number* must be at least 1 for the callback functions to work correctly. The default is 128.

`-m` *mappingfile*
: Specify the name of a configuration file that maps NIS+ objects (especially tables and columns) to LDAP (entries and attributes). See `NIS+LDAPmapping(4)`. The default path is `/var/nis`. The default mapping file is `NIS+LDAPmapping`. If this file exists, the `rpc.nisd` daemon will map data to and from LDAP. A template mapping file that covers the normal NIS+ directories and tables is installed as `/var/nis/NIS+LDAPmapping.template`.

  A NIS+ object must have a valid mapping entry in the mapping file in order to have data for that table read from or written to the LDAP repository.

  The `rpc.nisd(4)` file contains specifications for LDAP server addresses, LDAP authentication method, and the like. See `NIS+LDAPmapping(4)` for an overview of the setup you need to map NIS+ data to or from LDAP.

`-S` *level*
: Set the authorization security level of the service. The argument is a number between 0 and 2. By default, the daemon runs at security level 2.

  `0` Security level 0 is designed to be used for testing and initial setup of the NIS+ namespace. When running at level 0, the daemon does not enforce any access controls. Any client is allowed to perform any operation, including updates and deletions.

  `1` At security level 1, the daemon accepts both `AUTH_SYS` and `AUTH_DES` credentials for authenticating clients and authorizing them to perform NIS+ operations. This is not a secure mode of operation since `AUTH_SYS` credentials are easily forged. It should not be used on networks in which any untrusted users may potentially have access.

  `2` At security level 2, the daemon only accepts authentication using the security mechanisms configured by `nisauthconf(1M)`. The default security mechanism is `AUTH_DES`. Security level 2 is the default if the `-S` option is not used.

`-t` *netid*
: Use *netid* as the transport for communication between `rpc.nisd` and `rpc.nisd_resolv`. The default transport is `ticots(7D)` (`tcp` on SunOS 4.x systems).

`-v`	Verbose. With this option, the daemon sends a running narration of what it is doing to the syslog daemon (see `syslogd(1M)`) at `LOG_INFO` priority. This option is most useful for debugging problems with the service. See also `-A` option.
`-x` *attribute=value*	Specify the value of the named *attribute*. Attributes that control the NIS+ to LDAP mapping operation are derived as follows: 1. Retrieve from LDAP. 2. Override with values from the *mappingfile*, if any. See the `-m` option. 3. Override with values from the command line `-x` options. See `NIS+LDAPmapping(4)` and `rpc.nisd(4)` for the recognized attributes and their syntax. As a special case, you can use the `nisplusLdapConfig*` attributes to derive additional information from LDAP. You can only specify the `nisplusLdapConfig*` attributes in `rpc.nisd(4)` or by means of the command line.
`-Y`	Put the server into NIS (YP) compatibility mode. When operating in this mode, the NIS+ server will respond to NIS Version 2 requests using the version 2 protocol. Because the YP protocol is not authenticated, only those items that have read access to nobody (the unauthenticated request) will be visible through the V2 protocol. It supports only the standard Version 2 maps in this mode (see `-B` option and `NOTES` in `ypfiles(4)`). See `FILES`.
`-z` *number*	Specify the maximum RPC record size that can be used over connection oriented transports. The default is 9000 bytes. If you specify a size less than the default value, the default value will be used instead.

Examples

EXAMPLE 1 Setting up the NIS+ Service

The following example sets up the NIS+ service.

```
example% rpc.nisd
```

EXAMPLE 2 Setting Up NIS+ Service Emulating YP With DNS Forwarding

The following example sets up the NIS+ service, emulating YP with DNS forwarding.

```
example% rpc.nisd -YB
```

EXAMPLE 3 Specifying NIS+ and LDAP Mapping Information

The following example shows how to specify that all additional NIS+ and LDAP mapping information should be retrieved from DN "dc=x,dc=y,dc=z", from the LDAP server at IP address 1.2.3.4, port 389. The examples uses the simple authentication method and the `cn=nisplusAdmin,ou=People,` proxy user. The `-m` option is omitted for clarity in this example..

```
-x nisplusLDAPconfigDN=dc=x,dc=y,dc=z \
-x nisplusLDAPconfigPreferredServerList=127.0.0.1:389 \
-x nisplusLDAPconfigAuthenticationMethod=simple \
-x nisplusLDAPconfigProxyUser=cn=nisplusAdmin,ou=People, \
-x nisplusLDAPconfigProxyPassword=xyzzy
```

Environment Variables

`NETPATH` The transports that the NIS+ service will use can be limited by setting this environment variable. See `netconfig(4)`.

Files

`/var/nis/data/parent.object`	This file describes the namespace that is logically above the NIS+ namespace. The most common type of parent object is a DNS object. This object contains contact information for a server of that domain.
`/var/nis/data/root.object`	This file describes the root object of the NIS+ namespace. It is a standard XDR-encoded NIS+ directory object that can be modified by authorized clients using the `nis_modify(3NSL)` interface.
`/etc/default/rpc.nisd`	LDAP connection and general `rpc.nisd` configuration. You can override some of the settings by command-line options.
`/var/nis/NIS+LDAPmapping`	Default path for LDAP mapping file. See the discussion of the `-m` option.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

`svcs(1)`, `nis_cachemgr(1M)`, `nisauthconf(1M)`, `nisinit(1M)`, `nissetup(1M)`, `nisldapmaptest(1M)`, `nslookup(1M)`, `rpc.nisd_resolv(1M)`, `rpc.nispasswdd(1M)`, `svcadm(1M)`, `syslogd(1M)`, `nis_modify(3NSL)`, `NIS+LDAPmapping(4)`, `netconfig(4)`, `nisfiles(4)`, `resolv.conf(4)`, `rpc.nisd(4)`, `ypfiles(4)`, `attributes(5)`, `smf(5)`, `ticots(7D)`

Notes

NIS+ might not be supported in future releases of the Solaris Operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

The `rpc.nisd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/rpc/nisplus:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

Name rpc.nisd_resolv, nisd_resolv – NIS+ service daemon

Synopsis

```
rpc.nisd_resolv [-v | -V] [-F [-C fd]] [-t xx] [-p yy]
```

Description `rpc.nisd_resolv` is an auxiliary process which provides DNS forwarding service for NIS hosts requests to both `ypserv` and `rpc.nisd` that are running in the NIS compatibility mode. It is generally started by invoking `rpc.nisd(1M)` with the `-B` option or `ypserv(1M)` with the `-d` option. Although it is not recommended, `rpc.nisd_resolv` can also be started independently with the following options.

This command requires that the `/etc/resolv.conf` file be setup for communication with a DNS nameserver. The `nslookup` utility can be used to verify communication with a DNS nameserver. See `resolv.conf(4)` and `nslookup(1M)`.

Options

`-F` Run in foreground.

`-C` *fd* Use *fd* for service xprt (from `nisd`).

`-v` Verbose. Send output to the syslog daemon.

`-V` Verbose. Send output to stdout.

`-t` *xx* Use transport *xx*.

`-p` *yy* Use transient program# *yy*.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

See Also `nslookup(1M)`, `rpc.nisd(1M)`, `resolv.conf(4)`, `attributes(5)`

Notes NIS+ might not be supported in future releases of the Solaris Operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

Name rpc.nispasswdd, nispasswdd – NIS+ password update daemon

Synopsis

```
/usr/sbin/rpc.nispasswdd [-a attempts] [-c minutes] [-D]
     [-g] [-v]
```

Description `rpc.nispasswdd` daemon is an ONC+ RPC service that services password update requests from `nispasswd(1)` and `yppasswd(1)`. It updates password entries in the NIS+ `passwd` table.

`rpc.nispasswdd` is normally started from a system startup script after the NIS+ server (`rpc.nisd(1M)`) has been started. `rpc.nispasswdd` will determine whether it is running on a machine that is a master server for one or more NIS+ directories. If it discovers that the host is not a master server, then it will promptly exit. It will also determine if `rpc.nisd(1M)` is running in NIS (YP) compatibility mode (the `-Y`option) and will register as `yppasswdd` for NIS (YP) clients as well.

`rpc.nispasswdd` will syslog all failed password update attempts, which will allow an administrator to determine whether someone was trying to "crack" the passwords.

`rpc.nispasswdd` has to be run by a superuser.

Options

`-a` *attempts* Set the maximum number of attempts allowed to authenticate the caller within a password update request session. Failed attempts are `syslogd(1M)` and the request is cached by the daemon. After the maximum number of allowed attempts the daemon severs the connection to the client. The default value is set to `3`.

`-c` *minutes* Set the number of minutes a failed password update request should be cached by the daemon. This is the time during which if the daemon receives further password update requests for the same user and authentication of the caller fails, then the daemon will simply not respond. The default value is set to `30`minutes.

`-D` Debug. Run in debugging mode.

`-g` Generate DES credential. By default the DES credential is not generated for the user if they do not have one. By specifying this option, if the user does not have a credential, then one will be generated for them and stored in the NIS+ cred table.

`-v` Verbose. With this option, the daemon sends a running narration of what it is doing to the syslog daemon. This option is useful for debugging problems.

Exit Status

`0` success

`1` an error has occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

See Also svcs(1), nispasswd(1), passwd(1), yppasswd(1), rpc.nisd(1M), syslogd(1M), svcadm(1M), nsswitch.conf(4), attributes(5), smf(5)

Notes NIS+ might not be supported in future releases of the Solaris Operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

The `rpc.nispasswdd` service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/network/rpc/nisplus:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name rpc.rexd, rexd – RPC-based remote execution server

Synopsis

```
/usr/sbin/rpc.rexd [-s]
```

Description `rpc.rexd` is the Sun RPC server for remote program execution. This daemon is started by `inetd(1M)` whenever a remote execution request is made.

For non-interactive programs, the standard file descriptors are connected directly to TCP connections. Interactive programs involve pseudo-terminals, in a fashion that is similar to the login sessions provided by `rlogin(1)`. This daemon may use NFS to mount file systems specified in the remote execution request.

There is a `10240` byte limit for arguments to be encoded and passed from the sending to the receiving system.

Options The following option is supported:

`-s` Secure. When specified, requests must have valid DES credentials. If the request does not have a DES credential it is rejected. The default publickey credential is rejected. Only newer `on(1)` commands send DES credentials.

If access is denied with an authentication error, you may have to set your publickey with the `chkey(1)` command.

Specifying the `-s` option without presenting secure credentials will result in an error message: `Unix too weak auth (DesONly)!`

Security `rpc.rexd` uses `pam(3PAM)` for account and session management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the modules to be used for `rpc.rexd`. Here is a partial `pam.conf` file with `rpc.rexd` entries for account and session management using the UNIX module.

```
rpc.rexd   account requisite       pam_roles.so.1
rpc.rexd   account required        pam_projects.so.1
rpc.rexd   account required        pam_unix_account.so.1

rpc.rexd      session required      pam_unix_session.so.1
```

If there are no entries for the `rpc.rexd` service, the entries for the "other" service will be used. `rpc.rexd` uses the `getpwuid()` call to determine whether the given user is a legal user.

Files

`/dev/pts`*n*	Pseudo-terminals used for interactive mode
`/etc/passwd`	Authorized users
`/tmp_rex/rexd??????`	Temporary mount points for remote file systems

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

See Also chkey(1), on(1), rlogin(1), svcs(1), inetadm(1M), inetd(1M), svcadm(1M), pam(3PAM), pam.conf(4), publickey(4), attributes(5), pam_authtok_check(5), pam_authtok_get(5), pam_authtok_store(5), pam_dhkeys(5), pam_passwd_auth(5), pam_unix_account(5), pam_unix_auth(5), pam_unix_session(5), smf(5)

Diagnostics Diagnostic messages are normally printed on the console, and returned to the requestor.

Notes Root cannot execute commands using rexd client programs such as on(1).

The pam_unix(5) module is no longer supported. Similar functionality is provided by pam_authtok_check(5), pam_authtok_get(5), pam_authtok_store(5), pam_dhkeys(5), pam_passwd_auth(5), pam_unix_account(5), pam_unix_auth(5), and pam_unix_session(5).

The rpc.rexd service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/network/rpc/rex:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

Name rpc.rstatd, rstatd – kernel statistics server

Synopsis

```
/usr/lib/netsvc/rstat/rpc.rstatd
```

Description `rpc.rstatd` is a server which returns performance statistics obtained from the kernel. `rup(1)` uses `rpc.rstatd` to collect the `uptime` information that it displays.

`rpc.rstatd` is an RPC service.

Attributes See `attributes(5)` for descriptions of the following attributes:

Availability	SUNWrcmds

See Also `rup(1)`, `svcs(1)`, `inetadm(1M)`, `inetd(1M)`, `svcadm(1M)`, `services(4)`, `attributes(5)`, `smf(5)`

Notes The `rpc.rstatd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/rpc/rstat:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. Responsibility for initiating and restarting this service is delegated to `inetd(1M)`. Use `inetadm(1M)` to make configuration changes and to view configuration information for this service. The service's status can be queried using the `svcs(1)` command.

Name rpc.rusersd, rusersd – network username server

Synopsis

```
/usr/lib/netsvc/rusers/rpc.rusersd
```

Description `rpc.rusersd` is a server that returns a list of users on the host. The `rpc.rusersd` daemon may be started by `inetd`(1M) or `listen`(1M).

Attributes See `attributes`(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWrcmds

See Also `svcs`(1), `inetadm`(1M), `inetd`(1M), `listen`(1M), `pmadm`(1M), `sacadm`(1M), `svcadm`(1M), `attributes`(5), `smf`(5)

Notes The `rpc.rusersd` service is managed by the service management facility, `smf`(5), under the service identifier:

```
svc:/network/rpc/rusers:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm`(1M). Responsibility for initiating and restarting this service is delegated to `inetd`(1M). Use `inetadm`(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the `svcs`(1) command.

Name rpc.rwalld, rwalld – network rwall server

Synopsis

```
/usr/lib/netsvc/rwall/rpc.rwalld
```

Description `rpc.rwalld` is a server that handles `rwall(1M)` requests. It is implemented by calling `wall(1M)` on all the appropriate network machines. The `rpc.rwalld` daemon may be started by `inetd(1M)` or `listen(1M)`.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWrcmds

See Also `svcs(1)`, `inetadm(1M)`, `inetd(1M)`, `listen(1M)`, `rwall(1M)`, `svcadm(1M)`, `wall(1M)`, `attributes(5)`, `smf(5)`

Notes The `rpc.rwalld` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/rpc/wall:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. Responsibility for initiating and restarting this service is delegated to `inetd(1M)`. Use `inetadm(1M)` to make configuration changes and to view configuration information for this service. The service's status can be queried using the `svcs(1)` command.

Name rpc.smserverd – removable media device server

Synopsis

```
/usr/lib/smedia/rpc.smserverd
```

Description `rpc.smserverd` is a server that handles requests from client applications, including the Volume Management daemon (`vold(1M)`), for access to removable media devices. In addition to `vold`, `rmformat(1)` and the CDE Filemanager (when performing removable media operations) are `rpc.smserverd` clients. The `rpc.smserverd` daemon is started by `inetd(1M)` when a client makes a call to a Solaris-internal library to access a SCSI, IDE, or USB device. The daemon is not started if a client attempts to access a floppy or PCMCIA device. Once started, the daemon remains active until such time as it is idle for three minutes or more.

The `rpc.smserverd` daemon is provided for the exclusive use of the client applications mentioned above. It has no external, customer-accessible interfaces, including no configuration file.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWvolu

See Also `svcs(1)`, `inetadm(1M)`, `inetd(1M)`, `svcadm(1M)`, `vold(1M)`, `vold.conf(4)`, `attributes(5)`, `smf(5)`

Notes The `rpc.smserverd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/rpc/smserver
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. Responsibility for initiating and restarting this service is delegated to `inetd(1M)`. Use `inetadm(1M)` to make configuration changes and to view configuration information for this service. The service's status can be queried using the `svcs(1)` command.

Name rpc.sprayd, sprayd – spray server

Synopsis

```
/usr/lib/netsvc/spray/rpc.sprayd
```

Description `rpc.sprayd` is a server that records the packets sent by `spray(1M)`. The `rpc.sprayd` daemon may be started by `inetd(1M)` or `listen(1M)`.

The service provided by `rpc.sprayd` is not useful as a networking benchmark as it uses unreliable connectionless transports, (udp for example). It can report a large number of packets dropped when the drops were caused by the program sending packets faster than they can be buffered locally (before the packets get to the network medium).

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWrcmds

See Also `svcs(1)`, `inetadm(1M)`, `inetd(1M)` `listen(1M)`, `pmadm(1M)`, `sacadm(1M)`, `spray(1M)`, `svcadm(1M)`, `attributes(5)`, `smf(5)`

Notes The `rpc.sprayd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/rpc/spray:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. Responsibility for initiating and restarting this service is delegated to `inetd(1M)`. Use `inetadm(1M)` to make configuration changes and to view configuration information for this service. The service's status can be queried using the `svcs(1)` command.

Name rpc.yppasswdd, yppasswdd – server for modifying NIS password file

Synopsis

```
/usr/lib/netsvc/yp/rpc.yppasswdd [-D directory]
     [-nogecos] [-noshell] [-nopw]
     [-m argument1 argument2...]

/usr/lib/netsvc/yp/rpc.yppasswdd
     [passwordfile [adjunctfile]]
     [-nogecos] [-noshell] [-nopw]
     [-m argument1 argument2...]
```

Description `rpc.yppasswdd` is a server that handles password change requests from `yppasswd(1)`. It changes a password entry in the `passwd`, `shadow`, and `security/passwd.adjunct` files. The `passwd` and `shadow` files provide the basis for the `passwd.byname` and `passwd.byuid` maps. The `passwd.adjunct` file provides the basis for the `passwd.adjunct.byname` and `passwd.adjunct.byuid` maps. Entries in the `passwd`, `shadow` or `passwd.adjunct` files are changed only if the password presented by `yppasswd(1)` matches the encrypted password of the entry. All password files are located in the `PWDIR` directory.

If the `-D` option is given, the `passwd`, `shadow`, or `passwd.adjunct` files are placed under the directory path that is the argument to `-D`.

If the `-noshell`, `-nogecos` or `-nopw` options are given, these fields cannot be changed remotely using `chfn`, `chsh`, or `passwd(1)`.

If the `-m` option is given, a `make(1S)` is performed in `/var/yp` after any of the `passwd`, `shadow`, or `passwd.adjunct` files are modified. All arguments following the flag are passed to `make`.

The second of the listed syntaxes is provided only for backward compatibility. If the second syntax is used, the `passwordfile` is the full pathname of the password file and `adjunctfile` is the full pathname of the optional `passwd.adjunct` file. If a shadow file is found in the same directory as `passwordfile`, the `shadowfile` is used as described above. Use of this syntax and the discovery of a `shadowfile` file generates diagnostic output. The daemon, however, starts normally.

The first and second syntaxes are mutually exclusive. You cannot specify the full pathname of the `passwd`, `passwd.adjunct` files and use the `-D` option at the same time.

The daemon is started automatically on the master server of the passwd map by `ypstart(1M)`, which is invoked at boot time by the `svcs:/network/nis/server:default` service.

The server does not insist on the presence of a `shadow` file unless there is no `-D` option present or the directory named with the `-D` option is `/etc`. In addition, a `passwd.adjunct` file is not necessary. If the `-D` option is given, the server attempts to find a `passwd.adjunct` file in the `security` subdirectory of the named directory. For example, in the presence of `-D /var/yp` the server checks for a `/var/yp/security/passwd.adjunct` file.

If only a `passwd` file exists, then the encrypted password is expected in the second field. If both a `passwd` and a `passwd.adjunct` file exist, the encrypted password is expected in the second field of the adjunct file with *##username* in the second field of the `passwd` file. If all three files are in use, the encrypted password is expected in the `shadow` file. Any deviation causes a password update to fail.

If you remove or add a `shadow` or `passwd.adjunct` file after `rpc.yppasswdd` has started, you must stop and restart the daemon to enable it to recognize the change. See `ypstart(1M)` for information on restarting the daemon.

The `rpc.yppasswdd` daemon considers a shell that has a name that begins with 'r' to be a restricted shell. By default, the daemon does not check whether a shell begins with an '`r`'. However, you can tell it to do so by uncommenting the `check_restricted_shell_name=1` line in `/etc/default/yppasswdd`. The result will be to restrict a user's ability to change from his default shell. See `yppasswdd(4)`.

On start up, `yppasswdd` checks for the existence of a NIS to LDAP (N2L) configuration file, `/var/yp/NISLDAPmapping`. If the configuration file is present, the daemon runs in N2L mode. If the file is not present, `yppasswdd` runs in traditional, non-N2L mode.

In N2L mode, changes are written directly to the Directory Information Tree (DIT). If the changes are written successfully, the NIS map is updated. The NIS source files, `passwd`, `shadow`, and `passwd.adjunct`, for example, are not updated. Thus, in N2L mode, the `-D` option is meaningless. In N2L mode, `yppasswdd` propagates changes by calling `yppush(1M)` instead of `ypmake(1M)`. The `-m` option is thus unused.

During an NIS-to-LDAP transition, the `yppasswdd` daemon uses the N2L-specific map, `ageing.byname`, to read and write password aging information to the DIT. If you are not using password aging, then the `ageing.byname` mapping is ignored.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWypu

See Also

`svcs(1)`, `make(1S)`, `passwd(1)`, `yppasswd(1)`, `inetd(1M)`, `svcadm(1M)`, `ypmake(1M)`, `yppush(1M)`, `ypstart(1M)`, `NISLDAPmapping(4)`, `passwd(4)`, `shadow(4)`, `ypfiles(4)`, `yppasswdd(4)`, `ypserv(4)`, `attributes(5)`, `smf(5)`

Notes

If `make` has not been installed and the `-m` option is given, the daemon outputs a warning and proceeds, effectively ignoring the `-m` flag.

When using the `-D` option, you should make sure that the `PWDIR` of the `/var/yp/Makefile` is set accordingly.

The second listed syntax is supplied only for backward compatibility and might be removed in a future release of this daemon.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and cannot be used without permission.

The NIS server service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svcs:/network/nis/server:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

Name rpc.ypupdated, ypupdated – server for changing NIS information

Synopsis

```
/usr/lib/netsvc/yp/rpc.ypupdated [-is]
```

Description `ypupdated` is a daemon that updates information in the Network Information Service (NIS). `ypupdated` consults the `updaters(4)` file in the `/var/yp` directory to determine which NIS maps should be updated and how to change them.

By default, the daemon requires the most secure method of authentication available to it, either DES (secure) or UNIX (insecure).

On start up, `ypupdated` checks for the existence of a NIS to LDAP (N2L) configuration file, `/var/yp/NISLDAPmapping`. If the file is present, `ypupdated` generates an informational message and exits. `ypupdated` is not supported in N2L mode.

Options

`-i` Accept RPC calls with the insecure `AUTH_UNIX` credentials. This allows programmatic updating of the NIS maps in all networks.

`-s` Accept only calls authenticated using the secure RPC mechanism (`AUTH_DES` authentication). This disables programmatic updating of the NIS maps unless the network supports these calls.

Files

`/var/yp/updaters`	Configuration file for `rpc.updated` command.
`/var/yp/NISLDAPmapping`	Configuration file for N2L

System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)

Notes The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two services remains the same. Only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and it must not be used without permission.

Name rpld – Network Booting RPL (Remote Program Load) Server

Synopsis

```
/usr/sbin/rpld [-fdDMblgz] interface

/usr/sbin/rpld -a [-fdDMblgz]
```

Description The RPL server provides network booting functionality to x86 clients by listening to boot requests from them according to the RPL protocol specifications. `rpld` runs on both x86 and SPARC systems. Boot requests can be generated by clients using the boot floppy supplied in the distribution. Once the request has been received, the server validates the client and adds it to its internal service list. Subsequent requests from the client to download bootfiles will result in the sending of data frames from the server to the client specifying where to load the boot program in memory. When all the bootfiles have been downloaded, the server specifies where to start execution to initiate the boot process.

In the first synopsis, the interface parameter names the network interface upon which `rpld` is to listen for requests. For example:

```
/usr/sbin/rpld /dev/eri0

/usr/sbin/rpld /dev/smc0
```

In the second synopsis, `rpld` locates all of the network interfaces present on the system and starts a daemon process for each one.

The server starts by reading the default configuration file, or an alternate configuration file if one is specified. If no configuration file can be found, internal default values will be used. Alternatively, command line options are available to override any of the values in the configuration file. After the configuration options are set, it then opens the network interface as specified in the command line and starts listening to RPL boot requests.

Network boot clients have to have information pre-configured on a server for the RPL server to validate and serve them. This involves putting configuration information in both the `ethers(4)` and the `bootparams(4)` databases. The `ethers` database contains a translation from the physical node address to the IP address of the clients and is normally used by the RARP server. The `bootparams` database stores all other information needed for booting off this client, such as the number of bootfiles and the file names of the various boot components. Both databases can be looked up by the RPL server through NIS. See the sub-section `Client Configuration` for information on how to set up these databases.

To assist in the administration and maintenance of the network boot activity, there are two run-time signals that the server will accept to change some run-time parameters and print out useful status information. See the sub-section `Signals` for details.

The RPL server is not limited to the ability to boot only clients. If properly configured, the server should be able to download any bootfiles to the clients.

Client Configuration

The following configuration information is specific to booting x86 clients.

In order to allow clients to boot x86 from across the network, the client's information has to be pre-configured in two databases: `ethers(4)` and `bootparams(4)`. Both databases can be accessed through NIS. Refer to *Solaris 10 Installation Guide: Basic Installations* for information on how to configure a diskless x86 client. The discussion contained in the rest of this section is provided for your information only and should not be performed manually.

The `ethers` database contains a translation table to convert the physical node address to the IP address of the client. Therefore, an IP address must be assigned to the client (if this has not been done already), the node address of the client must be obtained, and then this information needs to be entered in the `ethers` database.

The bulk of the configuration is done in the `bootparams` database. This is a free-format database that essentially contains a number of keyword-value string pairs. A number of keywords have been defined for specific purposes, like the `bootparams` RPC in `bootparamd(1M)`. Three more keywords have been defined for the RPL server. They are `numbootfiles`, `bootfile`, and `bootaddr`. All three keywords must be in lowercase letters with no spaces before or after the equals symbol following the keyword.

`numbootfiles` Specifies the number of files to be downloaded to the network boot client. The format of this option is:

```
numbootfiles=n
```

Always use `numbootfiles=3` to boot x86 across the network.

`bootfile` Specifies the path name of the bootfile to be downloaded and where in memory to start loading the bootfile. A complete path name should be used. For example, assuming the client's IP address is 172.16.32.15:

```
bootfile=/rplboot/172.16.32.15.hw.com:45000
bootfile=/rplboot/172.16.32.15.glue.com:35000
bootfile=/rplboot/172.16.32.15.inetboot=8000
```

The path name following the equals symbol specifies the bootfile to be downloaded, and the hex address following the colon (:) is the absolute address of the memory location to start loading that bootfile. These addresses should be in the range of 7c00 to a0000 (i.e., the base 640K range excluding the interrupt vector and BIOS data areas). Address 45000 for this `hw.com` bootfile is also a suggested value and if possible should not be changed. The address of 35000 for `glue.com` is a suggested value that, if possible, should not be changed. The address of 8000 for `inetboot` is an absolute requirement and should never be changed.

These files, when created following the procedures in the *Solaris 10 Installation Guide: Basic Installations* are actually symbolic links to to the real file to be downloaded to the client.

`hw.com` is linked to a special driver that corresponds to the network interface card of the client. `glue.com` and `inetboot` are generic to all network boot clients.

The order of these bootfile lines is not significant, but because problems have been found with certain boot PROMs, it is highly recommended that the bootfile lines be ordered in descending order of the load addresses.

`bootaddr` The absolute address in memory to start executing after all the bootfiles have been downloaded. This address should always correspond to the address where `glue.com` is being loaded. If possible, always use:

```
bootaddr=35000
```

Options The following options are supported:

`-b` *background_mode* Specify `1` to run the server in the background and relinquish the controlling terminal, or `0` to run in the foreground without relinquishing the controlling terminal. This option corresponds to the *BackGround* setting in the configuration file. If you have specified that the error or warning messages be sent to standard output in the configuration file or by using the `-D` option above, the server cannot be run in background mode. Doing so will cause the server to exit after announcing the error.

`-d` *debug_level* Specify a level of `0` if you do not want any error or warning messages to be generated, or a level from `1` to `9` for increasing amounts of messages. This option corresponds to the *DebugLevel* setting in the configuration file. The default value is `0`. Note that it is best to limit the level to `8` or below; use of level `9` may generate so many debug messages that the performance of the RPL server may be impacted.

`-D` *debug_destination* Specify `0` to send error or warning messages to standard output, `1` to syslogd, and `2` to the log file. This option corresponds to the *DebugDest* setting in the configuration file. The default value is `2`.

`-f` *config_filename* Use this to specify a configuration file name other than the system default `/etc/rpld.conf` file.

`-g` *delay_granularity* This corresponds to the *DelayGran* setting in the configuration file. If retransmission requests from clients do occur, the delay granularity factor will be used to adjust the delay count for this client upwards or downwards. If the retransmission request is caused by data overrun, the delay count will be incremented by delay granularity units to increase the delay between data frames. If the retransmission request is caused by sending data too slowly, this will be used to adjust the delay count downwards to shorten the delay. Eventually the server will settle at the delay count value that

works best with the speed of the client and no retransmission request will be needed. The default value is `2`.

`-l` *log_filename* — Specify an alternate log file name to hold the error or warning messages in connection with the `-D 2` option or the configuration file *DebugDest = 2* setting. This option corresponds to the *LogFile* setting in the configuration file. The default is `/var/spool/rpld.log`.

`-M` *maximum_clients* — Specify the maximum number of simultaneous network boot clients to be served. This option corresponds to the *MaxClients* setting in the configuration file. A value of `−1` means unlimited, and the actual number will depend on available system resources. The default value is `−1`.

`-s` *start_delay_count* — This option corresponds to the *StartDelay* setting in the configuration file. Specify the number of delay units between outgoing data frames sent to clients to avoid retransmission requests from them. Using the LLC type `1` protocol, data transfer is a one-way, best-effort delivery mechanism. The server, without any type of delay mechanism, can overrun the client by sending data frames too quickly. Therefore, a variable delay is built into the server to limit the speed of sending data to the clients, thus avoiding the clients sending back retransmission requests. This value should be machine environment specific. If you have a fast server machine but slow client machines, you may want to set a large start delay count. If you have comparable server and client machines, the delay count may be set to `1`. The delay is only approximate and should not be taken as an accurate measure of time. There is no specific correlation between the delay unit and the actual time of delay. The default value is `20`.

`-z` *frame_size* — This option corresponds to the *FrameSize* setting in the configuration file. This specifies the size of the data frames used to send data to the clients. This is limited by the underlying physical medium. For `ethernet/802.3`, the maximum physical frame size is 1500 octets. The default value is `1500`. Note that the protocol overhead of LLC1 and RPL is 32 octets, resulting in a maximum data length of 1468 octets.

Signals The RPL server accepts two signals to change run-time parameters and display status information, respectively:

`HANGUP` — This will cause the RPL server to reread the default configuration file `/etc/rpld.conf` or an alternate configuration file if one is specified when the server is started. New values of certain parameters can be used immediately, such

as *DebugLevel*, *DebugDest*, *LogFile*, *DelayGran*, and *FrameSize*. For *MaxClients*, if the server is already serving more than the new value, the server will not accept additional boot requests until the number has fallen below the *MaxClients* parameter. For *StartDelay*, this will only affect new boot requests. All the existing delay counts for the various clients in service will not be affected. Finally, the *BackGround* parameter will have no effect once the server has been running. You cannot change the mode of service without first killing the server and then restarting it.

`USR1` This signal will cause the server to dump all the parameter values and the status of each individual boot client to the destination specified by *DebugDest*.

Solaris 10 Installation Guide: Basic Installations

Name rquotad – remote quota server

Synopsis

```
/usr/lib/nfs/rquotad
```

Description `rquotad` is an `rpc(4)` server which returns quotas for a user of a local file system which is mounted by a remote machine over the NFS. The results are used by `quota(1M)` to display user quotas for remote file systems. The `rquotad` daemon is normally invoked by `inetd(1M)`.

Usage See `largefile(5)` for the description of the behavior of `rquotad` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files

`quotas`	quota file at a UFS file system root

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnfssu

See Also `svcs(1)`, `automountd(1M)`, `inetadm(1M)`, `inetd(1M)`, `mount_nfs(1M)`, `quota(1M)`, `share_nfs(1M)`, `svcadm(1M)`, `rpc(4)`, `services(4)`, `attributes(5)`, `largefile(5)`, `smf(5)`

Solaris 10 Installation Guide: Basic Installations

Notes The `rquotad` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/nfs/rquota
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. Responsibility for initiating and restarting this service is delegated to `inetd(1M)`. Use `inetadm(1M)` to make configuration changes and to view configuration information for this service. The service's status can be queried using the `svcs(1)` command.

If it is disabled, it will be enabled by `mount_nfs(1M)`, `share_nfs(1M)`, and `automountd(1M)` unless its `application/auto_enable` property is set to `false`.

Name rsh, restricted_shell – restricted shell command interpreter

Synopsis

```
/usr/lib/rsh [-acefhiknprstuvx] [argument]...
```

Description `rsh` is a limiting version of the standard command interpreter `sh`, used to restrict logins to execution environments whose capabilities are more controlled than those of `sh` (see `sh(1)` for complete description and usage).

When the shell is invoked, it scans the environment for the value of the environmental variable, `SHELL`. If it is found and `rsh` is the file name part of its value, the shell becomes a restricted shell.

The actions of `rsh` are identical to those of `sh`, except that the following are disallowed:

- changing directory (see `cd(1)`),
- setting the value of `$PATH`,
- pecifying path or command names containing `/`,
- redirecting output (`>` and `>>`).

The restrictions above are enforced after *.profile* is interpreted.

A restricted shell can be invoked in one of the following ways:

1. `rsh` is the file name part of the last entry in the `/etc/passwd` file (see `passwd(4)`);
2. the environment variable `SHELL` exists and `rsh` is the file name part of its value; the environment variable `SHELL` needs to be set in the `.login` file;
3. the shell is invoked and `rsh` is the file name part of argument 0;
4. the shell is invoke with the `-r` option.

When a command to be executed is found to be a shell procedure, `rsh` invokes `sh` to execute it. Thus, it is possible to provide to the end-user shell procedures that have access to the full power of the standard shell, while imposing a limited menu of commands; this scheme assumes that the end-user does not have write and execute permissions in the same directory.

The net effect of these rules is that the writer of the *.profile* (see `profile(4)`) has complete control over user actions by performing guaranteed setup actions and leaving the user in an appropriate directory (probably *not* the login directory).

The system administrator often sets up a directory of commands (that is, `/usr/rbin`) that can be safely invoked by a restricted shell. Some systems also provide a restricted editor, `red`.

Exit Status Errors detected by the shell, such as syntax errors, cause the shell to return a non-zero exit status. If the shell is being used non-interactively execution of the shell file is abandoned. Otherwise, the shell returns the exit status of the last command executed.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also Intro(1), cd(1), login(1), rsh(1), sh(1), exec(2), passwd(4), profile(4), attributes(5)

Notes The restricted shell, /usr/lib/rsh, should not be confused with the remote shell, /usr/bin/rsh, which is documented in rsh(1).

Name rtc – provide all real-time clock and GMT-lag management

Synopsis

```
/usr/sbin/rtc [-c] [-z zone-name]
```

Description On x86 systems, the `rtc` command reconciles the difference in the way that time is established between UNIX and MS-DOS systems. UNIX systems utilize Greenwich Mean Time (GMT), while MS-DOS systems utilize local time.

Without arguments, `rtc` displays the currently configured time zone string. The currently configured time zone string is based on what was last recorded by `rtc -z` *zone-name*.

The `rtc` command is not normally run from a shell prompt; it is generally invoked by the system. Commands such as `date(1)` and `rdate(1M)`, which are used to set the time on a system, invoke `/usr/sbin/rtc -c` to ensure that daylight savings time (DST) is corrected for properly.

Options

`-c` This option checks for DST and makes corrections if necessary. It is normally run once a day by a `cron` job.

If there is no RTC time zone or `/etc/rtc_config` file, this option will do nothing.

`-z` *zone-name* This option, which is normally run by the system at software installation time, is used to specify the time zone in which the RTC is to be maintained. It updates the configuration file `/etc/rtc_config` with the name of the specified zone and the current GMT lag for that zone. If there is an existing `rtc_config` file, this command will update it. If not, this command will create it.

Files

`/etc/rtc_config` The data file used to record the time zone and GMT lag. This file is completely managed by `/usr/sbin/rtc`, and it is read by the kernel.

Name rtquery – query routing daemons for their routing tables

Synopsis

```
rtquery [-np1] [-w timeout] [-r addr] [-a secret] host...

rtquery [-t operation] host...
```

Description The `rtquery` command is used to query a RIP network routing daemon, `in.routed(1M)` or `GateD`, for its routing table by sending a request or poll command. The routing information in any routing response packets returned is displayed numerically and symbolically.

By default, `rtquery` uses the request command. When the -p option is specified, `rtquery` uses the poll command, an undocumented extension to the RIP protocol supported by `GateD`. When querying `GateD`, the poll command is preferred over the request command because the response is not subject to Split Horizon and/or Poisoned Reverse, and because some versions of `GateD` do not answer the request command. `in.routed` does not answer the poll command, but recognizes requests coming from `rtquery` and so answers completely.

The `rtquery` command is also used to turn tracing on or off in `in.routed`.

Options The following options are supported:

`-a passwd=`*XXX*
`-a md5_passwd=`*XXX*|*KeyID*
: Causes the query to be sent with the indicated cleartext or MD5 password.

`-n`
: Displays only the numeric network and host addresses instead of both numeric and symbolic names.

`-p`
: Uses the poll command to request full routing information from `GateD`. This is an undocumented extension RIP protocol supported only by `GateD`.

`-r` *addr*
: Asks about the route to destination *addr*.

`-t` *operation*
: Changes tracing, where *operation* is one of the actions listed below. Requests from processes not running with UID 0 or on distant networks are generally ignored by the daemon except for a message in the system log. `GateD` is likely to ignore these debugging requests.

  on=*tracefile*
  : Turns tracing on, directing tracing into the specified file. That file must have been specified when the daemon was started or have the name, `/var/log/in.routed.trace`.

  more
  : Increases the debugging level.

  off
  : Turns off tracing.

dump — Dumps the daemon's routing table to the current trace file.

`-w` *timeout* — Changes the delay for an answer from each host. By default, each host is given 15 seconds to respond.

`-1` — Queries using RIP version 1 instead of RIP version 2.

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Routing Information Protocol, RIPv1, RFC 1058

Routing Information Protocol, RIPv2, RFC 2453, STD 0056

Name runacct – run daily accounting

Synopsis `/usr/lib/acct/runacct [`*mmdd* `[`*state*`]]`

Description `runacct` is the main daily accounting shell procedure. It is normally initiated using `cron`. `runacct` processes connect, fee, disk, and process accounting files. It also prepares summary files for `prdaily` or billing purposes. `runacct` is distributed only to source code licensees.

`runacct` takes care not to damage active accounting files or summary files in the event of errors. It records its progress by writing descriptive diagnostic messages into `active`. When an error is detected, a message is written to `/dev/console`, mail (see `mail(1)`) is sent to `root` and `adm`, and `runacct` terminates. `runacct` uses a series of lock files to protect against re-invocation. The files `lock` and `lock1` are used to prevent simultaneous invocation, and `lastdate` is used to prevent more than one invocation per day.

`runacct` breaks its processing into separate, restartable *states* using `statefile` to remember the last *state* completed. It accomplishes this by writing the *state* name into `statefile`. `runacct` then looks in `statefile` to see what it has done and to determine what to process next. *states* are executed in the following order:

`SETUP`	Move active accounting files into working files.
`WTMPFIX`	Verify integrity of `wtmpx` file, correcting date changes if necessary.
`CONNECT`	Produce connect session records in `tacct.h` format.
`PROCESS`	Convert process accounting records into `tacct.h` format.
`MERGE`	Merge the connect and process accounting records.
`FEES`	Convert output of `chargefee` into `tacct.h` format, merge with connect, and process accounting records.
`DISK`	Merge disk accounting records with connect, process, and fee accounting records.
`MERGETACCT`	Merge the daily total accounting records in `daytacct` with the summary total accounting records in `/var/adm/acct/sum/tacct`.
`CMS`	Produce command summaries.
`USEREXIT`	Any installation dependent accounting programs can be included here.
`CLEANUP`	Clean up temporary files and exit. To restart `runacct` after a failure, first check the `active` file for diagnostics, then fix any corrupted data files, such as `pacct` or `wtmpx`. The `lock`, `lock1`, and `lastdate` files must be removed before `runacct` can be restarted. The argument *mmdd* is necessary if `runacct` is being restarted. *mmdd* specifies the month and day for which `runacct` will rerun the accounting. The entry point for processing is based on the contents of `statefile`; to override this, include the desired *state* on the command line to designate where processing should begin.

Examples

EXAMPLE 1 Starting `runacct`

The following example starts `runacct`:

```
example% nohup runacct 2> /var/adm/acct/nite/fd2log &
```

EXAMPLE 2 Restarting `runacct`

The following example restarts `runacct`:

```
example% nohup runacct 0601 2>> /var/adm/acct/nite/fd2log &
```

EXAMPLE 3 Restarting `runacct` at a Specific State

The following example restarts `runacct` at a specific state:

```
example% nohup runacct 0601 MERGE 2>> /var/adm/acct/nite/fd2log &
```

Files

`/var/adm/wtmpx`	History of user access and administration information
`/var/adm/pacct`*incr*	
`/var/adm/acct/nite/active`	
`/var/adm/acct/nite/daytacct`	
`/var/adm/acct/nite/lock`	
`/var/adm/acct/nite/lock1`	
`/var/adm/acct/nite/lastdate`	
`/var/adm/acct/nite/statefile`	

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWaccu

See Also

`acctcom(1)`, `mail(1)`, `acct(1M)`, `acctcms(1M)`, `acctcon(1M)`, `acctmerg(1M)`, `acctprc(1M)`, `acctsh(1M)`, `cron(1M)`, `fwtmp(1M)`, `acct(2)`, `acct.h(3HEAD)`, `utmpx(4)`, `attributes(5)`

Notes

It is not recommended to restart `runacct` in the SETUP *state*. Run SETUP manually and restart using:

`runacct` *mmdd* WTMPFIX

If `runacct` failed in the PROCESS *state,* remove the last `ptacct` file because it will not be complete.

The `runacct` command can process a maximum of

- 6000 distinct sessions

- 1000 distinct terminal lines
- 2000 distinct login names

during a single invocation of the command. If at some point the actual number of any one of these items exceeds the maximum, the command will not succeed.

Do not invoke `runacct` at the same time as `ckpacct`, as there may be a conflict if both scripts attempt to execute `turnacct switch` simultaneously.

Name rwall – write to all users over a network

Synopsis

```
/usr/sbin/rwall hostname...
/usr/sbin/rwall -n netgroup...
/usr/sbin/rwall -h hostname -n netgroup
```

Description `rwall` reads a message from standard input until EOF. It then sends this message, preceded by the line:

```
Broadcast Message . . .
```

to all users logged in on the specified host machines. With the `-n` option, it sends to the specified network groups.

Options

`-n` *netgroup* Send the broadcast message to the specified network groups.

`-h` *hostname* Specify the `hostname`, the name of the host machine.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWrcmdc

See Also `inetd(1M)`, `listen(1M)`, `pmadm(1M)`, `sacadm(1M)`, `wall(1M)`, `attributes(5)`

Notes The timeout is fairly short to allow transmission to a large group of machines (some of which may be down) in a reasonable amount of time. Thus the message may not get through to a heavily loaded machine.

Name sac – service access controller

Synopsis

```
sac -t sanity_interval

/usr/lib/saf/sac
```

Description The Service Access Controller (SAC) is the overseer of the server machine. It is started when the server machine enters multiuser mode. The SAC performs several important functions as explained below.

Customizing the SAC Environment

When `sac` is invoked, it first looks for the per-system configuration script `/etc/saf/_sysconfig`. `sac` interprets `_sysconfig` to customize its own environment. The modifications made to the SAC environment by `_sysconfig` are inherited by all the children of the SAC. This inherited environment may be modified by the children.

Starting Port Monitors

After it has interpreted the `_sysconfig` file, the `sac` reads its administrative file `/etc/saf/_sactab`. `_sactab` specifies which port monitors are to be started. For each port monitor to be started, `sac` forks a child (see `fork(2)`) and creates a `utmpx` entry with the `type` field set to `LOGIN_PROCESS`. Each child then interprets its per-port monitor configuration script `/etc/saf/`*pmtag*`/_config` , if the file exists. These modifications to the environment affect the port monitor and will be inherited by all its children. Finally, the child process `exec`s the port monitor, using the command found in the `_sactab` entry. (See `sacadm`; this is the command given with the `-c` option when the port monitor is added to the system.)

Polling Port Monitors to Detect Failure

The `-t` option sets the frequency with which `sac` polls the port monitors on the system. This time may also be thought of as half of the maximum latency required to detect that a port monitor has failed and that recovery action is necessary.

Administrative functions

The Service Access Controller represents the administrative point of control for port monitors. Its administrative tasks are explained below.

When queried (`sacadm` with either `-l` or `-L`), the Service Access Controller returns the status of the port monitors specified, which `sacadm` prints on the standard output. A port monitor may be in one of six states:

`ENABLED` The port monitor is currently running and is accepting connections. See `sacadm(1M)` with the `-e` option.

`DISABLED` The port monitor is currently running and is not accepting connections. See `sacadm` with the `-d` option, and see `NOTRUNNING`, below.

`STARTING` The port monitor is in the process of starting up. `STARTING` is an intermediate state on the way to `ENABLED` or `DISABLED`.

`FAILED` The port monitor was unable to start and remain running.

`STOPPING` The port monitor has been manually terminated but has not completed its shutdown procedure. `STOPPING` is an intermediate state on the way to `NOTRUNNING`.

`NOTRUNNING` The port monitor is not currently running. (See `sacadm` with `-k`.) This is the normal "not running" state. When a port monitor is killed, all ports it was monitoring are inaccessible. It is not possible for an external user to tell whether a port is not being monitored or the system is down. If the port monitor is not killed but is in the `DISABLED` state, it may be possible (depending on the port monitor being used) to write a message on the inaccessible port telling the user who is trying to access the port that it is disabled. This is the advantage of having a `DISABLED` state as well as the `NOTRUNNING` state.

When a port monitor terminates, the SAC removes the `utmpx` entry for that port monitor.

The SAC receives all requests to enable, disable, start, or stop port monitors and takes the appropriate action.

The SAC is responsible for restarting port monitors that terminate. Whether or not the SAC will restart a given port monitor depends on two things:

- The restart count specified for the port monitor when the port monitor was added by `sacadm`; this information is included in `/etc/saf/`*pmtag*`/_sactab`.
- The number of times the port monitor has already been restarted.

Security `sac` uses `pam(3PAM)` for session management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the session management module to be used for `sac`. Here is a partial `pam.conf` file with entries for `sac` using the UNIX session management module.

```
sac   session    required    pam_unix_session.so.1
```

If there are no entries for the `sac` service, then the entries for the "other" service will be used.

Options `-t` *sanity_interval* Sets the frequency (*sanity_interval*) with which `sac` polls the port monitors on the system.

Files `/etc/saf/_sactab`

`/etc/saf/_sysconfig`

`/var/adm/utmpx`

`/var/saf/_log`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also pmadm(1M), sacadm(1M), fork(2) pam(3PAM), pam.conf(4), attributes(5), pam_authtok_check(5), pam_authtok_get(5), pam_authtok_store(5), pam_dhkeys(5), pam_passwd_auth(5), pam_unix_account(5), pam_unix_auth(5), pam_unix_session(5)

Notes The pam_unix(5) module is no longer supported. Similar functionality is provided by pam_authtok_check(5), pam_authtok_get(5), pam_authtok_store(5), pam_dhkeys(5), pam_passwd_auth(5), pam_unix_account(5), pam_unix_auth(5), and pam_unix_session(5).

Name sacadm – service access controller administration

Synopsis

```
sacadm -a -p pmtag -t type -c cmd -v ver [-f dx] [-n count]
     [-y comment] [-z script]

sacadm -r -p pmtag

sacadm -s -p pmtag

sacadm -k -p pmtag

sacadm -e -p pmtag

sacadm -d -p pmtag

sacadm -l [-p pmtag | -t type]

sacadm -L [-p pmtag | -t type]

sacadm -g -p pmtag [-z script]

sacadm -G [-z script]

sacadm -x [-p pmtag]
```

Description `sacadm` is the administrative command for the upper level of the Service Access Facility hierarchy (port monitor administration). `sacadm` performs the following functions:

- adds or removes a port monitor
- starts or stops a port monitor
- enables or disables a port monitor
- installs or replaces a per-system configuration script
- installs or replaces a per-port monitor configuration script
- prints requested port monitor information

Requests about the status of port monitors (`-l` and `-L`) and requests to print per-port monitor and per-system configuration scripts (`-g` and `-G` without the `-z` option) may be executed by any user on the system. Other `sacadm` commands may be executed only by the super-user.

Options

`-a` Add a port monitor. When adding a port monitor, `sacadm` creates the supporting directory structure in `/etc/saf` and `/var/saf` and adds an entry for the new port monitor to `/etc/saf/_sactab`. The file `_sactab` already exists on the delivered system. Initially, it is empty except for a single line, which contains the version number of the Service Access Controller. Unless the command line that adds the new port monitor includes the `-f` option with the `-x` argument, the new port monitor will be started. Because of the complexity of the options and arguments that follow the `-a` option, it may be convenient to use a command script or the menu system to add port monitors.

`-c` *cmd* Execute the command string *cmd* to start a port monitor. The `-c` option may be used only with a `-a`. A `-a` option requires a `-c`.

`-d` Disable the port monitor *pmtag*.

`-e` Enable the port monitor *pmtag*.

`-f dx` The `-f` option specifies one or both of the following two flags which are then included in the flags field of the `_sactab` entry for the new port monitor. If the `-f` option is not included on the command line, no flags are set and the default conditions prevail. By default, a port monitor is started. A `-f` option with no following argument is illegal.

d Do not enable the new port monitor.

x Do not start the new port monitor.

`-g` The `-g` option is used to request output or to install or replace the per-port monitor configuration script `/etc/saf/`*pmtag*`/_config`. `-g` requires a `-p` option. The `-g` option with only a `-p` option prints the per-port monitor configuration script for port monitor *pmtag*. The `-g` option with a `-p` option and a `-z` option installs the file `script` as the per-port monitor configuration script for port monitor *pmtag*. Other combinations of options with `-g` are invalid.

`-G` The `-G` option is used to request output or to install or replace the per-system configuration script `/etc/saf/_sysconfig`. The `-G` option by itself prints the per-system configuration script. The `-G` option in combination with a `-z` option installs the file `script` as the per-system configuration script. Other combinations of options with a `-G` option are invalid.

`-k` Stop port monitor *pmtag*.

`-l` The `-l` option is used to request port monitor information. The `-l` by itself lists all port monitors on the system. The `-l` option in combination with the `-p` option lists only the port monitor specified by *pmtag*. A `-l` in combination with the `-t` option lists all port monitors of type `type`. Any other combination of options with the `-l` option is invalid.

`-L` The `-L` option is identical to the `-l` option except that the output appears in a condensed format.

`-n` *count* Set the restart count to *count*. If a restart count is not specified, count is set to `0`. A count of `0` indicates that the port monitor is not to be restarted if it fails.

`-p` *pmtag* Specifies the tag associated with a port monitor.

`-r` Remove port monitor *pmtag*. `sacadm` removes the port monitor entry from `/etc/saf/_sactab`. If the removed port monitor is not running, then no further action is taken. If the removed port monitor is running, the Service Access Controller (SAC) sends it `SIGTERM` to indicate that it should shut down. Note that the port monitor's directory structure remains intact.

`-s` Start a port monitor. The SAC starts the port monitor *pmtag*.

`-t type` Specifies the port monitor type.

`-v ver` Specifies the version number of the port monitor. This version number may be given as

`-v ‘`*pmspec* `-V‘`

where *pmspec* is the special administrative command for port monitor *pmtag*. This special command is `ttyadm` for `ttymon` and `nlsadmin` for `listen`. The version stamp of the port monitor is known by the command and is returned when *pmspec* is invoked with a `-V` option.

`-x` The `-x` option by itself tells the SAC to read its database file (`_sactab`). The `-x` option with the `-p` option tells port monitor *pmtag* to read its administrative file.

`-y` *comment* Include *comment* in the `_sactab` entry for port monitor *pmtag*.

`-z script` Used with the `-g` and `-G` options to specify the name of a file that contains a configuration script. With the `-g` option, `script` is a per-port monitor configuration script; with `-G` it is a per-system configuration script. Modifying a configuration script is a three-step procedure. First a copy of the existing script is made (`-g` or `-G`). Then the copy is edited. Finally, the copy is put in place over the existing script (`-g` or `-G` with `-z`).

Output If successful, `sacadm` will exit with a status of `0`. If `sacadm` fails for any reason, it will exit with a nonzero status. Options that request information will write the information on the standard output. In the condensed format (`-L`), port monitor information is printed as a sequence of colon-separated fields; empty fields are indicated by two successive colons. The standard format (`-l`) prints a header identifying the columns, and port monitor information is aligned under the appropriate headings. In this format, an empty field is indicated by a hyphen. The comment character is `#`.

Examples **EXAMPLE 1** A sample output of the `sacadm` command.

The following command line adds a port monitor. The port monitor tag is `npack`; its type is `listen`; if necessary, it will restart three times before failing; its administrative command is `nlsadmin`; and the configuration script to be read is in the file `script`:

```
sacadm -a -p npack -t listen -c /usr/lib/saf/listen npack
-v ‘nlsadmin -V‘ -n 3 -z script
```

Remove a port monitor whose tag is `pmtag`:

```
sacadm -r -p pmtag
```

Start the port monitor whose tag is `pmtag`:

EXAMPLE 1 A sample output of the `sacadm` command. *(Continued)*

```
sacadm -s -p pmtag
```

Stop the port monitor whose tag is `pmtag`:

```
sacadm -k -p pmtag
```

Enable the port monitor whose tag is `pmtag`:

```
sacadm -e -p pmtag
```

Disable the port monitor whose tag is `pmtag`:

```
sacadm -d -p pmtag
```

List status information for all port monitors:

```
sacadm -l
```

List status information for the port monitor whose tag is `pmtag`:

```
sacadm -l -p pmtag
```

List the same information in condensed format:

```
sacadm -L -p pmtag
```

List status information for all port monitors whose type is `listen`:

```
sacadm -l -t listen
```

Replace the per-port monitor configuration script associated with the port monitor whose tag is `pmtag` with the contents of the file `file.config`:

```
sacadm -g -p pmtag -z file.config
```

Files `/etc/saf/_sactab`

`/etc/saf/_sysconfig`

`/etc/saf/`*`pmtag`*`/_config`

Name saf – Service Access Facility

Description The SAF generalizes the procedures for service access so that login access on the local system and network access to local services are managed in similar ways. Under the SAF, systems may access services using a variety of port monitors, including ttymon, the listener, and port monitors written expressly for a user's application. The manner in which a port monitor observes and manages access ports is specific to the port monitor and not to any component of the SAF. Users may therefore extend their systems by developing and installing their own port monitors. One of the important features of the SAF is that it can be extended in this way by users.

Relative to the SAF, a service is a process that is started. There are no restrictions on the functions a service may provide. The SAF consists of a controlling process, the service access controller (SAC), and two administrative levels corresponding to two levels in the supporting directory structure. The top administrative level is concerned with port monitor administration, the lower level with service administration. The SAC is documented in the sac(1M) man page. The administrative levels and associated utilities are documented in the *System Administration Guide - Volume II*. The requirements for writing port monitors and the functions a port monitor must perform to run under the SAF and the SAC are documented here.

Port Monitors A port monitor is a process that is responsible for monitoring a set of homogeneous, incoming ports on a machine. A port monitor's major purpose is to detect incoming service requests and to dispatch them appropriately.

A port is an externally seen access point on a system. A port may be an address on a network (TSAP or PSAP), a hardwired terminal line, an incoming phone line, etc. The definition of what constitutes a port is strictly a function of the port monitor itself.

A port monitor performs certain basic functions. Some of these are required to conform to the SAF; others may be specified by the requirements and design of the port monitor itself. Port monitors have two main functions: managing ports and monitoring ports for indications of activity.

Port Management — The first function of a port monitor is to manage a port. The actual details of how a port is managed are defined by the person who defines the port monitor. A port monitor is not restricted to handling a single port; it may handle multiple ports simultaneously.

Some examples of port management are setting the line speed on incoming phone connections, binding an appropriate network address, reinitializing the port when the service terminates, outputting a prompt, etc.

Activity Monitoring — The second function of a port monitor is to monitor the port or ports for which it is responsible for indications of activity. Two types of activity may be detected.

The first is an indication to the port monitor to take some port monitor-specific action. Pressing the break key to indicate that the line speed should be cycled is an example of a port monitor activity. Not all port monitors need to recognize and respond to the same indications. The indication used to attract the attention of the port monitor is defined by the person who defines the port monitor.

The second is an incoming service request. When a service request is received, a port monitor must be able to determine which service is being requested from the port on which the request is received. The same service may be available on more than one port.

Other Port Monitor Functions

This section briefly describes other port monitor functions.

Restricting Access to the System

A port monitor must be able to restrict access to the system without disturbing services that are still running. In order to do this, a port monitor must maintain two internal states: enabled and disabled. The port monitor starts in the state indicated by the ISTATE environment variable provided by the sac. See sac(1M) for details. Enabling or disabling a port monitor affects all ports for which the port monitor is responsible. If a port monitor is responsible for a single port, only that port will be affected. If a port monitor is responsible for multiple ports, the entire collection of ports will be affected. Enabling or disabling a port monitor is a dynamic operation: it causes the port monitor to change its internal state. The effect does not persist across new invocations of the port monitor. Enabling or disabling an individual port, however, is a static operation: it causes a change to an administrative file. The effect of this change will persist across new invocations of the port monitor.

Creating `utmpx` Entries

Port monitors are responsible for creating `utmpx` entries with the type field set to USER_PROCESS for services they start. If this action has been specified, by using the `-fu` option in the `pmadm` command line that added the service, these `utmpx` entries may

	in turn be modified by the service. When the service terminates, the `utmpx` entry must be set to DEAD_PROCESS.
Port Monitor Process IDs and Lock Files	When a port monitor starts, it writes its process id into a file named `_pid` in the current directory and places an advisory lock on the file.
Changing the Service Environment: Running	`doconfig(3NSL)` Before invoking the service designated in the port monitor administrative file, `_pmtab`, a port monitor must arrange for the per-service configuration script to be run, if one exists, by calling the library function `doconfig(3NSL)`. Because the per-service configuration script may specify the execution of restricted commands, as well as for other security reasons, port monitors are invoked with root permissions. The details of how services are invoked are specified by the person who defines the port monitor.
Terminating a Port Monitor	A port monitor must terminate itself gracefully on receipt of the signal SIGTERM. The termination sequence is the following: 1. The port monitor enters the stopping state; no further service requests are accepted. 2. Any attempt to re-enable the port monitor will be ignored. 3. The port monitor yields control of all ports for which it is responsible. It must be possible for a new instantiation of the port monitor to start correctly while a previous instantiation is stopping. 4. The advisory lock on the process id file is released. Once this lock is released, the contents of the process id file are undefined and a new invocation of the port monitor may be started.

SAF Files

This section briefly covers the files used by the SAF.

The Port Monitor Administrative File

A port monitor's current directory contains an administrative file named `_pmtab`; `_pmtab` is maintained by the `pmadm` command in conjunction with a port monitor-specific administrative command.

The port monitor administrative command for a listen port monitor is `nlsadmin(1M)`; the port monitor administrative command for ttymon is `ttyadm(1M)`. Any port monitor written by a user must be provided with an administrative command specific to that port monitor to perform similar functions.

Per-Service Configuration Files

A port monitor's current directory also contains the per-service configuration scripts, if they exist. The names of the per-service configuration scripts correspond to the service tags in the `_pmtab` file.

Private Port Monitor Files

A port monitor may create private files in the directory `/var/saf/`*tag*, where *tag* is the name of the port monitor. Examples of private files are log files or temporary files.

The SAC/Port Monitor Interface

The SAC creates two environment variables for each port monitor it starts:PMTAG and ISTATE.

This variable is set to a unique port monitor tag by the SAC. The port monitor uses this tag to identify itself in response to `sac` messages. ISTATE is used to indicate to the port monitor what its initial internal state should be. ISTATE is set to “enabled” or “disabled” to indicate that the port monitor is to start in the enabled or disabled state respectively.

The SAC performs a periodic sanity poll of the port monitors. The SAC communicates with port monitors through FIFOs. A port monitor should open _pmpipe, in the current directory, to receive messages from the SAC and `../_sacpipe` to send return messages to the SAC.

Message Formats

This section describes the messages that may be sent from the SAC to a port monitor (`sac` messages), and from a port monitor to the SAC (port monitor messages). These messages are sent through FIFOs and are in the form of C structures.

`sac` Messages

The format of messages from the SAC is defined by the structure `sacmsg`:

```
struct sacmsg
{
    int sc_size; /* size of optional data portion */
    char sc_type; /* type of message */
```

```
};
```

The SAC may send four types of messages to port monitors. The type of message is indicated by setting the `sc_type` field of the `sacmsg` structure to one of the following:

SC_STATUS status request

SC_ENABLE enable message

SC_DISABLE disable message

SC_READDB message indicating that the port monitor's _pmtab file should be read

The `sc_size` field indicates the size of the optional data part of the message. See "Message Classes." For Solaris, `sc_size` should always be set to 0. A port monitor must respond to every message sent by the sac.

Port Monitor Messages

The format of messages from a port monitor to the SAC is defined by the structure `pmmsg`:

```
struct pmmsg {
    char pm_type;               /* type of message */
    unchar_t pm_state;          /* current state of port monitor */
    char pm_maxclass;           /* maximum message class this port
                                   monitor understands */
    char pm_tag[PMTAGSIZE + 1]; /* port monitor's tag */
    int pm_size;                /* size of optional data portion */
};
```

Port monitors may send two types of messages to the SAC. The type of message is indicated by setting the `pm_type` field of the `pmmsg` structure to one of the following:

PM_STATUS state information

PM_UNKNOWN negative acknowledgment

For both types of messages, the `pm_tag` field is set to the port monitor's tag and the `pm_state` field is set to the port monitor's current state. Valid states are:

PM_STARTING starting

PM_ENABLED enabled

PM_DISABLED disabled

PM_STOPPING stopping

The current state reflects any changes caused by the last message from the SAC. The status message is the normal return message. The negative acknowledgment should be sent only when the message received is not understood. `pm_size` indicates the size of the optional data part of the message. `pm_maxclass` is used to specify a message class. Both are discussed under

"Message Classes." In Solaris, always set `pm_maxclass` to 1 and `sc_size` to 0. Port monitors may never initiate messages; they may only respond to messages that they receive.

Message Classes The concept of message class has been included to accommodate possible SAF extensions. The messages described above are all class 1 messages. None of these messages contains a variable data portion; all pertinent information is contained in the message header. If new messages are added to the protocol, they will be defined as new message classes (for example, class 2). The first message the SAC sends to a port monitor will always be a class 1 message. Since all port monitors, by definition, understand class 1 messages, the first message the SAC sends is guaranteed to be understood. In its response to the SAC, the port monitor sets the `pm_maxclass` field to the maximum message class number for that port monitor. The SAC will not send messages to a port monitor from a class with a larger number than the value of `pm_maxclass`. Requests that require messages of a higher class than the port monitor can understand will fail. For Solaris, always set `pm_maxclass` to 1.

For any given port monitor, messages of class `pm_maxclass` and messages of all classes with values lower than `pm_maxclass` are valid. Thus, if the `pm_maxclass` field is set to 3, the port monitor understands messages of classes 1, 2, and 3. Port monitors may not generate messages; they may only respond to messages. A port monitor's response must be of the same class as the originating message. Since only the SAC can generate messages, this protocol will function even if the port monitor is capable of dealing with messages of a higher class than the SAC can generate. `pm_size` (an element of the pmmsg structure) and `sc_size` (an element of the `sacmsg` structure) indicate the size of the optional data part of the message. The format of this part of the message is undefined. Its definition is inherent in the type of message. For Solaris, always set both `sc_size` and `pm_size` to `0`.

Administrative Interface This section discusses the port monitor administrative files available under the SAC.

The SAC Administrative File _sactab The service access controller's administrative file contains information about all the port monitors for which the SAC is responsible. This file exists on the delivered system. Initially, it is empty except for a single comment line that contains the version number of the SAC. Port monitors are added to the system by making entries in the SAC's administrative file. These entries should be made using the administrative command `sacadm(1M)` with a `-a` option. `sacadm(1M)` is also used to remove entries from the SAC's administrative file. Each entry in the SAC's administrative file contains the following information.

`PMTAG` A unique tag that identifies a particular port monitor. The system administrator is responsible for naming a port monitor. This tag is then used by the SAC to identify the port monitor for all administrative purposes. PMTAG may consist of up to 14 alphanumeric characters.

`PMTYPE` The type of the port monitor. In addition to its unique tag, each port monitor has a type designator. The type designator identifies a group of port monitors that are different invocations of the same entity. ttymon and listen are examples of valid port monitor types. The type designator is used to facilitate the administration of

groups of related port monitors. Without a type designator, the system administrator has no way of knowing which port monitor tags correspond to port monitors of the same type. PMTYPE may consist of up to 14 alphanumeric characters.

`FLGS` The flags that are currently defined are:

d When started, do not enable the port monitor.

x Do not start the port monitor.

If no flag is specified, the default action is taken. By default a port monitor is started and enabled.

`RCNT` The number of times a port monitor may fail before being placed in a failed state. Once a port monitor enters the failed state, the SAC will not try to restart it. If a count is not specified when the entry is created, this field is set to 0. A restart count of 0 indicates that the port monitor is not to be restarted when it fails.

`COMMAND` A string representing the command that will start the port monitor. The first component of the string, the command itself, must be a full path name.

The Port Monitor Administrative File _pmtab

Each port monitor will have two directories for its exclusive use. The current directory will contain files defined by the SAF (`_pmtab`, `_pid`) and the per-service configuration scripts, if they exist. The directory `/var/saf/`*pmtag*, where *pmtag* is the tag of the port monitor, is available for the port monitor's private files. Each port monitor has its own administrative file. The `pmadm(1M)` command should be used to add, remove, or modify service entries in this file. Each time a change is made using `pmadm(1M)`, the corresponding port monitor rereads its administrative file. Each entry in a port monitor's administrative file defines how the port monitor treats a specific port and what service is to be invoked on that port. Some fields must be present for all types of port monitors. Each entry must include a service tag to identify the service uniquely and an identity to be assigned to the service when it is started (for example, root).

The combination of a service tag and a port monitor tag uniquely define an instance of a service. The same service tag may be used to identify a service under a different port monitor. The record must also contain port monitor specific data (for example, for a ttymon port monitor, this will include the prompt string which is meaningful to ttymon). Each type of port monitor must provide a command that takes the necessary port monitor-specific data as arguments and outputs these data in a form suitable for storage in the file. The `ttyadm(1M)` command does this for ttymon and `nlsadmin(1M)` does it for listen. For a user-defined port monitor, a similar administrative command must also be supplied. Each service entry in the port monitor administrative file must have the following format and contain the information listed below:

```
svctag:flgs:id:reserved:reserved:reserved:pmspecific# comment
```

SVCTAG is a unique tag that identifies a service. This tag is unique only for the port monitor through which the service is available. Other port monitors may offer the same or other services with the same tag. A service requires both a port monitor tag and a service tag to identify it uniquely. SVCTAG may consist of up to 14 alphanumeric characters. The service entries are defined as:

`FLGS` Flags with the following meanings may currently be included in this field:

- x Do not enable this port. By default the port is enabled.
- u Create a utmpx entry for this service. By default no utmpx entry is created for the service.

`ID` The identity under which the service is to be started. The identity has the form of a login name as it appears in `/etc/passwd`.

`PMSPECIFIC` Examples of port monitor information are addresses, the name of a process to execute, or the name of a STREAMS-based pipe to pass a connection through. This information will vary to meet the needs of each different type of port monitor.

`COMMENT` A comment associated with the service entry. Port monitors may ignore the *u* flag if creating a utmpx entry for the service is not appropriate to the manner in which the service is to be invoked. Some services may not start properly unless utmpx entries have been created for them (for example, login). Each port monitor administrative file must contain one special comment of the form:

VERSION=value

where *value* is an integer that represents the port monitor's version number. The version number defines the format of the port monitor administrative file. This comment line is created automatically when a port monitor is added to the system. It appears on a line by itself, before the service entries.

Monitor-Specific Administrative Command

Previously, two pieces of information included in the `_pmtab` file were described: the port monitor's version number and the port monitor part of the service entries in the port monitor's `_pmtab` file. When a new port monitor is added, the version number must be known so that the `_pmtab` file can be correctly initialized. When a new service is added, the port monitor part of the `_pmtab` entry must be formatted correctly. Each port monitor must have an administrative command to perform these two tasks. The person who defines the port monitor must also define such an administrative command and its input options. When the command is invoked with these options, the information required for the port monitor part of the service entry must be correctly formatted for inclusion in the port monitor's `_pmtab` file and must be written to the standard output. To request the version number the command must be invoked with a `-V` option; when it is invoked in this way, the port monitor's current

version number must be written to the standard output. If the command fails for any reason during the execution of either of these tasks, no data should be written to standard output.

The Port Monitor/Service Interface

The interface between a port monitor and a service is determined solely by the service. Two mechanisms for invoking a service are presented here as examples.

New Service Invocations

The first interface is for services that are started anew with each request. This interface requires the port monitor to first `fork(2)` a child process. The child will eventually become the designated service by performing an `exec(1)`. Before the `exec(1)` happens, the port monitor may take some port monitor-specific action; however, one action that must occur is the interpretation of the per-service configuration script, if one is present. This is done by calling the library routine `doconfig(3NSL)`.

Standing Service Invocations

The second interface is for invocations of services that are actively running. To use this interface, a service must have one end of a stream pipe open and be prepared to receive connections through it.

Port Monitor Requirements

To implement a port monitor, several generic requirements must be met. This section summarizes these requirements. In addition to the port monitor itself, an administrative command must be supplied.

Initial Environment

When a port monitor is started, it expects an initial execution environment in which:

- It has no file descriptors open
- It cannot be a process group leader
- It has an entry in `/etc/utmpx` of type LOGIN_PROCESS
- An environment variable, ISTATE, is set to “enabled” or “disabled” to indicate the port monitor's correct initial state
- An environment variable, PMTAG, is set to the port monitor's assigned tag
- The directory that contains the port monitor's administrative files is its current directory
- pThe port monitor is able to create private files in the directory `/var/saf/`*tag*, where *tag* is the port monitor's tag
- The port monitor is running with user id 0 (root)

Important Files

Relative to its current directory, the following key files exist for a port monitor.

`_config`	The port monitor's configuration script. The port monitor configuration script is run by the SAC. The SAC is started by `init(1M)` as a result of an entry in `/etc/inittab` that calls `sac(1M)`.
`_pid`	The file into which the port monitor writes its process id.
`_pmtab`	The port monitor's administrative file. This file contains information about the ports and services for which the port monitor is responsible.
`_pmpipe`	The FIFO through which the port monitor will receive messages from the SAC.
`svctag`	The per-service configuration script for the service with the tag *svctag*.
`../_sacpipe`	The FIFO through which the port monitor will send messages to `sac(1M)`.

Port Monitor Responsibilities

A port monitor is responsible for performing the following tasks in addition to its port monitor function:

Write its process id into the file `_pid` and place an advisory lock on the file
Terminate gracefully on receipt of the signal SIGTERM
Follow the protocol for message exchange with the SAC

A port monitor must perform the following tasks during service invocation:

Create a `utmpx` entry if the requested service has the `u` flag set in `_pmtab`

Port monitors may ignore this flag if creating a `utmpx` entry for the service does not make sense because of the manner in which the service is to be invoked. On the other hand, some services may not start properly unless utmpx entries have been created for them.

Interpret the per-service configuration script for the requested service, if it exists, by calling the `doconfig(3NSL)` library routine

Configuration Files and Scripts

The library routine `doconfig(3NSL)`, defined in `libnsl.so`, interprets the configuration scripts contained in the files `/etc/saf/_sysconfig` (the per-system configuration file), and `/etc/saf/`*pmtag*`/_config` (per-port monitor configuration files); and in `/etc/saf/`*pmtag*`/svctag` (per-service configuration files). Its syntax is:

```
#include <sac.h>
    int doconfig (int fd, char *script, long rflag);
```

`script` is the name of the configuration script; *fd* is a file descriptor that designates the stream to which stream manipulation operations are to be applied; *rflag* is a bitmask that indicates the mode in which script is to be interpreted. *rflag* may take two values, NORUN and NOASSIGN,

which may be or'd. If *rflag* is zero, all commands in the configuration script are eligible to be interpreted. If *rflag* has the NOASSIGN bit set, the assign command is considered illegal and will generate an error return. If *rflag* has the NORUN bit set, the run and runwait commands are considered illegal and will generate error returns. If a command in the script fails, the interpretation of the script ceases at that point and a positive integer is returned; this number indicates which line in the script failed. If a system error occurs, a value of −1 is returned. If a script fails, the process whose environment was being established should not be started. In the example, `doconfig(3NSL)` is used to interpret a per-service configuration script.

```
 . . .
        if ((i = doconfig (fd, svctag, 0)) != 0){
        error ("doconfig failed on line %d of script %s",i,svctag);
    }
```

The Per-System Configuration File

The per-system configuration file, `/etc/saf/_sysconfig`, is delivered empty. It may be used to customize the environment for all services on the system by writing a command script in the interpreted language described in this chapter and on the `doconfig(3NSL)` manpage. When the SAC is started, it calls the `doconfig(3NSL)` function to interpret the per-system configuration script. The SAC is started when the system enters multiuser mode.

Per-Port Monitor Configuration Files

Per-port monitor configuration scripts (`/etc/saf/`*pmtag*`/_config`) are optional. They allow the user to customize the environment for any given port monitor and for the services that are available through the ports for which that port monitor is responsible. Per-port monitor configuration scripts are written in the same language used for per-system configuration scripts. The per-port monitor configuration script is interpreted when the port monitor is started. The port monitor is started by the SAC after the SAC has itself been started and after it has run its own configuration script, `/etc/saf/_sysconfig`. The per-port monitor configuration script may override defaults provided by the per-system configuration script.

Per-Service Configuration Files

Per-service configuration files allow the user to customize the environment for a specific service. For example, a service may require special privileges that are not available to the general user.

Using the language described in the doconfig(3NSL) manpage, you can write a script that will grant or limit such special privileges to a particular service offered through a particular port monitor. The per-service configuration may override defaults provided by higher-level configuration scripts. For example, the per-service configuration script may specify a set of STREAMS modules other than the default set.

The Configuration Language

The language in which configuration scripts are written consists of a sequence of commands, each of which is interpreted separately. The following reserved keywords are defined: `assign`, `push`, `pop`, `runwait`, and `run`. The comment character is `#`. Blank lines are not significant. No line in a command script may exceed 1024 characters.

`assign` *variable*=*value*
: Used to define environment variables; *variable* is the name of the environment variable and *value* is the value to be assigned to it. The value assigned must be a string constant; no form of parameter substitution is available. *value* may be quoted. The quoting rules are those used by the shell for defining environment variables. `assign` will fail if space cannot be allocated for the new variable or if any part of the specification is invalid.

`push` *module1*[,*module2, module3*, . . .]
: Used to push STREAMS modules onto the stream designated by `fd`; *module1* is the name of the first module to be pushed, *module2* is the name of the second module to be pushed, and so on. The command will fail if any of the named modules cannot be pushed. If a module cannot be pushed, the subsequent modules on the same command line will be ignored and modules that have already been pushed will be popped.

`pop` [*module*]
: Used to pop STREAMS modules off the designated stream. If `pop` is invoked with no arguments, the top module on the stream is popped. If an argument is given, modules will be popped one at a time until the named module is at the top of the stream. If the named module is not on the designated stream, the stream is left as it was and the command fails. If *module* is the special

keyword `ALL`, then all modules on the stream will be popped. Only modules above the topmost driver are affected.

`runwait command`

The `runwait` command runs a command and waits for it to complete; `command` is the path name of the command to be run. The command is run with `/bin/sh -c` prepended to it; shell scripts may thus be executed from configuration scripts. The `runwait` command will fail if command cannot be found or cannot be executed, or if `command` exits with a nonzero status.

`run command`

The `run` command is identical to `runwait` except that it does not wait for command to complete; `command` is the path name of the command to be run. `run` will not fail unless it is unable to create achild process to execute the command. Although they are syntactically indistinguishable, some of the commands available to `run` and `runwait` are interpreter built-in commands. Interpreter built-ins are used when it is necessary to alter the state of a process within the context of that process. The `doconfig` interpreter built-in commands are similar to the shell special commands and, like these, they do not spawn another process for execution. See the sh(1) man page. The initial set of built-in commands is: `cd`, `ulimit`, `umask`.

Sample Port Monitor Code

This example shows an example of a "null" port monitor that simply responds to messages from the SAC.

```
# include <stdlib.h>
# include <stdio.h>
# include <unistd.h>
# include <fcntl.h>
# include <signal.h>
# include <sac.h>

char Scratch[BUFSIZ]; /* scratch buffer */
char Tag[PMTAGSIZE + 1]; /* port monitor's tag */
FILE *Fp; /* file pointer for log file */
FILE *Tfp; /* file pointer for pid file */
char State; /* portmonitor's current state*/

main(argc, argv)
```

```
    int argc;
    char *argv[];
{
    char *istate;
    strcpy(Tag, getenv("PMTAG"));
/*
 * open up a log file in port monitor's private directory
 */
    sprintf(Scratch, "/var/saf/%s/log", Tag);
    Fp = fopen(Scratch, "a+");
    if (Fp == (FILE *)NULL)
        exit(1);
    log(Fp, "starting");
/*
 * retrieve initial state (either "enabled" or "disabled") and set
 * State accordingly
 */
    istate = getenv("ISTATE");
    sprintf(Scratch, "ISTATE is %s", istate);
    log(Fp, Scratch);
    if (!strcmp(istate, "enabled"))
        State = PM_ENABLED;
    else if (!strcmp(istate, "disabled"))
        State = PM_DISABLED;
    else {
        log(Fp, "invalid initial state");
        exit(1);
    }
    sprintf(Scratch, "PMTAG is %s", Tag);
    log(Fp, Scratch);
/*
 * set up pid file and lock it to indicate that we are active
 */
    Tfp = fopen("_pid", "w");
    if (Tfp == (FILE *)NULL) {
        log(Fp, "couldn't open pid file");
        exit(1);
    }
    if (lockf(fileno(Tfp), F_TEST, 0) < 0) {
        log(Fp, "pid file already locked");
        exit(1);
    }

    log(Fp, "locking file");
    if (lockf(fileno(Tfp), F_LOCK, 0) < 0) {
        log(Fp, "lock failed");
        exit(1);
```

```
    }
    fprintf(Tfp, "%d", getpid());
    fflush(Tfp);

/*
 * handle poll messages from the sac ... this function never returns
 */
    handlepoll();
    pause();
    fclose(Tfp);
    fclose(Fp);
}

handlepoll()
{
    int pfd; /* file descriptor for incoming pipe */
    int sfd; /* file descriptor for outgoing pipe */
    struct sacmsg sacmsg; /* incoming message */
    struct pmmsg pmmsg; /* outgoing message */
/*
 * open pipe for incoming messages from the sac
 */
    pfd = open("_pmpipe", O_RDONLY|O_NONBLOCK);
    if (pfd < 0) {
        log(Fp, "_pmpipe open failed");
        exit(1);
    }
/*
 * open pipe for outgoing messages to the sac
 */
    sfd = open("../_sacpipe", O_WRONLY);
    if (sfd < 0) {
        log(Fp, "_sacpipe open failed");
        exit(1);
    }
/*
 * start to build a return message; we only support class 1 messages
 */
    strcpy(pmmsg.pm_tag, Tag);
    pmmsg.pm_size = 0;
    pmmsg.pm_maxclass = 1;
/*
 * keep responding to messages from the sac
 */
     for (;;) {
         if (read(pfd, &sacmsg, sizeof(sacmsg)) != sizeof(sacmsg)) {
             log(Fp, "_pmpipe read failed");
```

```
                exit(1);
            }
    /*
     * determine the message type and respond appropriately
     */
            switch (sacmsg.sc_type) {
                case SC_STATUS:
                    log(Fp, "Got SC_STATUS message");
                    pmmsg.pm_type = PM_STATUS;
                    pmmsg.pm_state = State;
                    break;
                case SC_ENABLE:
                    /*note internal state change below*/
                    log(Fp, "Got SC_ENABLE message");
                    pmmsg.pm_type = PM_STATUS;
                    State = PM_ENABLED;
                    pmmsg.pm_state = State;
                    break;
                case SC_DISABLE:
                    /*note internal state change below*/
                    log(Fp, "Got SC_DISABLE message");
                    pmmsg.pm_type = PM_STATUS;
                    State = PM_DISABLED;
                    pmmsg.pm_state = State;
                    break;
                case SC_READDB:
                    /*
                    * if this were a fully functional port
                    * monitor it would read _pmtab here
                    * and take appropriate action
                    */
                    log(Fp, "Got SC_READDB message");
                    pmmsg.pm_type = PM_STATUS;
                    pmmsg.pm_state = State;
                    break;
                default:
                    sprintf(Scratch, "Got unknown message <%d>",
                    sacmsg.sc_type);
                    log(Fp, Scratch);
                    pmmsg.pm_type = PM_UNKNOWN;
                    pmmsg.pm_state = State;
                    break;
            }
    /*
     * send back a response to the poll
     * indicating current state
     */
```

```
            if (write(sfd, &pmmsg, sizeof(pmmsg)) != sizeof(pmmsg))
                log(Fp, "sanity response failed");
        }
}
/*
 * general logging function
 */
log(fp, msg)
    FILE *fp;
    char *msg;
{
    fprintf(fp, "%d; %s\n", getpid(), msg);
    fflush(fp);
}
```

The sac.h Header File

The following example shows the sac.h header file.

```
/* length in bytes of a utmpx id */
# define IDLEN 4
/* wild character for utmpx ids */
# define SC_WILDC 0xff
/* max len in bytes for port monitor tag */
# define PMTAGSIZE 14
/*
 * values for rflag in doconfig()
 */
/* don't allow assign operations */
# define NOASSIGN 0x1
/* don't allow run or runwait operations */
# define NORUN 0x2
/*
 * message to SAC (header only). This header is forever fixed. The
 * size field (pm_size) defines the size of the data portion of the
 * message, which follows the header. The form of this optional data
 * portion is defined strictly by the message type (pm_type).
 */
struct pmmsg {
    char pm_type;               /* type of message */
    unchar_t pm_state;            /* current state of pm */
    char pm_maxclass;           /* max message class this port monitor
                                    understands */
    char pm_tag[PMTAGSIZE + 1]; /* pm's tag */
    int pm_size;                /* size of opt data portion */

 * ‘errno’ values for Saferrno, note that Saferrno is used by both
 * pmadm and sacadm and these values are shared between them
 */
# define E_BADARGS 1   /* bad args/ill-formed cmd line */
# define E_NOPRIV 2    /* user not priv for operation */
```

```
# define E_SAFERR 3    /* generic SAF error */
# define E_SYSERR 4    /* system error */
# define E_NOEXIST 5   /* invalid specification */
# define E_DUP 6       /* entry already exists */
# define E_PMRUN 7     /* port monitor is running */
# define E_PMNOTRUN 8  /* port monitor is not running */
# define E_RECOVER 9
   /* in recovery */
```

Directory Structure

This section gives a description of the SAF files and directories.

`/etc/saf/_sysconfig`	The per-system configuration script.
`/etc/saf/_sactab`	The SAC's administrative file. Contains information about the port monitors for which the SAC is responsible.
`/etc/saf/`*pmtag*	The home directory for port monitor *pmtag*.
`/etc/saf/`*pmtag*`/_config`	The per-port monitor configuration script for port monitor pmtag.
`/etc/saf/`*pmtag*`/_pmtab`	Port monitor pmtag's administrative file. Contains information about the services for which *pmtag* is responsible.
`/etc/saf/`*pmtag*`/`*svctag*	The file in which the per-service configuration script for service *svctag* (available through port monitor `pmtag`) is placed.
`/etc/saf/`*pmtag*`/_pid`	The file in which a port monitor writes its process id in the current directory and places an advisory lock on the file.
`/etc/saf/ pmtag /_pmpipe`	The file in which the port monitor receives messages from the SAC and `../_sacpipe` and sends return messages to the SAC.
`/var/saf/_log`	The SAC's log file.
`/var/saf/`*pmtag*	The directory for files created by port monitor *pmtag*, for example its log file.

List Of Commands

The following administrative commands relate to SAF.

`sacadm(1M)`	port monitor administrative command
`pmadm(1M)`	service administration command

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsr

Name sar, sa1, sa2, sadc – system activity report package

Synopsis

```
/usr/lib/sa/sadc [t n] [ofile]

/usr/lib/sa/sa1 [t n]

/usr/lib/sa/sa2 [-aAbcdgkmpqruvwy] [-e time] [-f filename]
     [-i sec] [-s time]
```

Description System activity data can be accessed at the special request of a user (see `sar(1)`) and automatically, on a routine basis, as described here. The operating system contains several counters that are incremented as various system actions occur. These include counters for CPU utilization, buffer usage, disk and tape I/O activity, TTY device activity, switching and system-call activity, file-access, queue activity, inter-process communications, and paging. For more general system statistics, use `iostat(1M)`, `sar(1)`, or `vmstat(1M)`.

`sadc` and two shell procedures, `sa1` and `sa2`, are used to sample, save, and process this data.

`sadc`, the data collector, samples system data *n* times, with an interval of *t* seconds between samples, and writes in binary format to *ofile* or to standard output. The sampling interval *t* should be greater than 5 seconds; otherwise, the activity of `sadc` itself may affect the sample. If *t* and *n* are omitted, a special record is written. This facility can be used at system boot time, when booting to a multi-user state, to mark the time at which the counters restart from zero. For example, when accounting is enabled, the `svc:/system/sar:default` service writes the restart mark to the daily data file using the command entry:

```
su sys -c "/usr/lib/sa/sadc /var/adm/sa/sa'date +%d'"
```

The shell script `sa1`, a variant of `sadc`, is used to collect and store data in the binary file `/var/adm/sa/sa`*dd*, where `dd` is the current day. The arguments *t* and *n* cause records to be written *n* times at an interval of *t* seconds, or once if omitted. The following entries in `/var/spool/cron/crontabs/sys` will produce records every 20 minutes during working hours and hourly otherwise:

```
0 * * * 0-6 /usr/lib/sa/sa1
20,40 8–17 * * 1–5 /usr/lib/sa/sa1
```

See `crontab(1)` for details.

The shell script `sa2`, a variant of `sar`, writes a daily report in the file `/var/adm/sa/sar`*dd*. See the `OPTIONS` section in `sar(1)` for an explanation of the various options. The following entry in `/var/spool/cron/crontabs/sys` will report important activities hourly during the working day:

```
5 18 * * 1–5 /usr/lib/sa/sa2 -s 8:00 -e 18:01 -i 1200 -A
```

Files

`/tmp/sa.adrfl`	address file
`/var/adm/sa/sadd`	Daily data file
`/var/adm/sa/sardd`	Daily report file

```
/var/spool/cron/crontabs/sys
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWaccu

See Also crontab(1), sag(1), sar(1), svcs(1), timex(1), iostat(1M), svcadm(1M), vmstat(1M), attributes(5), smf(5)

System Administration Guide: Advanced Administration

Notes The `sar` service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/system/sar
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name savecore – save a crash dump of the operating system

Synopsis `/usr/bin/savecore [-Lvd] [-f` *dumpfile*`] [`*directory*`]`

Description The `savecore` utility saves a crash dump of the kernel (assuming that one was made) and writes a reboot message in the shutdown log. It is invoked by the `dumpadm` service each time the system boots.

`savecore` can be configured by `dumpadm(1M)` to save crash dump data in either a compressed or uncompressed format. For the compressed format, `savecore` saves the crash dump data in the file *directory*`/vmcore.`*N*`.z`, where *N* in the pathname is replaced by a number which increments by one each time `savecore` is run in *directory*. The compressed file can be uncompressed in a separate step using the `-f` *dumpfile* option. For the uncompressed format, `savecore` saves the crash dump data in the file *directory*`/vmcore.`*N* and the kernel's namelist in *directory*`/unix.`*N*.

Before writing out a crash dump, `savecore` reads a number from the file *directory*`/minfree`. This is the minimum number of kilobytes that must remain free on the file system containing *directory*. If after saving the crash dump the file system containing *directory* would have less free space the number of kilobytes specified in `minfree`, the crash dump is not saved. if the `minfree` file does not exist, `savecore` assumes a `minfree` value of 1 megabyte.

The `savecore` utility also logs a reboot message using facility `LOG_AUTH` (see `syslog(3C)`). If the system crashed as a result of a panic, `savecore` logs the panic string too.

Options The following options are supported:

`-d` Disregard dump header valid flag. Force `savecore` to attempt to save a crash dump even if the header information stored on the dump device indicates the dump has already been saved.

`-f` *dumpfile* Save a crash dump from the specified file instead of from the system's current dump device. When given *directory*`/vmcore.`*N*`.z`, uncompress the file to `vmcore.`*N* and `unix.`*N*, where *N* is the same number as in the compressed name.

This option may also be useful if the information stored on the dump device has been copied to an on-disk file by means of the `dd(1M)` command.

`-L` Save a crash dump of the live running Solaris system, without actually rebooting or altering the system in any way. This option forces `savecore` to save a live snapshot of the system to the dump device, and then immediately to retrieve the data and to write it out to a new set of crash dump files in the specified directory. Live system crash dumps can only be performed if you have configured your system to have a dedicated dump device using `dumpadm(1M)`.

`savecore -L` does not suspend the system, so the contents of memory continue to change while the dump is saved. This means that live crash dumps are not fully self-consistent.

`-v` Verbose. Enables verbose error messages from `savecore`.

Operands The following operands are supported:

directory Save the crash dump files to the specified directory. If *directory* is not specified, `savecore` saves the crash dump files to the default `savecore` *directory*, configured by `dumpadm(1M)`.

Files

- *directory*`/vmcore.`*N*
- *directory*`/unix.`*N*
- *directory*`/bounds`
- *directory*`/minfree`
- `/var/crash/`‘`uname -n`‘ (default crash dump directory)

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

See Also `adb(1)`, `mdb(1)`, `svcs(1)`, `dd(1M)`, `dumpadm(1M)`, `svcadm(1M)`, `syslog(3C)`, `attributes(5)`, `smf(5)`

Notes The system crash dump service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/system/dumpadm:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

If the dump device is also being used as a swap device, you must run `savecore` very soon after booting, before the swap space containing the crash dump is overwritten by programs currently running.

Name scadm – administer System Controller (SC)

Synopsis

```
/usr/platform/platform-name/sbin/scadm subcommand [option]
     [argument]...
```

Description The `scadm` utility administers the System Controller (SC). This utility allows the host server to interact with the SC.

The `scadm` utility *must* be run as root.

The interface, output, and location in the directory hierarchy for `scadm` are uncommitted and might change.

platform-name is the name of the platform implementation. Use the `uname -i` command to identify the platform implementation. See `uname(1)`.

The `scadm` utility has a number of subcommands. Some subcommands have specific options and arguments associated with them. See `SUBCOMMANDS`, `OPTIONS`, `OPERANDS`, and `USAGE`.

SUBCOMMANDS Subcommands immediately follow the `scadm` command on the command line, and are separated from the command by a SPACE.

The following subcommands are supported

consolehistory Display the SC's console log. The SC maintains a running log which captures all console output. This log is maintained as a first-in, first-out buffer: New console output may displace old console output if the buffer is full. By default, only the last eight kilobytes of the console log file are displayed.

The optional `-a` argument specifies that the entire console log file be displayed.

It is possible for the SC to fill this log more quickly than the `consolehistory` subcommand can read it. This means that it is possible for some log data to be lost before it can be displayed. If this happens, the `consolehistory` subcommand displays "scadm: lost <number> bytes of console log data" in the log output, to indicate that some data was lost.

The format for the `consolehistory` subcommand is:

```
scadm consolehistory [-a]
```

The `consolehistory` subcommand is not available on all platforms. If this command is used on a platform that does not support it, `scadm` prints this message:

```
scadm: command/option not supported
```

and exit with non-zero status.

date — Display the SC's time and date

The format for the `date` subcommand is:

```
scadm date
```

download — Program the SC's firmware.

There are two parts to the firmware, the boot monitor and the main image.

By default, The `scadm` command's download programs the main firmware image. The `boot` argument selects programming of the boot monitor.

The format for the `download` subcommand is:

```
scadm download [boot] file
```

fruhistory — Display the contents of the "field replacable unit" log maintained by the SC. By default, only the last eight kilobytes of the fru history log file are displayed. The data in contained this log contains snapshots of the SC's "showfru" command, taken whenever the system is reset, or a hot-plug event is detected by the SC.

The optional `-a` argument specifies that the entire fru log file be displayed.

It is possible for the SC to fill this log more quickly than the `fruhistory` subcommand can read it. This means that it is possible for some log data to be lost before it can be displayed. If this happens, the `fruhistory` subcommand displays "scadm: lost <number> bytes of fru log data" in the log output, to indicate that some data was lost.

The format for the fruhistory subcommand is:

```
scadm fruhistory [-a]
```

The `fruhistory` subcommand is not available on all platforms. If this command is used on a platform which does not support it, `scadm` prints this message:

```
scadm: command/option not supported
```

and exit with non-zero status.

help — Display a list of commands.

The format for the `help` subcommand is:

```
scadm help
```

loghistory — Display the most recent entries in the SC event log. The optional `-a` argument causes the entire event log history to be displayed. The `-a`

argument is available only on platforms which support large log files. On platforms which do not support large log files, this flag has no additional effect.

It is possible for the SC to fill this log more quickly than the `loghistory` subcommand can read it. This means that it is possible for some log data to be lost before it can be displayed. If this happens, the `loghistory` subcommand displays "scadm: lost <number> events" in the log output, to indicate that some data was lost.

The format for the `loghistory` subcommand is:

```
scadm loghistory [-a]
```

resetrsc

Reset the SC. There are two types of resets allowed, a `hard` reset and a `soft` reset.The `hard` reset is done by default. The `soft` reset can be selected by using the `-s` option.

The format for the `resetrsc` subcommand is:

```
scadm resetrsc [-s]
```

send_event

Manually send a text based event. The SC can forward the event to the SC event log. You can configure the `-c` option to send a critical warning to email, alert to logged in SC users, and `syslog`. Critical events are logged to `syslog(3C)`. There is an `80` character limit to the length of the associated text message.

The format for the `send_event` subcommand is:

```
scadm send_event [-c] "message"
```

set

Set SC configuration variables to a value.

Examples of SC configuration variables include: SC IP address `netsc_ipaddr` and SC Customer Information `sc_customerinfo`. See the output from the `scadm help` command for a complete list of SC configuration variables.

The format for the `set` subcommand is:

```
scadm set variable value
```

show

Display the current SC configuration variable settings. If no variable is specified, `scadm` shows all variable settings.

The format for the `show` subcommand is:

```
scadm show [variable]
```

shownetwork

Display the current network configuration parameters for SC.

The format for the `shownetwork` subcommand is:

```
scadm shownetwork
```

useradd — Add user accounts to the SC. The SC supports up to sixteen separate users.

The format for the `useradd` subcommand is:

```
scadm useradd username
```

userdel — Delete a user account from SC.

The format for the `userdel` subcommand is:

```
scadm userdel username
```

userpassword — Set a password for the user account specified. This password overrides any existing password currently set. There is no verification of the old password before setting the new password.

The format for the `userpassword` subcommand is:

```
scadm userpassword username
```

userperm — Set the permission level for the user.

The format for the `userperm` subcommand is:

```
scadm userperm username [aucr]
```

usershow — Display details on the specified user account. If a username is not specified, all user accounts are displayed.

The format for the `usershow` subcommand is:

```
scadm usershow username
```

version — Display the version numbers of the SC and its components.

The format for the `version` subcommand is:

```
scadm version [-v]
```

Options The `resetrsc`, `send_event`, and `version` subcommands have associated options. Options follow subcommands on the command line and are separated from the subcommand by a SPACE.

The `resetrsc` subcommand supports the following options:

`-s` Perform a soft reset instead of a hard reset. A hard reset physically resets the SC hardware. The SC software jumps to the boot firmware, simulating a reset, for a soft reset.

The `send_event` subcommand supports the following options:

`-c` Send a critical event. Without the `-c`, `-send_event` sends a warning.

The `version` subcommand supports the following options:

`-v` Display a verbose output of version numbers and associated information.

The `consolehistory`, `fruhistory`, and `loghistory` subcommands support the following option:

`-a` Display the entire log. These subcommands normally display only the most recent log data. This flag causes them to display the entire log.

Operands The `download`, `send_event`, `set`, `show`, `useradd`, `userdel`, `userperm`, `usershow`, `userpassword`, and `userperm` subcommands have associated arguments (operands).

If the subcommand has an option, the arguments follow the option on the command line and is separated from the option by a SPACE. If the subcommand does not have an option, the arguments follow the subcommand on the command line and are separated from the subcommand by a SPACE. If there are more than one arguments, they are separated from each other by a SPACE.

The `download` subcommand supports the following arguments:

boot Program the boot monitor portion of the flash. The main portion of the flash is programmed without any arguments

file Specify *file* as the path to where the boot or main firmware image resides for download.

Examples of *file* are:

`/usr/platform/`*platform_type*`/lib/image/alommainfw`

or

`/usr/platform/`*platform_type*`/lib/image/alombootfw`

The `send_event` subcommand supports the following arguments:

"*message*" Describe event using the test contained in *message*. Enclose *message* in quotation marks.

The `set` subcommand supports the following arguments:

variable Set SC configuration *variable*.

value Set SC configuration variable to *value*.

The `show` subcommand supports the following arguments:

variable Display the value of that particular variable.

The `useradd` subcommand supports the following arguments:

username Add new SC account *username*.

The `userdel` subcommand supports the following arguments:

username Remove SC account *username*.

The `userperm` subcommand supports the following arguments:

`-aucr` Set permissions for SC user accounts. If no permissions are specified, all four permissions are disabled and read only access is assigned.

The following are the definitions for permissions:

a Allow user to administer or change the SC configuration variables

u Allow user to use the user commands to modify SC accounts

c Allow user to connect to console.

r Allow user to reset SC and to power on and off the host.

username Change permissions on SC account *username*.

The `-usershow` subcommand supports the following arguments:

username Display information on SC account *username*. If *username*is not specified, all accounts are displayed.

The `userpassword` subcommand supports the following arguments:

username Set SC password for *username*.

The `userperm` subcommand supports the following arguments:

username Change SC permissions for *username*.

Examples

EXAMPLE 1 Displaying the SC's Date and Time

The following command displays the SC's date and time.

```
scadm date
```

EXAMPLE 2 Setting the SC's Configuration Variables

The following command sets the SC's configuration variable `netsc_ipaddr` to `192.168.1.2`:

```
scadm set netsc_ipaddr 192.168.1.2
```

EXAMPLE 3 Displaying the Current SC's Configuration Settings:

The following command displays the current SC configuration settings:

```
scadm show
```

EXAMPLE 4 Displaying the Current Settings for a Variable

The following command displays the current settings for the `sys_hostname` variable:

```
scadm show sys_hostname
```

EXAMPLE 5 Sending a Text-Based Critical Event

The following command sends a critical event to the SC logs, alerts the current SC users, and sends an event to `syslog(3C)`:

```
scadm send_event -c "The UPS signaled a loss in power"
```

EXAMPLE 6 Sending an Informational Text-Based Event

The following command sends an non-critical informational text based event to the SC event log:

```
scadm send_event "The disk is close to full capacity"
```

EXAMPLE 7 Adding a User To the SC

The following command adds user `rscroot` to the SC:

```
scadm useradd rscroot
```

EXAMPLE 8 Deleting a User From the SC

The following command deletes user `olduser` from the SC:

```
scadm userdel olduser
```

EXAMPLE 9 Displaying User Details

The following command displays details of all user accounts:

```
scadm usershow
```

EXAMPLE 10 Displaying Details for a Specific User

The following command displays details of user account `rscroot`:

```
scadm usershow rscroot
```

EXAMPLE 11 Setting the User Permission Level

The following command sets the full permission level for user `rscroot` to `aucr`:

```
scadm userperm rscroot aucr
```

EXAMPLE 12 Setting the User Permission Level

The following command sets only console access for user `newuser` to `c`:

```
scadm userperm newuser c
```

EXAMPLE 13 Setting the User Permission Level

The following command sets the permission level for user `newuser` to read only access:

```
scadm userperm newuser
```

EXAMPLE 14 Displaying the Current Network Parameters

The following command displays the current network configuation parameters for the SC:

```
scadm shownetwork
```

EXAMPLE 15 Viewing the Consolehistory

The following command displays the the content console in the SC event log:

```
scadm consolehistory [-a]
```

EXAMPLE 16 Viewing the Fruhistory

The following command displays the content of the "field replacable unit" in the SC event log:

```
scadm fruhistory [-a]
```

EXAMPLE 17 Viewing the Loghistory

The following command displays the most recent entries in the SC event log:

```
scadm loghistory [-a]
```

EXAMPLE 18 Displaying Verbose Information

The following command displays verbose version information on the SC and its components:

```
scadm version -v
```

Exit Status

The following exit values are returned:

`0` Successful completion.

`non-zero` An error occurred.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWkvm

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Evolving

See Also uname(1), syslog(3C), attributes(5)

Name sckmd – Sun cryptographic key management daemon

Synopsis

```
/usr/platform/sun4u/lib/sckmd
```

Description `sckmd` is a server process that resides on a high-end system domain to maintain the Internet Protocol Security (IPsec) Security Associations (SAs) needed to secure communications between a Service Processor or System Controller (SC) and platform management software running within a domain. The `cvcd`(1M) and `dcs`(1M) daemons use these Security Associations. See `ipsec`(7P) for a description of Security Associations.

The `sckmd` daemon receives SAs from the Service Processor or SC and installs these SAs in a domain's Security Association Database (SADB) using `pf_key`(7P).

`sckmd` starts up at system boot time as an SMF service. The FMRI for the `sckmd` service is:

```
svc:/platform/sun4u/sckmd:default
```

A domain supports only one running `sckmd` process at a time.

Attributes See `attributes`(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsckmx.u, SUNWsckmu.u, SUNWsckmr
Interface Stability	Evolving

See Also `cvcd`(1M), `dcs`(1M), `ipsecconf`(1M), `ipsecalgs`(1M), `attributes`(5), `ipsec`(7P), `ipsecah`(7P), `ipsecesp`(7P), `pf_key`(7P)

Notes The `sckmd` service is used only on Sun Fire high-end systems and the SPARC Enterprise Server family. It provides a mechanism for exchanging IPsec keys between a domain and its System Controller (SC) or Service Processor. These platforms use IPsec to secure the communications between the SC or Service Processor and certain platform-specific daemons in the domain. Such daemons currently include `cvcd`(1M) and `dcs`(1M).

The documentation for each platform that supports `sckmd` describes how to configure its use of `IPsec` for such communications. Also, the documentation for each specific application describes how to configure its security policies and `IPsec` options in a manner appropriate for the target platform. Refer to the platform- and application-specific documentation for detailed information.

Name sconadm – register system information

Synopsis

```
/usr/sbin/sconadm register -a
     [-e softwareUpdate | -E softwareUpdate]
     [-h hostname] [-l logfile] [-N]
     [-p proxy_host[:proxy_port]]
     [-r registration_profile] [-u username]
     [-x proxy_username]

/usr/sbin/sconadm proxy [-l logfile]
     [-p proxy_host[:proxy_port]]
     [-r registration_profile] [-x proxy_username]
```

Description The `sconadm` utility is a command-line version of the Basic Registration GUI. In the first form of the command in the SYNOPSIS, `sconadm` uses the `register` subcommand to register a host with a registration server. In the second form, `sconadm` uses the `proxy` subcommand to configure all of the components for software update to use an HTTP web proxy.

The parameters specified with `-u`, `-e` (or `-E`), `-h`, `-p`, and `-x` override values specified in your registration profile. A template for this profile, owned by root, with read-only permissions, is stored in `/usr/lib/breg/data/RegistrationProfile.properties`. See `registration_profile(4)`.

For the `proxy` subcommand, the proxy password is stored in the `RegistrationProfile.properties` file, available if proxy authentication is needed. Storage in the profile prevents proxy passwords from being exposed as part of a listing of processes on a system.

Options The following options are supported:

`-a`	Accept “Terms of Use and Binary Code License”. Absence of this option means that you do not accept the license.
`-e` softwareUpdate	Enable client to be managed at the Sun-hosted Update Connection Service.
`-E` softwareUpdate	Disable client's ability to be managed at the Sun-hosted Update Connection Service.
`-h` *hostname*	Hostname of the machine you want to register.
`-l` *logfile*	Pathname of log file.
`-N`	Never register.
`-p` *proxy_host*[:*proxy_port*]	Proxy host name and optional proxy port number.
`-r` *registration_profile*	Pathname to a registration profile.
`-u` *username*	User name (a Sun Online Account).
`-x` *proxy_username*	User name on the proxy host.

Examples

Unless specified otherwise, the commands below require root privileges or privileges equivalent to root. See `privileges(5)`.

EXAMPLE 1 Registering a New System

Assume a file `registrationprofile.properties` in `/tmp` that contains the following:

```
userName=user123
password=abc123
hostName=
subscriptionKey=
portalEnabled=false
proxyHostName=
proxyPort=
proxyUserName=
proxyPassword=
```

To register a new system using the profile above, you enter:

```
/usr/sbin/sconadm register -a -r /tmp/registrationprofile.properties
```

EXAMPLE 2 Reregistering a System with a Different User

Assume a file `registrationprofile.properties` in `/tmp` with the contents shown below. Note the changed specification for `userName` and `password`.

```
userName=newuser
password=newpassword
hostName=
subscriptionKey=
portalEnabled=false
proxyHostName=
proxyPort=
proxyUserName=
proxyPassword=
```

To reregister a new system using the profile above, you enter the same command you entered to register the system:

```
/usr/sbin/sconadm register -a -r /tmp/registrationprofile.properties
```

EXAMPLE 3 Reregistering a System, Adding a Sun Subscription Key

Modify `registrationprofile.properties` as follows:

```
userName=newuser
password=newpassword
hostName=
subscriptionKey=abc12345678
portalEnabled=false
proxyHostName=
```

EXAMPLE 3 Reregistering a System, Adding a Sun Subscription Key *(Continued)*

```
proxyPort=
proxyUserName=
proxyPassword=
```

Run the command:

```
/usr/sbin/sconadm register -a -r /tmp/registrationprofile.properties
```

EXAMPLE 4 Reregistering and Enabling Access to all Update Connection Services

Modify `registrationprofile.properties` as follows:

```
userName=newuser
password=newpassword
hostName=
subscriptionKey=abc12345678
portalEnabled=false
proxyHostName=
proxyPort=
proxyUserName=
proxyPassword=
```

Note that `portalEnabled` is set to `false`. Run the command:

```
/usr/sbin/sconadm register -a -r /tmp/registrationprofile.properties \
-e softwareUpdate
```

EXAMPLE 5 Never Registering

To never register a system, enter:

```
/usr/sbin/sconadm register -N
```

EXAMPLE 6 Using a Proxy Server With Proxy Authentication

Edit `registrationprofile.properties` as follows:

```
userName=
password=
hostName=
subscriptionKey=
portalEnabled=
proxyHostName=webcache.mycompany.com
proxyPort=8080
proxyUserName=myCompanyProxyUserName
proxyPassword=myCompanyProxyPassword
```

Run the command:

EXAMPLE 6 Using a Proxy Server With Proxy Authentication *(Continued)*

```
/usr/sbin/sconadm proxy -r /tmp/registrationprofile.properties
```

EXAMPLE 7 Changing Proxy Host Settings

Edit `registrationprofile.properties` as follows:

```
userName=
password=
hostName=
subscriptionKey=
portalEnabled=
proxyHostName=webcache.mycompany.com
proxyPort=8080
proxyUserName=myCompanyProxyUserName
proxyPassword=myCompanyProxyPassword
```

Run the command:

```
/usr/sbin/sconadm proxy -r /tmp/registrationprofile.properties
```

Then, change the `proxyHostName` value by running the following command:

```
/usr/sbin/sconadm proxy -r /tmp/registrationprofile.properties \
-p newproxy.mycompany.com
```

After the preceding command all proxies use `newproxy.mycompany.com`.

EXAMPLE 8 Resetting a System Not to Use a Proxy

Edit `registrationprofile.properties` as follows:

```
userName=
password=
hostName=
subscriptionKey=
portalEnabled=
proxyHostName=
proxyPort=
proxyUserName=
proxyPassword=
```

Note that values for all proxy fields are null.

Run the command:

```
/usr/sbin/sconadm proxy -r /tmp/registrationprofile.properties
```

Exit Status

`0` Success.

`>0` An error occurred.

Files

`/usr/lib/breg/data/RegistrationProfile.properties`
Registration profile template.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

`registration_profile(4)`, `attributes(5)`, `privileges(5)`

Name sdpadm – SDP system configuration administration

Synopsis

```
/usr/sbin/sdpadm  status | enable | disable
```

Description The `sdpadm` command is used to display the system state of the Sockets Direct Protocol (SDP) protocol. The `sdpadm` command can optionally be used to set the state of the SDP protocol. See `sdp(7D)`.

By default the SDP protocol is disabled on the system. It can be enabled by using `sdpadm enable`.

Options The following subcommands are supported:

`status` Displays the system status of the SDP protocol

`enable` Enables the SDP protocol

`disable` Disables the SDP protocol

Usage The required privileges to change the state of the SDP protocol are controlled by the network configuration policy. If a user does not have the correct privileges to set the SDP policy, `sdpadm` returns the current state of SDP without having changed the state.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWibsdpu
Interface Stability	Uncommitted

Infiniband Specification Volume 1 (`http://www.infinibandta.org`)

Name sendmail – send mail over the internet

Synopsis

```
/usr/lib/sendmail [-Ac] [-Am] [-ba] [-bD] [-bd] [-bi] [-bl]
     [-bm] [-bp] [-bP] [-bs] [-bt] [-bv] [-B type] [-C file]
     [-D logfile] [-d X] [-F fullname] [-f name] [-G]
     [-h N] [-L tag] [-M xvalue] [-N notifications] [-n]
     [-Ooption =value] [-o xvalue] [-p protocol]
     [-Q [reason]] [-q [time]] [-q Xstring] [-R ret]
     [-r name] [-t] [-V envid] [-v] [-X logfile]
     [address]...
```

Description The `sendmail` utility sends a message to one or more people, routing the message over whatever networks are necessary. `sendmail` does internetwork forwarding as necessary to deliver the message to the correct place.

`sendmail` is not intended as a user interface routine. Other programs provide user-friendly front ends. `sendmail` is used only to deliver pre-formatted messages.

With no flags, `sendmail` reads its standard input up to an EOF, or a line with a single dot, and sends a copy of the letter found there to all of the addresses listed. It determines the network to use based on the syntax and contents of the addresses.

Local addresses are looked up in the local `aliases(4)` file, or in a name service as defined by the `nsswitch.conf(4)` file, and aliased appropriately. In addition, if there is a `.forward` file in a recipient's home directory, `sendmail` forwards a copy of each message to the list of recipients that file contains. Refer to the `NOTES` section for more information about `.forward` files. Aliasing can be prevented by preceding the address with a backslash.

There are several conditions under which the expected behavior is for the alias database to be either built or rebuilt. This cannot occur under any circumstances unless root owns *and* has exclusive write permission to the `/etc/mail/aliases*` files.

If a message is found to be undeliverable, it is returned to the sender with diagnostics that indicate the location and nature of the failure; or, the message is placed in a `dead.letter` file in the sender's home directory.

Service Management The `sendmail` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/smtp:sendmail
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

Enabling Access to Remote Clients On an unmodified system, access to `sendmail` by remote clients is enabled and disabled through the service management facility (see `smf(5)`). In particular, remote access is determined by the value of the `local_only` SMF property:

```
svc:/network/smtp:sendmail/config/local_only = true
```

A setting of `true`, as above, disallows remote access; `false` allows remote access. The default value is `true`.

The following example shows the sequence of SMF commands used to enable `sendmail` to allow access to remote systems:

```
# svccfg -s svc:/network/smtp:sendmail setprop config/local_only = false
# svcadm refresh svc:/network/smtp:sendmail
# svcadm restart svc:/network/smtp:sendmail
```

See `svcadm`(1M) and `svccfg`(1M).

Note, however, on a system where any of the `sendmail`(4) files have been customized, setting this property might not have the intended effect. See `sendmail`(4) for details.

Automated Rebuilding of Configuration Files

See `sendmail`(4) for details on which service properties can be set to automate (re)building of configuration files when the service is started.

Restricting Host Access

`sendmail` uses TCP Wrappers to restrict access to hosts. It uses the service name of `sendmail` for `hosts_access()`. For more information on TCP Wrappers, see `tcpd`(1M) and `hosts_access`(4) in the `SUNWtcpd` package. `tcpd`(1M) and `hosts_access`(4) are not part of the Solaris man pages.

Startup Options

The `/etc/default/sendmail` file stores startup options for `sendmail` so that the options are not removed when a host is upgraded. See also `sendmail`(4) for details on which service properties can be set to automate (re)building of configuration files when the service is started.

You can use the following variables in the `/etc/default/sendmail` startup file:

CLIENTOPTIONS=*string*
: Selects additional options to be used with the client daemon, which looks in the client-only queue (`/var/spool/clientmqueue`) and acts as a client queue runner. No syntax checking is done, so be careful when making changes to this variable.

CLIENTQUEUEINTERVAL=*#*
: Similar to the `QUEUEINTERVAL` option, `CLIENTQUEUEINTERVAL` sets the time interval for mail queue runs. However, the `CLIENTQUEUEINTERVAL` option controls the functions of the client daemon, instead of the functions of the master daemon. Typically, the master daemon is able to deliver all messages to the SMTP port. However, if the message load is too high or the master daemon is not running, then messages go into the client-only queue, `/var/spool/clientmqueue`. The client daemon, which checks in the client-only queue, then acts as a client queue processor.

ETRN_HOSTS=*string*
: Enables an SMTP client and server to interact immediately without waiting for the queue run intervals, which are periodic. The server can immediately deliver the portion of its queue that goes to the specified hosts. For more information, refer to the `etrn`(1M) man page.

MODE=-bd
Selects the mode to start `sendmail` with. Use the `-bd` option or leave it undefined.

OPTIONS=*string*
Selects additional options to be used with the master daemon. No syntax checking is done, so be careful when making changes to this variable.

QUEUEINTERVAL=#
Sets the interval for mail queue runs on the master daemon. # can be a positive integer that is followed by either `s` for seconds, `m` for minutes, `h` for hours, `d` for days, or `w` for weeks. The syntax is checked before `sendmail` is started. If the interval is negative or if the entry does not end with an appropriate letter, the interval is ignored and `sendmail` starts with a queue interval of 15 minutes.

QUEUEOPTIONS=p
Enables one persistent queue runner that sleeps between queue run intervals, instead of a new queue runner for each queue run interval. You can set this option to `p`, which is the only setting available. Otherwise, this option is not set.

Mail Filter API

`sendmail` supports a mail filter API called "milter". For more information, see `/usr/include/libmilter/README` and http://www.milter.org

Options

The following options are supported:

`-Ac`
Uses `submit.cf` even if the operation mode does not indicate an initial mail submission.

`-Am`
Uses `sendmail.cf` even if the operation mode indicates an initial mail submission.

`-ba`
Goes into `ARPANET` mode. All input lines must end with a RETURN-LINEFEED, and all messages are generated with a RETURN-LINEFEED at the end. Also, the `From:` and `Sender:` fields are examined for the name of the sender.

`-bd`
Runs as a daemon in the background, waiting for incoming SMTP connections.

`-bD`
Runs as a daemon in the foreground, waiting for incoming SMTP connections.

`-bi`
Initializes the `aliases(4)` database. Root must own *and* have exclusive write permission to the `/etc/mail/aliases*` files for successful use of this option.

`-bl`
Runs as a daemon (like `-bd`) but accepts only loopback SMTP connections.

`-bm`
Delivers mail in the usual way (default).

`-bp`
Prints a summary of the mail queues.

`-bP`
Prints the number of entries in the queues. This option is only available with shared memory support.

`-bs`
Uses the SMTP protocol as described in RFC 2821. This flag implies all the operations of the `-ba` flag that are compatible with SMTP.

`-bt`
Runs in address test mode. This mode reads addresses and shows the steps in parsing; it is used for debugging configuration tables.

`-bv`
Verifies names only. Does not try to collect or deliver a message. Verify mode is normally used for validating users or mailing lists.

`-B` *type*
Indicates body *type* (`7BIT` or `8BITMIME`).

`-C` *file*
Uses alternate configuration file.

`-D` *logfile*
Send debugging output to the indicated log file instead of `stdout`.

`-d` *X*
Sets debugging value to *X*.

`-f` *name*
Sets the name of the "from" person (that is, the sender of the mail).

`-F` *fullname*
Sets the full name of the sender.

`-G`
When accepting messages by way of the command line, indicates that they are for relay (gateway) submission. When this flag is set, `sendmail` might complain about syntactically invalid messages, for example, unqualified host names, rather than fixing them. `sendmail` does not do any canonicalization in this mode.

`-h` *N*
Sets the hop count to *N*. The hop count is incremented every time the mail is processed. When it reaches a limit, the mail is returned with an error message, the victim of an aliasing loop.

`-L` *tag*
Sets the identifier used in `syslog` messages to the supplied *tag*.

`-M`*xvalue*
Sets macro *x* to the specified *value*.

`-n`
Does not do aliasing.

`-N` *notifications*
Tags all addresses being sent as wanting the indicated *notifications*, which consists of the word "NEVER" or a comma-separated list of "SUCCESS", "FAILURE", and "DELAY" for successful delivery, failure and a message that is stuck in a queue somwhere. The default is "FAILURE,DELAY".

`-o`*xvalue*
Sets option *x* to the specified *value*. `Processing Options` are described below.

`-O`*option*=*value*
Sets *option* to the specified *value* (for long from names). `Processing Options` are described below.

`-p` *protocol*
Sets the sending protocol. The *protocol* field can be in form *protocol*`:`*host* to set both the sending protocol and the sending host. For example: `-pUUCP:uunet` sets the sending *protocol* to `UUCP` and the sending host to `uunet`. Some existing programs use `-oM` to set the *r* and *s* macros; this is equivalent to using `-p`.

`-q`[*time*]
Processes saved messages in the queue at given intervals. If *time* is omitted, processes the queue once. *time* is given as a tagged number, where *s* is seconds, *m* is minutes, *h* is hours, *d* is days, and *w* is weeks. For example, `-q1h30m` or `-q90m` would both set the timeout to one hour thirty minutes.

By default, sendmail runs in the background. This option can be used safely with `-bd`.

`-qp[`*time*`-]`
Similar to `-q`[*time*], except that instead of periodically forking a child to process the queue, `sendmail` forks a single persistent child for each queue that alternates between processing the queue and sleeping. The sleep time (*time*) is specified as the argument; it defaults to `1` second. The process always sleeps at least `5` seconds if the queue was empty in the previous queue run.

`-qf`
Processes saved messages in the queue once and does not `fork(2)`, but runs in the foreground.

`-qG` *name*
Processes jobs in queue group called *name* only.

`-q[!]I` *substr*
Limits processed jobs to those containing *substr* as a substring of the queue ID or not when `!` is specified.

`-q[!]Q` *substr*
Limits processed jobs to those quarantined jobs containing *substr* as a substring of the quarantine *reason* or not when `!` is specified.

`-q[!]R` *substr*
Limits processed jobs to those containing *substr* as a substring of one of the recipients or not when `!` is specified.

`-q[!]S` *substr*
Limits processed jobs to those containing *substr* as a substring of the sender or not when `!` is specified.

`-Q`[*reason*]
Quarantines a normal queue item with the given reason or unquarantines a quarantined queue item if no reason is given. This should only be used with some sort of item matching as described above.

`-r` *name*
An alternate and obsolete form of the `-f` flag.

`-R` *ret*
Identifies the information you want returned if the message bounces. *ret* can be `HDRS` for headers only or `FULL` for headers plus body.

`-t`
Reads message for recipients. `To:`,`Cc:`, and `Bcc:` lines are scanned for people to send to. The `Bcc:` line is deleted before transmission. Any addresses in the argument list is suppressed. The `NoRecipientAction` Processing Option can be used to change the behavior when no legal recipients are included in the message.

`-v`
Goes into verbose mode. Alias expansions are announced, and so forth.

`-V` *envid*
The indicated *envid* is passed with the envelope of the message and returned if the message bounces.

`-X` *logfile*
Logs all traffic in and out of `sendmail` in the indicated *logfile* for debugging mailer problems. This produces a lot of data very quickly and should be used sparingly.

Processing Options

There are a number of "random" options that can be set from a configuration file. Options are represented by a single character or by multiple character names. The syntax for the single character names of is:

`O`*xvalue*

This sets option *x* to be *value*. Depending on the option, *value* may be a string, an integer, a boolean (with legal values `t`, `T`, `f`, or `F`; the default is `TRUE`), or a time interval.

The multiple character or long names use this syntax:

`O` *Longname=argument*

This sets the option *Longname* to be *argument*. The long names are beneficial because they are easier to interpret than the single character names.

Not all processing options have single character names associated with them. In the list below, the multiple character name is presented first followed by the single character syntax enclosed in parentheses.

`AliasFile (A`*file*`)`
Specifies possible alias files.

`AliasWait (a` *N*`)`
If set, waits up to *N* minutes for an "@:@" entry to exist in the `aliases(4)` database before starting up. If it does not appear in *N* minutes, issues a warning. Defaults to 10 minutes.

`AllowBogusHELO`
Allows a `HELO SMTP` command that does not include a host name. By default this option is disabled.

`BadRcptThrottle=`*N*
If set and more than the specified number of recipients in a single SMTP envelope are rejected, sleeps for one second after each rejected RCPT command.

`BlankSub (B`*c*`)`
Sets the blank substitution character to *c*. Unquoted spaces in addresses are replaced by this character. Defaults to SPACE (that is, no change is made).

`CACertFile`
File containing one CA cert.

`CACertPath`
Path to directory with certs of CAs.

`CheckAliases (n)`
Validates the RHS of aliases when rebuilding the `aliases(4)` database.

`CheckpointInterval (C`*N*`)`
Checkpoints the queue every *N* (default `10`) addresses sent. If your system crashes during delivery to a large list, this prevents retransmission to any but the last *N* recipients.

`ClassFactor (z`*fact*`)`
The indicated factor *fact* is multiplied by the message class (determined by the `Precedence:` field in the user header and the `P` lines in the configuration file) and subtracted from the priority. Thus, messages with a higher `Priority:` are favored. Defaults to `1800`.

`ClientCertFile`
File containing the cert of the client, that is, this cert is used when `sendmail` acts as client.

`ClientKeyFile`
File containing the private key belonging to the client cert.

`ClientPortOptions`
Sets client SMTP options. The options are key=value pairs. Known keys are:

`Addr` *Address Mask*
Address Mask defaults to `INADDR_ANY`. The address mask can be a numeric address in dot notation or a network name.

`Family`
Address family (defaults to INET).

`Listen`
Size of listen queue (defaults to 10).

`Port`
Name/number of listening port (defaults to `smtp`).

`RcvBufSize`
The size of the TCP/IP receive buffer.

`SndBufSize`
The size of the TCP/IP send buffer.

`Modifier`
Options (flags) for the daemon. Can be:

`h`
Uses name of interface for `HELO` command.

If `h` is set, the name corresponding to the outgoing interface address (whether chosen by means of the `Connection` parameter or the default) is used for the `HELO`/`EHLO` command.

`ColonOkInAddr`
If set, colons are treated as a regular character in addresses. If not set, they are treated as the introducer to the RFC 822 "group" syntax. This option is on for version 5 and lower configuration files.

`ConnectionCacheSize (k`*N*`)`
The maximum number of open connections that are to be cached at a time. The default is `1`. This delays closing the current connection until either this invocation of `sendmail` needs to connect to another host or it terminates. Setting it to `0` defaults to the old behavior, that is, connections are closed immediately.

`ConnectionCacheTimeout (K`*timeout*`)`
The maximum amount of time a cached connection is permitted to idle without activity. If this time is exceeded, the connection is immediately closed. This value should be small (on the order of ten minutes). Before `sendmail` uses a cached connection, it always sends a `NOOP` (no operation) command to check the connection. If the `NOOP` command fails, it reopens the connection. This keeps your end from failing if the other end times out. The

point of this option is to be a good network neighbor and avoid using up excessive resources on the other end. The default is five minutes.

`ConnectionRateThrottle`
The maximum number of connections permitted per second. After this many connections are accepted, further connections are delayed. If not set or <= 0, there is no limit.

`ConnectionRateWindowSize`
Define the length of the interval for which the number of incoming connections is maintained. The default is 60 seconds.

`ControlSocketName`
Name of the control socket for daemon management. A running `sendmail` daemon can be controlled through this Unix domain socket. Available commands are: `help`, `restart`, `shutdown`, and `status`. The `status` command returns the current number of daemon children, the free disk space (in blocks) of the queue directory, and the load average of the machine expressed as an integer. If not set, no control socket is available. For the sake of security, this Unix domain socket must be in a directory which is accessible only by root; `/var/spool/mqueue/.smcontrol` is recommended for the socket name.

`CRLFile`
File containing certificate revocation status, useful for X.509v3 authentication.

`DaemonPortOptions (O`*options*`)`
Sets server SMTP options. The options are *key=value* pairs. Known keys are:

`Name`
User-definable name for the daemon (defaults to "`Daemon#`"). Used for error messages and logging.

`Addr`
Address mask (defaults `INADDR_ANY`).

The address mask may be a numeric address in dot notation or a network name.

`Family`
Address family (defaults to `INET`).

`InputMailFilters`
List of input mail filters for the daemon.

`Listen`
Size of listen queue (defaults to `10`).

`Modifier`
Options (flags) for the daemon; can be a sequence (without any delimiters) of:

`a`
Requires authentication.

`b`
Binds to interface through which mail has been received.

`c`
Performs hostname canonification (`.cf`).

`f`
Requires fully qualified hostname (`.cf`).

`h`
Uses name of interface for `HELO` command.

`u`
Allows unqualified addresses (`.cf`).

`C`
Does not perform hostname canonification.

`E`
Disallows `ETRN` (see RFC 2476).

`Name`
User-definable name for the daemon (defaults to `Daemon#`). Used for error messages and logging.

`Port`
Name/number of listening port (defaults to `smtp`).

`ReceiveSize`
The size of the TCP/IP receive buffer.

`SendSize`
The size of the TCP/IP send buffer.

`children`
Maximum number of children per daemon. See `MaxDaemonChildren`.

`DeliveryMode`
Delivery mode per daemon. See `DeliveryMode`.

`refuseLA`
`RefuseLA` per daemon.

`delayLA`
`DelayLA` per daemon.

`queueLA`
`QueueLA` per daemon.

`sendmail` listens on a new socket for each occurrence of the `DaemonPortOptions` option in a configuration file.

`DataFileBufferSize`
Sets the threshold, in bytes, before a memory-bases queue data file becomes disk-based. The default is 4096 bytes.

`DeadLetterDrop`
Defines the location of the system-wide dead.letter file, formerly hard-coded to `/var/tmp/dead.letter`. If this option is not set (the default), `sendmail` does not attempt to save to a system-wide `dead.letter` file in the event it cannot bounce the mail to the user or postmaster. Instead, it renames the `qf` file as it has in the past when the `dead.letter` file could not be opened.

`DefaultCharSet`
Sets the default character set to use when converting unlabeled 8 bit input to MIME.

`DefaultUser (g`*gid*`) or (u`*uid*`)`
Sets the default group ID for mailers to run in to *gid* or set the default userid for mailers to *uid*. Defaults to `1`. The value can also be given as a symbolic group or user name.

`DelayLA=`*LA*
When the system load average exceeds *LA*, `sendmail` sleeps for one second on most SMTP commands and before accepting connections.

`DeliverByMin=`*time*
Sets minimum time for `Deliver By SMTP Service Extension` (RFC 2852). If `0`, no time is listed, if less than `0`, the extension is not offered, if greater than `0`, it is listed as minimum time for the `EHLO` keyword `DELIVERBY`.

`DeliveryMode (d`*x*`)`
Delivers in mode *x*. Legal modes are:

`i`
Delivers interactively (synchronously).

`b`
Delivers in background (asynchronously).

`d`
Deferred mode. Database lookups are deferred until the actual queue run.

`q`
Just queues the message (delivers during queue run).

Defaults to `b` if no option is specified, `i` if it is specified but given no argument (that is, `Od` is equivalent to `Odi`).

`DHParameters`
File containing the DH parameters.

`DialDelay`
If a connection fails, waits this many seconds and tries again. Zero means “do not retry”.

`DontBlameSendmail`
If set, overrides the file safety checks. This compromises system security and should not be used. See http://www.sendmail.org/tips/DontBlameSendmail.php for more information.

`DontExpandCnames`
If set, $[... $] lookups that do DNS-based lookups do not expand CNAME records.

`DontInitGroups`
If set, the `initgroups(3C)` routine is never invoked. If you set this, agents run on behalf of users only have their primary (`/etc/passwd`) group permissions.

`DontProbeInterfaces`
If set, `sendmail` does not insert the names and addresses of any local interfaces into the `$=w class`. If set, you must also include support for these addresses, otherwise mail to addresses in this list bounces with a configuration error.

`DontPruneRoutes (R)`
If set, does not prune route-addr syntax addresses to the minimum possible.

`DoubleBounceAddress`
If an error occurs when sending an error message, sends that "double bounce" error message to this address.

`EightBitMode (8)`
Uses 8–bit data handling. This option requires one of the following keys. The key can selected by using just the first character, but using the full word is better for clarity.

`mimify`
Does any necessary conversion of `8BITMIME` to 7–bit.

`pass`
Passes unlabeled 8–bit input through as is.

`strict`
Rejects unlabeled 8–bit input.

`ErrorHeader (E`*file/message*`)`
Appends error messages with the indicated message. If it begins with a slash, it is assumed to be the pathname of a file containing a message (this is the recommended setting). Otherwise, it is a literal message. The error file might contain the name, email address, and/or phone number of a local postmaster who could provide assistance to end users. If the option is missing or `NULL`, or if it names a file which does not exist or which is not readable, no message is printed.

`ErrorMode (e`*x*`)`
Disposes of errors using mode *x*. The values for *x* are:

`e`
Mails back errors and gives `0` exit status always.

`m`
Mails back errors.

`p`
Prints error messages (default).

`q`
No messages, just gives exit status.

`w`
Writes back errors (mail if user not logged in).

`FallbackMXhost (V`*fallbackhost*`)`
If specified, the *fallbackhost* acts like a very low priority MX on every host. This is intended to be used by sites with poor network connectivity.

`FallBackSmartHost`
If specified, the *fallBackSmartHost* is used in a last-ditch effort for each host. This is intended to be used by sites with "fake internal DNS". That is, a company whose DNS accurately reflects the world inside that company's domain but not outside.

`FastSplit`
If set to a value greater than zero (the default is one), it suppresses the MX lookups on addresses when they are initially sorted, that is, for the first delivery attempt. This usually results in faster envelope splitting unless the MX records are readily available in a local DNS cache. To enforce initial sorting based on MX records set `FastSplit` to zero. If the mail is submitted directly from the command line, then the value also limits the number of processes to deliver the envelopes; if more envelopes are created they are only queued up and must be taken care of by a queue run. Since the default submission method is by way of SMTP (either from a MUA or by way of the Message Submission Program [MSP]), the value of `FastSplit` is seldom used to limit the number of processes to deliver the envelopes.

`ForkEachJob (Y)`
If set, delivers each job that is run from the queue in a separate process. Use this option if you are short of memory, since the default tends to consume considerable amounts of memory while the queue is being processed.

`ForwardPath (J`*path*`)`
Sets the path for searching for users' `.forward` files. The default is `$z/.forward`. Some sites that use the automounter may prefer to change this to `/var/forward/$u` to search a file with the same name as the user in a system directory. It can also be set to a sequence of paths separated by colons; `sendmail` stops at the first file it can successfully and safely open. For example, `/var/forward/$u:$z/.forward` searches first in `/var/forward/` *username* and then in *~username*`/.forward` (but only if the first file does not exist). Refer to the NOTES section for more information.

`HeloName=`*name*
Sets the name to be used for `HELO`/`EHLO` (instead of `$j`).

`HelpFile (H`*file*`)`
Specifies the help file for SMTP.

`HoldExpensive (c)`
If an outgoing mailer is marked as being expensive, does not connect immediately.

`HostsFile`
Sets the file to use when doing "file" type access of host names.

`HostStatusDirectory`
If set, host status is kept on disk between `sendmail` runs in the named directory tree. If a full path is not used, then the path is interpreted relative to the queue directory.

`IgnoreDots (i)`
Ignores dots in incoming messages. This is always disabled (that is, dots are always accepted) when reading SMTP mail.

`LogLevel (L`*n*`)`
Sets the default log level to *n*. Defaults to `9`.

`(M`*x value*`)`
Sets the macro *x* to *value*. This is intended only for use from the command line.

`MailboxDatabase`
Type of lookup to find information about local mail boxes, defaults to `pw` which uses `getpwnam(3C)`. Other types can be introduced by adding them to the source code, see `libsm/mbdb.c` for details.

`MatchGECOS (G)`
Tries to match recipient names using the GECOS field. This allows for mail to be delivered using names defined in the GECOS field in `/etc/passwd` as well as the login name.

`MaxDaemonChildren`
The maximum number of children the daemon permits. After this number, connections are rejected. If not set or <=0, there is no limit.

`MaxHopCount (h`*N*`)`
The maximum hop count. Messages that have been processed more than *N* times are assumed to be in a loop and are rejected. Defaults to `25`.

`MaxMessageSize`
The maximum size of messages that are accepted (in bytes).

`MaxMimeHeaderLength=`*M*`[/`*N*`]`
Sets the maximum length of certain MIME header field values to *M* characters. For some of these headers which take parameters, the maximum length of each parameter is set to *N* if specified. If `/`*N* is not specified, one half of *M* is used. By default, these values are `0`, meaning no checks are done.

`MaxNOOPCommands=`*N*
Overrides the default of 20 for the number of useless commands.

`MaxQueueChildren=`*N*
When set, this limits the number of concurrent queue runner processes to *N*. This helps to control the amount of system resources used when processing the queue. When there are multiple queue groups defined and the total number of queue runners for these queue groups would exceed `MaxQueueChildren` then the queue groups are not all run concurrently. That is, some portion of the queue groups run concurrently such that `MaxQueueChildren` is not be exceeded, while the remaining queue groups are run later (in round robin order). See `MaxRunnersPerQueue`.

`MaxQueueRunSize`
If set, limits the maximum size of any given queue run to this number of entries. This stops reading the queue directory after this number of entries is reached; job priority is not used. If not set, there is no limit.

`MaxRunnersPerQueue=`*N*
This sets the default maximum number of queue runners for queue groups. Up to *N* queue runners work in parallel on a queue group's messages. This is useful where the processing of a message in the queue might delay the processing of subsequent messages. Such a delay can be the result of non-erroneous situations such as a low bandwidth connection. The can be overridden on a per queue group basis by setting the `Runners` option. The default is `1` when not set.

`MeToo (M)`
Sends to me too, even if I am in an alias expansion.

`MaxRecipientsPerMessage`
If set, allows no more than the specified number of recipients in an SMTP envelope. Further recipients receive a 452 error code and are deferred for the next delivery attempt.

`MinFreeBlocks (b`*N*`/`*M*`)`
Insists on at least *N* blocks free on the file system that holds the queue files before accepting email by way of SMTP. If there is insufficient space, `sendmail` gives a `452` response to the `MAIL` command. This invites the sender to try again later. The optional *M* is a maximum message size advertised in the `ESMTP EHLO` response. It is currently otherwise unused.

`MinQueueAge`
Specifies the amount of time a job must sit in the queue between queue runs. This allows you to set the queue run interval low for better responsiveness without trying all jobs in each run. The default value is 0.

`MustQuoteChars`
Specifies the characters to be quoted in a full name phrase. `&,;:\()[]` are quoted automatically.

`NiceQueueRun`
Specifies the priority of queue runners. See `nice(1)`.

`NoRecipientAction`
Sets action if there are no legal recipient files in the message. The legal values are:

`add-apparently-to`
Adds an `Apparently-to:` header with all the known recipients (which may expose blind recipients).

`add-bcc`
Adds an empty `Bcc:` header.

`add-to`
Adds a `To:` header with all the known recipients (which may expose blind recipients).

`add-to-undisclosed`
Adds a `To: undisclosed-recipients:` header.

`none`
Does nothing, that is, leaves the message as it is.

`OldStyleHeaders (o)`
Assumes that the headers may be in old format, that is, spaces delimit names. This actually turns on an adaptive algorithm: if any recipient address contains a comma, parenthesis, or angle bracket, it is assumed that commas already exist. If this flag is not on, only commas delimit names. Headers are always output with commas between the names.

`OperatorChars or $o`
Defines the list of characters that can be used to separate the components of an address into tokens.

`PidFile`
Specifies the filename of the `pid` file. The default is `/var/run/sendmail.pid`. The filename is macro-expanded before it is opened, and unlinked when `sendmail` exits.

`PostmasterCopy (P`*`postmaster`*`)`
If set, copies of error messages are sent to the named *postmaster*. Only the header of the failed message is sent. Since most errors are user problems, this is probably not a good idea on large sites, and arguably contains all sorts of privacy violations, but it seems to be popular with certain operating systems vendors.

`PrivacyOptions (p`*`opt,opt,...`*`)`
Sets privacy options. Privacy is really a misnomer; many of these options are just a way of insisting on stricter adherence to the SMTP protocol.

The `goaway` pseudo-flag sets all flags except `noreceipts`, `restrictmailq`, `restrictqrun`, `restrictexpand`, `noetrn`, and `nobodyreturn`. If `mailq` is restricted, only people in the same group as the queue directory can print the queue. If queue runs are restricted, only root and the owner of the queue directory can run the queue. The `restrict-expand` pseudo-flag instructs sendmail to drop privileges when the -bv option is given by users who are neither root nor the `TrustedUser` so users cannot read private aliases, forwards, or `:include:` files. It adds the `NonRootSafeAddr` to the "DontBlame-Sendmail" option to prevent misleading unsafe address warnings. It also overrides the `-v` (verbose) command line option to prevent

information leakage. Authentication Warnings add warnings about various conditions that may indicate attempts to fool the mail system, such as using an non-standard queue directory.

The options can be selected from:

`authwarnings`
Puts `X-Authentication-Warning:` headers in messages.

`goaway`
Disallows essentially all SMTP status queries.

`needexpnhelo`
Insists on `HELO` or `EHLO` command before `EXPN`.

`needmailhelo`
Insists on `HELO` or `EHLO` command before `MAIL`.

`needvrfyhelo`
Insists on `HELO` or `EHLO` command before `VRFY`.

`noactualrecipient`
Do not put an X-Actual-Recipient line in a DNS that reveals the actual account to which an address is mapped.

`noetrn`
Disallows `ETRN` entirely.

`noexpn`
Disallows `EXPN` entirely.

`noreceipts`
Prevents return receipts.

`nobodyreturn`
Does not return the body of a message with DSNs.

`novrfy`
Disallows `VRFY` entirely.

`public`
Allows open access.

`restrictexpand`
Restricts `-bv` and `-v` command line flags.

`restrictmailq`
Restricts `mailq` command.

`restrictqrun`
Restricts `-q` command line flag.

`ProcessTitlePrefix` *string*
Prefixes the process title shown on "`/usr/ucb/ps auxww`" listings with *string*. The string is macro processed.

`QueueDirectory (Q`*dir*`)`
Uses the named *dir* as the queue directory.

`QueueFactor (q`*factor*`)`
Uses *factor* as the multiplier in the map function to decide when to just queue up jobs rather than run them. This value is divided by the difference between the current load average and the load average limit (`x` flag) to determine the maximum message priority to be sent. Defaults to `600000`.

`QueueFileMode=`*mode*
Defaults permissions for queue files (octal). If not set, `sendmail` uses `0600` unless its real and effective `uid` are different in which case it uses `0644`.

`QueueLA (x`*LA*`)`
When the system load average exceeds *LA*, just queues messages (that is, does not try to send them). Defaults to eight times the number of processors online when `sendmail` starts.

`QueueSortOrder=`*algorithm*
Sets the algorithm used for sorting the queue. Only the first character of the value is used. Legal values are `host` (to order by the name of the first host name of the first recipient), `filename` (to order by the name of the queue file name), `time` (to order by the submission/creation time), `random` (to order randomly), `modification` (to order by the modification time of the `qf` file (older entries first)), `none` (to not order), and `priority` (to order by message priority). Host ordering makes better use of the connection cache, but may tend to process low priority messages that go to a single host over high priority messages that go to several hosts; it probably shouldn't be used on slow network links. Filename and modification time ordering saves the overhead of reading all of the queued items before starting the queue run. Creation (submission) time ordering is almost always a bad idea, since it allows large, bulk mail to go out before smaller, personal mail, but may have applicability on some hosts with very fast connections. Random is useful if several queue runners are started by hand which try to drain the same queue since odds are they are working on different parts of the queue at the same time. Priority ordering is the default.

`QueueTimeout (T`*rtime*`/`*wtime*`)`
Sets the queue timeout to *rtime*. After this interval, messages that have not been successfully sent are returned to the sender. Defaults to five days (`5d`). The optional *wtime* is the time after which a warning message is sent. If it is missing or `0`, then no warning messages are sent.

`RandFile`
File containing random data (use prefix `file:`) or the name of the UNIX socket if EGD is used (use prefix `egd:`). Note that Solaris supports `random(7D)`, so this does not need to be specified.

`RecipientFactor (y`*fact*`)`
The indicated factor *fact* is added to the priority (thus *lowering* the priority of the job) for each recipient, that is, this value penalizes jobs with large numbers of recipients. Defaults to `30000`.

`RefuseLA (X`*LA*`)`
When the system load average exceeds *LA*, refuses incoming SMTP connections. Defaults to 12 times the number of processors online when `sendmail` starts.

`RejectLogInterval`
Log interval when refusing connections for this long (default: 3h).

`ResolverOptions (I)`
Tunes DNS lookups.

`RetryFactor (Z`*fact*`)`
The indicated factor *fact* is added to the priority every time a job is processed. Thus, each time a job is processed, its priority is decreased by the indicated value. In most environments this should be positive, since hosts that are down are all too often down for a long time. Defaults to `90000`.

`RrtImpliesDsn`
If this option is set, a `Return-Receipt-To:` header causes the request of a DSN, which is sent to the envelope sender as required by RFC 1891, not to the address given in the header.

`RunAsUser`
If set, becomes this user when reading and delivering mail. Intended for use of firewalls where users do not have accounts.

`SafeFileEnvironment`
If set, `sendmail` does a `chroot` into this directory before writing files.

`SaveFromLine (f)`
Saves Unix-style `From` lines at the front of headers. Normally they are assumed redundant and discarded.

`SendMimeErrors (j)`
If set, sends error messages in MIME format (see RFC 2045 and RFC 1344 for details). If disabled, `sendmail` does not return the DSN keyword in response to an `EHLO` and does not do Delivery Status Notification processing as described in RFC 1891.

`ServerCertFile`
File containing the cert of the server, that is, this cert is used when `sendmail` acts as server.

`ServerKeyFile`
File containing the private key belonging to the server cert.

`ServiceSwitchFile`
Defines the path to the service-switch file. Since the service-switch file is defined in the Solaris operating environment this option is ignored.

`SevenBitInput (7)`
Strips input to seven bits for compatibility with old systems. This should not be necessary.

`SharedMemoryKey`
Specifies key to use for shared memory segment. If not set (or `0`), shared memory is not be used. If this option is set, `sendmail` can share some data between different instances. For example, the number of entries in a queue directory or the available space in a file system. This allows for more efficient program execution, since only one process needs to update the data instead of each individual process gathering the data each time it is required.

`SharedMemoryKeyFile=`*file*
If `SharedMemoryKeyFile` is set to `-1`, the automatically selected shared memory key will be stored in the specified file.

`SingleLineFromHeader`
If set, `From:` lines that have embedded newlines are unwrapped onto one line.

`SingleThreadDelivery`
If this option and the `HostStatusDirectory` option are both set, uses single thread deliveries to other hosts.

`SmtpGreetingMessage or $e`
Specifies the initial SMTP greeting message.

`SoftBounce`
If set, issue temporary errors (`4xy`) instead of permanent errors (`5xy`). This can be useful during testing of a new configuration to avoid erroneous bouncing of mail.

`StatusFile (S`*file*`)`
Logs statistics in the named *file*. By default, this is `/etc/mail/sendmail.st`. As root, you must `touch(1)` this file to enable `mailstats(1)`.

`SuperSafe (s)`
This option can be set to `True`, `False`, `Interactive`, or `PostMilter`. If set to `True`, `sendmail` is set to super-safe when running things, that is, always instantiate the queue file, even if you are going to attempt immediate delivery. `sendmail` always instantiates the queue file before returning control to the client under any circumstances. This should really always be set to `True`. The `Interactive` value has been introduced in `8.12` and can be used together with `DeliveryMode=i`. It skips some synchronization calls which are effectively doubled in the code execution path for this mode. If set to `PostMilter`, `sendmail` defers synchronizing the queue file until any milters have signaled acceptance of the message. `PostMilter` is useful only when `sendmail` is running as an SMTP server; in all other situations it acts the same as True.

`TempFileMode (F`*mode*`)`
Specifies the file mode for queue files.

`Timeout (r`*timeouts*`)`
Timeout reads after time interval. The *timeouts* argument is a list of *keyword=value* pairs. All but *command* apply to client SMTP. For backward compatibility, a timeout with no

keyword= part is set all of the longer values. The recognized timeouts and their default values, and their minimum values specified in RFC 1123 section 5.3.2 are:

`aconnect`
all connections for a single delivery attempt [0, unspecified]

`command`
command read [1h, 5m]

`connect`
initial connect [0, unspecified]

`control`
complete control socket transaction [2m, none]

`datablock`
data block read [1h, 3m]

`datafinal`
reply to final `.` in data [1h, 10m]

`datainit`
reply to `DATA` command [5m, 2m]

`fileopen`
file open [60sec, none]

`helo`
reply to `HELO` or `EHLO` command [5m, none]

`hoststatus`
host retry [30m, unspecified]

`iconnect`
first attempt to connect to a host [0, unspecified]

`ident`
`IDENT` protocol timeout [5s, none]

`initial`
wait for initial greeting message [5m, 5m]

`lhlo`
wait for reply to an LMTP LHLO command [2m, unspecified]

`mail`
reply to `MAIL` command [10m, 5m]

`misc`
reply to `NOOP` and `VERB` commands [2m, none]

`queuereturn`
undeliverable message returned [5d]

`queuewarn`
deferred warning [4h]

`quit`
reply to `QUIT` command [2m, none]

`rcpt`
reply to `RCPT` command [1h, 5m]

`resolver.retrans`
Resolver's retransmission time interval (in seconds) [varies]. Sets both `Timeout.resolver.retrans.first` and `Timeout.resolver.retrans.normal`.

`resolver.retrans.first`
Resolver's retransmission time interval (in seconds) for the first attempt to deliver a message [varies].

`resolver.retrans.normal`
Resolver's retransmission time interval (in seconds) for all look-ups except the first delivery attempt [varies].

`resolver.retry`
Number of times to retransmit a resolver query [varies]. Sets both `Timeout.resolver.retry.first` and `Timeout.resolver.retry.normal`.

`resolver.retry.first`
Number of times to retransmit a resolver query for the first attempt to deliver a message [varies].

`resolver.retry.normal`
Number of times to retransmit a resolver query for all look-ups except the first delivery attempt [varies].

`rset`
reply to `RSET` command [5m, none]

`starttls`
response to an `SMTP STARTTLS` command [1h]

`TimeZoneSpec (t`*tzinfo*`)`
Sets the local time zone info to *tzinfo*, for example, "PST8PDT". Actually, if this is not set, the `TZ` environment variable is cleared (so the system default is used); if set but null, the user's `TZ` variable is used, and if set and non-null, the `TZ` variable is set to this value.

`TLSSrvOptions`
If this option is '`V`', then no client verification is performed,that is, the server does not ask for a certificate.

`TrustedUser`
The user parameter can be a user name (looked up in the passwd map) or a numeric user id. Trusted user for file ownership and starting the daemon. If set, generated alias databases and the control socket (if configured) are automatically owned by this user.

`TryNullMXList (w)`
If you are the "best" (that is, lowest preference) MX for a given host, you should normally detect this situation and treat that condition specially, by forwarding the mail to a UUCP feed, treating it as local, or whatever. However, in some cases (such as Internet firewalls) you may want to try to connect directly to that host as though it had no MX records at all. Setting this option causes `sendmail` to try this. The downside is that errors in your configuration are likely to be diagnosed as "host unknown" or "message timed out" instead of something more meaningful. This option is deprecated.

`UnixFromLine or $l`
The "From " line used when sending to files or programs.

`UnsafeGroupWrites`
If set, group-writable :include: and .forward files are considered "unsafe", that is, programs and files cannot be directly referenced from such files.

`UseErrorsTo (l)`
If there is an `Errors-To`: header, sends error messages to the addresses listed there. They normally go to the envelope sender. Use of this option causes `sendmail` to violate RFC 1123. This option is not recommended and deprecated.

`UseMSP`
Uses as mail submission program, that is, allows group writable queue files if the group is the same as that of a set-group-id `sendmail` binary.

`UserDatabaseSpec (U)`
Defines the name and location of the file containing User Database information.

`Verbose (v)`
Runs in verbose mode. If this is set, `sendmail` adjusts the `HoldExpensive` and `DeliveryMode` options so that all mail is delivered completely in a single job so that you can see the entire delivery process. The `Verbose` option should *never* be set in the configuration file; it is intended for command line use only.

`XscriptFileBufferSize`
Sets the threshold, in bytes, before a memory-bases queue transcript file becomes disk-based. The default is 4096 bytes.

If the first character of the user name is a vertical bar, the rest of the user name is used as the name of a program to pipe the mail to. It may be necessary to quote the name of the user to keep `sendmail` from suppressing the blanks from between arguments.

If invoked as `newaliases`, `sendmail` rebuilds the alias database, so long as the `/etc/mail/aliases*` files are owned by root *and* root has exclusive write permission. If invoked as `mailq`, `sendmail` prints the contents of the mail queue.

Operands

address
address of an intended recipient of the message being sent.

Usage

See `largefile(5)` for the description of the behavior of `sendmail` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Exit Status

`sendmail` returns an exit status describing what it did. The codes are defined in `/usr/include/sysexits.h`.

`EX_OK`
Successful completion on all addresses.

`EX_NOUSER`
User name not recognized.

`EX_UNAVAILABLE`
Catchall. Necessary resources were not available.

`EX_SYNTAX`
Syntax error in address.

`EX_SOFTWARE`
Internal software error, including bad arguments.

`EX_OSERR`
Temporary operating system error, such as “cannot fork”.

`EX_NOHOST`
Host name not recognized.

`EX_TEMPFAIL`
Message could not be sent immediately, but was queued.

Environment Variables

No environment variables are used. However, sendmail's start-up script, invoked by `svcadm(1M)`, reads `/etc/default/sendmail`. In this file, if the variable `ETRN_HOSTS` is set, the start-up script parses this variable and invokes `etrn(1M)` appropriately. `ETRN_HOSTS` should be of the form:

```
"s1:c1.1,c1.2        s2:c2.1 s3:c3.1,c3.2,c3.3"
```

That is, white-space separated groups of *server:client* where *client* can be one or more comma-separated names. The *:client* part is optional. *server* is the name of the server to prod; a mail queue run is requested for each *client* name. This is comparable to running:

```
/usr/lib/sendmail -qR client
```

on the host *server*.

Files

`dead.letter`
Unmailable text

`/etc/default/sendmail`
Contains default settings. You can override some of the settings by command line options.

`/etc/mail/aliases`
Mail aliases file (ASCII)

`/etc/mail/aliases.db`
Database of mail aliases (binary)

`/etc/mail/aliases.dir`
Database of mail aliases (binary)

`/etc/mail/aliases.pag`
Database of mail aliases (binary)

`/etc/mail/sendmail.cf`
Defines environment for `sendmail`

`/etc/mail/submit.cf`
Defines environment for MSP

`/etc/mail/trusted-users`
Lists users that are "trusted", that is, able to set their envelope from address using `-f` without generating a warning message. Note that this file is consulted by the default `sendmail.cf`, but not by the default `submit.cf`, in which the line referring to `/etc/mail/trusted-users` is commented out. See `sendmail(4)` for instructions on making changes to `submit.cf` and `sendmail.cf`.

`/var/spool/clientmqueue/*`
Temporary files and queued mail

RFC 2822 *Internet Message Format*, Pete Resnick, April 2001.

sendmail, Third Edition, Bryan Costales with Eric Allman, O'Reilly & Associates, Inc., 2003.

http://www.sendmail.org

http://www.milter.org

Notes The sendmail program requires a fully qualified host name when starting. A script has been included to help verify if the host name is defined properly (see check-hostname(1M)).

The permissions and the ownership of several directories have been changed in order to increase security. In particular, access to /etc/mail and /var/spool/mqueue has been restricted.

Security restrictions have been placed users using .forward files to pipe mail to a program or redirect mail to a file. The default shell (as listed in /etc/passwd) of these users must be listed in /etc/shells. This restriction does not affect mail that is being redirected to another alias.

Additional restrictions have been put in place on .forward and :include: files. These files and the directory structure that they are placed in cannot be group- or world-writable. See check-permissions(1M).

If you have interfaces that map to domains that have MX records that point to non-local destinations, you might need to enable the DontProbeInterfaces option to enable delivery to those destinations. In its default startup behavior, sendmail probes each interface and adds an interface's IP addresses, as well as any domains that those addresses map to, to its list of domains that are considered local. For domains thus added, being on the list of local domains is equivalent to having a 0-preference MX record, with localhost as the MX value. If this is not the result you want, enable DontProbeInterfaces.

Because of cryptographic import restrictions in some countries, symmetric key cryptographic algorithms are limited to 128-bit if the SUNWcry package is not installed. The SUNWcry package is not included with the Solaris software. This package is available instead as a separate, controlled download.

Name setuname – change machine information

Synopsis

```
setuname [-t] [-n node] [-s name]
```

Description The `setuname` utility changes the parameter value for the system name and node name. Each parameter can be changed using `setuname` and the appropriate option.

Either or both the `-s` and `-n` options must be given when invoking `setuname`.

The system architecture may place requirements on the size of the system and network node name. The command will issue a fatal warning message and an error message if the name entered is incompatible with the system requirements.

Options The following options are supported:

`-n` *node* Changes the node name. *node* specifies the new network node name and can consist of alphanumeric characters and the special characters dash, underbar, and dollar sign.

`-s` *name* Changes the system name. *name* specifies new system name and can consist of alphanumeric characters and the special characters dash, underbar, and dollar sign.

`-t` Temporary change. No attempt will be made to create a permanent change.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `attributes(5)`

Notes `setuname` attempts to change the parameter values in two places: the running kernel and, as necessary per implementation, to cross system reboots. A temporary change changes only the running kernel.

Name sf880drd – Sun Fire 880 Dynamic Reconfiguration daemon

Synopsis

```
sf880drd
```

Description The Sun Fire 880 Dynamic Reconfiguration daemon, `sf880drd`, is part of the PCI and system bus hotplug framework. `sf880drd` starts at boot time. It has no configuration options and does not report any system status.

`sf880drd` implements the Sun Fire `880` console-less system administration (per-slot pushbuttons and LED status indicators). It also manages various aspects of CPU/memory hotplug.

Files `/usr/platform/SUNW,Sun-Fire-880/lib/sf880drd`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsfdr.u

See Also `svcs(1)`, `cfgadm(1M)`, `cfgadm_pci(1M)`, `cfgadm_sbd(1M)`, `svcadm(1M)`, `attributes(5)`, `smf(5)`

Notes The `sf880drd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/platform/sun4u/sf880drd
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

Name sftp-server – SFTP server subsystem

Synopsis

```
/usr/lib/ssh/sftp-server
```

Description `sftp-server` implements the server side of the SSH File Transfer Protocol as defined in the IETF `draft-ietf-secsh-filexfer`.

`sftp-server` is a subsystem for `sshd(1M)` and must not be run directly. There are no options or config settings.

To enable the `sftp-server` subsystem for `sshd` add the following to `/etc/ssh/sshd_config`:

```
Subsystem   sftp     /usr/lib/ssh/sftp-server
```

See `sshd_config(4)` for a description of the format and contents of that file.

There is no relationship between the protocol used by `sftp-server` and the FTP protocol (RFC 959) provided by `in.ftpd`.

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Files `/usr/lib/ssh/sftp-server` Server-side binary

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsshdu
Interface Stability	Evolving

See Also `sftp(1)`, `ssh(1)`, `ssh-add(1)`, `ssh-keygen(1)`, `sshd(1M)`, `sshd_config(4)`, `attributes(5)`

To view license terms, attribution, and copyright for OpenSSH, the default path is `/var/sadm/pkg/SUNWsshdr/install/copyright`. If the Solaris operating environment has been installed anywhere other than the default, modify the given path to access the file at the installed location.

Author Markus Friedl

Name share – make local resource available for mounting by remote systems

Synopsis

```
share [-F FSType] [-o specific_options] [-d description]
      [pathname]
```

Description The `share` command exports, or makes a resource available for mounting, through a remote file system of type *FSType*. If the option `-F` *FSType* is omitted, the first file system type listed in `/etc/dfs/fstypes` is used as default. For a description of NFS specific options, see `share_nfs`(1M). *pathname* is the pathname of the directory to be shared. When invoked with no arguments, `share` displays all shared file systems.

Options

`-F` *FSType* — Specify the filesystem type.

`-o` *specific_options* — The *specific_options* are used to control access of the shared resource. (See `share_nfs`(1M) for the NFS specific options.) They may be any of the following:

`rw`	*pathname* is shared read/write to all clients. This is also the default behavior.
`rw=`*client*[`:`*client*]...	*pathname* is shared read/write only to the listed clients. No other systems can access *pathname*.
`ro`	*pathname* is shared read-only to all clients.
`ro=`*client*[`:`*client*]...	*pathname* is shared read-only only to the listed clients. No other systems can access *pathname*.

Separate multiple options with commas. Separate multiple operands for an option with colons. See EXAMPLES.

`-d` *description* — The `-d` flag may be used to provide a description of the resource being shared.

Examples

EXAMPLE 1 Sharing a Read-Only Filesystem

This line will share the `/disk` file system read-only at boot time.

```
share -F nfs -o ro /disk
```

EXAMPLE 2 Invoking Multiple Options

The following command shares the filesystem `/export/manuals`, with members of the netgroup having read-only access and users on the specified host having read-write access.

```
share -F nfs -o ro=netgroup_name,rw=host1:host2:host3 /export/manuals
```

Files

`/etc/dfs/dfstab`	list of `share` commands to be executed at boot time
`/etc/dfs/fstypes`	list of file system types, NFS by default
`/etc/dfs/sharetab`	system record of shared file systems

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also mountd(1M), nfsd(1M), share_nfs(1M), shareall(1M), unshare(1M), attributes(5)

Notes Export (old terminology): file system sharing used to be called exporting on SunOS 4.x, so the `share` command used to be invoked as exportfs(1B) or `/usr/sbin/exportfs`.

If `share` commands are invoked multiple times on the same filesystem, the last `share` invocation supersedes the previous—the options set by the last `share` command replace the old options. For example, if read-write permission was given to `usera` on `/somefs`, then to give read-write permission also to `userb` on `/somefs`:

```
example% share -F nfs -o rw=usera:userb /somefs
```

This behavior is not limited to sharing the root filesystem, but applies to all filesystems.

Name shareall, unshareall – share, unshare multiple resources

Synopsis

```
shareall [-F FSType [,FSType]...] [-| file]

unshareall [-F FSType [,FSType]...]
```

Description When used with no arguments, `shareall` shares all resources from `file`, which contains a list of `share` command lines. If the operand is a hyphen (–), then the `share` command lines are obtained from the standard input. Otherwise, if neither a `file` nor a hyphen is specified, then the file `/etc/dfs/dfstab` is used as the default.

Resources may be shared by specific file system types by specifying the file systems in a comma-separated list as an argument to `-F`.

`unshareall` unshares all currently shared resources. Without a `-F` flag, it unshares resources for all distributed file system types.

Options `-F` *FSType* Specify file system type. Defaults to the first entry in `/etc/dfs/fstypes`.

Files `/etc/dfs/dfstab`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `share(1M)`, `unshare(1M)`, `attributes(5)`

Name share_nfs – make local NFS file systems available for mounting by remote systems

Synopsis `share [-d` *description*`] [-F nfs] [-o` *specific_options*`]` *pathname*

Description The `share` utility makes local file systems available for mounting by remote systems. It starts the `nfsd(1M)` and `mountd(1M)` daemons if they are not already running.

If no argument is specified, then `share` displays all file systems currently shared, including NFS file systems and file systems shared through other distributed file system packages.

Options The following options are supported:

`-d` *description*
Provide a comment that describes the file system to be shared.

`-F nfs`
Share NFS file system type.

`-o` *specific_options*
Specify *specific_options* in a comma-separated list of keywords and attribute-value-assertions for interpretation by the file-system-type-specific command. If *specific_options* is not specified, then by default sharing is read-write to all clients. *specific_options* can be any combination of the following:

`aclok`
Allows the NFS server to do access control for NFS Version 2 clients (running SunOS 2.4 or earlier). When `aclok` is set on the server, maximal access is given to all clients. For example, with `aclok` set, if anyone has read permissions, then everyone does. If `aclok` is not set, minimal access is given to all clients.

`anon=`*uid*
Set *uid* to be the effective user ID of unknown users. By default, unknown users are given the effective user ID `UID_NOBODY`. If *uid* is set to −1, access is denied.

`index=file`
Load `file` rather than a listing of the directory containing this file when the directory is referenced by an NFS URL.

`log=tag`
Enables NFS server logging for the specified file system. The optional tag determines the location of the related log files. The `tag` is defined in `etc/nfs/nfslog.conf`. If no `tag` is specified, the default values associated with the *global* `tag` in `etc/nfs/nfslog.conf` is used. Support of NFS server logging is only available for NFS Version 2 and Version 3 requests.

`nosub`
Prevents clients from mounting subdirectories of shared directories. For example, if `/export` is shared with the `nosub` option on server *fooey* then a NFS client cannot do:

```
mount -F nfs fooey:/export/home/mnt
```

NFS Version 4 does not use the `MOUNT` protocol. The `nosub` option only applies to NFS Version 2 and Version 3 requests.

`nosuid`
By default, clients are allowed to create files on the shared file system with the setuid or setgid mode enabled. Specifying `nosuid` causes the server file system to silently ignore any attempt to enable the setuid or setgid mode bits.

`public`
Moves the location of the public file handle from `root` (`/`) to the exported directory for WebNFS-enabled browsers and clients. This option does not enable WebNFS service; WebNFS is always on. Only one file system per server may use this option. Any other option, including the `-ro=list` and `-rw=list` options can be included with the `public` option.

`ro`
Sharing is read-only to all clients.

`ro=`*access_list*
Sharing is read-only to the clients listed in *access_list*; overrides the `rw` suboption for the clients specified. See *access_list* below.

`root=`*access_list*
Only root users from the hosts specified in *access_list* have root access. See *access_list* below. By default, no host has root access, so root users are mapped to an anonymous user ID (see the `anon=`*uid* option described above). Netgroups can be used if the file system shared is using UNIX authentication (`AUTH_SYS`).

`rw`
Sharing is read-write to all clients.

`rw=`*access_list*
Sharing is read-write to the clients listed in *access_list*; overrides the `ro` suboption for the clients specified. See *access_list* below.

`sec=`*mode*[`:`*mode*]. . .
Sharing uses one or more of the specified security modes. The *mode* in the `sec=`*mode* option must be a node name supported on the client. If the `sec=` option is not specified, the default security mode used is `AUTH_SYS`. Multiple `sec=` options can be specified on the command line, although each mode can appear only once. The security modes are defined in `nfssec(5)`.

Each `sec=` option specifies modes that apply to any subsequent `window=, rw, ro, rw=, ro=` and `root=` options that are provided before another `sec=`option. Each additional `sec=` resets the security mode context, so that more `window=, rw, ro, rw=, ro=` and `root=` options can be supplied for additional modes.

`sec=`*none*
If the option `sec=`*none* is specified when the client uses `AUTH_NONE`, or if the client uses a security mode that is not one that the file system is shared with, then the credential of each NFS request is treated as unauthenticated. See the `anon=`*uid* option for a description of how unauthenticated requests are handled.

`secure`
This option has been deprecated in favor of the `sec=`*dh* option.

`window=`*value*
When sharing with `sec=`*dh*, set the maximum life time (in seconds) of the RPC request's credential (in the authentication header) that the NFS server allows. If a credential arrives with a life time larger than what is allowed, the NFS server rejects the request. The default value is 30000 seconds (8.3 hours).

access_list The *access_list* argument is a colon-separated list whose components may be any number of the following:

hostname
The name of a host. With a server configured for DNS or LDAP naming in the `nsswitch` "hosts" entry, any hostname must be represented as a fully qualified DNS or LDAP name.

netgroup
A netgroup contains a number of hostnames. With a server configured for DNS or LDAP naming in the `nsswitch` "hosts" entry, any hostname in a netgroup must be represented as a fully qualified DNS or LDAP name.

domain name suffix
To use domain membership the server must use DNS or LDAP to resolve hostnames to IP addresses; that is, the "hosts" entry in the `/etc/nsswitch.conf` must specify "dns" or "ldap" ahead of "nis" or "nisplus", since only DNS and LDAP return the full domain name of the host. Other name services like NIS or NIS+ cannot be used to resolve hostnames on the server because when mapping an IP address to a hostname they do not return domain information. For example,

```
NIS or NIS+   172.16.45.9 --> "myhost"
```

and

```
DNS or LDAP   172.16.45.9 -->
     "myhost.mydomain.mycompany.com"
```

The domain name suffix is distinguished from hostnames and netgroups by a prefixed dot. For example,

```
rw=.mydomain.mycompany.com
```

A single dot can be used to match a hostname with no suffix. For example,

```
rw=.
```

matches ”mydomain” but not ”mydomain.mycompany.com”. This feature can be used to match hosts resolved through NIS and NIS+ rather than DNS and LDAP.

network
The network or subnet component is preceded by an at-sign (@). It can be either a name or a dotted address. If a name, it is converted to a dotted address by `getnetbyname(3SOCKET)`. For example,

```
=@mynet
```

would be equivalent to:

`=@172.16` or `=@172.16.0.0`

The network prefix assumes an octet-aligned netmask determined from the zeroth octet in the low-order part of the address up to and including the high-order octet, if you want to specify a single IP address (see below). In the case where network prefixes are not byte-aligned, the syntax allows a mask length to be specified explicitly following a slash (/) delimiter. For example,

`=@theothernet/17` or `=@172.16.132/22`

...where the mask is the number of leftmost contiguous significant bits in the corresponding IP address.

When specifying individual IP addresses, use the same @ notation described above, without a netmask specification. For example:

```
=@172.16.132.14
```

Multiple, individual IP addresses would be specified, for example, as:

```
root=@172.16.132.20:@172.16.134.20
```

A prefixed minus sign (–) denies access to that component of *access_list*. The list is searched sequentially until a match is found that either grants or denies access, or until the end of the list is reached. For example, if host ”terra” is in the ”engineering” netgroup, then

```
rw=-terra:engineering
```

denies access to `terra` but

```
rw=engineering:-terra
```

grants access to `terra`.

Operands The following operands are supported:

pathname
The pathname of the file system to be shared.

Examples

EXAMPLE 1 Sharing A File System With Logging Enabled

The following example shows the `/export` file system shared with logging enabled:

```
example% share -o log /export
```

The default global logging parameters are used since no tag identifier is specified. The location of the log file, as well as the necessary logging work files, is specified by the global entry in `/etc/nfs/nfslog.conf`. The `nfslogd(1M)` daemon runs only if at least one file system entry in `/etc/dfs/dfstab` is shared with logging enabled upon starting or rebooting the system. Simply sharing a file system with logging enabled from the command line does not start the `nfslogd(1M)`.

Exit Status

The following exit values are returned:

`0`
: Successful completion.

`>0`
: An error occurred.

Files

`/etc/dfs/fstypes`
: list of system types, NFS by default

`/etc/dfs/sharetab`
: system record of shared file systems

`/etc/nfs/nfslogtab`
: system record of logged file systems

`/etc/nfs/nfslog.conf`
: logging configuration file

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnfssu

`mount(1M)`, `mountd(1M)`, `nfsd(1M)`, `nfslogd(1M)`, `share(1M)`, `unshare(1M)`, `getnetbyname(3SOCKET)`, `nfslog.conf(4)`, `netgroup(4)`, `attributes(5)`, `nfssec(5)`

Notes

If the `sec=` option is presented at least once, all uses of the `window=, rw, ro, rw=, ro=` and `root=` options must come `after` the first `sec=` option. If the `sec=` option is not presented, then `sec=`*sys* is implied.

If one or more explicit `sec=` options are presented, *sys* must appear in one of the options mode lists for accessing using the `AUTH_SYS` security mode to be allowed. For example:

```
share -F nfs /var
share -F nfs -o sec=sys /var
```

grants read-write access to any host using AUTH_SYS, but

```
share -F nfs -o sec=dh /var
```

grants no access to clients that use AUTH_SYS.

Unlike previous implementations of share_nfs, access checking for the window=, rw, ro, rw=, and ro= options is done per NFS request, instead of per mount request.

Combining multiple security modes can be a security hole in situations where the ro= and rw= options are used to control access to weaker security modes. In this example,

```
share -F nfs -o sec=dh,rw,sec=sys,rw=hosta /var
```

an intruder can forge the IP address for hosta (albeit on each NFS request) to side-step the stronger controls of AUTH_DES. Something like:

```
share -F nfs -o sec=dh,rw,sec=sys,ro /var
```

is safer, because any client (intruder or legitimate) that avoids AUTH_DES only gets read-only access. In general, multiple security modes per share command should only be used in situations where the clients using more secure modes get stronger access than clients using less secure modes.

If rw=, and ro= options are specified in the same sec= clause, and a client is in both lists, the order of the two options determines the access the client gets. If client hosta is in two netgroups - group1 and group2 - in this example, the client would get read-only access:

```
share -F nfs -o ro=group1,rw=group2 /var
```

In this example hosta would get read-write access:

```
share -F nfs -o rw=group2,ro=group1 /var
```

If within a sec= clause, both the ro and rw= options are specified, for compatibility, the order of the options rule is not enforced. All hosts would get read-only access, with the exception to those in the read-write list. Likewise, if the ro= and rw options are specified, all hosts get read-write access with the exceptions of those in the read-only list.

The ro= and rw= options are guaranteed to work over UDP and TCP but may not work over other transport providers.

The root= option with AUTH_SYS is guaranteed to work over UDP and TCP but may not work over other transport providers.

The root= option with AUTH_DES is guaranteed to work over any transport provider.

There are no interactions between the root= option and the rw, ro, rw=, and ro= options. Putting a host in the root list does not override the semantics of the other options. The access the host gets is the same as when the root= options is absent. For example, the following share command denies access to hostb:

```
share -F nfs -o ro=hosta,root=hostb /var
```

The following gives read-only permissions to `hostb`:

```
share -F nfs -o ro=hostb,root=hostb /var
```

The following gives read-write permissions to `hostb`:

```
share -F nfs -o ro=hosta,rw=hostb,root=hostb /var
```

If the file system being shared is a symbolic link to a valid pathname, the canonical path (the path which the symbolic link follows) are shared. For example, if `/export/foo` is a symbolic link to `/export/bar` (`/export/foo -> /export/bar`), the following `share` command results in `/export/bar` as the shared pathname (and not `/export/foo`).

```
example# share -F nfs /export/foo
```

An NFS mount of `server:/export/foo` results in `server:/export/bar` really being mounted.

This line in the `/etc/dfs/dfstab` file shares the `/disk` file system read-only at boot time:

```
share -F nfs -o ro /disk
```

The same command entered from the command line does not share the `/disk` file system unless there is at least one file system entry in the `/etc/dfs/dfstab` file. The `mountd(1M)` and `nfsd(1M)` daemons only run if there is a file system entry in `/etc/dfs/dfstab` when starting or rebooting the system.

The `mountd(1M)` process allows the processing of a path name the contains a symbolic link. This allows the processing of paths that are not themselves explicitly shared with `share_nfs`. For example, `/export/foo` might be a symbolic link that refers to `/export/bar` which has been specifically shared. When the client mounts `/export/foo` the `mountd` processing follows the symbolic link and responds with the `/export/bar`. The NFS Version 4 protocol does not use the `mountd` processing and the client's use of `/export/foo` does not work as it does with NFS Version 2 and Version 3 and the client receives an error when attempting to mount `/export/foo`.

Name showmount – show remote mounts

Synopsis

```
/usr/sbin/showmount [-ade] [hostname]
```

Description `showmount` lists the clients that have remotely mounted a filesystem from *host*. This information is maintained by the `mountd(1M)` server on *host*, and is saved across crashes in the file `/etc/rmtab`. The default value for *host* is the value returned by `hostname(1)`.

The `showmount` command does not display the names of NFS Version 4 clients.

Options

`-a` Print all remote mounts in the format:

```
hostname : directory
```

where `hostname` is the name of the client, and `directory` is the root of the file system that has been mounted.

`-d` List directories that have been remotely mounted by clients.

`-e` Print the list of shared file systems.

Files `/etc/rmtab`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnfscu

See Also `hostname(1)`, `mountd(1M)`, `attributes(5)`

Solaris 10 Installation Guide: Basic Installations

Bugs If a client crashes, its entry will not be removed from the list of remote mounts on the server.

Name showrev – show machine, software revision, and patch revision information

Synopsis

```
/usr/bin/showrev [-a] [-p | -p -R root_path] [-w]
     [-c command] [-s hostname]
```

Description `showrev` displays revision information for the current hardware and software. With no arguments, `showrev` shows the system revision information including hostname, hostid, release, kernel architecture, application architecture, hardware provider, domain, and kernel version.

If a command is supplied with the `-c` option, `showrev` shows the `PATH` and `LD_LIBRARY_PATH` and finds out all the directories within the `PATH` that contain it. For each file found, its file type, revision, permissions, library information, and checksum are printed as well.

Options The following options are supported:

`-a` Print all system revision information available. Window system and patch information are added.

`-c` *command* Print the revision information about *command*.

`-p` Print only the revision information about patches.

`-R` *root_path* Define the full path name of a directory to use as the *root_path*. By specifying the root path, `showrev` retrieves the revision information about the patch from package system information files located under a directory tree starting at *root_path*. The *root_path* can be specified when retrieving installed patch information in a client from a server, for example, `/export/root/client1`.

Note – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.

`-s` *hostname* Perform this operation on the specified *hostname*. The `-s` operation completes correctly only when *hostname* is running Solaris 2.5 or compatible versions.

`-w` Print only the OpenWindows revision information.

Output Varies, based on flags passed. If no flags are passed, output similar to the following appears:

```
 Hostname: system1
Hostid: 7233808e
Release: 5.10
Kernel architecture: sun4u
Application architecture: sparc
Hardware provider: Sun_Microsystems
Domain: a.network.COM
Kernel version: SunOS 5.10 generic
```

Exit Status The following error values are returned:

`0` Successful completion.

`>0` An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWadmc

See Also `arch(1)`, `ldd(1)`, `mcs(1)`, `sum(1)`, `patchadd(1M)`, `attributes(5)`

Bugs For the `-s` option to work when `hostname` is running a version of Solaris prior to 2.5, the Solstice AdminSuite must be installed on `hostname`.

Name shutdown – shut down system, change system state

Synopsis

```
/usr/sbin/shutdown [-y] [-g grace-period] [-i init-state]
     [message]
```

Description `shutdown` is executed by the super user to change the state of the machine. In most cases, it is used to change from the multi-user state (state 2) to another state.

By default, `shutdown` brings the system to a state where only the console has access to the operating system. This state is called single-user.

Before starting to shut down daemons and killing processes, `shutdown` sends a warning message and, by default, a final message asking for confirmation. *message* is a string that is sent out following the standard warning message "The system will be shut down in . . ." If the string contains more than one word, it should be contained within single (') or double (") quotation marks.

The warning message and the user provided *message* are output when there are 7200, 3600, 1800, 1200, 600, 300, 120, 60, and 30 seconds remaining before `shutdown` begins. See `EXAMPLES`.

System state definitions are:

state 0 — Stop the operating system.

state 1 — State 1 is referred to as the administrative state. In state 1 file systems required for multi-user operations are mounted, and logins requiring access to multi-user file systems can be used. When the system comes up from firmware mode into state 1, only the console is active and other multi-user (state 2) services are unavailable. Note that not all user processes are stopped when transitioning from multi-user state to state 1.

state s, S — State s (or S) is referred to as the single-user state. All user processes are stopped on transitions to this state. In the single-user state, file systems required for multi-user logins are unmounted and the system can only be accessed through the console. Logins requiring access to multi-user file systems cannot be used.

state 5 — Shut the machine down so that it is safe to remove the power. Have the machine remove power, if possible. The `rc0` procedure is called to perform this task.

state 6 — Stop the operating system and reboot to the state defined by the `initdefault` entry in `/etc/inittab`. The `rc6` procedure is called to perform this task.

Options

`-y` — Pre-answer the confirmation question so the command can be run without user intervention.

`-g` *grace-period* — Allow the super user to change the number of seconds from the 60-second default.

`-i` *init-state* If there are warnings, *init-state* specifies the state `init` is to be in. By default, system state 's' is used.

Examples

EXAMPLE 1 Using `shutdown`

In the following example, `shutdown` is being executed on host `foo` and is scheduled in 120 seconds. The warning message is output 2 minutes, 1 minute, and 30 seconds before the final confirmation message.

```
example# shutdown -i S -g 120 "===== disk replacement ====="
Shutdown started.   Tue Jun   7  14:51:40 PDT  1994

Broadcast Message from root (pts/1) on foo Tue Jun  7 14:51:41. . .
The system will be shut down in 2 minutes
===== disk replacement =====
Broadcast Message from root (pts/1) on foo Tue Jun  7 14:52:41. . .
The system will be shut down in 1 minutes
===== disk replacement =====
Broadcast Message from root (pts/1) on foo Tue Jun  7 14:53:41. . .
The system will be shut down in 30 seconds
===== disk replacement =====
Do you want to continue? (y or n):
```

Files

`/etc/inittab` controls process dispatching by `init`

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also

`boot(1M)`, `halt(1M)`, `init(1M)`, `killall(1M)`, `reboot(1M)`, `ufsdump(1M)`, `init.d(4)`, `inittab(4)`, `nologin(4)`, `attributes(5)`

Notes

When a system transitions down to the `S` or `s` state, the `/etc/nologin` file (see `nologin(4)`) is created. Upon subsequent transition to state 2 (multi-user state), this file is removed by a script in the `/etc/rc2.d` directory.

Name slpd – Service Location Protocol Daemon

Synopsis `/usr/lib/inet/slpd [-f` *configuration-file*`]`

Description The `slpd` daemon provides common server functionality for the Service Location Protocol ("SLP") versions 1 and 2, as defined by IETF in *RFC 2165* and *RFC 2608*. SLP provides a scalable framework for the discovery and selection of network services.

`slpd` provides the following framework services:

Directory Agent	This service automatically caches service advertisements from service agents to provide them to user agents, and makes directory agent advertisements of its services. This service is optional. `slpd` does not provide directory agent service by default. Directory agents are not databases, and they do not need to be maintained.
Service Agent Server	All service agents on the local host register and deregister with this server. This service responds to all requests for services, and forwards registrations to directory agents. By default, `slpd` is a service agent server.
Passive Directory Agent Discovery	This service listens for directory agent advertisements and maintains a table of active directory agents. When a user agent wishes to discover a directory agent, it can simply query `slpd`, obviating the need to perform discovery by means of multicast. By default, `slpd` performs this service.
Proxy Registration	This service can act as a proxy service agent for services that cannot register themselves. `slpd` reads the proxy registration file for information on services it is to proxy. By default, no services are registered by proxy.

All configuration options are available from the configuration file. `slpd` reads its configuration file upon startup.

Stop and start the slpd daemon using `svcadm(1M)`. Use the command `svcadm enable network/slp` to start the slpd daemon. Use the command `svcadm disable network/slp` to stop it.

The file `/etc/inet/slp.conf` must exist before the `slp` service can start the daemon. Only the example file `/etc/inet/slp.conf.example` is present by default. To enable SLP, copy `/etc/inet/slp.conf.example` to `/etc/inet/slp.conf`.

Options The following options are supported:

`-f` *configuration-file* Specify an alternate configuration file

Examples **EXAMPLE 1** Stopping the `slpd` daemon

The following command stops the `slpd` daemon:

```
example# svcadm disable network/slp
```

EXAMPLE 2 Restarting the `slpd` daemon

The following command restarts the `slpd` daemon:

```
example# svcadm restart network/slp
```

Files `/etc/inet/slp.conf` The default configuration file

`slpd.reg` The proxy registration file

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWslpu, SUNWslpr
CSI	Enabled
Interface Stability	Committed

See Also `svcs(1)`, `svcadm(1M)`, `slp_api(3SLP)`, `slp.conf(4)`, `slpd.reg(4)`, `attributes(5)`, `smf(5)`, `slp(7P)`

System Administration Guide: Network Services

Guttman, E., Perkins, C., Veizades, J., and Day, M., *RFC 2608, Service Location Protocol, Version 2*, The Internet Society, June 1999.

Notes The `slpd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/slp
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

Name smartcard – configure and administer a smart card

Synopsis

```
smartcard -c admin [-a application] [propertyname]...

smartcard -c admin [-a application]
     [-x { add|delete|modify } propertyname=value...]

smartcard -c admin -t service -j classname -x
     { add|delete|modify}

smartcard -c admin -t terminal
     { -j classname | -H libraryname } -d device -r userfriendlyreadername -n readername -x
     { add|delete|modify }
     [-R]

smartcard -c admin -t debug -j classname -l level -x
     { add|delete|modify}

smartcard -c admin -t override -x { add|delete|modify} propertyname=value

smartcard -c admin -I -k keytype -i filename

smartcard -c admin -E -k keytype -o filename

smartcard -c load -A aid [-r userfriendlyreadername] -P pin
     [-s slot] [-i inputfile] [-p propfile] [-v]
     [propertyname=value]...

smartcard -c load -u -P pin [-A aid]
     [-r userfriendlyreadername] [-s slot] [-v]

smartcard -c bin2capx -T cardname [-i inputfile]
     [-o outputfile] [-p propfile] [-I anothercapxfile]
     [-v] [propertyname=value]...

smartcard -c init -A aid [-r readername] [-s slot] -L

smartcard -c init -A aid [-r readername] -P pin [-s slot]
     [propertyname=value]...

smartcard -c enable

smartcard -c disable
```

Description The `smartcard` utility is used for all configurations related to a smart card. It comprises the following subcommands:

1. Administration of OCF properties. (`-c admin`)

   This subcommand is used to list and modify any of the OCF properties. With no arguments it will list all the current properties. It can only be executed by root. Some OCF properies are:

   `defaultcard`
   # default card for an application

```
defaultreader
    # default reader for an application

authmechanism
    # authentication mechanism

validcards
    # list of cards valid for an application
```

A complete listing can be obtained by using the `smartcard` utility as described in the EXAMPLES section.

2. Loading and Unloading of applets from the smart card (`-c load`) and performing initial configuration of a non-Java card.

   This subcommand administers the applets or properties on a smartcard. It can be used to load or unload applets and/or properties to and from a smart card. The applet is a Java class file that has been run through a converter to make the byte code JavaCard-compliant. This command can be used to load both an applet file in the standard format or a file converted to the `capx` format. If no `-r` option is specified, the loader tries to load to any connected reader, provided it has already been inserted using the `smartcard -c admin` command.

3. Converting card applets or properties to the `capx` format (`-c bin2capx`)

   This subcommand is used to convert a Java card applet or properties into a new format called `capx` before downloading it onto the smart card. Converting to this format enables the applet developer to add applet-specific information that is useful during the downloading process and identifies the applet.

   In the following example,

   ```
   smartcard -c bin2capx -i cyberflex.bin \
   -T CyberFlex aidto-000102030405060708090A0B0C0D0E0F fileID=2222 \
   instanceID=2223 and more.
   ```

   if no output file is specified, a default file with the name *input_filename*.`capx` is created in the current directory. The mandatory `-T` option requires the user to specify the card name for which the `capx` file is being generated.

   The following example

   ```
   smartcard -c bin2capx -T IButton
   ```

   tells the loader that the `capx` file contains the binary for `IButton`. A single `capx` file can hold binaries for multiple cards (1 per card.) Users can, for example, hold binary files for both CyberFlex and IButton in the same capx file as follows:

   ```
   smartcard -c bin2capx -T IButton -i IButton.jib -o file.capx
   ```

   In the following example,

   ```
   smartcard -c bin2capx -T CyberFlex -i cyberflex.bin \
   -l file.capx -o file.capx
   ```

the `-l` option is used to provide an already-generated `capx` file. The output is directed to the same `capx` file, resulting in `capx` file holding binaries for both cards.

4. Personalizing a smart card (`-c init`)

   This subcommand is used to set user-specific information required by an applet on a smart card. For example, the Sun applet requires a user name to be set on the card. This subcommand is also used to personalize information for non-Java cars.

5. Enabling and disabling the smart card desktop login (`-c {enable | disable}`)

Options The following options are supported:

`-a` *application*
Specify application name for the configuration parameter. Parameters may differ depending on the application. If no application name is specified, then `ocf` is the default application.

`-A` *aid*
Specify a unique alphanumeric string that identifies the applet. The *aid* argument must be a minimum of 5 characters and can be a maximum of 16 characters in length. If an applet with an identical *aid* already exists on the card, a load will result in an error.

`-c`
Specify subcommand name. Valid options are: `admin`, `load`, `bin2capx`, `init`, `enable`, and `disable`.

`-d` *device*
Specify device on which the reader is connected (for example, `/dev/cua/a`).

`-D`
Disable a system from using smart cards.

`-E`
Export the keys to a file.

`-H` *libraryname*
Specify the full path of the IFD handler library for the reader.

`-i` *filename*
Specify input file name.

`-I`
Import from a file.

`-j` *classname*
Specify fully-qualified class name.

`-k` *keytype*
Specify type of key (for example, `challenge_response`, `pki`.)

`-l`
Specify debug level (0–9), signifying level of debug information displayed.

`-L`
List all properties configurable in an applet.

`-n` *readername*
Specify reader name as required by the driver.

`-o` *filename*
Specify output file name.

`-p` *propfile*
Specify properties file name. This file could contain a list of property names and value pairs, in the format *propertyname=value*.

`-P` *pin*
Specify pin used to validate to the card.

`-r` *userfriendlyreadername*
Specify user-defined reader name where the card to be initialized is inserted.

`-R`
Restart the `ocf` server.

`-s` *slot*
Specify slot number. If a reader has multiple slots, this option specifies which slot to use for initialization. If a reader has only one slot, this option is not required. If no slot number is specified, by default the first slot of the reader is used.

`-t`
Specify type of property being updated. The valid values are:

`service`
Updating a card service provider details.

`terminal`
Updating a card reader provider details.

`debug`
OCF trace level.

`override`
Override a system property of the same name.

`-T` *cardname*
Specify card name.

`-u`
Unload the applet specified by the application ID from the card. If no application ID is specified, all applets are unloaded from the card.

`-v`
Verbose mode (displays helpful messages).

`-x`
Specify action to be taken. Valid values are: `add`, `delete`, or `modify`.

Examples

EXAMPLE 1 Viewing the Values of All Properties

Enter the following command to view the values of all the properties that are set:

```
% smartcard -c admin
```

EXAMPLE 2 Viewing the Values of Specific Properties

Enter the following command to view the values of specific properties:

```
% smartcard -c admin language country
```

EXAMPLE 3 Adding a Card Service

Enter the following command to add a card service factory for a CyberFlex card, available in the package `com.sun.services.cyberflex`, to the properties:

```
% smartcard -c admin -t service \
     -j com.sun.services.cyberflex.CyberFlexCardServiceFactory -x add
```

EXAMPLE 4 Adding a Reader

Enter the following command to add the IFD handler for the internal reader:

```
% smartcard -c admin -t terminal \
     -H /usr/lib/smartcard/ifdh_scmi2c.so -x add \
     -d /dev/scmi2c0 -r MyInternalReader -n SunISCRI
```

EXAMPLE 5 Deleting a Reader

Enter the following command to delete the SCM reader, added in the previous example, from the properties:

```
% smartcard -c admin -t terminal -r SCM -x delete
```

EXAMPLE 6 Changing the Debug Level

Enter the following command to change the debug level for all of the com.sun package to 9:

```
% smartcard -c admin -t debug -j com.sun -l 9  -x modify
```

EXAMPLE 7 Setting the Default Card for an Application

Enter one of the following commands to set the default card for an application (`dtlogin`) to be CyberFlex.

If the property default card does not exist, enter the following command:

```
% smartcard -c admin -a dtlogin -x add defaultcard=CyberFlex
```

If the property default card exists, enter the following command:

EXAMPLE 7 Setting the Default Card for an Application *(Continued)*

```
% smartcard -c admin -a dtlogin -x modify defaultcard=CyberFlex
```

EXAMPLE 8 Exporting Keys for a User into a File

Enter the following command to export the challenge-response keys for a user into a file:

```
% smartcard -c admin -k challenge_response -E -o /tmp/mykeys
```

EXAMPLE 9 Importing Keys from a File

Enter the following command to import the challenge-response keys for a user from a file:

```
% smartcard -c admin -k challenge_response -I -i /tmp/mykeys
```

EXAMPLE 10 Downloading an Applet into a Java Card

Enter the following command to download an applet into a Java card or to configure a PayFlex (non-Java) card inserted into an SCM reader for the capx file supplied in the `/usr/share/lib/smartcard` directory:

```
% smartcard -c load -r SCM \
     -i /usr/share/lib/smartcard/SolarisAuthApplet.capx
```

EXAMPLE 11 Downloading an Applet Binary

Enter the following command to download an applet binary from some place other that the capx file supplied with Solaris 8 into an IButton (the aid and input file are mandatory, the remaining parameters are optional):

```
% smartcard -c load -A A000000062030400  -i newapplet.jib
```

EXAMPLE 12 Downloading an Applet on a CyberFlex Access Card

On a CyberFlex Access Card, enter the following command to download an applet newapplet.bin at fileID 2222, instanceID 3333 using the specified verifyKey and a heap size of 2000 bytes:

```
% smartcard -c load -A newaid -i newapplet.bin \
     fileID=2222 instanceID=3333 verifyKey=newKey \
     MAC=newMAC heapsize=2000
```

EXAMPLE 13 Configuring a PayFlex Card

Enter the following command to configure a PayFlex (non-Java) card with specific aid, transport key, and initial pin:

```
% smartcard -c load -A A00000006203400 \
     pin=242424246A617661 transportKey=4746584932567840
```

EXAMPLE 14 Unloading an Applet from a Card

Enter the following command to unload an applet from iButton:

```
% smartcard -c load -u
```

EXAMPLE 15 Displaying Usage of `smartcard -c load`

Enter the following command to display the usage of the `smartcard -c load` command:

```
% smartcard -c load
```

EXAMPLE 16 Displaying All Configurable Parameters for an Applet

Enter the following command to display all the configurable parameters for an applet with aid 123456 residing on a card inserted into an SCM reader:

```
% smartcard -c init -r SM -A 123456 -L
```

EXAMPLE 17 Changing the PIN

Enter the following command to change the pin for the SolarisAuthApplet residing on a card or to change the PIN for a PayFlex (non-Java) card inserted into an SCM reader:

```
% smartcard -c init -A A000000062030400 -P oldpin pin=newpin
```

EXAMPLE 18 Displaying All Configurable Parameters for the SolarisAuthApplet.

Enter the following command to display all the configurable parameters for the SolarisAuthApplet residing on a card inserted into an SCM reader:

```
% smartcard -c init -A A000000062030400 -L
```

EXAMPLE 19 Setting a Property to a Value on a smart card

Enter the following command to set properties called `user` to the value `james` and `application` to the value `login` on a card inserted into an SCM reader that has a pin `testpin`:

```
% smartcard -c init -A A000000062030400 -r CyberFlex -P testpin \
     application=login user=james
```

EXAMPLE 20 Converting an Applet for the CyberFlex Card into `capx` Format.

Enter the following command to convert an applet for the CyberFlex card into the `capx` format required for downloading the applet into the card:

```
% smartcard -c bin2capx \
     -i /usr/share/lib/smartcard/SolarisAuthApplet.bin \
     -T CyberFlex -o /home/CorporateCard.capx -v memory=128 heapsize=12
```

EXAMPLE 21 Converting an Applet for the IButton Card into `capx` Format

Enter the following command to convert an applet for the IButton card into the `capx` format required for downloading the applet into the button:

EXAMPLE 21 Converting an Applet for the IButton Card into capx Format *(Continued)*

```
% smartcard -c bin2capx \
     -i /usr/share/lib/smartcard/SolarisAuthApplet.jib \
     -T IButton -o /home/CorporateCard.capx -v
```

Exit Status

The following exit values are returned:

`0`
Successful completion.

`1`
An error occurred.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWocf
Interface Stability	Stable

Notes

The command line options contain only alphanumeric input.

Name smattrpop – populate security attribute databases in a name service

Synopsis

```
smattrpop [-c ] [-f] [-m] [-p policy] [-r] -s scope -t scope
     [-v] database
```

Description The `smattrpop` command updates the `auth_attr(4)`, `exec_attr(4)`, `prof_attr(4)`, and `user_attr(4)` role-based access control databases in a target NIS, NIS+, LDAP, or local `/etc` files name service from the corresponding databases in a source name service or files.

This command processes the table entries from the source database and merges each source entry field into the same field in the corresponding table entry in the target database. If a source entry does not exist in the target database, the entry is created. If the source entry exists in the target database, the fields are merged or replaced according to the command options.

Any errors encountered while updating the target entry are reported to `stdout`, and the command continues with the next source database entry.

Options The following options are supported:

`-c` Performs cross-table checking. If you specify this option and a check error occurs, a message identifying the check error is written to `stdout`.

The target entry values are checked against entries in related databases:

- `auths` values — Each value must exist as the name of an authorization in the `auth_attr(4)` database.
- `profiles` values — Each value must exist as a name of a profile in the `prof_attr(4)` database.
- `roles` values — Each value must exist as the name of a role identity in the `user_attr(4)` database.
- For each `exec_attr(4)` entry in the source database, the name must exist as the name of a `profile` in the `prof_attr`(4) database.

`-f` Specifies that the value in each field in the source entry replaces the value in the corresponding field in the target entry, if the source entry field has a non-empty value.

`-m` For the `auths`, `profiles`, and `roles` attributes, specifies that the values in each field in the source entry are merged with the values in the corresponding target entry field. If a source value does not exist in the target field, the value is appended to the set of target values. If the target field is empty, the source values replace the target field. The attribute values that merge depend on the database being updated:

- `prof_attr`(4) — the `auths` and `profiles` attribute values are merged.
- `user_attr`(4) — the `auths`, `profiles`, and `roles` attribute values are merged.
- `exec_attr`(4) — the `uid`, `gid`, `euid`, and `egid` values are merged.

`-p` *policy* Specifies the value of the policy field in the `exec_attr`(4) database. Valid values are `suser` (standard Solaris superuser) and `tsol` (Trusted Solaris). If you specify this option, only the entries in the source `exec_attr` database with the specified policy are processed. If you omit this option, all entries in the source `exec_attr` database are processed.

`-r` Specifies that role identities in the `user_attr`(4) database in the source name service are processed. If you omit this option, only the normal user entries in the `user_attr` source database are processed.

`-s` *scope* Specifies the source name service or local file directory for database updates, using the following syntax:

type`:`*/server*/*domain*

where *type* indicates the type of name service. Valid values for *type* are:

- `file` — local files
- `nis` — NIS name service
- `nisplus` — NIS+ name service
- `ldap` — LDAP name service

server indicates the local host name of the Solaris system on which the `smattrpop` command is executed, and on which both the source and target databases exist.

domain specifies the management domain name for the name service.

You can use two special cases of *scope* values:

- To indicate the databases in the `/etc/security` local system directory, use the scope `file`:*/server*, where *server* is the name of the local system.
- To load from databases in an arbitrary directory on the Solaris server, use the scope `file`:*/server*/*pathname*, where where *server* is the name of the local system and *pathname* is the fully-qualified directory path name to the database files.

`-t` *scope* Specifies the target name service or local file directory for database updates, using the following syntax:

type`:`*/server*/*domain*

where *type* indicates the type of name service. Valid values for *type* are:

- `file` — local files
- `nis` — NIS name service
- `nisplus` — NIS+ name service
- `ldap` — LDAP name service

server indicates the local host name of the Solaris system on which the `smattrpop` command is executed, and on which both the source and target databases exist.

domain specifies the management domain name for the name service.

You can use two special cases of *scope* values:

- To indicate the databases in the `/etc/security` local system directory, use the scope `file:`/*server*, where *server* is the name of the local system.
- To update to databases in an arbitrary directory on the Solaris server, use the scope `file:`/*server*/*pathname*, where where *server* is the name of the local system and *pathname* is the fully-qualified directory path name to the database files.

`-v` Specifies that verbose messages are written. A message is written to `stdout` for each entry processed.

Operands The following operands are supported:

database Populates one or all databases. You can specify either the name of the database you want to process (for example, `auth_attr`), or `all` to process all databases. If you specify `all`, the databases are processed in the following order:

1. `auth_attr`(4)
2. `prof_attr`(4)
3. `exec_attr`(4)
4. `user_attr`(4)

Examples **EXAMPLE 1** Populating all tables in the NIS name service

The following example merges the values from all four attribute databases in the `/etc/security` directory of the local system into the corresponding tables in the NIS domain, `east.example.com`. The command is executed on the master server, `hoosier`, for the NIS domain and the source files are in the `/etc` and `/etc/security` directories on the NIS master server. No cross-table checking is performed. A summary message indicating the number of entries processed and updated for each table is written to `stdout`.

```
/usr/sadm/bin/smattrpop -s file:/hoosier \
          -t nis:/hoosier/east.example.com all
```

EXAMPLE 2 Updating the authorization table in the NIS+ name service

This example merges new authorization data from a local system file in the `auth_attr` text format into the existing `auth_attr` database in the NIS+ domain, `east.example.com`. The command is executed on the NIS+ master server, `foobar`. Values from the source `auth_attr` file replace the corresponding field values in the `NIS+` tables for each entry. A message is written to `stdout` for each entry processed. Database cross-checking is performed and any check error is written to `stdout`. A summary message indicating the number of entries processed and updated for the `auth_attr` database is written to `stdout`.

```
/usr/sadm/bin/smattrpop -c -f -v -s file:/foobar/var/temp \
          -t nisplus:/foobar/East.Sun.COM auth_attr
```

Environment Variables See environ(5) for a description of the JAVA_HOME environment variable, which affects the execution of the smattrpop command. If this environment variable is not specified, the /usr/java location is used. See smc(1M).

Exit Status Any errors encountered while updating the target entry are reported to stdout. The following exit values are returned:

0 The specified tables were updated. Individual entries may have encountered checking errors.

1 A syntax error occurred in the command line.

2 A fatal error occurred and the tables were not completely processed. Some entries may have been updated before the failure.

Files

/etc/security/auth_attr	Authorization description database. See auth_attr(4).
/etc/security/exec_attr	Execution profiles database. See exec_attr(4).
/etc/security/prof_attr	Profile description database. See prof_attr(4).
/etc/user_attr	Extended user attribute database. See user_attr(4).

Name smbios – display the contents of a System Management BIOS image

Synopsis `smbios [-BeOsx] [-i id] [-t type] [-w file] [file]`

Description The `smbios` utility displays the contents of the System Management BIOS (SMBIOS) image exported by the current system or stored in a file. SMBIOS is an industry-standard mechanism for low-level system software to export hardware configuration information to higher-level system management software. The SMBIOS data format itself is defined by the Distributed Management Task Force (DMTF). Refer to http://www.dmtf.org for more information about SMBIOS and to obtain a copy of the SMBIOS specification and implementation guidelines.

The SMBIOS image consists of a table of structures, each describing some aspect of the system software or hardware configuration. By default, `smbios` displays the entire contents of the current SMBIOS image. If the `-s` option is specified, `smbios` displays a summary of the structures that are present in the image. If the `-w` option is specified, `smbios` writes a copy of the SMBIOS image to the specified file. `smbios` can then be applied to the resulting file to display its content.

`smbios` attempts to display each structure and its content in a human- readable fashion. If `smbios` does not recognize a structure's type or content, the raw hexadecimal data for the structure is displayed.

Options The following options are supported:

`-B` Disable header validation for broken BIOSes.

By default, `smbios` attempts to validate the SMBIOS header by verifying the anchor strings, header checksums, and version number. This option might be necessary when a BIOS has a non-compliant header.

`-e` Display the contents of the SMBIOS entry point rather than the contents of the SMBIOS structure table.

`-i` *id* Display only the specified structure, named by its integer id.

`-O` Display obsolete structure types.

By default, `smbios` elides output for structures whose type is marked as obsolete in the DMTF SMBIOS specification.

`-s` Display only a summary listing of the structure identifiers and types, instead of the content of each selected structure.

`-t` *type* Display only those structures whose type matches the specified integer type, as defined the DMTF SMBIOS specification.

`-w` *file* Write a copy of the SMBIOS image to the specified file and exit.

The SMBIOS entry point is written to the start of the file with its structure table address set to the file offset of the structure table, and a new entry point checksum is computed.

`-x` Display raw hexadecimal data for the selected structures in addition to human-readable output.

By default, hexadecimal data is only displayed if `smbios` cannot display human-readable output for the selected structures.

Operands The following operands are supported:

file Specifies an alternate SMBIOS image to display instead of the current system's SMBIOS image.

Exit Status The following exit values are returned:

`0` Successful completion. All structures in the SMBIOS image were examined successfully.

`1` A fatal error occurred, such as failure to open the specified file or device, or corruption in the image.

`2` Invalid command-line options were specified.

Files `/dev/smbios` Kernel SMBIOS image device. This device special file is used to export a snapshot of the current system SMBIOS image.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	See below.

The command-line options are Evolving. The human-readable output is Unstable.

See Also `prtdiag(1M)`, `attributes(5)`, `smbios(7D)`

System Management BIOS Reference Specification (see http://www.dmtf.org)

Notes The implementation of a System Management BIOS image is entirely at the discretion of the system and BIOS vendors. Not all systems export an SMBIOS. The SMBIOS structure content varies widely between systems and BIOS vendors and frequently does not comply with the guidelines included in the specification. Some structure fields might not be filled in by the BIOS at all, and others might be filled inwith non-conforming values.

Name smc – start the Solaris Management Console

Synopsis

```
smc [ subcommand] [ args]

smc [ subcommand] [ args] -T tool_name
     [ - – tool_args]
```

Description The `smc` command starts the Solaris Management Console. The Solaris Management Console is a graphical user interface that provides access to Solaris system administration tools. It relies on Solaris Management Console servers running on one or more computers to perform modifications and report data. Each of these servers is a repository for code which the console can retrieve after the user of the console has authenticated himself or herself to the server.

The console can also retrieve toolboxes from the server. These toolboxes are descriptions of organized collections of tools available on that and possibly other servers. Once one of these toolboxes is loaded, the console will display it and the tools referenced in it.

The console can also run in a terminal (non-graphically), for use over remote connections or non-interactively from a script.

For information on the use of the graphical console, and for more detailed explanations of authentication, tools, and toolboxes, please refer to the Solaris Management Console online help available under the "Help" menu in the Solaris Management Console. To enable an NIS/NIS+ map to be managed from the Solaris Management Console, you must use the `smc edit` command to create a new toolbox for that map and enter the information about your NIS/NIS+ server where necessary. For instructions on creating a new toolbox, in the Solaris Management Console Help menu, select "Contents," then "About the Solaris Management Console Editor," then "To Create a Toolbox."

Subcommands The `smc` *subcommand*s are:

`open` The default subcommand for the Solaris Management Console is `open`. This will launch the console and allow you to run tools from the toolboxes you load. It does not need to be specified explicitly on the command line.

`edit` The `edit` subcommand will also launch the console, like the `open` subcommand. However, after loading a toolbox, you will not be able to run the referenced tools. Instead, you will be able to edit that toolbox, that is, add, remove, or modify any tools or folders in that toolbox.

SMF Administration The Solaris Management Console is implemented as a method that is managed by the service management facility (SMF) (see `smf(5)`), under the fault management resource identifier (FMRI):

```
svc:/application/management/wbem:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`.

The configuration properties of this service can be modified with svccfg(1M).

Through svcadm, the Solaris Management Console supports the following actions:

`start` Starts the CIM Object Manager (CIMOM) and Solaris Management Console server on the local host.

`stop` Stops the CIMOM and Solaris Management Console server on the local host.

`status` Gets the status of the CIMOM and Solaris Management Console server on the local host.

Controlling Remote Access

The Solaris Management Console supports an SMF property that controls remote access to WBEM-based applications, which include the Solaris Management Console. The property, `options/tcp_listen`, has default value of `false`, which disallows remote access. The value `true` allows remote access. See EXAMPLES.

Options

The following options are supported. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `- -domain` with the *domain* argument.

If *tool_args* are specified, they must be preceded by the `- -` option and separated from the double dashes by a space.

`- -auth-data` *13;file*

Specifies a file which the console can read to collect authentication data. When running the Solaris Management Console non-interactively, the console will still need to authenticate itself with the server to retrieve tools. This data can either be passed on the command line using the `-u`, `-p`, `-r`, and `-l` options (which is insecure, because any user can see this data), or it can be placed in a file for the console to read. For security reasons, this file should be readable only by the user running the console, although the console does not enforce this restriction.

The format of *file* is:

`hostname=`*host name*
`username=`*user name*
`password=`*password for user name*
`rolename=`*role name*
`rolepassword=`*password for role name*

Only one set of
`hostname-username-password-rolename-rolepassword`

may be specified in any one file. If the rolename is not specified, no role will be assumed.

`-B | - —toolbox` *13;toolbox*

Loads the specified toolbox. *toolbox* can be either a fully-qualified URL or a filename. If you specify an HTTP URL as, for example,

`http://`*host_name*`:`*port*`/. . .`

it must point to a *host_name* and *port* on which an Solaris Management Console server is running. If you omit *port*, the default port, `898`, is used. This option overrides the `-H` option.

`-D | - —domain` *13;domain*

Specifies the default domain that you want to manage. The syntax of *domain* is *type*:/*host_name*/*domain_name*, where *type* is `nis`, `nisplus`, `dns`, `ldap`, or `file`; *host_name* is the name of the machine that serves the domain; and *domain_name* is the name of the domain you want to manage. (*Note:* Do *not* use `nis+` for `nisplus`.) This option applies only to a single tool run in the terminal console.

If you do not specify this option, the Solaris Management Console assumes the `file` default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

`-h | - —help`

Prints a usage statement about the `smc` command and its subcommands to the terminal window. To print a usage statement for one of the subcommands, enter `-h` after the subcommand.

`-H | - —hostname` *13;host_name:port*

Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, `898`. If you do not specify *host_name*:*port*, the Solaris Management Console connects to the local host on port `898`. You may still have to choose a toolbox to load into the console. To override this behavior, use the `-B` option (see above), or set your console preferences to load a “home toolbox” by default.

`-J`*java_option*	Specifies an option that can be passed directly to the Java runtime (see `java`(1). Do not enter a space between `-J` and the argument. This option is most useful for developers.
`-l|- –rolepassword` *13;role_password*	Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
`-p|- –password` *13;password*	Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
`-r|- –rolename` *13;role_name*	Specifies a role name for authentication. If you are running the Solaris Management Console in a terminal and you do not specify this option, no role is assumed. The GUI console may prompt you for a role name, although you may not need to assume a role.
`-s|- –silent`	Disables informational messages printed to the terminal.
`-t`	Runs the Solaris Management Console in terminal mode. If this option is not given, the Solaris Management Console will automatically run in terminal mode if it cannot find a graphical display.
`- –trust`	Trusts all downloaded code implicitly. Use this option when running the terminal console non-interactively and you cannot let the console wait for user input.
`-T|- –tool` *13;tool_name*	Runs the tool with the Java class name that corresponds to *tool_name*. If you do not specify this option and the Solaris Management Console is running in terminal mode, the system prompts you. If the Solaris Management Console is running in graphical mode, the system either loads a toolbox or prompts you for one (see options `-H` and `-B`).

`-u	- –username` *13;user_name*	Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.
`-v	- –version`	Prints the version of the Solaris Management Console to the terminal. In the graphical console, this information can be found in the `About` box, available from the `Help` menu.
`-y	- –yes`	Answers `yes` to all yes/no questions. Use this option when running the terminal console non-interactively and you cannot let the console wait for user input.

Examples

EXAMPLE 1 Printing a Usage Statement

The following prints a usage statement about the `smc` command to the terminal window:

```
smc --help
```

EXAMPLE 2 Using SMF Property to Allow Remote Access

The following sequence of commands allows remote access to WBEM-based applications, including the Solaris Management Console.

```
# svccfg -s svc:/application/management/wbem \
    setprop options/tcp_listen = true
# svcadm refresh svc:/application/management/wbem
```

EXAMPLE 3 Passing an Option to Java

The following passes an option through to the Java VM, which sets the `com.example.boolean` system property to `true`. This system property is only an example; the Solaris Management Console does not use it.

```
smc -J-Dcom.example.boolean=true
```

Environment Variables

See `environ(5)` for a description of the following environment variable that affects the execution of the `smc` command:

`JAVA_HOME` If you do not specify this environment variable, your `PATH` is searched for a suitable java. Otherwise, the `/usr/j2se` location is used.

Exit Status

The following exit values are returned. Other error codes may be returned if you specify a tool (using `-T` *tool_name*) that has its own error codes. See the documentation for the appropriate tool.

`0` Successful completion.

`1` An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmcc

See Also auths(1), java(1), profiles(1), roles(1), smcconf(1M), svcadm(1M), svccfg(1M), attributes(5), environ(5), smf(5), X(7)

Name smccompile – build class list and compile Solaris Management Console service beans for remote use

Synopsis

```
/usr/sadm/bin/smccompile -c beanname

/usr/sadm/bin/smccompile -j tool | service [-n altjarname] jarfile

/usr/sadm/bin/smccompile -j library [-n altjarname] ALLTOOL | ALLSERVICE | ALL | attachedBeanna
```

Description The `smccompile` command is used by developers of tools, services, and libraries for the Solaris Management Console. For information regarding the Solaris Management Console, see `smc(1M)`.

`smccompile` compiles service class files given by the bean name for use with the Solaris Management Console. This step builds the extra proxy and stub classes for services to be used with Solaris Management Console tools. Solaris Management Console requires running `smccompile -c` before creating service jar files, and `smccompile -j` after creating tool, service, and library jars.

`smccompile`, in conjunction with `smcregister(1M)`, is intended to replace the `smcconf` command as the preferred interface for managing the Solaris Management Console repository as well as toolboxes from within scripts, due to significant performance enhancements over `smcconf`.

Options The following options are supported:

ALL	Specify that the library being registered to or unregistered from the repository is for use by all tools and services.
ALLSERVICE	Specify that the library being registered to or unregistered from the repository is for use by all services.
ALLTOOL	Specify that the library being registered to or unregistered from the repository is for use by all tools.
attachedBeaname	Specify the name of a registered jar to which the library jarfile should be attached to (or detached from). This is typically the same as *altjarname* (if provided) or *jarfile* used to register the jar to which this library is being attached or detached. An attached library means the library is only available for use by the tool or service to which it is being attached.
beanname	The full package path of the bean name to be compiled. An example bean name is: `com.mycompany.myproduct.MyService`.
`-c`	Compile and build service class files for the specified bean name. This step builds the extra proxy and stub classes for services to be used with Solaris Management Console tools. You must run `smccompile` with this option before creating service type jar files.

`-j`	Build a list of classes in text format, suitable as input to `smcregister` for registration with the Solaris Management Console repository. The output is written to standard out and should be redirected to a file. You must run `smccompile` with this option after creating any tool, service, or library jar.
jarfile	Specify the full path to the jar file to be registered. The name must be in the form *beanname*`.jar`, where *beanname* is the package path to the bean. If it is not, an alternate name must be given in that form using the `-n` option.
`-n` *altjarname*	Rename the jarfile in the repository to *altjarname*. Typically. this is the full bean name. For example, if the jarfile was `MyTool.jar`, then *altjarname* might be `com.mycompany.myproduct.MyTool.jar`. It is recommended that an *altjarname* containing the full package path be used. You must use this same name when registering the jar with `smcregister`.

Examples

EXAMPLE 1 Compiling a Service

The following command takes a Solaris Management Console service and builds its proxy and stub classes to make the service usable by Solaris Management Console tools:

```
/usr/sadm/bin/smccompile -c com.mycompany.myproject.MyServiceImpl
```

EXAMPLE 2 Building a Class List for a Service

The following command builds the class list file (`classlist.txt`) for a service suitable for use with the `smcregister(1M)` command:

```
/usr/sadm/bin/smccompile -j service \
     -n com.mycompany.myproject.MyServiceImpl.jar \
     ${HOME}/workarea/MyServiceImpl.jar > classlist.txt
```

The following command does the same thing without specifying an alternate name:

```
/usr/sadm/bin/smccompile -j service \
     ${HOME}/workarea/com.mycompany.myproject.MyServiceImpl.jar > classlist.txt
```

EXAMPLE 3 Building a Class List for a Tool

The following command builds the class list file (`classlist.txt`) for a tool suitable for use with the `smcregister`(1M) command:

```
/usr/sadm/bin/smccompile -j tool \
     -n com.mycompany.myproject.MyTool.jar \
     ${HOME}/workarea/MyTool.jar > classlist.txt
```

The following command does the same thing without specifying an alternate name:

EXAMPLE 3 Building a Class List for a Tool *(Continued)*

```
/usr/sadm/bin/smccompile -j tool \
     ${HOME}/workarea/com.mycompany.myproject.MyTool.jar > classlist.txt
```

EXAMPLE 4 Building a Class List for a Library Attached to All Tools

The following command builds the class list file (`classlist.txt`) for a library suitable for use with the `smcregister`(1M) command, and is attached to all tools:

```
/usr/sadm/bin/smccompile -j library \
     -n com.mycompany.myproject.MyLibrary.jar \
     ALLTOOL ${HOME}/workarea/MyLibrary.jar > classlist.txt
```

The following command does the same thing without specifying an alternate name:

```
/usr/sadm/bin/smccompile -j library \
    ALLTOOL \
    ${HOME}/workarea/com.mycompany.myproject.MyLibrary.jar > classlist.txt
```

EXAMPLE 5 Building a Class List for a Library Attached to a Specific Tool

The following command builds the class list file (`classlist.txt`) for a library suitable for use with the `smcregister`(1M) command, and is attached to a specific tool:

```
/usr/sadm/bin/smccompile -j library \
     -n com.mycompany.myproject.MyLibrary.jar \
     com.mycompany.myproject.MyTool.jar \
     ${HOME}/workarea/MyLibrary.jar > classlist.txt
```

The following command does the same thing without specifying an alternate name:

```
/usr/sadm/bin/smccompile -j library \
     com.mycompany.myproject.MyTool.jar \
     ${HOME}/workarea/com.mycompany.myproject.MyLibrary.jar > classlist.txt
```

Environment Variables

See `environ`(5) for descriptions of the following environment variables that affect the execution of `smccompile`:

JAVA_HOME — If you do not specify this environment variable, your PATH is searched for a suitable java. Otherwise, the `/usr/j2se` location is used.

Exit Status

The following exit values are returned:

`0` — Successful completion.

`1` — An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWMc

See Also smc(1M), smcconf(1M), smcregister(1M), attributes(5), environ(5)

Notes All standard shell quoting rules apply.

Name smcconf – configure the Solaris Management Console

Synopsis

```
/usr/sadm/bin/smcconf [-h] [-v] toolbox [action] [target]
     [parameters] [options]

/usr/sadm/bin/smcconf [-h] [-v] repository [action]
     [target] [parameters] [options]
```

Description The `smcconf` command configures the Solaris Management Console. See `smc(1M)`. This command enables you to add to, remove from, and list the contents of the toolboxes and bean repository.

Using `smcconf` to edit toolboxes is not as feature-rich as using the graphical editor in Solaris Management Console. The command line interface is intended for use in packaging scripts that do not require user interaction. To edit all the properties of a toolbox or to modify the hierarchy of folders in a toolbox, you must use the specialized graphical editor, that is, `smc edit`. See `smc(1M)`.

`smcregister` is intended to replace the `smcconf` command as the preferred interface for managing the Solaris Management Console repository as well as toolboxes from within scripts, due to significant performance enhancements over `smcconf`. See `smcregister(1M)`, `smccompile(1M)`, and the `Solaris Management Console SDK Guide` at `/usr/sadm/lib/smc/docs/sdkguide/index.html` for details.

Options The following options are supported:

`-h` Prints out a usage summary for the command.

`-v` Verbose option. Displays the debugging output at any time.

toolbox configuration

action Legal values are:

`add` Adds a *target* to the toolbox. Specify the path to the toolbox using the `-B` *toolboxpath* option and, optionally, provide locale information with the `-L` *locale* option.

`remove` Removes a *target* from the toolbox. Specify the path to the toolbox using the `-B` *toolboxpath* option and, as an alternative, provide locale information with the `-L` *locale* option.

`create` Creates a new toolbox with no tools in it. The only *target* recognized is `toolbox`.

`list` Lists the contents of the toolbox. No *target* is recognized. If you specify a *parameter*, it is taken as the path to a toolbox and the contents of that toolbox are listed. If you do not specify a *parameter*, the contents of the default toolbox are listed.

target Legal values are:

`tool` If the *action* is specified as `add`, this target adds a native Solaris Management Console tool from the toolbox. The required *parameter* is the full Java classname of the tool you are adding. If you specify a folder name with the `-F` option, the tool is placed inside that folder (the folder will not be created if it does not already exist). Otherwise, the tool is appended to the end of the toolbox and not placed inside any folder.

If the *action* is specified as `remove`, this target removes a native Solaris Management Console tool from the toolbox. The required *parameter* is the full Java classname of the tool you want to remove. If you specify a folder name with the `-F` option, any tool with the given name in that folder will be removed. If no folder name is specified, all tools with the given name in the toolbox are removed.

For the tool to appear in the console, the tool must also be registered in the repository. See the `repository configuration` section below for more information. If a tool is referenced in a toolbox but is not registered, it will not appear in the console when the toolbox is loaded.

Removing a tool from a toolbox does not remove the tool from the server repository.

`tbxURL` If the *action* is specified as `add` or `remove`, this target adds to or removes from the toolbox a link to another toolbox. The required *parameter* is the URL to the other toolbox.

The properties of addition and removal are the same as for the `tool` *target*.

`toolbox` If the *action* is specified as `create`, this target creates a skeleton toolbox with no tools. The required *parameter*s are: the toolbox name, description, and small and large icon paths. These must be followed by the `-B` *toolboxpath* and `-D` *scope* options.

`legacy` If the *action* is specified as `add` or `remove`, this target adds or removes legacy applications (command-line, X-windows, and web-based) to or from the toolbox. The `-N`, `-T`, `-E`, and `-B` options are required. The `-A` option is optional. Placement in the toolbox with the `-F` option follows the same rules as for the `tool` and `tbxURL` targets. See `NOTES` for more information about legacy applications.

`folder` If the *action* is specified as `add`, this target adds a folder to the toolbox. The required *parameter*s are: the folder name, description, and small and large icon paths.

If the *action* is specified as `remove`, this target removes a folder from the toolbox. If the folder to be removed is itself inside a folder, the containing folder must be specified with the `-F` option.

parameters Specifies values that might be required, depending on the combination of *action* and *target*.

options Supported options for various *action* and *target* combinations for the `toolbox` configuration are:

`-A` *parameters* Specifies the parameters to pass to the legacy application. This option is available only for the `legacy` target.

`-B` *toolboxpath* Specifies the path of the toolbox that is being modified. If this option is not given, the modifications will be performed on the default toolbox, "`This Computer`".

`-D` *scope* Specifies the scope (domain) in which the tool should be run. The legal values for *scope* are `file`, `nis`, `nisplus`, `dns`, and `ldap`. This can also be specified for a folder or a toolbox.

In the former case, all tools in that folder and its subfolders are run in that scope; in the latter, all tools in the toolbox are run in that scope.

`-E` *appPath* Specifies the absolute executable path of the legacy application. This option is available only for the `legacy` target.

`-F` *folder* Specifies the full path of the container folder. If this option is not given, the default folder is the 'root' folder of the toolbox.

`-H` [*host_name*][`:`*port*] Specifies the host and port from which a tool should be loaded. If *host_name* is not given, the default host is used. The default host is `localhost`, if the toolbox is loaded from the local file system, or the host from which the toolbox is loaded if loaded from a remote Solaris Management Console server. If `:port` is not given, the default port will be used. If

this option is not given at all, both the default host and the default port are used.

`-L` *locale* — Specifies the locale of the toolbox that is being modified. The default is the `C locale`.

`-N` *appName* — Specifies the name of the legacy application being registered. This is the name that appears in the console. This option is available only for the `legacy` target.

`-P` *key*:*value* — Specifies the key/value pairs that define parameters to a tool. Multiple key/value pairs can be specified at a time.

`-T` *appType* — Specifies the legacy application type. Legal values are `CLI`, `XAPP`, or `HTML`. This option is available only for the `legacy` target.

repository configuration

The Solaris Management Console repository stores information about the registered tools and services, as well as libraries (for instance, resource jars) and properties attached to tools or services.

action Legal values are:

`add` Adds information to the repository. If the `-f` option is given to `add`, the information overwrites any information of the same name already in the repository. If the `-f` option is not given, an error might be returned if the information is already in the repository.

`remove` Removes information from the repository.

`list` Lists the contents of the repository:

- All registered tools
- All registered services
- All libraries attached to all tools
- All libraries attached to all services
- All libraries attached to all tools and services

target Legal values are:

`bean` If the *action* is specified as `add`, this target will add a tool or service bean (which kind is determined by the contents of the bean) to the repository. The required *parameter* is the path to the jar file that contains the bean to be added.

If the *action* is specified as `remove`, this target will remove a tool or service bean from the repository. The required *parameter* is the full Java classname of the desired bean.

`library` If the *action* is specified as `add`, this target adds a "library" jar file to a tool or service bean. The two required *parameter*s are the full Java classname of the desired bean and the path to the jar file to be attached. The bean name can also be one of the "pseudo-beans," `ALL`, `ALLTOOL`, or `ALLSERVICE`, in which case the library is attached, respectively, to all beans, all tools, or all services in the repository.

If the *action* is specified as `remove`, this target detaches a "library" jar file from a tool or service bean. The two required *parameter*s are the full Java classname of the desired bean and the name of the jar file that is attached. As with the `add` action, the three "pseudo-beans" `ALL`, `ALLTOOL`, or `ALLSERVICE` can be used.

`property` If the *action* is specified as `add`, this target defines a property on a tool or service. One or more key/value pairs must be specified in the form,

`-P` *key*=*value*

Following this property list is a "pseudo-bean name," *pseudoBeanName*, as defined for the `library` target, on which the properties are defined. Optionally, a library name can follow the "pseudo-bean" name, in which case the properties are defined on the library that is attached to the named bean.

If the *action* is specified as `remove`, this target undefines a property on a tool or service. The key/value pairs, "pseudo-bean" name, and optional library are specified for the `add` action.

Examples

EXAMPLE 1 Adding Legacy Applications to a Toolbox

The following command adds to the default toolbox the command line interface (CLI) application, `/usr/bin/ls`, with arguments `-al -R`, giving it the name, `Directory Listing`:

```
/usr/sadm/bin/smcconf toolbox add legacy -N "Directory Listing" \
     -T CLI -E /usr/bin/ls -A "-al -R"
```

EXAMPLE 2 Adding a Folder to a Toolbox

The following command adds to the standard `Management Tools` toolbox a folder with the name, `New Folder`, the description, `This is a new folder`, and the small and large icons, `folder_s.gif` and `folder_l.gif`:

```
/usr/sadm/bin/smcconf toolbox add folder "New Folder" \
     "This is a new folder" folder_s.gif folder _l.gif \
     -B /var/sadm/smc/toolboxes/smc/smc.tbx
```

EXAMPLE 3 Adding a Native Solaris Management Console Tool to a Toolbox

The following command adds a native Solaris Management Console tool to the default toolbox. The Java classname of the tool is `HelloWorld.client.HelloTool` (the name, description, and icons visible in the console are provided by the tool itself). When loaded, it is run in the NIS domain, `syrinx`, which is hosted by the machine, `temple`, and is retrieved from port `2112` on the machine from which the toolbox was loaded:

```
/usr/sadm/bin/smcconf toolbox add tool HelloWorld.client.HelloTool \
     -D nis:/temple/syrinx -H :2112
```

EXAMPLE 4 Adding an Solaris Management Console Tool to the Repository

The following command adds the Java bean found in `HelloWorld.jar` to the repository. The jar file contains information that the bean is a tool:

```
/usr/sadm/bin/smcconf repository add bean HelloWorld.jar
```

EXAMPLE 5 Removing an Solaris Management Console Service from the repository

The following command removes a Java bean from the repository. Although the name of the bean implies that it is a service, that is merely a convention; the repository knows whether a particular registered bean is a tool or a service:

```
/usr/sadm/bin/smcconf repository remove bean \
     HelloWorld.server.HelloService
```

EXAMPLE 6 Attaching a Library to a Tool

The following command adds the library jar file, `HelloWorld_fr.jar` (probably a French localized version of the `HelloTool`'s resources) to the bean, `HelloWorld.client.HelloTool`:

```
/usr/sadm/bin/smcconf repository add library \
     HelloWorld.client.HelloTool HelloWorld_fr.jar
```

EXAMPLE 7 Attaching a Library to all Tools

The following command adds the library jar file, `widgets.jar`, to all tools in the repository. The library probably contains a widget set that might be useful to any registered tools:

```
/usr/sadm/bin/smcconf repository add library ALLTOOL widgets.jar
```

Environment Variables

See `environ(5)` for descriptions of the following environment variables that affect the execution of the `smcconf` command:

`JAVA_HOME` If you do not specify this environment variable, your PATH is searched for a suitable `java`. Otherwise, the `/usr/j2se` location is used.

`DISPLAY` If you do not set this environment variable, set it to null, or set it to an X(7) display to which you are not authorized to connect, the Solaris Management Console starts in terminal mode instead of graphical mode.

Exit Status The following exit values are returned:

`0` Successful completion.

`1` An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmc

See Also `smc(1M)`, `smccompile(1M)`, `smcregister(1M)`, `attributes(5)`, `environ(5)`

Notes All standard shell quoting rules apply.

Legacy applications (X-windows, command-line, and web-based applications) are handled differently from "native" Solaris Management Console tools. Legacy tools are handled by an instantiation of a native Solaris Management Console tool, `LegacyAppLauncher`, which, through the toolbox, is given the necessary information to run the legacy application: path, options, and so forth. Thus, you do not register a legacy application into the repository as you would a native Solaris Management Console tool. Instead, legacy applications appear only in toolboxes.

Name smcregister – configure the Solaris Management Console

Synopsis

```
/usr/sadm/bin/smcregister [-h] tool [-n altjarname] jarfile classlistfile xmlfile

/usr/sadm/bin/smcregister [-h] service [-n altjarname] jarfile classlistfile xmlfile
     [native_lib_list]

/usr/sadm/bin/smcregister [-h] library [-n altjarname] jarfile classlistfile | none ALLTOOL | ALLSERVICE |

/usr/sadm/bin/smcregister [-h] tool | service -u jarfile

/usr/sadm/bin/smcregister [-h] library -u jarfile ALL | ALLTOOL | ALLSERVICE | Attachedbeanname

/usr/sadm/bin/smcregister [-h] toolbox [-D] [action] [-f]
     [target] [parameters] [options]

/usr/sadm/bin/smcregister [-h] property key value ALL | ALLTOOL | ALLSERVICE | Attachedbeanname

/usr/sadm/bin/smcregister [-h] property -u key ALL | ALLTOOL | ALLSERVICE | Attachedbeanname

/usr/sadm/bin/smcregister [-h] repository list

/usr/sadm/bin/smcregister [-h] scripts regscript unregscript
```

Description The `smcregister` command configures the Solaris Management Console. For information regarding the Solaris Management Console, see smc(1M). This command enables you to add to, remove from, and list the contents of toolboxes and the Solaris Management Console repository.

`smcregister` also allows you to register scripts to perform registrations and unregistrations. Typically, a package containing one or more tools or services posts tool and service registrations immediately after installation. On Solaris, this is by way of invocations of `smcregister` from within a package post-install script. Similarly, unregistrations would be posted from within a package pre-remove script. These are per-machine registrations - that is, registration requests must be posted on each machine on which the Solaris Management Console server will be running. However, due to the way that diskless clients are installed, registration requests cannot be made at install time. Therefore, packages should include and install registration and unregistration scripts, and then register these scripts during installation by way of the `scripts` subcommand. These scripts should contain tool, toolbox, service, library or property configurations in any of its forms as listed in this man page. While these scripts function very much like package post-install and pre-remove scripts, do not assume the normal package environment is available. However, `PATH` can assumed to be `/usr/sbin:/usr/bin`

Using `smcregister` to edit toolboxes is not as feature-rich as using the Solaris Management Console's graphical editor. The command line interface is intended for use in packaging scripts that do not require user interaction. To edit all the properties of a toolbox or to modify the hierarchy of folders in a toolbox, you must use the specialized graphical editor, that is, `smc edit`. See `smc`(1M).

`smcregister` is intended to replace the `smcconf` command as the preferred interface for managing the Solaris Management Console repository as well as toolboxes from within scripts, due to significant performance enhancements over `smcconf`.

Options The following options are supported:

`-h` Prints out a usage summary for the command.

Scripts Configuration

regscript — The full path of a script containing registration commands. The script is executed upon the next restart of the Solaris Management Console server after the package containing the script is installed.

unregscript — The full path of a script containing unregistration commands. The script is executed upon the next restart of the Solaris Management Console server after the package containing the script is removed.

Toolbox Configuration

action — Legal values are:

- add — Adds a target to the toolbox. Specify the path to the toolbox using the `-B toolboxpath` option and, optionally, provide locale information with the `-L locale` option.
- create — Creates a new toolbox with no tools in it. The only target recognized is `toolbox`.
- list — Lists the contents of the toolbox. No target is recognized. If you specify a parameter, it is taken as the path to a toolbox and the contents of that toolbox are listed. If you do not specify a parameter, the contents of the default toolbox are listed.
- remove — Removes a target from the toolbox. Specify the path to the toolbox using the `-B toolboxpath` option and, optionally, provide locale information with the `-L locale` option.

`-D` — Defers execution of the `toolbox` command until the Solaris Management Console server is restarted. This is a convenient option for use in packaging scripts during install and un-install. Additionally, the command runs much faster than if run interactively (without `-D`).

target — Legal values are:

- folder — If the action is specified as `add`, this target adds a folder to the toolbox. There are four required parameters: the folder name, description, and small and large icon paths. If the action is specified as remove, this target removes a folder from the toolbox. If the folder to be removed is itself inside a folder, the containing folder must be specified with the `-F` option.
- legacy — If the action is specified as `add` or `remove`, this target adds or removes legacy applications (command line, `X-windows`, and

web-based) to or from the toolbox. The `-N`, `-T`, `-E`, and `-B` options are required, and the `-A` option is optional. Placement in the toolbox with the `-F` option follows the same rules as for the `tool` and `tbxURL` targets.See `NOTES` for more information about legacy applications.

tbxURL — If the action is specified as `add` or `remove`, this target adds to or removes from the toolbox a link to another toolbox. The required parameter is the URL to the other toolbox. The properties of addition and removal are the same as for the tool target.

tool — If the action is specified as `add`, this target adds a native Solaris Management Console tool from the toolbox. The required parameter is the full Java classname of the tool you are adding. If you specify a folder name with the `-F` option, the tool is placed inside that folder (the folder will not be created if it does not already exist). Otherwise, the tool is appended to the end of the toolbox and not placed inside any folder. If the action is specified as remove, this target removes a native Solaris Management Console tool from the toolbox. The required parameter is the full Java classname of the tool you wish to remove. If you specify a folder name with the `-F` option, any tool with the given name in that folder will be removed. If no folder name is specified, all tools with the given name in the toolbox will be removed. For the tool to show up in the console, the tool must also be registered in the repository. See the repository configuration section below for more information. If a tool is referenced in a toolbox but is not registered, it will not appear in the console when the toolbox is loaded. Removing a tool from a toolbox does not remove the tool from the server repository.

toolbox — If the action is specified as `create`, this target creates a skeleton toolbox with no tools. There are four required parameters: the toolbox name, description, and small and large icon paths. These must be followed by the `-B` *toolboxpath* and `-D` *scope* options.

parameters — Specifies values that may be required depending on the combination of action and target.

options — Supported options for various action and target combinations for the toolbox configuration are:

`-A` — Specifies the parameters to pass to the legacy application. This option is available only for the legacy target.

`-B`	Specifies the path of the toolbox that is being modified. If this option is not given, the modifications will be performed on the default toolbox, `This Computer`.
`-D`	Specifies the scope (domain) in which the tool should be run. The legal values for scope are `file`, `nis`, `nisplus`, `dns`, and `ldap`. This may also be specified for a folder or a toolbox. In the former case, all tools in that folder and its subfolders will be run in that scope; in the latter, all tools in the toolbox will be run in that scope.
`-E`	Specifies the absolute executable path of the legacy application. This option is available only for the legacy target.
`-f`	If the `-f` option is given to add, the information will overwrite any information of the same name already in the toolbox. If the `-f` option is not given, an error may be returned if the information is already in the toolbox.
`-F` *folder*	Specifies the full path of the container folder. If this option is not given, the default folder is the *root* folder of the toolbox.
`-H` [*host_name*][:*port*]	Specifies the host and port from which a tool should be loaded. If host_name is not given, the default host (localhost, if the toolbox is loaded from the local filesystem, or the host from which the toolbox is loaded if loaded from a remote Solaris Management Console server) will be used. If :*port* is not given, the default port will be used. If this option is not given at all, both the default host and the default port will be used.
`-L` *locale*	Specifies the locale of the toolbox which is being modified. The default is the `C` locale.
`-N` *appName*	Specifies the name of the legacy application being registered. This is the name that will appear in the console. This option is available only for the `legacy` target.

-P *key:value*	Specifies the key/value pairs that define parameters to a tool. Multiple key/value pairs can be specified at a time.
-T *appType*	Specifies the legacy application type. Legal values are `CLI`, `XAPP`, or `HTML`. This option is available only for the legacy target.

Tool, Service, and Library Configuration

See `NOTES` for more information about registration and unregistration of tools, services, and libraries.

ALL	Specify that the library being registered to or unregistered from the repository is for use by all tools and services.
ALLSERVICE	Specify that the library being registered to or unregistered from the repository is for use by all services.
ALLTOOL	Specify that the library being registered to or unregistered from the repository is for use by all tools.
attachedBeanname	The name of a registered jar to which the library jarfile should be attached to (or detached from). This is typically the same as *altjarname* (if provided) or *jarfile* used to register the jar to which this library is being attached or detached. An attached library means the library is only available for use by the tool or service to which it is being attached.
classlistfile	The classlist text file generated from the smccompile(1M) command. Library registration does not require that a classlist file be specified. Instead, you can substitute the keyword `none` in place of the classlist path argument to `smcregister`, in which case one will be generated automatically. Generating the classlist automatically during server startup will cause the next server restart to take longer, so it is strongly suggested that developers always provide a classlist file with their libraries. Auto-generation is more appropriately used to register 3rd-party library jars.
jarfile	The full path to the jar file to be registered/unregistered. The name must be in the form *beanname*`.jar`, where *beanname* is the package path to the bean. If it is not, an alternate name must be given in that form using the -n option.
-n *altjarname*	Rename the jarfile in the repository to *altjarname*. This would typically be the full bean name. For example, if the jarfile was `MyTool.jar`, then *altjarname* might be com.mycompany.myproduct.MyTool.jar. It is recommended that an *altjarname* containing the full package path be used.

native_lib_list List of up to 4 native libraries that can be associated with a service bean.

`-u` The operation will be to un-register the jar with the Solaris Management Console repository. The jarfile argument must be identical to the *altjarname* used to register the jar (if provided), or jarfile.

xmlfile The `xml` descriptor file that describes this jarfile. Every tool or services must have one. See the `Solaris Management Console SDK Guide` located at `/usr/sadm/lib/smc/docs/sdkguide/index.html`.

Repository Configuration The Solaris Management Console repository stores information about the registered tools and services, as well as libraries (for instance, resource jars) and properties attached to tools or services.

list Lists the contents of the repository:

- All registered tools
- All registered services
- All libraries attached to all tools
- All libraries attached to all services
- All libraries attached to all tools and services

Property Configuration See `NOTES` for more information about registration and unregistration of properties. If registering a property, this defines a property on a tool or service. Only one key value pair at a time can be registered.

beanname The name of a registered jar on which the properties will be defined. Optionally, a library name may follow the bean name, in which case the properties are defined on the library that is attached to the named bean.

If unregistering a property, this undefines a property from a tool or service. Only one key value pair at a time can be registered. The key, beanname, and optional library are specified as for registering a property.

Examples

EXAMPLE 1 Adding Legacy Applications to a Toolbox

The following command adds to the default toolbox the Command Line Interface (CLI) application, `/usr/bin/ls` with arguments `-al -R`, giving it the name, Directory Listing:

```
/usr/sadm/bin/smcregister toolbox add legacy -N "Directory Listing" \
     -T CLI -E /usr/bin/ls -A "-al -R"
```

Use this variation to defer execution of this command until the Solaris Management Console server is restarted:

```
/usr/sadm/bin/smcregister toolbox -D add legacy -N "Directory Listing" \
     -T CLI -E /usr/bin/ls -A "-al -R"
```

EXAMPLE 2 Adding a Folder to a Toolbox

The following command adds to the standard `Management Tools` toolbox a folder with the name, New Folder, the description, This is a new folder, and the small and large icons, `folder_s.gif` and `folder_l.gif`:

```
/usr/sadm/bin/smcregister toolbox add folder "New Folder" \
     "This is a new folder" folder_s.gif folder _l.gif \
     -B /var/sadm/smc/toolboxes/smc/smc.tbx
```

EXAMPLE 3 Adding a Native Solaris Management Console Tool to a Toolbox

The following command adds a native Solaris Management Console tool to the default toolbox. The Java classname of the tool is `com.mycompany.myproject.client.MyTool` (the name, description, and icons visible in the console are provided by the tool itself). When loaded, it will be run in the NIS domain, syrinx, which is hosted by the machine, temple, and will be retrieved from port 2112 on the machine from which the toolbox was loaded.

```
/usr/sadm/bin/smcregister toolbox add tool \
     com.mycompany.myproject.client.MyTool \
     -D nis:/temple/syrinx -H :2112
```

EXAMPLE 4 Adding an Solaris Management Console Tool to the Repository

The following command adds the Java bean found in MyTool.jar to the repository. The xml file contains information about the tool. The classlist file would have been generated by `smccompile -j`:

```
/usr/sadm/bin/smcregister tool -n com.mycompany.myproject.client.MyTool.jar \
     ${HOME}/workarea/MyTool.jar \
     ${HOME}/workarea/MyTool_classlist.txt \
     ${HOME}/workarea/MyTool.xml
```

Use this variation to add an Solaris Management Console tool to the repository without specifying an alternate name:

```
/usr/sadm/bin/smcregister tool  \
     ${HOME}/workarea/com.mycompany.myproject.client.MyTool.jar \
     ${HOME}/workarea/MyTool_classlist.txt \
     ${HOME}/workarea/MyTool.xml
```

EXAMPLE 5 Adding an Solaris Management Console Service to the Repository

The following command adds the Java bean found in MyServiceImpl.jar to the repository. The xml file contains information about the service. The classlist file would have been generated by `smccompile -j`. The extra proxy and stub classes included in the jar would have been generated by `smccompile -c`:

```
/usr/sadm/bin/smcregister service \
     -n com.mycompany.myproject.server.MyServiceImpl.jar \
```

EXAMPLE 5 Adding an Solaris Management Console Service to the Repository *(Continued)*

```
     ${HOME}/workarea/MyServiceImpl.jar \
     ${HOME}/workarea/MyServiceImpl_classlist.txt \
     ${HOME}/workarea/MyServiceImpl.xml
```

Use this variation to add a Solaris Management Console service to the repository without specifying an alternate name:

```
/usr/sadm/bin/smcregister service  \
     ${HOME}/workarea/com.mycompany.myproject.server.MyServiceImpl.jar \
     ${HOME}/workarea/MyServiceImpl_classlist.txt \
     ${HOME}/workarea/MyServiceImpl.xml
```

EXAMPLE 6 Removing an Solaris Management Console Tool From the Repository

The following command removes a Java tool bean from the repository:

```
/usr/sadm/bin/smcregister tool \
     -u com.mycompany.myproject.client.MyTool.jar
```

EXAMPLE 7 Removing an Solaris Management Console Service From the Repository

The following command removes a Java service bean from the repository:

```
/usr/sadm/bin/smcregister service \
     -u com.mycompany.myproject.server.MyServiceImpl.jar
```

EXAMPLE 8 Attaching a Library to a Specific Tool

The following command adds the library jar file, MyTool_fr.jar (probably a French localized version of the MyTool's resources) to the bean, com.mycompany.myproject.client.MyTool:

```
/usr/sadm/bin/smcregister library  \
     -n MyTool_fr.jar \
     ${HOME}/workarea/MyTool_fr.jar \
     ${HOME}/workarea/MyTool_fr_classlist.txt \
     com.mycompany.myproject.client.MyTool
```

EXAMPLE 9 Attaching a Library to All Tools

The following command adds the library jar file, widgets.jar, to all tools in the repository. The library probably contains a widget set which might be useful to any registered tools. The classlist file would have been generated by `smccompile -j`.

```
/usr/sadm/bin/smcregister library \
     ${HOME}/workarea/lib/widgets.jar\
     ${HOME}/workarea/lib/widgets_classlist.txt \
     ALLTOOL
```

Alternatively, to add a 3rd-party library jar to all tools, replace the classlist file with `none`:

EXAMPLE 9 Attaching a Library to All Tools *(Continued)*

```
/usr/sadm/bin/smcregister library \
     /opt/lib/XYZwidgets.jar none ALLTOOL
```

EXAMPLE 10 Detaching a Library from All Tools

The following command removes the Java library bean from the repository:

```
/usr/sadm/bin/smcregister library -u MyTool_fr.jar ALLTOOL
```

EXAMPLE 11 Detaching a Library from a Specific Tool

The following command detaches the library jar file, MyTool_fr.jar (probably a French localized version of the MyTool's resources) from the bean `com.mycompany.myproject.client.MyTool`, and removes it from the repository:

```
/usr/sadm/bin/smcregister library -u MyTool_fr.jar \
     com.mycompany.myproject.client.MyTool
```

EXAMPLE 12 Registering Scripts

The following command registers the following scripts containing registration and unregistration commands. MyProduct_reg.sh will be executed upon the next server restart after the file is installed by the owning package. MyProduct_unreg.sh will be executed upon the next server restart after the file is removed by the owning package:

```
/usr/sadm/bin/smcregister scripts \
     /usr/sadm/lib/myProduct/MyProduct_reg.sh \
     /usr/sadm/lib/myProduct/MyProduct_unreg.sh
```

Environment Variables

See `environ(5)` for descriptions of the following environment variables that affect the execution of `smcregister`:

JAVA_HOME — If you do not specify this environment variable, your `PATH` is searched for a suitable java. Otherwise, the `/usr/j2se` location is used.

Exit Status

The following exit values are returned:

`0` — Successful completion.

`1` — An error occurred.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmc

See Also smc(1M), smcconf(1M), smccompile(1M), attributes(5), environ(5)

Notes All standard shell quoting rules apply.

Legacy applications (`X-windows`, command-line, and web-based applications) are handled differently from native Solaris Management Console tools. Legacy tools are handled by an instantiation of a native Solaris Management Console tool, `LegacyAppLauncher`, which, through the toolbox, is given the necessary information to run the legacy application: path, options, and so forth. Thus, you do not register a legacy application into the repository as you would a native Solaris Management Console tool. Instead, legacy applications appear only in toolboxes.

Registration and unregistration of tools, services, libraries, and properties do not take effect until the Solaris Management Console server is restarted. Run `/etc/init.d/init.wbem stop` followed by `/etc/init.d/init.wbem start`

Name smcron – manage jobs in the crontab database

Synopsis

```
/usr/sadm/bin/smcron subcommand [ auth_args] - —
     [subcommand_args]
```

Description The `smcron` command manages jobs in the `crontab(1)` database.

subcommands `smcron` *subcommand*s are:

`add` Adds a job to the `crontab`(1) database. To add a job, the administrator must have the `solaris.jobs.user` authorization. To add a job to another user's `crontab` file, the administrator must have the `solaris.jobs.admin` authorization.

`delete` Deletes a job from the `crontab`(1) database. To delete a job, the administrator must have the `solaris.jobs.user` authorization. To delete a job from another user's `crontab` file, the administrator must have the `solaris.jobs.admin` authorization.

`list` Lists one or more jobs in the `crontab`(1) database. To list all jobs, the administrator must have the `solaris.jobs.user` authorization. To list a job in another user's `crontab` file, the administrator must have the `solaris.jobs.admin` authorization. No authorization is needed to list a user's own jobs.

`modify` Modifies a job in the `crontab`(1) database. To modify a job, the administrator must have the `solaris.jobs.user` authorization. To modify a job in another user's `crontab` file, the administrator must have the `solaris.jobs.admin` authorization.

Options The `smcron` authentication arguments, *auth_args*, are derived from the `smc(1M)` arg set and are the same regardless of which subcommand you use. The `smcron` command requires the Solaris Management Console to be initialized for the command to succeed (see `smc(1M)`). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, *subcommand_args*, must come after the *auth_args* and must be separated from them by the `- —` option.

auth_args The valid *auth_args* are `-D`, `-H`, `-l`, `-p`, `-r`, and `-u`; they are all optional. If no *auth_args* are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `- —domain` with the *domain* argument.

`-D | - —domain` *13;domain* Specifies the default domain that you want to manage. `smcron` accepts only `file` for this option. `file` is also the default value.

The `file` default domain means that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

`-H | - –hostname` *13;host_name:port*
: Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, `898`. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port `898`. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc(1M) -B` option, or set your console preferences to load a "home toolbox" by default.

`-l | - –rolepassword` *13;role_password*
: Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-p | - –password` *13;password*
: Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-r | - –rolename` *13;role_name*
: Specifies a role name for authentication. If you do not specify this option, no role is assumed.

`-u | - –username` *13;user_name*
: Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

`- –`
: This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `- –` option.

subcommand_args
: For the time-related subcommands described below, `-m`, `-M`, `-t`, and `-w`, you can enter multiple arguments, separated only by commas. `smcron` will construct `crontab` entries appropriate for your arguments. See EXAMPLES.

Note: Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

- For subcommand `add`:

  `-c` *command* — Specifies the command that you want to run.

  `-h` — (Optional) Displays the command's usage statement.

  `-m` *day_of_month* — (Optional) Specifies the day of the month you want to run the job. Valid values are 1–31. If you specify both `-t` and `-m` options, the job executes one day per month at the time specified by `-t`.

  `-M` *month* — (Optional) Specifies the month that you want to run the job. Valid values are 1–12. If you specify both `-t` and `-M` options, the job executes during the specified month at the time specified by `-t`.

  `-n` *name* — Specifies the unique name of the job.

  `-o` *owner* — (Optional) Specifies the user name that is the owner of the job. If you do not specify this option, the user name specified by the `-U` option is assumed.

  `-t` *time_of_day* — Specifies the time (in *hh*:*mm*) that you want to execute the command. If no other time-related options are specified (`-m`, `-M`, or `-w`), the job executes every day at the time specified by `-t`. If you specify both `-t` and `-w` options, the job executes one day per week at the time specified by `-t`. If you specify both `-t` and `-m` options, the job executes one day per month at the time specified by `-t`. If you specify both `-t` and `-M` options, the job executes each day during the specified month at the time specified by `-t`.

  `-w` *day_of_week* — (Optional) Specifies the day of the week you want to execute the command. Valid values are as follows:

  - `0`=Sunday
  - `1`=Monday
  - `2`=Tuesday
  - `3`=Wednesday
  - `4`=Thursday
  - `5`=Friday
  - `6`=Saturday

  If you specify both `-t` and `-w` options, the job executes one day per week at the time specified by `-t`.

- For subcommand `delete`:

  `-h` — (Optional) Displays the command's usage statement.

  `-n` *name* — Specifies the unique name of the job.

  `-o` *owner* — (Optional) Specifies the user name that is the owner of the job. If you do not specify this option, the user name specified by the `-U` option is assumed.

- For subcommand `list`:

  `-f` *n*|*s*|*v* (Optional) Specifies the format of the output. See EXAMPLES for examples of each output type.

  - *n* — Displays the data in native format, as it appears in the `crontab(1)` database.
  - *s* — Default format. Displays the data in summary format.
  - *v* — Displays the data in verbose format.

  `-h` (Optional) Displays the command's usage statement.

  `-o` *owner* (Optional) Lists all jobs for the specified owner (user name). If you do not specify this option, all jobs in the `crontab`(1) database are listed.

- For subcommand `modify`:

  `-c` *command* (Optional) Specifies the command that you want to run.

  `-h` (Optional) Displays the command's usage statement.

  `-m` *day_of_month* (Optional) Specifies the day of the month you want to run the job. Valid values are 1–31. If you specify both `-t` and `-m` options, the job executes one day per month at the time specified by `-t`.

  `-M` *month* (Optional) Specifies the month that you want to run the job. Valid values are 1–12. If you specify both `-t` and `-M` options, the job executes during the specified month at the time specified by `-t`.

  `-n` *name* Specifies the current unique name of the job.

  `-N` *new_name* (Optional) Specifies the new unique name of the job.

  `-o` *owner* (Optional) Specifies the user name that is the owner of the job. If you do not specify this option, the user name specified by the `-U` option is assumed.

  `-O` *new_owner* (Optional) Specifies the new owner of the job.

  `-t` *time_of_day* (Optional) Specifies the time (in *hh*:*mm*) that you want to execute the command. If no other time-related options are specified (`-m`, `-M`, or `-w`), then the job executes every day at the time specified by `-t`. If you specify both `-t` and `-w` options, the job executes one day per week at the time specified by `-t`. If you specify both `-t` and `-m` options, the job executes one day per month at the time specified by `-t`. If you specify both `-t` and `-M`, then the job executes each day during the specified month at the time specified by `-t`.

  `-w` *day_of_week* (Optional) Specifies the day of the week you want to execute the command. Valid values are as follows:

  - `0`=Sunday

- 1=Monday
- 2=Tuesday
- 3=Wednesday
- 4=Thursday
- 5=Friday
- 6=Saturday

If you specify both `-t` and `-w` options, the job executes one day per week at the time specified by `-t`.

Examples

EXAMPLE 1 Adding a Job

The following adds a new job, owned by `root`, that removes the old log files from `/tmp` daily at 1:30 AM.

```
./smcron add -H myhost -u root -p mypassword -- -n "Remove old logs" \
             -t 1:30 -c "rm /tmp/*.log" -o root
```

EXAMPLE 2 Deleting a Job

The following deletes the job `Remove old logs` owned by `root`:

```
./smcron delete -H myhost -u root -p mypassword -- \
          -n "Remove old logs" -o root
```

EXAMPLE 3 Listing Jobs in Native Format

The following lists all jobs in native, or `crontab`(1), format:

```
./smcron list -H myhost -u root -p mypassword -- -f n
MINUTE HOUR DATE MONTH DAY COMMAND

10 3 * * * /usr/sbin/logadm
15 3 * * 0 /usr/lib/fs/nfs/nfsfind
1 2 * * * [ -x /usr/sbin/rtc ] && /usr/sbin/rtc -c > /dev/null 2>&1
30 3 * * * [ -x /usr/lib/gss/gsscred_clean ] && /usr/lib/gss/gsscred_clean
```

EXAMPLE 4 Listing Jobs in Standard Format

The following lists all jobs owned by `lp` in standard format:

```
./smcron list -H myhost -u root -p mypassword -- -f s -o lp
NAME::OWNER::SCHEDULE::COMMAND

NoName_1765663371::lp::Weekly on Sundays at 3:13 AM::cd /var/lp/logs;
   if [ -f requests ]; then if [ -f requests.1 ]; then /bin/mv requests.1
   requests.2; fi; /usr/bin/cp requests requests.1; > requests; fi
NoName_512822673::lp::Weekly on Sundays at 4:15 AM::cd /var/lp/logs;
   if [ -f lpsched ]; then if [ -f lpsched.1 ]; then /bin/mv lpsched.1
   lpsched.2; fi; /usr/bin/cp lpsched lpsched.1; >lpsched; fi
```

EXAMPLE 5 Listing jobs in verbose format

The following lists all jobs in verbose format:

```
./smcron list -H myhost -u root -p mypassword -- -f v
NAME::OWNER::SCHEDULE::NEXT_RUN::STATUS::COMMAND

NoName_1075488942::root::Advanced::::Finished on Feb 10 3:10 with code 1
::/etc/cron.d/logchecker
databackup::root::Weekly on Sundays at 3:10 AM::3/19/00 3:10 AM
::Finished on Sep 19 3:10::/usr/lib/newsyslog
runlog::root::Daily at 2:01 AM::3/14/00 2:01 AM::Finished on Feb 11
 2:01 AM::/usr/sbin/rtc
```

EXAMPLE 6 Changing a Job

The following modifies the job `Remove old logs` owned by `root` to execute daily at 2:00 AM:

```
./smcron modify -H myhost -u root -p mypassword -- -n "Remove old logs" \
          -o root -t 2:00
```

EXAMPLE 7 Specifying Multiple Time Arguments

`smcron` allows you to specify a range of times for all of its time-related subcommands, `-m`, `-M`, `-t`, and `-w`. For example, the following command:

```
# smcron add -u root -p xxxx -- -n cronjob1 -w 1-4,5 \
-t 12:00,13:15,14:30 -c ls
```

...creates the following entry in `crontab`:

```
0,15,30 12,13,14 * * 1,2,3,4,6 ls #cronjob1
```

This job would run on Monday through Thursday and Saturday at the following times:

```
12:00 12:15 12:30
13:00 13:15 13:30
14:00 14:15 14:30
```

Environment Variables

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smcron` command. If this environment variable is not specified, the `/usr/java` location is used. See `smc(1M)`.

Exit Status

The following exit values are returned:

`0` Successful completion.

1 Invalid command syntax. A usage message displays.

2 An error occurred while executing the command. An error message displays.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga

See Also crontab(1), cron(1M), smc(1M), attributes(5), environ(5)

Notes The timezone of the `cron` daemon sets the system-wide timezone for `cron` entries. This, in turn, is by set by default system-wide using `/etc/default/init`.

If some form of *daylight savings* or *summer/winter time* is in effect, then jobs scheduled during the switchover period could be executed once, twice, or not at all.

Name smcwebserver – manage the server for the Sun Web Console

Synopsis `/usr/sbin/smcwebserver` *subcommand options*

Description The `smcwebserver` utility manages the Sun Web Console server. Sun Web Console is a browser-based interface that performs systems management. System administrators can manage systems, devices and services from the console.

When the console webserver is running, you can view the console by opening a browser and pointing to:

`https://`*host*`:6789`

host is the machine where the console has been installed and the console server is running.

The `smcwebserver` service is managed by the service management facility (SMF) (see `smf(5)`), under the fault management resource identifier (FMRI):

`svc:/system/webconsole`

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. `smcwebserver` can only be started by the superuser or someone in the Primary Administrator role.

The configuration properties of this service can be modified with `svccfg(1M)`.

`smcwebserver` supports an SMF property that controls remote access to the Sun Web Console server. The property, `options/tcp_listen`, has a default value of `false`, which disallows remote access. The value `true` allows remote access. See EXAMPLES.

Subcommands The following subcommands are supported:

disable — Disable automatic start or stop during system boot or shutdown. Until the administrator reruns the script with the `smcwebserver enable` subcommand the webserver can be started/stopped only when the administrator executes the script manually using the following command:

```
# /usr/sbin/smcwebserver [start | stop]
```

`enable` — Enable the webserver to startup automatically during subsequent system boot and gracefully stop during system shutdown.

`restart` — Stop and subsequently start the console webserver.

The format of the restart subcommand is:

`restart` [`-U` *username*]

`start` — Start the console webserver.

The format of the start subcommand is:

`start` [`-U` *username*]

`stop` Stop the console webserver.

`status` Display status of the console webserver.

The format of the status subcommand is:

`status` [`-p`]

Options The following options are supported:

`-U` *username* | `--username` *username* — The user identity to run the server as. Once the server has successfuly started under the specified identity, all subsequent starts will automatically be done under that identity until you change it via this option, or by changing the com.sun.web.console.user configuration property via the smreg(1M) command. The default is to run the server under the `noaccess` identity.

`-p` | `--parseable` — Display non-localized output suitable for programmatic parsing. If the server is running, the output will be:

running=yes

If the server is not running, the output will be:

running=no

`-h` | `--help` | `-?` — Display the usage statement.

`-V` | `--version` — Display console version information.

Examples **EXAMPLE 1** Displaying the Usage Statement

The following command displays the `smcwebserver` usage statement:

```
% smcwebserver --help
```

EXAMPLE 2 Determining if the Server is Running

The following shell command will start the server if it is not already running.

```
ans=‘smcwebserver -p | grep running | cut -d"=" -f2‘
if [ "$ans" = "no" ]; then
    smcwebserver start
fi
```

EXAMPLE 3 Using SMF Property to Allow Remote Access

The following sequence of commands allows remote access to the Sun Web Console server.

```
# svccfg -s svc:/system/webconsole \
    setprop options/tcp_listen = true
# svcadm refresh svc:/system/webconsole
```

Environment Variables

See `environ(5)` for descriptions of the following environment variables that affect the execution of `smcwebserver`:

`JAVA_HOME` If you do not specify this environment variable, your `PATH` is searched for a suitable java. Otherwise, depending on the OS, the following default locations are used:

Solaris: `/usr/j2se`

Linux: `/usr/java/j2sdk1.4*`

Exit Status

The following exit values are returned:

`0` Successful completion.

`1` An error occurred.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmcon
Interface Stability	Stable

Name smdiskless – manage diskless client support for a server

Synopsis `/usr/sadm/bin/smdiskless` *subcommand* `[` *auth_args*`] - –` `[`*subcommand_args*`]`

Description The `smdiskless` command manages diskless client support for a server.

`smdiskless` *subcommand*s are:

`add` Adds a new diskless client to a server. There are two usages for this command. The user can either specify all the optional arguments directly on the command line, or provide a `sysidcfg(4)` formatted file as input. A future enhancement will allow specifying both a `sysidcfg`(4) formatted file and optional arguments, which will override the values in the `sysidcfg`(4) file.

`delete` Deletes an existing diskless client from the system databases and removes any server support associated with the host, depending on the *os_server* type.

`list` Lists existing diskless clients served by *os_server*.

`modify` Modifies the specified attributes of the diskless client *os_server*.

Options The `smdiskless` authentication arguments, *auth_args*, are derived from the `smc(1M)` arg set and are the same regardless of which subcommand you use. The `smdiskless` command requires the Solaris Management Console to be initialized for the command to succeed (see `smc(1M)`). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, *subcommand_args*, must come after the *auth_args* and must be separated from them by the `- –` option.

auth_args The valid *auth_args* are `-D`, `-H`, `-l`, `-p`, `-r`, and `-u`; they are all optional. If no *auth_args* are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `- –domain`.

Note – `smdiskless` supports the `-–auth-data` *file* option, which enables you to specify a file the console can read to collect authentication data. See `smc(1M)` for a description of this option.

`-D` | `- –domain` *13;domain* Specifies the default domain that you want to manage. The syntax of *domain* is *type*:/*host_name*/*domain_name*, where *type* is `nis`, `nis+`, `dns`, `ldap`, or `file`; *host_name* is the name of the machine that serves the domain; and *domain_name* is the name of the domain you want to manage. (*Note:* Do *not* use `nis+` for `nisplus`.)

If you do not specify this option, the Solaris Management Console assumes the `file` default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

`-H | - —hostname` *13;host_name:port*
: Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, `898`. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port `898`. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc(1M) -B` option, or set your console preferences to load a "home toolbox" by default.

`-l | - —rolepassword` *13;role_password*
: Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-p | - —password` *13;password*
: Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-r | - —rolename` *13;role_name*
: Specifies a role name for authentication. If you do not specify this option, no role is assumed.

`-u | - —username` *13;user_name*
: Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

`- —`
: This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `- —` option.

subcommand_args
: *Note:* Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

- For subcommand `add`:

  `-h` (Optional) Displays the command's usage statement.

  `-i` *IP_address* Specifies the IP address for the host in the form of `172.16.200.1`.

  `-e` *ethernet_addr* Specifies the Ethernet address.

  `-n` *host* Specifies the client name.

  `-o` *os_server* (optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc(1M)` `-D` option. This option is useful in the event that the name service server and the OS server are not the same machine.

  `-x` os=*platform* Specifies the operating system. The syntax for *platform* is as follows:

  instruction_set.*implementation*.Solaris_*version*

  where

  - *instruction_set* is one of `sparc` or `i386`
  - *implementation* is the implementation architecture, that is, `i86pc` and `sun4u`.
  - *version* is the Solaris version number. The supported *version* numbers are `2.6`, `2.7` (for Solaris 7), `8`, `9`, and `10`. Examples are:

    ```
    sparc.sun4u.Solaris_8
    ```

  `-x` root=*pathname* (Optional) Specifies the absolute path of the directory in which to create the root directory for diskless clients. The default (and recommended) *pathname* is `/export/root/`*client_name*.

  `-x` swap=*pathname* (Optional) Specifies the absolute path of the directory in which to create the swap file for diskless clients. The default (and recommended) *pathname* is `/export/swap/`*client_name*.

  `-x` swapsize=*size* (Optional) Specifies the size, in megabytes, of the swap file for diskless clients. The default swap size is `24M`.

  `-x` dump=*pathname* (Optional) Specifies the absolute path of the dump directory for diskless clients. The default (and recommended) *pathname* is `/export/dump/`*client_name*.

  `-x` dumpsize=*size* (Optional) Specifies the size, in megabytes, of the dump file for diskless clients. The default swap size is `24M`.

  `-x` pw=*Y* (Optional) Prompts for the system's root password. The default is not to prompt.

The following options are used to configure workstations on first boot by sysidtool(1M). They can either be specified on the command line, or in a sysidcfg(4) formatted file. *Note:* Use the sysidcfg(4) file to:

- Add a DNS client.
- Specify use of the LDAP name service.
- Specify a security policy.

The keywords and functions supported by sysidtool and sysidcfg vary among Solaris releases. Consult the man pages for your operating system release (uname -r) to determine the level of support available.

-x tz=*timezone*	(Optional) Specifies the path of a timezone file, relative to /usr/share/lib/zoneinfo. The default is the server's timezone.
-x ns=NIS | NIS+ | NONE	(Optional) Specifies the client's nameservice. This is one of NIS, NIS+, or NONE . Use a sysidcfg(4) file to specify DNS or LDAP. The default ns value is NONE, which results in the use of the files source in nsswitch.conf. See nsswitch.conf(4) for a description of the files source.
-x nameserver=*hostname*	(Optional) Specifies the nameserver's hostname. The default is the server's nameserver.
-x domain=*domain*	(Optional) Specifies the client's domain. The default is the server's domain.
-x nameserver_ipaddress=*ip_address*	(Optional) Specifies the nameserver's IP address.
-x netmask=*ip_address*	(Optional) Specifies the client's IP address netmask. The default is the server's netmask.
-x locale=*locale*	(Optional) Specifies the client's system locale. The default is the C locale.
-x terminal=*term*	(Optional) Specifies the workstation's terminal type, typically, sun or xterms.
-x passwd=*root_password*	(Optional) Specifies the system's root password. The default is no password.
-x sysidcfg=*path_to_sysidcfg_file*	(Optional) Specifies the file to be placed in the /etc directory of the diskless client. On first boot, /etc/.UNCONFIGURED exists and sysidtool(1M) will run. If a file called

`/etc/sysidcfg` exists, `sysidtool`(1M) reads this file and uses the information for system configuration.

- For subcommand `delete`:

  `-h` (Optional) Displays the command's usage statement.

  `-n` *host* Specifies the hostname of the diskless client to delete. This host is deleted from relevant tables and OS Services for this client are deleted.

  `-o` *os_server* (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc`(1M) `-D` option. This option is useful in the event that the name service server and the OS server are not the same machine.

- For subcommand `list`:

  `-h` (Optional) Displays the command's usage statement.

  `-o` *os_server* (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc`(1M) `-D` option. This option is useful in the event that the name service server and the OS server are not the same machine.

- For subcommand `modify`:

  `-e` *ethernet_addr* Changes the specified diskless client's ethernet address to *ethernet_addr*.

  `-h` (Optional) Displays the command's usage statement.

  `-n` *host* Specifies the host name of the diskless client to modify.

  `-o` *os_server* (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc`(1M) `-D` option. This option is useful in the event that the name service server and the OS server are not the same machine.

  `-x` tz=*timezone* (Optional) Changes the specified diskless client's timezone.

Examples

EXAMPLE 1 Creating a new diskless client

The following command adds a new diskless client named `client1` which will run Solaris 10 on a `sun4u` machine:

```
example% /usr/sadm/bin/smdiskless add -- -i 172.16.200.1 \
            -e 8:0:11:12:13:14 -n client1 -x os=sparc.sun4u.Solaris_10 \
            -x root=/export/root/client1 -x swap=/export/swap/client1 \
            -x swapsize=32 -x tz=US/Eastern -x locale=en_US
```

EXAMPLE 2 Deleting an existing diskless client

The following command deletes the diskless client named `client1` from the OS server named `osserver`, where the OS server is using NIS+ and the NIS+ server is `nisplusserve`:

```
example% /usr/sadm/bin/smdiskless delete \
            -D nisplus:/nisplusserver/my.domain.com -- \
            -o osserver -n client1
```

EXAMPLE 3 Listing the diskless clients served by a host

The following command lists the diskless clients running on the OS server, `osserver`:

```
example% /usr/sadm/bin/smdiskless list -D file:/osserver/osserver -- \
            -o osserver
```

EXAMPLE 4 Modifying the attributes of the diskless client host

The following command modifies the ethernet address for the client named `client1` on the OS server, `osserver`, to be `8:0:11:12:13:15`:

```
example% /usr/sadm/bin/smdiskless modify -D file:/osserver/osserver -- \
            -o osserver -n client1 -e 8:0:11:12:13:15
```

Environment Variables

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smdiskless` command. If this environment variable is not specified, the `/usr/java1.2` location is used. See `smc(1M)`.

Exit Status

The following exit values are returned:

`0` Successful completion.

`1` Invalid command syntax. A usage message displays.

`2` An error occurred while executing the command. An error message displays.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdclnt

Name smexec – manage entries in the exec_attr database

Synopsis `/usr/sadm/bin/smexec` *subcommand* `[` *auth_args*`] - –` `[`*subcommand_args*`]`

Description The `smexec` command manages an entry in the `exec_attr(4)` database in the local `/etc` files name service or a NIS or NIS+ name service.

subcommands `smexec` *subcommand*s are:

`add` Adds a new entry to the `exec_attr(4)` database. To add an entry to the `exec_attr` database, the administrator must have the `solaris.profmgr.execattr.write` authorization.

`delete` Deletes an entry from the `exec_attr(4)` database. To delete an entry from the `exec_attr` database, the administrator must have the `solaris.profmgr.execattr.write` authorization.

`modify` Modifies an entry in the `exec_attr(4)` database. To modify an entry in the `exec_attr` database, the administrator must have the `solaris.profmgr.execattr.write` authorization.

Options The `smexec` authentication arguments, *auth_args*, are derived from the `smc(1M)` arg set and are the same regardless of which subcommand you use. The `smexec` command requires the Solaris Management Console to be initialized for the command to succeed (see `smc(1M)`). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, *subcommand_args*, must come after the *auth_args* and must be separated from them by the `- –` option.

auth_args The *auth_args* `-D`, `-H`, `-l`, `-p`, `-r`, and `-u` are described below. They are all optional. These options are a subset of the full complement of supported options described in `smc(1M)`.

If no *auth_args* are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `- –domain` with the *domain* argument.

`-D` | `- –domain` *13;domain* Specifies the default domain that you want to manage. The syntax of *domain* is *type*:/*host_name*/*domain_name*, where *type* is `nis`, `nisplus`, `dns`, `ldap`, or `file`; *host_name* is the name of the machine that serves the domain; and *domain_name* is the name of the domain you want to manage. (*Note:* Do *not* use `nis+` for `nisplus`.)

If you do not specify this option, the Solaris Management Console assumes the `file` default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

`-H | - —hostname` *13;host_name:port*
: Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, `898`. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port `898`. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc(1M) -B` option, or set your console preferences to load a "home toolbox" by default.

`-l | - —rolepassword` *13;role_password*
: Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-p | - —password` *13;password*
: Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-r | - —rolename` *13;role_name*
: Specifies a role name for authentication. If you do not specify this option, no role is assumed.

`-u | - —username` *13;user_name*
: Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

`- —`
: This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `- —` option.

subcommand_args
: *Note:* Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

To add or change privileges, the administrator must have the `solaris.admin.privilege.write` authorization. See `privileges(5)`.

- For subcommand `add`:

  `-c` *command_path*|*CDE_action* — Specifies the full path to the command or CDE action associated with the new `exec_attr` entry. Specifying a CDE action is available only if the system is configured with Solaris Trusted Extensions. See "Using Options that Require Solaris Trusted Extensions," below.

  `-g` *egid* — (Optional) Specifies the effective group ID that executes with the command.

  `-G` *gid* — (Optional) Specifies the real group ID that executes with the command.

  `-h` — (Optional) Displays the command's usage statement.

  `-n` *profile_name* — Specifies the name of the profile associated with the new `exec_attr` entry.

  `-t` *type* — Specifies the type for the command. Currently, the only acceptable value for *type* is `cmd`.

  `-u` *euid* — (Optional) Specifies the effective user ID that executes with the command.

  `-U` *uid* — (Optional) Specifies the real user ID that executes with the command.

  `-M` *limit_privs* — Specifies the privilege name(s) to add to the new `exec_attr(4)` entry. The default is `all` for *limit* privilege.

  To add or change privileges, the administrator must have the `solaris.admin.privilege.write` authorization. See `privileges(5)`.

  `-I` *inheritable_privs* — Specifies the inheritable privilege name(s) to add to the new `exec_attr(4)` entry.

- For subcommand `delete`:

  `-c` *command_path*|*CDE_action* — Specifies the full path to the command or CDE action associated with the `exec_attr` entry. Specifying a CDE action is available only if the system is

configured with Solaris Trusted Extensions. See "Using Options that Require Solaris Trusted Extensions," below.

`-h` — (Optional) Displays the command's usage statement.

`-n` *profile_name* — Specifies the name of the profile associated with the `exec_attr` entry.

`-t` *type* — Specifies the type `cmd` for command. Currently, the only acceptable value for *type* is `cmd`.

- For subcommand `modify`:

  `-c` *command_path*|*CDE_action* — Specifies the full path to the command or CDE action associated with the `exec_attr` entry you want to modify. Specifying a CDE action is available only if the system is configured with Solaris Trusted Extensions. See "Using Options that Require Solaris Trusted Extensions," below.

  `-g` *egid* — (Optional) Specifies the new effective group ID that executes with the command.

  `-G` *gid* — (Optional) Specifies the new real group ID that executes with the command.

  `-h` — (Optional) Displays the command's usage statement.

  `-n` *profile_name* — Specifies the name of the profile associated with the `exec_attr` entry.

  `-t` *type* — Specifies the type `cmd` for command. Currently, the only acceptable value for *type* is `cmd`.

  `-u` *euid* — (Optional) Specifies the new effective user ID that executes with the command.

  `-U` *uid* — (Optional) Specifies the new real user ID that executes with the command.

  `-M` *limit_privs* — Specifies the privilege name(s) to modify in an `exec_attr(4)` entry. The default is `all` for *limit* privilege.

  To add or change privileges, the administrator must have the `solaris.admin.privilege.write` authorization. See `privileges(5)`.

  `-I` *inheritable_privs* — Specifies the inheritable privilege name(s) to modify in an`exec_attr(4)` entry.

Using Options that Require Solaris Trusted Extensions

To use an option that requires the Solaris Trusted Extensions feature, you must use the `-B` *toolbox* option to specify a toolbox that contains support for Trusted Extensions. For example:

```
# smexec -add -c <CDE action> -n "User Manager" \
-B http://<server>/toolboxes/tsol_files.tbx
```

In the command above, <*server*> is the name of the machine running the Solaris Management Console. See smc(1M) for a description of the `-B` option.

Examples

EXAMPLE 1 Creating an `exec_attr` Database Entry

The following creates a new `exec_attr` entry for the `User Manager` profile on the local file system. The entry type is `cmd` for the command `/usr/bin/cp`. The command has an effective user ID of `0` and an effective group ID of `0`.

```
./smexec add -H myhost -p mypasswd -u root -- -n "User Manager" \
          -t cmd -c /usr/bin/cp -u 0 -g 0
```

EXAMPLE 2 Deleting an `exec_attr` Database Entry

The following example deletes an `exec_attr` database entry for the `User Manager` profile from the local file system. The entry designated for the command `/usr/bin/cp` is deleted.

```
./smexec delete -H myhost -p mypasswd -u root -- -n "User Manager" \
          -t cmd -c /usr/bin/cp
```

EXAMPLE 3 Modifying an `exec_attr` Database Entry

The following modifies the attributes of the `exec_attr` database entry for the `User Manager` profile on the local file system. The `/usr/bin/cp` entry is modified to execute with the real user ID of `0` and the real group ID of `0`.

```
./smexec modify -H myhost -p mypasswd -u root -- -n "User Manager" \
          -t cmd -c /usr/bin/cp -U 0 -G 0
```

Environment Variables

See environ(5) for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smexec` command. If this environment variable is not specified, the `/usr/java` location is used. See smc(1M).

Exit Status

The following exit values are returned:

`0` Successful completion.

`1` Invalid command syntax. A usage message displays.

`2` An error occurred while executing the command. An error message displays.

Files

The following file is used by the `smexec` command:

`/etc/security/exec_attr` Rights profiles database. See exec_attr(4).

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga
Interface Stability	Evolving

See Also smc(1M), exec_attr(4), attributes(5), environ(5)

Name smgroup – manage group entries

Synopsis `/usr/sadm/bin/smgroup` *subcommand* `[` *auth_args*`] - –` `[`*subcommand_args*`]`

Description The `smgroup` command manages one or more group definitions in the group database for the appropriate files in the local `/etc` files name service or a NIS or NIS+ name service.

The following `smgroup` *subcommand*s are supported

`add` Adds a new group entry. To add an entry, the administrator must have the `solaris.admin.usermgr.write` authorization.

`delete` Deletes a group entry. You can delete only one entry at a time. To delete an entry, the administrator must have the `solaris.admin.usermgr.write` authorization. *Note:* You cannot delete the system groups with IDs less than 100, or the groups 60001, 60002, or 65534.

`list` Lists one or more group entries in the form of a three-column list, containing the group name, group ID, and group members, separated by colons (`:`). To list entries, the administrator must have the `solaris.admin.usermgr.read` authorization.

`modify` Modifies a group entry. To modify an entry, the administrator must have the `solaris.admin.usermgr.write` authorization.

Options The `smgroup` authentication arguments, *auth_args*, are derived from the `smc(1M)` arg set and are the same regardless of which subcommand you use. The `smgroup` command requires the Solaris Management Console to be initialized for the command to succeed (see `smc(1M)`). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, *subcommand_args*, must come after the *auth_args* and must be separated from them by the `- –` option.

auth_args The valid *auth_args* are `-D`, `-H`, `-l`, `-p`, `-r`, and `-u`; they are all optional. If no *auth_args* are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `- –domain`.

The following *auth_args* are supported:

`-D` | `- –domain` *13;domain* Specifies the default domain that you want to manage. The syntax of *domain* is *type*:/*host_name*/*domain_name*, where *type* is `nis`, `nisplus`, `dns`, `ldap` or `file`; *host_name* is the name of the machine that serves the domain;

	and *domain_name* is the name of the domain you want to manage. (*Note:* Do *not* use `nis+` for `nisplus`.) If you do not specify this option, the Solaris Management Console assumes the `file` default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.
`-H | - —hostname` *13;host_name:port*	Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, `898`. If you do not specify *host_name*:*port*, the Solaris Management Console connects to the local host on port `898`. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc(1M) -B` option, or set your console preferences to load a "home toolbox" by default.
`-l | - —rolepassword` *13;role_password*	Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
`-p | - —password` *13;password*	Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
`-r | - —rolename` *13;role_name*	Specifies a role name for authentication. If you do not specify this option, no role is assumed.
`-u | - —username` *13;user_name*	Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.
`- —`	This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `- —` option.

subcommand_args Descriptions and other argument options that contain white spaces must be enclosed in double quotes.

The `add` subcommand supports the following *subcommand_args*:

`-g` *gid*	(Optional) Specifies the group ID for the new group. The group ID must be a non-negative decimal integer with a maximum value of 2MB (2,147,483,647). Group IDs 0–99 are reserved for the system and should be used with care. If you do not specify a *gid*, the system automatically assigns the next available *gid*. To maximize interoperability and compatibility, administrators are recommended to assign groups using the range of GIDs below 60000 where possible.
`-h`	(Optional) Displays the command's usage statement.
`-m` *group_member1* `-m` *group_member2* . . .	(Optional) Specifies the new members to add to the group.
`-n` *group_name*	Specifies the name of the new group. The group name must be unique within a domain, contain 2–32 alphanumeric characters, begin with a letter, and contain at least one lowercase letter.

The `delete` subcommand supports the following *subcommand_args*:

`-h`	(Optional) Displays the command's usage statement.
`-n` *group_name*	Specifies the name of the group you want to delete.

The `list` subcommand supports the following *subcommand_args*

`-h`	(Optional) Displays the command's usage statement.
`-n` *group_name*	(Optional) Specifies the name of the group you want to list. If you do not specify a group name, all groups are listed.

The `modify` subcommand supports the following *subcommand_args*

`-h`	(Optional) Displays the command's usage statement.

`-m` *group_member1* `-m` *group_member2* . . .	(Optional) Specifies the new members to add to the group. Note that *group_member* overwrites the existing member list in the group file.
`-n` *group_name*	Specifies the name of the group you want to modify.
`-N` *new_group*	(Optional) Specifies the new group name. The group name must be unique within a domain, contain 2–32 alphanumeric characters, begin with a letter, and contain at least one lowercase letter.

Examples

EXAMPLE 1 Creating a Test Group

The following creates the `test_group` group entry with a group ID of `123` and adds `test_member1` and `test_member2` to the group:

```
./smgroup add -H myhost -p mypasswd -u root -- -n test_group \
          -m test_member1 -m test_member2 -g 123
```

EXAMPLE 2 Deleting a Group

The following deletes `test_group`:

```
./smgroup delete -H myhost -p mypasswd -u root -- -n test_group
```

EXAMPLE 3 Displaying All Groups

The following displays all groups in a three-column list showing the group name, group ID, and group members:

```
./smgroup list -H myhost -p mypasswd -u root --
```

EXAMPLE 4 Displaying a Group

The following displays the `group_1` data in a three-column list showing the group name, group ID, and group members:

```
./smgroup list -H myhost -p mypasswd -u root -- -n group_1
```

EXAMPLE 5 Renaming a Group

The following renames a group from `finance` to `accounting`:

```
./smgroup modify -H myhost -p mypasswd -u root  -- \
          -n finance -N accounting
```

Environment Variables See environ(5) for a description of the JAVA_HOME environment variable, which affects the execution of the smgroup command. If this environment variable is not specified, the /usr/java location is used. See smc(1M).

Exit Status The following exit values are returned:

0 Successful completion.

1 Invalid command syntax. A usage message displays.

2 An error occurred while executing the command. An error message displays.

Files The following files are used by the smgroup command:

/etc/group Group file. See group(4).

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga

See Also smc(1M), group(4), attributes(5), environ(5)

Name smlog – manage and view WBEM log files

Synopsis

```
/usr/sadm/bin/smlog subcommand [auth_args] --
     [subcommand_args]
```

Description The `smlog` command manages WBEM log files and allows a user to view WBEM log file records.

Subcommands The `smlog` command supports the following subcommands:

backup — Backs up the entries in the current WBEM log file. The backup command then creates a new log file and makes this log file the current log file.

delete — Deletes an existing (backed up) WBEM log file.

list — Lists the names of all the WBEM log files available for viewing.

view — Allows the user to view the contents of the specified WBEM log file.

Options The `smlog` authentication arguments, *auth_args*, are derived from the `smc(1M)` `arg` set and are the same regardless of which subcommand you use. The `smlog` command requires the Solaris Management Console to be initialized for the command to succeed (see `smc(1M)`). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, *subcommand_args*, must come after the *auth_args* and must be separated from them by the `- —` option.

auth_args The valid *auth_args* are `-D`, `-H`, `-l`, `-p`, `-r`, and `-u`; they are all optional. If no *auth_args* are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `- —domain` with the *domain* argument.

`-D | - —domain` *13;domain* — Specifies the default domain that you want to manage. `smlog` accepts only `file` for this option. `file` is also the default value.

The `file` default domain means that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

`-H | - —hostname` *13;host_name:port* — Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, `898`. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port `898`. You may still have to choose a

toolbox to load into the console. To override this behavior, use the `smc -B` option (see `smc`(1M)), or set your console preferences to load a "home toolbox" by default.

`-l|- –rolepassword` *13;role_password*
: Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-p|- –password` *13;password*
: Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-r|- –rolename` *13;role_name*
: Specifies a role name for authentication. If you do not specify this option, no role is assumed.

`-u|- –username` *13;user_name*
: Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

`- –`
: This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `- –` option.

subcommand_args
: Descriptions and other `arg` options that contain white spaces must be enclosed in double quotes.

The `backup` subcommand supports the following *subcommand_args*:

`-h`
: Displays the command's usage statement.

  This *subcommand_arg* is optional.

The `delete` subcommand supports the following *subcommand_args*

`-h`
: Displays the command's usage statement.

  This *subcommand_arg* is optional.

`-n` *name*
: Specifies the name of the log file you want to delete.

The `list` subcommand supports the following *subcommand_args*:

`-h` Displays the command's usage statement.

This *subcommand_arg* is optional.

The `view` subcommand supports the following *subcommand_args*:

`-h` Displays the command's usage statement.

This *subcommand_arg* is optional.

`-n` *name* Specifies the name of the log file you want to view.

`-v` Displays the data in verbose format.

This *subcommand_arg* is optional.

Examples

EXAMPLE 1 Listing WBEM Log Files

The following command lists all available WBEM log files:

```
./smlog list -H myhost -p mypasswd -u root --

Log.01/03/2001.14:38:29
Log.01/04/2001.16:34:59
Log.01/08/2001.14:13:33
Log.01/11/2001.18:39:53
Log.01/12/2001.10:31:31
Log.12/21/2000.17:41:11
```

EXAMPLE 2 Displaying a WBEM Log File

The following command displays the contents of a log file:

```
./smlog view -H myhost -p mypasswd -u root -- -n Log.01/04/2001.16:34:59

Date and Time       Client     User   Source            Severity       Cate
gory        Summary
1/5/01 5:22:47 PM   hostname1  root   Solaris_OsService Informational  Appl
ication log No services found.
1/5/01 5:21:46 PM   hostname1  root   Solaris_OsService Informational  Appl
ication log No services found.
```

The `smlog` output wraps when it exceeds `80` characters.

Environment Variables

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smlog` command. If this environment variable is not specified, the `/usr/java1.2` location is used. See `smc(1M)`.

Exit Status

The following exit values are returned:

`0` Successful completion.

1 Invalid command syntax. A usage message displays.

2 An error occurred while executing the command. An error message displays.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga

See Also smc(1M), attributes(5), environ(5)

Name smmaillist – manage email alias entries

Synopsis `/usr/sadm/bin/smmaillist` *subcommand* `[` *auth_args*`] - –` `[`*subcommand_args*`]`

Description The `smmaillist` command manages one or more email alias entries for the appropriate files in the local `/etc` files name service or a NIS or NIS+ name service.

subcommands `smmaillist` *subcommand*s are:

`add` Creates a new email alias definition and adds it to the appropriate files. To add an entry, the administrator must have the `solaris.admin.usermgr.write` authorization.

`delete` Deletes an email alias entry. You can delete only one entry at a time. To delete an entry, the administrator must have the `solaris.admin.usermgr.write` authorization. *Note:* You cannot delete Postmaster or Mailer-Daemon aliases.

`list` Lists one or more email alias entries. To list an entry, the administrator must have the `solaris.admin.usermgr.read` authorization.

`modify` Modifies an email alias entry. To modify an entry, the administrator must have the `solaris.admin.usermgr.write` authorization.

Options The `smmaillist` authentication arguments, *auth_args*, are derived from the `smc`(1M) arg set and are the same regardless of which subcommand you use. The `smmaillist` command requires the Solaris Management Console to be initialized for the command to succeed (see `smc`(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, *subcommand_args*, must come after the *auth_args* and must be separated from them by the `- –` option.

auth_args The valid *auth_args* are `-D`, `-H`, `-l`, `-p`, `-r`, and `-u`; they are all optional. If no *auth_args* are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `- –domain` with the *domain* argument.

`-D` | `- –domain` *13;domain* Specifies the default domain that you want to manage. The syntax of *domain* is *type:/host_name/domain_name*, where *type* is `nis`, `nisplus`, `dns`, `ldap`, or `file`; *host_name* is the name of the machine that serves the domain; and *domain_name* is the name of the domain you want to manage. (*Note:* Do *not* use `nis+` for `nisplus`.)

	If you do not specify this option, the Solaris Management Console assumes the `file` default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.
`-H | - —hostname` *13;host_name:port*	Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, `898`. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port `898`. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc(1M) -B` option, or set your console preferences to load a "home toolbox" by default.
`-l | - —rolepassword` *13;role_password*	Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
`-p | - —password` *13;password*	Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
`-r | - —rolename` *13;role_name*	Specifies a role name for authentication. If you do not specify this option, no role is assumed.
`-u | - —username` *13;user_name*	Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.
`- —`	This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `- —` option.

subcommand_args *Note:* Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

- For subcommand `add`:

  `-a` *address1* `-a` *address2* . . . (Optional) Specifies the new email address. See `sendmail(1M)`.

  `-h` (Optional) Displays the command's usage statement.

  `-n` *alias_name* Specifies the name of the alias you want to add. See `sendmail`(1M).

- For subcommand `delete`:

  `-h` (Optional) Displays the command's usage statement.

  `-n` *alias_name* Specifies the alias you want to delete.

- For subcommand `list`:

  `-h` (Optional) Displays the command's usage statement.

  `-n` *alias_name* (Optional) Specifies the name of the alias you want to display. If you do not specify an alias, all aliases are listed.

- For subcommand `modify`:

  `-a` *address1* `-a` *address2* . . . (Optional) Specifies new email address(es) to replace the existing one(s). See `sendmail(1M)`.

  `-h` (Optional) Displays the command's usage statement.

  `-n` *alias_name* (Optional) Specifies the name of the alias you want to modify.

  `-N` *new_alias_name* Specifies the new alias name. Use only when renaming an alias. See `sendmail`(1M).

Examples

EXAMPLE 1 Creating an alias

The following creates the `coworkers` alias and adds the following member list: `bill@machine1`, `sue@machine2`, and `me@machine3` to the alias.

```
./smmaillist add -H myhost -p mypasswd -u root -- -n coworkers \
          -a bill@machine1 -a sue@machine2 -a me@machine3
```

EXAMPLE 2 Deleting a mail alias

The following deletes the `my_alias` alias:

```
./smmaillist delete -H myhost -p mypasswd -u root -- -n my_alias
```

EXAMPLE 3 Displaying members of a mail alias

The following displays the list of members belonging to the `my_alias` alias:

```
./smmaillist list -H myhost -p mypasswd -u root -- -n my_alias
```

EXAMPLE 4 Displaying members of all mail aliases

The following displays the list of members belonging to all mail aliases:

```
./smmaillist list -H myhost -p mypasswd -u root --
```

EXAMPLE 5 Renaming a mail alias

The following renames the `current_name` mail alias to `new_name`:

```
./smmaillist modify -H myhost -p mypasswd -u root -- \
          -n current_name -N new_name
```

EXAMPLE 6 Redefining an address list

The following changes the recipients of the alias `my_alias` to `bill@machine1`. Any previous recipients are deleted from the alias.

```
./smmaillist modify -H myhost -p mypasswd -u root -- \
          -n my_alias -a bill@machine1
```

Environment Variables

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smmaillist` command. If this environment variable is not specified, the `/usr/java` location is used. See `smc(1M)`.

Exit Status

The following exit values are returned:

`0` Successful completion.

`1` Invalid command syntax. A usage message displays.

`2` An error occurred while executing the command. An error message displays.

Files

The following files are used by the `smmaillist` command:

`/var/mail/aliases` Aliases for `sendmail(1M)`. See `aliases(4)`.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga

See Also

Name smmultiuser – manage bulk operations on user accounts

Synopsis

```
/usr/sadm/bin/smmultiuser subcommand [ auth_args] - —
    [subcommand_args]
```

Description The `smmultiuser` command allows bulk operations on user entries in the local `/etc` filesystem or a NIS or NIS+ name service, using either an input file or piped input. *Note:* Both input files and piped input contain a cleartext (non-encrypted) password for each new user entry.

subcommands `smmultiuser` *subcommand*s are:

`add` Adds multiple user entries to the appropriate files. To add an entry, the administrator must have the `solaris.admin.usermgr.write` authorization.

`delete` Deletes one or more user entries from the appropriate files. To delete an entry, the administrator must have the `solaris.admin.usermgr.write` authorization.

`modify` Modifies existing user entries in the user account database. To modify an entry, the administrator must have the `solaris.admin.usermgr.write` authorization. Here is the list of what can be modified using the `modify` subcommand:

1. UserName (only under certain conditions; see Note 2 in NOTES).
2. Password (only under certain conditions; see Note 3 in NOTES). To modify a password, the administrator must have the `solaris.admin.usermgr.pswd` authorization.
3. Description.
4. Primary Group ID.
5. Shell type.
6. FullName.

Options The `smmultiuser` authentication arguments, *auth_args*, are derived from the `smc`(1M) arg set and are the same regardless of which subcommand you use. The `smmultiuser` command requires the Solaris Management Console to be initialized for the command to succeed (see `smc`(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, *subcommand_args*, must come after the *auth_args* and must be separated from them by the `- —` option.

auth_args The valid *auth_args* are `-D`, `-H`, `-l`, `-p`, `-r`, `- —trust`, and `-u`; they are all optional. If no *auth_args* are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `- —domain`.

`-D` | `- —domain` *13;domain* Specifies the default domain that you want to manage. The syntax of *domain* is

	type:/*host_name*/*domain_name*, where *type* is `nis`, `nisplus`, `dns`, `ldap`, or `file`; *host_name* is the name of the machine that serves the domain; and *domain_name* is the name of the domain you want to manage. (*Note:* Do *not* use `nis+` for `nisplus`.) If you do not specify this option, the Solaris Management Console assumes the `file` default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.
`-H | - —hostname` *13;host_name:port*	Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, `898`. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port `898`. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc(1M)` `-B` option, or set your console preferences to load a "home toolbox" by default.
`-l | - —rolepassword` *13;role_password*	Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
`-p | - —password` *13;password*	Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
`-r | - —rolename` *13;role_name*	Specifies a role name for authentication. If you do not specify this option, no role is assumed.
`- —trust`	Trusts all downloaded code implicitly. Use this option when running the terminal console non-interactively and you cannot let the console wait for user input.

If using piped input into any of the `smmultiuser` subcommands, it will now be necessary to use the `- —trust` option with the `-L` *logfile* option. See EXAMPLES.

`-u | - —username` *13;user_name* — Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

`- —` — This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `- —` option.

subcommand_args *Note:* Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

- For subcommand `add`:

  `-h` — (Optional) Displays the command's usage statement.

  `-i` *input_file* — Specifies the input file containing the user account information. After the command is executed, the input file is removed. The input file must follow the `/etc/passwd` file format. If you do not specify the `-i` *input_file* option, you must include a *piped_input* operand immediately before the command. See EXAMPLES.

  `-L` *logfile* — (Optional) Specifies the full pathname to the text file that stores the command's success/failure data. *Note:* This text file is an ASCII—formatted log file; it is different from and unrelated to the output of the normal logging mechanism that also occurs within the Log Viewer tool. The `-L` *logfile* option is used to dump additional logging information to a text file.

- For subcommand `delete`:

  `-h` — (Optional) Displays the command's usage statement.

  `-i` *input_file* — Specifies the input file containing the user account information. After the command is executed, the input file is removed. The input file must follow the `/etc/passwd` file format. If you do not specify the `-i` *input_file* option, you must include a *piped_input* operand immediately before the command. See EXAMPLES.

  `-L` *logfile* — (Optional) Specifies the full pathname to the text file that stores the command's success/failure data.

- For subcommand `modify`:

  `-h` — (Optional) Displays the command's usage statement.

`-i` *input_file* Specifies the input file containing the user account information. After the command is executed, the input file is removed. The input file must follow the `/etc/passwd` file format. If you do not specify the `-i` *input_file* option, you must include a *piped_input* operand immediately before the command. See EXAMPLES. *Note:* When modifying passwords, use the piped input, since it is more secure than keeping passwords in a file. See Note 1 in NOTES.

`-L` *logfile* (Optional) Specifies the full pathname to the text file that stores the command's success/failure data.

Operands The following operands are supported:

piped_input You must include *piped_input* if you do not specify an *input_file*. Include the piped input immediately before the command. The piped input must follow the `/etc/passwd` file format. See EXAMPLES. *Note:* Use the `- –trust` option when using piped input with the `-L` *logfile* option to avoid the user prompt from the Security Alert Manager, which normally asks the user whether the log file should be created. Without the `- –trust` option, the piped input is improperly taken as the answer to the prompt before the user can answer "`Y`" or "`N`", and the logging operation will probably fail.

Examples **EXAMPLE 1** Creating multiple user accounts

The following reads in user account data from the `/tmp/foo` file and creates new user accounts on the local file system. The input file is formatted in the `/etc/passwd` format.

```
./smmultiuser add -H myhost -p mypasswd -u root --  -i /tmp/foo
```

EXAMPLE 2 Deleting multiple user accounts

The following reads in user account data from the `/tmp/foo` file and deletes the named user accounts from the local file system:

```
./smmultiuser delete -H myhost -p mypasswd -u root --  -i /tmp/foo
```

EXAMPLE 3 Creating a log file with piped input

The following example shows the use of the `smc`(1M) `- –trust` option that is required when creating a log file. It is applicable to the `delete` and `modify` subcommands also.

```
cat /tmp/users.txt | smmultiuser add --trust --  -L /tmp/mylog.txt
```

Environment Variables See `environ`(5) for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smprofile` command. If this environment variable is not specified, the `/usr/java` location is used. See `smc`(1M).

Exit Status The following exit values are returned:

`0` Successful completion.

`1` Invalid command syntax. A usage message displays.

`2` An error occurred while executing the command. An error message displays.

Files The following files are used by the `smprofile` command:

`/etc/passwd` Contains the file format to use for the *input_file* and *piped_input*. See `passwd(4)`.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga

See Also `smc(1M)`, `passwd(4)`, `attributes(5)`, `environ(5)`

Notes

1. The file format used by both the `add` and `modify` subcommands is the `/etc/passwd` format. But there is an allowance for a mutated version of this file format that contains an extra field at the end of each line to be used for the Full Name. If the extra field is appended to the end of each line, it will be used for the Full Name value, but if it is omitted, it will be assumed that no FullName modification is being done. The extra field is separated with a colon (`:`), just like all the other fields.

   Example of regulation `/etc/passwd` entry:

   ```
   rick2:x:101:10:description1:/home/rick2:/bin/sh
   ```

   Example of `/etc/passwd` variant entry:

   ```
   rick2:x:101:10:description1:/home/rick2:/bin/sh:Ricks_fullname
   ```

2. The modifies are all done based on lookups of the user name in the user tables. If a user name can not be found in this lookup, a secondary check will be made to see if the uid *and* FullName can be found in the user tables. If they are both found, assume that a user rename has occurred. If neither can be found, assume that the user account does not exist and cannot be modified.
3. If no password is supplied, assume that there is no change to the password information. If a password is being changed, it should be supplied in cleartext as piped input, although this is not required. The password can be supplied in the input file also. Once read in, the password will be changed accordingly.

Name smosservice – manage OS services

Synopsis `/usr/sadm/bin/smosservice` *subcommand* `[` *auth_args*`] - –` `[`*subcommand_args*`]`

Description The `smosservice` command manages OS services.

`smosservice` *subcommand*s are:

`add` Adds the specified OS services.

`delete` Deletes the specified OS services.

`list` Either lists all the installed OS services for the server if you do not specify a hostname, or lists the OS services for the specified diskless client if you do specify a hostname.

`patch` Manages patches on all existing diskless clients. For example, you can use this subcommand to initially establish a patch spool directory on an OS server. Then, you can apply the patch to the spool area, verifying the patch as needed. Once the patch exists in the spool area, you can apply the patch to the clone area. In addition, you can migrate the patched clone area to clients.

Options The `smosservice` authentication arguments, *auth_args*, are derived from the `smc(1M)` arg set and are the same regardless of which subcommand you use. The `smosservice` command requires the Solaris Management Console to be initialized for the command to succeed (see `smc(1M)`). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, *subcommand_args*, must come after the *auth_args* and must be separated from them by the `- –` option.

auth_args The valid *auth_args* are `-D`, `-H`, `-l`, `-p`, `-r`, and `-u`; they are all optional. If no *auth_args* are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `- –domain`.

`-D` | `- –domain` *13;domain* Specifies the default domain that you want to manage. The syntax of *domain* is *type*:/*host_name*/*domain_name*, where *type* is `nis`, `nis+`, `dns`, `ldap`, or `file`; *host_name* is the name of the machine that serves the domain; and *domain_name* is the name of the domain you want to manage. (*Note:* Do *not* use `nis+` for `nisplus`.)

If you do not specify this option, the Solaris Management Console assumes the `file` default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

`-H | - —hostname` *13;host_name:port*
: Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, `898`. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port `898`. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc(1M) -B` option, or set your console preferences to load a "home toolbox" by default.

`-l | - —rolepassword` *13;role_password*
: Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-p | - —password` *13;password*
: Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-r | - —rolename` *13;role_name*
: Specifies a role name for authentication. If you do not specify this option, no role is assumed.

`-u | - —username` *13;user_name*
: Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

`- —`
: This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `- —` option.

subcommand_args
: *Note:* Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

- For subcommand `add`:

  `-h` (Optional) Displays the command's usage statement.

  `-o` *os_server* (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc`(1M) `-D` option. This option is useful in the event that the name service server and the OS server are not the same machine.

  `-x` mediapath=*path* Specifies the full path to the Solaris CD image.

  `-x` platform=*platform* Specifies the OS service to add. The instruction architecture, machine class, OS, and version are given in the form:

  instruction_set.machine_class.Solaris_*os_version*

  for example, `sparc.sun4m.Solaris_10`

  `-x` cluster=*cluster* Specifies the Solaris cluster to install. For example, `SUNWCall`.

  `-x` locale=*locale*[*locale*, . . .] (Optional) Specifies the locales to install from the specified cluster. A comma-delimited list of locales can be specified.

- For subcommand `delete`:

  `-h` (Optional) Displays the command's usage statement.

  `-o` *os_server* (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that specified in the `smc`(1M) `-D` option. This option is useful in the event that the name service server and the OS server are not the same machine.

  `-x` rmplatform=*platform* Specifies the OS service to remove. The instruction architecture, machine class, OS, and version are given in the form:

  instruction_set.machine_class.Solaris_*os_version*

  for example, `sparc.all.Solaris_10`. *Note:* Only a machine class of `all` is supported.

- For subcommand `list`:

  `-h` (Optional) Displays the command's usage statement.

  `-o` *os_server* (Optional) Specifies the name of the host where the OS service filesystems reside. If this option is not specified, the host will be the same as that

specified in the smc(1M) -D option. This option is useful in the event that the name service server and the OS server are not the same machine.

- For subcommand patch:

  -a *patch_directory/patch_ID* — Adds the specified patch, *patch_ID*, to the spool directory. *patch_directory* specifies the source path of the patch to be spooled which includes the patchid directory name. Patches are spooled to /export/diskless/Patches/. If the patch being added obsoletes an existing patch in the spool, the obsolete patch is moved to the archive area, /export/diskless/Patches/Archive (to be restored if this new patch is ever removed).

  -h — (Optional) Displays the command's usage statement.

  -m — (Optional) Synchronizes spooled patches with offline copies of each diskless client OS service on the server. Spooled patches and applied patches are compared so that newly spooled patches can be installed and patches recently removed from the spool can be backed out. This option does not apply to patches directly to diskless client OS services or diskless clients; the -u option must be used to update the services and clients with the changes. Clients are not required to be down at this time, as all patching is done off line. *Note:* The server is fully available during this operation.

  -P — Lists all currently spooled patches with an associated synopsis. The list is split up into sections detailing the patches for each OS and architecture in this format:

```
Solaris os_rel1 architecture1:
patchid Synopsis
patchid Synopsis
......
Solaris os_rel1 architecture2:
patchid Synopsis
......
```

  -r *patchid* — Removes the specified patchid from the spool if it is not a requirement for any of the other patches in the spool. All archived patches that were obsoleted by the removed patch are restored to the spool.

  -U — (Optional) Updates all diskless client OS services and diskless clients with any changes after synchronizing

patches with the `-m` option. Clients must be brought down during this operation. Once execution has completed, each client should be booted again.

Examples

EXAMPLE 1 Creating a new OS service

The following command adds an OS service for Solaris 10 for the `sun4u` machine class where the OS server is *not* using a name service:

```
example% /usr/sadm/bin/smosservice add -- \
            -x mediapath=/net/imageserver/5.8/sparc \
            -x platform=sparc.sun4u.Solaris_10 \
            -x cluster=SUNWCXall -x locale=en_US
```

The following command adds an OS service for Solaris 10 for the `sun4u` machine class where the OS server is using NIS, the NIS server is `nisserver`, the OS server is `osserver`, and the port to which you connect on `osserver` is 898:

```
example% /usr/sadm/bin/smosservice add -D nis:/nisserver/my.domain.com -- \
            -H osserver:898 -- \
            -x mediapath=/net/imageserver/5.8/sparc \
            -x platform=sparc.sun4u.Solaris_10 \
            -x cluster=SUNWCXall -x locale=en_US \
            -o osserver
```

In the preceding example, the OS service is placed in `/export` on `osserver`, while the `hosts.byaddr`, `ethers`, and `bootparams` maps are updated on the NIS server.

EXAMPLE 2 Deleting an OS service

The following command deletes the OS service for Solaris 10 for the `sun4u` machine class where the OS server is using NIS, the NIS server is `nisserver`, and the OS server is `osserver`:

```
example% /usr/sadm/bin/smosservice delete\
            -D nis:/nisserver/my.domain.com -- \
            -x rmplatform=sparc.all.Solaris_10 \
            -o osserver
```

EXAMPLE 3 Listing installed OS services

The following command lists the OS services installed on the machine, `osserver`:

```
example% /usr/sadm/bin/smosservice list \
            -D file:/osserver/osserver -- -o osserver
```

Environment Variables

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smosservice` command. If this environment variable is not specified, the `/usr/java1.2` location is used. See `smc(1M)`.

Exit Status The following exit values are returned:

`0` Successful completion.

`1` Invalid command syntax. A usage message displays.

`2` An error occurred while executing the command. An error message displays.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWdclnt

See Also `smc(1M)`, `smdiskless(1M)`, `attributes(5)`, `environ(5)`

Name smpatch – download, apply, and remove updates

Synopsis

```
/usr/sbin/smpatch add -i update-id [auth-opts]
     [-i update-id] ... [-d update-dir] [-b BE_name]
     [-n system-name] ... [-x mlist=system-list-file] [-V]

/usr/sbin/smpatch add -x idlist=update-list-file
     [auth-opts]
     [-d update-dir] [-n system-name] ...
     [-b BE_name] [-x mlist=system-list-file] [-V]

/usr/sbin/smpatch analyze [auth-opts] [-i update-id] ...
     [-n system-name] ...
     [-x idlist=update-list-file] [-V]

/usr/sbin/smpatch download [auth-opts] [-i update-id] ...
     [-d update-dir] [-f] [-n system-name] ...
     [-t] [-x idlist=update-list-file] [-V]

/usr/sbin/smpatch get [auth-opts] [-n system-name] ...
     [parameter-name]... [-V]

/usr/sbin/smpatch messages [-a] [-V]

/usr/sbin/smpatch order -i update-id [auth-opts]
     [-i update-id] ... [-d update-dir]
     [-n system-name] ... [-V]

/usr/sbin/smpatch order -x idlist=update-list-file
     [auth-opts]
     [-d update-dir] [-n system-name] ... [-V]

/usr/sbin/smpatch remove -i update-id [auth-opts]
     [-n system-name] ... [-b BE_name] [-V]

/usr/sbin/smpatch set [auth-opts] [-n system-name] ...
     parameter-name=parameter-value... [-V]

/usr/sbin/smpatch unset [auth-opts] [-n system-name] ...
     parameter-name... [-V]

/usr/sbin/smpatch update [auth-opts] [-i update-id] ...
     [-d update-dir] [-n system-name] ... [-b BE_name]
     [-x idlist=update-list-file] [-V]
```

Description The `smpatch` command manages the update process on a single system or on multiple systems. Use this command to download, apply, and remove updates. Also, use the `smpatch` command to configure the update management environment for your system.

If you want to run the `smpatch` command in remote mode, your system must run at least the Developer Solaris Software Group of the Solaris 10 system.

The `smpatch analyze` command determines the updates that are appropriate for the systems you want to update. The `smpatch` command can download and apply updates that you specify

on the command line. Or, `smpatch` can download and apply updates based on an analysis of one or more systems. Use the `-i` option or the `-x idlist=` option to specify the particular updates.

All of the systems on which you want to apply updates must be running the same version of the Solaris Operating System, have the same hardware architecture, and have the same updates applied.

The list of updates that is generated by the analysis is based on all of the available updates from the Sun update server. No explicit information about your host system or its network configuration is transmitted to Sun. Only a request for the Sun update set is transmitted. The update set is scanned for updates that are appropriate for this host system, the results are displayed, and those updates are optionally downloaded.

`smpatch` supports the Live Upgrade feature of the Solaris operating system (see `live_upgrade(5)`). Through the `add`, `remove`, and `update` subcommands, described below, `smpatch` enables you to perform operations on a boot environment (BE). A BE is an operating system image, consisting of a particular set of operating system and application software packages.

The `smpatch` command supports the following subcommands:

`add`
: Applies one or more updates to one or more systems. You must specify at least one update to apply. By default, updates are applied to the local system.

  This subcommand attempts to apply *only* the updates you specify. If you specify an update that depends on another that has not been applied, the `add` command fails to apply the update you specified.

  This subcommand does not apply updates based on the specified update policy. To apply updates based on the update policy, use the `update` subcommand.

  Use the `-i` or `-x idlist=` option to specify the updates to apply. Note that all of the updates you specify, and those on which they depend, must exist in the download directory.

  Use the `-n` or the `-x mlist=` option to specify the systems on which to apply updates.

  Optionally use the `-d` option to specify an alternate download directory.

  If the updates on which the specified updates depend are unavailable, run the `smpatch download` subcommand to obtain the updates you need.

  When you use the `-b` *BE_name* option, the `add` subcommand applies a specified update to the BE *BE_name*, rather than to the currently running operating system. Upon successful installation of the update, `smpatch` activates *BE_name* (see `luactivate(1M)`) and informs you that you can, at that point, boot from *BE_name*.

`analyze`
: Analyzes a system to generate a list of the appropriate updates.

After analyzing the system, use the `update` subcommand or the `download` and `add` subcommands to download and apply the updates to your systems.

The list of updates is written to standard output, so you can redirect standard output to a file to create an update list.

If you supply a list of one or more updates, the list is augmented with the updates on which those updates depend. The list is also put in an order suitable for applying updates.

The `smpatch analyze` command depends on network services that are not available while the system is in single-user mode.

`download`
Downloads updates from the Sun update server to a system. You can optionally specify which updates to download. You can also specify the name of a system and download the appropriate updates to that system.

Use the `-i` or `-x idlist=` option to specify the updates to download.

Use the `-f` option to force the download of the exact update revision specified by `-i` *update-id*. If `-i` *update-id* does not specify a revision, the highest revision of the update is downloaded.

Use the `-t` option to download the `README` file for the update specified by `-i` *update-id*. If `-i` *update-id* does not specify a revision, the `README` file for the highest revision of the update is downloaded.

Use the `-n` option to analyze a remote system and to determine which updates to download. The updates, and those on which they depend, are downloaded from the Sun update server to the download directory of the system you specified.

The `smpatch download` command depends on network services that are not available while the system is in single-user mode.

`get`
Lists one or more of the `smpatch` configuration parameter values. See "Configuring Your Update Management Environment."

To see values for all parameters, run the `smpatch get` command with no arguments. The output shows an entry for all configuration parameters. Each entry appears on a line by itself. Each entry includes three fields: the parameter name, the value you have assigned it, and its default value. The fields are separated by one or more tab characters.

The following values have special meaning: `-` means that no value is set, "" means that the value is the null string, `\-` means that the value is `-`, and `\""` means that the value is "" (two double quotes).

In addition to these special values, these special characters might appear in the output: `\t` for a tab, `\n` for a newline, and `\\` for a backslash.

To see values for particular parameters, run the `smpatch get` command with one or more parameter names. The output lists one parameter value per line in the order in which the parameter names are specified on the command line.

`messages`
Displays messages from the message–of–the–day (MOTD) file. This file stores messages, some of which can be urgent, from Sun. By default, when there is a new message in this file, the message shown below is displayed in `stderr`:

```
You have new messages. To retrieve: smpatch messages [-a]
```

The preceding message appears at the top of any `smpatch analyze/download/update` reports. The `-a` option to the `messages` subcommand displays all messages. Without the `-a` option, only new (that is, as yet unread) messages are displayed.

The receiving of messages from the software update client is controlled by the property:

```
patchpro.report.motd.messages
```

When this property is enabled, the default condition, the client receives messages from Sun. To disable this property, enter:

```
# smpatch set patchpro.report.motd.messages=false
```

`order`
Sorts a list of updates into an order that can be used to apply updates.

The list of updates is written to standard output, so you can redirect standard output to a file to create an update list.

Use the `-i` or `-x idlist=` option to specify the updates to order. Note that all of the updates you specify must exist in the download directory.

`remove`
Removes a single update from a single system.

Use the `-i` option to specify which update to remove. Do not use the `-x idlist=` option. Optionally, use the `-n` option to specify the name of a system. Do not use the `-x mlist=` option. By default, the update is removed from the local system.

If the update that you want to remove is required by one or more of the updates that have already been applied to the system, the update is not removed.

When you use the `-b` *BE_name* option, the `remove` subcommand removes a specified update from the BE *BE_name*, rather than from the currently running operating system.

`set`
Sets the values of one or more configuration parameters. Nothing is written to standard output or standard error when you set parameters, even if a parameter value you set is invalid. This command does not validate the values you set.

`unset`
: Resets one or more configuration parameters to the default values. You must specify at least one configuration parameter.

`update`
: Updates a single local or remote system by applying appropriate updates. This subcommand analyzes the system, then downloads the appropriate updates from the Sun update server to your system. After the availability of the updates has been confirmed, the updates are applied based on the update policy.

  By default, standard updates and those that have `rebootafter` or `reconfigafter` properties are applied.

  If an update does not meet the policy for applying updates, the update is not applied. Instead, the ID of the update is written to a file in the download directory. After the update ID is written to the file, `smpatch` continues to apply the other updates. Later, you can use `patchadd` to manually apply any updates listed in this file. The updates listed in the file are still in the download directory.

  When you use the `-b` *BE_name* option, the `update` subcommand applies an update to the BE *BE_name*, rather than to the currently running operating system. Upon successful installation of the update, `smpatch` activates *BE_name* (see `luactivate(1M)`) and informs you that you can, at that point, boot from *BE_name*.

  Installation instructions for updates that require special handling are included in the README file for each update.

  The `smpatch update` command depends on network services that are not available while the system is in single-user mode.

Using Local Mode or Remote Mode

Starting with Solaris 9, the `smpatch` command is available in two modes: local mode and remote mode. *Local mode* can be run only on the local system and can be run by users who have the appropriate authorizations. This mode can be run while the system is in single-user mode. *Remote mode* can be used to perform tasks on remote systems and can be run by users or roles that have the appropriate authorizations.

By default, local mode is run. In local mode, the Solaris WBEM services are not used, and none of the authentication options or those options that refer to remote systems are available. The command in local mode runs faster than in remote mode.

If the Solaris WBEM services are running and you specify any of the remote or authentication options, the command in remote mode is used.

On Solaris 8 systems, the `smpatch` command only supports local mode operations.

Specifying the Source of Updates

Your system must specify the source of updates to use. By default, you obtain updates from the Sun update server. However, you can also obtain updates from an update server on your intranet or from a local collection of updates on your system.

You must specify the URL that points to the collection of updates. By default, the Sun update server is the source of updates. The URL is:

```
https://getupdates.sun.com/solaris/
```

The URL must point to an update server or to a collection of updates that is available to the local system. The value of this URL cannot be null.

Configuring Your Update Management Environment

You can use the `smpatch set` command to configure the update management environment for your system. Use these parameters:

`patchpro.patchset`
: Name of the update set to use. The default name is `current`.

`patchpro.download.directory`
: Path of the directory where downloaded updates are stored and from which updates are applied. The default location is `/var/sadm/spool`.

`patchpro.backout.directory`
: Path of the directory where update backout data is saved. When an update is removed, the data is retrieved from this directory as well. By default, backout data is saved in the package directories.

`patchpro.patch.source`
: URL that points to the collection of updates. The default URL is that of the Sun update server, `https://getupdates.sun.com/solaris/`.

`patchpro.proxy.host`
: Host name of your web proxy. By default, no web proxy is specified, and a direct connection to the Internet is assumed.

`patchpro.proxy.port`
: Port number used by your web proxy. By default, no web proxy is specified, and a direct connection to the Internet is assumed. The default port is `8080`.

`patchpro.proxy.user`
: Your user name used by your web proxy for authentication.

`patchpro.proxy.passwd`
: Password used by your web proxy for authentication.

`patchpro.install.types`
: Your policy for applying updates. The value is a list of zero or more colon-separated update properties that are permitted to be applied by an update operation (`smpatch update`).

  This policy *only* affects which updates are installed on your system. The policy does not affect which updates are downloaded.

By default, updates that have the `standard`, `rebootafter`, and `reconfigafter` properties can be applied. See "Setting an Update Policy."

Setting an Update Policy

Updates are classified as being standard or nonstandard. A *standard update* can be applied by `smpatch update`. Such an update is associated with the `standard` update property. `smpatch` applies standard updates immediately. These updates require no system restart. A *nonstandard update* has one of the following characteristics:

- An update that is associated with the `rebootafter`, `rebootimmediate`, `reconfigafter`, `reconfigimmediate`, or `singleuser` properties. Such a nonstandard update can be applied automatically during a system shutdown if permitted by the policy.
- An update that is associated with the `interactive` property. Such an update cannot be applied by using automated installation mechanisms like `smpatch update`. When you attempt to apply one of these updates using `smpatch update`, the update will be downloaded but not installed. You must examine the update's README file and perform whatever manual steps it describes. Typically, you are instructed to apply the update manually using `patchadd` or `smpatch add`.

Use `smpatch set` to specify the types of updates that `smpatch` can additionally apply during an update operation. Such updates might include those that require a reboot and those that must be applied while the system is in single-user mode.

This policy only affects which updates are installed on your system. The policy does not affect which updates are downloaded.

Specify the types of updates that can be applied by using the following command:

```
# smpatch set patchpro.install.types=update-property-list
```

update-property-list is a colon-separated list of one or more of the following update properties:

`interactive`
An update that cannot be applied by running the usual update management tools (`pprosvc`, `smpatch`, or `patchadd`). Before this update is applied, the user must perform special actions. Such actions might include checking the serial number of a disk drive, stopping a critical daemon, or reading the update's README file.

`rebootafter`
The effects of this update are not visible until after the system is rebooted.

`rebootimmediate`
When this update is applied, the system becomes unstable until the system is rebooted. An unstable system is one in which the behavior is unpredictable and data might be lost.

`reconfigafter`
The effects of this update are not visible until after a reconfiguration reboot (`boot -r`). See the `boot(1M)` man page.

`reconfigimmediate`
When this update is applied, the system becomes unstable until the system gets a reconfiguration reboot (`boot -r`). An unstable system is one in which the behavior is unpredictable and data might be lost.

`singleuser`
Do not apply this update while the system is in multiuser mode. You must apply this update on a quiet system with no network traffic and with extremely restricted I/O activity.

`standard`
This update can be applied while the system is in multiuser mode. The effects of the update are visible as soon as it is applied unless the application being updated is running while the update is applied. In this case, the effects of the update are visible after the affected application is restarted.

Options The `smpatch` command supports two kinds of options: authentication options and subcommand options.

Authentication Options The `smpatch` authentication options, *auth-opts*, apply to all of the subcommands.

If no authentication options are specified, certain defaults are assumed and the user might be prompted for additional information, such as a password for authentication purposes.

These authentication options are only available if the Solaris Management Console and the Solaris WBEM services are available on the local system. If the WBEM services are not running on the local system, `smpatch` performs update operations on the local system only. You can also "force" the use of the local-mode `smpatch` command by using the `-L` option.

The single letter options can also be specified by their equivalent option words preceded by two hyphens. For example, you can specify either `-l` or `--rolepassword`.

The following authentication options are supported:

`-H` | `--hostname` *host-name*:*port*
Specifies the host and port to which you want to connect. If you do not specify a port, the system connects to the default port, `898`. If you do not specify a host (*host-name*:*port*), the Solaris Management Console connects to the local host on port `898`. You might still have to choose a toolbox to load into the console. To override this behavior, use the `smc -B` command, or set your console preferences to load a home toolbox by default.

`-L`
Forces the `smpatch` command to use local mode, which does not rely on Solaris WBEM services. On Solaris 8 systems, this option does not do anything.

This option is mutually exclusive with the other authentication options.

`-l` | `--rolepassword` *role-password*
Specifies the password for *role-name*. If you specify *role-name* but do not specify *role-password*, you are prompted to supply *role-password*. Because passwords specified on the command line can be seen by any user on the system, this option is considered to be insecure.

`-p` | `--password` *password*
Specifies the password for *user-name*. If you do not specify a password, you are prompted to supply one. Because passwords specified on the command line can be seen by any user on the system, this option is considered to be insecure.

`-r` | `--rolename` *role-name*
Specifies a role name for authentication. If this option is not specified, no role is assumed.

`-u` | `--username` *user-name*
Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

Subcommand Options

The following options pertain to the `smpatch` subcommands:

`-b` *BE_name*
Specifies the name of BE that is to be created and updated (for the `add` and `update` subcommands), or to be removed, for the `remove` subcommand.

`-d` *update-dir*
Specifies an alternate download directory in which updates are downloaded and from which they are applied.

The default download directory is `/var/sadm/spool`.

The directory must be writable by `root` and be publicly readable.

update-dir uses one of the following forms:

- For remote mode, specify *host-name*:*/update-dir*, where */update-dir* is a fully qualified, shared directory.
- For local mode, specify */update-dir*, which is a fully qualified, shared directory.

This option is supported by the `add`, `download`, `order`, and `update` subcommands.

`-f`
Forces the download of the exact update revision specified by `-i` *update-id*. If `-i` *update-id* does not specify a revision, the highest revision of the update is downloaded.

This option is supported by the `download` subcommand.

`-h`
Displays information about the command-line options for the specified subcommand. This option is mutually exclusive with all other options.

`-i` *update-id*
Specifies the ID of an update.

You can specify more than one update ID by using the `-i` option for each update. You can also use the `-x idlist=` option to point to a list of update IDs.

When using the `remove` subcommand, you can specify exactly one update ID.

This option is supported by the `add`, `analyze`, `download`, `order`, `remove`, and `update` subcommands.

`-n` *system-name*
Specifies the name of the system on which to manage updates.

When using the `add` subcommand, you can specify more than one system by using the `-n` option for each system. When using the `analyze`, `download`, `remove`, and `update` subcommands, you can only specify a single system.

To specify more than one system for the `smpatch add` command, use the `-x mlist=` option. This option enables you to specify a list of systems instead of using the `-n` option to specify each system. The `-n` option and the `-x mlist=` option are mutually exclusive.

If you do not specify this option, the system is assumed to be the one specified by the `-H` option.

This option is supported only if the Solaris Management Console and the Solaris WBEM services are running on the local system and any system that is specified by this option.

This option is supported by the `add`, `analyze`, `download`, `get`, `order`, `remove`, `set`, `unset`, and `update` subcommands.

`-t`
Downloads the `README` file associated with the update specified by `-i` *update-id*. If `-i` *update-id* does not specify a revision, the `README` file for the highest revision of the update is downloaded.

This option is supported by the `download` subcommand.

`-V`
Displays version information for an `smpatch` subcommand.

`-x idlist=`*update-list-file*
Specifies the name of a file, *update-list-file*, that contains a list of updates to download or apply.

Each update ID in the file must be terminated by a newline character. The file name you specify must be a full path name.

You can use the `-i` option to specify a list of update IDs.

This option is supported by the `add`, `analyze`, `download`, `order`, and `update` subcommands.

`-x mlist=`*system-list-file*
Specifies the name of a file, *system-list-file*, that contains a list of systems on which to manage updates.

Each system name must be terminated by a newline character. The file name you specify must be a full path name.

You can use the `-n` option to specify a list of systems instead of using the `-x mlist=` option. The `-n` option and the `-x mlist=` option are mutually exclusive.

This option is supported only if the Solaris Management Console and the Solaris WBEM services are running on the local system and any system that is specified in *system-list-file*.

This option is supported by the `add` subcommand.

Examples

EXAMPLE 1 Analyzing Your System to Obtain the List of Appropriate Updates for the Local System

```
# smpatch analyze
```

Shows how to analyze your system to obtain the list of appropriate updates. After the analysis, you can download and apply the updates to your system.

EXAMPLE 2 Analyzing Your System to Obtain the List of Appropriate Updates for Another System

```
# smpatch analyze -n lab1
```

Shows how to analyze a different system, `lab1`, to obtain the list of appropriate updates. After the analysis, you can download and apply the updates to that system.

EXAMPLE 3 Applying Updates to Multiple Systems

```
# smpatch add -i 102893-01 -i 106895-09 -i 106527-05 \
-d fileserver:/files/updates/s10 -n lab1 -n lab2
```

Applies updates `102893-01`, `106895-09`, and `106527-05` to the systems `lab1` and `lab2`. The updates are located in the `/files/updates/s10` directory on the system named `fileserver`.

EXAMPLE 4 Applying Updates by Using an Update List File

```
# smpatch add -x idlist=/tmp/update/update_file \
-d /net/fileserver/export/updatespool/Solaris10 -n lab1 -n lab2
```

Applies the updates specified in the file `/tmp/update/update_file` to the systems `lab1` and `lab2`. The updates are located in the NFS-mounted directory named `/net/fileserver/export/updatespool/Solaris10`.

EXAMPLE 5 Applying Updates by Using an Update List File and a System List File

```
# smpatch add -x idlist=/tmp/update/update_file \
-x mlist=/tmp/update/sys_file
```

Applies the updates listed in the file `/tmp/update/update_file` to the systems listed in the file `/tmp/update/sys_file`. The updates are located in the default `/var/sadm/spool` directory on the local system.

EXAMPLE 6 Analyzing a System and Downloading Updates From the Sun Update Server

```
# smpatch download -n lab1
```

Analyzes the `lab1` system and downloads the appropriate updates from the Sun update server to the download directory.

EXAMPLE 7 Downloading Updates From the Sun Update Server

The command below downloads the `102893-01` and `106895-09` updates from the Sun update server to the `/files/updates/s10` directory.

```
# smpatch download -i 102893-01 -i 106895-09 -d /files/updates/s10
```

EXAMPLE 8 Downloading Specific Update Revisions From the Sun Update Server

The command below downloads the `102893-01` and `106895-02` updates from the Sun update server. The specific revisions are downloaded, not the highest available revision.

```
# smpatch download -f -i 102893-01 -i 106895-02
```

EXAMPLE 9 Downloading the Highest Available Update Revisions From the Sun Update Server

The command below downloads the `102893-01` and `106895-09` updates, which are the highest available revisions, from the Sun update server.

```
# smpatch download -f -i 102893 -i 106895
```

EXAMPLE 10 Downloading Update README Files From the Sun Update Server

The command below downloads the `README` files for updates `102893-01` and `106895-02`. Because update `102893` was specifi ed without a revision number, the `README` file for the highest available update revision, `102893-01`, is downloaded from the Sun update server.

```
# smpatch download -t -i 102893 -i 106895-02
```

EXAMPLE 11 Listing All Configuration Parameter Values

```
# smpatch get -p password
Loading Tool: com.sun.admin.patchmgr.cli.PatchMgrCli from mars
Login to mars as user root was successful.
Download of com.sun.admin.patchmgr.cli.PatchMgrCli from mars
was successful.
```

EXAMPLE 11 Listing All Configuration Parameter Values *(Continued)*

```
On machine mars:

patchpro.backout.directory  -      ""
patchpro.download.directory -      /var/sadm/spool
patchpro.install.types      -      rebootafter:reconfigafter:standard
patchpro.patch.source       -      https://getupdates.sun.com/solaris/
patchpro.patchset           -      current
patchpro.proxy.host         -      ""
patchpro.proxy.passwd       ****   ****
patchpro.proxy.port         -      8080
patchpro.proxy.user         -      ""
patchpro.sun.passwd         ****   ****
patchpro.sun.user           -      ""
```

Lists the configuration settings for the system.

EXAMPLE 12 Listing One or More Configuration Parameter Values

```
# smpatch get -L patchpro.patch.source patchpro.download.directory
https://getupdates.sun.com/solaris/
/var/sadm/spool
```

Uses `smpatch` in local mode to list the values of the `patchpro.patch.source` and the `patchpro.download.directory` parameters.

EXAMPLE 13 Reordering a List of Updates

```
# smpatch order -x idlist=/tmp/plist
```

Reorders the update list called `/tmp/plist` in an order that is suitable for applying the updates.

EXAMPLE 14 Removing an Update

```
# smpatch remove -i 102893-01
```

Removes update `102893-01`.

EXAMPLE 15 Specifying the Update Policy

The following command specifies the update policy.

```
# smpatch set \
patchpro.install.types=standard:singleuser:reconfigafter:rebootafter
```

Specifies the update policy for your system. The following types of updates are allowed to be applied to your system:

- Standard updates
- Updates that must be applied in single-user mode

EXAMPLE 15 Specifying the Update Policy *(Continued)*

- Updates that require that the system undergo a reconfiguration reboot after they have been applied
- Updates that require that the system undergo a reboot after they have been applied

EXAMPLE 16 Changing the Download Directory Location

```
# smpatch set patchpro.download.directory=/export/home/updates
```

EXAMPLE 17 Specifying a Local Web Proxy

```
# smpatch set patchpro.proxy.host=webaccess.corp.net.com \
patchpro.proxy.port=8080
```

Specifies the host name, `webaccess.corp.net.com`, and port, `8080`, of the local web proxy.

EXAMPLE 18 Resetting a Configuration Parameter Value

```
# smpatch unset patchpro.patch.source
```

Resets the value of the `patchpro.patch.source` parameter to its default value, which is the URL that points to the Sun update server.

EXAMPLE 19 Updating Your System

```
# smpatch update -L
```

Analyzes your local system, determines the appropriate updates, downloads those updates to the download directory, and applies those updates.

EXAMPLE 20 Adding an Update to a BE

The following command adds a specific update to the BE `altboot`.

```
# smpatch add -b altboot 111111-01
```

Following successful completion of this command, you can then boot from `altboot`.

EXAMPLE 21 Updating a BE

The following command performs an update on the BE `altboot`.

```
# smpatch update -b altboot
```

This command performs all of the usual analysis and dependency checking that occurs with any `update` command. Following successful completion of this command, you can then boot from `altboot`.

EXAMPLE 22 Obtaining `smpatch` Version Number

The following command returns the version number for an `smpatch` subcommand.

EXAMPLE 22 Obtaining `smpatch` Version Number *(Continued)*

```
# smpatch update -V
1.0.9
```

Environment Variables

See `environ`(5) for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smpatch` command. The default value of this variable is `/usr/java`. See the `smc`(1M) man page.

Exit Status

The following exit values are returned:

`0`
Successful completion.

`1`
Invalid command syntax. A usage message displays.

`2`
An error occurred while executing the command. An error message displays.

Attributes

See the `attributes(5)` man page for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWswmt
Interface Stability	Evolving

Sun Update Manager 1.0 Administration Guide

Name smprofile – manage profiles in the prof_attr and exec_attr databases

Synopsis

```
/usr/sadm/bin/smprofile subcommand [ auth_args] - –
    [subcommand_args]
```

Description The `smprofile` command manages one or more profiles in the `prof_attr(4)` or `exec_attr(4)` databases in the local `/etc` files name service or a NIS or NIS+ name service.

subcommands `smprofile` *subcommand*s are:

`add` Adds a new profile (right) to the `prof_attr(4)` database. To add a profile, the administrator must have the `solaris.profmgr.write` authorization.

`delete` Deletes a profile from the `prof_attr(4)` database, deletes all associated entries from the `exec_attr(4)` database, and deletes the assigned profile from the `user_attr(4)` database. To delete a profile, the administrator must have the `solaris.profmgr.execattr.write` and `solaris.profmgr.write` authorization.

`list` Lists one or more profiles from the `prof_attr`(4) or `exec_attr`(4) databases. To list a profile, the administrator must have the `solaris.profmgr.read` authorization.

`modify` Modifies a profile in the `prof_attr`(4) database. To modify a profile, the administrator must have the `solaris.profmgr.write` authorization.

Options The `smprofile` authentication arguments, *auth_args*, are derived from the `smc(1M)` arg set and are the same regardless of which subcommand you use. The `smprofile` command requires the Solaris Management Console to be initialized for the command to succeed (see `smc(1M)`). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, *subcommand_args*, must come after the *auth_args* and must be separated from them by the `- –` option.

auth_args The valid *auth_args* are `-D`, `-H`, `-l`, `-p`, `-r`, and `-u`; they are all optional. If no *auth_args* are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `- –domain` with the *domain* argument.

`-D | - –domain` *13;domain* Specifies the default domain that you want to manage. The syntax of *domain* is *type:/host_name/domain_name*, where *type* is `nis`, `nisplus`, `dns`, `ldap`, or `file`; *host_name* is the name of the machine that serves the domain; and *domain_name* is the name of the domain you want to manage. (*Note:* Do *not* use `nis+` for `nisplus`.)

	If you do not specify this option, the Solaris Management Console assumes the `file` default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.
`-H | - –hostname` *13;host_name:port*	Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, `898`. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port `898`. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc(1M)` `-B` option, or set your console preferences to load a "home toolbox" by default.
`-l | - –rolepassword` *13;role_password*	Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
`-p | - –password` *13;password*	Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
`-r | - –rolename` *13;role_name*	Specifies a role name for authentication. If you do not specify this option, no role is assumed.
`-u | - –username` *13;user_name*	Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.
`- –`	This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `- –` option.

subcommand_args *Note:* Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

To add privileges to or modify privileges in a profile entry, the administrator must have the `solaris.admin.privilege.write` authorization. See `privileges(5)`.

- For subcommand `add`:

  `-a` *addauth1* `-a` *addauth2* . . . (Optional) Specifies the authorization name(s) to add to the new profile. The administrator must have the `solaris.profmgr.write` authorization and must have the corresponding "grant" authorization. A "grant" authorization is one in which the lowest component of the authorization name is replaced by the word `grant`. For example, to grant some profile the `solaris.role.write` authorization, the administrator needs that authorization and also the `solaris.role.grant` authorization. For more information on granting authorizations, see `auth_attr(4)`.

  `-d` *description* Specifies the description of the new profile.

  `-h` (Optional) Displays the command's usage statement.

  `-m` *html_help* Specifies the HTML help file name for the new profile. The help file name must be put in the `/usr/lib/help/profiles/locale/C` directory.

  `-n` *name* Specifies the name of the new profile.

  `-p` *addprof1* `-p` *addprof2* . . . (Optional) Specifies the supplementary profile name(s) to add to the new profile.

  `-I` *inherited_privs* Specifies the inherited privilege name(s) to add to the new `prof_attr(4)` entry.

  To add privileges to or modify privileges in a profile entry, the administrator must have the `solaris.admin.privilege.write` authorization. See `privileges(5)`.

- For subcommand `delete`:

  `-h` (Optional) Displays the command's usage statement.

  `-n` *name* Specifies the name of the profile you want to delete.

- For subcommand `list`:

  `-h` (Optional) Displays the command's usage statement.

  `-l` (Optional) Displays the detailed output for each profile in a block of *key*:*value* pairs, followed by a blank line that delimits

each profile block. Each *key*:*value* pair is displayed on a separate line. All the attributes associated with a profile from the `prof_attr` and `exec_attr` databases are displayed. If you do not specify this option, only the specified profile name(s) and associated profile description(s) are displayed.

`-n` *name1* `-n` *name2* . . . (Optional) Specifies the profile(s) that you want to display. If you do not specify a profile name, all profiles are displayed.

- For subcommand `modify`:

  `-a` *addauth1* `-a` *addauth2* . . . (Optional) Specifies the authorization name(s) to add to the profile. The administrator must currently have been granted each of the specified authorizations and must have the ability to grant each of those authorizations to other users or roles. For more information on granting authorizations, see `auth_attr(4)`.

  `-d` *description* (Optional) Specifies the new description of the profile.

  `-h` (Optional) Displays the command's usage statement.

  `-m` *html_help* (Optional) Specifies the new HTML help file name of the profile. If you change this name, you must accordingly rename the help file name entered in the `/usr/lib/help/profiles/locale/C` directory.

  `-n` *name* Specifies the name of the profile you want to modify.

  `-p` *addprof1* `-p` *addprof2* . . . (Optional) Specifies the supplementary profile name(s) to add to the profile. The administrator must have the `solaris.profmgr.assign` authorization to add any profile and the `solaris.profmgr.delegate` authorization to add any profile that has been assigned to the authenticated user.

  `-q` *delprof1* `-q` *delprof2* . . . (Optional) Specifies the supplementary profile name(s) to delete from the profile. The administrator must have the `solaris.profmgr.assign` authorization to delete any profile and the `solaris.profmgr.delegate` authorization to delete any profile that has been assigned to the authenticated user.

  `-r` *delauth1* `-r` *delauth2* . . . (Optional) Specifies the authorization name(s) to delete from the profile. The administrator must have the `solaris.profmgr.write` authorization and must have the corresponding "grant" authorization. For more information about "grant" authorizations, see the `-a` option description for the `add` subcommand above.

-I *inherited_privs*

Specifies the inherited privilege name(s) to modify in the prof_attr(4) entry.

To add privileges to or modify privileges in a profile entry, the administrator must have the solaris.admin.privilege.write authorization. See privileges(5).

Examples

EXAMPLE 1 Creating a new profile

The following creates a new User Manager profile on the local file system. The new profile description is Manage users and groups, and the authorizations assigned are solaris.admin.usermgr.write and solaris.admin.usermgr.read. The supplementary profile assigned is Operator. The help file name is RtUserMgmt.html.

```
./smprofile add -H myhost -p mypasswd -u root -- -n "User Manager" \
   -d "Manage users and groups" -a solaris.admin.usermgr.write \
   -a solaris.admin.usermgr.read -p Operator -m RtUserMgmt.html
```

EXAMPLE 2 Deleting a profile

The following deletes the User Manager profile from the local file system:

```
./smprofile delete -H myhost -p mypasswd -u root -- -n "User Manager"
```

EXAMPLE 3 Listing all profiles

The following lists all profiles and their associated profile descriptions on the local file system.

```
./smprofile list -H myhost -p mypasswd -u root --
```

EXAMPLE 4 Modifying a profile

The following modifies the User Manager profile on the local file system. The new profile description is Manage world, the new authorization assignment is solaris.admin.usermgr.* authorizations, and the new supplementary profile assignment is All. (The -a option argument must be enclosed in double quotes when the wildcard character (*) is used.)

```
./smprofile modify -H myhost -p mypasswd -u root -- -n "User Manager" \
   -d "Manage world" -a "solaris.admin.usermgr.*" -p All
```

Environment Variables

See environ(5) for a description of the JAVA_HOME environment variable, which affects the execution of the smprofile command. If this environment variable is not specified, the /usr/java location is used. See smc(1M).

Exit Status

The following exit values are returned:

0 Successful completion.

1 Invalid command syntax. A usage message displays.

2 An error occurred while executing the command. An error message displays.

Files The following files are used by the `smprofile` command:

`/etc/security/exec_attr`	Rights profiles database. See `exec_attr(4)`.
`/etc/security/prof_attr`	Profile description database. See `prof_attr(4)`.
`/etc/user_attr`	Extended user attribute database. See `user_attr(4)`.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga
Interface Stability	Evolving

Name smreg – register objects for the Sun Web Console

Synopsis `/usr/sbin/smreg [-h | --help] subcommand options`

Description The `smreg` utility is a Command Line Interface (CLI) -based registration mechanism to manage the information in the console's registration databases. `smreg` adds management web applications, libraries, and configuration information to registration databases. It also validates an application's deployment descriptor to make sure it has certain required tags that enable the application to run in the console.

`smreg` has four subcommands: `add`, `remove`, `check`, and `list`.

Subcommands The following subcommands are supported:

add
Registers objects of a specified type. If the object is already registered, any new registration will replace the previous registration. The application registration descriptor `app.xml` is verified to ensure that meets some initial requirements.

The format of the `add` subcommand is:

add `-a` [`-x` *context*] *path*

add `-d` *path*

add `-l` [`-L`] [`-n` *lib_name*] `-s` ALL | *app_name path*

add `-m -b` *behavior* [`-s` *service*] `-o` *name=value ... module*

add `-p` [`-c` | `-e`] *name=value ...*

add `-h`

remove
Unregisters named objects.

The format of the remove subcommand is:

remove `-a` *app_name* | *context*

remove `-n` *app_name* | `-d` *path*

remove `-l -s` ALL | *app_name lib_name*

remove `-m` [`-s` *service*] *module*

remove `-p` [`-c` | `-e`] *name ...*

remove `-h`

`check`
Check an application.

The `check` subcommand parses the application's `web.xml` file to make sure that it has the *filter* and *filter-mapping* tags. The console requires these tags to run an application.

The required tags are as follows:

```
<filter>
  <filter-name>SessionManagerFilter</filter-name>
  <filter-class>
    com.sun.management.services.session.AppSessionManagerFilter
  </filter-class>
  <init-param>
    <param-name>ignore-paths</param-name>
    <param-value>
        images/*
    </param-value>
  </init-param>
</filter>
<filter-mapping>
  <filter-name>SessionManagerFilter</filter-name>
  <url-pattern>/*</url-pattern>
</filter-mapping>
```

Elements in the `web.xml` file must appear in a fixed order. For example, the *filter* tag must appear in the `web.xml` file before the *filter-mapping tag*. For more information, see the *Java Servlet Specifications 2.3.*

The `smreg check` subcommand parses the application's `web.xml` file, checking for the existence of these tags and for the correct tag content. That is, the embedded *filter-name* tag content must be `SessionManagerFilter`, and the *filter-class* tag content must be:

```
com.sun.management.services.session.AppSessionManagerFilter
```

If the tag content is not correct, the application will not be registered.

If the tags are not included in the application's `web.xml` file, the script prints to standard output a corrected version the `web.xml` file, with the tags embedded in the correct location. Because multiple *filter* tags are allowed in a file, `smreg` also includes the new tags as the first in a series.

The format for the `check` subcommand is:

`check` [`-d`] *path*

`check -h`

The `-d` is used strictly to maintain interface compatibility with 1.0-based application packages, and is otherwise ignored.

list

Prints list of registered objects.

The format of the list subcommand is:

`list` [`-a` | `-l` | `-m` | `-p`]

If no options are specified, then all registered objects are listed.

Options The following options are supported:

`-a` | `--application`
Object type is an application.

See *app_name* under ARGUMENTS for more information on the name by which an application is registered.

`-b` *behavior* | `--behavior` *behavior*
A flag value that controls behavior as authentication proceeds down the login module stack. See *behavior* under ARGUMENTS for more information on values allowed.

`-c` *name=value* ... | `--configuration` *name=value* ...
When used with `-p`, this option specifies that the property arguments are server configuration properties. The *name=value* pairs are written to a datastore, to be read during the next server startup. Any property name can be created, but only those recognized by the server will have any effect.

`-d` *path* | `--directory` *path*
This option is deprecated and is preserved only for compatibility with existing 1.0-based applications. It will be removed in a future release.

When used with the "add" subcommand, it has the same effect as "`-a`".

When used with the "remove" subcommand, *path* is the path to the original installation location of the application. This path will be mapped to the registered *app_name* so that the application can be unregistered using "`smreg remove -a` *app_name*". When used with the "check" subcommand, `-d` is ignored. The `-d` option is preserved strictly to maintain 1.0 interface compatibility.

`-e` *name=value* ... | `--environment` *name=value* ...
When used with `-p`, this option specifies that the property arguments are server environment properties. The *name=value* pairs are placed into the server's environment during the next server startup. Any environment name can be created, and is available for use by any application.

`-h` | `-?` | `--help`
Displays command and subcommand usage information.

`-l` | `--library`
Object type is a library JAR file.

Library JAR files that are not installed in the same location as the application, or are not registered at the same time as the application (for example, localization JAR files), can be registered separately by using this option. See *lib_name* under ARGUMENTS for more information on the name by which a library is registered.

A library can be registered with global scope so that it can be used by all applications, by specifying the `-s ALL` option. A library can be registered so that it may only be used by a specific application, by specifying the `-s` *app_name* option. If a library must be shared by more than one application but not globally, then a seperate registration is required for each instance in which the library is to be shared.

`-L` | `--link`
Specifies to register the library JAR as a symbolic link rather than as a file copy. This option is ignored on operating systems which do not support symbolic links.

`-m` | `--module`
Object type is a login module.

`-n` [*app_name* | *lib_name*] | `--name` [*app_name* | *lib_name*]
When used with the "add `-l`" subcommand, specifies the name by which an application or library is known to the registration service.

When used with the "remove" subcommand, specifies the name by which an application is known to the registry service. "`remove -n`" is deprecated and is preserved only for compatibility with existing 1.0-based applications. It will be removed in a future release.

See *app_name* under ARGUMENTS for more information on the name by which an application is registered.

See *lib_name* under ARGUMENTS for more information on the name by which a library is registered.

`-o` *name=value* ... | `--option` *name=value* ...
Options specific to the login module implementation. The options are specified as *name=value* pairs, each preceded by the `-o` option. Values containing more than one word must be enclosed in double quotes (").

`-p` | `--properties`
Object type is properties. This option is specified for use with either `-c` (for configuration properties) or `-e` (for environment properties). If neither `-c` nor `-e` are specified, then `-c` is assumed.

See the PROPERTIES section for information on specific configuration properties that are useful to a system administrator.

`-s` [ALL | *app_name*] | `--scope` [ALL | *app_name*]
When used with `-l`, specifies the sharing scope for the library being registered. A scope of `ALL` makes the library available to all applications. A scope of *app_name* makes the library available only to the application already registered as *app_name*. See *app_name* under ARGUMENTS for more information on the name by which an application is registered.

`-s` *service* | `--scope` *service*
When used with `-m`, specifies the login service scope for the module. If not specified, the default is `ConsoleLogin`, which is the web console's browser login service.

`-V` | `--version`
Display console version information.

`-x` *context* | `--context` *context*
The deployment context path for an application. This option is to be used to register applications built with the SDK version 2.1 or greater. If not provided and the application is unpacked, the context is the parent directory of the application's WEB-INF directory. This option is ignored when registering applications built with an SDK version prior to 2.1.

Arguments The subcommand arguments are:

app_name — The unique name of the registered application in the format of *pluginName_version*, where *pluginName* and *version* are tags extracted from the application's registration descriptor, `app.xml`. All subsequent references to the registered application must then be made by using this registered name.

path — When used with the "`add -a`", "`add -d`", or "`remove -d`" subcommands, the full directory path where the application has been installed.

When used with the `check` subcommand, if it is a directory then it is the full directory path where the application has been installed. If it is a file, then it is the path to a `web.xml`-compliant file.

When used with the "`add -l`" subcommand, the full path where the library JAR file is installed.

behavior — Specifies the authentication behavior. The possible values are: `required`, `requisite`, `sufficient`, or `optional`.

lib_name — The name by which a library JAR file is known to the registration service. By default, libraries will be registered using the basename of the path to the library. This default value can be overridden by using the `-n` *lib_name* option to register the object by using a globally unique name.

module — The fully-qualified class name of the module. For example: `com.sun.management.services.authentication.MyLoginModule`

Properties While the list of configuration properties is unlimitted, certain properties that may be useful to a system administrator are mentioned here:

session.timeout.value
This is the time interval of no user activity after which the user will be prompted to log in again to continue. The default session timeout is 15 minutes. Setting the value to -1 means there is no timeout. To set the session timeout to 5 minutes, run the following command:

```
# smreg add -p -c session.timeout.value=5
```

debug.trace.path
This is the directory where log files are created. The default is `/var/log/webconsole`. To set the directory to `/tmp/logs`, run the following command:

```
# smreg add -p -c debug.trace.path=/tmp/logs
```

java.home
This is the path to the Java Development Kit (JDK) that will be used to run the web server. The default is `/usr/j2se` on Solaris and `/usr/java/j2sdk1.4.2` on Linux. To set the path to `/usr/jdk142`, run the following command:

```
# smreg add -p -c java.home=/usr/jdk142
```

java.options
This contains the options for configuring the Java Virtual machine (JVM). The defaults are "-server -XX:+BackgroundCompilation". To include setting the initial Java heap size to 64MB, run the following command:

```
# smreg add -p -c java.options="-Xms64 \\
-server -XX:+BackgroundCompilation"
```

Examples

EXAMPLE 1 Registering an unpacked Application

The following command registers an application which has been installed unpacked in `/opt/myCompany/myApp`:

```
# smreg add -a /opt/myCompany/myApp
```

EXAMPLE 2 Unregistering an Application

The following command unregisters an application previous registered with an *app_name* of `com.myCompany.myApp_1.2`:

```
# smreg remove -a com.myCompany.myApp_1.2
```

EXAMPLE 3 Registering a Library JAR File with Global Scope

The following command registers `myLibrary.jar`, installed in `/opt/myCompany/MyApp`, as `com_myCompany_myLibrary.jar` for use by all applications:

```
# smreg add -l -n com_myCompany_myLibrary.jar \\
      -s ALL /opt/myCompany/MyApp/myLibrary.jar
```

EXAMPLE 4 Registering a Library JAR file with a Specific Application Scope

The following command registers Utilities.jar, installed in `/opt/SomeCompany/lib`, with the application already registered as `com.myCompany.myApp_1.2`:

```
# smreg add -l -s com.myCompany.myApp_1.2 \
/opt/SomeCompany/lib/Utilities.jar
```

EXAMPLE 5 Unregister a Library JAR File from Global Scope

The following command unregisters `com_myCompany_myLibrary.jar` from global scope so that it is not available to applications:

```
# smreg remove -l -s ALL com_myCompany_myLibrary.jar
```

EXAMPLE 6 Unregister a Library JAR File from a Specific Application Scope

The following command unregisters `Utilities.jar` so that it is not available to the registered application `com.myCompany.myApp_1.2`:

```
# smreg remove -l -s com.myCompany.myApp_1.2 Utilities.jar
```

EXAMPLE 7 Checking that Application's Deployment Descriptor Meets Sun Web Console Guidelines

Either of the following commands to check to see if the deployment descriptor located at `/opt/myCompany/myApp/WEB-INF/lib/web.xml` meets the Sun Web Console guideline:

```
# smreg check /opt/myCompany/myApp
  # smreg check /opt/myCompany/myApp/WEB-INF/lib/web.xml
```

EXAMPLE 8 Registering an Environment Property

The following command registers the environment property name `GREETING` with value "Hello World" and the name `FOO` with the value "bar" so that they appear in the server's environment and are available to any application:

```
# smreg add -p -e GREETING="Hello World" FOO=bar
```

EXAMPLE 9 Unregistering an Environment Property

The following command unregisters the environment property names `GREETING` and `FOO` so that they no longer appear in the server's environment and are not available to any application:

```
# smreg remove -p -e GREETING FOO
```

EXAMPLE 10 Registering a Login Module

The following command registers the module class `com.sun.management.services.authentication.myLoginModule` with "requisite" behavior and a `commandPath` argument:

```
# smreg add -m -b requisite \\
      -o commandPath="/usr/lib/webconsole" \\
      com.sun.management.services.authentication.myLoginModule
```

EXAMPLE 11 Unregistering a Login Module

The following command unregisters the module class `com.sun.management.services.authentication.myLoginModule`:

```
# smreg remove -m com.sun.management.services.authentication.myLoginModule
```

EXAMPLE 12 Print a List of All Registered Applications

```
# smreg list -a
```

Exit Status

The following exit values are returned:

`0` Successful completion.

`1` Usage error: missing or malformed arguments.

`2` An error occurred that prevents registration - either a console configuration problem, or badly-formatted `web.xml` or `app.xml`.

`3` Unable to determine OS for this machine.

`4` Detected OS for this machine is not supported.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmcon
Interface Stability	Obsolete

Name smrole – manage roles and users in role accounts

Synopsis

```
/usr/sadm/bin/smrole subcommand [ auth_args] - –
     [subcommand_args]
```

Description The `smrole` command manages roles and adds or deletes users in role accounts.

subcommands `smrole` *subcommand*s are:

`add` Adds a new role entry. To add an entry, the administrator must have the `solaris.role.write` authorization.

`delete` Deletes one or more roles. To delete an entry, the administrator must have the `solaris.role.write` authorization.

`list` Lists one or more roles. If you do not specify a role name, all roles are listed. To list an entry, the administrator must have the `solaris.admin.usermgr.read` authorization.

`modify` Adds or deletes users from a role account. To modify an entry, the administrator must have the `solaris.role.write` authorization.

Options The `smrole` authentication arguments, *auth_args*, are derived from the smc(1M) arg set and are the same regardless of which subcommand you use. The `smrole` command requires the Solaris Management Console to be initialized for the command to succeed (see smc(1M)). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, *subcommand_args*, must come after the *auth_args* and must be separated from them by the `- –` option.

auth_args The *auth_args* are `-D`, `-H`, `-l`, `-p`, `-r`, and `-u` are described below. They are all optional. These options are a subset of the full complement of supported options described in smc(1M).

If no *auth_args* are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `- –domain` with the *domain* argument.

`-D` | `- –domain` *13;domain* Specifies the default domain that you want to manage. The syntax of *domain* is *type*:/*host_name*/*domain_name*, where *type* is `nis`, `nisplus`, `dns`, `ldap`, or `file`; *host_name* is the name of the machine that serves the domain; and *domain_name* is the name of the domain you want to manage. (*Note:* Do *not* use `nis+` for `nisplus`.)

	If you do not specify this option, the Solaris Management Console assumes the `file` default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.
`-H | - —hostname` *13;host_name:port*	Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, `898`. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port `898`. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc(1M) -B` option, or set your console preferences to load a "home toolbox" by default.
`-l | - —rolepassword` *13;role_password*	Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
`-p | - —password` *13;password*	Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
`-r | - —rolename` *13;role_name*	Specifies a role name for authentication. If you do not specify this option, no role is assumed.
`-u | - —username` *13;user_name*	Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.
`- —`	This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `- —` option.

subcommand_args *Note:* Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

To add or change privileges, the administrator must have the `solaris.admin.privilege.write` authorization. See `privileges(5)`.

- For subcommand `add`:

  `-a` *adduser1* `-a` *adduser2* . . .
  (Optional) Specifies the user name(s) to add to the new role. The administrator must have the `solaris.role.assign` authorization.

  `-c` *comment*
  (Optional) Includes a short description of the role. Consists of a string of up to 256 printable characters, excluding the colon (`:`).

  `-d` *dir*
  (Optional) Specifies the home directory of the new role, limited to 1024 characters.

  `-F` *full_name*
  (Optional) Specifies the full, descriptive name of the role. The *full_name* must be unique within a domain, and can contain alphanumeric characters and spaces. If you use spaces, you must enclose the *full_name* in double quotes.

  `-G` *group1* `-G` *group2* . . .
  (Optional) Specifies the new role's supplementary group membership in the system group database with the character string names of one or more existing groups. *Note:* You cannot assign a primary group to a role. A role's primary group is always `sysadmin` (group 14).

  `-h`
  (Optional) Displays the command's usage statement.

  `-n` *rolename*
  Specifies the name of the role you want to create.

  `-p` *addprof1* `-p` *addprof2* . . .
  (Optional) Specifies the profile(s) to add to the role. To assign a profile to a role, the administrator must have the `solaris.profmgr.assign` or `solaris.profmgr.delegate` authorization.

  `-P` *password*
  (Optional) Specifies the role's password. The *password* can contain up to eight characters. If you do not specify a password, the system prompts you for one. To set the password, the administrator must have the `solaris.admin.usermgr.pswd` authorization. *Note:* When you specify a password using the `-P` option, you type the password in plain text. Specifying a password using this method introduces a security gap while the command is running. However, if you do not specify a password (and the system prompts you for one), the echo is turned off when you type in the password.

`-s` *shell*	(Optional) Specifies the full pathname of the program used as the role's shell on login. Valid entries are `/bin/pfcsh` (C shell), `/bin/pfksh` (Korn shell), and `/bin/pfsh` (Bourne shell), the default.
`-u` *uid*	(Optional) Specifies the ID of the role you want to add. If you do not specify this option, the system assigns the next available unique ID greater than 100.
`-x` *autohome*=Y|N	(Optional) Sets the role's home directory. The home directory path in the password entry is set to `/home/`*login name*.
`-x` perm=*home_perm*	(Optional) Sets the permissions on the role's home directory. *perm* is interpreted as an octal number, and the default is `0775`.
`-x` serv=*homedir_server*	(Optional) If `-D` is `nis`, `nisplus`, or `ldap`, use this option to specify the name of the server where the user's home directory resides. Users created in a local scope must have their home directory server created on their local machines.
`-M` *limit_privs*	Specifies the privilege name(s) to add to the new `user_attr(4)` entry. The default is `all` for *limit* privilege. To add or change privileges, the administrator must have the `solaris.admin.privilege.write` authorization. See `privileges(5)`.
`-D` *default_privs*	Specifies the default privilege name(s) to add to the new `user_attr(4)` entry.

The options to the `add` subcommand listed below are available only if a system is configured with Solaris Trusted Extensions. See "Using Options that Require Solaris Trusted Extensions," below.

`-x` clear=*clearanceval*	(Optional) Specifies the role's clearance. *clearanceval* can be a string value or a hex value. If this option is not specified, the default, `admin_high`, is in effect. To set the clearance, the administrator must have the `solaris.admin.usermgr.labels` authorization.
`-x` label=*labelval*	(Optional) Specifies the role's minimum label. *labelval* can be a string label or a

hex label. If this option is not specified, the default, `admin_low`, is in effect. To set the minimum label, the administrator must have the `solaris.admin.usermgr.labels` authorization.

`-x` labelview=HIDE|SHOW — (Optional) Specifies the second part of the `labelview` *key-value* pair. If `SHOW` is specified, `labelview=*showsl` will be recorded. If `HIDE` is specified, `labelview=*hidesl` will be recorded. The asterisk portion can be replaced by "`internal,`", "`external,`", or ""(null). If this option is not specified, the default, `SHOW`, is in effect.

`-x` view=INTERNAL|EXTERNAL|DEFAULT — (Optional) Specifies the label view type for the `labelview` in `user_attr`. If `INTERNAL` is specified, `labelview=internal` will be recorded; if `EXTERNAL` is specified, `labelview=external` will be recorded; if `DEFAULT` is specified, nothing will be recorded in `user_attr`. If this option is not specified, the default, `INTERNAL`, is in effect.

- For subcommand `delete`:

  `-h` — (Optional) Displays the command's usage statement.

  `-n` *rolename1* `-n` *rolename2* . . . — Specifies the name of the role(s) you want to delete.

- For subcommand `list`:

  `-h` — (Optional) Displays the command's usage statement.

  `-l` — (Optional) Displays the output for each user in a block of *key*:*value* pairs (for example, `user name:root`), followed by a blank line that delimits each user block. Each *key*:*value* pair is displayed on a separate line. The keys are: `autohome setup`, `comment`, `home directory`, `login shell`, `primary group`, `secondary groups`, `server`, `user ID (UID)`, and `user name`.

  `-n` *role1* `-n` *role2* . . . — (Optional) Specifies the role(s) that you want to list. If you do not specify a role name, all roles are listed.

- For subcommand `modify`:

`-a` *adduser1* `-a` *adduser2* . . .	(Optional) Specifies the user name(s) to add to the new role. The administrator must have the `solaris.role.assign` authorization, or must have the `solaris.role.delegate` authorization and be a member of the role being modified.
`-c` *comment*	(Optional) Includes a short description of the role. Consists of a string of up to 256 printable characters, excluding the colon (`:`).
`-d` *dir*	(Optional) Specifies the home directory of the new role, limited to 1024 characters.
`-F` *full_name*	(Optional) Specifies the full, descriptive name of the role. The *full_name* must be unique within a domain, and can contain alphanumeric characters and spaces. If you use spaces, you must enclose the *full_name* in double quotes.
`-G` *group1* `-G` *group2* . . .	(Optional) Specifies the new role's secondary group membership in the system group database with the character string names of one or more existing groups. *Note:* You cannot assign a primary group to a role. A role's primary group is always `sysadmin` (group 14).
`-h`	(Optional) Displays the command's usage statement.
`-n` *rolename*	Specifies the name of the role you want to modify.
`-N` *new_rolename*	(Optional) Specifies the new name of the role.
`-p` *addprof1* `-p` *addprof2* . . .	(Optional) Specifies the profile(s) to add to the role. To assign a profile to a role, the administrator must have the `solaris.profmgr.assign` or `solaris.profmgr.delegate` authorization.
`-P` *password*	(Optional) Specifies the role's password. The *password* can contain up to eight characters. To set the password, the administrator must have the `solaris.admin.usermgr.pswd` authorization. *Note:* When you specify a password, you type the password in plain text. Specifying a password using this method introduces a security gap while the command is running.
`-q` *delprof1* `-q` *delprof2* . . .	(Optional) Specifies the profile(s) to delete from the role.
`-r` *deluser1* `-r` *deluser2* . . .	(Optional) Specifies the user name(s) to delete from the role.

`-s` *shell*	(Optional) Specifies the full pathname of the program used as the role's shell on login. Valid entries are `/bin/pfcsh` (C shell), `/bin/pfksh` (Korn shell), and `/bin/pfsh` (Bourne shell), the default.
`-x` *autohome*=Y|N	(Optional) Sets the role's home directory. The home directory path in the password entry is set to `/home/`*login_name*.
`-x` *perm=home_perm*	(Optional) Sets the permissions on the role's home directory. *perm* is interpreted as an octal number, and the default is 0775.
`-M` *limit_privs*	Specifies the privilege name(s) to modify in a `user_attr(4)` entry. To add or change privileges, the administrator must have the `solaris.admin.privilege.write` authorization. See `privileges(5)`.
`-D` *default_privs*	Specifies the default privilege name(s) to modify in a `user_attr(4)` entry.

The options to the `modify` subcommand listed below are available only if a system is configured with Solaris Trusted Extensions. See "Using Options that Require Solaris Trusted Extensions," below.

`-x` clear=*clearanceval*	(Optional) Specifies the role's clearance. *clearanceval* can be a string value or a hex value. If this option is not specified, the default, `admin_high`, is in effect. To set the clearance, the administrator must have the `solaris.admin.usermgr.labels` authorization.
`-x` label=*labelval*	(Optional) Specifies the role's minimum label. *labelval* can be a string label or a hex label. If this option is not specified, the default, `admin_low`, is in effect. To set the minimum label, the administrator must have the `solaris.admin.usermgr.labels` authorization.
`-x` labelview=HIDE|SHOW	(Optional) Specifies the second part of the `labelview` *key-value* pair. If `SHOW` is

specified, `labelview=*showsl` will be recorded. If `HIDE` is specified, `labelview=*hidesl` will be recorded. The asterisk portion can be replaced by "`internal,`", "`external,`", or ""(null). If this option is not specified, the default, `SHOW`, is in effect.

`-x view=INTERNAL|EXTERNAL|DEFAULT` — (Optional) Specifies the label view type for the `labelview` in `user_attr`. If `INTERNAL` is specified, `labelview=internal` will be recorded; if `EXTERNAL` is specified, `labelview=external` will be recorded; if `DEFAULT` is specified, nothing will be recorded in `user_attr`. If this option is not specified, the default, `INTERNAL`, is in effect.

Using Options that Require Solaris Trusted Extensions

To use an option that requires the Solaris Trusted Extensions feature, you must use the `-B` *toolbox* option to specify a toolbox that contains support for Trusted Extensions. For example:

```
# smrole add -H myhost -p mypasswd -u root -- -n role1 \
-F "Engineering Admin" -P abc123 -x clear=clearanceval \
-B http://<server>/toolboxes/tsol_files.tbx
```

In the command above, <*server*> is the name of the machine running the Solaris Management Console. See `smc(1M)` for a description of the `-B` option.

Examples

EXAMPLE 1 Creating a Role Account

The following creates the `role1` account with a full name of `Engineering Admin` and a password of `abc123` on the local file system, and assigns `user1` and `user2` to the role. This role has `Name Service Security` and `Audit Review` rights. The system assigns the next available unique UID greater than 100.

```
./smrole add -H myhost -p mypasswd -u root -- -n role1 \
          -F "Engineering Admin" -P abc123 -a user1 -a user2 \
          -p "Name Service Security" -p "Audit Review"
```

EXAMPLE 2 Deleting Role Accounts

The following deletes the `role1` and `role2` accounts from the local file system.

```
./smrole delete -H myhost -p mypasswd -u root -- -n role1 -n role2
```

EXAMPLE 3 Listing Role Accounts

The following lists all role accounts on the local file system in summary form.

```
./smrole list -H myhost -p mypasswd -u root --
```

EXAMPLE 4 Modifying a Role Account

The following modifies the `role1` account so the role defaults to the Korn shell, includes the `user3` account, and does not include the `user2` account.

```
./smrole modify -H myhost -p mypasswd -u root -- -n role1 \
          -s /bin/pfksh  -a user3 -r user2
```

Environment Variables

See `environ(5)` for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smrole` command. If this environment variable is not specified, the `/usr/java` location is used. See `smc(1M)`.

Exit Status

The following exit values are returned:

`0` Successful completion.

`1` Invalid command syntax. A usage message displays.

`2` An error occurred while executing the command. An error message displays.

Files

The following files are used by the `smrole` command:

`/etc/aliases`	Mail aliases. See `aliases(4)`.
`/etc/auto_home`	Automatic mount points. See `automount(1M)`.
`/etc/group`	Group file. See `group(4)`.
`/etc/passwd`	Password file. See `passwd(4)`.
`/etc/security/policy.conf`	Configuration file for security policy. See `policy.conf(4)`.
`/etc/shadow`	Shadow password file. See `shadow(4)`.
`/etc/user_attr`	Extended user attribute database. See `user_attr(4)`.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga
Interface Stability	Evolving

Name smrsh – restricted shell for sendmail

Synopsis `smrsh -c` *command*

Description The `smrsh` program is intended as a replacement for the `sh` command in the `prog` mailer in `sendmail(1M)` configuration files. The `smrsh` program sharply limits commands that can be run using the `|program` syntax of `sendmail`. This improves overall system security. `smrsh` limits the set of programs that a programmer can execute, even if `sendmail` runs a program without going through an `alias` or `forward` file.

Briefly, `smrsh` limits programs to be in the directory `/var/adm/sm.bin`, allowing system administrators to choose the set of acceptable commands. It also rejects any commands with the characters: `,`, `<`, `>`, `|`, `;`, `&`, `$`, `\r` (RETURN), or `\n` (NEWLINE) on the command line to prevent end run attacks.

Initial pathnames on programs are stripped, so forwarding to `/usr/ucb/vacation`, `/usr/bin/vacation`, `/home/server/mydir/bin/vacation`, and `vacation` all actually forward to`/var/adm/sm.bin/vacation`.

System administrators should be conservative about populating `/var/adm/sm.bin`. Reasonable additions are utilities such as `vacation(1)` and `procmail`. Never include any shell or shell-like program (for example, `perl`) in the `sm.bin` directory. This does not restrict the use of `shell` or `perl` scrips in the `sm.bin` directory (using the `#!` syntax); it simply disallows the execution of arbitrary programs.

Options The following options are supported:

`-c` *command* Where *command* is a valid command, executes *command*.

Files `/var/adm/sm.bin` directory for restricted programs

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

See Also `sendmail(1M)`, , `attributes(5)`

Name smserialport – manage serial port

Synopsis

```
/usr/sadm/bin/smserialport subcommand [auth_args] --
    [subcommand_args]
```

Description The `smserialport` command manages serial ports.

Sub-commands The following `smserialport` sub-commands (*subcommand*) are supported:

configure — Configures a serial port's basic settings for a device such as a terminal, modem or no connection.

delete — Deletes a given port. You can disable a port and prevent new services from being spawned for incoming connections, without interfering with existing services.

list — Lists all serial ports.

modify — Modifies a serial port's parameters.

Options There are two kinds of options: authentication arguments (*args*) and sub-command arguments (*subcommand_args*).

Authentication Arguments The `smserialport` authentication arguments, *args*, are derived from the `smc(1M)` argument set and are the same regardless of which sub-command you use.

Valid *args* are `-D`, `-H`, `-l`, `-p`, `-r`, and `-u`; they are all optional. If no *args* are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes.

The single letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `--domain`.

Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

The following authentification arguments (*args*) are supported:

`-D` | `--domain` *domain* — Specifies the default domain that you want to manage. `smserialport` accepts only the *file* value for this option. *file* is also the default value.

The *file* default domain means that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the *domain* for all other tools.

`-H` | `--hostname` *host_name*:*port* — Specifies the host and port to which you want to connect. If you do not specify a port, the system connects to the default port, `898`. If you do not specify

a host (*host_name*:*port*, the Solaris Management Console connects to the local host on port `898`. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc -B` option, or set your console preferences to load a `home toolbox` by default.

`-l` | `--rolepassword` *role_password*
: Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-p` | `--password` *password*
: Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Because passwords specified on the command line can be seen by any user on the system, this option is considered insecure.

`-r` | `--rolename` *role_name*
: Specifies a role name for authentication. If you do not specify this option, no role is assumed.

`-u` | `--username` *user_name*
: Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

`--`
: This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `--` option.

Sub-command Arguments

The sub-command specific options, *subcommand_args*, must come after the *args* and must be separated from them by the `--` option. Enclose descriptions and *arg* options that contain white space in double quotes.

configure
: The `configure` sub-command requires the following sub-command argument:

  `-n` *port_name*
  : Specifies the name of the serial port to reconfigure.

  The following sub-command arguments are optional for the `configure` sub-command:

  `-b` *baudrate*
  : Specifies the port baud rate. The supported baud rate are `38400`, `19200`, `9600`, `4800`, `2400`, `1200`, `300` and `auto`. The default is `9600`.

	`-c` *comment*	Specifies a short comment description of the service. The default is a description of the requested device type.
	`-h`	Displays the command's usage statement.
	`-l` *login_prompt*	Specifies the login prompt. The default is *tty*`'`*port_name*`'` `login:`.
	`-t` *terminal_type*	Specifies the terminal type. The default is `tvi925`.
	`-x` device=*device_name*	Specifies the device to be configured. Valid device_names are: `terminal`, `modemdialin`, `modemdialout`, `modemdialinout` or `initializeonly` for no connection. The default is `terminal`.
	`-x` service=y | n	Specifies the status of service, that is `y` for enabled or `n` for disabled. The default is `y`.

delete — The `delete` sub-command requires the following sub-command arguments:

`-n` *port_name* Specifies the name of the serial port to be disabled.

The following sub-command arguments are optional for the `delete` sub-command:

`-h` Displays the command's usage statement.

list — The `list` sub-command does not require any sub-command arguments.

The following sub-command arguments are optional for the `list` sub-command:

`-h` Displays the command's usage statement.

`-v` Displays the data in verbose format.

modify — The `modify` sub-command requires the following sub-command arguments:

`-n` *port_name* Specifies the name of the serial port to modify.

The following sub-command arguments are optional for the `modify` sub-command:

`-b` *baudrate*	Specifies the port baud rate. The supported baud rate are `38400`, `19200`, `9600`, `4800`, `2400`, `1200`, `300` and `auto`.
`-c` *comment*	A short comment description of the service.
`-h`	Displays the command usage statement.

-l *login_prompt*	Specifies the login prompt.
-t *terminal_type*	Specifies the terminal type.
-x bidirectional=y | n	Specifies the bi-directional port flag, y for set or n for not set. When this flag is set, the line can be used in both directions.
-x connect_on_carrier=y | n	Specifies if to connect on carrier, that is y or n.
-x initialize_only=y | n	Specifies if the service invocation. If y the service is invoked only once. This can be used to configure a particular device without actually monitoring it, as with software carrier.
-x service_program=*command*	Specifies the full pathname of the service command to invoke when a connection request is received.
-x service_status=y | n	Specifies the status of service, that is y for enabled or n for disabled.
-x software_carrier=y | n	Specifies the carrier detection. y for software or n for hardware.
-x timeout=*timeout*	Specifies the time to close a port if the open on the port succeeds, and no input data is received in timeout seconds. The supported *timeout* are never, 30, 60 and 90.

Examples

EXAMPLE 1 Listing Serial Ports

The following example lists the serial ports:

```
example% ./smserialport list -H myhost -u root -p mypassword --

Port Service  Baud-Rate Terminal-Type Prompt       Comment
a    enabled  9600      xterm         as           welcome
b    enabled  9600      tvi925        ttyb login:
```

EXAMPLE 2 Modifying Serial Ports

The following example contains two commands. The first command modifies serial port b for a baud rate of 4800, an xterm as terminal type, a b: for login prompt and a comment. The second command lists the ports.

```
example% ./smserialport modify -H myhost -u root -p mypassword -- \
     -n b -b 4800 -t xterm -l b: -c "modified port b"
```

EXAMPLE 2 Modifying Serial Ports *(Continued)*

```
example% ./smserialport list -H myhost -u root -p mypassword --

Port Service  Baud-Rate Terminal-Type Prompt      Comment
a    enabled  9600      xterm         as          welcome
b    enabled  4800      xterm         b:          modified port b
```

EXAMPLE 3 Deleting a Serial Port

The following example contains two commands. The first command deletes serial port b. The second command lists the ports.

```
example% ./smserialport delete -H myhost -u root \
     -p mypassword -- -n b

example% ./smserialport list -H myhost -u root -p mypassword --

Port Service  Baud-Rate Terminal-Type Prompt      Comment
a    enabled  9600      xterm         as          welcome
b    disabled 9600      tvi925        ttyb login:
```

EXAMPLE 4 Configuring a Serial Port

The following example contains two commands. The first command configures serial port b for a bi-directional modem. The second command lists the ports.

```
example% ./smserialport configure -H myhost -u root  \
     -p mypassword -- -n b -x device=modemdialinout

example% ./smserialport list -H myhost -u root -p mypassword --
Port Service  Baud-Rate Terminal-Type Prompt      Comment
a    enabled  9600      xterm         as          welcome
b    enabled  9600      tvi925        ttyb login: Modem - Dial In and Out
```

Environment Variables

See environ(5) for descriptions of the following environment variables that affect the execution of smserialport: JAVA_HOME. If this environment variable is not specified, the /usr/java location is used. See smc(1M).

Exit Status

The following exit values are returned:

0 Successful completion.

1 Invalid command syntax. A usage message displays.

2 An error occurred while executing the command. An error message displays.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga

See Also tip(1), pmadm(1M), sacadm(1M), smc(1M), ttyadm(1M), ttymon(1M), attributes(5), environ(5)

Name smtnrhdb – manage entries in the tnrhdb database

Synopsis `/usr/sadm/bin/smtnrhdb` *subcommand* `[`*auth_args*`] -- `*subcommand_args*`]`

Description The `smtnrhdb` command adds, modifies, deletes, and lists entries in the `tnrhdb` database.

The `tnrhdb` database specifies which remote-host template to use for each host, including the local host, in the distributed system. If a host's IP address cannot be matched to some entry in the `tnrhdb` database, communication with the host is not permitted.

The `smtnrhdb` command requires the Solaris Management Console to be initialized for the command to succeed (see `smc(1M)`). After rebooting the Solaris Management Console server, the first `smc` connection can time out, so you might need to retry the command.

Valid Host Addresses and Wildcards

The trusted network software uses a network "longest prefix of matching bits" mechanism when looking for a host. The software looks first for the IP address of the host. If the software does not find this address, then the software falls back to searching for an IP address with the longest prefix of a matching bit pattern, and so on.

Note – The actual numeric value of the subnet address or other subnetting information on the system (for example, from the `netmasks(4)` file) are not considered by this mechanism.

Using the "longest prefix of matching bits" mechanism, an IPv4 address of 0.0.0.0 is a wildcard address with a prefix length of 0 and hence matches any IPv4 address. For more information about prefi x lengths in IPv4 and IPv6 addresses, see *System Administration Guide: IP Services*.

The `smtnrhdb` command accepts a hostname, IP address, and wildcard address with as optional prefix as valid addresses. See *subcommand_args*, below, for the format of valid addresses.

Sub-commands `smtnrhdb` *subcommand*s are:

`add`
Adds a new entry to the `tnrhdb` database. To add an entry, the administrator must have the `solaris.network.host.write` and `solaris.network.security.write` authorizations.

`delete`
Deletes an entry from the `tnrhdb` database. To delete an entry, the administrator must have the `solaris.network.host.write` and `solaris.network.security.write` authorizations.

`list`
Lists all entries in the `tnrhdb` database. To list an entry, the administrator must have the `solaris.network.host.read` and `solaris.network.security.read` authorizations.

`modify`
Modifies an entry in the `tnrhdb` database. To modify an entry, the administrator must have the `solaris.network.host.write` and `solaris.network.security.write` authorizations.

Options The `smtnrhdb` authentication arguments, *auth_args*, are derived from the `smc` arg set. These arguments are the same regardless of which subcommand you use.

The subcommand-specific options, *subcommand_args*, must be preceded by the `--` option.

auth_args The valid *auth_args* are `-D`, `-H`, `-l`, `-p`, `-r`, and `-u`; they are all optional. If no *auth_args* are specified, certain defaults will be assumed and the user might be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `--domain`.

`-D` | `--domain` *domain*
Specifies the default domain that you want to manage. The syntax of *domain=type:/host_name/domain_name*, where *type* is `dns`, `ldap`, or `file`; *host_name* is the name of the server; and *domain_name* is the name of the domain you want to manage.

If you do not specify this option, the Solaris Management Console assumes the `file` default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

`-H` | `--hostname` *host_name:port*
Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, `898`. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port `898`.

`-l` | `--rolepassword` *role_password*
Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-p` | `--password` *password*
Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-r` | `--rolename` *role_name*
Specifies a role name for authentication. If you do not specify this option, no role is assumed.

`-u` | `--username` *user_name*
Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

`--`
This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `--` option.

subcommand_args *Note:* Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

`-h`
Displays the command's usage statement.

`-H` *hostname*
Specifies the name of the host. For the list subcommand, the hostname argument is not specified. This is not required if the ipaddress subcommand argument is specified.

`-i` *ipaddress*
Specifies the IP address of the host. This is not required if the hostname subcommand argument is specified. This option is not valid with the `-w` option.

`-n` *templatename*
Specifies the name of an existing template.

`-p` *prefixlen*
Specifies the prefix length (in bits) of a wildcard representation of the IP address. The prefix is the left-most portion of the IP address. This option is valid only with the `-w` option. For example, when the value of `-w` *ipaddress-wildcard* is 192.168.0.0, a *prefixlen* value of 24 indicates that the wildcard matches all addresses on the 192.168.0 network. With a *prefixlen* of 32, the wildcard 192.168.0.0 matches all addresses on the 192.168.0.0 network.

`-w` *ipaddress-wildcard*
Specifies the IP address of the subnet using a wildcard.

- One of the following sets of arguments must be specified for subcommand `add`:

  `-H` *hostname* `-n` *templatename* `|`
  `-i` *ipaddress* `-n` *templatename* `|`
  `-w` *ipaddress-wildcard* `-n` *templatename* `[ -p` *prefixlen* `] |`
  `-h`

- One of the following sets of arguments must be specified for subcommand `modify`:

  `-H` *hostname* `-n` *templatename* `|`
  `-i` *ipaddress* `-n` *templatename* `|`
  `-w` *ipaddress-wildcard* `-n` *templatename* `[ -p` *prefixlen* `] |`
  `-h`

- One of the following sets of arguments must be specified for subcommand `delete`:

  `-H` *hostname* `|`
  `-i` *ipaddress* `|`
  `-w` *ipaddress-wildcard* `[ -p` *prefixlen* `] |`
  `-h`

- The subcommand `list` takes the following argument:

  `-h`

Examples

EXAMPLE 1 Specifying the Template Name for a Wildcard IP Address

The admin role specifies the template name, `cipso_lan`, for a series of hosts that use the IP address wildcard `192.168.113.0` on the local file system. Since no authorization arguments were specified, the administrator connects to port 898 of the local host on the local server with the file domain type, which are the defaults. The administrator is prompted for the admin password.

```
$ usr/sadm/bin/smtnrhdb add -- -w 192.168.113.0 -n cipso_lan
```

EXAMPLE 2 Deleting an Entry in the `tnrhdb` Database

The admin role connects to port 898 (which happens to be the default) of the LDAP server and deletes a host entry from the database by specifying its IP address, `192.168.113.8`. Since the domain was not specified, the file domain type and local server are used by default. The administrator is prompted for the admin password.

```
# /usr/sadm/bin/smtnrhdb delete \
-D ldap:/example.domain -i 192.168.113.8
```

EXAMPLE 3 Adding a Subnet to the `tnrhdb` Database

The following command adds all the addresses on the 192.168.55.0 subnet, from 192.168.55.1 to 192.168.55.255, to the `tnrhdb` database:

```
# /usr/sadm/bin/smtnrhdb add \
-D file:/machine1.ExampleCo.COM/machine1.ExampleCo.COM \
 -- -w 192.168.55.0 -n cipso
Authenticating as user: root
Type /? for help, pressing <enter> accepts the default denoted by [ ]
Please enter a string value for: password ::
Loading Tool: com.exampleco.admin.hostmgr.cli.smtnrhdb.HostMgrTnrhdbCli
from machine1.ExampleCo.COM
Login to machine1.ExampleCo.COM as user root was successful.
Download of com.exampleco.admin.hostmgr.cli.smtnrhdb.HostMgrTnrhdbCli
from machine1.ExampleCo.COM
was successful.
```

EXAMPLE 4 Adding Subnet 192.168.0 to the `tnrhdb` Database

The following command adds all the addresses on the 192.168.0 subnet, from 192.168.0.1 to 192.168.0.255 to the `tnrhdb` database. The prefix, 24, indicates that the first 24 bits (192.168.0) are fixed. Only the final zero is a wildcard.

```
# /usr/sadm/bin/smtnrhdb add \
-D file:/machine1.ExampleCo.COM/machine1.ExampleCo.COM \
 -- -w 192.168.0.0 -p 24 -n cipso

Login to machine1.ExampleCo.COM as user root was successful.
Download of com.exampleco.admin.hostmgr.cli.smtnrhdb.HostMgrTnrhdbCli
from machine1.ExampleCo.COM was successful.
```

Exit Status The following exit values are returned:

`0`
Successful completion.

`1`
Invalid command syntax. A usage message displays.

`2`
An error occurred while executing the command. An error message displays.

Files The following files are used by the `smtnrhdb` command:

`/etc/security/tsol/tnrhdb`
Trusted network remote-host database.

System Administration Guide: Security Services

Notes The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

Name smtnrhtp – manage entries in the trusted network template database

Synopsis `/usr/sadm/bin/smtnrhtp` *subcommand* [*auth_args*] -- [*subcommand_args*]

Description The `smtnrhtp` command adds, modifies, deletes, and lists entries in the `tnrhtp` database.

`smtnrhtp` *subcommand*s are:

`add` Adds a new entry to the `tnrhtp` database. To add an entry, the administrator must have the `solaris.network.security.read` and `solaris.network.security.write` authorizations.

`modify` Modifies an entry in the `tnrhtp` database. To modify an entry, the administrator must have the `solaris.network.security.read` and `solaris.network.security.write` authorizations.

`delete` Deletes an entry from `tnrhtp` database. To delete an entry, the administrator must have the `solaris.network.security.read` and `solaris.network.security.write` authorizations.

`list` Lists entries in the `tnrhtp` database. To list an entry, the administrator must have the `solaris.network.security.read` authorizations.

Options The `smtnrhtp` authentication arguments, *auth_args*, are derived from the `smc` argument set and are the same regardless of which subcommand you use. The `smtnrhtp` command requires the Solaris Management Console to be initialized for the command to succeed (see `smc(1M)`). After rebooting the Solaris Management Console server, the first smc connection can time out, so you might need to retry the command.

The subcommand-specific options, *subcommand_args*, must be *preceded* by the `--` option.

auth_args The valid *auth_args* are `-D`, `-H`, `-l`, `-p`, `-r`, and `-u`; they are all optional. If no *auth_args* are specified, certain defaults will be assumed and the user might be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `--domain`.

`-D` | `--domain` *domain*
Specifies the default domain that you want to manage. The syntax of *domain=type:/host_name/domain_name*, where *type* is `dns`, `ldap`, or `file`; *host_name* is the name of the server; and *domain_name* is the name of the domain you want to manage.

If you do not specify this option, the Solaris Management Console assumes the `file` default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

`-H` | `--hostname` *host_name:port*
Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, `898`. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port `898`.

`-l` | `--rolepassword` *role_password*
Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-p` | `--password` *password*
Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-r` | `--rolename` *role_name*
Specifies a role name for authentication. If you do not specify this option, no role is assumed.

`-u` | `--username` *user_name*
Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

`--`
This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `--` option.

subcommand_args Descriptions and other argument options that contain white spaces must be enclosed in double quotes.

`-h`	Displays the command's usage statement.
`-n` *templatename*	Specifies the name of the template.
`-t` *hosttype*	Specifies the host type of the new host. Valid values are `unlabeled` and `cipso`. The `cipso` host type is for hosts that use CIPSO (Common IP Security Options - Tag Type 1 only) to label packets.
`-x doi=`*doi-value*	Specifies the DOI value (the domain of interpretation). In the case of the `unlabeled` host type, this is the domain of interpretation for the `def_label`. The domain of interpretation defines the set of rules for translating between the external or internal representation of the security attributes and their network representation. When systems that are configured with Trusted Extensions software have the same `doi`, they share that set of rules. In the case of the `unlabeled` host type, these systems also share the same

interpretation for the default attributes that are assigned to the unlabeled templates that have that same `doi`.

`-x max=`*maximum-label* — Specifies the maximum label. Together with `min`, this value specifies the label accreditation range for the remote hosts that use this template. Values can be a hex value or string (such as `admin_high`).

`-x min=`*minimum-label* — Specifies the minimum label. Together with `max`, this value specifies the label accreditation range for the remote hosts that use this template. For gateway systems, `min` and `max` define the default range for forwarding labeled packets. The label range for routes is typically set by using a `route`(1M) subcommand with the `-secattr` option. When the label range for routes is not specified, the `min` to `max` range in the security template is used. Values can be a hex value or string (such as `admin_low`).

`-x label=`*default-label* — Specifies the default label to be applied to incoming data from remote hosts that do not support these attributes. This option does not apply if *hosttype* is `cipso`. Values can be a hex value or string (such as `admin_low`).

`-x slset=`*l1*,*l2*,*l3*,*l4* — Specifies a set of sensitivity labels. For gateway systems, the labels in `slset` are used for forwarding labeled packets. `slset` is optional. You can specify up to four label values, separated by commas. Values can be a hex value or string (such as `admin_low`).

- One of the following sets of arguments must be specified for subcommand `add`:

  `-n` *template name* (

  `-t cipso` [`-x doi=`*doi-value* `-x min=`*minimum-label* `-x max=`*maximum-label* `-x slset=`*l1*,*l2*,*l3*,*l4*] |

  `-t` unlabeled [`-x doi=`*doi-value* `-x min=`*minimum-label* `-x max=`*maximum-label* `-x label=`*default-label* `-x slset=`*l1*,*l2*,*l3*,*l4*] |

  `-h`

)

- One of the following sets of arguments must be specified for subcommand `modify`:

  `-n` *template name* (

  `-t cipso` [`-x doi=`*doi-value* `-x min=`*minimum-label* `-x max=`*maximum-label* `-x slset=`*l1*,*l2*,*l3*,*l4*] |

  `-t` unlabeled [`-x doi=`*doi-value* `-x min=`*minimum-label* `-x max=`*maximum-label* `-x label=`*default-label*`-x slset=`*l1*,*l2*,*l3*,*l4*] |

  `-h`

)

If the host type is changed, all options for the new host type must be specified.

- One of the following sets of arguments must be specified for subcommand `delete`:

  `-n` *templatename* |
  `-h`

- The following argument can be specified for subcommand `list`:

  `-n` *templatename* |
  `-h`

Examples

EXAMPLE 1 Adding a New Entry to the Network Template Database

The admin role connects to port `898` of the LDAP server and creates the `unlabeled_ntk` entry in the `tnrhtp` database. The new template is assigned a host type of `unlabeled`, a domain of interpretation of `1`, minimum label of `public`, maximum label of `restricted`, and a default label of `needtoknow`. The administrator is prompted for the admin password.

```
$ /usr/sadm/bin/smtnrhtp \
add -D ldap:directoryname -H servername:898 -- \
-n unlabeled_ntk -t unlabeled -x DOI=1 \
-x min=public -x max=restricted -x label="need to know"
```

Exit Status

The following exit values are returned:

`0` Successful completion.

`1` Invalid command syntax. A usage message displays.

`2` An error occurred while executing the command. An error message displays.

Files

The following files are used by the `smtnrhtp` command:

`/etc/security/tsol/tnrhtp` Trusted network remote-host templates.

Notes

The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

Warnings Changing a template while the network is up can change the security view of an undetermined number of hosts.

Allowing unlabeled hosts onto a Solaris Trusted Extensions network is a security risk. To avoid compromising the rest of your network, such hosts must be *trusted* in the sense that the administrator is certain that these unlabeled hosts will not be used to compromise the distributed system. These hosts should also be physically protected to restrict access to authorized individuals. If you cannot guarantee that an unlabeled host is physically secure from tampering, it and similar hosts should be isolated on a separate branch of the network.

If the security template is modified while the network is up, the changes do not take effect immediately unless `tnctl(1M)` is used to update the template entries. Otherwise, the changes take effect when next polled by the trusted network daemon, `tnd(1M)`. Administrators are allowed to add new templates and modify attributes of existing templates while the network is up.

Name smtnzonecfg – manage entries in the zone configuration database for Trusted Extensions networking

Synopsis `/usr/sadm/bin/smtnzonecfg` *subcommand* [*auth_args*] `--` [*subcommand_args*]

Description The `smtnzonecfg` command adds, modifies, deletes, and lists entries in the `tnzonecfg` database.

`smtnzonecfg` *subcommand*s are:

`add` Adds a new entry to the `tnzonecfg` database. To add an entry, the administrator must have the `solaris.network.host.write` and `solaris.network.security.write` authorizations.

`modify` Modifies an entry in the `tnzonecfg` database. To modify an entry, the administrator must have the `solaris.network.host.write` and `solaris.network.security.write` authorizations.

`delete` Deletes an entry from the `tnzonecfg` database. To delete an entry, the administrator must have the `solaris.network.host.write` and `solaris.network.security.write` authorizations.

`list` Lists entries in the `tnzonecfg` database. To list an entry, the administrator must have the `solaris.network.host.read` and `solaris.network.security.read` authorizations.

Options The `smtnzonecfg` authentication arguments, *auth_args*, are derived from the `smc` argument set and are the same regardless of which subcommand you use. The `smtnzonecfg` command requires the Solaris Management Console to be initialized for the command to succeed (see `smc`(1M)). After rebooting the Solaris Management Console server, the first smc connection can time out, so you might need to retry the command.

The subcommand-specific options, *subcommand_args*, must be *preceded* by the `--` option.

auth_args The valid *auth_args* are `-D`, `-H`, `-l`, `-p`, `-r`, and `-u`; they are all optional. If no *auth_args* are specified, certain defaults will be assumed and the user can be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `--domain`.

`-D` | `--domain` *domain*
Specifies the default domain that you want to manage. The syntax of *domain=type:/host_name/domain_name*, where *type* is `dns`, `ldap`, or `file`; *host_name* is the name of the server; and *domain_name* is the name of the domain you want to manage.

If you do not specify this option, the Solaris Management Console assumes the `file` default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis. This option specifies the domain for all other tools.

`-H` | `--hostname` *host_name:port*
Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, `898`. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port `898`.

`-l` | `--rolepassword` *role_password*
Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-p` | `--password` *password*
Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

`-r` | `--rolename` *role_name*
Specifies a role name for authentication. If you do not specify this option, no role is assumed.

`-u` | `--username` *user_name*
Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

`--`
This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `--` option.

subcommand_args Descriptions and other argument options that contain white spaces must be enclosed in double quotes.

`-h`
Displays the command's usage statement.

`-n` *zonename*
Specifies the zone name for the entry. This name is used when the zone is configured. See `zonecfg(1M)`, under the `-z zonename` option, for the constraints on zone names. The specified zone name must be one of the configured zones on the system. The following command returns a list of configured zones:

```
/usr/sbin/zoneadm list -c
```

`-l` *label*
Specifies the label for the zone. This field is used to label the zone when the zone is booted. Each zone must have a unique label.

`-x policymatch=0|1`
Specifies the policy match level for non-transport traffic. Only values of `0` (match the label) or `1` (be within the label range of the zone) are accepted.

ICMP packets that are received on the global zone IP address are accepted based on the label range of the global zone's security template if the global zone's *policymatch* field is set to 1. When this field is set to 0 for a zone, the zone will not respond to an ICMP echo request from a host with a different label.

This subcommand argument is optional. If not specified, it will have a default value of 0.

`-x mlpzone=“”|`*port/protocol*
Specifies the multilevel port configuration entry for zone-specific IP addresses. Multiple *port/protocol* combinations are separated by a semi-colon. The empty string can be specified to remove all existing MLP zone values. This subcommand argument is optional.

An MLP is used to provide multilevel service in the global zone as well as in non-global zones. As an example of how a non-global zone can use an MLP, consider setting up two labeled zones, `internal` and `public`. The `internal` zone can access company networks; the `public` zone can access public internet but not the company's internal networks. For safe browsing, when a user in the `internal` zone wants to browse the Internet, the `internal` zone browser forwards the URL to the `public` zone, and the web content is then displayed in a `public` zone web browser. That way, if the download in `public` zone compromises the web browser, it cannot affect the company's internal network. To set this up, TCP port `8080` in the `public` zone is an MLP (`8080/tcp`), and the security template for the `public` zone has a label range from `PUBLIC` to `INTERNAL`.

`-x mlpshared=“”|`*port/protocol*
Specifies the multilevel port configuration entry for shared IP addresses. Multiple *port/protocol* combinations are separated by a semi-colon. The empty string can be specified to remove all existing MLP shared values. This subcommand argument is optional.

A shared IP address can reduce the total number of IP addresses that are needed on the system, especially when configuring a large number of zones. Unlike the case of the zone-specific IP address, when MLPs are declared on shared IP addresses, only the global zone can receive the incoming network traffic that is destined for the MLP.

- One of the following sets of arguments must be specified for subcommand `add`:

```
-n zonename -l label [-x policymatch=policy-match-level \
-x mlpzone=port/protocol;.... | \
-x mlpshared=port/protocol;.... ]
-h
```

- One of the following sets of arguments must be specified for subcommand `modify`:

```
-n zonename [-l label] [-x policymatch=policy-match-level \
-x mlpzone=port/protocol;.... |\
-x mlpshared=port/protocol;.... ]
-h
```

- One of the following arguments must be specified for subcommand `delete`:

```
-n zonename |
-h
```

- The following argument can be specified for subcommand `list`:

```
-n zonename |
-h
```

Examples

EXAMPLE 1 Adding a New Entry to the Zone Configuration Database

The admin role creates a new zone entry, `public`, with a label of `public`, a policy match level of 1, and a shared MLP port and protocol of 666 and TCP. The administrator is prompted for the admin password.

```
$ /usr/sadm/bin/smtnzonecfg add -- -n public -l public \
-x policymatch=1 -x mlpshared=666/tcp
```

EXAMPLE 2 Modifying an Entry in the Zone Configuration Database

The admin role changes the `public` entry in the `tnzonecfg` database to `needtoknow`. The administrator is prompted for the admin password.

```
$ /usr/sadm/bin/smtnzonecfg modify -- -n public -l needtoknow
```

EXAMPLE 3 Listing the Zone Configuration Database

The admin role lists the entries in the `tnzonecfg` database. The administrator is prompted for the admin password.

```
$ /usr/sadm/bin/smtnzonecfg list --
```

Exit Status

The following exit values are returned:

`0` Successful completion.

1 Invalid command syntax. A usage message displays.

2 An error occurred while executing the command. An error message displays.

Files

The following files are used by the `smtnzonecfg` command:

`/etc/security/tsol/tnzonecfg` Trusted zone configuration database.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Notes The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

Name smuser – manage user entries

Synopsis

```
/usr/sadm/bin/smuser subcommand [ auth_args] - —
     [subcommand_args]
```

Description The `smuser` command manages one or more user entries in the local `/etc` filesystem or a NIS or NIS+ target name service.

subcommands `smuser` *subcommand*s are:

`add` Adds a new user entry to the appropriate files. You can use a template and input file instead of supplying the additional command line options. If you use a template and command line options, the command line options take precedence and override any conflicting template values. To add an entry, the administrator must have the `solaris.admin.usermgr.write` authorization.

`delete` Deletes one or more user entries from the appropriate files. To delete an entry, the administrator must have the `solaris.admin.usermgr.write` authorization. *Note:* You cannot delete the system accounts with IDs less than 100, or 60001, 60002, or 65534.

`list` Lists one more user entries from the appropriate files. To list entries, the administrator must have the `solaris.admin.usermgr.read` authorization.

`modify` Modifies a user entry in the appropriate files. To modify an entry, the administrator must have the `solaris.admin.usermgr.write` authorization.

Options The `smuser` authentication arguments, *auth_args*, are derived from the `smc(1M)` arg set and are the same regardless of which subcommand you use. The `smuser` command requires the Solaris Management Console to be initialized for the command to succeed (see `smc(1M)`). After rebooting the Solaris Management Console server, the first Solaris Management Console connection might time out, so you might need to retry the command.

The subcommand-specific options, *subcommand_args*, must come after the *auth_args* and must be separated from them by the `- —` option.

auth_args The valid *auth_args* are `-D`, `-H`, `-l`, `-p`, `-r`, and `-u` are described below. They are all optional. These options are a subset of the full complement of supported options described in `smc(1M)`.

If no *auth_args* are specified, certain defaults will be assumed and the user may be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `- —domain` with the *domain* argument.

`-D | - —domain` *13;domain* Specifies the default domain that you want to manage. The syntax of *domain* is *type*:/*host_name*/*domain_name*, where *type* is `nis`, `nisplus`, `dns`, `ldap`, or `file`; *host_name* is

	the name of the machine that serves the domain; and *domain_name* is the name of the domain you want to manage. (*Note:* Do *not* use `nis+` for `nisplus`.) If you do not specify this option, the Solaris Management Console assumes the `file` default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.
`-H | - —hostname` *13;host_name:port*	Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, `898`. If you do not specify *host_name:port*, the Solaris Management Console connects to the local host on port `898`. You may still have to choose a toolbox to load into the console. To override this behavior, use the `smc(1M) -B` option, or set your console preferences to load a "home toolbox" by default.
`-l | - —rolepassword` *13;role_password*	Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
`-p | - —password` *13;password*	Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.
`-r | - —rolename` *13;role_name*	Specifies a role name for authentication. If you do not specify this option, no role is assumed.
`-u | - —username` *13;user_name*	Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.
`- —`	This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the `- —`

option.

subcommand_args *Note:* Descriptions and other arg options that contain whitespace must be enclosed in double quotes.

To add or change privileges, the administrator must have the `solaris.admin.privilege.write` authorization. See `privileges(5)`.

- For subcommand `add`:

`-c` *comment*	(Optional) Includes a short description of the login, which is typically the user's name. Consists of a string of up to 256 printable characters, excluding the colon (:).
`-d` *dir*	(Optional) Specifies the home directory of the new user, limited to 1024 characters.
`-e` *ddmmyyyy*	(Optional) Specifies the expiration date for a login. After this date, no user can access this login. This option is useful for creating temporary logins. Specify a null value (“ ”) to indicate that the login is always valid. The administrator must have the `solaris.admin.usermgr.pswd` authorization.
`-f` *inactive*	(Optional) Specifies the maximum number of days allowed between uses of a login ID before that ID is declared invalid. Normal values are positive integers. Enter zero to indicate that the login account is always active.
`-F` *full_name*	(Optional) Specifies the full, descriptive name of the user. The *full_name* must be unique within a domain and can contain alphanumeric characters and spaces. If you use spaces, you must enclose the *full_name* in double quotes.
`-g` *group*	(Optional) Specifies the new user's primary group membership in the system group database with an existing group's integer ID.
`-G` *group1* `-G` *group2* . . .	(Optional) Specifies the new user's supplementary group membership in the system group database with the character string names of one or more existing groups. Duplicates of groups specified with the `-g` and `-G` options are ignored.
`-h`	(Optional) Displays the command's usage statement.
`-n` *login*	Specifies the new user's login name. The login name must be unique within a domain, contain 2–32 alphanumeric characters, begin with a letter, and contain at least one lowercase letter.

`-P` *password*	(Optional) Specifies up to an eight-character password assigned to the user account. *Note:* When you specify a password, you type the password in plain text. Specifying a password using this method introduces a security gap while the command is running. To set the password, the administrator must have the `solaris.admin.usermgr.pswd` authorization.
`-s` *shell*	(Optional) Specifies the full pathname (limited to 1024 characters) of the program used as the user's shell on login. Valid entries are a user-defined shell, `/bin/csh` (C shell), `bin/ksh` (Korn shell), and the default, `/bin/sh` (Bourne shell).
`-t` *template*	(Optional) Specifies a template, created using the User Manager tool, that contains a set of pre-defined user attributes. You may have entered a name service server in the template. However, when a user is actually added with this template, if a name service is unavailable, the user's local server will be used for both the Home Directory Server and Mail Server.
`-u` *uid*	(Optional) Specifies the user ID of the user you want to add. If you do not specify this option, the system assigns the next available unique user ID greater than 100.
`-x` *autohome*=Y|N	(Optional) Sets the home directory to automount if set to `Y`. The user's home directory path in the password entry is set to `/home/`*login name*.
`-x` *mail=mail_server*	(Optional) Specifies the host name of the user's mail server, and creates a mail file on the server. Users created in a local scope must have a mail server created on their local machines.
`-x` *perm=home_perm*	(Optional) Sets the permissions on the user's home directory. *perm* is interpreted as an octal number, and the default is `0775`.
`-x` *pwmax=days*	(Optional) Specifies the maximum number of days that the user's password is valid. The administrator must have the `solaris.admin.usermgr.pswd` authorization.
`-x` *pwmin=days*	(Optional) Specifies the minimum number of days between user password changes. The administrator must have the `solaris.admin.usermgr.pswd` authorization.
`-x` *pwwarn=days*	(Optional) Specifies the number of days relative to *pwmax* that the user is warned about password expiration prior to the password expiring. The administrator must have the `solaris.admin.usermgr.pswd` authorization.

`-x` *serv=homedir_server*	(Optional) Specifies the name of the server where the user's home directory resides. Users created in a local scope must have their home directory server created on their local machines.
`-M` *limit_privs*	Specifies the privilege name(s) to add to the new `user_attr(4)` entry. The default is `all` for limit privilege. To add or change privileges, the administrator must have the `solaris.admin.privilege.write` authorization. See `privileges(5)`.
`-D` *default_privs*	Specifies the default privilege name(s) to add to the new `user_attr(4)` entry.

The following options to the `add` subcommand are available only if a system is configured with Solaris Trusted Extensions. See "Using Options that Require Solaris Trusted Extensions," below.

`-x` clear=*clearanceval*	(Optional) Specifies the role's clearance. *clearanceval* can be a string value or a hex value. If this option is not specified, the default is the user's system default clearance. To set the clearance, the administrator must have the `solaris.admin.usermgr.labels` authorization.
`-x` idlecmd=LOGOUT|LOCK	Specifies the command to execute if the system has been idled. If `LOGOUT` is specified, `idlecmd=logout` will be recorded in `user_attr`. If `LOCK` is specified, `idlecmd=lock` will be recorded in `user_attr`. If this option is not specified, the default is the `IDLECMD` in the `/etc/security/policy.conf` file.
`-x` idletime=*minutes*	(Optional) Specifies the number of minutes before the specified idle command gets executed. Any integer value in the range from 1 to 120 is valid. This value is recorded in `user_attr` as `idletime=`*val*. If this option is not specified, the default is the `IDLETIME` in the `/etc/security/policy.conf` file.

-x label=*labelval*	(Optional) Specifies the user's minimum label. *labelval* can be a string label or a hex label. If this option is not specified, the default is the user's system default minimum label. To set the minimum label, the administrator must have the `solaris.admin.usermgr.labels` authorization.
-x labelview=HIDE|SHOW	(Optional) Specifies the second part of the `labelview` *key-value* pair. If `SHOW` is specified, `labelview=*showsl` will be recorded. If `HIDE` is specified, `labelview=*hidesl` will be recorded. The asterisk portion can be replaced by "`internal,`", "`external,`", or ""(null). If this option is not specified, the default is the `LABELVIEW` in the `/etc/security/policy.conf` file.
-x lock=Y|N	(Optional) Specifies if an account is locked after a specified number of failed logins. This value is recorded in `user_attr` as `lock_after_retries`. If this option is not specified, the default is the `LOCK_AFTER_RETRIES` in the `/etc/security/policy.conf` file.
-x view=INTERNAL|EXTERNAL|DEFAULT	(Optional) Specifies the label view type for the `labelview` in `user_attr`. If `INTERNAL` is specified, `labelview=internal` will be recorded; if `EXTERNAL` is specified, `labelview=external` will be recorded; if `DEFAULT` is specified, nothing will be recorded in `user_attr`. If this option is not specified, the default action, that nothing gets recorded in `user_attr`, is in effect.

- For subcommand `delete`:

-h	(Optional) Displays the command's usage statement.
-n *login1*	Specifies the login name of the user you want to delete.

`-n` *login2* . . . (Optional) Specifies the additional login name(s) of the user(s) you want to delete.

- For subcommand `list`:

  `-h` (Optional) Displays the command's usage statement.

  `-l` Displays the output for each user in a block of *key:value* pairs (for example, `user name:root`) followed by a blank line to delimit each user block. Each *key:value* pair is displayed on a separate line. The keys are: `autohome setup`, `comment`, `days to warn`, `full name`,`home directory`, `home directory permissions`, `login shell`, `mail server`, `max days change`, `max days inactive`, `min days change`, `password expires`, `password type`, `primary group`, `rights`, `roles`, `secondary groups`, `server`, `user ID (UID)`, and `user name`.

  `-n` *login1* Specifies the login name of the user you want to list.

  `-n` *login2* . . . (Optional) Specifies the additional login name(s) of the user(s) you want to list.

- For subcommand `modify`:

  `-a` *addrole1* `-a` *addrole2* . . . (Optional) Specifies the role(s) to add to the user account. To assign a role to a user, the administrator must have the `solaris.role.assign` authorization or must have the `solaris.role.delegate` authorization and be a member of each of the roles specified.

  `-c` *comment* (Optional) Describes the changes you made to the user account. Consists of a string of up to 256 printable characters, excluding the colon (:).

  `-d` *description* (Optional) Specifies the user's home directory, limited to 1024 characters.

  `-e` *ddmmyyyy* (Optional) Specifies the expiration date for a login in a format appropriate to the locale. After this date, no user can access this login. This option is useful for creating temporary logins. Specify a null value (" ") to indicate that the login is always valid.

  `-f` *inactive* (Optional) Specifies the maximum number of days allowed between uses of a login ID before the ID is declared invalid. Normal values are positive integers. Specify zero to indicate that the login account is always active.

  `-F` *full_name* (Optional) Specifies the full, descriptive name of the user. The *full_name* must be unique within a domain and can

	contain alphanumeric characters and spaces. If you use spaces, you must enclose the *full_name* in double quotes.
`-g` *group*	(Optional) Specifies the new user's primary group membership in the system group database with an existing group's integer ID.
`-G` *group1* `-G` *group2* . . .	(Optional) Specifies the new user's supplementary group membership in the system group database with the character string names of one or more existing groups. Duplicates of groups specified with the `-g` and `-G` options are ignored.
`-h`	(Optional) Displays the command's usage statement.
`-n` *name*	Specifies the user's current login name.
`-N` *new_name*	(Optional) Specifies the user's new login name. The login name must be unique within a domain, contain 2–32 alphanumeric characters, begin with a letter, and contain at least one lowercase letter.
`-p` *addprof1* `-p` *addprof2* . . .	(Optional) Specifies the profile(s) to add to the user account. To assign a profile to a user, the administrator must have the `solaris.profmgr.assign` or `solaris.profmgr.delegate` authorization.
`-P` *password*	(Optional) Specifies up to an eight-character password assigned to the user account. When you specify a password, you type the password in plain text. Specifying a password using this method introduces a security gap while the command is running.
`-q` *delprof1* `-q` *delprof2* . . .	(Optional) Specifies the profile(s) to delete from the user account.
`-r` *delrole1* `-r` *delrole2* . . .	(Optional) Specifies the role(s) to delete from the user account.
`-s` *shell*	(Optional) Specifies the full pathname (limited to 1024 characters) of the program used as the user's shell on login. Valid entries are a user-defined shell, `/bin/csh` (C shell), `bin/ksh` (Korn shell), and the default, `/bin/sh` (Bourne shell).l)
`-x` *autohome*=Y|N	(Optional) Sets up the home directory to automount if set to `Y`. The user's home directory path in the password entry is set to `/home/`*login name*.

`-x` *pwmax=days*	(Optional) Specifies the maximum number of days that the user's password is valid.
`-x` *pwmin=days*	(Optional) Specifies the minimum number of days between password changes.
`-x` *pwwarn=days*	(Optional) Specifies the number of days relative to *pwmax* that the user is warned about password expiration before the password expires.
`-M` *limit_privs*	Specifies the privilege name(s) to modify in the `user_attr(4)` entry. The default is `all` for limit privilege. To add or change privileges, the administrator must have the `solaris.admin.privilege.write` authorization. See `privileges(5)`.
`-D` *default_privs*	Specifies the default privilege name(s) to modify in the `user_attr(4)` entry.

The following options to the `modify` subcommand are available only if a system is configured with Solaris Trusted Extensions. See "Using Options that Require Solaris Trusted Extensions," below.

`-x` clear=*clearanceval*	(Optional) Specifies the role's clearance. *clearanceval* can be a string value or a hex value. If this option is not specified, the default is the user's system default clearance. To set the clearance, the administrator must have the `solaris.admin.usermgr.labels` authorization.
`-x` idlecmd=LOGOUT|LOCK	Specifies the command to execute if the system has been idled. If `LOGOUT` is specified, `idlecmd=logout` will be recorded in `user_attr`. If `LOCK` is specified, `idlecmd=lock` will be recorded in `user_attr`. If this option is not specified, the default is the `IDLECMD` in the `/etc/security/policy.conf` file.
`-x` idletime=*minutes*	(Optional) Specifies the number of minutes before the specified idle command gets executed. Any integer value in the range from 1 to 120 is valid.

	This value is recorded in `user_attr` as `idletime=`*val*. If this option is not specified, the default is the `IDLETIME` in the `/etc/security/policy.conf` file.
-x label=*labelval*	(Optional) Specifies the user's minimum label. *labelval* can be a string label or a hex label. If this option is not specified, the default is the user's system default minimum label. To set the minimum label, the administrator must have the `solaris.admin.usermgr.labels` authorization.
-x labelview=HIDE|SHOW	(Optional) Specifies the second part of the `labelview` *key-value* pair. If `SHOW` is specified, `labelview=*showsl` will be recorded. If `HIDE` is specified, `labelview=*hidesl` will be recorded. The asterisk portion can be replaced by "`internal,`", "`external,`", or ""(null). If this option is not specified, the default is the `LABELVIEW` in the `/etc/security/policy.conf` file.
-x lock=Y|N	(Optional) Specifies if an account is locked after a specified number of failed logins. This value is recorded in `user_attr` as `lock_after_retries`. If this option is not specified, the default is the `LOCK_AFTER_RETRIES` in the `/etc/security/policy.conf` file.
-x view=INTERNAL|EXTERNAL|DEFAULT	(Optional) Specifies the label view type for the `labelview` in `user_attr`. If `INTERNAL` is specified, `labelview=internal` will be recorded; if `EXTERNAL` is specified, `labelview=external` will be recorded; if `DEFAULT` is specified, nothing will be recorded in `user_attr`. If this option is not specified, the default action, that nothing gets recorded in `user_attr`, is in effect.

Using Options that Require Solaris Trusted Extensions

To use an option that requires the Solaris Trusted Extensions feature, you must use the `-B` *toolbox* option to specify a toolbox that contains support for Trusted Extensions. For example:

```
# smuser add -H myhost -p mypasswd -x idlecmd=LOGOUT \
-B http://<server>/toolboxes/tsol_files.tbx
```

In the command above, <*server*> is the name of the machine running the Solaris Management Console. See smc(1M) for a description of the `-B` option.

Examples

EXAMPLE 1 Creating a New User Account

The following creates a new user account on the local file system. The account name is `user1`, and the full name is `Joe Smith`. The comment field verifies that the account is for Joe Smith. The system will assign the next available user ID greater than 100 to this account. There is no password set for this account, so when Joe Smith logs in for the first time, he will be prompted to enter a password.

```
./smuser add -H myhost -p mypasswd -u root -- -F "Joe Smith" \
             -n user1 -c "Joe's account"
```

EXAMPLE 2 Deleting a User Account

The following deletes the `user1` account from the local file system:

```
./smuser delete -H myhost -p mypasswd -u root -- -n user1
```

EXAMPLE 3 Listing All User Accounts

The following lists all user accounts on the local file system in summary form:

```
./smuser list -H myhost -p mypasswd -u root --
```

EXAMPLE 4 Modifying a User Account

The following modifies the `user1` account to default to a Korn shell, and assigns the account to the `qa_group` secondary group.

```
./smuser modify -H myhost -p mypasswd -u root -- -n user1 \
             -s /bin/ksh -G qa_group
```

Environment Variables

See environ(5) for a description of the `JAVA_HOME` environment variable, which affects the execution of the `smuser` command. If this environment variable is not specified, the `/usr/java` location is used. See smc(1M).

Exit Status

The following exit values are returned:

`0` Successful completion.

`1` Invalid command syntax. A usage message displays.

`2` An error occurred while executing the command. An error message displays.

Files The following files are used by the `smuser` command:

`/etc/aliases`	Mail aliases. See `aliases(4)`.
`/etc/auto_home`	Automatic mount points. See `automount(1M)`.
`/etc/group`	Group file. See `group(4)`.
`/etc/passwd`	Password file. See `passwd(4)`.
`/etc/security/policy.conf`	Configuration file for security policy. See `policy.conf(4)`.
`/etc/shadow`	Shadow password file. See `shadow(4)`.
`/etc/user_attr`	Extended user attribute database. See `user_attr(4)`.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga
Interface Stability	Evolving

See Also `automount(1M)`, `smc(1M)`, `aliases(4)`, `group(4)`, `passwd(4)`, `policy.conf(4)`, `shadow(4)`, `user_attr(4)`, `attributes(5)`, `environ(5)`

Name snmpbulkget – communicate with a network entity using SNMP GETBULK requests

Synopsis

```
snmpbulkget [application options] [common options] oid
     [oid]...
```

Description The `snmpbulkget` utility is an SNMP application that uses the SNMP `GETBULK` operation to send information to a network manager. You can specify one or more object identifiers (OIDs) on the command line. Each variable name must be entered in the format specified in `snmp_variables(4)`.

If the network entity has an error processing the request packet, an error packet is returned and a message displayed, indicating the way in which the request was malformed.

Options The following options are supported:

`-Cn`*num* Set the `non-repeaters` field in the `GETBULK` PDU. This specifies the number of supplied variables that should not be iterated over. The default is 0.

`-Cr`*num* Set the `max-repetitions` field in the `GETBULK` PDU. This specifies the maximum number of iterations over the repeating variables. The default is 10.

In addition to this option, `snmpbulkget` takes the common options described in the `snmpcmd(1M)` manual page.

Examples **EXAMPLE 1** Retrieving Multiple Objects

The following `snmpbulkget` command retrieves the variable `system.sysDescr.0` (which is the lexicographically next object to `system`) and the first five objects in the `ifTable`:

```
# snmpbulkget -v2c -Cn1 -Cr5 -Os -c public zeus system ifTable
```

This command produces output such as the following:

```
sysDescr.0 = STRING: "SunOS zeus.net.cmu.edu 4.1.3_U1 1 sun4m"
ifIndex.1 = INTEGER: 1
ifIndex.2 = INTEGER: 2
ifDescr.1 = STRING: "lo0"
[...]
```

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

Exit Status

`0` Successful completion.

`1` A usage syntax error. A usage message is displayed. Also used for timeout errors.

2 An error occurred while executing the command. An error message is displayed.

See Also snmpcmd(1M), snmp_variables(4), attributes(5)

RFC 1905

Notes As the name implies, `snmpbulkget` uses the SNMP `GETBULK` message, which is not available in SNMPv1.

Name snmpbulkwalk – communicate with a network entity using SNMP BULK requests

Synopsis

```
/usr/sfw/bin/snmpbulkwalk [application_options]
     [common_options] [oid]
```

Description The `snmpbulkwalk` utility is an SNMP application that uses SNMP `GETBULK` requests to query a network entity efficiently for a tree of information.

You can specify an object identifier (OID) on the command line. This OID identifies the portion of the object identifier space that will be searched using `GETBULK` requests. All variables in the subtree below the given OID are queried and their values returned. Each variable name is given in the format specified in `snmp_variables(4)`. If no OID argument is present, `snmpbulkwalk` searches MIB-2.

If a network entity has an error processing the request packet, an error packet is returned and a message is displayed. The message helps to pinpoint the way in which the request was malformed.

If the tree search causes attempts to search beyond the end of the MIB, the message "End of MIB" is displayed.

Options The following options are supported:

`-Cc` Do not check whether the returned OIDs are increasing. Some agents (agents for Laser-Jet printers are an example) return OIDs out of order, but can complete the walk anyway. Other agents return OIDs that are out of order and can cause `snmpbulkwalk` to loop indefinitely. By default, `snmpbulkwalk` tries to detect this behavior and warns you when it hits an agent acting illegally. Use `-Cc` to turn off this behavior.

`-Ci` Include the given OID in the search range. Normally, `snmpbulkwalk` uses `GETBULK` requests starting with the OID you specify and returns all results in the MIB tree beyond that OID. Use this option to include the OID specified on the command line in the printed results if it is a valid OID in the tree itself.

`-Cn`*num* Set the non-repeaters field in the GETBULK PDUs. This specifies the number of supplied variables that should not be iterated over. The default is 0.

`-Cp` Upon completion of the walk, display the number of variables found.

`-Cr`*num* Set the `max-repetitions` field in the `GETBULK` PDUs. This specifies the maximum number of iterations over the repeating variables. The default is 10.

In addition to these options, `snmpbulkwalk` takes the common options described in the `snmpcmd(1M)` manual page.

Examples

EXAMPLE 1 Retrieving Variables Under `system`

The following command retrieves all of the variables under `system`:

```
# snmpbulkwalk -v2c -Os -c public zeus system
```

The return from `snmpbulkwalk` is as follows:

```
sysDescr.0 = STRING: "SunOS zeus.net.cmu.edu 4.1.3_U1 1 sun4m"
sysObjectID.0 = OID: enterprises.hp.nm.hpsystem.10.1.1
sysUpTime.0 = Timeticks: (155274552) 17 days, 23:19:05
sysContact.0 = STRING: ""
sysName.0 = STRING: "zeus.net.cmu.edu"
sysLocation.0 = STRING: ""
sysServices.0 = INTEGER: 72
```

In contrast to `snmpwalk(1M)`, this information will be gathered in a single transaction with the agent, rather than one transaction per variable found. `snmpbulkwalk` is thus more efficient in terms of network utilization, which might be especially important when retrieving large tables.

Exit Status

`0` Successful completion.

`1` A usage syntax error. A usage message displays. Also used for timeout errors.

`2` An error occurred while executing the command. An error message displays.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

See Also

`snmpcmd(1M)`, `snmpwalk(1M)`, `snmp_variables(4)`, `attributes(5)`

Notes

As the name implies, `snmpbulkwalk` uses the SNMP `GETBULK` message, which is not available in SNMP v1.

Name snmpcmd – commands to communicate with a network entity using SNMP requests

Synopsis `snmpcmd [options] agent [parameters]`

Description This manual page describes the common options for the following SNMP commands:

- `snmpbulkget(1M)`
- `snmpbulkwalk(1M)`
- `snmpdf(1M)`
- `snmpget(1M)`
- `snmpgetnext(1M)`
- `snmpnetstat(1M)`
- `snmpset(1M)`
- `snmptrap(1M)`
- `snmpusm(1M)`
- `snmpvacm(1M)`
- `snmpwalk(1M)`

The command line applications use the SNMP protocol to communicate with an SNMP-capable network entity, an agent. Individual applications usually (but not invariably) take additional parameters that are given after the agent specification. These parameters are documented in the manual pages for each application.

Options The following options are supported:

`-a` *authProtocol*	Set the authentication protocol (`MD5`|`SHA`) used for authenticated SNMPv3 messages. Overrides the `defAuthType` token in the `snmp.conf` file.
A *authPassword*	Set the authentication pass phrase used for authenticated SNMPv3 messages. Overrides the `defAuthPassphrase` token in the `snmp.conf` file. Insecure to specify pass word phrases on the command line, see `snmp.conf(4)`.
`-c` *community*	Set the community string for SNMPv1/v2c transactions. Overrides the `defcommunity` token in the `snmp.conf` file.
`-d`	Dump (in hexadecimal) the sent and received SNMP packets.
`-D` *token*[,...]	Turn on debugging output for the given *token*(s). Try `ALL` for extremely verbose output.
`-e` *engineID*	Set the authoritative (security) *engineID* used for SNMPv3 `REQUEST` messages. This is the `engineID` of the agent or proxy (for example, 800000020109840301). This value will be discovered if not supplied.

`-E` *engineID*
: Set the context *engineID* used for SNMPv3 REQUEST messages `scopedPdu`. This is the `engineID` of the agent (for example, 800000020109840301). This will be the authoritative `engineID` if not specified.

`-h`, `--help`
: Display a brief usage message and then exit.

`-H`
: Display a list of configuration file directives understood by the command and then exit.

`-I` brRhu
: Specifies input parsing options. See INPUT OPTIONS below.

`-l` *secLevel*
: Set the securityLevel used for SNMPv3 messages (`noAuthNoPriv`|`authNoPriv`|`authPriv`). Appropriate pass phrase(s) must be provided when using any level higher than `noAuthNoPriv`. Overrides the `defSecurityLevel` token in the `snmp.conf` file.

`-m` *miblist*
: Specifies a colon-separated list of MIB modules to load for this application. This overrides the environment variable `MIBS`.

  The special keyword `ALL` is used to specify all modules in all directories when searching for MIB files. Every file whose name does not begin with a period (`.`) will be parsed as if it were a MIB file.

  If the *miblist* has a leading plus sign (+), then the listed MIB modules are loaded in addition to MIB modules specified in the environment variable `MIBS`.

  If a `mibfile` token is specified in the `snmp.conf` file, the `-m MIB` option overrides the `mibfile` token.

`-M` *dirlist*
: Specifies a colon-separated list of directories to search for MIBs. This overrides the environment variable `MIBDIRS`.

  If *dirlist* has a leading plus sign (+), then the given directories are added to the list of MIB directories. Without the leading +, the given directory list overrides the list specified with the environment variable `MIBDIRS`. Note that the directories listed at the end of the list have precedence over directories at the beginning of the list.

  If no value is specified for the environment variable `MIBDIRS`, then the command will still search a default `mib` directory, after it searches the MIB directories specified on the `-M` option. The default directory is `/etc/sma/snmp/mibs`. To avoid having a default `mib` directory searched, set the `MIBDIRS` environment

variable to the empty string (""). Even if the default MIB directory is searched, the directories specified in the `-M` option have precedence in the search order over the default directory.

If the `-M` option is specified and either a `mibfile` or `mibdirs` token is also specified in the `snmp.conf` file, the directories in the `-M` option have precedence in the MIB search order, over the directories set with either the `mibdirs` token and the `mibfile` token.

`-n` *contextName* — Set the destination *contextName* used for SNMPv3 messages. The default *contextName* is the empty string (""). Overrides the `defContext` token in the `snmp.conf` file.

`-O` anEebqQfsSvXTuxUt — Specifies output printing options. See OUTPUT OPTIONS below.

`-P` cdeRuwW — Specifies MIB parsing options. See MIB PARSING OPTIONS below.

`-r` *retries* — Specifies the number of retries to be used in the requests. The default is 5.

`-t` *timeout* — Specifies the timeout in seconds between retries. The default is 1.

`-u` *secName* — Set the `securityName` used for authenticated SNMPv3 messages. Overrides the `defSecurityName` token in the `snmp.conf` file.

`-v` 1 | 2c | 3 — Specifies the protocol version to use: 1 (RFCs 1155-1157), 2c (RFCs 1901-1908), or 3 (RFCs 2571-2574). The default is version 1. This option overrides the `defVersion` token in the `snmp.conf` file.

`-V`, `--version` — Display version information for the application and then exit.

`-x` *privProtocol* — Set the privacy protocol (DES) used for encrypted SNMPv3 messages.

`-X` *privPassword* — Set the privacy pass phrase used for encrypted SNMPv3 messages. Overrides the `defPrivPassphrase` token in the `snmp.conf` file. Note that it is insecure to specify password phrases on the command line. See `snmp.conf(4)`.

`-Z` *boots*,*time* — Set the `engineBoots` and `engineTime` used for authenticated SNMPv3 messages. This will initialize the local notion of the agents *boots*/*time* with an authenticated value stored in the LCD. This value will be discovered if not supplied.

The string *agent* specifies the remote SNMP entity with which to communicate. The format of this parameter is defined in the AGENT SPECIFICATION section below.

Agent Specification

The *agent* specification (see SYNOPSIS) takes the form:

[*transport-specifier*:]*transport-address*

At its simplest, the *agent* specification consists of a hostname or an IPv4 address in the standard, "dotted quad" notation. In this case, communication will be attempted using UDP/IPv4 to port 161 of the given host. Otherwise, the *transport-address* part of the specification is parsed according to the following table:

<transport-specifier>	<transport-address> format
udp	*hostname*[:*port*]

Note that *transport-specifier* strings are case-insensitive so that, for example, "tcp" and "TCP" are equivalent. Here are some examples, along with interpretations:

```
myhost:161
```

Perform query using UDP/IPv4 datagrams sent to `myhost` on port 161. The `:161` is redundant here because that is the default SNMP port.

```
udp:myhost
```

Identical to the previous specification. The `udp:` is redundant here because UDP/IPv4 is the default transport.

MIB Parsing Options

The Net-SNMP MIB parser mostly adheres to the Structure of Management Information (SMI). As that specification has changed through time, and in recognition of the diversity in compliance expressed in MIB files, additional options provide more flexibility in reading MIB files.

`-Pw` Show some warning messages in resolving the MIB files. Can be also set with the configuration token `mibWarningLevel`.

`-PW` Show additional warning messages. Can be also set with the configuration token `mibWarningLevel`.

`-Pe` Show MIB errors. Can be also set with the configuration token `showMibErrors`. An example of an error that would be shown is if an imported module is not found during MIB parsing.

`-Pc` Allow ASN.1 comment to extend to the end of the MIB source line (that is, disallow the use of two dashes (`--`) to terminate comments). This overcomes some problems with manually maintained MIB files. Can be also set with the configuration token `strictCommentTerm`.

`-Pd` Toggles the default of whether or not to save the `DESCRIPTION`s of the MIB objects when parsing. Since the default is to save the `DESCRIPTION`s, specifying `-Pd` causes the `DESCRIPTION`s not to be saved during MIB parsing. For example:

```
snmptranslate -Td -OS -IR system.sysDescr.0
```

will show a description, while:

```
snmptranslate -Td -OS -IR -Pd system.sysDescr.0
```

will not show a description. Collecting the `DESCRIPTION` information into the parsed hierarchy increases the memory used by the size of each `DESCRIPTION` clause.

`-Pu` Allow underline characters in symbols. Can be also set with the configuration token `mibAllowUnderline`.

`-PR` Replace MIB objects using the last read MIB file. The parser replaces MIB objects in its hierarchy whenever it sees a subidentifier and name match.

Caution – Setting this option might result in an incorrect hierarchy. Can be also set with the configuration token `mibReplaceWithLatest`.

Output Options Output display can be controlled by passing various parameters to the `-O` flag. The following examples demonstrate this feature.

The default output displays as follows:

```
snmpget -c public -v 1 localhost system.sysUpTime.0
SNMPv2-MIB::sysUpTime.0 = Timeticks: (14096763) 1 day, 15:09:27.63
```

`-Oq` Removes the equal sign and type information:

```
system.sysUpTime.0 1:15:09:27.63
```

`-OQ` Removes the type information:

```
system.sysUpTime.0 = 1:15:09:27.63
```

`-Of` Gives you the complete OID:

```
.iso.org.dod.internet.mgmt.mib-2.system.sysUpTime.0 = \
Timeticks: (14096763) 1 day, 15:09:27.63
```

`-Os` Deletes all but the last symbolic part of the OID:

```
sysUpTime.0 = Timeticks: (14096763) 1 day, 15:09:27.63
```

`-OS` A variation on `-Os` that adds the name of the MIB that defined the object:

```
SNMPv2-MIB::sysUpTime.0 = Timeticks: (14096763) 1 day, 15:09:27.63
```

Starting with release 5.0, this is the default output format.

`-Ou` Displays the OID in the UCD-style (inherited from the original CMU code). That means removing a series of "standard" prefixes, if relevant, and breaking down the

OID into the displayable pieces. For example, the OID `vacmSecruityModel.0.3.119.101.115` is broken down by default and the string hidden in the OID is shown. The result would be: `vacmSecurityModel.0."test"`. The `-Ob` option disables this feature.

```
system.sysUpTime.0 = Timeticks: (14096763) 1 day, 15:09:27.63
```

`-On` Displays the OID numerically:

```
.1.3.6.1.2.1.1.3.0 = Timeticks: (14096763) 1 day, 15:09:27.63
```

`-Oe` Removes the symbolic labels from enumerations:

```
snmpget -c public -v 1 localhost ip.ipForwarding.0
ip.ipForwarding.0 = INTEGER: forwarding(1)
snmpget -c public -v 1 -Oe localhost ip.ipForwarding.0
ip.ipForwarding.0 = INTEGER: 1
```

`-Ob` When OIDs contain a index to a table, they are broken into the displayable pieces and shown to you. For example, the OID `vacmSecurityModel.0.3.119.101.115` is nicely broken down by default and the string hidden in the OID is shown to you as `vacmSecurityModel.0."wes"`. The `-Ob` option disables this feature and displays it as `vacmSecurityModel.0.3.119.101.115` once again.

`-OE` Modifies the index strings to include a backslash (`\`) to escape the quotes, to allow them to be reused in shell commands, such as `vacmSecurityModel.0.\"wes\"`

`-OX` Modifies the output of index OIDs to look more "program-like". Square brackets are placed around each index and the `DISPLAY-HINT` information and string conversions are used to format each index. If you take an entry from the `IPV6-MIB::ipv6RouteTable`, it is indexed with an IPv6 address and two integers, and if you are used to IPv6 addresses you know that decimal OIDs are not the preferred notation. Compare:

```
snmpgetnext -OS host IPV6-MIB:ipv6RouteTable
IPV6-MIB::ipv6RouteIfIndex.63.254.1.0.255.0.0.0.0.0.0.0.0.0.0.64.1 \
= INTEGER: 2

snmpgetnext -OSX host IPV6-MIB:ipv6RouteTable
IPV6-MIB::ipv6RouteIfIndex[3ffe:100:ff00:0:0:0:0:0][64][1] = INTEGER: 2
```

`-Oa` If a string-valued object definition does not include a display hint, then the library attempts to determine whether it is an ASCII or binary string, and displays the value accordingly. This flag bypasses this check, and displays all strings as ASCII. Note that this does not affect objects that do have a display hint.

`-Ox` This works similarly to `-Oa`, but displays strings as hexadecimal values.

`-OT` If hexadecimal code is displayed, this will also display any printable characters after the hexadecimal codes.

`-Ov` Output only the variable value, not the OID:

```
snmpget -c public -v 1 -Ov localhost ip.ipForwarding.0
INTEGER: forwarding(1)
```

`-OU` Do not display the `UNITS` suffix at the end of the value.

`-Ot` Output timeticks values as raw numbers:

```
system.sysUpTime.0 = 14096763
```

Note that most of these options can be turned on or off by default by tuning the `snmp.conf` file. See `snmp.conf(4)` for details.

Input Options

The `-I` flag specifies various options that control how your input to the program is parsed. By default, unless one of the following flags is specified, all input parsing methods are used: First the OID is parsed in the normal way, then `-IR` is used, then `-Ib` is used. The use of one of the following flags forces a command to use only one method.

`-IR` Specifies random access lookup, so that if the entire OID path is not specified, it will search for a node in the MIB tree with the given name. Normally, you'd have to specify the `vacmSecurityModel` OID above as:

```
 .iso.org.dod.internet.snmpV2.snmpModules.snmpVacmMIB.vacmMIBObjects. \
vacmSecurityToGroupTable.vacmSecurityToGroupEntry.vacmSecurityModel.0.\
"wes"
```

But the use of the `-IR` flag allows you to shorten that to `vacmSecurityModel.0."wes"`. This OID needs to be quoted to prevent the shell from swallowing the double quotes: But the use of the -IR flag allows you to shorten that to just vacmSecurityModel.0."wes". This OID must be quoted to prevent the shell from swallowing the double quotes: `'vacmSecurityModel.0."wes"'`.

For more information, see the RANDOM ACCESS MIBS section, below.

`-Ib` Indicates that the expression you gave the command is a regular expression that should be used to search for the best match possible in the MIB tree. This would allow you to specify the `vacmSecurityModel` MIB node as something as generic as `vacmsecuritymodel` (since case-insensitive searches are done) or `vacm.\(**model`. Note that multiple matches are obviously possible (`.\(**` matches everything). The best result is calculated as the one that matches the closest to the beginning of the node name and the highest in the tree. A side effect of this option is that you cannot specify indexes or multiple nodes, because the period (`.`) is treated as part of the regular expression.

`-Iu` Use the traditional UCD-style input approach of assuming that OIDs are rooted at the `mib-2` point in the tree (unless they start with an explicit period (`.`)) If random access lookup is in effect (which is the default for most commands), then this will affect only

OIDs specified with a leading numeric subidentifier (and no initial period). Thus an input of `snmpcmd ... 1` would refer to `iso` (from v5.0 onwards) while `snmpcmd -Iu ... 1` would refer to `system`.

`-Ir` By default, indices into tables and values to be assigned to objects are checked against the range and type specified in the MIB. The `-Ir` flag disables this check. This flag is mostly useful when you are testing an agent. For normal operation, it is useful to get your requests checked before they are sent to the remote agent. The diagnostic that the library can provide is also much more precise.

`-Ih` By default, the library will use DISPLAY-HINT information when assigning values. This flag disables this behavior. The result is that, instead of:

```
snmpset localhost HOST-RESOURCES-MIB::hrSystemDate.0 = \
2002-12-10,2:4:6.8
```

you will have to write:

```
snmpset localhost HOST-RESOURCES-MIB::hrSystemData.0 x \
"07 D2 0C 0A 02 04 06 08"
```

Random Access MIBs

In previous releases of the UCD-SNMP package (and if using the `-Iu` option), an object identifier such as `system.sysDescr.0` is looked up in a single "well known" place, built into the SNMP library (or specified by the `P@REFIX` environment variable). The standard place is `.iso.org.dod.internet.mgmt.mib-2`. The identifier can alternatively be a complete object identifier. This is designated by a leading "dot" if using UCD-input style, and is the first thing tried otherwise. To simplify the specification of object identifiers the library supports random access to the identifiers in the MIBs. This is requested by the `-IR` option to the SNMP applications. Additionally, `-Os` prints OIDs in this manner. Using this, `system.sysDescr.0` can also be entered as `sysDescr.0`.

To search only a single MIB for the identifier (if it appears in more than one), specify it as `SNMPv2-MIB::sysDescr.0`. Use `-OS` to print output OIDs in this manner; this is the default since v5.0. This notation also ensures that the specified MIB is loaded, that is, it need not be mentioned in the `-m` option (or `MIBS` environment variable).

Environment Variables

`P@REFIX` The standard prefix for object identifiers (if using UCD-style output). Defaults to `.iso.org.dod.internet.mgmt.mib-2`.

`MIBS` The list of MIBs to load. Defaults to:

```
SNMPv2-TC:SNMPv2-MIB:IF-MIB:IP-MIB:TCP-MIB:UDP-MIB:SNMP-VACM-MIB
```

Overridden by the `-m` option.

`MIBDIRS` The list of directories to search for MIBs. Defaults to `/etc/sma/snmp/mibs`. Overridden by the `-m` option.

Files

`/etc/sma/snmp/snmpd.conf`	Agent configuration file. See `snmpd.conf(4)`.
`~/.snmp/snmp.conf`	
`~/.snmp/snmp.conf`	Application configuration files. See `snmp.conf(4)`.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

Name snmpconf – creates and modifies SNMP configuration files

Synopsis

```
snmpconf

snmpconf -g basic_setup

snmpconf [options] [file_to_create]
```

Description The `snmpconf` utility is a simple script that walks you through setting up a configuration file, step-by-step. It works by asking you a series of questions. It creates the configuration file based on your responses.

In its default mode of operation, `snmpconf` prompts you with menus showing sections of the various configuration files it knows about. When you selects a section, a submenu is shown listing the descriptions of the tokens that can be created in that section. When a description is selected, you are prompted with questions that determine the specification of the selected token.

When you quit `snmpconf`, any configuration files that have been edited are saved to the local directory. `snmpconf` supplies comments in the configuration files for each change.

A particularly useful option is the `-g` switch, which walks you through a specific set of configuration questions. For an example, invoke:

```
# snmpconf -g basic_setup
```

This command walks you through an initial setup of the `snmpd` daemon.

Options The following options are supported:

`-f` Force overwriting existing files in the current directory without prompting the user.

`-i` When finished, install the files in the location where the global system commands expect to find them.

`-p` When finished, install the files into the user's home directory's `.snmp` subdirectory. Applications will search for configuration files in this location.

`-I` *directory* When finished, install the files into the directory *directory*.

`-a` Do not issue queries. Read in the various known configuration files and write them back out again. This has the effect of "auto-commenting" the configuration files for you.

`-r` all | none Read in either all or none of the found configuration files. Normally, `snmpconf` prompts you for which files you wish to read in.

`-R` *file,...* Read in a specific list of configuration files.

`-g` *groupname* Groups of configuration entries can be created that can be used to walk a user through a series of questions to create an initial configuration file. There are no menus to navigate, just a list of questions. The command:

```
# snmpconf -g basic_setup
```

provides a good example.

`-G` List all the known groups.

`-c` *configdir* `snmpconf` uses a directory of configuration information to learn about the files and questions that it should be asking. This option tells the utility to use a different location for configuring itself.

`-q` Run slightly more quietly than the default. Because this is an interactive program, this option is not recommended. It removes information from the output that might be helpful to you.

`-d` Turn on copious debugging output.

`-D` Add more (beyond `-d`) debugging output in the form of Perl variable dumps.

Examples

EXAMPLE 1 Adding Comments to `snmpd.conf`

The following command reads in an `snmpd.conf` file and adds comments describing what each token does.

```
# snmpconf -R /etc/sma/snmp/snmpd.conf -a -f snmpd.conf
```

Exit Status

`0` Successful completion.

`1` A usage syntax error. A usage message displays.

Attributes

See `attributes(5)` for descriptions of the following attributes:

Name snmpd – daemon to respond to SNMP request packets

Synopsis `/usr/sfw/sbin/snmpd [`*options*`] [`*listening addresses*`]`

Description The `snmpd` daemon is an SNMP agent that binds to a port and awaits requests from SNMP management software. Upon receiving a request, it processes the request(s), collects the requested information, performs any requested operation(s), and, finally, returns information to the requester.

Options The following options are supported:

`-a` Log the source addresses of incoming requests.

`-A` Append to the log file rather than truncating it.

`-c` *file* Read *file* as a configuration file.

`-C` Do not read any configuration files except the one optionally specified by the `-c` option.

Note that this behavior also covers the persistent configuration files. This can result in dynamically-assigned values being reset following an agent restart, unless the relevant persistent configuration files are explicitly loaded using the `-c` option.

`-d` Dump (in hexadecimal) the sent and received SNMP packets.

`-D`[*token*[,...]] Turn on debugging output for the given *token*(s). Without any tokens specified, this option defaults to printing all of the tokens (which is equivalent to the keyword `ALL`). Use `ALL` for extremely verbose output. Note that you must not put a space between the `-D` flag and the listed *token*s.

`-f` Do not `fork()` from the calling shell.

`-g` *GID* Change to the numerical group ID *GID* after opening listening sockets.

`-h`, `--help` Display a brief usage message and then exit.

`-H` Display a list of configuration file directives understood by the agent and then exit.

`-I -`*initlist* This option specifies which modules you do (or do not) want to be initialized when the agent starts up. If the comma-separated *initlist* is preceded with an hyphen (`-`), it is the list of modules that you do not want to be started. Otherwise, *initlist* is the list of modules to be started.

To obtain a list of compiled modules, run the agent with the arguments `-Dmib_init -H` This command assumes you have debugging support compiled in.

`-l` [*file*]	Log all output from the agent (including stdout and stderr) to *file*. If no filename is given, log to a default file set at compile time, normally `/var/log/snmpd.log`.
`-L`	Do not open a log file. Send all messages to stderr instead.
`-P` *file*	Save the process ID of the daemon in *file*.
`-q`	Print simpler output for easier automated parsing.
`-r`	Do not require root access to run the daemon. Specifically, do not exit if files accessible only to root (such as `/dev/kmem`) cannot be opened.
`-s`	Use syslog for logging. See `syslogd(1M)`
`-S` d[0–7]	Specifies the `syslog` facility to use when logging to `syslog`. `d` means `LOG_DAEMON` and the integers 0 through 7 refer to `LOG_LOCAL0` through `LOG_LOCAL7`. `LOG_DAEMON` is the default.
`-u` *UID*	Change to the user ID *UID* (which can be given in numerical or text form) after opening listening sockets.
`-v --version`	Display version information for the agent and then exit.
`-V`	Symbolically dump SNMP transactions.
`-x` *address*	Listens for `AgentX` connections on *address* rather than on the default `/var/agentx/master`. The address can either be a Unix domain socket path or the address of a network interface. The format is the same as the format of listening addresses described below. Note that it is a possible security risk to expose the master agent listening address through TCP/UDP. See section 9 of RFC 2741 for more details.
`-X`	Run as an `AgentX` subagent rather than as an SNMP master agent.

Listening Addresses

By default, `snmpd` listens for incoming SNMP requests only on UDP port 161. However, it is possible to modify this behavior by specifying one or more listening addresses as arguments to the daemon. A listening address takes the form:

`[`<*transport-specifier*>`:]`<*transport-address*>

At its simplest, a listening address can consist of only a port number, in which case `snmpd` listens on that UDP port on all IPv4 interfaces. Otherwise, the <*transport-address*> part of the specification is parsed according to the following table:

<*transport-specifier*>	<*transport-address*> **format**
`udp`	*hostname*[:*port*] or *IPv4-address*[:*port*]
`tcp`	*hostname*[:*port*] or *IPv4-address*[:*port*]

<*transport-specifier*>	<*transport-address*> **format**
`unix`	*pathname*

Currently transports TCP/UDP over IPv4/IPv6 and unix domain sockets. Note that <*transport-specifier*> strings are case-insensitive so that, for example, `tcp` and `TCP` are equivalent. Below are some examples, with accompanying explanations.

`127.0.0.1:161`	Listen on UDP port 161, but only on the loopback interface. This prevents `snmpd` from being queried remotely. The `:161` is redundant because that is the default SNMP port.
`TCP:1161`	Listen on TCP port 1161 on all IPv4 interfaces.
`unix:/tmp/local-agent`	Listen on the Unix domain socket `/tmp/local-agent`.
`/tmp/local-agent`	Identical to the previous specification, because the Unix domain is the default transport if and only if the first character of <*transport-address*> is a slash (`/`).
`udp6:10161`	Listen on port 10161 on all IPv6 interfaces.

Note that not all the transport domains listed above will always be available. For example, hosts with no IPv6 support will not be able to use `udp6` transport addresses, and attempts to do so will result in the error "Error opening specified endpoint".

Files `snmpd` checks for the existence of and parses the following files:

`snmp.conf`	Common configuration for the agent and applications. See `snmp.conf(4)` for details.
`snmpd.local.conf`	Agent-specific configuration. See `snmp.conf(4)` for details. These files are optional and can be used to configure access control, trap generation, subagent protocols, and other features. In addition to these two configuration files, the agent will read any files with the names `snmpd.conf` and `snmpd.local.conf` in a colon-separated path specified in the `SNMPCONFPATH` environment variable, the default location upon agent startup are `/etc/sma/snmp` and `/usr/local/share/snmp`.
`/etc/sma/snmp/mibs`	The agent loads all files in this directory as MIBs. It does not, however, load any file that begins with a dot (`.`) or descend into subdirectories.

Exit Status

`0` Successful completion.

`1` A usage syntax error. A usage message is displayed. Also used for timeout errors.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmagt
Interface Stability	Stable

See Also svcadm(1M), svccfg(1M), snmp.conf(4), attributes(5), smf(5)

Notes In addition to basic privileges, to run successfully, the agent requires PRIV_NET_PRIVADDR. See privileges(5).

The snmpd service is managed by the service management facility, smf(5), under the service identifiers:

```
svc:/application/management/sma
svc:/application/management/seaport
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

The service uses the solaris.smf.manage.sma privilege. If /etc/sma/snmp/snmpd.conf contains DISABLE=YES, then the service does not start and displays the message:

```
snmpd disabled by config file /etc/sma/snmp/snmpd.conf
```

Name snmpdelta – monitor deltas of integer valued SNMP variables

Synopsis

```
/usr/sfw/bin/snmpdelta [common options] [-Cf] [-Ct] [-Cs]
     [-CS] [-Cm] [-CF configfile] [-Cl] [-Cp period]
     [-CP peaks] [-Ck] [-CT] [-Cv vars/pkt] agent OID
     [OID]...
```

Description The `snmpdelta` command monitors the specified integer-valued OIDs and reports changes over time.

The operand *agent* identifies a target SNMP agent, which is instrumented to monitor a given set of objects. At its simplest, the *agent* specification will consist of a hostname or an IPv4 address. With such an operand, the command attempts communication with the agent, using UDP/IPv4 to port 161 of the given target host. See `snmpcmd(1M)` for a full list of the possible formats for *agent*.

The operand *OID* is an object identifier that uniquely identifies the object type within a MIB. Multiple OIDs can be specified in a single `snmpdelta` command.

Options See `snmpcmd(1M)` for a list of *common options*. In addition to the *common options*, `snmpdelta` supports the options described below.

`-Cf` Do not fix errors and then retry the request. Without this option, if multiple OIDs have been specified for a single request and if the request for one or more of the OIDs fails, `snmpdelta` will retry the request so that data for OIDs apart from the ones that failed will still be returned. Specifying `-Cf` tells `snmpdelta` not to retry a request, even if there are multiple OIDs specified.

`-Ct` Determines time interval from the monitored entity.

`-Cs` Displays a timestamp.

`-CS` Generates a "sum count" in addition to the individual instance counts. The "sum count" is the total of all the individual deltas for each time period.

`-Cm` Displays the maximum value ever attained.

`-CF` *configfile* Tells `snmpdelta` to read its configuration from the specified file. This option allows the input to be set up in advance rather than having to be specified on the command line.

`-Cl` Tells snmpdelta to write its configuration to files whose names correspond to the MIB instances monitored. For example:

```
% snmpdelta -c public -v 1 -Cl localhost ifInOctets.1
```

...will create a file `localhost-ifInOctets.1`.

`-Cp` Specifies the number of seconds between polling periods. Polling involves sending a request to the agent. The default polling period is one second.

`-CP` *peaks* Specifies the reporting period in number of polling periods. If this option is specified, `snmpdelta` polls the agent *peaks* number of times before reporting the results. The result reported includes the average value over the reporting period. In addition, the highest polled value within the reporting period is shown.

`-Ck` When the polling period (`-Cp`) is an increment of 60 seconds and the timestamp is displayed in the output (`-Cs`), then the default display shows the timestamp in the format *hh:mm mm/dd*. This option causes the timestamp format to be *hh:mm:ss mm/dd* (adding seconds).

`-CT` Display output in tabular form.

`-Cv` *vars/pkt* Specifies the maximum number of OIDs allowed to be packaged in a single PDU. Multiple PDUs can be created in a single request. The default value of variables per packet is 60. This option is useful if a request response results in an error because the request packet is too big.

Examples

EXAMPLE 1 Obtaining Timestamped Output

The following command uses the `-Cs` option to timestamp output. This example assumes that there are at least three entries in your `ifTable`.

```
% snmpdelta -c public -v 1 -Cs localhost \
IF-MIB::ifInUcastPkts.3 IF-MIB::ifOutUcastPkts.3

[20:15:43 6/14] ifInUcastPkts.3 /1 sec: 158
[20:15:43 6/14] ifOutUcastPkts.3 /1 sec: 158
[20:15:44 6/14] ifInUcastPkts.3 /1 sec: 184
[20:15:44 6/14] ifOutUcastPkts.3 /1 sec: 184
[20:15:45 6/14] ifInUcastPkts.3 /1 sec: 184
[20:15:45 6/14] ifOutUcastPkts.3 /1 sec: 184
[20:15:46 6/14] ifInUcastPkts.3 /1 sec: 158
[20:15:46 6/14] ifOutUcastPkts.3 /1 sec: 158
[20:15:47 6/14] ifInUcastPkts.3 /1 sec: 184
[20:15:47 6/14] ifOutUcastPkts.3 /1 sec: 184
[20:15:48 6/14] ifInUcastPkts.3 /1 sec: 184
[20:15:48 6/14] ifOutUcastPkts.3 /1 sec: 184
[20:15:49 6/14] ifInUcastPkts.3 /1 sec: 158
[20:15:49 6/14] ifOutUcastPkts.3 /1 sec: 158
^C
```

EXAMPLE 2 Displaying Output in Tabular Form

The following command uses the `-CT` option to format output as a table. This example assumes that there are at least three entries in your `ifTable`.

```
% snmpdelta -c public -v 1 -Cs -CT localhost \
IF-MIB:ifInUcastPkts.3 IF-MIB:ifOutcastPkts.3 \
```

EXAMPLE 2 Displaying Output in Tabular Form *(Continued)*

```
localhost ifInUcastPkts.3 ifOutUcastPkts.3

[20:15:59 6/14] 184.00 184.00
[20:16:00 6/14] 158.00 158.00
[20:16:01 6/14] 184.00 184.00
[20:16:02 6/14] 184.00 184.00
[20:16:03 6/14] 158.00 158.00
[20:16:04 6/14] 184.00 184.00
[20:16:05 6/14] 184.00 184.00
[20:16:06 6/14] 158.00 158.00
^C
```

EXAMPLE 3 Sending Output to a File

The following example uses a number of options. This example assumes that there are at least four entries in your `ifTable`. Because the `-Cl` option is specified, the output is sent to a file and not to the screen.

```
% snmpdelta -c public -v 1 -Ct -Cs -CS -Cm -Cl -Cp 60 -CP 60 \
interlink.sw.net.cmu.edu .1.3.6.1.2.1.2.2.1.16.3 \
.1.3.6.1.2.1.2.2.1.16.4
```

Exit Status

`0` Successful completion.

`1` A usage syntax error. A usage message is displayed. Also used for timeout errors and for cases where an SNMP client session could not be opened.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

See Also `snmpcmd(1M)`, `snmp_variables(4)`, `attributes(5)`

Name snmpdf – get a listing of disk space usage on a remote machine by means of SNMP

Synopsis

```
/usr/sfw/bin/snmpdf [common options] [-Cu] agent
```

Description The `snmpdf` command is a networked verison of the `df(1M)` command. It checks the disk space on the remote machine by examining the `HOST-RESOURCES-MIB`'s `hrStorageTable` or the `UCD-SNMP-MIB`'s `dskTable`. By default, the `hrStorageTable` is preferred, as it typically contains more information than the `dskTable`. However, the `-Cu` argument can be passed to `snmpdf` to force the usage of `dskTable`.

The *agent* operand identifies a target SNMP agent, which is instrumented to monitor specified objects. At its simplest, the *agent* specification consists of a host name or an IPv4 address. In this situation, the command attempts communication with the agent using UDP/IPv4 to port 161 of the target host.

See the `snmpcmd(1M)` manual page for a full list of the possible formats for *agent*.

See the `snmpd.conf(4)` manual page for guidance on setting up `dskTable` using the disk directive in the `snmpd.conf` file.

Options The following options are supported:

common options — See `snmpcmd(1M)` for a list of possible values for *common options*, as well as their descriptions.

`-Cu` — Forces the command to use `dskTable` in `UCD-SNMP-MIB` instead of the default to determine the storage information. Generally, the default use of `hrStorageTable` in `HOST-RESOURCES-MIB` is preferred because it usually contains more information than `dskTable`.

Examples **EXAMPLE 1** Obtaining Disk Usage of a Remote System

The following command returns a display of the disk usage of a remote system.

```
Description size (kB) Used     Available Used%
/           7524587   2186910  5337677   29%
/proc       0         0        0          0%
/etc/mnttab 0         0        0          0%
/var/run    1223088   32       1223056    0%
/tmp        1289904   66848    1223056    5%
/cache      124330    2416     121914     1%
/vol        0         0        0          0%
Real Memory 524288    447456   76832     85%
Swap Space  1420296   195192   1225104   13%
```

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

Exit Status

`0` Successful completion.

`1` A usage syntax error. A usage message is displayed. Also used for timeout errors.

`2` An error occurred while executing the command. An error message is displayed.

See Also `df(1M)`, `snmpcmd(1M)`, `snmp.conf(4)`, `snmpd.conf(4)`, `attributes(5)`

Name snmpdx – Sun Solstice Enterprise Master Agent

Synopsis

```
/usr/lib/snmp/snmpdx [-hy] [-a filename] [-c config-dir]
     [-d debug-level] [-i filename] [-m GROUP -m SPLIT]
     [-o filename] [-p port] [-r filename]
```

Description The Master Agent, `snmpdx`, is the main component of Solstice Enterprise Agent (SEA) technology. It runs as a daemon process and listens to User Datagram Protocol (UDP) port 161 for SNMP requests. The Master Agent also opens another port to receive SNMP trap notifications from various subagents. These traps are forwarded to various managers, as determined by the configuration file.

Upon invocation, `snmpdx` reads its various configuration files and takes appropriate actions by activating subagents, determining the subtree Object Identifier (OID) for various subagents, populating its own Management Information Bases (MIBs), and so forth. The Master Agent invokes subagents, registers subagents, sends requests to subagents, receives responses from subagents, and traps notifications from subagents.

The Master Agent is invoked by the service management facility `smf(5)` at boot time if `svc:/application/management/snmpdx` is enabled (see NOTES) and contents of the resource configuration file `/etc/snmp/conf/snmpdx.rsrc` are non-trivial.

Note – The SMA (Systems Management Agent) is the default SNMP agent in the Solaris operating system. See `netsnmp(5)`. `snmpdx` is Obsolete and may not be supported in a future release of Solaris.

Options The following options are supported:

`-a`*filename*	Specify the full path of the access control file used by the Master Agent. The default access control file is `/etc/snmp/conf/snmpdx.acl`.
`-c`*config-dir*	Specify the full path of the directory containing the Master Agent configuration files. The default directory is `/etc/snmp/conf`.
`-d`*debug-level*	Debug. Levels from 0 to 4 are supported, giving various levels of debug information. The default is 0 which means no debug information is given.
`-h`	Help. Print the command line usage.
`-i`*filename*	Specify the full path of the enterprise-name OID map. This file contains the PID used by the Master Agent for recovery after a crash. It contains tuples of the UNIX process ID, port number, resource name, and agent name. The default file is `/var/snmp/snmpdx.st`.
`-m GROUP | -m SPLIT`	Specify the mode to use for forwarding of SNMP requests.

`GROUP` Multiple variables can be included in each request from the Master Agent to the subagents. This results in, at mose, one send-request per agent.

`SPLIT` Each variable in the incoming request results in one send-request to each subagent.

The default is `GROUP`.

`-o`*filename* Specify the full path of the file containing the tuple (enterprise-name, OID). For example, (Sun Microsystems, 1.3.1.6.1.4.32). The Master Agent uses this file as a base for look-up in the trap-filtering and forwarding process. The default file is `/etc/snmp/conf/enterprises.oid`.

`-p`*port* Specify the port number. The default port number is 161.

`-r`*filename* Specify the full path of the resource file to be used by the Master Agent. This file stores information about the subagents that the Master Agent invokes and manages. The default resource file is `/etc/snmp/conf/snmpdx.rsrc`.

`-y` Set a recovery indicator to invoke the recovery module. The recovery process discovers which subagents in the previous session are still active; those subagents not active are re-spawned by the Master Agent.

Files

`/etc/snmp/conf/enterprises.oid`	Enterprise-name OID map
`/etc/snmp/conf/snmpdx.acl`	Access control file
`/etc/snmp/conf/snmpdx.rsrc`	Resource configuration file
`/var/snmp/snmpdx.st`	Master Agent status file
`/var/snmp/mib/snmpdx.mib`	Master Agent MIB file

Exit Status The following error values are returned:

`0`	Successful completion.
non-zero	An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsasnm
Interface Stability	Obsolete

See Also attributes(5), netsnmp(5), smf(5)

Notes The snmpdx service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/application/management/snmpdx
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name snmpget – communicate with a network entity using SNMP GET requests

Synopsis `/usr/sfw/bin/snmpget [`*common options*`] [-Cf]` *oid* `[`*oid*`]...`

Description The `snmpget` utility is an SNMP application that uses the SNMP `GET` request to query for information on a network entity. You can specify one or more object identifiers (OIDs) as arguments on the command line. Each variable name must be specified in the format specified in `snmp_variables(4)`.

For example, the command:

```
# snmpget -c public zeus system.sysDescr.0
```

retrieves the variable `system.sysDescr.0`:

```
system.sysDescr.0 = "SunOS zeus.net.cmu.edu 4.1.3_U1 1 sun4m"
```

If the network entity has an error processing the request packet, an error packet is returned and a message displayed. The message indicates the way in which the request was malformed. If there were other variables in the request that were correctly formed, the request will be resent without the bad variable.

Options The following option is supported:

`-Cf` If `-Cf` is not specified, some applications (including `snmpgetnext(1M)` and `snmpget`) attempt to fix errors returned by the agent that you were talking to and resend the request. The `-Cf` option suppresses this fix-and-resend feature.

Fix-and-resend is useful if you specified a nonexistent OID in your request and you are using SNMPv1, which requires "all or nothing" types of requests. In the following example note that `system.sysUpTime` is an incomplete OID, because it requires the `.0` index appended to it:

```
# snmpget -v1 -Cf -c public localhost system.sysUpTime \
system.sysContact.0
Error in packet
Reason: (noSuchName) There is no such variable name in this MIB.
This name doesn't exist: system.sysUpTime

# snmpget -v1 -c public localhost system.sysUpTime system.sysContact.0
Error in packet
Reason: (noSuchName) There is no such variable name in this MIB.
This name doesn't exist: system.sysUpTime

system.sysContact.0 = STRING: root@localhost
```

In addition to this option, `snmpwalk` takes the common options described in the `snmpcmd(1M)` manual page.

Exit Status

`0` Successful completion.

`1` A usage syntax error. A usage message is displayed. Also used for timeout errors.

`2` An error occurred while executing the command. An error message is displayed.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

See Also `snmpcmd(1M)`, `snmp_variables(4)`, `attributes(5)`

Name snmpgetnext – communicate with a network entity using SNMP GETNEXT requests

Synopsis

```
snmpgetnext [-Cf] [common options] oid [oid]...
```

Description The `snmpgetnext` utility is an SNMP application that uses the SNMP `GETNEXT` request to query for information on a network entity. You can specify one or more object identifiers (OIDs) as arguments on the command line. Each variable name must be specified in the format specified in `snmp_variables(4)` . For each variable, the one that is lexicographically "next" in the remote entity's MIB is returned.

For example, the command:

```
# snmpgetnext -c public zeus interfaces.ifTable.ifEntry.ifType.1
```

retrieves the variable `interfaces.ifTable.ifEntry.ifType.2`:

```
interfaces.ifTable.ifEntry.ifType.2 = softwareLoopback(24)
```

If the network entity has an error processing the request packet, an error packet is returned and a message displayed. The message indicates the way in which the request was malformed.

Options The following options are supported:

`-Cf` If `-Cf` is not specified, some applications (including `snmpget(1M)` and `snmpgetnext`) attempt to fix errors returned by the agent that you were talking to and resend the request. The `-Cf` option suppresses this fix-and-resend feature.

Fix-and-resend is useful if you specified a nonexistent OID in your request and you are using SNMPv1, which requires "all or nothing" types of requests.

In addition to this option, `snmpgetnext` takes the common options described in the `snmpcmd(1M)` manual page.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

Exit Status

`0` Successful completion.

`1` A usage syntax error. A usage message is displayed. Also used for timeout errors.

`2` An error occurred while executing the command. An error message is displayed.

See Also `snmpcmd(1M)`, `snmpget(1M)`, `snmp_variables(4)`, `attributes(5)`

Name snmpnetstat – show network status using SNMP

Synopsis

```
/usr/sfw/bin/snmpnetstat [common options] [-a] [-n] agent

/usr/sfw/sma_snmp/bin/snmpnetstat [common options] [-iorns] agent

/usr/sfw/sma_snmp/bin/snmpnetstat [common options] [-in]
     [-I interface] agent [interval]

/usr/sfw/sma_snmp/bin/snmpnetstat [common options] [-an]
     [-s] [-P protocol] agent
```

Description The `snmpnetstat` command symbolically displays the values of various network-related information retrieved from a remote system using the SNMP protocol. There are a number of output formats, depending on the options for the information presented. Referring to the SYNOPSIS, above:

- The first form of the command displays a list of active sockets.
- The second form presents the values of other network-related information according to the option selected.
- The third form, with an interval specified, continuously displays the information regarding packet traffic on the configured network interfaces.
- The fourth form displays statistics about the named protocol.

The operand *agent* identifies a target SNMP agent that is instrumented to monitor the given objects. At its simplest, the *agent* specification consists of a host name or an IPv4 address. In this situation, the command attempts communication with the agent using UDP/IPv4 to port 161 of the target host. See `snmpcmd(1M)` for a full list of the possible formats for *agent*.

The version 1 and version 2c community specifies the community name for the transaction with the remote system.

Options The following options are supported:

common options	See `snmpcmd(1M)` for a list of possible values for common options, as well as their descriptions.
`-a`	With the default display, show the state of all sockets. Normally, sockets used by server processes are not shown.
`-i`	Show the state of all of the network interfaces. The interface display provides a table of cumulative statistics regarding packets transferred, errors, and collisions. The network addresses of the interface and the maximum transmission unit (MTU) are also displayed.
`-o`	Show an abbreviated interface status, giving octets in place of packets. This is useful when observing virtual interfaces (such as Frame Relay circuits) on a router.

`-I` *interface*	Show information only about this interface; used with an interval as described below.
`-n`	Show network addresses as numbers. (Normally, `snmpnetstat` interprets addresses and attempts to display them symbolically). This option can be used with any of the display formats.
`-P` *protocol*	Show statistics about *protocol*, which is either a well-known name for a protocol or an alias for it. Some protocol names and aliases are listed in the file `/etc/protocols` or in a naming service. A null response typically means that there are no interesting numbers to report. The program will complain if *protocol* is unknown or if there is no statistics routine for it.
`-s`	Show per-protocol statistics. When used with the `-r` option, show routing statistics instead.
`-r`	Show the routing tables. When `-s` is also present, show per-protocol routing statistics instead of the routing tables.
interval	When `snmpnetstat` is invoked with an interval argument, it displays a running count of statistics related to network interfaces. *interval* is the number of seconds between reporting of statistics.

`snmpnetstat` supports the following types of display:

active sockets display (default)	The default display, for active sockets, shows the local and remote addresses, protocol, and the internal state of the protocol. Address formats are of the form *host.port* or *network.port* if a socket's address specifies a network but no specific host address. When known, the host and network addresses are displayed symbolically according to `/etc/hosts` and `/etc/networks`, respectively. If a symbolic name for an address is unknown, or if the `-n` option is specified, the address is printed numerically, according to the address family. For more information regarding the Internet "dot format," refer to `inet(3SOCKET)`. Unspecified, or wildcard, addresses and ports appear as "`\(**`".
interface display	The interface display provides a table of cumulative statistics regarding packets transferred, errors, and collisions. The network addresses of the interface and the maximum transmission unit (MTU) are also displayed.

routing table display	The routing table display indicates the available routes and their status. Each route consists of a destination host or network and a gateway to use in forwarding packets. The flags field shows the state of the route (`U` if the route is up), whether the route is to a gateway (G), whether the route was created dynamically by a redirect (D), and whether the route has been modified by a redirect (M). Direct routes are created for each interface attached to the local host. The gateway field for such entries shows the address of the outgoing interface. The interface entry indicates the network interface used for the route.
interface display with an interval	When `snmpnetstat` is invoked with an interval argument, it displays a running count of statistics related to network interfaces. This display consists of a column for the primary interface and a column summarizing information for all interfaces. The primary interface can be replaced with another interface with the `-I` option. The first line of each screen of information contains a summary since the system was last rebooted. Subsequent lines of output show values accumulated over the preceding interval.
active sockets display for a single protocol	When a protocol is specified with the `-P` option, the information displayed is similar to that in the default display for active sockets, except the display is limited to the given protocol.

Note that figures `snmpnetstat` reports in the `Ipkts` column (part of the interface display) might differ from figures in the `Ipkts` column in `netstat(1M)`. `snmpnetstat` displays a total of unicast, multicast, and broadcast packets. `netstat` omits broadcast packets from its total.

Examples

EXAMPLE 1 Displaying Active Sockets

The following is an example of `snmpnetstat`'s default display, which is to display active sockets.

```
% snmpnetstat -v 2c -c public -a testhost

Active Internet (tcp) Connections (including servers)
Proto Local Address Foreign Address (state)
```

EXAMPLE 1 Displaying Active Sockets *(Continued)*

```
tcp   *.echo        *.*             LISTEN
tcp   *.discard     *.*             LISTEN
tcp   *.daytime     *.*             LISTEN
tcp   *.chargen     *.*             LISTEN
tcp   *.ftp         *.*             LISTEN
tcp   *.telnet      *.*             LISTEN
tcp   *.smtp        *.*             LISTEN

Active Internet (udp) Connections
Proto Local Address
udp   *.echo
udp   *.discard
udp   *.daytime
udp   *.chargen
udp   *.time

% snmpnetstat -v 2c -c public -i testhost

Name Mtu  Network   Address  Ipkts     Ierrs  Opkts  Oerrs Queue
eri0 1500 10.6.9/24 testhost 170548881 245601 687976 0     0
lo0  8232 127      localhost 7530982   0      7530982 0    0
```

EXAMPLE 2 Displaying Statistics for a Specific Protocol

The following example shows how snmpnetstat displays statistics for a specific protocol.

```
% snmpnetstat -v 2c -c public -P tcp testhost

Active Internet (tcp) Connections
Proto Local Address Foreign Address (state)
tcp   *.echo        *.*             LISTEN
tcp   *.discard     *.*             LISTEN
tcp   *.daytime     *.*             LISTEN
tcp   *.chargen     *.*             LISTEN
tcp   *.ftp         *.*             LISTEN
tcp   *.telnet      *.*             LISTEN
tcp   *.smtp        *.*             LISTEN
```

Exit Status

`0` Successful completion.

`1` A usage syntax error. A usage message is displayed.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

See Also iostat(1M), netstat(1M), snmpcmd(1M), vmstat(1M), attributes(5)

Name snmpset – communicate with a network entity using SNMP SET requests

Synopsis

```
snmpset [common options] oid type value [oid type value]...
```

Description The `snmpset` utility is an SNMP application that uses the SNMP `SET` request to set information on a network entity. A type and a value must accompany each object identifier. Each variable name must be entered in the format specified in `snmp_variables(4)`.

The *type* is a single character, one of:

```
i INTEGER
u UNSIGNED
c COUNTER32
s STRING
x HEX STRING
d DECIMAL STRING
n NULLOBJ
o OBJID
t TIMETICKS
a IPADDRESS
b BITS
```

If you have the proper MIB file loaded, you can, in most cases, replace the type with an equal sign (=). For an object of type `OCTET STRING` this assumes a string such as the "s"-type notation. For other types, `snmpset` interprets the data in the way you would expect.

For example, the command:

```
snmpset -c private -v 1 test-hub system.sysContact.0 s dpz@noc.rutgers.edu
ip.ipforwarding.0 = 2
```

sets the variables `sysContact.0` and `ipForwarding.0`, as follows:

```
system.sysContact.0 = STRING: "dpz@noc.rutgers.edu"
ip.ipForwarding.0 = INTEGER: not-forwarding(2)
```

If the network entity has an error processing the request packet, an error packet is returned and a message displayed, indicating the way in which the request was malformed.

Options `snmpset` takes the common options described in the `snmpcmd(1M)` manual page.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

Exit Status

`0`	Successful completion.
`1`	A usage syntax error. A usage message is displayed. Also used for timeout errors.
`2`	An error occurred while executing the command. An error message is displayed.

See Also `snmpcmd(1M)`, `snmp_variables(4)`, `attributes(5)`

Name snmptable – obtain and display an SNMP table

Synopsis

```
/usr/sfw/bin/snmptable [common options] [-Cb] [-CB] [-Cb]
     [-Ch] [-CH] [-Ci] [-Cf string] [-Cw width] [agent]
     [table-oid]
```

Description The `snmptable` command is an SNMP application that repeatedly uses the SNMP `GETNEXT` or `GETBULK` requests to query for information on a network entity. The operand *table-oid* must specify an SNMP table. Both numeric and symbolic (string) OIDs are supported.

The operand *agent* identifies a target SNMP agent that is instrumented to monitor manageable objects. At its simplest, the *agent* specification consists of a hostname or an IPv4 address. With such an address, the command attempts communication with the agent, using UDP/IPv4 to port 161 of the given target host. See `snmpcmd(1M)` for a full list of the possible formats for *agent*.

Options See `snmpcmd(1M)` for a list of *common options*. In addition to the *common options*, `snmptable` supports the options described below.

`-Cb` Display only a brief heading. Any common prefix of the table field names is not displayed.

`-CB` Use only `GETNEXT`, not `GETBULK`, requests to retrieve data.

`-Cf` *string* The string *string* is used to separate table columns. With this option, each table entry is printed in compact form, using only the specified string to separate the columns. This option can be useful if you intend to import the table into a database. Without this option, the table is displayed in vertically aligned columns.

`-Ch` Display only the column headings.

`-CH` Do not display the column headings or the table name. Only raw data is displayed.

`-Ci` Prepends the index of the entry to all printed lines.

`-Cw` *width* Specifies the width of the lines when the table is printed. If a line is longer than *width*, lines are truncated to fit within *width*.

Examples **EXAMPLE 1** Retrieving an SNMP Table

The following commands retrieve two-column SNMP tables.

```
% snmptable -v 2c -c public localhost at.atTable

SNMP table: at.atTable RFC1213-MIB::atTable
    atIfIndex atPhysAddress atNetAddress
    1 8:0:20:20:0:ab 130.225.243.33
```

EXAMPLE 1 Retrieving an SNMP Table *(Continued)*

```
% snmptable -v 2c -c public -Cf + localhost at.atTable

SNMP table: at.atTable
atIfIndex+atPhysAddress+atNetAddress
        1+8:0:20:20:0:ab+130.225.243.33
```

Exit Status

`0` Successful completion.

`1` A usage syntax error. A usage message is displayed. Also used for timeout errors.

`2` An error occurred while executing the command. An error message is displayed.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

See Also `snmpcmd(1M)`, `snmp_variables(4)`, `attributes(5)`

Bugs The test for *table-oid* actually specifying a table is not perfect. Note also that the test requires the defining MIB file to be loaded.

Name snmptest – communicate with a network entity using SNMP requests

Synopsis `/usr/sfw/bin/snmptest [`*common options*`] agent`

Description `snmptest` is a flexible SNMP application that can monitor and manage information on a network entity.

Invoking `snmptest` invokes a command line interpreter that accepts commands. This intepreter enables you to send different types of SNMP requests to target agents.

The operand *agent* identifies a target SNMP agent that is instrumented to monitor manageable objects. At its simplest, the *agent* specification consists of a host name or an IPv4 address. In this situation, the command attempts communication with the agent, using UDP/IPv4 to port 161 of the target host. See `snmpcmd(1M)` for a full list of the possible formats for *agent*.

After you invoke `snmptest`, the command line intepreter prompts with:

```
Variable:
```

At this point you can enter one or more variable names, one per line. A blank line ends the parameter input and sends the request (variables entered) in a single packet to the remote entity. Each variable name is given in the format specified in `snmp_variables(4)`. For example, the command:

```
snmptest -c public -v 1 zeus
Variable: system.sysDescr.0
Variable:
```

...returns information about the request and reply packets, as well as the data:

```
requestid 0x5992478A errstat 0x0 errindex 0x0
system.sysDescr.0 = STRING: "Unix 4.3BSD"
```

The `errstatus` value shows the error status code for the call. The possible values for errstat are in the header file `/usr/sfw/include/net-snmp/library/snmp.h`. The `errindex` value identifies the variable that has an error. Index values are assigned to all the variables entered at the `Variable:` prompt. The first value is assigned an index of 1.

Upon startup, the program defaults to sending a `GET` request packet. The type of request can be changed by typing one of the following commands at the `Variable:` prompt:

`$G` Send a `GET` request.

`$N` Send a `GETNEXT` request.

`$S` Send a `SET` request.

`$B` Send a `GETBULK` request. Note that `GETBULK` is not available in SNMPv1.

`$I` Send an inform request.

`$T` Send an SNMPv2 trap request.

Other values that can be entered at the `Variable:` prompt are:

`$D` Toggle the dumping of each sent and received packet.

`$QP` Toggle a quicker, less verbose output form.

`$Q` Quit the program.

The following are valid request types:

`GET` request — When in "`GET` request" mode (`$G` or default), you can enter an OID at the `Variable:` prompt. You can enter multiple OIDs, one per prompt. Enter a blank line to send the `GET` request.

`GETNEXT` request — The "`GETNEXT` request" mode (`$N`) is similar to the "`GET` request" mode, described above.

`SET` request — When in the "`SET` request" mode (`$S`), more information is requested by the prompt for each variable. The prompt:

```
Type [i|s|x|d|n|o|t|a]:
```

...requests the type of the variable be entered. Depending on the type of value you want to set, type one of the following:

- `i` integer
- `u` unsigned integer
- `s` octet string in ASCII
- `x` octet string in hex bytes, separated by whitespace
- `d` octet string as decimal bytes, separated by whitespace
- `a` IP address in dotted IP notation
- `o` object identifier
- `n` null
- `t` timeticks

At this point a value will be prompted for. To enter an integer value, just type the integer (in decimal). If it is a decimal string, type in whitespace-separated decimal numbers, one per byte of the string. Again, enter a blank line at the prompt for the variable name to send the packet.

`GETBULK` request — The "`GETBULK` request" mode (`$B`) is similar to the "`SET` request" mode. Note, however, that `GETBULK` is not available in SNMPv1.

Inform request	The "Inform request" mode ($I) is similar to the "SET request" mode. However, this type of request is not available in SNMPv1. Also, the *agent* specified in the `snmptest` command should correspond to the target `snmptrapd` agent.
SNMPv2 trap request	The "SNMPv2 trap request" mode ($T) is similar to the "SET request" mode. However, this type of request is not available in SNMPv1. Also, the *agent* specified in the `snmptest` command should correspond to the target `snmptrapd` agent.

Options `snmptest` takes the common options described in the `snmpcmd(1M)`.

Examples **EXAMPLE 1** Sending a GET Request for Two OIDs

The following is an example of sending a `GET` request for two OIDs:

```
% snmptest -v 2c -c public testhost:161

Variable: system.sysDescr.0
Variable: system.sysContact.0
Variable:
Received Get Response from 128.2.56.220
requestid 0x7D9FCD63 errstat 0x0 errindex 0x0
SNMPv2-MIB::sysDescr.0 = STRING: SunOS testhost 5.9 Generic_112233-02 sun4u
SNMPv2-MIB::sysContact.0 = STRING: x1111
```

EXAMPLE 2 Sending a GETNEXT Request

The following is an example of sending a `GETNEXT` request:

```
Variable: $N
Request type is Getnext Request
Variable: SNMPv2-MIB::sysORUpTime.1
Variable:
Received Get Response from 128.2.56.220
requestid 0x7D9FCD64 errstat 0x0 errindex 0x0
SNMPv2-MIB::sysORUpTime.2 = Timeticks: (6) 0:00:00.06
Variable:
```

EXAMPLE 3 Sending a SET Request

The following is an example of sending a `SET` request:

```
Variable: $S
Request type is Set Request
Variable: system.sysLocation.0
Type [i|u|s|x|d|n|o|t|a]: s
Value: building 17
Variable:
Received Get Response from 128.2.56.220
```

EXAMPLE 3 Sending a SET Request *(Continued)*

```
requestid 0x7D9FCD65 errstat 0x0 errindex 0x0
SNMPv2-MIB::sysLocation.0 = STRING: building A
Variable:
```

EXAMPLE 4 Sending a GETBULK Request

The following is an example of sending a `GETBULK` request:

```
Variable: $B
Request type is Bulk Request
Enter a blank line to terminate the list of non-repeaters
and to begin the repeating variables
Variable:
Now input the repeating variables
Variable: system.sysContact.0
Variable: system.sysLocation.0
Variable:
What repeat count? 2
Received Get Response from 128.2.56.220
requestid 0x2EA7942A errstat 0x0 errindex 0x0
SNMPv2-MIB::sysName.0 = STRING: testhost
SNMPv2-MIB::sysORLastChange.0 = Timeticks: (58) 0:00:00.58
SNMPv2-MIB::sysLocation.0 = STRING: bldg A
SNMPv2-MIB::sysORID.1 = OID: IF-MIB::ifMIB
Variable:
```

EXAMPLE 5 Sending an Inform Request

The following is an example of sending an Inform request:

```
snmptest -v 2c -c public snmptrapd_host:162
Variable: $I
Request type is Inform Request
(Are you sending to the right port?)
Variable: system.sysContact.0
Type [i|u|sIx|d|n|o|t|a]: s
Value: x12345
Variable:
Inform Acknowledged
Variable:
```

The `snmptrapd_host` will show:

```
snmptrapd_host [<ip address>]: Trap SNMPv2-MIB::sysContact.0 = STRING: x12345
```

EXAMPLE 6 Sending an SNMPv2 Trap Request

The following is an example of sending an SNMPv2 Trap request:

EXAMPLE 6 Sending an SNMPv2 Trap Request *(Continued)*

```
snmptest -v 2c -c public snmptrapd_host:162
Variable: $T
Request type is SNMPv2 Trap Request
(Are you sending to the right port?)
Variable: system.sysLocation.0
Type [i|u|s|x|d|n|o|t|a]: s
Value: building a
Variable:
```

The `snmptrapd_host` will show:

```
snmptrapd_host [<ip address>]: Trap SNMPv2-MIB::sys.0 = STRING:
building A
```

Exit Status

`0` Successful completion.

`1` A usage syntax error. A usage message is displayed. Also used for timeout errors.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

`snmpcmd(1M)`, `snmpget(1M)`, `snmpset(1M)`, `snmp_variables(4)`, `attributes(5)`

Name snmptranslate – translate SNMP OID values into a more useful form

Synopsis

```
/usr/sfw/bin/snmptranslate [-D token...] [-h] [-m miblist]
     [-M dirlist] [-T transopts] [common options] OID
     [OID]...
```

Description `snmptranslate` is an application that translates one or more SNMP object identifier values from their symbolic (text) forms into their numerical forms or vice-versa.

OID is either a numeric or text object identifier.

Options The following options are supported:

`-D` *token*[,...] Turn on debugging output for the specified *token*(s). Use `ALL` for extremely verbose output.

`-h` Display a brief usage message and then exit.

`-m` *miblist* Specifies a colon-separated list of MIB modules to load for this application. This overrides the environment variable `MIBS`.

The special keyword `ALL` is used to specify all modules in all directories when searching for MIB files. Every file whose name does not begin with "." is parsed as if it were a MIB file.

`-M` *dirlist* Specifies a colon-separated list of directories to search for MIBs. This overrides the environment variable `MIBDIRS`.

`-T` *transopts* Provides control over the translation of the OID values. The following *transopts* are available:

- `-Td` Display full details of the specified OID.
- `-Tp` Display a graphical tree, rooted at the specified OID.
- `-Ta` Dump the loaded MIB in a trivial form.
- `-Tl` Dump a labeled form of all objects.
- `-To` Dump a numeric form of all objects.
- `-Ts` Dump a symbolic form of all objects.
- `-Tt` Dump a tree form of the loaded MIBs (mostly useful for debugging).
- `-V` Display version information for the application and then exit.
- `-w` *width* Specifies the width of `-Tp` and `-Td` output. The default is very large.

In addition to the preceding options, `snmptranslate` takes the OID input (`-I`), MIB parsing (`-M`) and OID output (`-O`) options described in the `INPUT OPTIONS`, `MIB PARSING OPTIONS` and `OUTPUT OPTIONS` sections of snmpcmd(1M).

Examples

EXAMPLE 1 Expanding `sysDescr`

The following command translates `sysDescr` to a more qualified form:

```
% snmptranslate -On -IR sysDescr

.1.3.6.1.2.1.1.1
```

The following command does further translation of `sysDescr`:

```
% snmptranslate -Onf -IR sysDescr

.iso.org.dod.internet.mgmt.mib-2.system.sysDescr
```

Again, the following command does further translates `sysDescr`:

```
% snmptranslate -Td -IR -OS system.sysDescr

SNMPv2-MIB::sysDescr
sysDescr OBJECT-TYPE
 -- FROM SNMPv2-MIB
 -- TEXTUAL CONVENTION DisplayString
 SYNTAX OCTET STRING (0..255)
 DISPLAY-HINT "255a"
 MAX-ACCESS read-only
 STATUS current
 DESCRIPTION "A textual description of the entity. This
 value should include the full name and
 version identification of the system's
 hardware type, software operating-system,
 and networking software."
::= { iso(1) org(3) dod(6) internet(1) mgmt(2) mib-2(1) system(1) 1 }
```

EXAMPLE 2 Displaying a Tree

The following command displays the tree shown below:

```
% snmptranslate -Tp -IR -OS system

+--system(1)
 |
 +-- -R-- String sysDescr(1)
 | Textual Convention: DisplayString
 | Size: 0..255
 +-- -R-- ObjID sysObjectID(2)
 +-- -R-- TimeTicks sysUpTime(3)
```

EXAMPLE 2 Displaying a Tree *(Continued)*

```
|  |
|  +-- sysUpTimeInstance(0)
|
+-- -RW- String sysContact(4)
| Textual Convention: DisplayString
| Size: 0..255
+-- -RW- String sysName(5)
| Textual Convention: DisplayString
| Size: 0..255
+-- -RW- String sysLocation(6)
| Textual Convention: DisplayString
| Size: 0..255
+-- -R-- INTEGER sysServices(7)
|        Range: 0..127
+-- -R-- TimeTicks sysORLastChange(8)
| Textual Convention: TimeStamp
|
+--sysORTable(9)
   |
   +--sysOREntry(1)
      |  Index: sysORIndex(1)
      |
      +-- ---- INTEGER sysORIndex(1)
      |        Range: 1..2147483647
      +-- -R-- ObjID sysORID(2)
      +-- -R-- String sysORDescr(3)
      | Textual Convention: DisplayString
      | Size: 0..255
      +-- -R-- TimeTicks sysORUpTime(4)
               Textual Convention: TimeStamp
```

EXAMPLE 3 Dumping MIB Contents

The commands shown below produce the dumps that follow.

```
% snmptranslate -Ta | head

dump DEFINITIONS ::= BEGIN
org ::= { iso 3 }
dod ::= { org 6 }
internet ::= { dod 1 }
directory ::= { internet 1 }
mgmt ::= { internet 2 }
experimental ::= { internet 3 }
private ::= { internet 4 }
```

EXAMPLE 3 Dumping MIB Contents *(Continued)*

```
security ::= { internet 5 }
snmpV2 ::= { internet 6 }
```

Here is use of the `-Tl` option:

```
% snmptranslate -Tl | head

.iso(1).org(3)
.iso(1).org(3).dod(6)
.iso(1).org(3).dod(6).internet(1)
.iso(1).org(3).dod(6).internet(1).directory(1)
.iso(1).org(3).dod(6).internet(1).mgmt(2)
.iso(1).org(3).dod(6).internet(1).mgmt(2).mib-2(1)
.iso(1).org(3).dod(6).internet(1).mgmt(2).mib-2(1).system(1)
.iso(1).org(3).dod(6).internet(1).mgmt(2).mib-2(1).system(1).sysDescr(1)
.iso(1).org(3).dod(6).internet(1).mgmt(2).mib-2(1).system(1).sysObjectID(2)
.iso(1).org(3).dod(6).internet(1).mgmt(2).mib-2(1).system(1).sysUpTime(3)
```

Here is the use of the `-To` option:

```
% snmptranslate -To | head

.1.3
.1.3.6
.1.3.6.1
.1.3.6.1.1
.1.3.6.1.2
.1.3.6.1.2.1
.1.3.6.1.2.1.1
.1.3.6.1.2.1.1.1
.1.3.6.1.2.1.1.2
.1.3.6.1.2.1.1.3
```

Here is the use of the `-Ts` option:

```
% snmptranslate -Ts | head

.iso.org
.iso.org.dod
.iso.org.dod.internet
.iso.org.dod.internet.directory
.iso.org.dod.internet.mgmt
.iso.org.dod.internet.mgmt.mib-2
.iso.org.dod.internet.mgmt.mib-2.system
.iso.org.dod.internet.mgmt.mib-2.system.sysDescr
.iso.org.dod.internet.mgmt.mib-2.system.sysObjectID
.iso.org.dod.internet.mgmt.mib-2.system.sysUpTime
```

EXAMPLE 3 Dumping MIB Contents *(Continued)*

Here is the use of the `-Tt` option:

```
% snmptranslate -Tt | head

org(3) type=0
  dod(6) type=0
    internet(1) type=0
      directory(1) type=0
      mgmt(2) type=0
        mib-2(1) type=0
          system(1) type=0
            sysDescr(1) type=2 tc=4 hint=255a
            sysObjectID(2) type=1
            sysUpTime(3) type=8
```

Exit Status

`0` Successful completion.

`1` A usage syntax error. A usage message is displayed. Also used for matching object errors, after which an error message is displayed.

`2` An error occurred while executing the command. An error message is displayed.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

See Also `snmpcmd(1M)`, `snmp_variables(4)`, `attributes(5)`

Name snmptrap, snmpinform – send an SNMP trap to a manager

Synopsis

```
snmptrap -v 1 [common options] [-Ci] enterprise-oid agent generic-trap specific-trap uptime
     [oid type value]...

snmptrap -v {2c | 3} [common options] [-Ci] uptime trap-oid
     [oid type value]...

snmptrap -v {2c | 3} [common options] uptime trap-oid
     [oid type value]...
```

Description The `snmptrap` utility is an SNMP application that uses the SNMP `TRAP` operation to send information to a network manager. You can specify one or more object identifiers (OIDs) on the command line. A type and a value must accompany each object identifier. Each variable name must be entered in the format specified in `snmp_variables(4)`.

When invoked as `snmpinform`, or when you specify the `-Ci` option to `snmptrap`, it sends an `INFORM-PDU`, expecting a response from the trap receiver, and retransmitting if required. Otherwise, it sends a `TRAP-PDU` or `TRAP2-PDU`.

If any of the required version 1 parameters—`enterprise-oid`, `agent`, and `uptime`—are specified as empty, they default to 1.3.6.1.4.1.3.1.1 (`enterprises.cmu.1.1`), `hostname`, and `host-uptime` respectively.

The *type* is a single character, one of:

```
i INTEGER
u UNSIGNED
c COUNTER32
s STRING
x HEX STRING
d DECIMAL STRING
n NULLOBJ
o OBJID
t TIMETICKS
a IPADDRESS
b BITS
```

For example, the following command sends a generic `linkUp` trap to `manager`, for interface 1:

```
# snmptrap -v 1 -c public manager enterprises.spider test-hub 3 0 ''
interfaces.iftable.ifentry.ifindex.1 i 1
```

Options The following option is supported:

`-Ci` Sends an `INFORM-PDU`, as described above. Applies only to `snmptrap`. This option provides the equivalent function of `snmpinform`.

In addition to this option, `snmptrap` takes the common options described in the `snmpcmd(1M)` manual page.

Exit Status `0` Successful completion.

1 A usage syntax error. A usage message is displayed.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmcmd
Interface Stability	External

See Also snmpcmd(1M), snmp_variables(4), attributes(5)

Name snmptrapd – receive and log SNMP trap messages

Synopsis `/usr/sfw/sbin/snmptrapd [`*options*`] [`*listening addresses*`]`

Description The `snmptrapd` utility is an SNMP application that receives and logs SNMP `TRAP` and `INFORM` messages.

The default is to listen on UDP port 162 on all IPv4 interfaces. Because 162 is a privileged port, `snmptrapd` must be be run as root.

Options This command supports the following options:

`-a`	Ignore `authenticationFailure` traps.
`-c` *file*	Read *file* as a configuration file.
`-C`	Do not read any configuration files except the one optionally specified by the `-c` option.
`-d`	Dump (in hexadecimal) the sent and received SNMP packets.
`-D` *token*[,...]	Turn on debugging output for the specified *token*(s). Use `ALL` for extremely verbose output.
`-e`	Print event numbers (rising/falling alarm, and so forth).
`-f`	Do not call `fork()` from the calling shell.
`-F` *format*	When logging to standard output, use the format in the string *format*. See *Format Specifications* below for more details.
`-h`, `--help`	Display a brief usage message and then exit.
`-H`	Display a list of configuration file directives understood by the trap daemon and then exit.
`-l` d | 0–7	Specifies the `syslog(3C)` facility to use when logging to syslog. `d` means `LOG_DAEMON`; `0` through `7` means `LOG_LOCAL0` through `LOG_LOCAL7`. `LOG_LOCAL0` is the default.
`-m` *miblist*	Specifies a colon-separated list of MIB modules to load for this application. This overrides the environment variable `MIBS`.
`-M` *dirlist*	Specifies a colon-separated list of directories to search for MIBs. This overrides the environment variable `MIBDIRS`.
`-n`	Do not attempt to translate source addresses of incoming packets into host names.
`-o` *file*	Log formatted incoming traps to *file*. Upon receipt of a `SIGHUP`, the daemon will close and reopen the log file. This feature is useful when rotating the log file with other utilities such as `logrotate`.

`-P`	Print formatted incoming traps to `stderr`.
`-s`	Log formatted incoming traps to `syslog(3C)`. These `syslog` messages are sent with a level of `LOG_WARNING` and facility as determined by the `-l` flag (`LOG_LOCAL0` by default). This is the default unless you use the `-o` or `-P` flag.
`-u` *file*	Save the process ID of the trap daemon in *file*.
`-v`, `--version`	Print version information for the trap daemon and then exit.

In addition to the preceding options, `snmptrapd` takes the same output formatting options as the other Net-SNMP commands. See the section *OUTPUT OPTIONS* in `snmpcmd(1M)`.

For extensibility and configuration information, see `snmptrapd.conf(4)`.

Format Specifications

`snmptrapd` interprets format strings similarly to `printf(3C)`. It interprets the following formatting sequences:

`%%`	A literal percent sign(`%`).
`%t`	Decimal number of seconds since the operating system's epoch, as returned by `time(2)`.
`%y`	Current year on the local system.
`%m`	Current (numeric) month on the local system.
`%l`	Current day of month on the local system.
`%h`	Current hour on the local system.
`%j`	Current minute on the local system.
`%k`	Current second on the local system.
`%T`	The value of the `sysUpTime.0` *varbind* in seconds.
`%Y`	The year field from the `sysUpTime.0` *varbind*.
`%M`	The numeric month field from the `sysUpTime.0` *varbind*.
`%L`	The day of month field from the `sysUpTime.0` *varbind*.
`%H`	The hour field from the `sysUpTime.0` *varbind*.
`%J`	The minute field from the `sysUpTime.0` *varbind*.
`%K`	The seconds field from the `sysUpTime.0` *varbind*.
`%a`	The contents of the `agent-addr` field of the PDU (v1 `TRAP`s only).
`%A`	The hostname corresponding to the contents of the `agent-addr` field of the PDU, if available. Otherwise the contents of the `agent-addr` field of the PDU (v1 `TRAP`s only).
`%b`	PDU source address (note that this is not necessarily an IPv4 address).

`%B` PDU source hostname if available, otherwise PDU source address (which is not necessarily an IPv4 address).

`%N` Enterprise string.

`%w` Trap type (numeric, in decimal).

`%W` Trap description.

`%q` Trap sub-type (numeric, in decimal).

`%P` Security information from the PDU (community name for v1/v2c, user and context for v3).

`%v` List of trap's variable-bindings.

In addition to these values, you can also specify an optional field width and precision, just as in `printf(3C)`, and a flag value. The following flags are valid:

`-` left justify

`0` use leading zeros

`#` use alternate form

The "use alternate form" flag changes the behavior of some format flags. Normally, the fields that display time information base it on the local timezone, but this flag tells them to use GMT instead. Also, the variable-binding list is normally a tab-separated list, but this flag changes it to a comma-separated one. The alternate form for the uptime is similar to "3 days, 0:14:34.65".

Listening Addresses

By default, `snmptrapd` listens for incoming SNMP `TRAP` and `INFORM` packets on UDP port 162 on all IPv4 interfaces. However, it is possible to modify this behavior by specifying one or more listening addresses as arguments to `snmptrapd`. See `snmpd(1M)` for more information about the format of listening addresses.

NOTIFICATION-LOG-MIB Support

As of Net-SNMP 5.0, the `snmptrapd` application supports the `NOTIFICATION-LOG-MIB`. It does this by opening an AgentX subagent connection to the master `snmpd` agent and registering the notification log tables. As long as the `snmpd` application is started first, it will attach itself to it. Thus you should be able to view the last recorded notifications by means of the `nlmLogTable` and `nlmLogVariableTable`. See `snmptrapd.conf(4)` and the `dontRetainLogs` token for turning off this support. See the `NOTIFICATION-LOG-MIB` for more details about the MIB itself.

Examples

EXAMPLE 1 Using `snmptrapd`

To get a message such as `14:03 TRAP3.1 from humpty.example.edu` you can use a command similar to:

```
# snmptrapd -P -F "%02.2h:%02.2j TRAP%w.%q from %A\n"
```

EXAMPLE 1 Using `snmptrapd` *(Continued)*

If you want the same effect, but in GMT rather than local time, use:

```
# snmptrapd -P -F "%#02.2h:%#02.2j TRAP%w.%q from %A\n"
```

EXAMPLE 2 Viewing Traps on the Host on Which You Invoke `snmptrapd`

To view traps on the host from which you invoke `snmptrapd`, enter:

```
# snmptrapd -P
```

The preceding command sends output to stdout rather than to a log file.

Exit Status

`0` Successful completion.

`1` A usage syntax error. A usage message is displayed. Also used for timeout errors.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmagt

Name snmpusm – create and maintain SNMPv3 users on a remote entity

Synopsis

```
snmpusm [common options] AGENT create user [clonefrom-user]

snmpusm [common options] AGENT delete user

snmpusm [common options] AGENT cloneFrom user clonefrom-user

snmpusm [common options] [-Co] [-Ca] [-Cx] AGENT passwd old-passphrase new-passphrase
```

Description The `snmpusm` utility is an SNMP application that can be used to do simple maintenance on an SNMP agent's User-based Security Module (USM) table. The user needs write access to the usmUserTable MIB table. You can create, delete, clone, and change the passphrase of users configured on a running SNMP agent.

The SNMPv3 USM specifications (see RFC 3414) dictate that users are created and maintained by adding and modifying rows to the `usmUserTable` MIB table. To create a new user you simply create the row using `snmpset(1M)`. User's profiles contain private keys that are never transmitted over the wire in clear text, regardless of whether the administration requests are encrypted.

The secret key for a user is initially set by cloning another user in the table, so that a new user inherits the cloned user's secret key. A user can be cloned only once, however, after which they must be deleted and re-created to be re-cloned. The authentication and privacy security types are also inherited during this cloning (for example, MD5 vs. SHA1). To change the secret key for a user, you must know the user's old passphrase as well as the new one. The `passwd` subcommand of the `snmpusm` command requires both the new and the old passphrases be supplied. After cloning from the appropriate template, you should immediately change the new user's passphrase.

The Net-SNMP agent must first be initialized so that at least one user is setup in it before you can use this command to clone new ones. See the `snmpd.conf(4)` manual page for a description of the `createUser` configuration parameter.

Passphrases must be a minimum of eight characters in length.

Options See `snmpcmd(1M)` for a description of *common options*.

Examples Assume for our examples that the following VACM and USM configurations lines are in the `snmpd.conf` file for a Net-SNMP agent. These lines set up a default user named `initial` with the authentication passphrase `setup_passphrase`. Establishing these parameters enables the initial setup of an agent.

```
# VACM configuration entries
rwuser initial
# The name of the new user that is going to be created
rwuser wes
# USM configuration entries
createUser initial MD5 setup_passphrase DES
```

Note that the `initial` user's setup should be removed after creating a real user to whom you grant administrative privileges. The real user is `wes` in this example.

EXAMPLE 1 Creating a New User

The following command creates a new user, `wes`, which is cloned from `initial`. `wes` inherits that user's passphrase, `setup_passphrase`.

```
# snmpusm -v3 -u initial -n "" -l authNoPriv -a MD5 -A setup_passphrase \
 localhost create wes initial
```

EXAMPLE 2 Changing the User's Passphrase

After creating the user `wes` with the same passphrase as the user `initial`, we need to change his passphrase for `wes`. The following command changes it from `setup_passphrase`, which was inherited from `initial`, to `new_passphrase`.

```
# snmpusm -v 3 -u wes -n "" -l authNoPriv -a MD5 -A setup_passphrase \
localhost passwd setup_passphrase new_passphrase
```

EXAMPLE 3 Testing the New User

If the preceding commands were successful, the following command should perform an authenticated SNMPv3 GET request to the agent.

```
# snmpget -v 3 -u wes -n "" -l authNoPriv -a MD5 -A new_passphrase \
localhost sysUpTime.0
```

Following a successful test, remove the VACM `group` `snmpd.conf` entry for the user `initial`. At this point, you have a valid user `wes` that you can use for future transactions.

Exit Status

`0` Successful completion.

`1` A usage syntax error. A usage message is displayed. Also used for timeout errors.

`2` An error occurred while executing the command. An error message is displayed.

Attributes

RFC 3414

Name snmpvacm – perform maintenance on an SNMP agent's View-based Access Control Module (VACM) table

Synopsis `/usr/sfw/bin/snmpvacm [`*common options*`] [`*subcommand options*`] AGENT subcommand subcommand-ar`

Description `snmpvacm` is a SNMP application that can be used to do maintenance on an SNMP agent's View-based Access Control Module (VACM) table. The VACM table defines a set of services that can be used for checking access rights, that is, checking whether a specific type of access to a specific managed object is allowed. `snmpvacm` supports three types of entries--group, view, and access. The agent maintains these entries in memory and stores VACM groups, views, and access entries in the persistent configuration file upon agent shutdown.

Subcommands This section describes the `snmpvacm` subcommands.

`createSec2Group` Creates SNMPv3 security to group name entries. A group name is used to define an access control policy for a group of principals.

Creates SNMPv3 security to group name entries. A group name is used to define an access control policy for a group of principals.

`snmpvacm [`*common options*`] createSec2Group MODEL SECURITYNAME GROUPNAME`

`MODEL` An integer greater then zero representing a SNMPv3 security model, such as USM. The reserved values are as follows:

`1` reserved for SNMPv1

`2` reserved for SNMPv2c

`3` User-Based Security Model (USM)

`SECURITYNAME` A string representing a security name for the principal, represented in a security-model-independent format, which is mapped from this entry to a `GROUPNAME`.

`GROUPNAME` A string that identifies the group to which this table entry (the combination of `securityModel` and `securityName`) belongs.

`deleteSec2Group` Deletes SNMPv3 security to group name entries. The group entry to be deleted is indexed by the specified `MODEL` and `SECURITYNAME`.

`snmpvacm [`*common options*`] deleteSec2Group MODEL SECURITYNAME`

`MODEL` An integer greater then zero representing a SNMPv3 security model, such as USM. The reserved values are as follows:

`1` reserved for SNMPv1

2 reserved for SNMPv2c

3 User-Based Security Model (USM)

`SECURITYNAME` A string representing a security name for the principal, represented in a security-model-independent format, which is mapped from this entry to a GROUPNAME.

`createView` Creates a MIB view. A MIB view is a family of view subtrees, which are pairings of OID subtree values with bit string mask values.

Each MIB view is defined by two sets of view subtrees, included in or excluded from the MIB view.

`snmpvacm [`*common options*`] [-Ce] createView NAME SUBTREE MASK`

`-Ce` An optional flag used when the MIB view type needs to be "excluded" from the MIB view. If not used, the type is defaulted to "included".

`NAME` The OID subtree which when combined with the corresponding instance of MASK defines a family of view subtrees.

`SUBTREE` The OID subtree which when combined with the corresponding instance of MASK defines a family of view subtrees.

`MASK` The bit mask, a hex string, which, in combination with the corresponding instance SUBTREE, defines a family of view subtrees.

The mask indicates which sub-identifiers of the associated subtree OID are significant to a particular MIB view instance.

`deleteView` Deletes a MIB view. A MIB view is a family of view subtrees. A view subtree is a pairing of an OID subtree value with a bit string mask value.

`snmpvacm [`*common options*`] deleteView NAME SUBTREE`

`NAME` A string representing a MIB view name that is associated to a subtree/mask pairing.

`SUBTREE` The OID subtree which, when combined with the corresponding instance of MASK, defines a family of view subtrees.

`createAccess` Creates SNMPv3 access configuration entries. These entries are used to store the access rights defined for the groups. Each entry is indexed by a

group name, a context prefix, a security model, and a security level. A group and view needs to be defined in order to make use of the access check.

```
snmpvacm [common options] createAccess GROUPNAME
[CONTEXTPREFIX] SECURITYMODEL SECURITYLEVEL
CONTEXTMATCH READVIEWNAME WRITEVIEWNAME
NOTIFYVIEWNAME
```

`GROUPNAME` The name of the group to which this access right applies.

`CONTEXTPREFIX` A string representing a `contextName` must match the value of the instance of this object exactly when `CONTEXTMATCH` is set to “exact” or partially when `CONTEXTMATCH` is set to “prefix”.

If not specified, the value reverts to the default, an empty string, "".

`SECURITYMODEL` An integer representing the `securityModel` that must be used in order to gain access to this access right.

`SECURITYLEVEL` An integer representing the minimum security level that must be used to gain access to this access right. A security level of `noAuthNoPriv` is less than `authNoPriv` and `authNoPriv` is less than `authPriv`.

Integer values supported:

1 `noAuthNoPriv`

2 `authNoPriv`

3 `authPriv`

`CONTEXTMATCH` An integer whose value determines the type of match required. When set to "exact", the context name must exactly match the value in `CONTEXTPREFIX`. If set to "prefix", the context name must match the first few starting characters of the value in `CONTEXTPREFIX`.

Integer values supported:

1 exact

2 prefix

`READVIEWNAME` The authorized MIB view name used for read access. If the value is an empty string, then there is no active view configured for read access.

`WRITEVIEWNAME` The authorized MIB view name used for write access. If the value is an empty string, then there is no active view configured for write access.

`NOTIFYVIEWNAME` The authorized MIB view name used for notify access. If the value is an empty string, then there is no active view configured for notify access.

`deleteAccess` Deletes SNMPv3 access configuration entries, given a group name, context prefix, security model, and security level.

```
snmpvacm [common options] deleteAccess GROUPNAME
[CONTEXTPREFIX] SECURITYMODEL SECURITYLEVEL
```

`GROUPNAME` The name of the group to which this access right applies.

`CONTEXTPREFIX` A string representing a `contextName` must match the value of the instance of this object exactly when `CONTEXTMATCH` is set to "exact" or partially when `CONTEXTMATCH` is set to "prefix".

`SECURITYMODEL` An integer representing the `securityModel` that must be used to gain access to this access right.

`SECURITYLEVEL` An integer representing the minimum security level that must be used to gain access to this access right. A security level of `noAuthNoPriv` is less than `authNoPriv` and `authNoPriv` is less than `authPriv`.

The following integer values are supported:

1 `noAuthNoPriv`

2 `authNoPriv`

3 `authPriv`

Examples

For the following examples, the user is my_user and the password is my_password. Use `net-snmp-config` to create the first user (`my_user`). Then clone `my_user` to configure another SNMPv3 user, `my_user_2`. See snmpusm(1M).

EXAMPLE 1 Creating a VACM Group Entry

Create a VACM group entry, as follows:

EXAMPLE 1 Creating a VACM Group Entry *(Continued)*

```
snmpvacm -v 3 -u my_user -l authPriv -a MD5 -A
        my_password -x DES -X my_password localhost createSec2Group
        3 my_user_2 my_group
```

Run snmpwalk(1M) to verify the group name was created:

```
snmpwalk -v 3 -u my_user -l authPriv -a MD5 -A
        my_password -x DES -X my_password localhost
        SNMP-VIEW-BASED-ACM-MIB::vacmGroupName
```

In addition to other configured VACM group entries, you will note an entry such as the following:

```
SNMP-VIEW-BASED-ACM-MIB::vacmGroupName.3."my_user_2" = STRING: my_group
```

EXAMPLE 2 Creating a MIB View Entry

The command below creates a MIB view entry applicable only to the system group MIB.

```
snmpvacm -v 3 -u my_user -l authPriv -a MD5 -A
        my_password -x DES -X my_password localhost createView
        my_view .1.3.6.1.2.1.1 FF
```

Run snmpwalk(1M) to verify the `my_view` MIB view was created:

```
snmpwalk -v 3 -u my_user -l authPriv -a MD5 -A
        my_password -x DES -X my_password localhost
        SNMP-VIEW-BASED-ACM-MIB::vacmViewTreeFamilyTable
```

In `snmpwalk` output, observe the lines, such as those below, related to the `my_view` MIB view.

```
SNMP-VIEW-BASED-ACM-MIB::vacmViewTreeFamilyMask."my_view".2.1.3.6.1.2.1.1\
= Hex-STRING: FF
SNMP-VIEW-BASED-ACM-MIB::vacmViewTreeFamilyType."my_view".2.1.3.6.1.2.1.1\
= INTEGER: included(1)
SNMP-VIEW-BASED-ACM-MIB::vacmViewTreeFamilyStorageType.\
"my_view".2.1.3.6.1.2.1.1 = INTEGER: nonVolatile(3)
SNMP-VIEW-BASED-ACM-MIB::vacmViewTreeFamilyStatus.\
"my_view".2.1.3.6.1.2.1.1 = INTEGER: active(1)
```

EXAMPLE 3 Creating an Access Entry

The command below creates an access entry using the following components:

- the "`my_group`" entry created above
- an empty prefix string ("")
- the USM security model (3)
- the security level (3)

EXAMPLE 3 Creating an Access Entry *(Continued)*

- the context match (1)
- the read view name ("my_view")
- the write view name ("")
- the notify view name ("")

```
snmpvacm -v 3 -u my_user -l authPriv -a MD5 -A
        my_password -x DES -X my_password localhost createAccess
        my_group "" 3 3 1 my_view "" ""
```

Run snmpwalk(1M) to verify the access entry was created:

```
snmpwalk -v 3 -u my_user -l authPriv -a MD5 -A
        my_password -x DES -X my_password localhost
        SNMP-VIEW-BASED-ACM-MIB::vacmAccessTable

SNMP-VIEW-BASED-ACM-MIB::vacmAccessContextMatch."my_group"."".3.authPriv\
= INTEGER: exact(1)
SNMP-VIEW-BASED-ACM-MIB::vacmAccessReadViewName."my_group"."".3.authPriv\
= STRING: my_view
SNMP-VIEW-BASED-ACM-MIB::vacmAccessWriteViewName."my_group"."".3.authPriv\
= STRING:
SNMP-VIEW-BASED-ACM-MIB::vacmAccessNotifyViewName."my_group"."".3.authPriv\
= STRING:
SNMP-VIEW-BASED-ACM-MIB::vacmAccessStorageType."my_group"."".3.authPriv\
= INTEGER: nonVolatile(3)
SNMP-VIEW-BASED-ACM-MIB::vacmAccessStatus."my_group"."".3.authPriv\
= INTEGER: active(1)
```

EXAMPLE 4 Testing the Configuration

Test the preceding setup by verifying the access setup. You do this by accessing an object in the system group and another object outside this range. Note the use of the user name `my_user_2`.

```
snmpget -mALL -v 3 -u my_user_2 -l authPriv -a MD5
        -A my_password -x DES -X my_password localhost sysObjectID.0
```

At this point, when you to access an object outside the access range, the attempt fails with an appropriate error:

```
snmpgetnext -mALL -v 3 -u my_user_2 -l authPriv -a MD5
        -A my_password -x DES -X my_password localhost ifTable

    RFC1213-MIB::ifTable = No more variables left in this MIB View (It is
        past the end of the MIB tree)
```

Exit Status

`0` Successful completion.

`1` A usage syntax error. A usage message displays. Also used for time out errors.

`2` An error occurred while executing the command. An error message displays.

RFC 3415

Name snmpwalk – communicate with a network entity using SNMP GETNEXT requests

Synopsis

```
snmpwalk [application options] [common options] [oid]
```

Description The `snmpwalk` utility is an SNMP application that uses SNMP `GETNEXT` requests to query a network entity for a tree of information.

You can specify an object identifier (OID) on the command line. This OID specifies which portion of the object identifier space will be searched using `GETNEXT` requests. All variables in the subtree below the specified OID are queried and their values returned. Each variable name must be entered in the format specified in `snmp_variables(4)`.

If no OID argument is present, `snmpwalk` searches MIB-2. If the network entity has an error processing the request packet, an error packet is returned and a message displayed, indicating t the way in which the request was malformed.

If the tree search causes attempts to search beyond the end of the MIB, the message "End of MIB" is displayed.

Options The following options are supported:

`-Cc` Do not check whether the returned OIDs are increasing. Some agents (for example, agents for Laser-Jet printers) return OIDs out of order, but can complete the walk anyway. Other agents return OIDs that are out of order and can cause `snmpwalk` to loop indefinitely. By default, `snmpwalk` tries to detect this behavior and warns you when it encounters an agent acting illegally. Use `-Cc` to turn off this feature.

`-Ci` Include the given OID in the search range. Normally, snmpwalk uses `GETNEXT` requests starting with the OID you specify and returns all results in the MIB tree beyond that OID. This option allows you to include the OID specified on the command line in the displayed results (assuming the OID is a valid OID in the tree).

`-Cp` Upon completion of the walk, display the number of variables found.

In addition to these options, `snmpwalk` takes the common options described in the `snmpcmd(1M)` manual page.

Examples **EXAMPLE 1** Retrieving All of the Variables Under `system`

The following command retrieves all of the variables under `system`:

```
# snmpwalk -Os -c public -v 1 zeus system
```

Output from this command will be similar to:

```
sysDescr.0 = STRING: "SunOS zeus.net.cmu.edu 4.1.3_U1 1 sun4m"
sysObjectID.0 = OID: enterprises.hp.nm.hpsystem.10.1.1
sysUpTime.0 = Timeticks: (155274552) 17 days, 23:19:05
sysContact.0 = STRING: ""
sysName.0 = STRING: "zeus.net.cmu.edu"
```

EXAMPLE 1 Retrieving All of the Variables Under `system` *(Continued)*

```
sysLocation.0 = STRING: ""
sysServices.0 = INTEGER: 72
```

Attributes

Name snmpXdmid – Sun Solstice Enterprise SNMP-DMI mapper subagent

Synopsis

```
/usr/lib/dmi/snmpXdmid  -s hostname [-h] [-c config-dir]
 [-d debug-level]
```

Description The `snmpXdmid` utility is a subagent in the Solstice Enterprise Agent Desktop Management Interface package. It maps the SNMP requests forwarded by the Master Agent (`snmpdx(1M)`) into one or more equivalent DMI requests. Further, it remaps the DMI response into SNMP response back to `snmpdx`. By default, `snmpXdmid` also forwards the DMI indications as SNMP traps to `snmpdx`. The feature is configurable and can be disabled by setting `TRAP_FORWARD_TO_MAGENT=0` in the `snmpXdmid` configuration file, `snmpXdmid.conf`.

This subagent runs as a daemon in the system. The subagent uses a set of .MAP files located in `/var/dmi/map` to map the SNMP Object Identifier (OID) into a corresponding DMI component. The map files are generated using the MIF-to-MIB utility, `miftomib`. They are read by `snmpXdmid` when a corresponding MIF file gets registered with the DMI Service Provider (`dmispd(1M)`).

Note – The SMA (Systems Management Agent) is the default SNMP agent in Solaris. See `sma_snmp(5)`. `snmpdx` is Obsolete and may not be supported in a future release of Solaris.

The `snmpXdmid.conf` file is used for configuration information. Each entry in the file consists of a keyword followed by an equal sign (=), followed by a parameter string. The keyword must begin in the first position. A line beginning with a pound sign (#) is treated as a comment and the subsequent characters on that line are ignored. The keywords currently supported are:

`WARNING_TIMESTAMP`
Indication subscription expiration, warning time.

`EXPIRATION_TIMESTAMP`
Indication subscription expiration timestamp.

`FAILURE_THRESHOLD`
DMISP retries before dropping indication due to comm errors.

`TRAP_FORWARD_TO_MAGENT`

`0`	Drop indication at the subagent level.
non-zero	Forward indications as SNMP traps to `snmpdx`.

By default, the configuration file `snmpXdmid.conf` is located in the `/etc/dmi/conf` directory. You can specify an alternative directory with the `-c` option.

Options The following options are supported:

`-c` *config-dir*	Specify the directory where `snmpXdmid.conf` file is located.
`-d` *debug-level*	Debug. Levels from 1 to 5 are supported, giving various levels of debug information.

`-h` Help. Print the command line usage.

`-s` *hostname* Specify the host on which `dmispd` is running.

Files `/etc/dmi/conf/snmpXdmid.conf` DMI mapper configuration file

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsadmi
Interface Stability	Obsolete

Name snmpXwbemd – SNMP Adapter Subagent for WBEM

Synopsis

```
/usr/sadm/lib/wbem/snmpXwbemd [-d] [-h] [-p port]
```

Description The `snmpXwbemd` daemon is a subagent in the Web-Based Enterprise Management (WBEM) services package.

This daemon maps the Simple Network Management Protocol (SNMP) requests forwarded by the Solstice Enterprise Agents (SEA) Master Agent `snmpdx(1M)` into one or more equivalent WBEM Common Information Model (CIM) properties and instances. Further, it remaps the response from the CIM Object Manager into a SNMP response, which it passes back to `snmpdx`(1M).

A mapping file contains the corresponding Object Identifier (OID), class name, property name, and Abstract Syntax Notation 1 (ASN.1) type for each object. You can also create your own mapping file.

Options The following options are supported:

`-d` Displays all debug information.

`-h` Displays help by printing the correct command line usage.

`-p` Specifies the port number to use.

Operands The following operand is supported:

port Specifies the port number you want to use.

Examples **EXAMPLE 1** An Example of a `050SUNWwbcou.map` File

This mapping file that Sun Microsystems provides contains definitions of objects, in this format:

```
#
#pragma ident    "@(#)050SUNWwbcou.map    1.0    01/04/03 SMI"
#
# Copyright (c) 2001 by Sun Microsystems, Inc.
# All rights reserved.
#
# *** Description of contents ***
#
# First non-commented non-blank line contains required Version label.
# Remaining non-commented non-blank lines are considered map entries
# used as described below:
#
# Column 1 - SNMP OID - Uniquely describes an SNMP variable
# Column 2 - CIM Class Name - CIM class associated with this variable
# Column 3 - CIM Property Name - CIM property that maps to SNMP OID variable
# Column 4 - ASN.1 type - SNMP datatype that dictates how data is mapped
#            to/from SNMP requests.  Supported types are: SnmpString, SnmpOid,
```

EXAMPLE 1 An Example of a `050SUNWwbcou.map` File *(Continued)*

```
#            SnmpTimeticks, SnmpCounter, SnmpInt, SnmpGauge, SnmpIpAddress,
#            SnmpOpaque)
# Column 5 and greater are ignored
#
Version 1.0

1.3.6.1.2.1.1.1.0 Solaris_ComputerSystem Description SnmpString

Name snoop – capture and inspect network packets

Synopsis

```
snoop  [-aqrCDNPSvV] [-t [r |  a |  d]] [-c maxcount]
 [-d device] [-i filename] [-n filename] [-o filename]
 [-p first [, last]] [-s snaplen] [-x offset [, length]]
 [expression]
```

Description `snoop` captures packets from the network and displays their contents. `snoop` uses both the network packet filter and streams buffer modules to provide efficient capture of packets from the network. Captured packets can be displayed as they are received, or saved to a file (which is *RFC 1761*–compliant) for later inspection.

`snoop` can display packets in a single-line summary form or in verbose multi-line forms. In summary form, with the exception of certain VLAN packets, only the data pertaining to the highest level protocol is displayed. If a packet has a VLAN header and its VLAN ID is non-zero, then `snoop` will show that the packet is VLAN tagged. For example, an NFS packet will have only NFS information displayed. Except for VLAN information under the condition just described, the underlying RPC, UDP, IP, and Ethernet frame information is suppressed, but can be displayed if either of the verbose options are chosen.

In the absence of a name service, such as LDAP or NIS, `snoop` displays host names as numeric IP addresses.

`snoop` requires an interactive interface.

Options

`-C`
List the code generated from the filter expression for either the kernel packet filter, or `snoop`'s own filter.

`-D`
Display number of packets dropped during capture on the summary line.

`-N`
Create an IP address-to-name file from a capture file. This must be set together with the `-i` option that names a capture file. The address-to-name file has the same name as the capture file with `.names` appended. This file records the IP address to hostname mapping at the capture site and increases the portability of the capture file. Generate a `.names` file if the capture file is to be analyzed elsewhere. Packets are not displayed when this flag is used.

`-P`
Capture packets in non-promiscuous mode. Only broadcast, multicast, or packets addressed to the host machine will be seen.

`-S`
Display size of the entire link layer frame in bytes on the summary line.

`-V`
Verbose summary mode. This is halfway between summary mode and verbose mode in degree of verbosity. Instead of displaying just the summary line for the highest level protocol in a packet, it displays a summary line for each protocol layer in the packet. For

instance, for an NFS packet it will display a line each for the ETHER, IP, UDP, RPC and NFS layers. Verbose summary mode output may be easily piped through `grep` to extract packets of interest. For example, to view only RPC summary lines, enter the following: `example# snoop -i rpc.cap -V | grep RPC`

`-a`
Listen to packets on `/dev/audio` (warning: can be noisy).

`-c` *maxcount*
Quit after capturing *maxcount* packets. Otherwise keep capturing until there is no disk space left or until interrupted with Control-C.

`-d` *device*
Receive packets from the network using the interface specified by *device*, for example, `eri0` or `hme0`. The program netstat(1M), when invoked with the `-i` flag, lists all the interfaces that a machine has. Normally, `snoop` will automatically choose the first non-loopback interface it finds.

`-i` *filename*
Display packets previously captured in *filename*. Without this option, `snoop` reads packets from the network interface. If a *filename*`.names` file is present, it is automatically loaded into the `snoop` IP address-to-name mapping table (See `-N` flag).

`-n` *filename*
Use *filename* as an IP address-to-name mapping table. This file must have the same format as the `/etc/hosts` file (IP address followed by the hostname).

`-o` *filename*
Save captured packets in *filename* as they are captured. (This *filename* is referred to as the "capture file".) The format of the capture file is RFC 1761–compliant. During packet capture, a count of the number of packets saved in the file is displayed. If you wish just to count packets without saving to a file, name the file `/dev/null`.

`-p` *first* [, `last`]
Select one or more packets to be displayed from a capture file. The *first* packet in the file is packet number 1.

`-q`
When capturing network packets into a file, do not display the packet count. This can improve packet capturing performance.

`-r`
Do not resolve the IP address to the symbolic name. This prevents `snoop` from generating network traffic while capturing and displaying packets. However, if the `-n` option is used, and an address is found in the mapping file, its corresponding name will be used.

`-s` *snaplen*
Truncate each packet after *snaplen* bytes. Usually the whole packet is captured. This option is useful if only certain packet header information is required. The packet truncation is done within the kernel giving better utilization of the streams packet buffer. This means

less chance of dropped packets due to buffer overflow during periods of high traffic. It also saves disk space when capturing large traces to a capture file. To capture only IP headers (no options) use a *snaplen* of 34. For UDP use 42, and for TCP use 54. You can capture RPC headers with a *snaplen* of 80 bytes. NFS headers can be captured in 120 bytes.

`-t [ r | a | d ]`
Time-stamp presentation. Time-stamps are accurate to within 4 microseconds. The default is for times to be presented in `d` (delta) format (the time since receiving the previous packet). Option `a` (absolute) gives wall-clock time. Option `r` (relative) gives time relative to the first packet displayed. This can be used with the `-p` option to display time relative to any selected packet.

`-v`
Verbose mode. Print packet headers in lots of detail. This display consumes many lines per packet and should be used only on selected packets.

`-x`*offset* [, *length*]
Display packet data in hexadecimal and ASCII format. The *offset* and *length* values select a portion of the packet to be displayed. To display the whole packet, use an *offset* of 0. If a *length* value is not provided, the rest of the packet is displayed.

Operands *expression*
Select packets either from the network or from a capture file. Only packets for which the expression is true will be selected. If no expression is provided it is assumed to be true.

Given a filter expression, `snoop` generates code for either the kernel packet filter or for its own internal filter. If capturing packets with the network interface, code for the kernel packet filter is generated. This filter is implemented as a streams module, upstream of the buffer module. The buffer module accumulates packets until it becomes full and passes the packets on to `snoop`. The kernel packet filter is very efficient, since it rejects unwanted packets in the kernel before they reach the packet buffer or `snoop`. The kernel packet filter has some limitations in its implementation; it is possible to construct filter expressions that it cannot handle. In this event, `snoop` tries to split the filter and do as much filtering in the kernel as possible. The remaining filtering is done by the packet filter for `snoop`. The `-C` flag can be used to view generated code for either the packet filter for the kernel or the packet filter for `snoop`. If packets are read from a capture file using the `-i` option, only the packet filter for `snoop` is used.

A filter *expression* consists of a series of one or more boolean primitives that may be combined with boolean operators (`AND`, `OR`, and `NOT`). Normal precedence rules for boolean operators apply. Order of evaluation of these operators may be controlled with parentheses. Since parentheses and other filter expression characters are known to the shell, it is often necessary to enclose the filter expression in quotes. Refer to Example 2 for information about setting up more efficient filters.

The primitives are:

`host` *hostname*
: True if the source or destination address is that of `hostname`. The *hostname* argument may be a literal address. The keyword `host` may be omitted if the name does not conflict with the name of another expression primitive. For example, `pinky` selects packets transmitted to or received from the host `pinky`, whereas `pinky and dinky` selects packets exchanged between hosts `pinky AND dinky`.

  The type of address used depends on the primitive which precedes the `host` primitive. The possible qualifiers are `inet`, `inet6`, `ether`, or none. These three primitives are discussed below. Having none of the primitives present is equivalent to "inet host hostname or inet6 host hostname". In other words, snoop tries to filter on all IP addresses associated with hostname.

inet or *inet6*
: A qualifier that modifies the `host` primitive that follows. If it is *inet*, then `snoop` tries to filter on all IPv4 addresses returned from a name lookup. If it is *inet6*, `snoop` tries to filter on all IPv6 addresses returned from a name lookup.

ipaddr, *atalkaddr*, or *etheraddr*
: Literal addresses, IP dotted, AppleTalk dotted, and Ethernet colon are recognized. For example,

  - "`172.16.40.13`" matches all packets with that IP
  - "`2::9255:a00:20ff:fe73:6e35`" matches all packets with that IPv6 address as source or destination;
  - "`65281.13`" matches all packets with that AppleTalk address;
  - "`8:0:20:f:b1:51`" matches all packets with the Ethernet address as source or destination.

  An Ethernet address beginning with a letter is interpreted as a hostname. To avoid this, prepend a zero when specifying the address. For example, if the Ethernet address is `aa:0:45:23:52:44`, then specify it by add a leading zero to make it `0aa:0:45:23:52:44`.

`from` or `src`
: A qualifier that modifies the following `host`, `net`, *ipaddr*, *atalkaddr*, *etheraddr*, `port` or `rpc` primitive to match just the source address, port, or RPC reply.

`to` or `dst`
: A qualifier that modifies the following `host`, `net`, *ipaddr*, *atalkaddr*, *etheraddr*, `port` or `rpc` primitive to match just the destination address, port, or RPC call.

`ether`
: A qualifier that modifies the following `host` primitive to resolve a name to an Ethernet address. Normally, IP address matching is performed. This option is not supported on media such as IPoIB (IP over InfiniBand).

`ethertype` *number*
True if the Ethernet type field has value *number*. If *number* is not 0x8100 (VLAN) and the packet is VLAN tagged, then the expression will match the encapsulated Ethernet type.

`ip`, `ip6`, `arp`, `rarp`, `pppoed`, `pppoes`
True if the packet is of the appropriate ethertype.

`vlan`
True if the packet has `ethertype` VLAN and the VLAN ID is not zero.

`vlan-id` *id*
True for packets of ethertype VLAN with the id *id*.

`pppoe`
True if the ethertype of the packet is either `pppoed` or `pppoes`.

`broadcast`
True if the packet is a broadcast packet. Equivalent to `ether[2:4] = 0xffffffff` for Ethernet. This option is not supported on media such as IPoIB (IP over InfiniBand).

`multicast`
True if the packet is a multicast packet. Equivalent to "`ether[0] & 1 = 1`" on Ethernet. This option is not supported on media such as IPoIB (IP over InfiniBand).

`bootp`, `dhcp`
True if the packet is an unfragmented IPv4 UDP packet with either a source port of `BOOTPS (67)` and a destination port of `BOOTPC (68)`, or a source port of `BOOTPC (68)` and a destination of `BOOTPS (67)`.

`dhcp6`
True if the packet is an unfragmented IPv6 UDP packet with either a source port of `DHCPV6-SERVER` (547) and a destination port of `DHCPV6-CLIENT` (546), or a source port of `DHCPV6-CLIENT` (546) and a destination of `DHCPV6-SERVER` (547).

`apple`
True if the packet is an Apple Ethertalk packet. Equivalent to "`ethertype 0x809b or ethertype 0x80f3`".

`decnet`
True if the packet is a DECNET packet.

`greater` *length*
True if the packet is longer than *length*.

`less` *length*
True if the packet is shorter than *length*.

`udp`, `tcp`, `icmp`, `icmp6`, `ah`, `esp`
True if the IP or IPv6 protocol is of the appropriate type.

`net` *net*
True if either the IP source or destination address has a network number of *net*. The `from` or `to` qualifier may be used to select packets for which the network number occurs only in the source or destination address.

`port` *port*
True if either the source or destination port is *port*. The *port* may be either a port number or name from `/etc/services`. The `tcp` or `udp` primitives may be used to select TCP or UDP ports only. The `from` or `to` qualifier may be used to select packets for which the *port* occurs only as the source or destination.

`rpc` *prog* [, *vers* [, `proc`]]
True if the packet is an RPC call or reply packet for the protocol identified by *prog*. The *prog* may be either the name of an RPC protocol from `/etc/rpc` or a program number. The *vers* and `proc` may be used to further qualify the program *version* and *procedure* number, for example, `rpc nfs,2,0` selects all calls and replies for the NFS null procedure. The `to` or `from` qualifier may be used to select either call or reply packets only.

`ldap`
True if the packet is an LDAP packet on port 389.

`gateway` *host*
True if the packet used *host* as a gateway, that is, the Ethernet source or destination address was for *host* but not the IP address. Equivalent to "`ether host` *host* and not host *host*".

`nofrag`
True if the packet is unfragmented or is the first in a series of IP fragments. Equivalent to `ip[6:2] & 0x1fff = 0`.

expr relop expr
True if the relation holds, where *relop* is one of >, <, >=, <=, =, `!=`, and `expr` is an arithmetic expression composed of numbers, packet field selectors, the `length` primitive, and arithmetic operators +, –, *, &, |, ^, and %. The arithmetic operators within `expr` are evaluated before the relational operator and normal precedence rules apply between the arithmetic operators, such as multiplication before addition. Parentheses may be used to control the order of evaluation. To use the value of a field in the packet use the following syntax:

base`[expr [: size ] ]`

where `expr` evaluates the value of an offset into the packet from a *base* offset which may be `ether`, `ip`, `ip6`, `udp`, `tcp`, or `icmp`. The `size` value specifies the size of the field. If not given, 1 is assumed. Other legal values are 2 and 4. For example,

```
ether[0] & 1 = 1
```

is equivalent to `multicast`

`ether[2:4] = 0xffffffff`

is equivalent to `broadcast`.

`ip[ip[0] & 0xf * 4 : 2] = 2049`

is equivalent to `udp[0:2] = 2049`

`ip[0] & 0xf > 5`

selects IP packets with options.

`ip[6:2] & 0x1fff = 0`

eliminates IP fragments.

`udp and ip[6:2]&0x1fff = 0 and udp[6:2] != 0`

finds all packets with UDP checksums.

The `length` primitive may be used to obtain the length of the packet. For instance "`length > 60`" is equivalent to "`greater 60`", and "`ether[length − 1]`" obtains the value of the last byte in a packet.

`and`
Perform a logical AND operation between two boolean values. The AND operation is implied by the juxtaposition of two boolean expressions, for example "`dinky pinky`" is the same as "`dinky AND pinky`".

`or` or `,`
Perform a logical OR operation between two boolean values. A comma may be used instead, for example, "`dinky,pinky`" is the same as "`dinky OR pinky`".

`not` or `!`
Perform a logical NOT operation on the following boolean value. This operator is evaluated before AND or OR.

`slp`
True if the packet is an SLP packet.

`sctp`
True if the packet is an SCTP packet.

`ospf`
True if the packet is an OSPF packet.

Examples

EXAMPLE 1 Using the `snoop` Command

Capture all packets and display them as they are received:

```
example# snoop
```

Capture packets with host `funky` as either the source or destination and display them as they are received:

EXAMPLE 1 Using the snoop Command *(Continued)*

```
example# snoop funky
```

Capture packets between funky and pinky and save them to a file. Then inspect the packets using times (in seconds) relative to the first captured packet:

```
example# snoop -o cap funky pinky
example# snoop -i cap -t r | more
```

To look at selected packets in another capture file:

```
example# snoop -i pkts -p 99,108
 99   0.0027   boutique -> sunroof     NFS C GETATTR FH=8E6
100   0.0046   sunroof -> boutique     NFS R GETATTR OK
101   0.0080   boutique -> sunroof NFS C RENAME FH=8E6C MTra00192 to .nfs08
102   0.0102   marmot -> viper        NFS C LOOKUP FH=561E screen.r.13.i386
103   0.0072   viper -> marmot       NFS R LOOKUP No such file or directory
104   0.0085   bugbomb -> sunroof    RLOGIN C PORT=1023 h
105   0.0005   kandinsky -> sparky    RSTAT C Get Statistics
106   0.0004   beeblebrox -> sunroof  NFS C GETATTR FH=0307
107   0.0021   sparky -> kandinsky    RSTAT R
108   0.0073   office -> jeremiah      NFS C READ FH=2584 at 40960 for 8192
```

To look at packet 101 in more detail:

```
example# snoop -i pkts -v -p101
ETHER:  ----- Ether Header -----
ETHER:
ETHER:  Packet 101 arrived at 16:09:53.59
ETHER:  Packet size = 210 bytes
ETHER:  Destination = 8:0:20:1:3d:94, Sun
ETHER:  Source      = 8:0:69:1:5f:e,  Silicon Graphics
ETHER:  Ethertype = 0800 (IP)
ETHER:
IP:   ----- IP Header -----
IP:
IP:   Version = 4, header length = 20 bytes
IP:   Type of service = 00
IP:         ..0. .... = routine
IP:         ...0 .... = normal delay
IP:         .... 0... = normal throughput
IP:         .... .0.. = normal reliability
IP:   Total length = 196 bytes
IP:   Identification 19846
IP:   Flags = 0X
IP:   .0.. .... = may fragment
IP:   ..0. .... = more fragments
IP:   Fragment offset = 0 bytes
IP:   Time to live = 255 seconds/hops
```

EXAMPLE 1 Using the snoop Command *(Continued)*

```
IP:   Protocol = 17 (UDP)
IP:   Header checksum = 18DC
IP:   Source address = 172.16.40.222, boutique
IP:   Destination address = 172.16.40.200, sunroof
IP:
UDP:  ----- UDP Header -----
UDP:
UDP:  Source port = 1023
UDP:  Destination port = 2049 (Sun RPC)
UDP:  Length = 176
UDP:  Checksum = 0
UDP:
RPC:  ----- SUN RPC Header -----
RPC:
RPC:  Transaction id = 665905
RPC:  Type = 0 (Call)
RPC:  RPC version = 2
RPC:  Program = 100003 (NFS), version = 2, procedure = 1
RPC:  Credentials: Flavor = 1 (Unix), len = 32 bytes
RPC:     Time = 06-Mar-90 07:26:58
RPC:     Hostname = boutique
RPC:     Uid = 0, Gid = 1
RPC:     Groups = 1
RPC:  Verifier   : Flavor = 0 (None), len = 0 bytes
RPC:
NFS:  ----- SUN NFS -----
NFS:
NFS:  Proc = 11 (Rename)
NFS:  File handle = 000016430000000100080000305A1C47
NFS:                597A00000008000020463l4AFC450000
NFS:  File name = MTra00192
NFS:  File handle = 000016430000000100080000305A1C47
NFS:                597A00000008000020463l4AFC450000
NFS:  File name = .nfs08
NFS:
```

To view just the NFS packets between `sunroof` and `boutique`:

```
example# snoop -i pkts rpc nfs and sunroof and boutique
1   0.0000   boutique -> sunroof    NFS C GETATTR FH=8E6C
2   0.0046    sunroof -> boutique   NFS R GETATTR OK
3   0.0080   boutique -> sunroof   NFS C RENAME FH=8E6C MTra00192 to .nfs08
```

To save these packets to a new capture file:

```
example# snoop -i pkts -o pkts.nfs rpc nfs sunroof boutique
```

To view encapsulated packets, there will be an indicator of encapsulation:

EXAMPLE 1 Using the snoop Command *(Continued)*

```
example# snoop ip-in-ip
sunroof -> boutique ICMP Echo request    (1 encap)
```

If -V is used on an encapsulated packet:

```
example# snoop -V ip-in-ip
sunroof -> boutique  ETHER Type=0800 (IP), size = 118 bytes
sunroof -> boutique  IP D=172.16.40.222 S=172.16.40.200 LEN=104, ID=27497
sunroof -> boutique  IP  D=10.1.1.2 S=10.1.1.1 LEN=84, ID=27497
sunroof -> boutique  ICMP Echo request
```

EXAMPLE 2 Setting Up A More Efficient Filter

To set up a more efficient filter, the following filters should be used toward the end of the expression, so that the first part of the expression can be set up in the kernel: `greater`, `less`, `port`, `rpc`, `nofrag`, and `relop`. The presence of `OR` makes it difficult to split the filtering when using these primitives that cannot be set in the kernel. Instead, use parentheses to enforce the primitives that should be `OR`'d.

To capture packets between `funky` and `pinky` of type `tcp` or `udp` on `port` 80:

```
example# snoop funky and pinky and port 80 and tcp or udp
```

Since the primitive `port` cannot be handled by the kernel filter, and there is also an `OR` in the expression, a more efficient way to filter is to move the `OR` to the end of the expression and to use parentheses to enforce the `OR` between `tcp` and `udp`:

```
example# snoop funky and pinky and (tcp or udp) and port 80
```

Exit Status

`0` Successful completion.

`1` An error occurred.

Files

`/dev/audio`	Symbolic link to the system's primary audio device.
`/dev/null`	The null file.
`/etc/hosts`	Host name database.
`/etc/rpc`	RPC program number data base.
`/etc/services`	Internet services and aliases.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Callaghan, B. and Gilligan, R. *RFC 1761, Snoop Version 2 Packet Capture File Format*. Network Working Group. February 1995.

Warnings The processing overhead is much higher for realtime packet interpretation. Consequently, the packet drop count may be higher. For more reliable capture, output raw packets to a file using the `-o` option and analyze the packets off-line.

Unfiltered packet capture imposes a heavy processing load on the host computer, particularly if the captured packets are interpreted realtime. This processing load further increases if verbose options are used. Since heavy use of `snoop` may deny computing resources to other processes, it should not be used on production servers. Heavy use of `snoop` should be restricted to a dedicated computer.

`snoop` does not reassemble IP fragments. Interpretation of higher level protocol halts at the end of the first IP fragment.

`snoop` may generate extra packets as a side-effect of its use. For example it may use a network name service (NIS or NIS+) to convert IP addresses to host names for display. Capturing into a file for later display can be used to postpone the address-to-name mapping until after the capture session is complete. Capturing into an NFS-mounted file may also generate extra packets.

Setting the `snaplen` (`-s` option) to small values may remove header information that is needed to interpret higher level protocols. The exact cutoff value depends on the network and protocols being used. For NFS Version 2 traffic using UDP on 10 Mb/s Ethernet, do not set `snaplen` less than 150 bytes. For NFS Version 3 traffic using TCP on 100 Mb/s Ethernet, `snaplen` should be 250 bytes or more.

`snoop` requires information from an RPC request to fully interpret an RPC reply. If an RPC reply in a capture file or packet range does not have a request preceding it, then only the RPC reply header will be displayed.

Name soconfig – configure transport providers for use by sockets

Synopsis

```
/sbin/soconfig -f file

/sbin/soconfig family type protocol [path]
```

Description The `soconfig` utility configures the transport provider driver for use with sockets. It specifies how the family, type, and protocol parameters in the `socket(3SOCKET)` call are mapped to the name of a transport provider such as `/dev/tcp`. This utility can be used to add an additional mapping or remove a previous mapping.

The `init(1M)` utility uses `soconfig` with the `sock2path(4)` file during the booting sequence.

Options The following options are supported:

`-f` *file* Set up the `soconfig` configuration for each driver according to the information stored in `file`. A `soconfig` file consists of lines of at least the first three fields listed below, separated by spaces:

family type protocol path

These fields are described in the `OPERANDS` section below.

An example of `file` can be found in the `EXAMPLES` section below.

Operands The following operands are supported:

family The protocol family as listed in the `/usr/include/sys/socket.h` file, expressed as an integer.

type The socket type as listed in the `/usr/include/sys/socket.h` file, expressed as an integer.

protocol The protocol number as specified in the family-specific `include` file, expressed as an integer. For example, for `AF_INET` this number is specified in `/usr/include/netinet/in.h`. An unspecified protocol number is denoted with the value zero.

path The string that specifies the path name of the device that corresponds to the transport provider. If this parameter is specified, the configuration will be added for the specified family, type, and protocol. If this parameter is not specified, the configuration will be removed.

Examples **EXAMPLE 1** Using `soconfig`

The following example sets up `/dev/tcp` for family `AF_INET` and type `SOCK_STREAM`:

```
example# soconfig 2 2 0 /dev/tcp
```

The following is a sample file used with the `-f` option. Comment lines begin with a number sign (#):

EXAMPLE 1 Using `soconfig` *(Continued)*

```
#     Family   Type  Protocol    Path
      2        2       0         /dev/tcp
      2        2       6         /dev/tcp

      2        1       0         /dev/udp
      2        1       17        /dev/udp

      1        2       0         /dev/ticotsord
      1        1       0         /dev/ticlts

      2        4       0         /dev/rawip
```

Files `/etc/sock2path` file containing mappings from sockets to transport providers

Network Interface Guide

Name soladdapp – add an application to the Solstice application registry

Synopsis

```
/usr/snadm/bin/soladdapp [-r registry] -n name -i icon -e executable
    [args]
```

Description `soladdapp` adds an application to the Solstice application registry. After it is added, the application is displayed in the Solstice Launcher main window (see `solstice(1M)`).

Options

`-r` *registry*	Define the full path name of the Solstice registry file.
`-n` *name*	Define the name of the tool to be registered.
`-i` *icon*	Define the full path name of the tool icon.
`-e` *executable*	Define the full path name of the tool.
args	Specify any arguments to use with the tool.

When executed without options, `soladdapp` uses `/opt/SUNWadm/etc/.solstice_registry` (the default registry path).

Return Values

`0`	on success
`1`	on failure
`2`	if the registry is locked
`3`	if the entry is a duplicate.

Examples **EXAMPLE 1** A sample display of the `soladdapp` command.

The following adds an application called Disk Manager to the Solstice application registry for display in the Solstice Launcher main window.

```
# soladdapp -r /opt/SUNWadm/etc/.solstice_registry -n "Disk Manager"
-i /opt/SUNWdsk/etc/diskmgr.xpm -e /opt/SUNWdsk/bin/diskmgr
```

Files

`/opt/SUNWadm/etc/.solstice_registry`	The default registry path.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsadml

See Also `soldelapp(1M)`, `solstice(1M)`, `attributes(5)`

Notes Globally registered applications are used by local and remote users sharing the software in a particular `/opt` directory. They can be added only using `soladdapp`.

Name soldelapp – remove an application from the Solstice application registry

Synopsis

```
/usr/snadm/bin/soldelapp [-r registry] -n name
```

Description `soldelapp` removes an application from the Solstice application registry. After removal, the application is no longer displayed in the Solstice Launcher main window (see `solstice(1M)`).

Options

`-r` *registry* Define the full path name of the Solstice registry file.

`-n` *name* Define the name of the tool to be removed.

When executed without options, `soldelapp` uses `/opt/SUNWadm/etc/.solstice_registry` (the default registry path).

Return Values

`0` on success

`1` on failure

`2` if the registry is locked

`3` if *name* is not found in the registry

`4` if the named registry or default registry is not found

Examples **EXAMPLE 1** A sample display of the `soldelapp` command.

The following removes an application called Disk Manager from the Solstice application registry and the Solstice Launcher main window.

```
# soldelapp -r /opt/SUNWadm/etc/.solstice_registry -n "Disk Manager"
```

Files `/opt/SUNWadm/etc/.solstice_registry` The default registry file.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsadml

See Also `soladdapp(1M)`, `solstice(1M)`, `attributes(5)`

Notes Globally registered applications are used by local and remote users sharing the software in a particular `/opt` directory. They can be removed only using `soldelapp`.

Name solstice – access system administration tools with a graphical user interface

Synopsis

```
/bin/solstice
```

Description `solstice` used on a system presents the `Solstice Launcher`, a graphical user interface that provides access to the Solstice AdminSuite product family of system administration tools. The tools that appear in the launcher depend on what Solstice products you installed on your system.

Help is available by using the Help button.

Usage The `Solstice Launcher` allows you to do the following tasks:

Launch applications	Use the `Solstice Launcher` to launch system administration tools.
Register applications	Use the `Solstice Launcher` to add and register applications locally with the launcher.
Remove applications	Use the `Solstice Launcher` to remove locally registered applications.
Customize application properties	Use the `Solstice Launcher` to show, hide, or remove applications in the launcher, reorder the icons, change the launcher window width, modify applications properties, and add applications.

Files `/$HOME/.solstice_registry` Local registry information.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsadml

See Also `soladdapp(1M)`, `soldelapp(1M)`, `attributes(5)`

Notes The `Solstice Launcher` adds or removes local applications that are private to the user (not local to the system) only. The properties of globally registered applications that are used by local and remote users sharing the software from a particular `/opt` directory cannot be modified from the `Solstice Launcher`. To register global applications for use by local and remote users, use the `soladdapp(1M)` command. To remove globally registered applications, use the `soldelapp(1M)` command.

Name sppptun – PPP tunneling driver utility

Synopsis

```
sppptun plumb

sppptun plumb protocol device

sppptun unplumb interface

sppptun query
```

Description The `sppptun` utility is used to configure and query the Solaris PPP tunneling device driver, `/dev/sppptun`. Currently, only PPP over Ethernet (PPPoE) is supported, so the `plumb` and `unplumb` arguments are used to specify Ethernet interfaces that are to be used for PPPoE, and the `query` option lists the plumbed interfaces.

The use of `sppptun` to add interfaces is similar to the use of `ifconfig(1M)` to add interfaces to IP. The plumbing is done once for each interface, preferably at system start-up time, and is not normally manipulated on a running system. If multiple instances of PPP are run over a single interface, they share the plumbing to that interface. Plumbing for each session is not required (and not possible for PPPoE).

The proper way to plumb interfaces for PPPoE is to list the interfaces, one per line, in the `/etc/ppp/pppoe.if` file.

Usage

`sppptun plumb`	When specified with no additional arguments, the plumb argument lists the protocols that are supported by the utility. These are the strings that are used as the *protocol* argument below.
`sppptun plumb` *protocol device*	This plumbs a new interface into the driver. The *protocol* parameter is `pppoe` for the PPP-carrying "Session Stage" connection or `pppoed` for the PPPoE "Discovery Stage" connection. Both connections must be present for each Ethernet interface that is to be used for PPPoE. The *device* parameter is the path name of the Ethernet interface to use (use `ifconfig(1M)` to list available devices). If the path begins with `/dev/`, then this portion may be omitted.
`sppptun unplumb` *interface*	This removes an existing interface from the driver and terminates any PPP sessions that were using the interface. The *interface* parameter is the name of the interface as reported when the interface was plumbed.
`sppptun query`	Displays the canonical names of all interfaces plumbed into the `/dev/sppptun` device driver.

Examples **EXAMPLE 1** Setting up to Use PPPoE on `hme0`

Plumb the `hme0` interface.

EXAMPLE 1 Setting up to Use PPPoE on `hme0` *(Continued)*

```
# sppptun plumb pppoed hme0
hme0:pppoed
# sppptun plumb pppoe hme0
hme0:pppoe
```

Remove the `hme0` interface.

```
# sppptun unplumb hme0:pppoed
# sppptun unplumb hme0:pppoe
```

EXAMPLE 2 Script to Remove All Plumbed Interfaces

```
#!/bin/sh
for intf in ‘sppptun query‘
do
        sppptun unplumb $intf
done
```

Exit Status The following exit values are returned:

`0` Successful completion.

`1` One or more errors occurred.

Files

`/etc/ppp/pppoe.if`	list of Ethernet interfaces to be plumbed at boot time
`/usr/sbin/sppptun`	executable command
`/dev/sppptun`	Solaris PPP tunneling device driver

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpppdt

See Also `pppd(1M)`, `pppoec(1M)`, `pppoed(1M)`, `sppptun(7M)`

RFC 2516, Method for Transmitting PPP Over Ethernet (PPPoE), Mamakos et al, February 1999

Name spray – spray packets

Synopsis

```
/usr/sbin/spray [-c count] [-d delay] [-l length]
     [-t nettype] host
```

Description `spray` sends a one-way stream of packets to *host* using RPC, and reports how many were received, as well as the transfer rate. The *host* argument can be either a name or an Internet address.

`spray` is not useful as a networking benchmark, as it uses unreliable connectionless transports, UDP for example. `spray` can report a large number of packets dropped when the drops were caused by `spray` sending packets faster than they can be buffered locally, that is, before the packets get to the network medium.

Options

`-c` *count* Specify how many packets to send. The default value of *count* is the number of packets required to make the total stream size 100000 bytes.

`-d` *delay* Specify how many microseconds to pause between sending each packet. The default is `0`.

`-l` *length* The *length* parameter is the numbers of bytes in the Ethernet packet that holds the RPC call message. Since the data is encoded using XDR, and XDR only deals with 32 bit quantities, not all values of *length* are possible, and `spray` rounds up to the nearest possible value. When *length* is greater than 1514, then the RPC call can no longer be encapsulated in one Ethernet packet, so the *length* field no longer has a simple correspondence to Ethernet packet size. The default value of *length* is `86 bytes`, the size of the RPC and UDP headers.

`-t` *nettype* Specify class of transports. Defaults to `netpath`. See `rpc(3NSL)` for a description of supported classes.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWrcmdc

See Also `rpc(3NSL)`, `attributes(5)`

Name sshd – secure shell daemon

Synopsis

```
sshd [-deiqtD46] [-b bits] [-f config_file]
     [-g login_grace_time] [-h host_key_file]
     [-k key_gen_time] [-p port] [-V client_protocol_id]
```

Description The `sshd` (Secure Shell daemon) is the daemon program for `ssh(1)`. Together these programs replace `rlogin` and `rsh`, and provide secure encrypted communications between two untrusted hosts over an insecure network. The programs are intended to be as easy to install and use as possible.

`sshd` is the daemon that listens for connections from clients. It forks a new daemon for each incoming connection. The forked daemons handle key exchange, encryption, authentication, command execution, and data exchange.

This implementation of `sshd` supports both SSH protocol versions 1 and 2 simultaneously. Because of security weaknesses in the v1 protocol, sites should run only v2, if possible. In the default configuration, only protocol v2 is enabled for the server. To enable v1 and v2 simultaneously, see the instructions in `sshd_config(4)`.

Support for v1 is provided to help sites with existing `ssh` v1 clients and servers to transition to v2. v1 might not be supported in a future release.

SSH Protocol Version 1

Each host has a host-specific RSA key (normally 1024 bits) used to identify the host. Additionally, when the daemon starts, it generates a server RSA key (normally 768 bits). This key is normally regenerated every hour if it has been used, and is never stored on disk.

Whenever a client connects the daemon responds with its public host and server keys. The client compares the RSA host key against its own database to verify that it has not changed. The client then generates a 256–bit random number. It encrypts this random number using both the host key and the server key, and sends the encrypted number to the server. Both sides then use this random number as a session key which is used to encrypt all further communications in the session. The rest of the session is encrypted using a conventional cipher, currently Blowfish or 3DES, with 3DES being used by default. The client selects the encryption algorithm to use from those offered by the server.

Next, the server and the client enter an authentication dialog. The client tries to authenticate itself using `.rhosts` authentication, `.rhosts` authentication combined with RSA host authentication, RSA challenge-response authentication, or password-based authentication.

Rhosts authentication is normally disabled because it is fundamentally insecure, but can be enabled in the server configuration file if desired. System security is not improved unless `rshd(1M)`, `rlogind(1M)`, `rexecd(1M)`, and `rexd(1M)` are disabled (thus completely disabling `rlogin(1)` and `rsh(1)` into the machine).

SSH Protocol Version 2

Version 2 works similarly to version 1: Each host has a host-specific DSA/RSA key. However, when the daemon starts, it does not generate a server key. Forward security is provided through a Diffie-Hellman key agreement. This key agreement results in a shared session key. The rest of the session is encrypted using a symmetric cipher, currently 128-bit AES, Blowfish, 3DES, or AES. The client selects the encryption algorithm to use from those offered by the server. Additionally, session integrity is provided through a cryptographic message authentication code (`hmac-sha1` or `hmac-md5`).

Protocol version 2 provides a public key based user authentication method (PubKeyAuthentication) GSS–API based user authentication, conventional password authentication, and a generic prompt/reply protocol for password-based authentication.

Command Execution and Data Forwarding

If the client successfully authenticates itself, a dialog for preparing the session is entered. At this time the client can request things like allocating a pseudo-tty, forwarding X11 connections, forwarding TCP/IP connections, or forwarding the authentication agent connection over the secure channel.

Finally, the client either requests a shell or execution of a command. The sides then enter session mode. In this mode, either side may send data at any time, and such data is forwarded to/from the shell or command on the server side, and the user terminal on the client side.

When the user program terminates and all forwarded X11 and other connections have been closed, the server sends command exit status to the client, and both sides exit.

`sshd` can be configured using command-line options or the configuration file `/etc/ssh/ssh_config`, described in `ssh_config(4)`. Command-line options override values specified in the configuration file.

`sshd` rereads its configuration file when it receives a hangup signal, `SIGHUP`, by executing itself with the name it was started as, that is, `/usr/lib/ssh/sshd`.

Host Access Control

The `sshd` daemon uses TCP Wrappers to restrict access to hosts. It uses the service name of `sshd` for `hosts_access()`. For more information on TCP Wrappers see `tcpd(1M)` and `hosts_access(3)` man pages, which are part of the `SUNWsfman` package (they are not SunOS man pages). TCP wrappers binaries, including `libwrap`, are in `SUNWtcpd`, a required package for `SUNWsshdu`, the package containing `sshd`.

Options

The options for `sshd` are as follows:

`-b` *bits*
Specifies the number of bits in the server key (the default is 768).

`-d`
Debug mode. The server sends verbose debug output to the system log, and does not put itself in the background. The server also will not fork and will only process one connection. This option is only intended for debugging for the server. Multiple `-d` options increase the debugging level. Maximum is 3.

`-e`
When this option is specified, `sshd` will send the output to standard error instead of to the system log.

`-f` *configuration_file*
Specifies the name of the configuration file. The default is `/etc/ssh/sshd_config`. `sshd` refuses to start if there is no configuration file.

`-g` *login_grace_time*
Gives the grace time for clients to authenticate themselves (the default is 300 seconds). If the client fails to authenticate the user within this number of seconds, the server disconnects and exits. A value of zero indicates no limit.

`-h` *host_key_file*
Specifies a file from which a host key is read. This option must be given if `sshd` is not run as root (as the normal host key files are normally not readable by anyone but root). The default is `/etc/ssh/ssh_host_key` for protocol version 1, and `/etc/ssh/ssh_host_rsa_key` and `/etc/ssh/ssh_host_dsa_key` for protocol version 2. It is possible to have multiple host key files for the different protocol versions and host key algorithms.

`-i`
Specifies that `sshd` is being run from `inetd`. `sshd` is normally not run from `inetd` because it needs to generate the server key before it can respond to the client, and this may take tens of seconds. Clients would have to wait too long if the key was regenerated every time. However, with small key sizes (for example, 512) using `sshd` from `inetd` may be reasonable.

`-k` *key_gen_time*
(SSHv1-specific) Specifies how often the server key is regenerated (the default is 3600 seconds, or one hour). The motivation for regenerating the key fairly often is that the key is not stored anywhere, and after about an hour, it becomes impossible to recover the key for decrypting intercepted communications even if the machine is cracked into or physically seized. A value of zero indicates that the key will never be regenerated.

`-o` *option*
Can be used to specify options in the format used in the configuration file. This is useful for specifying options for which there are no separate command-line flags.

`-p` *port*
Specifies the port on which the server listens for connections (the default is 22).

`-q`
Quiet mode. Nothing is sent to the system log. Normally the beginning, authentication, and termination of each connection is logged.

`-t`
Test mode. Check only the validity of the configuration file and the sanity of the keys. This is useful for updating sshd reliably as configuration options might change.

`-D`
When this option is specified `sshd` does not detach and does not become a daemon. This allows easy monitoring of `sshd`.

`-4`
Forces `sshd` to use IPv4 addresses only.

`-6`
Forces `sshd` to use IPv6 addresses only.

Extended Description

`authorized_keys` File Format

The `$HOME/.ssh/authorized_keys` file lists the public keys that are permitted for RSA authentication in protocol version 1 and for public key authentication (`PubkeyAuthentication`) in protocol version 2. The `AuthorizedKeysFile` configuration option can be used to specify an alternative file.

Each line of the file contains one key (empty lines and lines starting with a hash mark [#] are ignored as comments).

For each RSA key for protocol version 1, the file consists of the following space-separated fields:

options bits exponent modulus comment

For the public key for protocol version 2, the file consists of the following space-separated fields:

options key-type base64-encoding-key comment

For protocol version 2, *key-type* is one of `ssh-rsa` or `ssh-dsa`.

The options field is optional; its presence is determined by whether the line starts with a number. (The option field never starts with a number.) The bits, exponent, and modulus fields give the RSA key; the comment field is a convenient place for you to identify the key.

Lines in this file are usually several hundred bytes long (because of the size of the key modulus). You will find it very inconvenient to type them in; instead, copy the public key file and edit it.

Permissions of this file must be set so that it is not world or group writable. See the `StrictModes` option of `sshd_config(4)`.

The options (if present) consist of comma-separated option specifications. No spaces are permitted, except within double quotes. The following option specifications are supported:

`from="`*pattern-list*`"`
Specifies that, in addition to public key authentication, the canonical name of the remote host must be present in the comma-separated list of patterns ('`*`' and '`?`' serve as wildcards). The list can also contain negated patterns by prefixing the patterns with '`!`'. If the canonical host name matches a negated pattern, the key is not accepted.

The purpose of this option is to give you the option of increasing security: public key authentication by itself does not trust the network or name servers or anything but the key. However, if someone manages to steal the key, possession of the key would permit the intruder to log in from anywhere in the world. This option makes using a stolen key more difficult, because name servers and routers would have to be compromised, in addition to just the key.

`command="`*command*`"`
Specifies that the *command* is executed whenever this key is used for authentication. The command supplied by the user (if any) is ignored. The command is run on a `pty` if the client requests a `pty`; otherwise it is run without a `tty`. If an 8-bit clean channel is required, one must not request a `pty` or should specify `no-pty`. You can include a quote in the command by escaping it with a backslash. This option might be useful to restrict certain public keys from performing a specific operation. An example is a key that permits remote backups but nothing else. Note that the client can specify TCP/IP and/or X11 forwarding unless they are explicitly prohibited from doing so. Also note that this option applies to shell, command, or subsystem execution.

`environment="`*NAME*`=`*value*`"`
Specifies that the string *NAME*`=`*value* is to be added to the environment when logging in using this key. Environment variables set this way override other default environment values. Multiple options of this type are permitted. Environment processing is disabled by default and is controlled via the `PermitUserEnvironment` option.

`no-port-forwarding`
Forbids TCP/IP forwarding when this key is used for authentication. Any port forward requests by the client will return an error. This might be used, for example, in connection with the `command` option.

`no-X11-forwarding`
Forbids X11 forwarding when this key is used for authentication. Any X11 forward requests by the client will return an error.

`no-agent-forwarding`
Forbids authentication agent forwarding when this key is used for authentication.

`no-pty`
Prevents `tty` allocation (a request to allocate a `pty` will fail).

`permitopen="`*host*`:`*port*`"`
Limit local `ssh -L` port forwarding such that it can connect only to the specified host and port. IPv6 addresses can be specified with an alternative syntax: *host*/*port*. You can invoke multiple `permitopen` options, with each instance separated by a comma. No pattern matching is performed on the specified hostnames. They must be literal domains or addresses.

ssh_known_hosts File Format

The `/etc/ssh/ssh_known_hosts` and `$HOME/.ssh/known_hosts` files contain host public keys for all known hosts. The global file should be prepared by the administrator (optional), and the per-user file is maintained automatically: whenever the user connects from an unknown host its key is added to the per-user file.

For the RSA key for protocol version 1, these files consist of the following space-separated fields:

hostnames bits exponent modulus comment

For the public key for protocol version 2, these files consist of the following space-separated fields:

hostnames key-type base64-encoding-key comment

For protocol version 2, *key-type* is one of `ssh-rsa` or `ssh-dsa`.

Hostnames is a comma-separated list of patterns (* and ? act as wildcards); each pattern in turn is matched against the canonical host name (when authenticating a client) or against the user-supplied name (when authenticating a server). A pattern can also be preceded by ! to indicate negation: if the host name matches a negated pattern, it is not accepted (by that line) even if it matched another pattern on the line.

Alternately, hostnames can be stored in a hashed form, which hides host names and addresses should the file's contents be disclosed. Hashed hostnames start with a vertical bar (|) character. Only one hashed hostname can appear on a single line and none of the above negation or wildcard operators may be applied.

Bits, exponent, and modulus are taken directly from the RSA host key; they can be obtained, for example, from `/etc/ssh/ssh_host_rsa_key.pub`. The optional comment field continues to the end of the line, and is not used.

Lines starting with a hash mark (#) and empty lines are ignored as comments.

When performing host authentication, authentication is accepted if any matching line has the proper key. It is thus permissible (but not recommended) to have several lines or different host keys for the same names. This will inevitably happen when short forms of host names from different domains are put in the file. It is possible that the files contain conflicting information; authentication is accepted if valid information can be found from either file.

The lines in these files are typically hundreds of characters long. You should definitely not type in the host keys by hand. Rather, generate them by a script or by taking `/etc/ssh/ssh_host_rsa_key.pub` and adding the host names at the front.

Environment Variables

`sshd` sets the following environment variables for commands executed by `ssh` users:

`DISPLAY`
: Indicates the location of the X11 server. It is automatically set by `sshd` to point to a value of the form *hostname*:*n*, where *hostname* indicates the host where the shell runs, and *n* is an integer greater than or equal to 1. `ssh` uses this special value to forward X11 connections

over the secure channel. Unless you have important reasons to do otherwise, you should not set DISPLAY explicitly, as that will render the X11 connection insecure and will require you to manually copy any required authorization cookies.

HOME
Set to the path of the user's home directory.

LANG, LC_ALL, LC_COLLATE, LC_CTYPE, LC_MESSAGES, LC_MONETARY, LC_NUMERIC, LC_TIME
A locale setting. The locale defaults to that of sshd (usually the system-wide default locale), or is negotiated between the client and server during initial key exchange (as per RFC 4253).

Following initial key exchange, each of the variables can be overriden in the following sequence:

1. If a locale setting is set in a client's environment and that client supports "Environment Variable Passing" (see RFC 4254), then the setting will be passed over to the server side.
2. If the public key authentication method was used to authenticate the server and the PermitUserEnvironment variable in sshd_config(4) is set to yes on the server side, then the setting can be changed through the use of the environment option in the client's AuthorizedKeysFile file.
3. The setting can be change in the client's ~/.ssh/environment file on the server.

See PermitUserEnvironment in sshd_config(4) as to when the AuthorizedKeysFile and ~/.ssh/environment files are processed and used for setting the user environment.

LOGNAME
Synonym for USER. Set for compatibility with systems that use this variable.

MAIL
Set to point to the user's mailbox.

SSH_AUTH_SOCK
Indicates the path of a unix-domain socket used to communicate with the agent.

SSH_CONNECTION
Identifies the client and server ends of the connection. The variable contains four space-separated values: client IP address, client port number, server IP address and server port number.

SSH_CLIENT
Identifies the client end of the connection. The variable contains three space-separated values: client IP address, client port number, and server port number.

SSH_TTY
Set to the name of the tty (path to the device) associated with the current shell or command. If the current session has no tty, this variable is not set.

`TZ`
Indicates the present timezone, if `TIMEZONE` is set in `/etc/default/login` or if `TZ` was set when the daemon was started.

`HZ`
If set in `/etc/default/login`, the daemon sets it to the same value.

`SHELL`
The user's shell, if `ALTSHELL=YES` in `/etc/default/login`.

`PATH`
Set to the value of `PATH` or `SUPATH` (see `login(1)`) in `/etc/default/login`, or, if not set, to `/usr/bin:/bin`.

`USER`
Set to the name of the user logging in.

Additionally, `sshd` reads `$HOME/.ssh/environment` and adds lines of the format `VARNAME=`*value* to the environment.

Examples

In the following examples, certain lines might wrap due to line length limits in your display. You should nevertheless consider the wrapped line as a single line.

EXAMPLE 1 `authorized_key` File Entries

The following are examples of `authorized_key` file entries for protocol 1:

```
1024 33 12121...312314325 ylo@foo.bar

from="*.niksula.hut.fi,!pc.niksula.hut.fi" 1024 35 23...2334 ylo@niksula

command="dump /home",no-pty,no-port-forwarding 1024 33 23...2323 backup.hut.fi
```

EXAMPLE 2 `authorized_key` File Entries for Protocol 2

The following are examples of `authorized_key` file entries for protocol 2:

```
ssh-rsa AAAAB3NzaC1y.....EU88ovYKg4GfclWGCFYTuw8= ylo@foo.bar
from="*.niksula.hut.fi" ssh-rsa AAAAB3NzaC...uw8= ylo@niksula
command="dump /home",no-pty,no-port-forwarding ssh-rsa AA..8= backup.hut.fi
```

EXAMPLE 3 `ssh_known_hosts` File Entries for Protocol 1

The following are examples of `ssh_known_hosts` file entries for protocol 1:

```
closenet,closenet.hut.fi,...,130.233.208.41 1024 37 159...93 closenet.hut.fi
```

EXAMPLE 4 `ssh_known_hosts` File Entries for Protocol 2

The following are examples of `ssh_known_hosts` file entries for protocol 2:

```
closenet,closenet.hut.fi,...,130.233.208.41 ssh-rsa AA..8= closenet.hut.fi
```

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Files `/etc/default/login`
Contains defaults for several `sshd_config` parameters, environment variables, and other environmental factors.

The following parameters affect environment variables (see `login(1)` and descriptions of these variables, above):

- `TIMEZONE`
- `HZ`
- `ALTSHELL`
- `PATH`
- `SUPATH`

The following `/etc/default/login` parameters supply default values for corresponding `sshd_config(4)` parameters:

- `CONSOLE` (see `PermitRootLogin` in `sshd_config(4)`)
- `PASSREQ` (see `PermitEmptyPasswords` in `sshd_config(4)`)
- `TIMEOUT` (see `LoginGraceTime` in `sshd_config(4)`)

The following `/etc/default/login` parameters:

- `UMASK`
- `ULIMIT`

...set the `umask(2)` and file size limit of, respectively, the shells and commands spawned by `sshd`.

Finally, two `/etc/default/login` parameters affect the maximum allowed login attempts per-connection using interactive user authentication methods (for example, `keyboard-interactive` but not `publickey`), as per `login(1)`:

- `RETRIES`
- `SYSLOG_FAILED_LOGINS`

`/etc/ssh/sshd_config`
Contains configuration data for `sshd`. This file should be writable by root only, but it is recommended (though not necessary) that it be world-readable.

`/etc/ssh/ssh_host_key`
`/etc/ssh/ssh_host_dsa_key`
`/etc/ssh/ssh_host_rsa_key`
Contains the private part of the host key. This file should only be owned by root, readable only by root, and not accessible to others. `sshd` does not start if this file is group/world-accessible.

`/etc/ssh/ssh_host_key.pub`
`/etc/ssh/ssh_host_dsa_key.pub`
`/etc/ssh/ssh_host_rsa_key.pub`
Contains the public part of the host key. This file should be world-readable but writable only by root. Its contents should match the private part. This file is not used for encryption; it is provided only for the convenience of the user so its contents can be copied to known hosts files. These two files are created using `ssh-keygen(1)`.

`/var/run/sshd.pid`
Contains the process ID of the `sshd` listening for connections. If there are several daemons running concurrently for different ports, this contains the pid of the one started last. The content of this file is not sensitive; it can be world-readable. You can use the `PidFile` keyword in `sshd_config` to specify a file other than `/var/run/sshd.pid`. See `sshd_config(4)`.

`/etc/ssh/ssh_known_hosts` and `$HOME/.ssh/known_hosts`
These files are consulted when using `rhosts` with public key host authentication to check the public key of the host. The key must be listed in one of these files to be accepted. The client uses the same files to verify that the remote host is the one it intended to connect. These files should be writable only by root or the owner. `/etc/ssh/ssh_known_hosts` should be world-readable, and `$HOME/.ssh/known_hosts` can but need not be world-readable.

`/etc/nologin`
If this file exists, `sshd` refuses to let anyone except root log in. The contents of the file are displayed to anyone trying to log in, and non-root connections are refused. The file should be world-readable.

`$HOME/.ssh/authorized_keys`
Lists the public keys (RSA or DSA) that can be used to log into the user's account. This file must be readable by root. This might, on some machines, imply that it is world-readable if the user's home directory resides on an NFS volume. It is recommended that it not be accessible by others. The format of this file is described above. Users will place the contents of their `identity.pub`, `id_dsa.pub` and/or `id_rsa.pub` files into this file, as described in `ssh-keygen(1)`.

`$HOME/.rhosts`
This file contains host-username pairs, separated by a space, one per line. The given user on the corresponding host is permitted to log in without password. The same file is used by `rlogind` and `rshd`. The file must be writable only by the user; it is recommended that it not be accessible by others. It is also possible to use `netgroups` in the file. Either host or user name may be of the form +@*groupname* to specify all hosts or all users in the group.

`$HOME/.shosts`
For `ssh`, this file is exactly the same as for `.rhosts`. However, this file is not used by `rlogin` and `rshd`, so using this permits access using SSH only.

`/etc/hosts.equiv`
This file is used during `.rhosts` authentication. In its simplest form, this file contains host names, one per line. Users on these hosts are permitted to log in without a password, provided they have the same user name on both machines. The host name can also be followed by a user name; such users are permitted to log in as any user on this machine (except root). Additionally, the syntax *+@group* can be used to specify netgroups. Negated entries start with a hyphen (`-`).

If the client host/user is successfully matched in this file, login is automatically permitted, provided the client and server user names are the same. Additionally, successful RSA host authentication is normally required. This file must be writable only by root; it is recommended that it be world-readable.

Warning: It is almost never a good idea to use user names in `hosts.equiv`. Beware that it really means that the named user(s) can log in as anybody, which includes `bin`, `daemon`, `adm`, and other accounts that own critical binaries and directories. For practical purposes, using a user name grants the user root access. Probably the only valid use for user names is in negative entries. This warning also applies to `rsh`/`rlogin`.

`/etc/ssh/moduli`
A private file.

`/etc/ssh/shosts.equiv`
This file is processed exactly as `/etc/hosts.equiv`. However, this file might be useful in environments that want to run both `rsh`/`rlogin` and `ssh`.

`$HOME/.ssh/environment`
This file is read into the environment at login (if it exists). It can contain only empty lines, comment lines (that start with `#`), and assignment lines of the form *name*=*value*. The file should be writable only by the user; it need not be readable by anyone else. Environment processing is disabled by default and is controlled by means of the `PermitUserEnvironment` option.

`$HOME/.ssh/rc`
If this file exists, it is run with `/bin/sh` after reading the environment files but before starting the user's shell or command. If X11 spoofing is in use, this will receive the `proto cookie` pair in standard input (and `DISPLAY` in environment). This must call `xauth` in that case.

The primary purpose of `$HOME/.ssh/rc` is to run any initialization routines that might be needed before the user's home directory becomes accessible; AFS is a particular example of such an environment. If this file exists, it is run with `/bin/sh` after reading the environment files, but before starting the user's shell or command. It must not produce any output on stdout; stderr must be used instead. If X11 forwarding is in use, it will receive the `proto cookie` pair in its standard input and `DISPLAY` in its environment. The script must call `xauth` because `sshd` will not run `xauth` automatically to add X11 cookies.

This file will probably contain some initialization code followed by something similar to:

```
if read proto cookie && [ -n "$DISPLAY" ]
then
  if [ `echo $DISPLAY | cut -c1-10`  =  'localhost:' ]
  then
    # X11UseLocalhost=yes
    echo add unix:`echo $DISPLAY |
    cut -c11-` $proto $cookie
  else
    # X11UseLocalhost=no
    echo add $DISPLAY $proto $cookie
  fi | xauth -q -
fi
```

If this file does not exist, `/etc/ssh/sshrc` is run, and if that does not exist, `xauth` is used to store the cookie. `$HOME/.ssh/rc` should be writable only by the user, and need not be readable by anyone else.

`/etc/ssh/sshrc`
Similar to `$HOME/.ssh/rc`. This can be used to specify machine-specific login-time initializations globally. This file should be writable only by root, and should be world-readable.

Security `sshd` supports the use of several user authentication mechanisms: a public key system where keys are associated with users (through users' `authorized_keys` files), a public key system where keys are associated with hosts (see the `HostbasedAuthentication` configuration parameter), a GSS-API based method (see the `GssAuthentication` and `GssKeyEx` configuration parameters) and three initial authentication methods: `none`, `password`, and a generic prompt/reply protocol, `keyboard-interactive`.

`sshd` negotiates the use of the GSS-API with clients only if it has a GSS-API acceptor credential for the "host" service. This means that, for GSS-API based authentication, the server must have a Kerberos V `keytab` entry (see below) or the equivalent for any other GSS-API mechanism that might be installed.

In order for Kerberos authentication to work, a `host/`<*FQDN*> Kerberos principal must exist for each Fully Qualified Domain Name associated with the `in.sshd` server. Each of these `host/`<*FQDN*> principals must have a `keytab` entry in the `/etc/krb5/krb5.keytab` file on the `in.sshd` server. An example principal might be:

```
host/bigmachine.eng.example.com
```

See `kadmin`(1M) or `gkadmin`(1M) for instructions on adding a principal to a `krb5.keytab` file. See *System Administration Guide: Security Services* for a discussion of Kerberos authentication.

GSS-API authorization is covered in `gss_auth_rules`(5).

`sshd` uses `pam`(3PAM) for the three initial authentication methods as well as for account management, session management, and password management for all authentication methods.

Specifically, `sshd` calls `pam_authenticate()` for the "none," "password" and "keyboard-interactive" SSHv2 `userauth` types, as well as for for the null and password authentication methods for SSHv1. Other SSHv2 authentication methods do not call `pam_authenticate()`. `pam_acct_mgmt()` is called for each authentication method that succeeds.

`pam_setcred()` and `pam_open_session()` are called when authentication succeeds and `pam_close_session()` is called when connections are closed.

`pam_open_session()` and `pam_close_session()` are also called when SSHv2 channels with `ptys` are opened and closed.

Each SSHv2 `userauth` type has its own PAM service name:

SSHv2 Userauth	PAM Service Name
none	sshd-none
password	sshd-password
keyboard-interactive	sshd-kbdint
pubkey	sshd-pubkey
hostbased	sshd-hostbased
gssapi-with-mic	sshd-gssapi
gssapi-keyex	sshd-gssapi

For SSHv1, `sshd -v1` is always used.

If `pam_acct_mgmt()` returns `PAM_NEW_AUTHTOK_REQD` (indicating that the user's authentication tokens have expired), then `sshd` forces the use of "keyboard-interactive" `userauth`, if version 2 of the protocol is in use. The "keyboard-interactive" `userauth` will call `pam_chauthtok()` if `pam_acct_mgmt()` once again returns `PAM_NEW_AUTHTOK_REQD`. By this means, administrators are able to control what authentication methods are allowed for SSHv2 on a per-user basis.

Setting up Host-based Authentication

To establish host-based authentication, you must perform the following steps:

- Configure the client.
- Configure the server.
- Publish known hosts.
- Make appropriate entries in `/etc/ssh/shosts.equiv` and `~/.shosts`.

These steps are expanded in the following paragraphs.

- On a client machine, in the system-wide client configuration file, `/etc/ssh/ssh_config`, you must have the entry:

  ```
  HostbasedAuthentication yes
  ```

  See `ssh_config(4)` and `ssh-keysign(1M)`.
- On the server, in the system-wide server configuration file, `/etc/ssh/sshd_config`, you must have the entry:

  ```
  HostbasedAuthentication yes
  ```

  If per-user `.shost` files are to be allowed (see last step), in the same file, you must have:

  ```
  IgnoreRhosts no
  ```

  See `sshd_config(4)` for a description of these keywords.
- To publish known hosts, you must have entries for the clients from which users will be allowed host-based authentication. Make these entries in either or both of the system-wide file (`/etc/ssh/ssh_known_hosts`) or the per-user file (`~/.ssh/known_hosts`).
- Note that `sshd` uses `.shosts`, not `.rhosts`. If you want the functionality provided by `.rhosts`, but do not want to use `rlogin` or `rsh` because of their security shortcomings, you can use `.shosts` in conjunction with `sshd`. To use this feature, make appropriate entries in `/etc/ssh/shosts.equiv` and `~/.shosts`, in the format specified in `rhosts(4)`.

  For the vast majority of network environments, `.shosts` is preferred over `.rhosts`.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsshdu
Interface Stability	Evolving

The interface stability of `/etc/ssh/moduli` is Private.

See Also `login(1)`, `scp(1)`, `ssh(1)`, `ssh-add(1)`, `ssh-agent(1)`, `ssh-keygen(1)`, `svcs(1)`, `gkadmin(1M)`, `kadmin(1M)`, `sftp-server(1M)`, `ssh-keysign(1M)`, `svcadm(1M)`, `pam(3PAM)`, `rhosts(4)`, `ssh_config(4)`, `sshd_config(4)`, `attributes(5)`, `gss_auth_rules(5)`, `kerberos(5)`, `pam_roles(5)`, `smf(5)`

System Administration Guide: Security Services

Notes The `sshd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/ssh:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

sshd always sets PAM_RHOST and sets PAM_AUSER in the case of host-based userauth. This behavior allows for remote logins to roles using host-based authentication. See pam_roles(5).

Name ssh-keysign – ssh helper program for host-based authentication

Synopsis

```
ssh-keysign
```

Description `ssh-keysign` is used by `ssh(1)` to access the local host keys and generate the digital signature required during host-based authentication with SSH protocol version 2. This signature is of data that includes, among other items, the name of the client host and the name of the client user.

`ssh-keysign` is disabled by default and can be enabled only in the global client configuration file `/etc/ssh/ssh_config` by setting `HostbasedAuthentication` to `yes`.

`ssh-keysign` is not intended to be invoked by the user, but from `ssh`. See `ssh(1)` and `sshd(1M)` for more information about host-based authentication.

Files

`/etc/ssh/ssh_config`	Controls whether `ssh-keysign` is enabled.
`/etc/ssh/ssh_host_dsa_key` `/etc/ssh/ssh_host_rsa_key`	These files contain the private parts of the host keys used to generate the digital signature. They should be owned by root, readable only by root, and not accessible to others. Because they are readable only by root, `ssh-keysign` must be `set-uid` root if host-based authentication is used.

Security ssh-keysign will not sign host-based authentication data under the following conditions:

- If the `HostbasedAuthentication` client configuration parameter is not set to `yes` in `/etc/ssh/ssh_config`. This setting cannot be overriden in users' `~/.ssh/ssh_config` files.
- If the client hostname and username in `/etc/ssh/ssh_config` do not match the canonical hostname of the client where `ssh-keysign` is invoked and the name of the user invoking `ssh-keysign`.

In spite of `ssh-keysign`'s restrictions on the contents of the host-based authentication data, there remains the ability of users to use it as an avenue for obtaining the client's private host keys. For this reason host-based authentication is turned off by default.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsshu
Interface Stability	Evolving

See Also `ssh(1)`, `sshd(1M)`, `ssh_config(4)`, `attributes(5)`

Authors Markus Friedl, `markus@openbsd.org`

History `ssh-keysign` first appeared in Ox 3.2.

Name statd – network status monitor

Synopsis

```
/usr/lib/nfs/statd
```

Description `statd` is an intermediate version of the status monitor. It interacts with `lockd`(1M) to provide the crash and recovery functions for the locking services on NFS. `statd` keeps track of the clients with processes which hold locks on a server. When the server reboots after a crash, `statd` sends a message to the `statd` on each client indicating that the server has rebooted. The client `statd` processes then inform the `lockd` on the client that the server has rebooted. The client `lockd` then attempts to reclaim the lock(s) from the server.

`statd` on the client host also informs the `statd` on the server(s) holding locks for the client when the client has rebooted. In this case, the `statd` on the server informs its `lockd` that all locks held by the rebooting client should be released, allowing other processes to lock those files.

`lockd` is started by `automountd`(1M), `mount_nfs`(1M), and `share`(1M) if NFS automounts are needed.

Files

`/var/statmon/sm`	lists hosts and network addresses to be contacted after a reboot
`/var/statmon/sm.bak`	lists hosts and network addresses that could not be contacted after last reboot
`/var/statmon/state`	includes a number which changes during a reboot
`/usr/include/rpcsvc/sm_inter.x`	contains the rpcgen source code for the interface services provided by the statd daemon.

Attributes See `attributes`(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnfscu

See Also `svcs`(1), `automountd`(1M), `lockd`(1M), `mount_nfs`(1M), `share`(1M), `svcadm`(1M), `attributes`(5), `smf`(5)

System Administration Guide: IP Services

Notes The crash of a server is only detected upon its recovery.

The `statd` service is managed by the service management facility, `smf`(5), under the service identifier:

```
svc:/network/nfs/status
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

If it is disabled, it will be enabled by mount_nfs(1M), share_nfs(1M), and automountd(1M) unless its application/auto_enable property is set to false.

Name stclient – Service Tag Administration Program

Synopsis

```
stclient -x [-r root_dir]

stclient -a [-i instance_URN] -p product_name -e product_version
     -t product_URN [-F parent_URN] -P product_parent
     [-I product_defined_instance_id] -m product_vendor -A platform_arch
     -z container -S source [-r root_dir]

stclient -u -i instance_URN -F parent_URN -I product_defined_instance_id
     [-r root_dir]

stclient -d -i instance_URN [-r root_dir]

stclient -g -i instance_URN [-r root_dir]

stclient -f -t product_URN [-r root_dir]

stclient -h

stclient -v
```

Description The `stclient` command displays, finds, adds, updates and deletes records in the Service Tag registry. The registry is in the XML file `/var/sadm/servicetag/registry/servicetag.xml`, and contains the inventory of the product instances installed in the machine. Each record has a unique product instance identifier which is generated when the service tag is added in the registry. This product instance identifier is used as a key when finding, updating or deleting the service tag records. The extract option prints out the registry contents in XML format in stdout.

The `stclient` command also runs in interactive mode. This mode is invoked by running `stclient` without any parameters. A menu of all the available options are displayed, and the user is prompted to enter different parameters depending on the option chosen.

Any user can extract or get the contents of the registry, but only users with the appropriate privileges, the "svctag" user, or the creator of the service tag is authorized to update or delete a service tag record.

Options The following options are supported:

`-p` *product_name*	Sets the product name of the service tag to be added. For example, "stclient -p "Solaris 10 Operating System"" sets the product name to the "Solaris 10 Operating System".
`-e` *product_version*	Sets the product version of the service tag to be added. For example, "stclient -r 5.10" sets the product version to "5.10".
`-t` *product_URN*	Sets the Sun product unique identifier of the service tag to be added. For example, "stclient -t urn:uuid:5005588c-36f3-11d6-9cec-fc96f718e113" sets

	the Sun product unique identifier to "urn:uuid:5005588c-36f3-11d6-9cec-fc96f718e113".
`-i` *instance_URN*	Sets the product instance unique identifier of the service tag. For example, "stclient -i 3a444ab2-1dd2-11b2-a69d-830020782a6b" sets the product instance unique identifier to "3a444ab2-1dd2-11b2-a69d-830020782a6b" This field may also be set when the service tag is added but is not typically used. The generation of the instance ID is normally left to the `stclient`.
`-F` *product_parent_URN*	Sets the Sun product unique identifier of parent product. For example, "stclient -F urn:uuid:5005588c-36f3-11d6-9cec-fc96f718e113" sets the Sun product unique identifier of parent product to "urn:uuid:5005588c-36f3-11d6-9cec-fc96f718e113".
`-P` *product_parent*	Sets the parent product of the service tag. For example, "stclient -P JES" sets the product parent to "JES".
`-I` *product_defined_instance_id*	Sets the product defined instance identifier. For example, "stclient -I ser:abc-klm-000-7190" sets the product defined instance identifier to "ser:abc-klm-000-7190".
`-m` *product_vendor*	Sets the vendor of the product. For example, "stclient –m Sun" sets the product vendor to "Sun".
`-A` *platform_arch*	Sets the platform architecture that the product is running on. For example, "stclient –A sparc" sets the platform architecture to "sparc"
`-z` *container*	Sets the container that the product is running on. For example, "stclient -z "global zone"" sets the container to "global zone".
`-S` *source*	Sets the source of this service tag, naming the entity that created it.
`-r` *root_dir*	Sets the root directory where the command searches for the registry. The command searches `/var/sadm/servicetag/registry` by default. When this option is used, the command looks for the Registry in the specified root directory, (for example, "`-r /home/user1`" searches `/home/user1/var/sadm/servicetag`). This is typically used for testing.

Operands

Function Letters The function portion of the key is specified by one of the following letters:

x Extract. Extracts and prints the contents of the Service Tag registry in XML format. An alternate root directory may be specified for testing purposes.

a Add. Adds a service tag in the registry. A unique product instance identifier may be supplied and is automatically generated if not provided. This field is returned by the command. The required fields for add are product name, product version, product URN, product parent, vendor, platform architecture, container and source.

u Update. Updates a service tag in the registry using the product instance URN as the key. The parent URN and product defined instance id fields can be updated.

d Delete. Deletes a service tag in the registry using the product instance URN as the key.

E Extract Environment. Enumerates to standard output the environmental or "agent"' information associated with the registered Service Tags on this system.

g Get. Gets and prints a service tag from the registry using the product instance URN as the key.

f Find. Finds and prints all the instance URNs of a given product URN.

h Help. Displays the command options.

v Version. Displays the version number of the command.

Exit Status

The following exit values are returned:

`0` Successful completion.

`> 0` An error occurred.

Examples

EXAMPLE 1 Adding a Service Tag in the Registry

To add a service tag, enter the following:

```
# stclient -a -p "Java Enterprise Web Server 6.0" -e 6.0 \
   -t urn:uuid:f2b8b59c-6eba-11d7-986f-9f5d47ec72fe  \
   -P Java Enterprise Server -m Sun -A sparc -z global -s patch
```

The screen displays the following:

```
Java Enterprise Web Server 6.0 6.0 added
Product instance URN=urn:st:7fc61914-1dd2-11b2-b992-830020782a6b
```

EXAMPLE 2 Updating a Service Tag in the Registry

To update a service tag, enter the following:

EXAMPLE 2 Updating a Service Tag in the Registry *(Continued)*

```
# stclient -u -i 7fc61914-1dd2-11b2-b992-830020782a6b \
   -I urn:st:product.defined.id
```

The screen displays the following:

```
Service tag updated
```

EXAMPLE 3 Extracting a Service Tag Registry

To extract a service tag, enter the following:

```
# stclient -x
```

The screen displays output similar to the following:

```
<?xml version="1.0" encoding="UTF-8"?>
<registry urn="urn:uuid:1234ab-00e1-11b3-98737646873" version="1.0">
   <service_tag>
  .
  .
  .
   </service_tag>
 </registry>
```

EXAMPLE 4 Finding all product instances

To find all product instances, enter the following:

```
# stclient -f -t urn:uuid:f2b8b59c-6eba-11d7-986f-9f5d47ec72fe \
   fc61914-1dd2-11b2-b992-830020782a6b
```

EXAMPLE 5 Listing the Environmental Information

To list the environmental information associated with the registered Service Tags on this system, enter the following:

```
# stclient -E
```

The screen displays output similar to the following:

```
<?xml version="1.0" encoding="UTF-8"?>
<agent>
   <agent_urn>urn:st:af15ee62-0bb3-ef2d-fa96-85a11996cc71</agent_urn>
  .
  .
  .
   </system_info>
 </agent>
```

Environment Variables See environ(5)for descriptions of the following environment variables that affect the execution of `stclient`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWservicetagu
Interface Stability	Committed

Name stmsboot – administration program for the Solaris I/O multipathing feature

Synopsis

```
/usr/sbin/stmsboot [[-D (fp | mpt | mpt_sas | iscsi) ] -d | -e | -u]
      | -L | -l controller_number]
```

Description The Solaris I/O multipathing feature is a multipathing solution for storage devices that is part of the Solaris operating environment. This feature was formerly known as Sun StorEdge Traffic Manager (STMS) or MPxIO.

The `stmsboot` program is an administrative command to manage enumeration of multipath–capable devices with Solaris I/O multipathing. Solaris I/O multipathing-enabled devices are enumerated under `scsi_vhci(7D)`, providing multipathing capabilities. Solaris I/O multipathing-disabled devices are enumerated under the physical controller.

In the `/dev` and `/devices` trees, Solaris I/O multipathing-enabled devices receive new names that indicate that they are under Solaris I/O multipathing control. This means a device will have a different name from its original name (after enabling) when it is under Solaris I/O multipathing control. The `stmsboot` command automatically updates `/etc/vfstab` and dump configuration to reflect the device names changes when enabling or disabling Solaris I/O multipathing. One reboot is required for changes to take effect.

Options The following options are supported:

`-e [ -E fp | mpt | mpt_sas | iscsi ]`
Enables Solaris I/O multipathing on all supported multipath-capable controller ports, including `fp(7d)`, `mpt(7D)`, `mpt_sas(7D)`, and `iscsi(7D)` port drivers. Multipath-capable ports include fibre channel (`fp(7d)`) controller ports and SAS (`mpt(7D)` or `mpt_sas(7D)`) controller ports. Following this enabling, you are prompted to reboot. During the reboot, `vfstab` and the dump configuration will be updated to reflect the device name changes. Specifying `-D mpt`, `-D mpt_sas`, or `-D fp` limits the enabling operation to ports attached using the specified driver.

`-d [ -D fp | mpt | mpt_sas | iscsi ]`
Disables Solaris I/O multipathing on all supported multipath-capable controller ports, including `fp(7d)`, `mpt(7D)`, `mpt_sas(7D)`, and `iscsi(7D)` port drivers. Multipath-capable ports include fibre channel (`fp(7d)`) controller ports and SAS (`mpt(7D)` or `mpt_sas(7D)`) controller ports. Following this disabling, you are prompted to reboot. During the reboot, `vfstab` and the dump configuration will be updated to reflect the device name changes. Specifying `-D mpt`, `-D mpt_sas`, or `-D fp` limits the disabling operation to ports attached using the specified driver.

`-u [ -D fp | mpt | mpt_sas | iscsi ]`
Updates `vfstab` and the dump configuration after you have manually modified the configuration to have Solaris I/O multipathing enabled or disabled on specific `fp(7d)`, `mpt(7D)`, `mpt_sas(7D)`, and `iscsi(7D)` controller ports. This option prompts you to reboot. During the reboot, `vfstab` and the dump configuration will be updated to reflect the device name changes.

`-L`
Display the device name changes from non-Solaris I/O multipathing device names to Solaris I/O multipathing device names for multipath-enabled controller ports. If Solaris I/O multipathing is not enabled, then no mappings are displayed.

`-l` *controller_number*
Display the device name changes from non-Solaris I/O multipathing device names to Solaris I/O multipathing device names for the specified controller. If Solaris I/O multipathing is not enabled, then no mappings are displayed.

Note that `mpt_sas(7D)` has MPxIO turned on by default. This means that when using the `-L` or `-l` option with `-D mpt_sas`, `stmsboot` does not display any non-multipathed and multipathed device names.

Usage

The primary function of `stmsboot` is to control the enabling and disabling of Solaris I/O multipathing on the host. The utility automatically updates `vfstab(4)` and `dumpadm(1M)` configuration to reflect device name changes. The system administrator is responsible for modifying application configuration (for example, backup software, DBMS, and so forth) to reflect updated device names.

The `-L` and `-l` options display the mapping between multipathed and non-multipathed device names. These options function only after changes to the Solaris I/O multipathing configuration have taken effect, that is, following the reboot after invoking `stmsboot -e`.

ZFS datasets, including ZFS root datasets, are correctly handled by `stmsboot`.

Examples

EXAMPLE 1 Enabling Solaris I/O Multipathing

To enable Solaris I/O multipathing for all multipath-capable controllers, run:

```
# stmsboot -e
```

To enable Solaris I/O multipathing on multipath-capable `mpt(7D)` controller ports, enter:

```
# stmsboot -D mpt -e
```

To enable Solaris I/O multipathing on multipath-capable `mpt_sas(7D)` controller ports, enter:

```
# stmsboot -D mpt_sas -e
```

To enable Solaris I/O Multipathing on multipath-capable fibre channel controller ports, enter:

```
# stmsboot -D fp -e
```

To enable Solaris I/O Multipathing on multipath-capable iSCSI controller ports, enter:

```
# stmsboot -D iscsi -e
```

EXAMPLE 2 Disabling Solaris I/O Multipathing

To disable Solaris I/O multipathing on all multipath-capable controllers, enter:

```
# stmsboot -d
```

To disable Solaris I/O multipathing on multipath-capable mpt(7D) controller ports, enter:

```
# stmsboot -D mpt -d
```

To disable Solaris I/O multipathing on multipath-capable mpt_sas(7D) controller ports, enter:

```
# stmsboot -D mpt_sas -d
```

To disable Solaris I/O multipathing on multipath-capable iSCSI controller ports, enter:

```
# stmsboot -D iscsi -d
```

To disable Solaris I/O multipathing on multipath-capable fibre channel controller ports, enter:

```
# stmsboot -D fp -d
```

EXAMPLE 3 Enabling Solaris I/O Multipathing on Selected Ports

To enable Solaris I/O multipathing on specific fibre channel controller ports and disable the feature on others, manually edit the `/kernel/drv/fp.conf` file. (See fp(7d).) The following command will update vfstab(4) and dumpadm(1M) configurations to reflect the changed device names:

```
# stmsboot -u
```

A similar procedure involving the `/kernel/drv/mpt.conf` file should be followed for devices attached by means of the mpt(7D) driver. For devices attached by means of the iscsi(7D) driver, follow a similar procedure that uses the `/kernel/drv/iscsi.conf` file.

Attributes

See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs, system/library
Interface Stability	Obsolete

Solaris SAN Configuration and Multipathing Guide (see `http://docs.sun.com`)

Consult a particular storage product's system administrator's guide and release notes for further information specific to that product.

Notes

Solaris I/O multipathing is not supported on all devices. After enabling Solaris I/O multipathing, only supported devices are placed under Solaris I/O multipathing control. Non-supported devices remain unchanged.

For Solaris releases prior to the current release, the `-e` and `-d` options replace `mpxio-disable` property entries with a global `mpxio-disable` entry in `fp.conf`.

Enabling Solaris I/O Multipathing on a Sun StorEdge Disk Array

The following applies to Sun StoreEdge T3, 3910, 3960, 6120, and 6320 storage subsystems.

To place your Sun StorEdge disk subsystem under Solaris I/O multipathing control, in addition to enabling Solaris I/O multipathing, the `mp_support` of the subsystem must be set to `mpxio` mode. The preferred sequence is to change the subsystem's `mp_support` to `mpxio` mode, then run `stmsboot -e`. If Solaris I/O multipathing is already enabled but the subsystem's `mp_support` is not in `mpxio` mode, then change the `mp_support` to `mpxio` mode and run `stmsboot -u`.

Refer to the *Sun StorEdge Administrator's Guide* for your subsystem for more details.

Using `ufsdump`

The `ufsdump(1M)` command records details of filesystem dumps in `/etc/dumpdates` (see `ufsdump(4)`). Among other items, the entries contain device names. An effect of the "active" `stmsboot` options (`-e`, `-d`, and `-u`) is to change the device name of a storage device.

Because `stmsboot` does not modify `dumpdates`, entries will refer to obsolete device names, that is, device names that were in effect before Solaris I/O multipathing configuration changes were performed. In this situation `ufsdump` will behave as if no previous dump of the filesystem had been performed. A level 0 dump will be performed.

Procedure to Use `stmsboot` in Conjunction with Sun Cluster

If possible, invoke `stmsboot -e` before installing Sun Cluster software. After executing `stmsboot`, install Sun Cluster software normally.

If Sun Cluster software is installed before executing `stmsboot`, follow this procedure:

On each machine in the cluster where Solaris I/O multipathing is required, execute:

```
# stmsboot -e
```

...and allow the system to reboot.

When the system comes up, enter the following two commands:

1. # **/usr/cluster/bin/scdidadm -C**
2. # **/usr/cluster/bin/scdidadm -r**

   The preceding commands update `did` mappings with new device names while preserving `did` instance numbers for disks that are connected to multiple cluster nodes. `did` instance numbers of the local disks might not be preserved. For this reason, the `did` disk names for local disks might change.
3. Update `/etc/vfstab` to reflect any new `did` disk names for your local disks.

4. Reboot the system.

To disable the Solaris multipathing feature, use `stmsboot -d` (instead of `stmsboot -e`), then follow the procedure above.

To view mappings between the old and new device names, run `stmsboot -L`. To view `did` device name mappings, run `/usr/cluster/bin/scdidadm -L`.

With active-passive storage arrays, it is possible that while your host is rebooting the array controller could failover the path that a particular target is using. In this scenario, `fsck(1M)` will fail to open the physical path listed in `/etc/vfstab`. The `svc:/system/filesystem/local:default` SMF service will transition to a maintenance state as a result. To rectify this, consult the documentation for your storage array to failback the path. The `mpathadm(1M)` can assist with determining the active and passive path(s).

Limitations On x86 platforms, the current Solaris release does not support disabling Solaris I/O multipathing of boot devices attached by means of fibre channel. Solaris I/O multipathing is always enabled for supported fibre channel-attached boot devices. Disabling Solaris I/O multipathing in this situation must be performed on a per-port basis. See `fp(7d)`.

Executing `devfsadm -C` removes obsolete device entries that `stmsboot` relies on. This will prevent correct operation of the `-d` option for boot devices (regardless of platform type) and the `-L` option.

Name strace – print STREAMS trace messages

Synopsis `strace [`*mid sid level*`]...`

Description `strace` without arguments writes all STREAMS event trace messages from all drivers and modules to its standard output. These messages are obtained from the STREAMS log driver (see `log(7D)`). If arguments are provided, they must be in triplets of the form *mid, sid, level*, where *mid* is a STREAMS module ID number, *sid* is a sub-ID number, and *level* is a tracing priority level. Each triplet indicates that tracing messages are to be received from the given module/driver, sub-ID (usually indicating minor device), and priority level equal to, or less than the given level. The token `all` may be used for any member to indicate no restriction for that attribute.

The format of each trace message output is:

<*seq*> <`time`> <*ticks*> <*level*> <*flags*> <*mid*> <*sid*> <*text*>

<*seq*>	trace sequence number
<`time`>	time of message in *hh:mm:ss*
<*ticks*>	time of message in machine ticks since boot
<*level*>	tracing priority level
<*flags*>	E : message is also in the error log F : indicates a fatal error N : mail was sent to the system administrator (hardcoded as root)
<*mid*>	module ID number of source
<*sid*>	sub-ID number of source
<*text*>	formatted text of the trace message

Once initiated, `strace` will continue to execute until terminated by the user.

Examples **EXAMPLE 1** A sample output of the `strace` command:

The following example outputs all trace messages from the module or driver whose module ID is `41`:

```
strace  41 all all
```

The following example outputs those trace messages from driver or module ID `41` with sub-IDs `0`, `1`, or `2`:

```
strace  41 0 1  41 1 1  41 2 0
```

Messages from sub-IDs `0` and `1` must have a tracing level less than or equal to `1`. Those from sub-ID `2` must have a tracing level of `0`.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also attributes(5), log(7D)

STREAMS Programming Guide

Notes

- There is no restriction to the number of `strace` processes opening the STREAMS log driver at a time.
- The log-driver records the list of the triplets specified in the command invocation, and compares each potential trace message against this list to decide if it should be formatted and sent up to the `strace` process. Hence, long lists of triplets will have a greater impact on overall STREAMS performance. Running `strace` will have the most impact on the timing of the modules and drivers generating the trace messages that are sent to the `strace` process. If trace messages are generated faster than the `strace` process can handle them, some of the messages will be lost. This last case can be determined by examining the sequence numbers on the trace messages output.

Name strclean – STREAMS error logger cleanup program

Synopsis

```
strclean [-a age] [-d logdir]
```

Description `strclean` is used to clean up the STREAMS error logger directory on a regular basis (for example, by using `cron`. By default, all files with names matching `error.*` in `/var/adm/streams` that have not been modified in the last three days are removed.

Options The following options are supported:

`-a` *age* The maximum age in days for a log file can be changed using the `-a` option.

`-d` *logdir* A directory other than `/var/adm/streams` can be specified using the `-d` option.

Examples **EXAMPLE 1** A sample of using the `strclean` command.

This example has the same result as running `strclean` with no arguments:

```
example%  strclean -d /var/adm/streams -a 3
```

Files `/var/adm/streams/error.*`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `cron(1M)`, `strerr(1M)`, `attributes(5)`

STREAMS Programming Guide

Notes `strclean` is typically run from `cron` on a daily or weekly basis.

Name strerr – STREAMS error logger daemon

Synopsis

```
strerr
```

Description `strerr` receives error log messages from the STREAMS-based log driver (see `log(7D)`) and appends them to a log file. The resultant error log files reside in the directory `/var/adm/streams`, and are named `error.`*mm*`-dd`, where *mm* is the month and `dd` is the day of the messages contained in each log file.

The format of an error log message is:

<*seq*> <`time`> <*ticks*> <*flags*> <*mid*> <*sid*> <*text*>

<*seq*> error sequence number

<`time`> time of message in hh:mm:ss

<*ticks*> time of message in machine ticks since boot priority level

<*flags*> `T` : the message was also sent to a tracing process `F` : indicates a fatal error `N` : send mail to the system administrator (hardcoded as root)

<*mid*> module ID number of source

<*sid*> sub-ID number of source

<*text*> formatted text of the error message

Messages that appear in the error log are intended to report exceptional conditions that require the attention of the system administrator. Those messages which indicate the total failure of a STREAMS-based driver or module should have the `F` flag set. Those messages requiring the immediate attention of the administrator will have the `N` flag set, which causes the error logger to send the message to the system administrator using `mail`. The priority level usually has no meaning in the error log but will have meaning if the message is also sent to a tracer process.

Once initiated, `strerr` continues to execute until terminated by the user. It is commonly executed asynchronously.

Files `/var/adm/streams/error.`*mm*`-dd` error log file.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `attributes(5)`, `log(7D)`

STREAMS Programming Guide

Notes There is no restriction to the number of `strerr` processes opening the STREAMS–based log driver at a time.

If a module or driver is generating a large number of error messages, running the error logger will cause a degradation in STREAMS performance. If a large burst of messages are generated in a short time, the log driver may not be able to deliver some of the messages. This situation is indicated by gaps in the sequence numbering of the messages in the log files.

Name sttydefs – maintain line settings and hunt sequences for TTY ports

Synopsis

```
/usr/sbin/sttydefs -a ttylabel [-b] [-f final-flags]
     [-i initial-flags] [-n nextlabel]

/usr/sbin/sttydefs -l [ttylabel]

/usr/sbin/sttydefs -r ttylabel
```

Description `sttydefs` is an administrative command that maintains the line settings and hunt sequences for the system's TTY ports by making entries in, and deleting entries from the `/etc/ttydefs` file.

`sttydefs` with a `-a` or `-r` option may be invoked only by the super-user. `sttydefs` with `-l` may be invoked by any user on the system.

Options The following options are supported:

`-a` *ttylabel* — Add a record to the `ttydefs` file, using *ttylabel* as its label. The following describes the effect of the `-b`, `-n`, `-i`, or `-f` options when used in conjunction with the `-a` option:

`-b` — Enable autobaud. Autobaud allows the system to set the line speed of a given TTY port to the line speed of the device connected to the port without the user's intervention.

`-f` *final-flags* — Specify the value to be used in the *final-flags* field in `/etc/ttydefs`. *final-flags* must be in a format recognized by the `stty` command. *final-flags* are the `termio(7I)` settings used by `ttymon` after receiving a successful connection request and immediately before invoking the service on the port. If this option is not specified, `sttydefs` will set *final-flags* equal to the `termio(7I)` flags `9600` and `sane`.

`-i` *initial-flags* — Specify the value to be used in the *initial-flags* field in `/etc/ttydefs`. *initial-flags* must be in a format recognized by the `stty` command. These flags are used by `ttymon` when searching for the correct baud rate. They are set prior to writing the prompt. If this option is not specified, `sttydefs` will set *initial-flags* equal to the `termio(7I)` flag `9600`.

`-n` *nextlabel* — Specify the value to be used in the *nextlabel* field in `/etc/ttydefs`. If this option is not specified, `sttydefs` will set *nextlabel* equal to *ttylabel*.

`-l`[*ttylabel*] — If a *ttylabel* is specified, `sttydefs` displays the record from `/etc/ttydefs` whose TTY label matches the specified *ttylabel*. If no *ttylabel* is specified, `sttydefs` displays the entire contents of `/etc/ttydefs`. `sttydefs` verifies that each entry it displays is correct and that the entry's *nextlabel* field references an existing

`-r` *ttylabel* — Remove any record in the `ttydefs` file that has *ttylabel* as its label.

Output If successful, `sttydefs` will exit with a status of `0`. `sttydefs -l` will generate the requested information and send it to standard output.

Examples **EXAMPLE 1** A sample of `sttydefs` command.

The following command lists all the entries in the `ttydefs` file and prints an error message for each invalid entry that is detected.

```
example# sttydefs -l
```

The following shows a command that requests information for a single label and its output:

```
example# sttydefs -l 9600
----------------------------------------------------------------
9600:9600 hupcl erase ^h:9600 sane ixany tab3 hupcl erase ^h::4800
----------------------------------------------------------------
ttylabel:    9600
initial flags:    9600 hupcl erase ^h
final flags:    9600 sane ixany tab3 hupcl erase ^h
autobaud:    no
nextlabel:      4800
```

The following sequence of commands will add the labels `1200`, `2400`, `4800`, and `9600` and put them in a circular list:

```
sttydefs -a 1200 -n 2400 -i 1200 -f "1200 sane"
sttydefs -a 2400 -n 4800 -i 2400 -f "2400 sane"
sttydefs -a 4800 -n 9600 -i 4800 -f "4800 sane"
sttydefs -a 9600 -n 1200 -i 9600 -f "9600 sane"
```

Files `/etc/ttydefs`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `attributes(5)`, `termio(7I)`

Name su – become superuser or another user

Synopsis

```
su [-] [username [arg...]]
```

Description The su command allows one to become another user without logging off or to assume a role. The default user *name* is root (superuser).

To use su, the appropriate password must be supplied (unless the invoker is already root). If the password is correct, su creates a new shell process that has the real and effective user ID, group IDs, and supplementary group list set to those of the specified *username*. Additionally, the new shell's project ID is set to the default project ID of the specified user. See getprojent(3PROJECT), setproject(3PROJECT). The new shell will be the shell specified in the shell field of *username*'s password file entry (see passwd(4)). If no shell is specified, /usr/bin/sh is used (see sh(1)). If superuser privilege is requested and the shell for the superuser cannot be invoked using exec(2), /sbin/sh is used as a fallback. To return to normal user ID privileges, type an EOF character (CTRL-D) to exit the new shell.

Any additional arguments given on the command line are passed to the new shell. When using programs such as sh, an *arg* of the form -c *string* executes *string* using the shell and an *arg* of -r gives the user a restricted shell.

To create a login environment, the command "su –" does the following:

- In addition to what is already propagated, the LC* and LANG environment variables from the specified user's environment are also propagated.
- Propagate TZ from the user's environment. If TZ is not found in the user's environment, su uses the TZ value from the TIMEZONE parameter found in /etc/default/login.
- Set MAIL to /var/mail/*new_user*.

If the first argument to su is a dash (-), the environment will be changed to what would be expected if the user actually logged in as the specified user. Otherwise, the environment is passed along, with the exception of $PATH, which is controlled by PATH and SUPATH in /etc/default/su.

All attempts to become another user using su are logged in the log file /var/adm/sulog (see sulog(4)).

Security su uses pam(3PAM) with the service name su for authentication, account management, and credential establishment.

Examples **EXAMPLE 1** Becoming User bin While Retaining Your Previously Exported Environment

To become user bin while retaining your previously exported environment, execute:

```
example% su bin
```

EXAMPLE 2 Becoming User bin and Changing to bin's Login Environment

To become user bin but change the environment to what would be expected if bin had originally logged in, execute:

```
example% su - bin
```

EXAMPLE 3 Executing command with user bin's Environment and Permissions

To execute command with the temporary environment and permissions of user bin, type:

```
example% su - bin -c "command args"
```

Environment Variables

Variables with LD_ prefix are removed for security reasons. Thus, su bin will not retain previously exported variables with LD_ prefix while becoming user bin.

If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of su for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables are set in the environment, the "C" (U.S. style) locale determines how su behaves.

LC_CTYPE — Determines how su handles characters. When LC_CTYPE is set to a valid value, su can display and handle text and filenames containing valid characters for that locale. su can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. su can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

LC_MESSAGES — Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

Files

$HOME/.profile — user's login commands for sh and ksh

/etc/passwd — system's password file

/etc/profile — system-wide sh and ksh login commands

/var/adm/sulog — log file

/etc/default/su — the default parameters in this file are:

- SULOG — If defined, all attempts to su to another user are logged in the indicated file.
- CONSOLE — If defined, all attempts to su to root are logged on the console.

PATH	Default path. (/usr/bin:)
SUPATH	Default path for a user invoking su to root. (/usr/sbin:/usr/bin)
SYSLOG	Determines whether the syslog(3C) LOG_AUTH facility should be used to log all su attempts. LOG_NOTICE messages are generated for su's to root, LOG_INFO messages are generated for su's to other users, and LOG_CRIT messages are generated for failed su attempts.

/etc/default/login — the default parameters in this file are:

TIMEZONE	Sets the TZ environment variable of the shell.

Name sulogin – access single-user mode

Synopsis

```
sulogin
```

Description The `sulogin` utility is automatically invoked by `init` when the system is first started. It prompts the user to type the root password to enter system maintenance mode (single-user mode) or to type EOF (typically CTRL-D) for normal startup (multi-user mode). The user should never directly invoke `sulogin`.

The `sulogin` utility can prompt the user to enter the root password on a variable number of serial console devices, in addition to the traditional console device. See `consadm(1m)` and `msglog(7D)` for a description of how to configure a serial device to display the single-user login prompt.

Files

`/etc/default/sulogin` Default value can be set for the following flag:

PASSREQ — Determines if login requires a password. Default is `PASSREQ=YES`.

`/etc/default/login` Default value can be set for the following flag:

`SLEEPTIME` — If present, sets the number of seconds to wait before login failure is printed to the screen and another login attempt is allowed. Default is `4` seconds. Minimum is `0` seconds. Maximum is `5` seconds.

Both `su(1M)` and `login(1)` are affected by the value of `SLEEPTIME`.

Attributes See `attributes(5)` for descriptions of the following attributes:

Name suninstall – install the Solaris operating system

Synopsis

```
suninstall
```

Description `install-solaris(1M)` is now the preferred command for starting and restarting the Solaris Installation program. It should be used instead of `suninstall`. `suninstall` is symbolically linked to `install-solaris`.

`suninstall` is a forms-based and graphical subsystem for installing the operating system.

`suninstall` exists only on the Solaris installation media (CD or DVD) and should only be invoked from there. Refer to the *Solaris 10 Installation Guide: Basic Installations* for more details.

suninstall allows installation of the operating system onto any standalone system. suninstall loads the software available on the installation media. Refer to the *Solaris 10 Installation Guide: Basic Installations* for disk space requirements.

Usage Refer to the *Solaris 10 Installation Guide: Basic Installations* for more information on the various menus and selections.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcdrom (Solaris installation media)

See Also `pkginfo(1)`, `install(1M)`, `install-solaris(1M)`, `pkgadd(1M)`, `attributes(5)`

Solaris 10 Installation Guide: Basic Installations

Notes It is advisable to exit `suninstall` by means of the exit options in the `suninstall` menus.

Name SUNWgfb_config – fbconfig module for configuring Sun XVR-1000 Graphics Accelerator

Synopsis

```
fbconfig [-dev device-filename]
     [-active a | b | both | auto]
     [-res video-mode [now | try] [noconfirm]]
     [-file machine | system]
     [-doublewide enable | disable | reverse]
     [-doublehigh enable | disable | reverse]
     [-multisample enable | disable | auto [static | dynamic]]
     [-samples samples-per-pixel]
     [-g gamma-correction-value] [-master a | b | input]
     [-clearpixel0 | 255]

fbconfig [-dev device-filename] -stream a | b
     [-port hd15 | dvid | svideo | auto]
     [-res video-mode [now | try] [noconfirm]]
     [-file machine | system]
     [-offset xoff-value [yoff-value]]
     [-slave [enable | disable] [internal | external]]

fbconfig [-dev device-filename] -defaults

fbconfig [-dev device-filename]
     [-propt | -prconf | -res \?]

fbconfig [-help | -list]
```

Description `SUNWgfb_config` is the Sun XVR-1000 Graphics Accelerator device dependent layer for `fbconfig(1M)`. It configures the Sun XVR-1000 Graphics Accelerator and some of the X11 window system defaults. The device can drive two monitors, each with a unique video stream (called stream a and stream b).

The first form of `SUNWgfb_config` shown in the synopsis above sets card options, which are options common to both stream a and stream b, and apply to the entire card.

The second form is used to set stream options, which are options specific to either stream a or stream b. The second form usage requires the `-stream` option to define which stream is affected.

Both the first form and the second form store the specified options in the `OWconfig` file. These options will be used to initialize the device the next time the window system is run on that device. Updating options in the `OWconfig` file provides persistence of these options across window system sessions and system reboots. For `-res` with `now` or `try`, `-slave`, `-master`, `-port`, and `-g` , the device will be immediately programmed.

The third form, which invokes the `-defaults` option, sets all card options and all stream options to their default values and saves these defaults in the `OWconfig` file.

The fourth form, which invokes the `-prconf`, `-propt`, and `-res \?` options, queries the device for status that is card-specific.

The fifth form, which invokes the `-help`, and `-list` options, provides instruction on using `SUNWgfb_config` and a list of available devices. Additionally for the fifth form, all other options are ignored.

You can specify options for only one device at a time. Specifying options for multiple devices requires multiple invocations of `SUNWgfb_config`.

Only Sun XVR-1000 Graphics Accelerator-specific options can be specified through `SUNWgfb_config`. The normal window system options for specifying default depth, default visual class, and so forth are still specified as device modifiers on the command line when the X server is started.

You can also specify the `OWconfig` file that is to be updated. By default, the machine-specific file in the `/etc/openwin` directory tree is updated. You can use the `-file` option to specify an alternate file. For example, the system-global `OWconfig` file in the `/usr/openwin` directory tree can be updated instead.

General Options

`-dev` *device-filename*

Specifies the device's special file. The default is `/dev/fb`.

`-file machine|system`

Specifies which `OWconfig` file to update. If *machine* is specified, the machine-specific `OWconfig` file in the `/etc/openwin` directory tree is updated. If *system* is specified, the global `OWconfig` file in the `/usr/openwin` directory tree is updated. If the specified file does not exist, it is created. This option has no effect unless other options are specified. The default is *machine*.

`-res` *video-mode*`[now | try] [noconfirm]`

Specifies the video mode used to drive the monitor connected to the specified device. If `-res` is invoked with `now` or `try`, you must specify a `-stream` option or a device, such as `/dev/fbs/gfb0a`. If `-active` is set to `both` or `auto`, then both stream *video-mode* values will be modified.

The *video-mode* argument specifies resolution and timing information for the display (for example, `SUNW_STD_1280x1024x76`). The naming convention for the *video-mode* specifier is:

origin_type_widthxheightxrate

The elements of the specifier are described as follows:

origin This can be one of:

- `SUNW`, Sun derived resolution
- `VESA`, Video Electronics Standards Association-derived resolution
- `other`, other source

type This can be one of:

- `STD`, normal resolution, usable by most display devices
- `DIG`, resolution tuned only for LCD flat panels
- `INT`, interlaced
- `STEREO`, stereo

`width` screen width in pixels

`height` screen height in pixels

`rate` vertical frequency of the screen refresh

Note that some video-modes supported by the device, might not be supported by the monitor. The list of video-modes supported by the device and the monitor can be obtained by running `SUNWgfb_config` with the `-res \?` option (the fourth form shown in the command synopsis above).

The `-res` option also accepts additional, optional arguments, listed below, immediately following the video mode specification. Either `now` or `try` (`try` subsumes `now`) and `noconfirm` can be present.

`now` If present, not only is the video mode updated in the `OWconfig` file, but the device is immediately programmed to display this video mode. This is useful for changing the video mode before starting the window system.

Note – It is recommended that you not use this suboption with `SUNWgfb_config` while the configured device is being used (for example, while running the window system). Unpredictable results can occur. To run `SUNWgfb_config` with the `now` suboption, first bring the window system down. If the `now` suboption is used within a window system session, the video mode is changed immediately, but the width and height of the affected screen do not change until the window system is exited and reentered. In addition, the system might not recognize changes in stereo mode.

`noconfirm` Using the `-res` option, the user can put the system into an unusable state, with no video output. To reduce the chance of this, the default behavior of `SUNWgfb_config` is to display a warning message and to ask the user whether to continue. The `noconfirm` bypasses this confirmation. This option is useful when `SUNWgfb_config` is being run from a shell script.

`try` If present, the specified video mode will be programmed on a trial basis. The user is asked to confirm the video mode by typing **y** within 10 seconds. Alternatively, the user can

terminate the trial before 10 seconds elapse by typing any character other than **y** or carriage return. Such input is considered a no and the previous video mode is restored. With a negative response, `SUNWgfb_config` does not change the video mode in the `OWconfig` file; other options specified still take effect. If a carriage return is typed, the user is asked (**y** or **n**) whether to keep the new video mode.

This sub-option should not be used with `SUNWgfb_config` while the configured device is being used (for example, while running the window system) as unpredictable results may occur. To run `SUNWgfb_config` with the `try` sub-option, the window system should be brought down first.

`-defaults` — Resets all option values to their default values. Writes these values to the `OWconfig` file.

`-propt` — Displays the current values of all options in the `OWconfig` file specified by the `-file` option for the device specified by the `-dev` option. Displays the values of options as they will be in the `OWconfig` file after the call to `SUNWgfb_config` completes. The following is an example display:

```
--- OpenWindows Configuration for /dev/fbs/gfb0 ---
OWconfig: machine
Active Streams: both
Samples Per Pixel: 2
Multisample Allocation Model: static
```

```
Multisample Mode: auto
Doublewide: disable
Gamma Correction Value: 2.22

--- OpenWindows Configuration for Stream a ---
Video Mode: SUNW_STD_1280x1024x76

--- OpenWindows Configuration for Stream b ---
Video Mode: VESA_STD_640x480x60
```

`-prconf` Displays the XVR-1000 hardware configuration. The following is an example display:

```
--- Hardware Configuration for /dev/fb (SUNWgfb0) ---
Type:   Sun Graphics Accelerator
Part:   501-5865
Memory:
        MAJC:           32MB
        Texture:        256MB total
        3DRAM64:        5.0M pixels

Versions:  FCode 1.14  MCode 0.19  MAJC 2.1  FBC3 3.0  XChip 2.0

Video Streams:
   Stream a
         Current resolution Setting: SUNW_STD_1280x1024x76
         Monitor/EDID data (13W3)
                 Monitor Manufacturer: SUN
                 Monitor Name:  GDM-5410
                 EDID:  Version 1, Revision 2
   Stream b
         Current resolution Setting: VESA_STD_640x480x60
         Port: svideo
```

`-help` Displays a list of the `SUNWgfb_config` command line options, along with a brief explanation of each.

`-res \?` Displays list of defined *video-mode* names.

Card Options

`-active a | b | both | auto`

Specifies which streams are enabled. `both` select both streams. The default is `auto`, which means whichever stream is chosen by the console.

`-multisample` `enable` | `disable` | `auto` [`static` | `dynamic`]

The suboptions for `-multisample` are described as follows:

`disable` No multisample is possible.

`enable` Multisample is possible but is selected on a per-application basis.

`auto` All Sun OpenGL applications are rendered using multisampling.

`static` Multisample allocation occurs at X startup/config load time. The config *samples-per-pixel* or `max` parameter specifies the depth that is pre-allocated.

`dynamic` OpenGL tasks allocate buffers themselves.

`-samples` *samples-per-pixel*
Specifies the number of samples/pixel to pre-allocate in static mode. Provides a hint to OpenGL in dynamic mode. The allowable choices for *samples-per-pixel* are 2, 3, 4, 5, 6, 8, 10, 16, and `max`. The default is `max`, which means to use the maximum number of samples that can be supported with the amount of memory available.

`-doublewide` `enable` | `disable` | `reverse`
This option makes it easy for you to combine both streams into one side-by-side virtual display. If you specify `enable`, stream a is to the left of stream b. If `reverse` is specified, stream b is to the left of stream b. Both will be the same resolution defined with the `-res` option. If you specify `disable`, only one stream will be enabled. `-doublewide` precludes `-doublehigh`.

`-doublehigh` `enable` | `disable` | `reverse`
This option makes it easy for you to combine both streams into one virtual display, with one monitor on a shelf above the other. If you specify `enable`, stream a is above stream b. If `reverse` is specified, stream b is above stream a. Both will be the same resolution defined with the `-res` option. If you specify `disable`, only one stream will be enabled. `-doublehigh` precludes `-doublewide`.

`-g` *gamma-correction value*
This option changes the gamma correction value. By default the gamma correction value is 2.22. Any value less than zero is illegal. This option can be used while the window system is running. Changing the gamma correction value will affect all the windows being displayed using gamma-corrected visuals. The gamma correction value is also saved in the `OWconfig` file for the next time the window system starts.

`-master` `a` | `b` | `input`
This option controls the setting frame pins on the stereo/sync connector on the device. It also controls which stream drives stereo glasses, which attach to the same connector.

If `a` (the default) or `b` is selected, the card is setup to be a sync master, and the frame sync signal from the corresponding stream will be sent out this connector.

If you select `input`, the card is setup to take its frame sync from another card through this connector. This sync can then be used to sync either or both streams by setting the stream-specific `-slave` option(s) to `external`.

If stereo glasses are used, the `a` or `b` options select which stream is used for the sync signal to the glasses.

`-clearpixel 0 | 255`
Selects the overlay transparent color. This is the pixel value (color index) used by the transparent overlay visual to display the underlay (RGB) pixel contents. The default is 255 (all bits 1), but some applications require 0. All other color indices display a colormap color.

Stream Options

`-stream a | b`
Specifies for which stream options will be set. It is a required option for each of the other options in this section. It is optional for `-res`. Only one `-stream` option can be specified.

`-port hd15 | dvid | svideo | auto`
Directs stream b to the appropriate output connector: `hd-15`, `dvid`, or `svideo`. If `auto`, then the output connector for stream b is selected by the console. Stream a is always output through the 13W3 connector.

`-offset` *xoff-value* [*yoff-value*]
Offsets the display of the stream (specified by `-stream`) relative to the adjoining edge of the other stream when doublewide or doublehigh is enabled. This can be used to cause an overlap.

xoff-value Number of pixels offset in horizontal direction for the right-hand stream when doublewide is enabled. Positive direction is to the right (create a gap); negative is to the left (overlap the streams). Default is 0, which means the two edges touch.

yoff-value Number of pixels offset in vertical direction for the bottom stream when doublehigh is enabled. Positive direction is down (create a gap); negative is up (overlap the streams). Default is 0, which means the two edges touch.

`-slave [ enable | disable ] [ internal | external ]`
This option allows you to specify the sync source for the specified stream. `internal` indicates that the sync source is the other stream of this device. `external` indicates the sync is taken from a source outside the device. If you use `external`, you also need to use the card option `-master input`.

Defaults

For a given invocation of `SUNWgfb_config`, if an option does not appear on the command line, the corresponding `OWconfig` option is not updated. It retains its previous value.

When the window system is run, if an option has never been specified through `SUNWgfb_config`, a default value is used. The option defaults are as follows:

Option	Default
–dev	/dev/fb
–file	machine
–res	none

–samples	max
–multisample	enable/dynamic
–clearpixel	255
–master	a
–slave	disable/external
–doublewide	not set
–g	2.22
-active	auto
-port	auto
-offset	0/0

The default for the `-res` option of `none` means that, when the window system is run, the screen resolution will be the video mode that is currently programmed in the device. This provides compatibility for users who are used to specifying the device resolution through the PROM.

Examples

EXAMPLE 1 Switching Resolution of a Monitor

The following example switches to the resolution of 1280 by 1024 at 76 Hz:

```
example% fbconfig -stream a -res -SUNW_STD_1280x1024x76
```

Files

`/usr/lib/fbconfig/SUNWgfb_config` device special file

Name SUNWifb_config – configure the Sun Expert3D Graphics Accelerator

Synopsis

```
/usr/lib/fbconfig/SUNWifb_config [-dev device-filename]
     [-res video-mode [now | try] [noconfirm | nocheck]]
     [-file machine | system] [-deflinear true | false]
     [-defoverlay true | false]
     [-linearorder first | last]
     [-overlayorder first | last]
     [-expvis enable | disable] [-slave enable | disable]
     [-accum enable | disable] [-g gamma-correction-value]
     [-gfile gamma-correction-file] [-propt] [-prconf]
     [-defaults] [-slave] [] [-samples 1 | 2 | 4 | 8 | 16]
     [-multisample enable | disable | auto]

/usr/lib/fbconfig/SUNWifb_config [-propt] [prconf]

/usr/lib/fbconfig/SUNWifb_config [-help] [-res \?]
```

Description `SUNWifb_config` configures the Sun Expert3D Graphics Accelerator, Sun Expert3D-Lite, and Sun XVR-500 Graphics Accelerators, and some of the X11 window system defaults for the graphics accelerator.

The first form of `SUNWifb_config` shown in the synopsis above stores the specified options in the `OWconfig` file. These options will be used to initialize the Sun Expert3D device the next time the window system is run on that device. Updating options in the `OWconfig` file provides persistence of these options across window system sessions and system reboots.

The second and third forms of `SUNWifb_config`, which invoke only the `-prconf`, `-propt`, `-help`, and `-res \?` options, do not update the `OWconfig` file. Additionally, for the third form of the command, all other options are ignored.

Options may be specified for only one Sun Expert3D device at a time. Specifying options for multiple Sun Expert3D devices requires multiple invocations of `SUNWifb_config`.

Only options specific to the Sun Expert3D device can be specified through `SUNWifb_config`. The normal window system options for specifying default depth, default visual class and so forth are still specified as device modifiers on the `openwin` command line (see the `Xsun`(1) manual page in the *OpenWindows Desktop Reference Manual*).

Options The following options are supported:

`-dev` *device-filename*
: Specifies the Sun Expert3D special file. The default is `/dev/fbs/ifb0`.

`-file`*machine*| *system*
: Specifies which `OWconfig` file to update. If *machine* is specified, the machine-specific `OWconfig` file in the `/etc/openwin` directory tree is updated. If *system* is specified, the global `OWconfig` file in the `/usr/openwin` directory tree is updated. If the

specified file does not exist, it is created. This option has no effect unless other options are specified. The default is *machine*.

`-res` *video-mode*

Specifies the video mode used to drive the monitor connected to the specified Sun Expert3D device.

The format of these built-in video modes is:

*width*x*height*x*rate*

where *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh. The `s` suffix of `960x680x112s` and `960x680x108s` means that these are stereo video modes. The `i` suffix of `640x480x60i` and `768x575x50i` designates interlaced video timing. If absent, non-interlaced timing will be used. As a convenience, `-res` also accepts formats with `@` (at sign) in front of the refresh rate instead of `x`. For example: `1280x1024@76`. Note that some video-modes supported by the Sun Expert3D device might not be supported by the monitor. The list of video-modes supported by the Sun Expert3D device and the monitor can be obtained by running `SUNWifb_config` with the `-res \?` option (shown in the command synopsis above). The following is a list of all possible video-modes supported on the Sun Expert3D device:

	1024x768x60 1024x768x70 1024x768x75 1024x768x75 1024x768x77 1024x800x84 1152x900x66 1152x900x76 1280x800x76 1280x1024x60 1280x1024x67 1280x1024x76 1280x1024x85 1280x1024x112s (Stereo) 960x680x112s (Stereo) 960x680x108s (Stereo) 640x480x60 640x480x60i (Interlaced) 768x575x50i (Interlaced) 1440x900x76 1600x1000x66 1600x1000x76 1600x1280x76 1792x1344x75 1920x1080x72 1920x1200x70 1920x1200x75
Symbolic names	For convenience, some of the above video modes have symbolic names defined for them. Instead of the form *width* x *height* x *rate*, one of these names may be supplied as the argument to `-res`. The meaning of the symbolic name none is that when the window system is run the screen resolution will be the

video mode that is currently programmed in the device.

Name	Corresponding Video Mode
svga	1024x768x60
1152	1152x900x76
1280	1280x1024x76
stereo	960x680x112s
ntsc	640x480x60i
pal	768x575x50i
none	(see text above)

The `res` option also accepts additional, optional arguments immediately following the video mode specification. Any or all of the following might be present.

`now`

If present, not only will the video mode be updated in the `OWconfig` file, but the Sun Expert3D device will be immediately programmed to display this video mode. (This is useful for changing the video mode before starting the window system).

Note that it is inadvisable to use this suboption with `SUNWifb_config` while the configured device is being used (for example, while running the window system); unpredictable results might occur. To run `SUNWifb_config` with the `now` suboption, first bring the window system down. If the `now` suboption is used within a window system

session, the video mode will be changed immediately, but the width and height of the affected screen will not change until the window system is exited and reentered again. In addition, the system may not recognize changes in stereo mode. Consequently, this usage is strongly discouraged.

`noconfirm` Using the `-res` option, the user could potentially put the system into an unusable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this, the default behavior of `SUNWifb_config` is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. The `noconfirm` option instructs `SUNWifb_config` to bypass this confirmation and to program the requested video mode anyway. This option is useful when `SUNWifb_config` is being run from a shell script.

`nocheck` If present, the normal error checking based on the monitor sense code (described above) will be suspended. The video mode specified by the user

will be accepted regardless of whether it is appropriate for the currently attached monitor. (This option is useful if a different monitor is to be connected to the Sun Expert3D device). Use of this option implies `noconfirm` as well.

`try`

If present, the specified video mode will be programmed on a trial basis. The user will be asked to confirm the video mode by typing **y** within 10 seconds. Or the user may terminate the trial before 10 seconds are up by typing any character. Any character other than **y** or carriage return is considered a no and the previous video mode will be restored and `SUNWifb_config` will not change the video mode in the `OWconfig` file (other options specified will still take effect). If a carriage return is typed, the user is prompted for a yes or no answer on whether to keep the new video mode.

This sub-option should not be used with `SUNWifb_config` while the configured device is being used (for example, while running the window system) as unpredictable results may occur. To run `SUNWifb_config` with the

`try` sub-option, the window system should be brought down first.

`-deflinear true | false`

The Sun Expert3D device possesses two types of visuals: linear and nonlinear. Linear visuals are gamma corrected and nonlinear visuals are not. There are two visuals that have both linear and nonlinear versions: 24-bit TrueColor and 8-bit StaticGray. If `true`, the default visual is set to the linear visual that satisfies other specified default visual selection options (specifically, the `Xsun`(1) `-defdepth` and `-defclass` options described in the *OpenWindows Desktop Reference Manual*). If `false`, or if there is no linear visual that satisfies the other default visual selection options, the non-linear visual specified by these other options will be chosen to be the default. This option cannot be used when the `-defoverlay` option is present, because the Sun Expert3D does not possess a linear overlay visual.

`-defoverlay true | false`

The Sun Expert3D device provides an 8-bit PseudoColor visual whose pixels are disjoint from the rest of the Sun Expert3D visuals. This is called the overlay visual. Windows created in this visual will not damage windows created in other visuals. The converse, however, is not true. Windows created in other visuals will damage overlay windows. If the value of this option is `true`, the overlay visual will be made the default visual. If `false`, the nonoverlay visual that satisfies the other default visual selection options, such as `-defdepth` and `-defclass`, will be chosen as the default visual. See the `Xsun`(1) manual page in the *OpenWindows Desktop Reference Manual*. Whenever `-defoverlay true` is used, the default depth and class chosen on the `openwin` command line must be 8-bit PseudoColor. If not, a warning message will be printed and the `-defoverlay` option will be treated as `false`. This option cannot be used when the `-deflinear` option is present, because the Sun Expert3D device does not possess a linear overlay visual.

`-linearorder first | last`

If `first`, linear visuals will come before their non-linear counterparts on the X11 screen visual list for the Sun Expert3D screen. If `last`, the nonlinear visuals will come before the linear ones.

`-overlayorder first | last`

If `-first`, the depth 8 PseudoColor Overlay visual will come before the non-overlay visual on the X11 screen visual list for the Sun Expert3D screen. If `last`, the non-overlay visual will come before the overlay one.

`-expvis enable | disable`

If enabled, OpenGL Visual Expansion will be activated. Multiple instances of selected visual groups (8-bit PseudoColor, 24-bit TrueColor, and so forth) can be found in the screen visual list.

`-slave enable | disable`

If enabled, the video for this frame buffer will be synced with the video of the display which is connected to it. For applications which support it buffers will also be swapped synchronously.

`-accum enable | disable`

If enabled, frame buffer memory is allocated for accelerated accumulation buffer for windows. If disabled, software accumulation buffering will be done for windows. Accelerated accumulation buffers for pBuffers are always available as memory allows.

`-g` *gamma-correction_value*

This option allows changing the gamma correction value. All linear visuals provide gamma correction. By default the gamma correction value is 2.22. Any value less than zero is illegal. The gamma correction value is applied to the linear visual, which then has an effective gamma value of 1.0, which is the value returned by `XSolarisGetVisualGamma()`. See `XSolarisGetVisualGamma`(3) for a description of that function.This option can be used while the window system is running. Changing the gamma correction value will affect all the windows being displayed using the linear visuals.

`-gfile` *gamma-correction_file*

This option loads gamma correction table from the specified file. This file should be formatted to provide the gamma correction values for R, G and B channels on each line. Each of these values

should be in hexadecimal format and separated from each other by at least one space. Also, this file should provide 1024 such triplets. An example of this file is as follows.

```
0x00 0x00 0x000
0x01 0x01 0x001
0x02 0x02 0x002
...
...
0x3ff 0x3ff 0x3ff
```

Using this option, the gamma correction table can be loaded while the window system is running. The new gamma correction will affect all the windows being displayed using the linear visuals. Note that, when gamma correction is being done using a user-specified table, the gamma correction value is undefined. By default, the window system assumes a gamma correction value of 2.22 and loads the gamma table it creates corresponding to this value.

`-defaults` Resets all option values to their default values.

`-propt` Prints the current values of all Sun Expert3D options in the `OWconfig` file specified by the `-file` option for the device specified by the `-dev` option. Prints the values of options as they will be in the `OWconfig` file after the call to `SUNWifb_config` completes. This is a typical display:

```
--- OpenWindows Configuration for /dev/fbs/ifb0 ---
OWconfig: machine
Video Mode: 1280x1024x76
Accum: Disabled (do not allocate an accumulation buffer)
Default Visual: Non-Linear Normal Visual
Visual Ordering: Linear Visuals are last
                 Overlay Visuals are last
OpenGL Visual Expansion: enabled
Gamma Correction Value: 2.22
Gamma Correction Table: Available
```

`-prconf` Prints the Sun Expert3D hardware configuration. This is a typical display:

```
--- Hardware Configuration for /dev/fbs/ifb0 ---
PROM Information: @(#)ifb.fth 1.25 99/10/12 SMI
```

```
EDID Data: Available - EDID version 1 revision 1
Monitor possible resolutions: 1024x768x60, 1024x768x70, 1024x768x75,
1152x900x66, 1152x900x76, 1280x1024x67, 1280x1024x76, 960x680x112s,
640x480x60
Current resolution setting: 1280x1024x76
```

`-help` — Prints a list of the `SUNWifb_config` command-line options, along with a brief explanation of each.

`-samples` `1` | `2` | `4` | `8` | `16` — Requested number of samples to compute per display pixel. The requested number of samples per pixel will be used if `-multisample` is not disabled and resouces exist for the request.

Query the number of samples used with `-propt` (see above) or the `xglinfo` utility. The `xglinfo` utility can return the number of multisamples after you specify the option `-multisample enable`.

The default is `16`.

`-multisample` `enable` | `disable` | `auto` — If set to `disable`, no multisample is possible. If set to `enable`, multisample is possible but is selected on a per-window basis using a library interface. If set to `auto`, all Sun OpenGL windows are rendered using multisampling.

Query the number of samples used with `-propt` (see above) or the `xglinfo` utility. The `xglinfo` utility can return the number of multisamples if `-multisample` is set to `enable`.

The default is `disable`.

The `xglinfo` utility is shipped with the Sun OpenGL package, `SUNWglrt`. The man page for `xglinfo` is part of another Sun OpenGL package, `SUNWgldoc`.

Defaults For a given invocation of `SUNWifb_config` command line if an option does not appear on the command line, the corresponding `OWconfig` option is not updated; it retains its previous value. When the window system is run, if an Sun Expert3D option has never been specified via `SUNWifb_config`, a default value is used. The option defaults are as follows:

Option	Default
-dev	/dev/fbs/ifb0
-file	machine
-res	none
-deflinear	false

```
-defoverlay     false
-linearorder    last
-overlayorder   last
-expvis         enable
-slave          disable
-accum          enable
-g              2.22
-samples        16
-multisample    disable
```

The default for the `-res` option of `none` means that, when the window system is run, the screen resolution will be the video mode that is currently programmed in the device. This design choice provides compatibility for users who are used to specifying the device resolution through the PROM. On some devices (for example, GX), this is the only way of specifying the video mode. This means that the PROM ultimately determines the default Sun Expert3D video mode.

Examples

EXAMPLE 1 Changing Monitor Resolution

The following example switches the monitor type to the resolution of 1280 x 1024 at 76 Hz:

```
example% /usr/lib/fbconfig/SUNWifb_config -res 1280x1024x76
```

     [-prconf] [-defaults]

fbconfig [-propt] [-prconf]

fbconfig [-help] [-res ?]
```

Description `SUNWjfb_config` configures the Sun XVR-600 and XVR-1200 Graphics Accelerator and some of the X11 window system defaults for the Sun XVR-600 and XVR-1200.

You can specify options for only one device at a time. If you want to specify options for multiple devices, you must invoke the `SUNWjfb_config` utility multiple times.

You can use the `SUNWjfb_config` utility to specify Sun XVR-600 or XVR-1200 specific options. Use the normal window system options to specify default depth, default visual class and so forth. Specify these as device modifiers on the command line. See `Xsun`(1)

You can also specify which `OWconfig` file to update. By default, `SUNWjfb_config` updates the machine-specific file in the `/etc/openwin`. You can specify an alternate file by using the `-file` option. For example, the system-global `OWconfig` file in the `/usr/openwin` directory tree can be updated instead.

Both of these standard `OWconfig` files can only be written by root. Consequently, the `SUNWjfb_config` program, which is owned by the root user, always runs with setuid root permission.

The first form of `SUNWjfb_config` shown in the `SYNOPSIS` section stores the specified options in the OWconfig file. These options initialize the Sun XVR-600 and XVR-1200 device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots.

The second and third forms which invoke only the `-prconf`, `-propt`, `-help`, and `-res ?` options, do not update the OWconfig file. Additionally, for the third form all other options are ignored.

Options The following options are supported:

`-accum enable | disable`
Enable or disable frame buffer memory. If enabled, frame buffer memory is allocated for the accelerated accumulation buffer for windows. If disabled, software accumulation buffering for windows is used. Accelerated accumulation buffers for pBuffers are always available as memory allows.

`-dev` *device-filename*
Specify the SunSun XVR-600 or XVR-1200 special file. The default is `/dev/fbs/jfb0`.

`-defaults`
Reset all option values except `-dev` to their default values.

This option sets the resolution override to `none` which implies the last video mode setting is preserved. If no monitor is attached, the video mode is set to `1152x900x66`.

`-deflinear true | false`
Both the Sun XVR-600 and XVR-1200 possess two types of visuals: linear and nonlinear. Linear visuals are gamma corrected and nonlinear visuals are not. There are two visuals that have both linear and nonlinear versions: 24-bit TrueColor and 8-bit StaticGray.

If the value of this option is `true`, the default visual is set to the linear visual that satisfies other specified default visual selection options (specifically, the `Xsun` `defdepth` and `defclass` options; see `Xsun`(1)). If `false`, or if there is no linear visual that satisfies the other default visual selection options, the non-linear visual specified by these other options is chosen as the default visual. This option cannot be used when the `-defoverlay` option is present, because the Sun XVR-600 and XVR-1200 do not possess a linear overlay visual.

`-defoverlay true | false`
Both the Sun XVR-600 and XVR-1200 provide an 8-bit PseudoColor visual whose pixels are disjoint from the rest of the visuals. This is called the overlay visual. Windows created in this visual will not damage windows created in other visuals. The converse, however, is not true. Windows created in other visuals will damage overlay windows.

If the value of this option is `true`, the overlay visual is the default visual. If `false`, the nonoverlay visual that satisfies the other default visual selection options, such as `defdepth` and `defclass`, is chosen as the default visual. See `Xsun`(1). Whenever `-defoverlay true` is used, the default depth and class chosen on the `openwin` command line must be 8-bit PseudoColor. If not, a warning message is printed and the `-defoverlay` option is treated as `false`. This option cannot be used when the `-deflinear` option is present, because the Sun XVR-600 and XVR-1200 do not possess a linear overlay visual.

`-defdepth 8 | 24`
Set the depth (bits per pixel) on the device. Possible values for the `-defdepth` option are `8` or `24`. You must log out of the current window system session and log back in again for the change to take effect. Any depth setting in the Xserver command line takes precedence over what is set using `fbconfig`. The default is determined by the X Server `smf(5)` default depth property. You can query this property with the following command:

```
% /usr/sbin/svccfg -s svc:/application/x11/x11-server listprop \
'options/default_depth'
```

`-doublehigh enable | disable`
Configure the two outputs of the Sun XVR-1200 into one vertical virtual display. The default is `disable`.

This option is not applicable to the Sun XVR-600 device.

`-doublewide enable | disable`
Configure the two outputs of the Sun XVR-1200 into one horizontal virtual display. The default is `disable`.

This option is not applicable to the Sun XVR-600 device.

`-fake8 enable | disable`
Enable or disable simple 8 bit X windows to be rendered without a hardware colormap to reduce colormap flashing. You might notice performance reductions. The default is `disable`.

`-file machine|system`
Specifies which `OWconfig` file to update. If *machine* is specified, the machine-specific `OWconfig` file in the `/etc/openwin` directory tree is updated. If *system* is specified, the global `OWconfig` file in the `/usr/openwin` directory tree is updated. If the specified file does not exist, it is created. This option has no effect unless other options are specified. The default is *machine*.

`-g` *gamma-correction value*
Change the gamma correction value. All linear visuals provide gamma correction. By default, the gamma correction value is `2.22`. Any value less than zero is illegal. This option can be used while the window system is running. Changing the gamma correction value affects all of the windows displayed by linear visuals.

`-gfile` *gamma-correction file*
Load the gamma correction table from the file specified by *gamma-correction file*. You should format this file to provide the gamma correction values for `R`, `G`, and `B` channels on each line. Specify each value in hexadecimal format and separate it from another value by at least 1 space. The *gamma-correction file* file should provide 1024 such triplets.

You can load the gamma correction table with this option can while the window system is running. The new gamma correction affects all the window being displayed using the linear visuals. When gamma correction is done using a user specified table, the gamma correction

value is undefined. By default, the window system assumes a gamma correction value of `2.22` and loads the gamma table it creates corresponding to this value.

The following is an example of a *gamma-correction file* file:

```
0x000 0x000 0x000
0x001 0x001 0x001
0x002 0x002 0x002
...
...
0x3ff 0x3ff 0x3ff
```

`-help`
Print a list of the `SUNWjfb_config` command line options, along with a brief explanation of each.

`-multisample available | disable |forceon`
If set to disable, no multisample is possible. If set to `available`, multisample is possible but is selected on a per-window basis using a library interface. If set to `forceon`, all Sun OpenGL windows are rendered using multisampling. Query the number of samples used with `-propt` or the `xglinfo`(1) utility. The `xglinfo` utility can return the number of multisamples if `-multisample` is set to enable. The default is `disable`.

`-offset` *xval yval*
Adjust the position of the specified stream by the value specified. This option is only implemented in `-doublewide` and `-doublehigh` modes. For `-doublewide`, use the *xval* to position the rightmost stream. Negative is left (overlaps with the left stream). For `-doublehigh`, use the *yval* to position the bottom stream. Negative is up (overlaps with top stream). The default is `[0, 0]`.

`-outputs swapped | direct`
If either `-doublewide` or `-doublehigh` are enabled, reverse the position of the two outputs relative to each other. The default is `direct`.

`-propt`
Print the current values of all Sun XVR-600 and XVR-1200 options in the OWconfig file specified by the `-file` option for the device specified by the `-dev` option. Print the values of options as they will be in the OWconfig file after the call to `SUNWjfb_config` completes.

This is a typical display:

```
# fbconfig -dev jfb2 -propt

--- OpenWindows Configuration for /dev/fbs/jfb2 ---

OWconfig: machine
Video Mode: 1280x1024x60
Accum: Enabled (allocate an accumulation buffer if possible)

Multisample Information:
```

```
    Multisample Mode: Disabled (multisample visuals
       will not be available)
    Samples Per Pixel: N/A (multisampling disabled)

   Screen Information:
    DoubleWide: Disabled
    DoubleHigh: Disabled
    Output Configuration: Direct
    Offset/Overlap: [0, 0]

   Visual Information:
    Default Visual: Non-Linear Normal Visual
    Visual Ordering: Linear Visuals are last
    Gamma Correction Value: 2.22
    Gamma Correction Table: Available
    Fake8 rendering: disabled
    Default Visual Depth (defdepth): 8
```

`-prconf`

Print the Sun XVR-1200 hardware configuration. This is a typical display:

```
# fbconfig -dev jfb2 -prconf

--- Hardware Configuration for /dev/fbs/jfb2 ---

Type: XVR-1200
Sun Serial Number: 3753101000022
Hardware Revision: -01 rev01
Manufacture Date: Thu Aug 8  12:54:16 2002
PROM Information: @(#)jfb.fth 1.8 02/10/18 SMI

Monitor/Resolution Information:
   EDID Data: Available - EDID version 1 revision 3
   Monitor type: Sun P/N 365-1415 S/N 0216ME0353
   Current resolution setting: 1280x1024x60 (custom)
   Monitor possible resolutions: 1024x768x60, 1024x768x70,
   1024x768x75, 1152x900x66, 1280x1024x60, 1280x1024x75,
   1280x1024x76, 640x480x60, 800x600x75

Framelock Configuration:
   Slave Mode: Disabled

Memory Information:
   Total Video Memory: 134217728
   Video Memory Used: 15728640
   Total Texture Memory: 268435456
   Texture Memory Used: 0
   Total Display List Memory: 33554432
```

`-res` *video-mode* `[ now |try [ noconfirm | nocheck ]]`

Specify the video mode of the monitor connected to the specified Sun XVR-600 or XVR-1200 device.

The `-res` option requires you to specify the video-mode. You can specify *video-mode* in the format of *width*x*height*x*rate* or as a symbolic name.

*width*x*height*x*rate*

Specify *video-mode* in the format of *width*x*height*x*rate*, where *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh.

You can use the `s` suffix to specify stero video modes. The `s` suffix of `960x680x112s` and `960x680x108s` means that these are stereo video modes.

The `-res` option also accepts formats with `@` (at sign) in front of the refresh rate instead of `x`, (`280x1024@76`). Some video-modes, supported by Sun XVR-600 and XVR-1200, might not be supported by the monitor.

The list of video-modes supported by the Sun XVR-600 and XVR-1200 device and the monitor can be obtained by running `SUNWjfb_config` with the `-res ?` option. See `SYNOPSIS`.

Symbolic Names

Some video modes have symbolic names defined for them. Instead of using the *width*x*height*x*rate* format, you can specify one of the symbolic names as the argument to the `-res` option. The meaning of the symbolic name `none` is that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.

The following symbolic names and their corresponding video modes are supported:

```
svga          1024x768x60
1152          1152x900x76
1280          1280x1024x76
stereo        960x680x112s
ntsc          640x480x60i
pal           768x575x50i
none          Programmed video mode
```

The `-res` option accepts additional, optional arguments immediately following the video mode specification. The following additional, optional arguments are supported:

`now`

If present, updates the video mode be updated in the `OWconfig file`. Programs the Sun XVR-600 or XVR-1200 device to display the video mode. This is useful for changing the video mode before starting the window system.

Do not use this suboption with `SUNWjfb_config` while the configured device is being used, for example, while running the window system. Unpredictable results can occur.

If you want to run SUNWjfb_config with the now suboption, first bring the window system down. If you use the now suboption within a window system session, the video mode is changed immediately. The width and height of the affected screen will not change until the window system is exited and re-entered again. Additionally, the system might not recognize changes in stereo mode. This usage is discouraged.

noconfirm

Using the -res option, the user could potentially put the system into an unusable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this, the default behavior of SUNWjfb_config is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. The -noconfirm option instructs SUNWjfb_config to bypass this confirmation and to program the requested video mode anyway. This option is useful when SUNWjfb_config is run from a shell script.

nocheck

If present, the normal error checking based on the monitor sense code is suspended. The video mode specified is accepted regardless of whether it is appropriate for the currently attached monitor. This option is useful if a different monitor is to be connected to the Sun XVR-600 or XVR-1200 device. Use of this option implies noconfirm.

try

If present, programs the specified video mode on a trial basis. You are asked to confirm the video mode by entering a y within 10 seconds. You can terminate the trial before 10 seconds by entering any character but y or RETURN.

Terminating the trial by entering a character other than y or RETURN restores the previous video mode. SUNWjfb_config does not change the video mode in the OWconfig file. Other specified options still take effect. If a carriage return is typed, the user is prompted for a yes or no answer on whether to keep the new video mode. This option implies the now suboption.

If you want to run SUNWjfb_config with the now suboption, first bring the window system down. If you use the now suboption within a window system session, the video mode is changed immediately. The width and height of the affected screen will not change until the window system is exited and re-entered again. Additionally, the system might not recognize changes in stereo mode. This usage is strongly discouraged.

-samples 1 | | 4 | 8 | 16 | adaptive

Request the number of samples to compute per display pixel. The requested number of samples per pixel will be used if -multisample is not disabled and resources exist for the request. If set to adaptive, variable multisampling is possible, whith the minimum samples per pixel set to 2. Query the number of samples used with -propt or the xglinfo(1) utility. The xglinfo utility can return the number of multisamples after you specify the option -multisample enable. The default is 16.

`-slave disable | multiview | stereo | bnc`
Enable or disable a specific port. Specify `multiview` for the DB9 connector, `stereo` for the mini-DIN connector, or `bnc` for the bnc connector. Specify disable to disable a specific port. If set, the option is an exclusive slave instance in the Framelock Configuration Setup. The default is `disable`.

`multiview` and `bnc` are only applicable to the Sun XVR-1200 device.

Defaults For a given invocation of `SUNWjfb_config` command line if an option does not appear on the command line, the corresponding OWconfig option is not updated; it retains its previous value.

When the window system is run, if an option has never been specified by way of `SUNWjfb_config`, a default value is used. The options and their corresponding defaults are as follows:

Option	Default
`-dev`	`/dev/fbs/jfb0`
`-file`	`machine`
`-res`	`none`
`-deflinear`	`false`
`-defoverlay`	`false`
`-linearorder`	`last`
`-slave`	`disable`
`-accum`	`enable`
`-g`	`2.22`
`-samples`	`16`
`-multisample`	`disable`
`-doublewide`	`disable`
`-doublehigh`	`disable`
`-outputs`	`direct`
`-offset`	`[0,0]`

The default for the `-res` option of none means that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.

This provides compatibility for users who are used to specifying the device resolution through the PROM. This means that the PROM ultimately determines the default video mode.

Examples

EXAMPLE 1 Switching the Resolution of the Monitor Type

The following example switches the monitor type to 1280 × 1024 at 76 Hz resolution:

```
example% fbconfig –dev jfb0 –res 1280x1024x76
```

Files

`/dev/fbs/jfb`*n*
Device special file for the XVR-600 or XVR-1200 high performance single screen

`/dev/fbs/jfb`*n*`a`
Device special file for the XVR-1200 first video out

`/dev/fbs/jfb`*n*`b`
Device special file for the XVR-1200 second video out

`/usr/lib/jfb.ucode`
`jfb` microcode file

`/usr/sbin/jfbdaemon`
`jfb` microcode loader file

Name SUNWkfb_config – fbconfig module for configuring the Sun XVR-2500 Graphics Device

Synopsis

```
/usr/lib/fbconfig/SUNWkfb_config [-dev device-filename]
     [-res video-mode] [-file machine | system]
     [-deflinear true | false] [-defoverlay true | false]
     [-deftransparent true | false]
     [-slave disable | multiview]
     [-g gamma-correction-value]
     [-gfile gamma-correction-file]
     [-doublewide enable | disable]
     [-doublehigh enable | disable]
     [-multisample available | disable | forceon]
     [-samples 1 | 2 | 4 | 8 | 16 ] [-offset xval yval]
     [-propt] [-prconf] [-defaults]

/usr/lib/fbconfig/SUNWkfb_config [-propt] [-prconf]

/usr/lib/fbconfig/SUNWkfb_config [-help] [-res ?]
```

Description `SUNWkfb_config` configures the Sun XVR-2500 Graphics Accelerator and some of the X11 window system defaults for the Sun XVR-2500.

The first form of `SUNWkfb_config` shown in the `SYNOPSIS` section stores the specified options in the `OWconfig` file. These options initialize the Sun XVR-2500 device the next time the window system is run on that device. Updating options in the `OWconfig` file provides persistence of these options across window system sessions and system reboots.

The second and third forms which invoke only the `-prconf`, `-propt`, `-help`, and `-res ?` options, do not update the `OWconfig` file. For the third form, all other options are ignored.

You can specify options for only one device at a time. If you want to specify options for multiple devices, invoke the `SUNWkfb_config` utility multiple times.

Only the Sun XVR-2500 options can be specified through the `SUNWkfb_config` utility. Use the normal window system options to specify default depth (see `svccfg(1M)`), default visual class and so forth. Specify these as device modifiers on the command line. See `Xsun`(1).

You can also specify which `OWconfig` file to update. By default, `SUNWkfb_config` updates the machine-specific file in the `/etc/openwin` directory tree. Use the `-file` option to specify an alternate file. For example, the system-global `OWconfig` file in the `/usr/openwin` directory tree can be updated instead.

Both of these standard `OWconfig` files can only be written by root. Consequently, the `SUNWkfb_config` program, which is owned by the root user, always runs with setuid root permission.

Options The following options are supported:

`-defaults`

Resets all option values except `-dev` to their default values. This option sets the resolution override to `none` which implies that the last video mode setting is preserved. If no monitor is attached, the video mode is set to `1152x900x66`.

`-deflinear true | false`

This option selects the default X visual. The Sun XVR-2500 device supports two types of visuals: linear and nonlinear. Linear visuals are gamma corrected and nonlinear visuals are not.

If the value of this option is `true`, the default visual is set to default depth 24 and the default class is TrueColor with gamma correction enabled. If `false`, a non-linear visual that satisfies the other default visual selection options, such as the default depth and default class, is chosen as the default visual. See `Xsun`(1).

The `-deflinear`, `-defoverlay`, and `-deftransparent` options all select the default X visual. Only one option may be enabled at the same time. If more than one of these options is entered, the last selection takes precedence and the other options are disabled.

`-defoverlay true | false`

This option selects the default X visual. The Sun XVR-2500 device provides an 8-bit PseudoColor visual whose pixels are disjoint from the rest of the visuals. This is called the overlay visual. Windows created in this visual will not damage windows created in other visuals. The converse, however, is not true. Windows created in other visuals will damage overlay windows.

If the value of this option is `true`, the overlay visual is the default visual. The default depth is 8 bit and the default class is PseudoColor. If `false`, the nonoverlay

visual that satisfies the other default visual selection options, such as the default depth and the default class, is chosen as the default visual. See `Xsun`(1).

The `-deflinear`, `-defoverlay`, and `-deftransparent` options all select the default X visual. Only one option may be enabled at the same time. If more than one of these options is entered, the last selection takes precedence and the other options are disabled.

`-deftransparent` `true` | `false`

This option selects the default X visual. The Sun XVR-2500 device provides an 8-bit PseudoColor visual whose pixels are disjoint from the rest of the visuals. This is called the overlay visual. Windows created in this visual will not damage windows created in other visuals.

If the value of this option is `true`, the overlay visual used as the default is a transparent overlay visual. A visual with transparency supports a colormap with 255 colors and one transparent pixel. The default depth is 8 bit and the default class is PseudoColor. If `false`, the nonoverlay visual that satisfies the other default visual selection options, such as the default depth and the default class, is chosen as the default visual. See `Xsun`(1).

The `-deflinear`, `-defoverlay`, and `-deftransparent` options all select the default X visual. Only one option may be enabled at the same time. If more than one of these options is entered, the last selection takes precedence and the other options are disabled.

`-dev` *device-filename*

Specifies the SunXVR-2500 special file. The default is `/dev/fbs/kfb0`.

`-doublehigh enable | disable`

Configures the two outputs of the Sun XVR-2500 device into one vertical virtual display. The default is `disable`.

`-doublewide enable | disable`

Configures the two outputs of the Sun XVR-2500 device into one horizontal virtual display. The default is `disable`.

`-file machine|system`

Specifies which `OWconfig` file to update. If *machine* is specified, the machine-specific `OWconfig` file in the `/etc/openwin` directory tree is updated. If *system* is specified, the global `OWconfig` file in the `/usr/openwin` directory tree is updated. If the specified file does not exist, it is created. This option has no effect unless other options are specified. The default is *machine*.

`-g` *gamma-correction value*

Changes the gamma correction value. All linear visuals provide gamma correction. By default, the gamma correction value is `2.22`. Any value less than zero is illegal. This option can be used while the window system is running. Changing the gamma correction value affects all of the windows displayed by linear visuals.

`-gfile` *gamma-correction file*

Loads the gamma correction table from the file specified by *gamma-correction file*. Format this file to provide the gamma correction values for `R`, `G`, and `B` channels on each line. Specify each value in hexadecimal format, separated from another value by at least one space. The *gamma-correction file* file should provide 1024 such triplets.

You can load the gamma correction table with this option while the window system is running. The new gamma correction affects all the windows being displayed using the linear visuals. When gamma correction is done using a user specified table, the gamma correction value is undefined. By default, the window system

assumes a gamma correction value of `2.22` and loads the gamma table it creates corresponding to this value.

The following is an example of a *gamma-correction file* file:

```
0x000 0x000 0x000
0x001 0x001 0x001
0x002 0x002 0x002
...
...
0x3ff 0x3ff 0x3ff
```

`-help` — Prints a list of the `SUNWkfb_config` command line options, along with a brief explanation of each.

`-multisample available | disable | forceon` — If set to `disable`, no multisample is possible. If set to `available`, multisample is possible but is selected on a per-window basis using a library interface. If set to `forceon`, all Sun OpenGL windows are rendered using multisampling. Query the number of samples used with `-propt` or the `xglinfo`(1) utility. The `xglinfo` utility can return the number of multisamples if `-multisample` is set to `available`. The default is `disable`.

`-offset` *xval yval* — Adjusts the position of the specified stream by the value specified. This option is only implemented in `-doublewide` and `-doublehigh` modes. For `-doublewide`, use the *xval* to position the rightmost stream. Negative is left (overlaps with the left stream). For `-doublehigh`, use the *yval* to position the bottom stream. Negative is up (overlaps with top stream). The default is `[0, 0]`.

`-prconf` — Prints the Sun XVR-2500 hardware configuration. This is a typical display:

```
--- Hardware Configuration for /dev/fbs/kfb2 ---

Type: XVR-2500
PROM Information: @(#) xvr2500.fth 14.106 05/08/15 SMI
```

```
Monitor/Resolution Information:
   Monitor Manufacturer: SUN
   Product code: 1352
   Serial #: 7225675
   Manufacture date: 1997, week 51
   Monitor dimensions: 48x31 cm
   Monitor preferred resolution: 1920x1200x70
   Separate sync supported: yes
   Composite sync supported: yes
   EDID: Version 1, Revision 1
   Supported resolutions: 1920x1200x70, SUNW_STD_1600x1000x76,
    SUNW_STD_1600x1000x66, SUNW_STD_1440x900x76, 1920x1080x70,
    1600x900x76, 1600x900x66, 1440x810x76, 1280x720x76,
    1920x1080x72, VESA_STD_720x400x70, VESA_STD_720x400x88,
    VESA_STD_640x480x60, VESA_STD_640x480x67,
    VESA_STD_800x600x56, VESA_STD_800x600x60,
    VESA_STD_800x600x72, VESA_STD_800x600x75,
    VESA_STD_1024x768x70, VESA_STD_1280x1024x75,
   Current resolution setting: SUNW_STD_1280x1024x76

Framelock Configuration:
 Slave Mode: Disabled
```

`-propt`

Prints the current values of all Sun XVR-2500 options in the `OWconfig` file specified by the `-file` option for the device specified by the `-dev` option. Prints the values of options as they will be in the `OWconfig` file after the call to `SUNWkfb_config` completes.

This is a typical display:

```
--- OpenWindows Configuration for /dev/fbs/kfb2 ---

OWconfig: machine
Video Mode: SUNW_STD_1280x1024x76

Multisample Information:
 Multisample Mode: Disabled (multisample visuals
    will not be available)
 Samples Per Pixel: N/A (multisampling disabled)

Screen Information:
 DoubleWide: Disabled
 DoubleHigh: Disabled
 Offset/Overlap: [0, 0]
```

```
Visual Information:
 Default Visual: Non-Linear Normal Visual
 Gamma Correction Value: using gamma value 2.22
```

`-res` *video-mode*

Specifies the video mode of the monitor connected to the specified Sun XVR-2500 device.

You must specify the video mode with the `-res` option. You can specify *video-mode* in the format of *width*x*height*x*rate* or as a symbolic name. The format of these built-in video modes is:

*width*x*height*x*rate*

width is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh.

You can use the `s` suffix to specify stereo video modes. The `s` suffix of `960x680x112s` and `960x680x108s` means that these are stereo video modes.

As a convenience, the `-res` option also accepts formats with `@` (at sign) in front of the refresh rate instead of `x`, as for example, `1280x1024@76`. Some video-modes supported by the Sun XVR-2500 device may not be supported by the monitor.

You can obtain the list of video-modes supported by the Sun XVR-2500 device and the monitor by running `SUNWkfb_config` with the `-res ?` option. See `SYNOPSIS`.

Symbolic Names

Some video modes have symbolic names defined for them. Instead of using the *width*x*height*x*rate* format, you can specify one of the symbolic names as the argument to the `-res` option. The meaning of the symbolic name `none` is that when the window system is run, the screen resolution is the video mode that is currently programmed in the device.

The following symbolic names and their corresponding video modes are supported:

```
Name          Cprresponding Video Mode
svga          1024x768x60
1152          1152x900x76
1280          1280x1024x76
stereo        960x680x112s
none          (see text above)
```

`-samples 1 | 2 | 4 | 8 | 16`	Requests the number of samples to compute per display pixel. The requested number of samples per pixel is used if `-multisample` is not disabled and resources exist for the request. Query the number of samples used with `-propt` or the `xglinfo`(1) utility. The `xglinfo` utility can return the number of multisamples after you specify the option `-multisample available`. The default is `4`.
`-slave disable | multiview`	If you set the `multiview` argument for the `-slave` option, the device synchronizes video with a master through the multiview ribbon cable. Both devices should be running the same resolution and the option should be issued when the window system is running. The default is `disable`.

Defaults For a given invocation of the `SUNWkfb_config` command line, if an option does not appear on the command line, the corresponding `OWconfig` option is not updated and retains its previous value.

When the window system is run, if a Sun XVR-2500 option has never been specified by way of `SUNWkfb_config`, a default value is used. The options and their corresponding defaults are as follows:

Option	Default
`-dev`	`/dev/fbs/kfb0`
`-file`	`machine`
`-res`	`none`
`-deflinear`	`false`
`-defoverlay`	`false`
`-deftransparent`	`false`
`-slave`	`disable`
`-g`	`2.22`
`-samples`	`4`
`-multisample`	`disable`

Option	Default
-doublewide	disable
-doublehigh	disable
-outputs	direct
-offset	[0,0]

The default for the -res option of none means that when the window system is run, the screen resolution is the video mode that is currently programmed in the device.

Examples

EXAMPLE 1 Switching the Resolution of the Monitor Type

The following example switches the monitor type to 1280 × 1024 at 76 Hz resolution:

```
example% fbconfig –dev kfb0 –res 1280x1024x76
```

Files

/dev/fbs/kfb*n*	Device special file for the XVR-2500 high performance single screen
/usr/sbin/kfbdaemon	The kfb memory manager

Name SUNWnfb_config – fbconfig module for configuring XVR-300 Graphics Accelerator

Synopsis

```
fbconfig [-dev device-filename]
     [-res video-mode [now | try] [noconfirm | nocheck]]
     [-file machine | system] [-fake8 enable | disable]
     [-doublewide enable | disable]
     [-doublehigh enable | disable]
     [-clone enable | disable] [-outputs swapped | direct]
     [-depth 8 | 24] [-offset xval yval] [-defaults]

fbconfig [-propt] [-prconf]

fbconfig [-help] [-res ?]
```

Description `SUNWnfb_config` is the XVR-300 device dependent layer for `fbconfig`. It configures the XVR-300 Graphics Accelerator and some of the X11 window system defaults for XVR-300. The XVR-300 provides the capability to drive two monitors, each with a unique video stream (Stream #1 and Stream #2).

The first form of `SUNWnfb_config` shown in the `SYNOPSIS` section sets options for the XVR-300. This form stores the specified options in the `OWconfig` file. These options will be used to initialize the XVR-300 device the next time the window system is run on that device. Updating options in the `OWconfig` file provides persistence of these options across window system sessions and system reboots. For `-res now`, the XVR-300 device will be immediately programmed.

The second form, which invokes the `-prconf` and `-propt` options, queries the XVR-300 for status.

The third form, which invokes the `-help` and `-res ?` options, provides instruction on using `SUNWnfb_config`. Additionally, for the third form all other options are ignored.

Options may be specified for only one XVR-300 device at a time. Specifying options for multiple XVR-300 devices requires multiple invocations of `SUNWnfb_config`.

Only XVR-300-specific options can be specified through `SUNWnfb_config`. The normal window system options for specifying default depth, default visual class and so forth can still be specified as device modifiers on the command line when the X Server is started. See the `dtlogin`(1) reference to Xservers File.

The user can also specify the `OWconfig` file that is to be updated. By default, the machine-specific file in the `/etc/openwin` directory tree is updated. The `-file` option can be used to specify an alternate file to use. For example, the system-global `OWconfig` file in the `/usr/openwin` directory tree can be updated instead.

Options `-dev` *device-filename*

Specifies the XVR-300 special file. The default is `/dev/fb`.

`-file machine | system`
Specifies which `OWconfig` file to update. If `machine`, the machine-specific `OWconfig` file in the `/etc/openwin` directory tree is used. If `system`, the global `OWconfig` file in the `/usr/openwin` directory tree is used. If the file does not exist, it is created.

`-res` *video-mode* [`now` | `try`] [`noconfirm` | `nocheck`]
Specifies the video mode used to drive the monitor connected to the specified XVR-300 device. Video modes are built-in.

video-mode Specifies resolution and timing information for the display (for example, 1280x1024x76). The format of the *video-mode* specifier is: *width*x*height*x*rate*. *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh. As a convenience, `-res` also accepts formats with `@` preceding the refresh rate instead of `x`. For example, `1280x1024@76`.

`Symbolic names`. For convenience, some video modes have symbolic names defined for them. Instead of the form *width*x*height*x*rate*, one of these names may be supplied as the argument to `-res`. The meaning of the symbolic name `none` is that when the window system is run, the screen resolution will be the video mode that is currently programmed in the device.

Some video-modes supported by XVR-300 may not be supported by the monitor. The list of video-modes supported by the XVR-300 device and the monitor can be obtained by running `SUNWnfb_config` with the `-res ?` option (the third form shown in the command `SYNOPSIS` section).

`-res` option arguments. The `-res` option also accepts additional, optional arguments immediately following the video mode specification. Any or all of these may be present.

`now` If present, not only will the video mode be updated in the `OWconfig` file, but the XVR-300 device will be immediately programmed to display this video mode. (This is useful for changing the video mode before starting the window system).

It is inadvisable to use this suboption with `SUNWnfb_config` while the configured device is being used (for example, while running the window system) because unpredictable results may occur. To run `SUNWnfb_config` with the `now` suboption, first bring the window system down. If the `now` suboption is used within a window system session, the video mode will be changed immediately, but the width and height of the affected screen won't change until the

window system is exited and reentered again. Consequently, this usage is discouraged.

`noconfirm` Using the `-res` option, the user could put the system into an unusable state, which has no video output. To reduce the chance of this, the default behavior of `SUNWnfb_config` is to print a warning message and to ask the user whether to continue. The `noconfirm` suboption bypasses this confirmation. This suboption is useful when `SUNWnfb_config` is being run from a shell script.

`nocheck` If present, the normal error checking based on the monitor sense code will be suspended. The video mode specified by the user will be accepted regardless of whether it is appropriate for the currently attached monitor. This suboption is useful if a different monitor is to be connected to the XVR-300 device. Use of this suboption implies `noconfirm` as well.

`try` If present, the specified video mode will be programmed on a trial basis. The user will be asked to confirm the video mode by typing 'y' within 10 seconds. Or the user may terminate the trial before 10 seconds are up by typing any character. Any character other than 'y' or carriage return is considered a no and the previous video mode will be restored and `SUNWnfb_config` will not change the video mode in the `OWconfig` file (other options specified will still take effect). If a carriage return is typed, the user is prompted for a yes or no answer on whether to keep the new video mode. This option implies the `now` suboption (see the warning note on the `now` suboption).

`-doublewide enable | disable`
This option allows you to configure the two outputs of the Sun XVR-300 into one horizontal virtual display. Both video outputs will be set to the same resolution. Default is `disable`.

`-doublehigh enable | disable`
This option allows you to configure the two outputs of the Sun XVR-300 into one vertical virtual display. Both video outputs will be set to the same resolution. Default is `disable`.

`-clone enable | disable`
If this option is set to `enable`, the two outputs will display identically. Default is `disable`.

`-outputs swapped | direct`
If either `doublewide` or `doublehigh` is enabled, this option allows you to reverse the positions of the two outputs relative to each other. Default is `direct`.

`-fake8 enable | disable`
If enabled, simple 8 bit X windows will be rendered without a hardware colormap to reduce colormap flashing. Some performance reductions may be observed. Default is `disable`.

`-depth 8 | 24`
Sets the default depth for the window system to start with. Possible values are `8` or `24`. Log out of the current window system session and log back in for the change to take effect. Any defdepth setting in the Xserver command line takes precedence over what is set using `fbconfig`. Default is `24`. This option is only supported on Solaris 9. For Solaris 10 and above, use `/usr/sbin/svccfg` to configure depth.

`-offset` *xval yval*
Adjusts the position of the specified stream by the value specified. Currently only implemented in `-doublewide` and `-doublehigh` modes. For `-doublewide`, the *xval* is used to position the rightmost stream. Negative is left (overlaps with the left stream). For `-doublehigh`, the *yval* is used to position the bottom stream. Negative is up (overlaps with top stream). Positive values are treated as 0. Default is [0, 0]

`-defaults`
Resets all option values to their default values.

`-propt`
Prints the current values of all XVR-300 options in the `OWconfig` file specified by the `-file` option for the device specified by the `-dev` option. Prints the values of options as they will be in the `OWconfig` file after the call to `SUNWnfb_config` completes. This is a typical display:

```
--- Graphics Configuration for /dev/fbs/nfb0 ---

OWconfig: machine
Video Mode: NONE

Screen Information:
        Doublewide: Disable
        Doublehigh: Disable
        Clone: Disable
        Offset/Overlap: [0, 0]
        Output Configuration: Direct
        Fake8 Rendering: Disable
```

`-prconf`
Prints the XVR-300 hardware configuration. This is a typical display:

```
--- Hardware Configuration for /dev/fbs/nfb0 ---

Type: XVR-300
ASIC: version 0x5b64  REV : version 0x3800080
PROM: version 1.6

Monitor/Resolution Information:
```

       Current resolution setting: 1152x900x66
```

`-help`

Prints a list of the `SUNWnfb_config` command line options, along with a brief explanation of each.

`-res ?`
Prints list of defined *video-mode* names.

Defaults For a given invocation of a `SUNWnfb_config` command line if an option does not appear on the command line, the corresponding `OWconfig` option is not updated and retains its previous value.

When the window system is run, if an XVR-300 option has never been specified via `SUNWnfb_config`, a default value is used. The option defaults are as follows:

Option	Default
–dev	/dev/fb
–file	machine
–res	none
–fake8	disable
–doublewide	disable
–doublehigh	disable
–clone	disable
–outputs	direct
–offset	[0,0]

The default for the `-res` option of `none` means that when the window system is run, the screen resolution will be the video mode that is currently programmed in the XVR-300 PROM.

This provides compatibility for users who are used to specifying the device resolution through the XVR-300 PROM. On some devices (for example, GX) this is the only way of specifying the video mode. This means that the PROM ultimately determines the default XVR-300 video mode.

Examples **EXAMPLE 1** Switching the monitor type

The following example switches the monitor type to the resolution of 1280 × 1024 at 76 Hz:

```
example% fbconfig -res 1280x1024x76
```

Files

`/dev/fbs/nfb`*n*	Device special file for XVR-300 single screen
`/dev/fbs/nfb`*n*`a`	Device special file for the XVR-300 first video out
`/dev/fbs/nfb`*n*`b`	Device special file for the XVR-300 second video out
`/usr/lib/fbconfig/SUNWnfb_config`	Device dependent configuration module

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Name SUNWpfb_config – fbconfig module for configuring the XVR-50 and the Sun XVR-100 Graphics Accelerator

Synopsis

```
For XVR-50:
/usr/lib/fbconfig/SUNWpfb_config [-dev device-filename]
     [-res video-mode [now | try] [noconfirm | nocheck]]
     [-file  machine | system]
     [-fake8  enable | disable]
     [-g  enable | disable | gamma-value]
     [-defaults]

For Sun XVR-100:
/usr/lib/fbconfig/SUNWpfb_config [-dev device-filename]
     [-res video-mode [now | try] [noconfirm | nocheck]]
     [-file  machine | system]
     [-fake8  enable | disable]
     [-g  enable | disable | gamma-value]
     [-doublewide  enable | disable]
     [-doublehigh  enable | disable]
     [-outputs  swapped | direct]
     [-depth  8 | 24]
     [-offset  xval yval]
     [-defaults]

For Sun XVR-100 and XVR-50:
/usr/lib/fbconfig/SUNWpfb_config [-pt] [-prconf]

/usr/lib/fbconfig/SUNWpfb_config [-help] [-res \?]
```

Description `SUNWpfb_config` is the XVR-50 and the Sun XVR-100 device dependent layer for `fbconfig(1M)`. It configures the XVR-50 and the Sun XVR-100 Graphics Accelerator and some of the X11 window system defaults for the XVR-50 and Sun XVR-100. The Sun XVR-100 provides the capability to drive two monitors, each with a unique video stream (Stream #1 and Stream #2). The XVR-50 drives one video stream.

The first two forms of `SUNWpfb_config` shown in the `SYNOPSIS` section sets options for the XVR-50 and the Sun XVR-100 devices. It stores the specified options in the `OWconfig` file. These options initialize the XVR-50 and the Sun XVR-100 devices the next time the window system is run on that device. Updating options in the `OWconfig` file provides persistence of these options across window system sessions and system reboots. The XVR-50 and the Sun XVR-100 devices are immediately programmed if you specify the `-res now`.

The third form, which invokes the `-prconf` and `-propt` options, queries the XVR-50 and the Sun XVR-100 device for status.

The fourth form, which invokes the `-help`, and `-res \?` options, provides instruction on using `SUNWpfb_config`. Additionally, for the fourth form all other options are ignored.

You can only specify options for only one XVR-50 or Sun XVR-100 device at a time. If you want to specify options for multiple XVR-50 or Sun XVR-100 devices, you must use multiple invocations of the `SUNWpfb_config` command.

You can only use `SUNWpfb_config` to specify XVR-50 or Sun XVR-100 specific options. You can use the normal window system options to specify the default depth, default visual class and so forth as device modifiers on the command line when the X Server is started. See `dtlogin`(1) for information regarding the Xservers File.

You can also specify the `OWconfig` file to update. The machine-specific file in the `/etc/openwin` directory tree is updated by default. You can used the `-file` option to specify an alternate file. For example, you can update the system-global `OWconfig` file in the `/usr/openwin` directory tree instead.

Options The following options are supported:

`-defaults`
Reset all option values to their default values.

`-depth` 8 | 24
Set the depth (bits per pixel) for the window system. Possible values for the `-depth` option are `8` or `24`. You must log out of the current window system session and log back in again for the change to take effect. Any depth setting in the Xserver command line takes precedence over what is set using `fbconfig`. The default is `8`. This option is only available with Solaris 8 or Solaris 9.

`-dev` *device-filename*
Specify the XVR-50 or the Sun XVR-100 special file. The default is `/dev/fb`.

`-doublehigh enable | disable`
Configure the two outputs of the Sun XVR-100 into one vertical virtual display. You must log out of the current window system session and log back in again for the change to take effect. The default is `disable`.

`-doublewide enable | disable`
Configure the two outputs of the Sun XVR-100 into one horizontal virtual display. You must log out of the current window system session and log back in again for the change to take effect. The default is `disable`.

`-fake8` enable | disable
Enable or disable simple 8 bit X windows to be rendered without a hardware colormap to reduce colormap flashing. You might notice performance reductions. You must log out of the current window system session and log back in again for the change to take effect. The default is `disable`.

`-file machine|system`
Specifies which `OWconfig` file to update. If machine is specified, the machine-specific `OWconfig` file in the `/etc/openwin` directory tree is updated. If system is specified, the

global `OWconfig` file in the `/usr/openwin` directory tree is updated. If the specified file does not exist, it is created. This option has no effect unless other options are specified. The default is machine.

`-g` enable | disable | *gamma-value*
This option allows you to change the gamma correction value. All linear visuals provide gamma correction. By default , the gamma correction value is 2.22. Any value less than zero is illegal.

This option can be used while the window system is running. Changing the gamma correction value will affect all the windows being displayed using the linear visuals. You must log out of the current window system session and log back in again for the change to take effect. The default is `disable`.

`-help`
Print a list of the `SUNWpfb_config` command line options, along with a brief explanation of each option.

`-offset` *xval yval*
Adjust the position of the secondary stream on the Sun XVR-100. This option is currently implemented only for the `-doublewide` and `-doublehigh` modes. For `-doublewide`, use the *xval* to position the DVI stream, if `-outputs` are direct (VGA stream if `-outputs` are swapped). A negative value specifies the overlapped region with the primary stream. This is similar for `-doublehigh`, except the *yval* is used. Positive values are treated as 0. You must log out of the current window system session and log back in again for the change to take effect. The default is `[0, 0]`.

`-outputs` swapped | direct
Reverse the positions of the `-doublewide` or `-doublehigh` outputs relative to each other on the Sun XVR-100. You must log out of the current window system session and log back in again for the change to take effect. The default is `direct`.

`-propt`
Print the current values of all XVR-50 and Sun XVR-100 options in the OWconfig file specified by the `-file` option for the device specified by the `-dev` option. Print the values of options as they will be in the OWconfig file after the call to `SUNWpfb_config` completes.

This is a typical display for the Sun XVR-100:

```
--- Graphics Configuration for /dev/fbs/pfb0 ---

OWconfig: machine
Video Mode: not set
Depth: not set

Screen Information:
        Doublewide: Disable
        Doublehigh: Disable
        Offset/Overlap: [0.0]
```

```
        Output Configuration: Direct
        Fake8 Rendering: Disable
        Gamma Configuration: Disable
```

`-prconf`
Print the XVR-50 and Sun XVR-100 hardware configuration.

This is a typical display:

```
--- Hardware Configuration for /dev/fbs/pfb0 ---

Type: XVR-100
ASIC: version 0x5159            REV : version 0x3000000
PROM: version 4.2

Monitor/Resolution Information:
        EDID Data: Not Available
        Current resolution setting: 1152x900x66

Depth Information:
        Possible depths:  8, 24
        Current depth: 8
```

`-res` *video-mode* `[ now | try [ noconfirm | nocheck ]]`
Specify the video mode that drives the monitor connected to the specified XVR-50 or Sun XVR-100 device.

Video modes are built-in. The `-res` option requires you to specify the video-mode. You can specify *video-mode* in the format of *width*x*height*x*rate* or as a symbolic name.

video-mode
Specify *video-mode* in the format of *width*x*height*x*rate*, where *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh. An example video mode specified in this format is `1280x1024x60`.

The `-res` option also accepts formats with `@` preceding the refresh rate instead of `x` (`1280x1024@60`).

Symbolic Names
Some video modes have symbolic names defined for them. Instead of the form *width*x*height*x*rate* format, you can specify one of the symbolic names as the argument to the `-res` option. The meaning of the symbolic name "`none`" is that when the window system is run the screen resolution is the video mode that is currently programmed in the device.

The following symbolic names and their corresponding video modes are supported:

```
Name    Corresponding Video Mode
svga          1024x768x60
```

```
1152          1152x900x76
1280          1280x1024x75
none          Programmed video mode
```

Some video-modes, supported by XVR-50 and Sun XVR-100, might not be supported by the monitor. Use the `-res \?` option to obtain the list of video-modes supported by the XVR-50 and Sun XVR-100 device and the monitor.

The `–res` option also accepts additional, optional arguments immediately following the video mode specification. The following additional, optional arguments are supported:

`nocheck` If present, the normal error checking based on the monitor sense code is suspended. The video mode specified by the user is accepted regardless of whether it is appropriate for the currently attached monitor. This option is useful if a different monitor is to be connected to the XVR-50 or the Sun XVR-100 device. Use of this option implies `noconfirm` as well.

`noconfirm` You could put the system into an unusable state using the `-res` option, which has no video output. To reduce the chance of this, the default behavior of `SUNWpfb_config` is to print a warning message and to ask the user whether to continue. The `noconfirm` option bypasses this confirmation. This option is useful when you are running `SUNWpfb_config` from a shell script.

`now` If present, updates the video mode in the `OWconfig` file and immediately programs the XVR-50 or Sun XVR-100 device to display this video mode. This is useful for changing the video mode before starting the window system.

Do not use this suboption with `SUNWpfb_config` while the configured device is being used (for example, while running the window system) as unpredictable results can occur.

If you want to run `SUNWpfb_config` with the `now` suboption, first bring the window system down, and executed from the console command line. If you use the `now` option within a window system session, the video mode is changed immediately. The width and height of the affected screen will not change until the window system is exited and re-entered again. Additionally, the system might not recognize changes in stereo mode. This usage is discouraged.

`try` If present, programs the specified video mode on a trial basis. You are asked to confirm the video mode by entering a `y` within 10 seconds. You can terminate the trial before 10 seconds by entering any character but `y` or <RETURN>.

This sub-option should not be used with `SUNWpfbconfig` while the configured device is being used (for example, while running the window system) as unpredictable results may occur. To run `SUNWpfbconfig` with the `try` sub-option, the window system should be brought down first, and executed from the console command line.

`-res \?`
Print a list of defined *video-mode* names.

Defaults For a given invocation of `SUNWpfb_config` command line if an option does not appear on the command line, the corresponding OWconfig option is not updated; it retains its previous value.

When the window system is run, if a XVR-50 or Sun XVR-100 option has never been specified by `SUNWpfb_config`, a default value is used. The options and their corresponding defaults for a XVR-50 are as follows:

```
Option                  Default

-dev                    /dev/fb
-file                   machine
-res                    none
-fake8                  disable
-g                      disable
```

The options and their corresponding defaults for a Sun XVR-100 are as follows:

```
Option                  Default

-dev                    /dev/fb
-file                   machine
-res                    none
-fake8                  disable
-g                      disable
-depth                  8 (Solaris 8 and Solaris 9)
-doublewide             disable
-doublehigh             disable
-outputs                direct
-offset                 [0,0]
```

The default for the `-res` option `none` means that when the window system is run, the screen resolution will be the video mode that is currently programmed in the XVR-50 or Sun XVR-100 PROM.

This provides compatibility for users who are used to specifying the device resolution through the XVR-50 or the Sun XVR-100 PROM. On some devices (e.g. GX) this is the only way of specifying the video mode. This means that the PROM ultimately determines the default XVR-50 or Sun XVR-100 video mode.

Examples

EXAMPLE 1 Switching the Monitor Type

The following example switches the monitor type to the resolution of 1280 × 1024 at 60 Hz:

```
example% fbconfig –res 1280x1024x60
```

Files

`/dev/fbs/pfb`*n*	Device special file for XVR-50 or Sun XVR-100 single screen
`/dev/fbs/pfb`*n*`a`	Device special file for the Sun XVR-100 first video out
`/dev/fbs/pfb`*n*`b`	Device special file for the Sun XVR-100 second video out
`/usr/lib/fbconfig/SUNWpfb_config`	Device special file

Attributes

Name SUNWzulu_config – fbconfig module for configuring SunXVR-4000 Graphics Accelerator

Synopsis

```
fbconfig [-dev device-filename] [-file machine | system]
     [options... | -defaults]

fbconfig [-dev device-filename] [-propt] [-prconf]

fbconfig [-dev device-filename] [-list | -help | -res \?]

fbconfig [-dev device-filename]
     [-doublewide enable | disable]
     [-doublehigh enable | disable]
     [-outputs direct | swapped | streamA | streamB]
     [-master a | b] [-clearpixel 0 | 255]

fbconfig [-dev device-filename] [-res video_mode]
     [-multisample available | disable | forceon]
     [-samples samples-per-pixel]
     [-jitter regular | random | permuted | auto]

fbconfig [-dev device-filename] [-stream a | b]
     [-filter cylinder | gaussian | mitchell | catmull]
     -filter_file filter_filename
     [-offset xoff-value yoff-value]
     [-g gamma-correction-value]
     [-slave [ enable | disable] [framelock [internal | external] |
      genlock | bothlock]]
     [-genlock [defaults] [hphase ±hphs] [vphase ±vphs]
     [sync [auto |tip | tri | slice]] [pol [auto | pos | neg]]]
```

Description `SUNWzulu_config` is the Sun XVR-4000 Graphics Accelerator device-dependent layer for `fbconfig(1M)`. It configures the Sun XVR-4000 Graphics Accelerator and some of the X11 window system defaults and some interactions with 3D-accelerated graphics (through OpenGL).

The first through third synopses, above, show the general form of a `SUNWzulu_config` command. The fourth synopsis (with `-res` as the first option) shows card options. The fifth synopsis is for managed-area options. The sixth and last synopsis shows stream options. These option categories—card, managed-area, and streams—are used mainly to explain the `SUNWzulu_config` functions. Where appropriate, you can use options of different types on the same command line.

The Sun XVR-4000 device can support one or two unique video streams (called `stream a` and `stream b`), each of which can drive a display device.

Option Classes The many options that `fbconfig` can select on the Sun XVR-4000 Graphics Accelerator are divided into the following categories:

general options — Shared among different invocation forms or used for query without selecting device settings.

card options	Of the entire XVR-4000 Graphics Accelerator, shared between up to two video streams.
managed area options	Pertain to an area of the frame buffer managed by X and possibly shared between two video streams.
stream options	Specific to a video stream.

Device Usage and Invocation Forms

To use the device to provide a single X managed area with one video stream, use a stream-independent device argument (for example, `-dev zulu0`) without a trailing `a` or `b`. The device name (for example, `/dev/fb` or `/dev/fbs/zulu0`), without any trailing stream indicator should appear on the `Xsun` command line. Stream options will control `stream a` (the only stream used).

To enable two streams from a single X managed area (without needing X's `+xinerama` option), use the device name (for example, `-dev zulu0`) without any trailing `a` or `b`. Enable card option `-doublewide` or `-doublehigh`. Without using the `-stream` option, any stream options you specify are applied to both streams. Stream options can differ between the video streams if `fbconfig` is be run separately for each stream, using the `-stream a | b` option, as shown in EXAMPLES (second example), below.

To use the device's two streams as independent X screens, run `fbconfig` separately for each stream (`-dev zulu0a` and `-dev zulu0b`), as shown in EXAMPLES (third example). Card options `-doublehigh` and `-doublewide` are not available. The device names with trailing stream indicators (for example, `/dev/fbs/zulu0a` and `/dev/fbs/zulu0b`) must be added to the `Xsun` command line to use these independent X screens. The `-stream` option is not needed; the stream is implied by the stream-specific device name.

The `fbconfig` utility checks settings for the two stream devices to assure X can use them simultaneously. Therefore, you might need to use `fbconfig` to reduce resouce consumption (for example, `-samples`) used by one stream's device (for example, `zulu0a`) before you can use `fbconfig` to increase consumption by the other stream's device (for example, `zulu0b`).

The first form of `SUNWzulu_config` shown in SYNOPSIS, above, stores the specified options in the `OWconfig` file associated with the device and (for stream options) the stream. These options are used to initialize the device the next time the window system is started on that device-filename. Updating options in the `OWconfig` file provides persistence of these options across window system sessions and system reboots. You can select the `OWconfig` file that is to be updated using the `-file` option. For `-jitter` and all stream options, the device will also be immediately programmed.

The second form, which invokes any of the `-prconf` and `-propt` options, queries the device for status that is card-specific.

The third form, which invokes the `-help`, `-list`, or `-res \?` options, provides instruction on using `SUNWzulu_config`, a list of available devices, or a list of available resolutions. When using this form, all other options are ignored.

You can specify options for only one device at a time. Specifying options for multiple devices (or multiple independent X managed areas or streams) requires multiple invocations of `fbconfig`.

Only Sun XVR-4000 Graphics Accelerator-specific options can be specified through `SUNWzulu_config`. Window system options for specifying default depth, default visual class, `-nobanner`, and so forth are still specified as device modifiers on the `Xsun` command line when the X server is started, probably in CDE's `Xservers` file. See the `Xsun(1)` man page in the OpenWindows man page collection and `/usr/dt/config/Xservers`.

Options This section is subdivided into general, card, managed area, and stream options.

General Options

`-dev` *device-filename* — Specifies the device's special file, such as `/dev/fbs/zulu0` or the basename such as `zulu0` as a shorthand. The default is `/dev/fb`. See "Device Usage and Invocation Forms," above.

`-file machine|system` — Specifies which `OWconfig` file to update. If *machine* is specified, the machine-specific `OWconfig` file in the `/etc/openwin` directory tree is updated. If *system* is specified, the global `OWconfig` file in the `/usr/openwin` directory tree is updated. If the specified file does not exist, it is created. This option has no effect unless other options are specified. The default is *machine*.

`-defaults` — Resets all option values to their default values, listed in the DEFAULTS section, below. For example, invoking `-defaults` on `zulu0`, `zulu0a`, or `zulu0b` will reset all card, managed area, and stream options for all these `zulu0` subdevices.

`-propt` — Displays the current values of all options in the `OWconfig` file specified by the `-file` option for the device specified by the `-dev` option. Displays the values of options as they will be in the `OWconfig` file after the call to `SUNWzulu_config` completes. The following is an example display:

```
--- OpenWindows Configuration for /dev/fbs/zulu0 ---

OWconfig File: machine

Card:
        Double(wide/high):      disable
        Stream to Port Mapping: direct (Stream A to Port A; B to B)
        Clearpixel Value:       255

Managed Area:
```

```
        Resolution:             SUNW_STD_1280x1024x76
        Samples Per Pixel:      max
        Multisample Mode:       forceon
        Jitter Table:           auto

Video Streams:
   Stream A:
        Offset (x,y):           (0, 0)
        Gamma Correction Value: 2.22
        Filter Type:            mitchell

   Stream B:
        Offset (x,y):           (0, 0)
        Gamma Correction Value: 2.22
        Filter Type:            mitchell

Framelock:
        Framelock/Stereo Port:  Output from Stream A
        Stream A Sync:          Free Run (no frame sync)
        Stream B Sync:          Free Run (no frame sync)
```

`-prconf` Displays the current XVR-4000 hardware configuration, including version numbers of each class of chip. The following is an example display:

```
--- Hardware Configuration for /dev/fbs/zulu0 ---
Type:   XVR-4000 Graphics Accelerator
Part:   501-5588

Memory:
        MAJC:           128MB
        Texture:        1GB total
        3DRAM64:        10.0M samples

Versions:
        Fcode 1.19    MCode 1.4       MAJC 2.1
         FBC3 3.0    Master 1.0   Convolve 0.0
        Sched 1.0       I/O 1.0       FPGA 0.0

Power Level:
        Monitor Power:  On
        Board Power:    On

Video Streams:
   Stream A:
        Current resolution setting: SUNW_STD_1280x1024x76
        Flags:  Allocated Default Primary
        Samples per pixel: 6
```

```
                    Port:   13W3a
                    Monitor/EDID data (13W3)
                             Monitor Manufacturer: SUN
                             Monitor Name:  GDM-5410
                             EDID:  Version 1, Revision 2

               Stream B:
                    Current resolution setting: SUNW_STD_1280x1024x76
                    Flags:  Allocated
                    Samples per pixel: 2
                    Port:   13W3b
                    Monitor/EDID data (13W3)
                             Monitor Manufacturer: SUN
                             EDID:  Version 1, Revision 3
```

`-help` Displays a list of the `SUNWzulu_config` command line options, along with a brief explanation of each.

`-res \?` Displays list of defined video mode names supported by the XVR-4000 Graphics Accelerator and the display device.

Card Options

`-doublewide enable | disable` This option makes it easy for you to combine both streams into one side-by-side virtual display. When enabled with `-outputs direct`, stream a is to the left of stream b. Both streams will use the same video mode defined with the `-res` option. If you specify `disable`, only stream a will be enabled. Enabling `-doublewide` disables `-doublehigh`.

`-doublehigh enable | disable` This option makes it easy for you to combine both streams into one virtual display with one display device above the other. When enabled with `-outputs direct`, stream a is above stream b. Both streams will use the same video mode defined with the `-res` option. If you specify `disable`, only stream a will be enabled. Enabling `-doublehigh` disables `-doublewide`.

`-outputs direct | swapped | streamA | streamB` Controls the internal routing of video streams to output ports (that is, backplane 13W3 connectors). The choices are:

		`direct` Stream a to output port a, stream b to output port b `swapped` Stream a to output port b, stream b to output port a `streamA` Stream a to both output ports `streamB` Stream b to both output ports The default is `direct`. `swapped` can be used to reverse the connectors when `-doublewide` or `-doublehigh` is enabled. The `streamA` and `streamB` arguments are incompatible with stream-specific device names (for example, `zulu0a` or `zulu0b`). When the `-res` option selects an S-video (NTSC or PAL composite) video mode, the svideo output port is automatically selected, sometimes overriding `-outputs` selection.
	`-master a | b`	This option controls which stream drives the `FIELD` and `FRAME_OUT` pins on the device's stereo/sync connector. This pin can drive stereo shutter glasses, and allow another device to framelock to this device's output. The default is `a`. Independent of this option, the `-slave external` option allows a stream to sync to another card by means of this connector's `FIELD_IN` pin.
	`-clearpixel 0 | 255`	Selects the overlay transparent color. This is the pixel value (color index) used by the transparent overlay visual to display the underlay (RGB) pixel contents. The default is `255` (all bits 1), but some applications require `0`. All other color indices display a colormap color.
Managed Area Options	`-res` *video_mode*	The *video_mode* argument specifies resolution and timing information for the display (for example,

SUNW_STD_1280x1024x76). The naming convention for the video mode specifier is:

*origin_type_width*x*height*x*rate*

The elements of the specifier are described as follows:

origin This can be one of:

- SUNW — Sun-derived resolution
- VESA — Video Electronics Standards Association-derived resolution
- *other* — other source

type This can be one or more of:

- STD — normal resolution, usable by most display devices
- DIG — resolution tuned only for LCD flat panels
- INT — interlaced
- STEREO — stereo

width screen width in pixels

height screen height in pixels

rate vertical frequency of the screen refresh (in hertz, that is, video frames per second)

Note that some video modes supported by the XVR-4000 might not be supported by the display device. The list of video modes supported by the device and the display device can be obtained by running SUNWzulu_config with the -res \? option.

-multisample available | disable | forceon

The -multisample option controls whether a multisample buffer is allocated

by the window system and used by OpenGL applications. The suboptions are:

`disable` No multisample rendering is possible. Only one sample per pixel is allocated, despite the `-samples` option value. Furthermore, display filtering is disabled.

`available` Multisample is possible but is selected on a per-application basis. (Each process may choose whether to multisample at the density allocated when the window system started, or not to multisample at all. Intermediate densities are not possible.)

`forceon` Sun OpenGL will use multisample rendering for all applications. There may be a minor performance penalty for rendering at higher sample densities.

Multisample allocation occurs when the window system starts up. This is the only allocation mode supported on the Sun XVR-4000 Graphics Accelerator.

`-samples` *samples-per-pixel*

Specifies the number of samples per pixel to allocate when multisample is not `disable`. Allowable choices are 1 to 16 or `max`, but a very high sample density can be allocated only at low resolution. Setting sample density to 1 is not equivalent to disabling multisampling; samples will still be subject to filtering and jitter. Sample resolutions (without frame rates) and their maximum sample densities follow.

Resolution	Maximum Density	Maximum Balanced Density
width by height	(single stream)	(one stream + another)
1920 by 1200	4 samples	2 + 2 samples
1600 by 1200	5 samples	3 + 2 samples
1600 by 1024	6 samples	3 + 3 samples
1280 by 1024	8 samples	4 + 4 samples
1152 by 900	9 samples	5 + 4 samples
1024 by 800	11 samples	5 + 5 samples
800 by 600	15 samples	7 + 7 samples
768 by 575	15 samples	7 + 7 samples
640 by 480	16 samples	9 + 9 samples

The default is `max`, which means to use the maximum number of samples that can be supported with the amount of memory available, possibly dependent on the video timing (horizontal frequency).

For dual independent streams, if the first stream used by the window system (typically, the first in the `Xservers` file) chooses `max`, it takes most of the memory and video resources. The second stream can then use only a low sample density. If it also chooses `max`, X automatically finds the highest sample density remaining, such as 1 or 2 samples per pixel. To assign sample density more evenly, set each stream's density explicitly. `SUNWzulu_config` allows a combination of resolutions and sample densities only if they will coexist successfully. You might have to reduce one stream's sample density (or choose `max`) before you can increase the other stream's.

`-jitter regular | random | permuted | auto`

Indirectly determines the subpixel (X,Y) locations of the samples stored in the

sample buffer. (The sample density also affects the sample locations.) Choices are:

`regular` Samples are regularly-spaced both vertically and horizontally. The sample locations repeat every pixel or two in X and Y.

`random` Samples are pseudo-randomly (irregularly) spaced within the pixel. The sample locations repeat every 2 pixels in X and Y.

`permuted` Samples are pseudo-randomly spaced within the pixel, and also permuted (stirred) in hardware so that the sample locations repeat every 128 pixels in X and Y. At moderate to high sample density, this choice can improve visual quality. At low sample density, straight lines or edges can appear jagged.

`auto` Automatically selects the best jitter option for the current sample density. This is the default.

The same jitter selection must be used by OpenGL when rendering and by the display subsystem when refreshing the display from the sample buffer. The jitter value is changed immediately in hardware, but any multisamples already in the sample buffer were rendered using the prior jitter selection; that will look incorrect (for example, unstraight lines or edges) if the jitter selection is changed.

When a new OpenGL application starts up, it will render using the new jitter selection. (The window system need not be restarted.) The jitter value is also saved in the `OWconfig` file for the next time the window system starts.

Stream Options `-stream a | b`

Determines whether stream options will be set for stream `a` or stream `b`. The "Device Usage and Invocation Forms" section, above, describes the usage and the default. The `-stream` option is required only to set different stream options for the two video streams enabled using card option `-doublewide` or `-doublehigh`.

`-filter cylinder | gaussian | mitchell | catmull`
`-filter_file` *filter_filename*

There are two ways to configure filtering. The `-filter` option is the simpler. It selects from these predefined filters:

`cylinder` Poorest visual quality, most like a box filter.

`gaussian` Blurriest; suitable for users who want to forgo detail to avoid all visible sampling artifacts.

`mitchell` The best photo-realistic compromise between sharp detail and noticeable blurriness. This filter is the default.

`catmull` The Catmull-Rom filter produces images a little sharper than Mitchell, but are more likely to have visible sampling artifacts, widely known as "jaggies".

The `-filter_file` option allows a user to provide his own filter by producing a filter file and copying or linking it into the directory `/etc/openwin/server/etc/filters` or `/usr/openwin/server/etc/filters`. (Both directories are writable by super-user by default.) The *filter_filename* must not start with `/` or `../` nor contain the substring `/../`, but can contain subdirectory components.

`fbconfig` and X search the directories above in the order listed. If the *filter_filename* is present and valid, the file takes precedence over a predefined filter.

The format of the file is a sequence of floating-point radius and weight values, each value separated by whitespace. Radius values must be monotonically increasing from 0. Weight values must be between -1.0 and +1.0, inclusive. Though more values can be present in the file, only values through radius 2.0 are used. Whitespace and comment lines prefixed with a hash mark (#) are ignored.

Example files contain the (irregular) radius values for which the device uses weight values. The file reader interpolates between existing values if the required radius is not present.

A valid filter option is changed immediately in hardware and saved in the `OWconfig` file for the next time the window system starts. However, when `multisample` is disabled, no filtering occurs.

`-offset` *xoff-value yoff-value*
Offsets the display of the stream (specified by `-stream`) relative to the adjoining edge of the other stream when doublewide or doublehigh is enabled. This can be used to cause an overlap.

xoff-value Number of pixels offset in horizontal direction for the righthand stream when doublewide is enabled. Positive direction is to the right (create a gap); negative is to the left (overlap the streams). Default is 0, which means the two edges abut.

yoff-value Number of pixels offset in vertical direction for the bottom stream when doublehigh is enabled. Positive direction is down (create a gap); negative is up (overlap the streams). Default is 0, which means the two edges touch.

`-g` *gamma-correction-value*
This option changes the gamma correction value. By default the gamma correction value is 2.22. Any value less than zero is illegal. This option can be used while the window system is running. Changing the gamma correction value will affect all the windows being displayed using gamma-corrected visuals. The gamma correction value is also saved in the `OWconfig` file for the next time the window system starts.

`-slave` [`enable` | `disable`]
[`framelock` [`internal` | `external`] | `genlock` | `bothlock`]
This option allows you to enable a synchronization technique for the specified stream. Available techniques:

`framelock` [`internal` | `external`] This provides "asynchronous frame reset": multiple streams all start a frame at roughly the same time. This allows stereo shutters to view the same eye's image from all the synchronized display devices. Using `framelock` requires the incoming synchronization signal have the same frame rate as the stream's video format.

When using `framelock` (or `bothlock`), you can also specify the synchronization source:

`internal` Indicates that the sync source is the other stream of this device.

`external` Indicates the sync is taken from a source outside the device. Using `external` requires a Frame Lock Cable (part number 530-2754) to be

connected. If `-slave enable` is used without specifying a technique, `framelock external` is used.

`genlock` — This provides pixel-accurate horizontal synchronization, which is important in some video mixing situations. Use of `genlock` requires a genlock cable. Use of `bothlock` is recommended, when possible. Certain video formats are incompatible with `genlock`.

`bothlock` — This enables both `framelock` and `genlock` techniques, and requires both framelock (if `external`) and genlock cables.

`-genlock` [`defaults`] [`hphase` ±*hphs*][`vphase` ±*vphs*] [`sync` [`auto`|`tip`|`tri`|`slice`]] [`pol` [`auto`|`pos`|`neg`]]

When `-slave` is enabled and the genlock technique is selected, the selections chosen with the `-genlock` option determine genlock details. These details are used immediately by the hardware, and saved in the `OWconfig` file for future use. Note that they may no longer be desired after changing to a different video format.

`defaults` — Reset all genlock details to their defaults.

`hphase` ±*hphs* — The horizontal phase allows a pixel offset between the external video format and the stream's output. It may be specified as an absolute integer ranging from 0 to the total number of pixel clocks in a horizontal period (active video plus blanked pixels). Or, if the *hphs* starts with a + or -, the value will be added to the current horizontal phase and and saved, modulo the valid range. Small deltas can be used repeatedly until the desired effect is observed.

`vphase` ±*vphs* — The vertical phase allows a scanline offset between the external video format and the stream's output. It can be specified as an absolute integer ranging from 0 to the total number of scanlines in a frame (active video plus blanked scanlines). Or, if the *vphs* starts with a + or -, the value will be added to the current vertical phase and and saved, modulo the valid range. Small deltas can be used repeatedly until the desired effect is observed.

`sync` [`auto`|`tip` | `slice` | `tri`] — This option controls the details of input sync signal sampling, if necessary:

`auto` — Sample the genlock input pulses as most appropriate for the (Sun) video format. This is

the default, and should be used whenever the sync master is also a Sun video format.

`tip` Consider the sync to have occurred at the minimum signal value. This can be used with RS-170 (NTSC or PAL) or with TTL signals.

`slice` Consider the frame sync to have occurred halfway between the minimum and maximum value (sync tip and back porch "blank" levels). This can be used with RS-170 (NTSC or PAL) or with TTL signals.

`tri` Synchronize to a tri-level signal, used by HDTV analog formats.

`pol` [`auto`|`pos`|`neg`] When the sync master is not a Sun video format, it might be necessary to choose which edge of the genlock input sync pulse should be used for genlock.

`auto` Choose rising or falling edge for sync pulse, whichever is most appropriate for the video format. This is the default, and should be used whenever the sync master is also a Sun video format.

`pos` Synchronize with a rising edge of a sync pulse.

`neg` Synchronize with a falling edge of a sync pulse.

Defaults For a given invocation of `SUNWzulu_config`, if an option does not appear on the command line, the corresponding `OWconfig` option is not updated. It retains its previous value.

When the window system starts, if an option has never been specified through `SUNWzulu_config`, a default value is used. The option defaults are as follows:

```
Option Class    Option          Default

General         -dev            /dev/fb
General         -file           machine
                        (/etc/openwin/server/etc/OWconfig)

Card            -doublewide     disable
Card            -doublehigh     disable
Card            -master         a
Card            -outputs        direct
Card            -clearpixel     255

Managed Area    -res            SUNW_STD_1280x1024x76
```

```
Managed Area   -multisample   forceon
Managed Area   -samples       max
Managed Area   -jitter        auto

Stream         -offset        0,0
Stream         -filter        mitchell
Stream         -slave         disable/external/framelock
Stream         -genlock       hphase 0/vphase 0/auto/auto
Stream         -g             2.22
```

Examples

EXAMPLE 1 Switching Resolution of a Monitor

The following example switches to the resolution of 1280 by 1024 at 76 hertz:

```
% fbconfig -dev zulu0 -res SUNW_STD_1280x1024x76
```

EXAMPLE 2 Using Two Side-by-side Monitors with One Large X Screen

The following example enables use of two side-by-side monitors to display together a single large shared X window system "screen" (frame buffer managed area):

```
% fbconfig -dev zulu0 -doublewide enable
```

If the wrong monitor is on the left, they can be swapped in software:

```
% fbconfig -dev zulu0 -outputs swapped
```

A stream option selects a Gaussian (blurry) filter for video stream b:

```
% fbconfig -dev zulu0 -stream b -filter gaussian
```

For the two examples above, the factory-installed `/usr/dt/config/Xservers` file is sufficient (if `/dev/fb` is a link to the Sun XVR-4000 Graphics Accelerator device). If an `/etc/dt/config/Xservers` file exists, for Example 1 or 2, the file would refer to device `zulu0` (not `zulu0a` or `zulu0b`):

```
:0 Local local_uid@console root /usr/openwin/bin/Xsun -dev /dev/fbs/zulu0
```

EXAMPLE 3 Using Two Displays as Independent X Screens

The following example enables use of two displays, each with their own X window system managed frame buffer area and resolution. The larger resolution is not multisampled or filtered, so the smaller resolution will have more samples available to it.

```
% fbconfig -dev zulu0a -res SUNW_STD_1920x1200x75 -multisample disable
% fbconfig -dev zulu0b -res SUNW_STD_1280x1024x76 -samples max
```

In this example, and assuming the display device for stream b is to the right of that for stream a, the `/etc/dt/config/Xservers` file might contain (as one long line):

EXAMPLE 3 Using Two Displays as Independent X Screens *(Continued)*

```
:0 Local local_uid@console root /usr/openwin/bin/Xsun -nobanner
       -dev /dev/fbs/zulu0a -dev /dev/fbs/zulu0b right
```

Files

`/dev/fb`	default device file
`/usr/lib/fbconfig/SUNWzulu_config`	device configuration program
`/etc/openwin/server/etc/filters/`	root file system directory for filter files
`/usr/openwin/server/etc/filters/`	`/usr` file system directory for filter files

An administrator might also have to edit `/etc/dt/config/Xservers`.

Attributes See `attributes(5)` for descriptions of the following attributes:

Name svcadm – manipulate service instances

Synopsis

```
/usr/sbin/svcadm [-v] enable [-rst] {FMRI | pattern}...

/usr/sbin/svcadm [-v] disable [-st] {FMRI | pattern}...

/usr/sbin/svcadm [-v] restart {FMRI | pattern}...

/usr/sbin/svcadm [-v] refresh {FMRI | pattern}...

/usr/sbin/svcadm [-v] clear {FMRI | pattern}...

/usr/sbin/svcadm [-v] mark [-It] instance_state
     {FMRI | pattern}...

/usr/sbin/svcadm [-v] milestone [-d] milestone_FMRI
```

Description `svcadm` issues requests for actions on services executing within the service management facility (see `smf(5)`). Actions for a service are carried out by its assigned service restarter agent. The default service restarter is `svc.startd` (see `svc.startd(1M)`).

Options The following options are supported:

`-v` Print actions verbosely to standard output.

Subcommands

Common Operations The subcommands listed below are used during the typical administration of a service instance.

For subcommands taking one or more operands, if the operand specifies a service (instead of a service instance), and that service has only a single instance, `svcadm` operates on that instance. If an abbreviated *FMRI* (a fault management resource identifier) or pattern matches more than one service, a warning message is displayed and that operand is ignored. See `smf(5)`.

In the case that the service has more than one instance, `svcadm` return a non-zero exit status.

`enable [-rst]` {*FMRI* | *pattern*}... Enables the service instances specified by the operands. For each service instance, the assigned restarter will try to bring it to the online state. This action requires permission to modify the "general" property group of the service instance (see `smf_security(5)`).

If the `-r` option is specified, `svcadm` enables each service instance and recursively enables its dependencies.

If the `-s` option is specified, `svcadm` enables each service instance and then waits for each service instance to enter the `online` or `degraded` state. `svcadm`

will return early if it determines that the service cannot reach these states without administrator intervention.

If the `-t` option is specified, `svcadm` temporarily enables each service instance. Temporary enable only lasts until reboot. This action requires permission to modify the "restarter_actions" property group of the service instance (see `smf_security(5)`). By default, `enable` is persistent across reboot.

`disable` [`-st`] {*FMRI* | *pattern*}. . .

Disables the service instance specified by the operands. For each service instance, the assigned restarter will try to bring it to the disabled state. This action requires permission to modify the "general" property group of the service instance (see `smf_security(5)`).

If the `-s` option is specified, `svcadm` disables each service instance and then waits for each service instance to enter the disabled state. `svcadm` will return early if it determines that the service cannot reach this state without administrator intervention.

If the `-t` option is specified, `svcadm` temporarily disables each service instance. Temporary disable only lasts until reboot. This action requires permission to modify the "restarter_actions" property group of the service instance (see `smf_security(5)`). By default, `disable` is persistent across reboot.

`restart` {*FMRI* | *pattern*}. . .

Requests that the service instances specified by the operands be restarted. This action requires permission to modify the "restarter_actions" property group of the service instance (see `smf_security(5)`).

This subcommand can restart only those services that are in the online or degraded states, as those states are defined in `smf(5)`.

`refresh` {*FMRI* | *pattern*}. . .

For each service instance specified by the operands, requests that the assigned restarter update the service's running configuration snapshot with the values from the current configuration. Some of these values take effect immediately (for example, dependency changes). Other values do not take effect until the next service `restart`. See the restarter and service documentation for more information.

If the service is managed by svc.startd(1M), the `refresh` method will be invoked if it exists to request the service reread its own configuration. For other restarters, see the restarter documentation.

This action requires permission to modify the "restarter_actions" property group of the service instance (see smf_security(5)).

`clear` {*FMRI* | *pattern*}...

For each service instance specified by the operands, if the instance is in the `maintenance` state, signal to the assigned restarter that the service has been repaired. If the instance is in the `degraded` state, request that the assigned restarter take the service to the `online` state. This action requires permission to modify the "restarter_actions" property group of the service instance (see smf_security(5)).

Exceptional Operations

The following subcommands are used for service development and temporary administrative manipulation.

`mark [-It]` *instance_state* {*FMRI* | *pattern*}...

If *instance_state* is "maintenance", then for each service specified by the operands, `svcadm` requests that the assigned restarter place the service in the `maintenance` state. See svc.startd(1M) and inetd(1M) for a detailed description of the actions taken for each restarter.

If *instance_state* is "degraded", then for services specified by the operands in the online state, `svcadm` requests that the restarters assigned to the services move them into the `degraded` state.

If the `-I` option is specified, the request is flagged as immediate.

The `-t` option is only valid for maintenance requests. When this option is specified, the request is flagged as temporary, and its effect will only last until the next reboot.

`milestone [-d]` *milestone_FMRI*

If *milestone_FMRI* is the keyword "none", all services other than the master restarter,

`svc:/system/svc/restarter:default`, will be temporarily disabled.

If *milestone_FMRI* is the keyword "all", temporary enable and disable requests for all services will be nullified.

If *milestone_FMRI* is one of the following:

```
svc:/milestone/single-user:default
svc:/milestone/multi-user:default
svc:/milestone/multi-user-server:default
```

then temporary enable and disable requests for the indicated service and all services it depends on (directly or indirectly) will be nullified. All other services will be temporarily disabled.

Changing the system's current milestone with the "milestone" subcommand will not change the current run level of the system. To change the system's run level, invoke `/sbin/init` directly.

This action requires permission to modify the "options_ovr" property group of the `svc:/system/svc/restarter:default` service instance (see `smf_security(5)`).

The `-d` option immediately changes the milestone to the requested milestone, as above. Additionally, it makes the specified milestone the default boot milestone, which persists across reboot. The default milestone is defined by the `options/milestone` property on the master restarter, `svc:/system/svc/restarter:default`. If this property is absent, "all" is the default. This action requires permission to modify the "options" property group of the `svc:/system/svc/restarter:default` service instance (see `smf_security(5)`).

Operands The following operands are supported:

FMRI An *FMRI* that specifies one or more instances. *FMRI*s can be abbreviated by specifying the instance name, or the trailing portion of the service name. For example, given the *FMRI*:

```
svc:/network/smtp:sendmail
```

All the following are valid abbreviations:

```
sendmail
:sendmail
smtp
smtp:sendmail
network/smtp
```

While the following are invalid:

```
mail
network
network/smt
```

If the *FMRI* specifies a service, then the command applies to all instances of that service. Abbreviated forms of *FMRI*s are unstable, and should not be used in scripts or other permanent tools.

pattern A pattern that is matched against the *FMRI*s of service instances according to the "globbing" rules described by `fnmatch(5)`. If the pattern does not begin with "svc:", then "svc:/" is prepended.

If an abbreviated *FMRI* or pattern matches more than one service, a warning message is displayed and that operand is ignored.

Examples

EXAMPLE 1 Restarting a Service Instance

The following command restarts the NFS server. The full *FMRI* for the default service instance is: `svc:/network/nfs/server:default`

However, you can abbreviate the full *FMRI* as follows:

```
# svcadm restart nfs/server
```

EXAMPLE 2 Disabling the Standard HTTP Server

The following command disables the standard HTTP server, using an abbreviated *FMRI*:

```
$ svcadm disable http
```

EXAMPLE 3 Enabling an Instance and Its Dependent Instances

The following command enables the `foo:bar` instance, and all instances on which it depends:

```
$ svcadm enable -r foo:bar
```

EXAMPLE 4 Synchronously enabling an instance

The following command enables the `foo:bar` instance. The command will not return until the instance comes online or `svcadm` determines it is not possible for the service to come online.

```
$ svcadm enable -s foo:bar
```

EXAMPLE 5 Restricting and Restoring the Running Services

The following command restricts the running services to single user mode:

```
# svcadm milestone milestone/single-user
```

The following command restores the running services:

```
# svcadm milestone all
```

Exit Status

The following exit values are returned:

`0` Successful completion.

`1` A fatal error occurred. One or more error messages are displayed on standard error.

`2` Invalid command line options were specified.

`3` `svcadm` determined that a service instance that it was waiting for could not reach the desired state without administrator intervention due to a problem with the service instance itself.

`4` `svcadm` determined that a service instance that it was waiting for could not reach the desired state without administrator intervention due to a problem with the service's dependencies.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	See below.

The interactive output is Uncommitted. The invocation and non-interactive output are Committed.

See Also svcprop(1), svcs(1), inetd(1M), init(1M), svccfg(1M), svc.startd(1M), libscf(3LIB), contract(4), attributes(5), smf(5), smf_security(5)

Notes The amount of time svcadm will spend waiting for services and their dependencies to change state is implicitly limited by their method timeouts. For example, a service using the default restarter whose start method hangs will be transitioned to the maintenance state when its timeout expires. svcadm will then consider it impossible for this service to come online without administrator intervention.

Attempts to synchronously enable a service which depends (directly or indirectly) on a file may fail with an exit status indicating that dependencies are unsatisfied if the caller does not have the privileges necessary to search the directory containing the file. This limitation may be removed in a future Solaris release.

Name svccfg – import, export, and modify service configurations

Synopsis

```
/usr/sbin/svccfg [-v] [-s FMRI]

/usr/sbin/svccfg [-v] [-s FMRI] subcommand [args]...

/usr/sbin/svccfg [-v] [-s FMRI] -f command-file
```

Description The `svccfg` command manipulates data in the service configuration repository. `svccfg` can be invoked interactively, with an individual subcommand, or by specifying a command file that contains a series of subcommands.

Changes made to an existing service in the repository typically do not take effect for that service until the next time the service instance is refreshed. See the `refresh` subcommand on the `svcadm(1M)` man page for more details.

Options The following options are supported:

`-f` *command-file*
Reads and executes `svccfg` subcommands from *command-file*.

`-s` *FMRI*
Selects the entity indicated by *FMRI* (a fault management resource identifier) before executing any subcommands. See `smf(5)`.

`-v`
Verbose.

Subcommands Subcommands are divided into the categories specified in the subsections that follow.

All subcommands that accept *FMRI*s also accept abbreviated or globbed patterns. Instances and services can be abbreviated by specifying the instance name, or the trailing portion of the service name. For example, given the *FMRI*:

```
svc:/network/smtp:sendmail
```

All the following are valid abbreviations:

```
sendmail
:sendmail
smtp
smtp:sendmail
network/smtp
```

While the following are invalid:

```
mail
network
network/smt
```

Abbreviated forms of *FMRI*s are unstable, and should not be used in scripts or other permanent tools. If a pattern matches more than one instance or service, an error message is printed and no action is taken.

General Subcommands

`end`
`exit`
`quit`
Exits immediately.

`repository` *repfile*
Uses *repfile* as a repository. By default, `svccfg` uses the system repository.

Use repository only with files from the identical version of Solaris, including patches, that you are currently running. Do not use this subcommand with the system repository, `/etc/svc/repository.db`.

`set` [`-v`|`-V`]
Sets optional behavior. If no options are specified, set displays the options currently in effect.

`-v`
Turns on verbose mode.

`-V`
Turns off verbose mode.

Service Profile Subcommands

`apply` *file*
If *file* is a service profile, then service instances specified within the file are enabled or disabled according to it. See `smf(5)` for a description of service profiles. This command requires privileges to modify the "general/enabled" property of the service instances. See `smf_security(5)` for the privileges required to modify properties. If *file* is not a service profile, the subcommand fails.

`extract` [> *file*]
Prints a service profile which represents the enabled status of the service instances in the repository to standard output. The output may be redirected to a file.

Service Manifest Subcommands

`archive`
Dumps a full XML service description for all services, instances, and their persistent properties in the repository. This does not include transient properties such as service state, and is suitable for a relocatable repository backup.

`export` *service_FMRI* [>*file*]
The service description for the specified service and its instances is written to standard output or redirected to the given file. Dependencies with a boolean "external" property set to true are omitted in the belief that they were created on behalf of another service.

Without the `-a` option, property groups containing protected information (identified by the presence of the `read_authorization` property—see `smf_security(5)`) will be exported without their property values. When the `-a` option is specified, all values will be archived. An error results if there are insufficient privileges to read these values.

Note that `export` requires a service FMRI. If you specify an instance (including an abbreviation, such as `apache2` or `sendmail`, that specifies an instance), the command fails.

`import` *file*
If *file* is a service manifest, then the services and instances it specifies are imported into the repository. According to the file, dependencies may be created in other services. See `smf(5)` for a description of service manifests. See `smf_security(5)` for the privileges required to create and modify service configurations.

For existing services and instances, properties which have not changed since the last `import` snapshot was taken are upgraded to those specified by the manifest. Conflicts (properties which have been changed both in the repository and the manifest) are reported on the standard error stream. `svccfg` will never upgrade the "general/enabled" and "general/restarter" properties, since they represent administrator preference.

`inventory` *file*
If *file* is determined to be a service manifest, then the FMRIs of the services and instances the *file* describes are printed. For each service, the FMRIs of its instances are displayed before the FMRI of the service.

`validate` *file*
file is processed similarly to `import`, but no changes are made to the repository. If any errors are detected, `svccfg`(1M) exits with a nonzero exit status.

Entity Selection, Modification, and Navigation Subcommands

An "entity" refers to a scope, service, or service instance.

`add` *name*
A new entity with the given name is created as a child of the current selection. See `smf_security(5)` for the privileges required to create entities.

`delete` [`-f`] {*name* | *fmri*}
The named child of the current selection or the entity specified by *fmri* is deleted. Attempts to delete service instances in the "online" or "degraded" state will fail unless the `-f` flag is specified. If a service or service instance has a "dependents" property group of type "framework", then for each of its properties with type "astring" or "fmri", if the property has a single value which names a service or service instance then the dependency property group in the indicated service or service instance with the same name as the property will be deleted. See `smf_security(5)` for the privileges required to delete service configurations.

`list` [*pattern*]
The child entities of the current selection whose names match the glob pattern *pattern* are displayed (see `fnmatch(5)`). ':properties' is also listed for property-bearing entities, namely services and service instances.

`select` {*name* | *fmri*}
If the argument names a child of the current selection, it becomes the current selection. Otherwise, the argument is interpreted as an FMRI and the entity that the argument specifies becomes the current selection.

`unselect`
The parent of the current selection becomes the current selection.

Property Inspection and Modification Subcommands

`addpg` *name type* [*flags*]
Adds a property group with the given *name* and type to the current selection. *flags* is a string of characters which designates the flags with which to create the property group. 'P' represents SCF_PG_FLAG_NONPERSISTENT (see `scf_service_add_pg(3SCF)`). See `smf_security(5)` for the privileges required to create property groups.

`addpropvalue` *pg/name* [*type:*] *value*
Adds the given value to a property. If *type* is given and the property exists, then if *type* does not agree with the property's *type*, the subcommand fails. The values may be enclosed in double-quotes. String values containing double-quotes or backslashes must be enclosed by double-quotes and the contained double-quotes and backslashes must be quoted by backslashes. Nonexistent properties are created, in which case the *type* specifier must be present. See `scf_value_create(3SCF)` for a list of available property types. See `smf_security(5)` for the privileges required to modify properties.

`delpg` *name*
Deletes the property group *name* of the current selection. See `smf_security(5)` for the privileges required to delete property groups.

`delprop` *pg*[*/name*]
Deletes the named property group or property of the current selection. See `smf_security(5)` for the privileges required to delete properties.

`delpropvalue` *pg/name globpattern*
Deletes all values matching the given *glob* pattern in the named property. Succeeds even if no values match. See `smf_security(5)` for the privileges required to modify properties.

`editprop`
Comments of commands to reproduce the property groups and properties of the current selection are placed in a temporary file and the program named by the EDITOR environment variable is invoked to edit it. Upon completion, the commands in the temporary file are executed. The default editor is `vi(1)`. See `smf_security(5)` for the privileges required to create, modify, or delete properties.

`listpg` [*pattern*]
Displays the names, types, and flags of property groups of the current selection. If an argument is given, it is taken as a glob pattern and only property groups with names which match the argument are listed.

`listprop` [*pattern*]
Lists property groups and properties of the current selection. For property groups, names, types, and flags are listed. For properties, names (prepended by the property group name and a slash (/)), types, and values are listed. See `scf_value_create(3SCF)` for a list of available property types. If an argument is supplied it is taken as a glob pattern and only property groups and properties with names which match the argument are listed.

`setenv` [`-i` | `-s`] [`-m` *method_name*] *envvar value*
Sets a method environment variable for a service or instance by changing the "environment" property in the *method_name* property group, if that property group has type "method". If *method_name* is not specified and the `-i` option is used, the "method_context" property group is used, if an instance is currently selected. If the `-s` option is used and a service is currently selected, its "method_context" property group is used. If the `-s` option is used and an instance is currently selected, the "method_context" property group of its parent is used. If neither the `-i` option nor the `-s` option is used, the "start" property group is searched for in the currently selected entity and, if an instance is currently selected, its parent is also searched. If the "inetd_start" property group is not located, it is searched for in a similiar manner.

Once the property is located, all values which begin with *envvar* followed by a "=" are removed, and the value "*envvar=value*" is added. See `smf_security(5)` for the privileges required to modify properties.

`setprop` *pg/name* = [*type:*] *value*
setprop *pg/name* = [*type:*] ([*values* ...])
Sets the *name* property of the *pg* property group of the current selection to the given values of type *type*. See `scf_value_create(3SCF)` for a list of available property types. If the property already exists and the *type* disagrees with the existing *type* on the property, the subcommand fails. Values may be enclosed in double-quotes. String values which contain double-quotes or backslashes must be enclosed by double-quotes and the contained double-quotes and backslashes must be quoted by backslashes. If the named property does not exist, it is created, as long as the type is specified. See `smf_security(5)` for the privileges required to create or modify properties.

`unsetenv` [`-i` | `-s`] [`-m` *method_name*] *envvar value*
Removes a method environment variable for a service or instance by changing the "environment" property in the *method_name* property group, if that property group has type "method". If *method_name* is not specified and the `-i` option is used, the "method_context" property group is used, if an instance is currently selected. If the `-s` option is used and a service is currently selected, its "method_context" property group is used. If the `-s` option is used and an instance is currently selected, the "method_context" property group of its parent is used. If neither the `-i` option nor the `-s` option is used, the "start" property group is searched for in the currently selected entity and, if an instance is currently selected, its parent is also searched. If the "inetd_start" property group is not located, it is searched for in a similiar manner.

Once the property is located, all values which begin with *envvar* followed by "=" are removed. See `smf_security(5)` for the privileges required to modify properties.

Snapshot Navigation and Selection Subcommands

`listsnap`
Displays snapshots available for the currently selected instance.

`revert` [*snapshot*]
Reverts the properties of the currently selected instance and its service to those recorded in the named snapshot. If no argument is given, use the currently selected snapshot and deselect it on success. The changed property values can be made active via the `refresh` subcommand of `svcadm(1M)`. See `smf_security(5)` for the privileges required to change properties.

`selectsnap` [*name*]
Changes the current snapshot to the one named by *name*. If no *name* is specified, deselect the currently selected snapshot. Snapshots are read-only.

Examples

EXAMPLE 1 Importing a Service Description

The following example imports a service description for the `seismic` service in the XML manifest specified on the command line.

```
# svccfg import /var/svc/manifest/site/seismic.xml
```

Note that the manifest must follow the format specified in `service_bundle(4)`.

EXAMPLE 2 Exporting a Service Description

To export a service description on the local system:

```
$ svccfg export dumpadm >/tmp/dump.xml
```

EXAMPLE 3 Deleting a Service Instance

To delete a service instance:

```
$ svccfg delete network/inetd-upgrade:default
```

EXAMPLE 4 Checking Properties in an Alternate Repository

To examine the state of a service's properties after loading an alternate repository, use the sequence of commands shown below. One might use such commands, for example, to determine whether a service was enabled in a particular repository backup.

```
# svccfg
svc:> repository /etc/svc/repository-boot
svc:> select telnet:default
svc:/network/telnet:default> listprop general/enabled
general/enabled  boolean  false
svc:/network/telnet:default> exit
```

EXAMPLE 5 Enabling Debugging

To modify `LD_PRELOAD` for a start method and enable the use of `libumem(3LIB)` with debugging features active:

```
$ svccfg -s system/service setenv LD_PRELOAD libumem.so
$ svccfg -s system/service setenv UMEM_DEBUG default
```

Environmental Variables

EDITOR
The command to run when the `editprop` subcommand is used. The default editor is `vi(1)`.

Exit Status

The following exit values are returned:

`0`
Successful execution.

`1`
One or more subcommands resulted in failure. Error messages are written to the standard error stream.

`2`
Invalid command line options were specified.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	See below.

The interactive output is Uncommitted. The invocation and non-interactive output are Committed.

Name svc.configd – Service Management Facility repository daemon

Synopsis

```
/lib/svc/bin/svc.configd
```

Description `svc.configd` is the repository daemon for the Service Management Facility. `svc.configd` is invoked automatically during system startup, and restarted if any failures occur. `svc.configd` should never be invoked directly.

Interaction with `svc.configd` is by way of `libscf(3LIB)` and the command line tools:`svcs(1)`, `svcprop(1)`, `svcadm(1M)`, and `svccfg(1M)`.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsr

See Also `svcs(1)`, `svcprop(1)`, `svcadm(1M)`, `svccfg(1M)`, `libscf(3LIB)`, `attributes(5)`

Name svc.startd – Service Management Facility master restarter

Synopsis

```
/lib/svc/bin/svc.startd

svc:/system/svc/restarter:default
```

Description `svc.startd` is the master restarter daemon for Service Management Facility (SMF) and the default restarter for all services. `svc.startd` starts, stops, and restarts services based on administrative requests, system failures, or application failures.

`svc.startd` maintains service state, as well as being responsible for managing faults in accordance with the dependencies of each service.

`svc.startd` is invoked automatically during system startup. It is restarted if any failures occur. `svc.startd` should never be invoked directly.

See `smf_restarter(5)` for information on configuration and behavior common to all restarters.

`svcs(1)` reports status for all services managed by the Service Configuration Facility. `svcadm(1M)` allows manipulation of service instances with respect to the service's restarter.

Environment Variables Environment variables with the "SMF_" prefix are reserved and may be overwritten.

`svc.startd` supplies the "SMF_" environment variables specified in `smf_method(5)` to the method. PATH is set to "`/usr/sbin:/usr/bin`" by default. By default, all other environment variables supplied to `svc.startd` are those inherited from `init(1M)`.

Duplicate entries are reduced to a single entry. The value used is undefined. Environment entries that are not prefixed with "<*name*>=" are ignored.

Restarter Options `svc.startd` is not configured by command line options. Instead, configuration is read from the service configuration repository. You can use `svccfg(1M)` to set all options and properties.

The following configuration variables in the `options` property group are available to developers and administrators:

`boot_messages`
: An *astring* (as defined in `scf_value_is_type`; see `scf_value_create(3SCF)`) that describes the default level of messages to print to the console during boot. The supported message options include `quiet` and `verbose`. The `quiet` option prints minimal messages to console during boot. The `verbose` option prints a single message per service started to indicate success or failure. You can use the `boot -m` option to override the `boot_messages` setting at boot time. See `kernel(1M)`.

`logging`
: Control the level of global service logging for `svc.startd`. An *astring* (as defined in `scf_value_is_type`; see `scf_value_create(3SCF)`) that describes the default level of messages to log to `syslog` (see `syslog(3C)` and `svc.startd`'s global logfile,

/var/svc/log/svc.startd.log. The supported message options include quiet, verbose, and debug. The quiet option sends error messages requiring administrative intervention to the console, syslog and svc.startd's global logfile. The verbose option sends error messages requiring administrative intervention to the console, syslog and svc.startd's global logfile, and information about errors which do not require administrative intervention to svc.startd's global logfile. A single message per service started is also sent to the console. The debug option sends svc.startd debug messages to svc.startd's global logfile, error messages requiring administrative intervention to the console, syslog and svc.startd's global logfile, and a single message per service started to the console.

`milestone`
An FMRI which determines the milestone used as the default boot level. Acceptable options include only the major milestones:

```
svc:/milestone/single-user:default
svc:/milestone/multi-user:default
svc:/milestone/multi-user-server:default
```

or the special values all or none. all represents an idealized milestone that depends on every service. none is a special milestone where no services are running apart from the master svc:/system/svc/restarter:default. By default, svc.startd uses all, a synthetic milestone that depends on every service. If this property is specified, it overrides any initdefault setting in inittab(4).

`system/reconfigure`
Indicates that a reconfiguration reboot has been requested. Services with actions that must key off of a reconfiguration reboot may check that this property exists and is set to 1 to confirm a reconfiguration boot has been requested.

This property is managed by svc.startd and should not be modified by the administrator.

Configuration errors, such as disabling svc.startd are logged by syslog, but ignored.

SERVICE STATES

Services managed by svc.startd can appear in any of the states described in smf(5). The state definitions are unmodified by this restarter.

SERVICE REPORTING

In addition to any logging done by the managed service, svc.startd provides a common set of service reporting and logging mechanisms.

Reporting properties svc.startd updates a common set of properties on all services it manages. These properties are a common interface that can be used to take action based on service instance health. The svcs(1) command can be used to easily display these properties.

`restarter/state`
`restarter/next_state`
The current and next (if currently in transition) state for an instance.

`restarter/auxiliary_state`
A caption detailing additional information about the current instance state. The auxiliary state available for services managed by `svc.startd` is:

maintenance

```
fault_threshold_reached
stop_method_failed
administrative_request
```

`restarter/state_timestamp`
The time when the current state was reached.

`restarter/contract`
The primary process contract ID, if any, that under which the service instance is executing.

Logs

By default, `svc.startd` provides logging of significant restarter actions for the service as well as method standard output and standard error file descriptors to `/var/svc/log/`*service*`:`*instance*`.log`. The level of logging to system global locations like `/var/svc/log/svc.startd.log` and `syslog` is controlled by the `options/logging` property.

SERVICE DEFINITION

When developing or configuring a service managed by `svc.startd`, a common set of properties are used to affect the interaction between the service instance and the restarter.

Methods

The general form of methods for the fork/exec model provided by `svc.startd` are presented in `smf_method(5)`. The following methods are supported as required or optional by services managed by `svc.startd`.

`refresh` Reload any appropriate configuration parameters from the repository or `config` file, without interrupting service. This is often implemented using `SIGHUP` for system daemons. If the service is unable to recognize configuration changes without a restart, no refresh method is provided.

This method is optional.

`start` Start the service. Return success only after the application is available to consumers. Fail if a conflicting instance is already running, or if the service is unable to start.

This method is required.

`stop` Stop the service. In some cases, the stop method can be invoked when some or all of the service has already been stopped. Only return an error if the service is not entirely stopped on method return.

This method is required.

If the service does not need to take any action in a required method, it must specify the `:true` token for that method.

`svc.startd` honors any method context specified for the service or any specific method. The method expansion tokens described in `smf_method(5)` are available for use in all methods invoked by `svc.startd`.

Properties

An overview of the general properties is available in `smf(5)`. The specific way in which these general properties interacts with `svc.startd` follows:

`general/enabled`
If enabled is set to true, the restarter attempts to start the service once all its dependencies are satisfied. If set to false, the service remains in the disabled state, not running.

`general/restarter`
If this FMRI property is empty or set to `svc:/system/svc/restarter:default`, the service is managed by `svc.startd`. Otherwise, the restarter specified is responsible (once it is available) for managing the service.

`general/single_instance`
If `single_instance` is set to true, `svc.startd` only allows one instance of this service to transition to online or degraded at any time.

Additionally, `svc.startd` managed services can define the optional properties listed below in the `startd` property group.

`startd/duration`
The `duration` property defines the service's model. It can be set to `transient`, `child` also known as "`wait`" model services, or `contract` (the default).

`startd/ignore_error`
The `ignore_error` property, if set, specifies a comma-separated list of ignored events. Legitimate string values in that list are `core` and `signal`. The default is to restart on all errors.

`startd/need_session`
The `need_session` property, if set to true, indicates that the instance should be launched in its own session. The default is not to do so.

`startd/utmpx_prefix`
The `utmpx_prefix` string property defines that the instance requires a valid `utmpx` entry prior to start method execution. The default is not to create a `utmpx` entry.

SERVICE FAILURE

`svc.startd` assumes that a method has failed if it returns a non-zero exit code or if fails to complete before the timeout specified expires. If `$SMF_EXIT_ERR_CONFIG` or `$SMF_EXIT_ERR_FATAL` is returned, `svc.startd` immediately places the service in the

maintenance state. For all other failures, `svc.startd` places the service in the offline state. If a service is offline and its dependencies are satisfied, `svc.startd` tries again to start the service (see `smf(5)`).

If a contract or transient service does not return from its start method before its defined timeout elapses, `svc.startd` sends a `SIGKILL` to the method, and returns the service to the offline state.

If three failures happen in a row, or if the service is restarting more than once a second, `svc.startd` places the service in the maintenance state.

The conditions of service failure are defined by a combination of the service model (defined by the `startd/duration` property) and the value of the `startd/ignore_error` property.

A contract model service fails if any of the following conditions occur:

- all processes in the service exit
- any processes in the service produce a core dump
- a process outside the service sends a service process a fatal signal (for example, an administrator terminates a service process with the `pkill` command)

The last two conditions may be ignored by the service by specifying core and/or signal in `startd/ignore_error`.

Defining a service as transient means that `svc.startd` does not track processes for that service. Thus, the potential faults described for contract model services are not considered failures for transient services. A transient service only enters the maintenance state if one of the method failure conditions occurs.

"`Wait`" model services are restarted whenever the child process associated with the service exits. A child process that exits is not considered an error for "`wait`" model services, and repeated failures do not lead to a transition to maintenance state.

LEGACY SERVICES

`svc.startd` continues to provide support for services invoked during the startup run level transitions. Each `/etc/rc?.d` directory is processed after all managed services which constitute the equivalent run level milestone have transitioned to the online state. Standard `init` scripts placed in the `/etc/rc?.d` directories are run in the order of their sequence numbers.

The milestone to run-level mapping is:

`milestone/single-user`	Single-user (`S`)
`milestone/multi-user`	Multi-user (`2`)
`milestone/multi-user-server`	Multi-user with network services (`3`)

Additionally, `svc.startd` gives these legacy services visibility in SMF by inserting an instance per script into the repository. These legacy instances are visible using standard SMF interfaces such as `svcs(1)`, always appear in the `LEGACY-RUN` state, cannot be modified, and can not be specified as dependencies of other services. The initial start time of the legacy service is captured as a convenience for the administrator.

Files

`/var/svc/log`	Directory where `svc.startd` stores log files.
`/etc/svc/volatile`	Directory where `svc.startd` stores log files in early stages of boot, before `/var` is mounted read-write.

Example **EXAMPLE 1** Turning on Verbose Logging

To turn on verbose logging, type the following:

```
# /usr/sbin/svccfg -s system/svc/restarter:default
svc:/system/svc/restarter:default> addpg options application
svc:/system/svc/restarter:default> setprop options/logging = \
astring: verbose
svc:/system/svc/restarter:default> exit
```

This request will take effect on the next restart of `svc.startd`.

Name swap – swap administrative interface

Synopsis

```
/usr/sbin/swap -a swapname [swaplow] [swaplen]

/usr/sbin/swap -d swapname [swaplow]

/usr/sbin/swap -l

/usr/sbin/swap -s
```

Description The `swap` utility provides a method of adding, deleting, and monitoring the system swap areas used by the memory manager.

Options The following options are supported:

`-a` *swapname* [*swaplow*] [*swaplen*]

Add the specified swap area. This option can only be used by the superuser or by one who has assumed the Primary Administrator role. *swapname* is the name of the swap area or regular file. For example, on system running a UFS root file system, specify a slice, such as `/dev/dsk/c0t0d0s1`, or a regular file for a swap area. On a system running a ZFS file system, specify a ZFS volume, such as `/dev/zvol/dsk/rpool/swap`, for a swap area. Using a regular file for swap is not supported on a ZFS file system. In addition, you cannot use the same ZFS volume for both the swap area and a dump device when the system is running a ZFS root file system.

swaplow is the offset in 512-byte blocks into the file where the swap area should begin. *swaplen* is the desired length of the swap area in 512-byte blocks. The value of *swaplen* can not be less than `16`. For example, if *n* blocks are specified, then (*n*-1) blocks would be the actual swap length. *swaplen* must be at least one page in length. The size of a page of memory can be determined by using the `pagesize` command. See `pagesize(1)`. Since the first page of a swap file is automatically skipped, and a swap file needs to be at least one page in length, the minimum size should be a multiple of 2 pagesize bytes. The size of a page of memory is machine-dependent.

swaplow + *swaplen* must be less than or equal to the size of the swap file. If *swaplen* is not specified, an area will be added starting at *swaplow* and extending to the end of the designated file. If neither *swaplow* nor *swaplen* are specified, the whole file will be used except for the first page. Swap areas are normally added automatically during system startup by the `/sbin/swapadd` script. This script adds all swap areas which have been specified in the `/etc/vfstab` file; for the syntax of these specifications, see `vfstab(4)`.

To use an NFS or local file system *swapname*, you should first create a file using `mkfile(1M)`. A local file system swap file can now be added to the running system by just running the `swap -a` command. For NFS mounted swap files, the server needs to export the file. Do this by performing the following steps:

1. Add the following line to `/etc/dfs/dfstab`:

   ```
   share -F nfs -o \
   rw=clientname,root=clientname path-to-swap-file
   ```

2. Run shareall(1M).
3. Have the client add the following line to /etc/vfstab:

   server:*path-to-swap-file* - *local-path-to-swap-file* nfs \
   - - - *local-path-to-swap-file* - - swap - - -

4. Have the client run mount:

   # mount *local-path-to-swap-file*

5. The client can then run swap -a to add the swap space:

   # swap -a *local-path-to-swap-file*

-d *swapname*
Delete the specified swap area. This option can only be used by the super-user. *swapname* is the name of the swap file: for example, /dev/dsk/c0t0d0s1 or a regular file. *swaplow* is the offset in 512-byte blocks into the swap area to be deleted. If *swaplow* is not specified, the area will be deleted starting at the second page. When the command completes, swap blocks can no longer be allocated from this area and all swap blocks previously in use in this swap area have been moved to other swap areas.

-l
List the status of all the swap areas. The output has five columns:

path
The path name for the swap area.

dev
The major/minor device number in decimal if it is a block special device; zeroes otherwise.

swaplo
The *swaplow* value for the area in 512-byte blocks.

blocks
The *swaplen* value for the area in 512-byte blocks.

free
The number of 512-byte blocks in this area that are not currently allocated.

The list does not include swap space in the form of physical memory because this space is not associated with a particular swap area.

If swap -l is run while *swapname* is in the process of being deleted (by swap-d), the string INDEL will appear in a sixth column of the swap stats.

-s
Print summary information about total swap space usage and availability:

allocated
The total amount of swap space in bytes currently allocated for use as backing store.

`reserved`
The total amount of swap space in bytes not currently allocated, but claimed by memory mappings for possible future use.

`used`
The total amount of swap space in bytes that is either allocated or reserved.

`available`
The total swap space in bytes that is currently available for future reservation and allocation.

These numbers include swap space from all configured swap areas as listed by the `-l` option, as well swap space in the form of physical memory.

Usage On the 32-bit operating system, only the first 2 Gbytes -1 are used for swap devices greater than or equal to 2 Gbytes in size. On the 64-bit operating system, a block device larger than 2 Gbytes can be fully utilized for swap up to 2^{63} –1 bytes.

Environment Variables See `environ(5)` for descriptions of the following environment variables that affect the execution of `swap`: `LC_CTYPE` and `LC_MESSAGE`.

Attributes See `attributes(5)` for descriptions of the following attributes:

Notes For information about setting up a swap area with ZFS, see the *ZFS Administration Guide*.

Warnings No check is done to determine if a swap area being added overlaps with an existing file system.

Name sync – update the super block

Synopsis

```
sync
```

Description `sync` executes the `sync` system primitive. If the system is to be stopped, `sync` must be called to ensure file system integrity. It will flush all previously unwritten system buffers out to disk, thus assuring that all file modifications up to that point will be saved. See `sync(2)` for details.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

Name syncinit – set serial line interface operating parameters

Synopsis

```
/usr/sbin/syncinit device
     [ [baud_rate] | [keyword=value,]... | [single-word option]]
```

Description The `syncinit` utility allows the user to modify some of the hardware operating modes common to synchronous serial lines. This can be useful in troubleshooting a link, or necessary to the operation of a communications package.

If run without options, `syncinit` reports the options as presently set on the port. If options are specified, the new settings are reported after they have been made.

Options Options to `syncinit` normally take the form of a keyword, followed by an equal sign and a value. The exception is that a baud rate may be specified as a decimal integer by itself. Keywords must begin with the value shown in the options table, but may contain additional letters up to the equal sign. For example, `loop=` and `loopback=` are equivalent.

The following options are supported:

Keyword	Value	Effect
`loop`	yes	Set the port to operate in `internal loopback` mode. The receiver is electrically disconnected from the DCE receive data input and tied to the outgoing transmit data line. Transmit data is available to the DCE. The Digital Phase-Locked Loop (DPLL) may not be used as a clock source in this mode. If no other clocking options have been specified, perform the equivalent of `txc=baud` and `rxc=baud`.
	no	Disable internal loopback mode. If no other clocking options have been specified, perform the equivalent of `txc=txc` and `rxc=rxc`.
`echo`	yes	Set the port to operate in `auto-echo` mode. The transmit data output is electrically disconnected from the transmitter and tied to the receive data input. Incoming receive data is still visible. Use of this mode in combination with local loopback mode has no value, and should be rejected by the device driver. The `auto-echo` mode is useful to make a system become the endpoint of a remote loopback test.
	no	Disable `auto-echo` mode.
`nrzi`	yes	Set the port to operate with `NRZI` data encoding.
	no	Set the port to operate with `NRZ` data encoding.
`txc`	`txc`	Transmit clock source will be the `TxC` signal (pin 15).
	`rxc`	Transmit clock source will be the `RxC` signal (pin 17).
	`baud`	Transmit clock source will be the internal `baud rate generator`.
	`pll`	Transmit clock source will be the output of the `DPLL` circuit.

`rxc`	`rxc`	Receive clock source will be the `RxC` signal (pin 17).
	`txc`	Receive clock source will be the `TxC` signal (pin 15).
	`baud`	Receive clock source will be the internal `baud rate generator`.
	`pll`	Receive clock source will be the output of the `DPLL` circuit.
`speed`	*integer*	Set the baud rate to *integer* bits per second.

There are also several single-word options that set one or more paramaters at a time:

Keyword	Equivalent to Options:
`external`	`txc=txc rxc=rxc loop=no`
`sender`	`txc=baud rxc=rxc loop=no`
`internal`	`txc=pll rxc=pll loop=no`
`stop`	`speed=0`

Examples

EXAMPLE 1 Using `syncinit`

The following command sets the first CPU port to loop internally, using internal clocking and operating at 38400 baud:

```
example# syncinit zsh0 38400 loop=yes
device: /dev/zsh  ppa: 0
speed=38400, loopback=yes, echo=no, nrzi=no, txc=baud, rxc=baud
```

The following command sets the same port's clocking, local loopback and baud rate settings to their default values:

```
example# syncinit zsh0 stop loop=no
device: /dev/zsh  ppa: 0
speed=0, loopback=no, echo=no, nrzi=no, txc=txc, rxc=rxc
```

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also

`syncloop(1M)`, `syncstat(1M)`, `Intro(2)`, `ioctl(2)`, `attributes(5)`, `zsh(7D)`

Diagnostics

device `missing minor device number`	The name *device* does not end in a decimal number that can be used as a minor device number.

`bad speed:` *arg*	The string *arg* that accompanied the `speed=` option could not be interpreted as a decimal integer.
`Bad arg:` *arg*	The string *arg* did not make sense as an option.
`ioctl failure code =` *errno*	An `ioctl(2)` system called failed. The meaning of the value of *errno* may be found in `Intro(2)`.

Warnings Do not use `syncinit` on an active serial link, unless needed to resolve an error condition. Do not use this command casually or without being aware of the consequences.

Name syncloop – synchronous serial loopback test program

Synopsis `/usr/sbin/syncloop [-cdlstv]` *device*

Description The `syncloop` command performs several loopback tests that are useful in exercising the various components of a serial communications link.

Before running a test, `syncloop` opens the designated port and configures it according to command line options and the specified test type. It announces the names of the devices being used to control the hardware channel, the channel number (ppa) corresponding to the *device* argument, and the parameters it has set for that channel. It then runs the loopback test in three phases.

The first phase is to listen on the port for any activity. If no activity is seen for at least four seconds, `syncloop` proceeds to the next phase. Otherwise, the user is informed that the line is active and that the test cannot proceed, and the program exits.

In the second phase, called the "first-packet" phase, `syncloop` attempts to send and receive one packet. The program will wait for up to four seconds for the returned packet. If no packets are seen after five attempts, the test fails with an excoriating message. If a packet is returned, the result is compared with the original. If the length and content do not match exactly, the test fails.

The final phase, known as the "multiple-packet" phase, attempts to send many packets through the loop. Because the program has verified the integrity of the link in the first-packet phase, the test will not fail after a particular number of timeouts. If a packet is not seen after four seconds, a message is displayed. Otherwise, a count of the number of packets received is updated on the display once per second. If it becomes obvious that the test is not receiving packets during this phase, the user may wish to stop the program manually. The number and size of the packets sent during this phase is determined by default values, or by command line options. Each returned packet is compared with its original for length and content. If a mismatch is detected, the test fails. The test completes when the required number of packets have been sent, regardless of errors.

After the multiple-packet phase has completed, the program displays a summary of the hardware event statistics for the channel that was tested. The display takes the following form:

```
CRC errors   Aborts   Overruns   Underruns   In<-Drops-> Out
        0         0          0           0   0             0
```

This is followed by an estimated line speed, which is an approximation of the bit rate of the line, based on the number of bytes sent and the actual time that it took to send them.

Options The options for `syncloop` are described in the following table:

Option	Parameter	Default	Description
`-c`	*packet_count*	100	Specifies the number of packets to be sent in the multiple-packet phase.
`-d`	*hex_data_byte*	*random*	Specifies that each packet will be filled with bytes with the value of *hex_data_byte*.
`-l`	*packet_length*	100	Specifies the length of each packet in bytes.
`-s`	*line_speed*	9600	Bit rate in bits per second.
`-v`			Sets verbose mode. If data errors occur, the expected and received data is displayed.
`-t`	*test_type*	*none*	A number, from 1 to 4, that specifies which test to perform. The values for *test_type* are as follows: 1: Internal loopback test. Port loopback is on. Transmit and receive clock sources are internal (baud rate generator). 2: External loopback test. Port loopback is off. Transmit and receive clock sources are internal. Requires a loopback plug suitable to the port under test. 3: External loopback test. Port loopback is off. Transmit and receive clock sources are external (modem). Requires that one of the local modem, the remote modem, or the remote system be set in a loopback configuration. 4: Test using predefined parameters. User defines hardware configuration and may select port parameters using the `syncinit(1M)` command.

All numeric options except `-d` are entered as decimal numbers (for example, `-s 19200`). If you do not provide the `-t` *test_type* option, `syncloop` prompts for it.

Examples

EXAMPLE 1 A sample display of using the `syncloop` command.

In the following command `syncloop` uses a packet length of 512 bytes over the first CPU port:

```
example# syncloop -l 512 zsh0
```

In response to the above command, `syncloop` prompts you for the test option you want.

The following command performs an internal loopback test on the first CPU port, using 5000 packets and a bit rate of 56Kbps:

```
example# syncloop -t 1 -s 56000 -c 5000 zsh0
```

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also syncinit(1M), syncstat(1M), attributes(5), zsh(7D)

Diagnostics

device `missing minor device number`	The name *device* does not end in a decimal number that can be used as a minor device number.
`invalid packet length:` *nnn*	The packet length was specified to be less than zero or greater than 4096.
`poll: nothing to read`	
`poll: nothing to read or write.`	The poll(2) system call indicates that there is no input pending and/or that output would be blocked if attempted.
`len` *xxx* `should be` *yyy*	The packet that was sent had a length of *yyy*, but was received with a length of *xxx*.
nnn `packets lost in outbound queueing`	
nnn `packets lost in inbound queueing`	A discrepancy has been found between the number of packets sent by `syncloop` and the number of packets the driver counted as transmitted, or between the number counted as received and the number read by the program.

Warnings To allow its tests to run properly, as well as prevent disturbance of normal operations, `syncloop` should only be run on a port that is not being used for any other purpose at that time.

Name syncstat – report driver statistics from a synchronous serial link

Synopsis

```
/usr/sbin/syncstat [-c] device [interval]
```

Description The `syncstat` command reports the event statistics maintained by a synchronous serial device driver. The report may be a single snapshot of the accumulated totals, or a series of samples showing incremental changes. Prior to these it prints the device name being used to query a particular device driver, along with a number indicating the channel number (ppa) under control of that driver.

Event statistics are maintained by a driver for each physical channel that it supports. They are initialized to zero at the time the driver module is loaded into the system, which may be either at boot time or when one of the driver's entry points is first called.

The *device* argument is the name of the serial device as it appears in the `/dev` directory. For example, `zsh0` specifies the first on-board serial device.

The following is a breakdown of `syncstat` output:

`speed`	The line speed the device has been set to operate at. It is the user's responsibility to make this value correspond to the modem clocking speed when clocking is provided by the modem.
`ipkts`	The total number of input packets.
`opkts`	The total number of output packets.
`undrun`	The number of transmitter underrun errors.
`ovrrun`	The number of receiver overrun errors.
`abort`	The number of aborted received frames.
`crc`	The number of received frames with CRC errors.
`isize`	The average size (in bytes) of input packets.
`osize`	The average size (in bytes) of output packets.

Options

`-c` Clear the accumulated statistics for the device specified. This may be useful when it is not desirable to unload a particular driver, or when the driver is not capable of being unloaded.

interval `syncstat` samples the statistics every *interval* seconds and reports incremental changes. The output reports line utilization for input and output in place of average packet sizes. These are the relationships between bytes transferred and the baud rate, expressed as percentages. The loop repeats indefinitely, with a column heading printed every twenty lines for convenience.

Examples

EXAMPLE 1 Sample output from the `syncstat` command:

```
example# syncstat zsh0

speed ipkts opkts undrun ovrrun abort crc isize osize
9600  15716 17121   0      0      1    3   98    89

example# syncstat -c zsh0

speed ipkts opkts undrun ovrrun abort crc isize osize
9600   0     0     0      0      0     0    0     0
```

In the following sample output a new line of output is generated every five seconds:

```
example# syncstat zsh0 5

ipkts opkts undrun ovrrun abort crc iutil outil
12    10      0     0      0     0   5%    4%
22    60      0     0      0     0   3%    90%
36    14      0     0      0     1   51%   2%
```

Diagnostics

`bad interval:` *arg*	The argument *arg* is expected to be an interval and could not be understood.
device `missing minor device number`	The name *device* does not end in a decimal number that can be used as a minor device number.
`baud rate not set`	The *interval* option is being used and the baud rate on the device is zero. This would cause a divide-by-zero error when computing the line utilization statistics.

Warnings

Underrun, overrun, frame-abort, and CRC errors have a variety of causes. Communication protocols are typically able to handle such errors and initiate recovery of the transmission in which the error occurred. Small numbers of such errors are not a significant problem for most protocols. However, because the overhead involved in recovering from a link error can be much greater than that of normal operation, high error rates can greatly degrade overall link throughput. High error rates are often caused by problems in the link hardware, such as

cables, connectors, interface electronics or telephone lines. They may also be related to excessive load on the link or the supporting system.

The percentages for input and output line utilization reported when using the *interval* option may occasionally be reported as slightly greater than 100% because of inexact sampling times and differences in the accuracy between the system clock and the modem clock. If the percentage of use greatly exceeds 100%, or never exceeds 50%, then the baud rate set for the device probably does not reflect the speed of the modem.

Name sysdef – output system definition

Synopsis

```
/usr/sbin/sysdef [-i] [-n namelist]

/usr/sbin/sysdef [-h] [-d] [-i] [-D]
```

Description The `sysdef` utility outputs the current system definition in tabular form. It lists all hardware devices, as well as pseudo devices, system devices, loadable modules, and the values of selected kernel tunable parameters.

It generates the output by analyzing the named bootable operating system file (*namelist*) and extracting the configuration information from it.

The default system *namelist* is `/dev/kmem`.

Options

`-i` Prints the configuration information from `/dev/kmem`. This is the default and only needs to be specified if the configuration information from both `/dev/kmem` and the system file specified with the "`-n` *namelist*" option is needed.

`-n` *namelist* Specifies a *namelist* other than the default (`/dev/kmem`). The *namelist* specified must be a valid bootable operating system.

`-h` Prints the identifier of the current host in hexadecimal. If `sysdef -h` is executed within a non-global zone and the zone emulates a host identifier, then the zone's host identifier is printed. This numeric value is not guaranteed to be unique.

`-d` The output includes the configuration of system peripherals formatted as a device tree.

`-D` For each system peripheral in the device tree, display the name of the device driver used to manage the peripheral.

Examples **EXAMPLE 1** Sample output format

The following example displays the format of the `sysdef -d` output:

```
example% sysdef -d
Node 'SUNW,Ultra-5_10', unit #-1
    Node 'packages', unit #-1 (no driver)
        Node 'terminal-emulator', unit #-1 (no driver)

Name syseventadm – sysevent event specification administration

Synopsis

```
syseventadm add [-R rootdir] [-v vendor] [-p publisher]
     [-c class] [-s subclass] [-u username] path [args]

syseventadm remove [-R rootdir] [-v vendor] [-p publisher]
     [-c class] [-s subclass] [-u username] [path [args]]

syseventadm list [-R rootdir] [-v vendor] [-p publisher]
     [-c class] [-s subclass] [-u username] [path [args]]

syseventadm restart
```

Description The `syseventadm` command is an administrative front-end to add, remove and list `sysevent` event handlers. You can also restart the sysevent daemon by use of the restart command. `syseventadm` can only be run by root.

The `syseventadm add` command adds a handler for a `sysevent` event specified by at least one of vendor, publisher or class. If *class* is specified, it may be qualified with a *sub-class*. Only the values specified for *vendor*, *publisher*, *class* and *sub-class* when adding the handler are matched against `sysevent` events to determine if the specification matches the event and the handler should be run. *path* is the full pathname of the command to be run in response to matching events, with optional arguments (*args*). If username is specified, the command is invoked as user *username*, otherwise as root.

The `syseventadm remove` command removes handlers for matching sysevent event specifications. Event specifications may be matched by specifying at least one of *vendor*, *publisher*, *class*, *username* or *path*. If *class* is specified, it may be qualified with a *sub-class*. Any of *vendor*, *publisher*, *class*, *sub-class*, *username*, *path* or *args* not specified match the corresponding fields of all events. Handlers for all matching specifications are removed.

The `syseventadm list` command lists the handlers for matching `sysevent` event specifications using the same match criteria as the `remove` command but without the requirement that at least one of *vendor*, *publisher*, *class*, *username* or *path* be specified. With no match criteria, all specifications are listed. The list command output format is: [vendor=*vendor*] [publisher=*publisher*] [class=*class*] [subclass=*subclass*] [username=*username*] *path* [*args*] where each of *class*, *sub-class*, *vendor*, *publisher* and *username* is listed only if part of the match criteria for the listed specification.

The `syseventadm restart` command informs the `syseventd` daemon to reread the `sysevent` registry after a change has been made by adding or removing one or more `sysevent` handler specifications.

Argument Macro Substitution The `sysevent` handling facility provides extensive macro capability for constructing the command line arguments to be executed in response to an event. Macro expansion applies only to the command line *args* specified for an event handler, with macros expanded with data from the event itself. Pre-defined macros are provided for the event *class*, *subclass*, *publisher* and *vendor* information. Macros not matching one of the pre-defined macro names cause the

attribute list attached to the event to be searched for an attribute of that name, with the value of the matching attribute substituted on the command line.

Macros are introduced by the `$` character, with the macro name being the following token separated by a SPACE or TAB character. If the macro name is embedded in text, it may be delineated by `${` and `}`. A `\` before the `$` causes macro expansion not to occur.

$*class*	The class string defining the event
$*publisher*	The publisher string defining the event
$*sequence*	The sequence number of the event.
$*subclass*	The subclass string defining the event
$*timestamp*	The timestamp of the event.
$*vendor*	The vendor string defining the event

Macro names other than those pre-defined are compared against the attribute list provided with the event. An attribute with name matching the macro name causes the value of the attribute to be substituted as ASCII text on the generated command line.

Use of a macro for which no attribute with that name is defined, or for which multiple attributes with that name are provided, cause an error and the command is not invoked.

Attributes with signed data types (`DATA_TYPE_INT16`, `DATA_TYPE_INT32` and `DATA_TYPE_INT64`) are expanded as decimal digits.

Attributes with unsigned data types (`DATA_TYPE_BYTE`, `DATA_TYPE_UINT16`, `DATA_TYPE_UINT32`, `DATA_TYPE_UINT64` and `DATA_TYPE_HTTIME`) are expanded as hexadecimal digits with a `0x` prefix.

Attributes with string data type (`DATA_TYPE_STRING`) are expanded with the string data. The data is not quoted. If if it desired that the quoted strings be generated on the command line, put quotes around the macro call in the arguments.

Array types are expanded with each element expanded as defined for that scalar type, with a space separating each element substitution.

Options The `add`, `list` and `remove` subcommands support the following options:

`-c` *class*	Specify the event class, *class*.
`-p` *publisher*	Specify the event publisher, *publisher*.
`-R` *rootdir*	Specify an alternate root path, *rootdir*.

Note – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system,

might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

`-s` *subclass* Specify the event subclass, *subclass*.

`-u` *username* Specify the username (*username*) to invoke the command.

`-v` *vendor* Specify the vendor (*vendor*) that defines the event. Events defined by third-party software should specify the company's stock symbol as *vendor*. Sun-defined events use `SUNW`.

Operands The `add`, `list` and `remove` subcommands support the following options:

args Command arguments

path Full path of command to be run in response to event

Examples **EXAMPLE 1** Adding an Event Handler

The following example adds an event handler for an event defined by vendor `MYCO` ("My Company"), class `EC_ENV` and sub-class `ESC_ENV_TEMP`. The command to be run is `/opt/MYCOenv/bin/ec_env_temp`, with arguments being the class name, sub-class name and pathname derived from the event attributes. The `$` characters are preceded by a backslash to circumvent shell interpretation. There is no need to restart the service after the change since the registry is maintained on `$ALTROOT`.

```
# syseventadm add -R \$ALTROOT -v MYCO -c EC_ENV -s ESC_ENV_TEMP \
     /opt/MYCOenv/bin/ec_env_temp \$class \$subclass \$pathname
```

Note the caveat on the use of the `-R` option in the description of that option, above.

EXAMPLE 2 Removing an Event Handler

The following example removes the event handler added in Example 1.

```
# syseventadm remove -R \$ALTROOT -v MYCO -c EC_ENV -s ESC_ENV_TEMP \
     /opt/MYCOenv/bin/ec_env_temp \${class} \${subclass} \${pathname}
```

Note the caveat on the use of the `-R` option in the description of that option, above.

EXAMPLE 3 Listing Event Handlers

The following example lists all event handlers for events of class `EC_ENV`, subclass `ESC_ENV_TEMP`, as defined by vendor `MYCO`:

```
# syseventadm list -v MYCO -c EC_ENV -s ESC_ENV_TEMP \
     vendor=MYCO class=EC_ENV subclass=ESC_ENV_TEMP \
     /opt/MYCOenv/bin/ec_env_temp \${class} \${subclass} \${pathname}
```

EXAMPLE 4 Listing Event Handlers

The following example lists all event handlers defined by vendor `VRTS`.

```
# syseventadm list -v VRTS
```

EXAMPLE 5 Removing Event Handlers

The following example removes all event handlers defined by vendor `VRTS`, and restarts service.

```
# syseventadm remove -v VRTS
# syseventadm restart
```

EXAMPLE 6 Listing All Event Handlers Specified to Run a Command

The following example lists all event handlers specified to run the command `/opt/MYCOenv/bin/ec_env_temp`:

```
# syseventadm list /opt/MYCOenv/bin/ec_env_temp
```

EXAMPLE 7 Removing Event Handlers and Restarting Service

The following example removes all event handlers specified to run the command `/opt/MYCOenv/bin/ec_env_temp`, and restarts service:

```
# syseventadm remove /opt/MYCOenv/bin/ec_env_temp
# syseventadm restart
```

Exit Status

The following exit values are returned:

`0` Successful completion.

`1` No matching event specification found (remove or list commands only).

`2` Incorrect command usage.

`3` Permission denied.

`4` Command failed.

`5` Out of memory.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also

`syseventd(1M)`, `sysevent_post_event(3SYSEVENT)`, `attributes(5)`, `ddi_log_sysevent(9F)`

Notes To avoid upgrade problems, packages delivering a sysevent event handler should install the event handler by running `syseventadm` from the package's postinstall script. The event handler can then be removed by running `syseventadm` from the package's preremove script using the same arguments as when added.

Name syseventconfd – kernel system event command invocation daemon

Synopsis

```
/usr/lib/sysevent/syseventconfd [-r rootdir]
```

Description `syseventconfd` is the user-level daemon that invokes user-level commands in response to kernel system events received from `syseventd(1M)`.

Options The following options are supported:

`-r` *rootdir* Cause `syseventconfd` to use an alternate root path when creating its door. The root path must match the root path used to invoke `syseventd`.

Files

`/etc/sysevent/syseventconfd_event_service`
`syseventconfd` event service door file

`/usr/lib/sysevent/modules/sysevent_conf_mod.so`
`syseventd` loadable module (SLM) managing `sysevent.conf` files

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `svcs(1)`, `svcadm(1M)`, `syseventd(1M)`, `attributes(5)`, `smf(5)`

Notes The `syseventconfd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/system/sysevent:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

Name syseventd – kernel system event notification daemon

Synopsis `/usr/lib/sysevent/syseventd [-d` *debug_level*`] [-r` *rootdir*`]`

Description `syseventd` is a user-level daemon that accepts delivery of system event buffers from the kernel. Once an event buffer has been delivered to `syseventd`, it, in turn, attempts to propagate the event to all interested end event subscribers.

Event subscribers take the form of a `syseventd` loadable module (SLM). syseventd passes the event buffer to each of its subscribers and in return expects a notification as to the successful or unsuccessful delivery attempt.

Upon successful delivery of the event buffer to all interested event subscribers, `syseventd` frees the event buffer from the kernel event queue.

Options The following options are supported:

`-d` *debug_level* Enable debug mode. Messages are printed to the invoking user's terminal.

`-r` *rootdir* Cause `syseventd` to use an alternate root path when creating its door and lock files. Modules continue to be loaded from the standard module directories.

Exit Status The following exit values are returned:

`0` Successful completion.

`non-zero` An error occurred.

Files `/etc/sysevent/syseventd_daemon.lock`
daemon lock file

`/etc/sysevent/sysevent_door`
kernel to `syseventd` door file

`/usr/lib/sysevent/modules`
SLM directory repository

`/usr/platform/‘uname –i‘/lib/sysevent/modules`
SLM directory repository

`/usr/platform/‘uname –m‘/lib/sysevent/modules`
SLM directory repository

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also svcs(1), svcadm(1M), syseventconfd(1M), attributes(5), smf(5)

Notes The sysevent d service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/system/sysevent:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name sysidconfig – execute system configuration applications, or define set of system configuration applications

Synopsis

```
sysidconfig [-lv] [-a application] [-b basedir]
     [-r application]
```

Description Invoked without any options, the `sysidconfig` program executes a list of applications. An application on this list is referred to as a "system configuration application." Every application on this list will be passed one command-line argument, `-c`. This flag will cause the system configuration application to perform its configuration function. Without options, `sysidconfig` should only be invoked by startup scripts, which occurs during the initial installation and during a reconfigure reboot.

All applications on the list will be executed, if possible. All activity taken by the `sysidconfig` program is logged in the `sysidconfig` log file, `/var/log/sysidconfig.log`. If one or more of the applications on the list are either not present at execution time, are not executable, or execute but return a failure code upon completion, then that information will be logged as well. Successful completion of the program can be assumed if no error message is present in the log file. Programs are executed sequentially, with only one configuration application active at a time.

Executed with the `-l`, `-a`, or `-r` options, the `sysidconfig` program allows the super-user to list the defined configuration applications, and to add items to or remove items from that list. Running `sysidconfig` with options is the only way to view or manipulate the list. Only the super-user can execute the `sysidconfig` program with options.

The `-b` and `-v` options change the behavior of `sysidconfig`, and can be used with or without the list manipulation options discussed above. The `-b` *basedir* option is used to specify a reference `root` directory other than the default, `/`. The `-v` option duplicates the log file output on `stdout`.

By default, no SPARC based applications exist on this list. However, the x86 based systems are delivered with one application, `kdmconfig(1M)`, on the list. `kdmconfig` is not delivered on SPARC based systems.

This application is an extension of the `sysidtool(1M)` suite of programs. It is executed during initial installation and during a reconfigure reboot, before the window system has been started. Graphical User Interface (GUI) applications will not execute successfully if they are added to the list of configuration applications via `sysidconfig -a`.

This program is referenced, but not fully described, in the `sysidtool(1M)` manual page.

Options The valid options are:

`-a` *application* Add the named application to the list of defined applications. When next invoked without arguments, `sysidconfig` will run this newly added application after all previously defined applications. *application* must be a fully qualified path name that is not currently on the list of applications to execute.

`-b` *basedir* Specify an alternate base directory (`/` is defined as the default base directory if no other is specified). The specified directory is used as the `root` directory when adding, listing, removing, or executing configuration applications. The log file where information is recorded is in `/var/log`, relative to the specified *basedir*. In the log file, the *basedir* is not noted. This means, for example, that if the super-user on a diskless client's server executes:

```
sysidconfig -b /export/root/client -a /sbin/someapp
```

then the diskless client *client* would have `/sbin/`*someapp* executed upon reconfigure reboot. The diskless client's log file would note that `/sbin/`*someapp* was added, not `/export/root/client/sbin/`*someapp*.

Note – The root file system of any non-global zones must not be referenced with the `-b` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.

`-l` List defined configuration applications. Applications will be executed one at a time, in the order shown in the list.

`-r` *application* Remove the named application from the list of defined applications. *application* must be a fully qualified path name and it must be on the existing list of applications to execute.

`-v` Verbose mode. This option echoes all information sent to the log file to `stdout`. Such information includes timestamp information about when the program was executed, the names of applications being executed, and results of those executions.

Return Values The `sysidconfig` program will return `0` if it completes successfully.

When executed with the `-r` or `-a` options, error conditions or warnings will be reported on `stderr`. If the requested action completes successfully, an exit code of `0` will be returned.

Errors `EPERM` The program was executed by a user other than the super-user.

`EINVAL` Option `-l`, `-a`, or `-r` was passed and the action could not be completed successfully.

Files `/var/log/sysidconfig.log` `sysidconfig` log file

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWadmap

See Also sys-unconfig(1M), sysidtool(1M), attributes(5)

x86 Only kdmconfig(1M)

Diagnostics When run without options, a log of the `sysidconfig` program's activity can be found in `/var/log/sysidconfig.log`. This file contains a timestamp log of each program executed, its resulting `stderr` output, and its exit code. If an application in the list was not found or is not executable, that will also be noted.

Name sysidtool, sysidnet, sysidns, sysidsys, sysidroot, sysidpm, sysidnfs4, sysidkbd – system configuration

Synopsis

```
/usr/sbin/sysidnet

/usr/sbin/sysidns

/usr/sbin/sysidsys

/usr/sbin/sysidroot

/usr/sbin/sysidpm

/usr/sbin/sysidnfs4

/usr/sbin/sysidkbd
```

Description `sysidtool` is a suite of programs that configure a new system, or one that has been unconfigured with `sys-unconfig(1M)`. The `sysidtool` programs run automatically at system installation, or during the first boot after a machine has been successfully unconfigured.

These programs have no effect except at such times, and should never be run manually.

The `sysidtool` programs set up the appropriate information in the machine's configuration files, in the kernel, and on the machine's network interface. The following list shows the available commands and the information for which each of the commands lists.

`sysidnet`: network configuration
Machine's default locale. Machine's console type. Machine's host name. Machine's IP address.

`sysidns`: name service configuration
Name service choice: NIS, NIS+, DNS, LDAP, or none. Machine's IP subnet mask (if no NIS/NIS+ server can automatically be located on the machine's sub-network. Domain name for chosen name service. Hostname and IP address of name server(s). DNS search list (DNS name service only)

`sysidsys`: miscellaneous system configuration
Machine's IP subnet mask (if an NIS/NIS+ server was automatically located on the machine's sub-network). Machine's time zone. Date and time.

`sysidroot`: control superuser information
Machine's root password.

`sysidpm`: power management configuration
Auto-shutdown confirmation if the system is Energystar-V2 compliant, that is, a new system model shipped after October 1, 1995.

`sysidnfs4`: NFSv4 domain configuration
Domain name to be used by NFSv4 client(s) and server(s) to transmit user and group id's as strings of the general form "[*user*|*group*]@*domain*".

`sysidkbd`: keyboard layout configuration
: The corresponding keytable is loaded into the kernel according to the configured keyboard layout.

`sysidconfig`: host– or platform-specific configuration
: This command controls specification and execution of custom configuration applications that can be specified for a particular host or a particular platform. See `sysidconfig(1M)`.

The `sysidtool` programs attempt to obtain system configuration information from various name service databases, for example, NIS, or from the `sysidcfg(4)` file, and you are prompted to provide the information if it cannot be found. However, you can avoid one or more of the prompts by preconfiguring the appropriate configuration information in the name service databases or in the `sysidcfg(4)` file.

To preconfigure the information in the name service databases, you must use the name service commands or the Solstice AdminSuite tools. See *Solaris 10 Installation Guide: Basic Installations* for more details about how to preconfigure the system configuration information.

The machine's configuration information is set up in its `/etc` and `/var` files.

If a system has more than one network interface, you can use `sysidtool` to configure all interfaces on the system.

You cannot use the name service databases or the `sysidcfg(4)` file to suppress the Power Management configuration prompt. However, you can suppress it by creating either the `/autoshutdown` or `/noautoshutdown` file before installation reboot. Accordingly, the auto-shutdown feature is silently configured. The `/autoshutdown` or `/noautoshutdown` files are removed by `sysidpm` before it exits.

If you have non-global zones installed and the `nfs4_domain` keyword exists in the `sysidcfg` file, the first boot of a non-global zone sets the domain. Otherwise, the Solaris interactive installation program comes up and you are prompted to provide a domain name before the boot process completes. See `sysidcfg(4)` and *Solaris 10 Installation Guide: Custom JumpStart and Advanced Installations*.

`sysidkbd` prompts for the keyboards with `zero-bCountryCode` and then sets the keyboard layout string in the `/etc/default/kbd` file. If the `sysidkbd` gets the valid keyboard layout string, the string will be set into the entry “LAYOUT=” in the file.

Files

```
/etc/.UNCONFIGURED
/etc/nodename
/etc/hostname.??[0-9]
/etc/default/init
/etc/defaultdomain
```

`/etc/passwd` password file. See `passwd(4)`.

`/etc/shadow` shadow password file. See `shadow(4)`.

```
/etc/inet/hosts
/etc/inet/netmasks
/var/nis/NIS_COLD_START
/var/yp/aliases
/var/yp/binding/*/ypservers
/etc/.sysIDtool.state
```

`/etc/power.conf` Power Management configuration file. See `power.conf(4)`.

`/etc/.PM_RECONFIGURE` If this file is present during system reboot, the `sysidpm` program is run. This file is removed by `sysidpm`.

```
/etc/.NFS4inst_state.domain
/etc/default/kdb
```

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWadmap, SUNWpmu

Solaris 10 Installation Guide: Custom JumpStart and Advanced Installations

Notes NIS+ might not be supported in future releases of the Solaris Operating system. Tools to aid the migration from NIS+ to LDAP are available in the current Solaris release. For more information, visit http://www.sun.com/directory/nisplus/transition.html.

Name syslogd – log system messages

Synopsis

```
/usr/sbin/syslogd [-d] [-f configfile] [-m markinterval]
     [-p path] [-t | -T]
```

Description `syslogd` reads and forwards system messages to the appropriate log files or users, depending upon the priority of a message and the system facility from which it originates. The configuration file `/etc/syslog.conf` (see `syslog.conf(4)`) controls where messages are forwarded. `syslogd` logs a mark (timestamp) message every *markinterval* minutes (default `20`) at priority `LOG_INFO` to the facility whose name is given as `mark` in the `syslog.conf` file.

A system message consists of a single line of text, which may be prefixed with a priority code number enclosed in angle-brackets (`< >`); priorities are defined in `<sys/syslog.h>`.

`syslogd` reads from the STREAMS log driver, `/dev/log`, and from any transport provider specified in `/etc/netconfig`, `/etc/net/transport/hosts`, and `/etc/net/transport/services`.

`syslogd` reads the configuration file when it starts up, and again whenever it receives a `HUP` signal (see `signal.h(3HEAD)`, at which time it also closes all files it has open, re-reads its configuration file, and then opens only the log files that are listed in that file. `syslogd` exits when it receives a `TERM` signal.

As it starts up, `syslogd` creates the file `/var/run/syslog.pid`, if possible, containing its process identifier (PID).

If message ID generation is enabled (see `log(7D)`), each message will be preceded by an identifier in the following format: `[ID` *msgid facility*`.`*priority*`]`. *msgid* is the message's numeric identifier described in `msgid(1M)`. *facility* and *priority* are described in `syslog.conf(4)`. `[ID 123456 kern.notice]` is an example of an identifier when message ID generation is enabled.

If the message originated in a loadable kernel module or driver, the kernel module's name (for example, `ufs`) will be displayed instead of `unix`. See `EXAMPLES` for sample output from `syslogd` with and without message ID generation enabled.

In an effort to reduce visual clutter, message IDs are not displayed when writing to the console; message IDs are only written to the log file. See Examples.

The `/etc/default/syslogd` file contains the following default parameter settings, which are in effect if neither the `-t` nor `-T` option is selected. See `FILES`.

The recommended way to allow or disallow message logging is through the use of the service management facility (`smf(5)`) property:

```
svc:/system/system-log/config/log_from_remote
```

This property specifies whether remote messages are logged. `log_from_remote=true` is equivalent to the `-t` command-line option and `false` is equivalent to the `-T` command-line option. The default value for `-log_from_remote` is `false`. See NOTES, below.

`LOG_FROM_REMOTE`
Specifies whether remote messages are logged. `LOG_FROM_REMOTE=NO` is equivalent to the `-t` command-line option. The default value for `LOG_FROM_REMOTE` is `YES`.

Options

The following options are supported:

`-d`
Turn on debugging. This option should only be used interactively in a root shell once the system is in multi-user mode. It should *not* be used in the system start-up scripts, as this will cause the system to hang at the point where `syslogd` is started.

`-f` *configfile*
Specify an alternate configuration file.

`-m` *markinterval*
Specify an interval, in minutes, between mark messages.

`-p` *path*
Specify an alternative log device name. The default is `/dev/log`.

`-T`
Enable the `syslogd` UDP port to turn on logging of remote messages. This is the default behavior. See Files.

`-t`
Disable the `syslogd` UDP port to turn off logging of remote messages. See Files.

Examples

EXAMPLE 1 `syslogd` Output Without Message ID Generation Enabled

The following example shows the output from `syslogd` when message ID generation *is not* enabled:

```
Sep 29 21:41:18 cathy unix: alloc /: file system full
```

EXAMPLE 2 `syslogd` Output with ID generation Enabled

The following example shows the output from `syslogd` when message ID generation *is* enabled. The message ID is displayed when writing to log file`/var/adm/messages`.

```
Sep 29 21:41:18 cathy ufs: [ID 845546 kern.notice]
                                    alloc /: file system full
```

EXAMPLE 3 `syslogd` Output with ID Generation Enabled

The following example shows the output from `syslogd` when message ID generation *is* enabled when writing to the console. Even though message ID is enabled, the message ID is not displayed at the console.

```
Sep 29 21:41:18 cathy ufs: alloc /: file system full
```

EXAMPLE 4 Enabling Acceptance of UDP Messages from Remote Systems

The following commands enable `syslogd` to accept entries from remote systems.

```
# svccfg -s svc:/system/system-log setprop config/log_from_remote = true
# svcadm restart svc:/system/system-log
```

Files

`/etc/syslog.conf`
Configuration file

`/var/run/syslog.pid`
Process ID

`/etc/default/syslogd`
Contains default settings. You can override some of the settings by command-line options.

`/dev/log`
STREAMS log driver

`/etc/netconfig`
Transport providers available on the system

`/etc/net/transport/hosts`
Network hosts for each transport

`/etc/net/transport/services`
Network services for each transport

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

`logger(1)`, `svcs(1)`, `msgid(1M)`, `svcadm(1M)`, `svccfg(1M)`, `syslog(3C)`, `syslog.conf(4)`, `attributes(5)`, `signal.h(3HEAD)`, `smf(5)`, `log(7D)`

Notes

The `mark` message is a system time stamp, and so it is only defined for the system on which `syslogd` is running. It can not be forwarded to other systems.

When `syslogd` receives a `HUP` signal, it attempts to complete outputting pending messages, and close all log files to which it is currently logging messages. If, for some reason, one (or more) of these files does not close within a generous grace period, `syslogd` discards the pending messages, forcibly closes these files, and starts reconfiguration. If this shutdown procedure is disturbed by an unexpected error and `syslogd` cannot complete reconfiguration, `syslogd` sends a mail message to the superuser on the current system stating that it has shut down, and exits.

Care should be taken to ensure that each window displaying messages forwarded by `syslogd` (especially console windows) is run in the system default locale (which is `syslogd`'s locale). If

this advice is not followed, it is possible for a `syslog` message to alter the terminal settings for that window, possibly even allowing remote execution of arbitrary commands from that window.

The `syslogd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/system/system-log:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

When `syslogd` is started by means of `svcadm(1M)`, if a value is specified for `LOG_FROM_REMOTE` in the `/etc/defaults/syslogd` file, the SMF property `svc:/system/system-log/config/log_from_remote` is set to correspond to the `LOG_FROM_REMOTE` value and the `/etc/default/syslogd` file is modified to replace the `LOG_FROM_REMOTE` specification with the following comment:

```
# LOG_FROM_REMOTE is now set using svccfg(1m), see syslogd(1m).
```

If neither `LOG_FROM_REMOTE` nor `svc:/system/system-log/config/log_from_remote` are defined, the default is to log remote messages.

On installation, the initial value of `svc:/system/system-log/config/log_from_remote` is `false`.

Name sys-unconfig – undo a system's configuration

Synopsis `/usr/sbin/sys-unconfig`

Description The `sys-unconfig` command is used to restore a system's configuration to an "as-manufactured" state, ready to be reconfigured again. The system's configuration consists of hostname, Network Information Service (NIS) domain name, timezone, IP address, IP subnet mask, and root password. This operation is the inverse of those performed by the `sysidnet(1M)`, `sysidns(1M)`, and `sysidsys(1M)` programs run at boot. See `sysidtool(1M)`.

`sys-unconfig` does the following:

- Saves current `/etc/inet/hosts` file information in `/etc/inet/hosts.saved`.
- If the current `/etc/vfstab` file contains NFS mount entries, saves the `/etc/vfstab` file to `/etc/vfstab.orig`.
- Restores the default `/etc/inet/hosts` file.
- Removes the default hostname in `/etc/hostname.`*interface* files for all interfaces configured when this command is run. To determine which interfaces are configured, run the command '`ifconfig -a`'. The `/etc/hostname.`*interface* files corresponding to all of the interfaces listed in the resulting output, with the exception of the loopback interface (lo0), will be removed.
- Removes the default domainname in `/etc/defaultdomain`.
- Restores the timezone to PST8PDT in `/etc/TIMEZONE`.
- Disables the Network Information Service (NIS) and Network Information Service Plus (NIS+) if either NIS or NIS+ was configured.
- Removes the file `/etc/inet/netmasks`.
- Removes the file `/etc/defaultrouter`.
- Removes the password set for root in `/etc/shadow`.
- Removes the file `/etc/.rootkey`.
- Executes all system configuration applications. These applications are defined by prior executions of a `sysidconfig -a` *application*. (See `sysidconfig(1M)`). When `sys-unconfig` is run, all system configuration applications are passed one argument, `-u`.
- Removes the file `/etc/resolv.conf`.
- Removes the file `/etc/sysidcfg`.
- Disables LDAP by removing `/var/ldap/ldap_client_cache`, `/var/ldap/ldap_client_file`, `/var/ldap/ldap_client_cred`, and `/var/ldap/cachemgr.log`.
- Regenerates keys for `sshd(1M)`.

When `sys-unconfig` is finished, it performs a system shutdown. `sys-unconfig` is a potentially dangerous utility and can only be run by the super user.

Files

`/etc/default/init`	process control initialization
`/etc/defaultdomain`	determines host's domain name
`/etc/defaultrouter`	specifies an IPv4 host's default router
`/etc/hostname.`*interface*	identifies symbolic host name associated with network interface *interface*
`/etc/inet/hosts`	host name database
`/etc/inet/netmasks`	network mask database
`/etc/nodename`	local source for system name
`/etc/.rootkey`	super-user's secret key
`/etc/shadow`	shadow password file
`/etc/sysidcfg`	system identification configuration file for diskless booting
`/etc/vfstab`	virtual file system table
`/var/nis/NIS_COLD_START`	list of NIS+ servers that serve a host's default domain
`/var/yp/binding/*/ypservers`	identifies NIS servers to which the client is allowed to bind

Attributes See `attributes(5)` for descriptions of the following attributes:

Notes `sys-unconfig` is not available on diskless clients.

Name tapes – creates /dev entries for tape drives attached to the system

Synopsis `/usr/sbin/tapes [-r root_dir]`

Description devfsadm(1M) is now the preferred command for `/dev` and `/devices` and should be used instead of `tapes`.

`tapes` creates symbolic links in the `/dev/rmt` directory to the actual tape device special files under the `/devices` directory tree. `tapes` searches the kernel device tree to see what tape devices are attached to the system. For each equipped tape drive, the following steps are performed:

1. The `/dev/rmt` directory is searched for a `/dev/rmt/`*n* entry that is a symbolic link to the `/devices` special node of the current tape drive. If one is found, this determines the logical controller number of the tape drive.
2. The rest of the special devices associated with the drive are checked, and incorrect symbolic links are removed and necessary ones added.
3. If none are found, a new logical controller number is assigned (the lowest-unused number), and new symbolic links are created for all the special devices associated with the drive.

`tapes` does not remove links to non-existent devices; these must be removed by hand.

`tapes` is run each time a reconfiguration-boot is performed, or when add_drv(1M) is executed.

Notice to Driver Writers tapes(1M) considers all devices with the node type `DDI_NT_TAPE` to be tape devices; these devices must have their minor name created with a specific format. The minor name encodes operational modes for the tape device and consists of an ASCII string of the form [`l`,`m`,`h`,`c`,`u`][`b`][`n`].

The first character set is used to specify the tape density of the device, and are named low (`l`), medium (`m`), high (`h`), compressed (`c`), and ultra (`u`). These specifiers only express a relative density; it is up to the driver to assign specific meanings as needed. For example, 9 track tape devices interpret these as actual bits-per-inch densities, where `l` means 800 BPI, `m` means 1600 BPI , and `h` means 6250 BPI, whereas 4mm DAT tapes defines `l` as standard format, and `m`, `h`, `c` and `u` as compressed format. Drivers may choose to implement any or all of these format types.

During normal tape operation (non-BSD behavior), once an EOF mark has been reached, subsequent reads from the tape device return an error. An explicit IOCTL must be issued to space over the EOF mark before the next file can be read. `b` instructs the device to observe BSD behavior, where reading at EOF will cause the tape device to automatically space over the EOF mark and begin reading from the next file.

`n` or no-rewind-on-close instructs the driver to not rewind to the beginning of tape when the device is closed. Normal behavior for tape devices is to reposition to BOT when closing. See mtio(7I).

The minor number for tape devices should be created by encoding the device's instance number using the tape macro `MTMINOR` and ORing in the proper combination of density, BSD behavior, and no-rewind flags. See `mtio(7I)`.

To prevent `tapes` from attempting to automatically generate links for a device, drivers must specify a private node type and refrain from using the node type string `DDI_NT_TAPE` when calling`ddi_create_minor_node(9F)`.

Options The following options are supported:

`-r` *root_dir* Causes `tapes` to presume that the `/dev/rmt` directory tree is found under *root_dir*, not directly under `/`.

Errors If `tapes` finds entries of a particular logical controller linked to different physical controllers, it prints an error message and exits without making any changes to the `/dev` directory, since it cannot determine which of the two alternative logical to physical mappings is correct. The links should be manually corrected or removed before another reconfiguration boot is performed.

Examples **EXAMPLE 1** Creating Tape Device Nodes From Within the Driver's `attach()` Function

This example demonstrates creating tape device nodes from within the `xktape` driver's `attach(9E)` function.

```
#include <sys/mtio.h>
struct tape_minor_info {
    char *minor_name;
    int   minor_mode;
};
/*
 * create all combinations of logical tapes
*/
static struct tape_minor_info example_tape[] = {
   {"",    0},                    /* default tape */
   {"l",   MT_DENSITY1},
   {"lb",  MT_DENSITY1 | MT_BSD},
   {"lbn", MT_DENSITY1 | MT_BSD | MT_NOREWIND},
   {"m",   MT_DENSITY2},
   {"mb",  MT_DENSITY2 | MT_BSD},
   {"mbn", MT_DENSITY2 | MT_BSD | MT_NOREWIND},
   {"h",   MT_DENSITY3},
   {"hb",  MT_DENSITY3 | MT_BSD},
   {"hbn", MT_DENSITY3 | MT_BSD | MT_NOREWIND},
   {"c",   MT_DENSITY4},
   {"cb",  MT_DENSITY4 | MT_BSD},
   {"cbn", MT_DENSITY4| MT_BSD | MT_NOREWIND},
   {NULL,  0},
};
```

EXAMPLE 1 Creating Tape Device Nodes From Within the Driver's `attach()` Function *(Continued)*

```
int
xktapeattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
   int instance;
   struct tape_minor_info *mdp;
      /* other stuff in attach... */
   instance = ddi_get_instance(dip);

   for (mdp = example_tape; mdp->minor_name != NULL; mdp++) {
            ddi_create_minor_node(dip, mdp->minor_name, S_IFCHR,
                 (MTMINOR(instance) | mdp->minor_mode), DDI_NT_TAPE, 0);
 }
```

Installing the `xktape` driver on a Sun Fire 4800, with the driver controlling a SCSI tape (target 4 attached to an `isp(7D)` SCSI HBA) and performing a reconfiguration-boot creates the following special files in `/devices`.

```
# ls -l /devices/ssm@0,0/pci@18,700000/pci@1/SUNW,isptwo@4
crw-rw-rw-   1 root sys   33,136 Aug 29 00:02  xktape@4,0:
crw-rw-rw-   1 root sys   33,200 Aug 29 00:02  xktape@4,0:b
crw-rw-rw-   1 root sys   33,204 Aug 29 00:02  xktape@4,0:bn
crw-rw-rw-   1 root sys   33,152 Aug 29 00:02  xktape@4,0:c
crw-rw-rw-   1 root sys   33,216 Aug 29 00:02  xktape@4,0:cb
crw-rw-rw-   1 root sys   33,220 Aug 29 00:02  xktape@4,0:cbn
crw-rw-rw-   1 root sys   33,156 Aug 29 00:02  xktape@4,0:cn
crw-rw-rw-   1 root sys   33,144 Aug 29 00:02  xktape@4,0:h
crw-rw-rw-   1 root sys   33,208 Aug 29 00:02  xktape@4,0:hb
crw-rw-rw-   1 root sys   33,212 Aug 29 00:02  xktape@4,0:hbn
crw-rw-rw-   1 root sys   33,148 Aug 29 00:02  xktape@4,0:hn
crw-rw-rw-   1 root sys   33,128 Aug 29 00:02  xktape@4,0:l
crw-rw-rw-   1 root sys   33,192 Aug 29 00:02  xktape@4,0:lb
crw-rw-rw-   1 root sys   33,196 Aug 29 00:02  xktape@4,0:lbn
crw-rw-rw-   1 root sys   33,132 Aug 29 00:02  xktape@4,0:ln
crw-rw-rw-   1 root sys   33,136 Aug 29 00:02  xktape@4,0:m
crw-rw-rw-   1 root sys   33,200 Aug 29 00:02  xktape@4,0:mb
crw-rw-rw-   1 root sys   33,204 Aug 29 00:02  xktape@4,0:mbn
crw-rw-rw-   1 root sys   33,140 Aug 29 00:02  xktape@4,0:mn
crw-rw-rw-   1 root sys   33,140 Aug 29 00:02  xktape@4,0:n
```

`/dev/rmt` will contain the logical tape devices (symbolic links to tape devices in `/devices`).

```
# ls -l /dev/rmt
/dev/rmt/0    -> ../../devices/[....]/xktape@4,0:
/dev/rmt/0b   -> ../../devices/[....]/xktape@4,0:b
/dev/rmt/0bn  -> ../../devices/[....]/xktape@4,0:bn
```

EXAMPLE 1 Creating Tape Device Nodes From Within the Driver's `attach()` Function *(Continued)*

```
/dev/rmt/0c   -> ../../devices/[....]/xktape@4,0:c
/dev/rmt/0cb  -> ../../devices/[....]/xktape@4,0:cb
/dev/rmt/0cbn -> ../../devices/[....]/xktape@4,0:cbn
/dev/rmt/0cn  -> ../../devices/[....]/xktape@4,0:cn
/dev/rmt/0h   -> ../../devices/[....]/xktape@4,0:h
/dev/rmt/0hb  -> ../../devices/[....]/xktape@4,0:hb
/dev/rmt/0hbn -> ../../devices/[....]/xktape@4,0:hbn
/dev/rmt/0hn  -> ../../devices/[....]/xktape@4,0:hn
/dev/rmt/0l   -> ../../devices/[....]/xktape@4,0:l
/dev/rmt/0lb  -> ../../devices/[....]/xktape@4,0:lb
/dev/rmt/0lbn -> ../../devices/[....]/xktape@4,0:lbn
/dev/rmt/0ln  -> ../../devices/[....]/xktape@4,0:ln
/dev/rmt/0m   -> ../../devices/[....]/xktape@4,0:m
/dev/rmt/0mb  -> ../../devices/[....]/xktape@4,0:mb
/dev/rmt/0mbn -> ../../devices/[....]/xktape@4,0:mbn
/dev/rmt/0mn  -> ../../devices/[....]/xktape@4,0:mn
/dev/rmt/0n   -> ../../devices/[....]/xktape@4,0:n
```

Writing Device Drivers

Bugs `tapes` silently ignores malformed minor device names.

Name taskstat – prints ASET tasks status

Synopsis

```
/usr/aset/util/taskstat  [-d aset_dir]
```

Description `taskstat` is located in the `/usr/aset/util` directory. `/usr/aset` is the default operating directory of the Automated Security Enhancement Tool (ASET). An alternative working directory can be specified by the administrators through the `aset -d` command or the `ASETDIR` environment variable. See `aset`(1M). Because `aset` dispatches its tasks to run in the background, when it returns, these tasks may or may not have completed. `taskstat` prints the status of the tasks, listing those that are completed and those that are still executing.

The ASET reports, which are located in the `/usr/aset/reports` directory (see the `-d` option), are not complete until all the tasks finish executing.

Options

`-d` *aset_dir* Specify the working directory for ASET. By default, this directory is `/usr/aset`. With this option, the `reports` directory will be located under *aset_dir*.

Attributes See `attributes`(5) for descriptions of the following attributes:

System Administration Guide: Basic Administration

Name tcxconfig – configure default linearity of 24-bit TrueColor Visual for OpenWindows

Synopsis

```
/usr/sbin/tcxconfig [linear | nonlinear]
```

Description The `tcxconfig` script changes the default linearity of a 24-bit TrueColor Visual for OpenWindows on a system with an S24 frame buffer. When the S24 graphics driver for OpenWindows is installed, the default 24-bit TrueColor Visual is nonlinear. You can run `tcxconfig` with an argument that specifies the setting you want.

OpenWindows should not be running when you execute the `tcxconfig` script with an option. Start OpenWindows after `tcxconfig` has set the linearity you desire.

Options If you specify no option, `tcxconfig` displays the current default setting.

You must become superuser before you can execute `tcxconfig` with one of the following options.

`linear` Set linear visual to be the default 24-bit TrueColor Visual. This means colors will be gamma-corrected.

`nonlinear` Set nonlinear visual to be the default 24-bit TrueColor Visual.

Exit Status The following exit values are returned:

`0` success

`1` an error has occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

System Administration Commands - Part 3

Name th_define – create fault injection test harness error specifications

Synopsis

```
th_define [-n name -i instance| -P path] [-a acc_types]
     [-r reg_number] [-l offset [length]]
     [-c count [failcount]] [-o operator [operand]]
     [-f acc_chk] [-w max_wait_period [report_interval]]

or

th_define [-n name -i instance| -P path]
     [-a log [acc_types] [-r reg_number] [-l offset [length]]]
     [-c count [failcount]] [-s collect_time] [-p policy]
     [-x flags] [-C comment_string]
     [-e fixup_script [args]]

or

th_define [-h]
```

Description The `th_define` utility provides an interface to the `bus_ops` fault injection `bofi` device driver for defining error injection specifications (referred to as errdefs). An errdef corresponds to a specification of how to corrupt a device driver's accesses to its hardware. The command line arguments determine the precise nature of the fault to be injected. If the supplied arguments define a consistent errdef, the `th_define` process will store the errdef with the `bofi` driver and suspend itself until the criteria given by the errdef become satisfied (in practice, this will occur when the access counts go to zero).

You use the `th_manage(1M)` command with the `start` option to activate the resulting errdef. The effect of `th_manage` with the `start` option is that the `bofi` driver acts upon the errdef by matching the number of hardware accesses—specified in *count*, that are of the type specified in *acc_types*, made by instance number *instance*—of the driver whose name is *name*, (or by the driver instance specified by *path*) to the register set (or DMA handle) specified by *reg_number*, that lie within the range *offset* to *offset* + *length* from the beginning of the register set or DMA handle. It then applies *operator* and *operand* to the next *failcount* matching accesses.

If *acc_types* includes `log`, `th_define` runs in automatic test script generation mode, and a set of test scripts (written in the Korn shell) is created and placed in a sub-directory of the current directory with the name <*driver*>`.test.`<*id*> (for example, `glm.test.978177106`). A separate, executable script is generated for each access handle that matches the logging criteria. The log of accesses is placed at the top of each script as a record of the session. If the current directory is not writable, file output is written to standard output. The base name of each test file is the driver name, and the extension is a number that discriminates between different access handles. A control script (with the same name as the created test directory) is generated that will run all the test scripts sequentially.

Executing the scripts will install, and then activate, the resulting error definitions. Error definitions are activated sequentially and the driver instance under test is taken offline and brought back online before each test (refer to the `-e` option for more information). By default, logging applies to all `PIO` accesses, all interrupts, and all DMA accesses to and from areas

mapped for both reading and writing. You can constrain logging by specifying additional *acc_types*, *reg_number*, *offset* and *length*. Logging will continue for *count* matching accesses, with an optional time limit of *collect_time* seconds.

Either the `-n` or `-P` option must be provided. The other options are optional. If an option (other than `-a`) is specified multiple times, only the final value for the option is used. If an option is not specified, its associated value is set to an appropriate default, which will provide maximal error coverage as described below.

Options The following options are available:

`-n` *name*
: Specify the name of the driver to test. (String)

`-i` *instance*
: Test only the specified driver instance (-1 matches all instances of driver). (Numeric)

`-P` *path*
: Specify the full device path of the driver to test. (String)

`-r` *reg_number*
: Test only the given register set or DMA handle (-1 matches all register sets and DMA handles). (Numeric)

`-a` *acc_types*
: Only the specified access types will be matched. Valid values for the *acc_types* argument are `log`, `pio`, `pio_r`, `pio_w`, `dma`, `dma_r`, `dma_w` and `intr`. Multiple access types, separated by spaces, can be specified. The default is to match all hardware accesses.

  If *acc_types* is set to `log`, logging will match all `PIO` accesses, interrupts and DMA accesses to and from areas mapped for both reading and writing. `log` can be combined with other *acc_types*, in which case the matching condition for logging will be restricted to the specified addional *acc_types*. Note that `dma_r` will match only DMA handles mapped for reading only; `dma_w` will match only DMA handles mapped for writing only; `dma` will match only DMA handles mapped for both reading and writing.

`-l` *offset* [*length*]
: Constrain the range of qualifying accesses. The *offset* and *length* arguments indicate that any access of the type specified with the `-a` option, to the register set or DMA handle specified with the `-r` option, lie at least *offset* bytes into the register set or DMA handle and at most *offset* + *length*

bytes into it. The default for *offset* is 0. The default for *length* is the maximum value that can be placed in an `offset_t` C data type (see `types.h`). Negative values are converted into unsigned quantities. Thus, `th_define -l 0 -1` is maximal.

`-c` *count* [*failcount*]

Wait for *count* number of matching accesses, then apply an operator and operand (see the `-o` option) to the next *failcount* number of matching accesses. If the access type (see the `-a` option) includes logging, the number of logged accesses is given by *count* + *failcount* - 1. The -1 is required because the last access coincides with the first faulting access.

Note that access logging may be combined with error injection if *failcount* and *operator* are nonzero and if the access type includes logging and any of the other access types (`pio`, `dma` and `intr`) See the description of access types in the definition of the `-a` option, above.

When the *count* and *failcount* fields reach zero, the status of the errdef is reported to standard output. When all active errdefs created by the `th_define` process complete, the process exits. If *acc_types* includes `log`, *count* determines how many accesses to log. If *count* is not specified, a default value is used. If *failcount* is set in this mode, it will simply increase the number of accesses logged by a further *failcount* - 1.

`-o` *operator* [*operand*]

For qualifying PIO read and write accesses, the value read from or written to the hardware is corrupted according to the value of *operator*:

`EQ` *operand* is returned to the driver.

`OR` *operand* is bitwise ORed with the real value.

`AND` *operand* is bitwise ANDed with the real value.

`XOR` *operand* is bitwise XORed with the real value.

For PIO write accesses, the following operator is allowed:

`NO` Simply ignore the driver's attempt to write to the hardware.

Note that a driver performs PIO via the `ddi_get`*X*`()`, `ddi_put`*X*`()`, `ddi_rep_get`*X*`()` and `ddi_rep_put`*X*`()` routines (where *X* is 8, 16, 32 or 64). Accesses made using `ddi_get`*X*`()` and `ddi_put`*X*`()` are treated as a single access, whereas an access made using the `ddi_rep_*`(9F) routines are broken down into their respective number of accesses, as given by the *repcount* parameter to these DDI calls. If the access is performed via a DMA handle, *operator* and *value* are applied to every access that comprises the DMA request. If interference with interrupts has been requested then the operator may take any of the following values:

`DELAY` After *count* accesses (see the `-c` option), delay delivery of the next *failcount* number of interrupts for *operand* number of microseconds.

`LOSE` After *count* number of interrupts, fail to deliver the next *failcount* number of real interrupts to the driver.

`EXTRA` After *count* number of interrupts, start delivering *operand* number of extra interrupts for the next *failcount* number of real interrupts.

The default value for *operand* and *operator* is to corrupt the data access by flipping each bit (XOR with -1).

`-f` *acc_chk*

If the *acc_chk* parameter is set to 1 or `pio`, then the driver's calls to `ddi_check_acc_handle(9F)` return `DDI_FAILURE` when the access count goes to 1. If the *acc_chk* parameter is set to 2 or `dma`, then the driver's calls to `ddi_check_dma_handle(9F)` return `DDI_FAILURE` when the access count goes to 1.

`-w` *max_wait_period* [*report_interval*]

Constrain the period for which an error definition will remain active. The option applies only to non-logging errdefs. If an error definition remains active for *max_wait_period* seconds, the test will be aborted. If *report_interval* is set to a nonzero value, the current status of the error definition is reported to standard output every *report_interval* seconds. The default value is zero. The status of the errdef is reported in parsable format (eight fields, each separated by a colon (`:`) character, the last of which is a string enclosed by double quotes and the remaining seven fields are integers):

ft:*mt*:*ac*:*fc*:*chk*:*ec*:*s*:*"message"* which are defined as follows:

ft	The UTC time when the fault was injected.
mt	The UTC time when the driver reported the fault.
ac	The number of remaining non-faulting accesses.
fc	The number of remaining faulting accesses.
chk	The value of the *acc_chk* field of the errdef.
ec	The number of fault reports issued by the driver against this errdef (*mt* holds the time of the initial report).
s	The severity level reported by the driver.
"message"	Textual reason why the driver has reported a fault.

`-h`

Display the command usage string.

`-s` *collect_time*

If *acc_types* is given with the `-a` option and includes `log`, the errdef will log accesses for *collect_time* seconds (the default is to log until the log becomes full). Note that, if the errdef

specification matches multiple driver handles, multiple logging errdefs are registered with the `bofi` driver and logging terminates when all logs become full or when *collect_time* expires or when the associated errdefs are cleared. The current state of the log can be checked with the `th_manage(1M)` command, using the `broadcast` parameter. A log can be terminated by running `th_manage(1M)` with the `clear_errdefs` option or by sending a `SIGALRM` signal to the `th_define` process. See `alarm(2)` for the semantics of `SIGALRM`.

`-p` *policy*

Applicable when the *acc_types* option includes `log`. The parameter modifies the policy used for converting from logged accesses to errdefs. All policies are inclusive:

- Use `rare` to bias error definitions toward rare accesses (default).
- Use `operator` to produce a separate error definition for each operator type (default).
- Use `common` to bias error definitions toward common accesses.
- Use `median` to bias error definitions toward median accesses.
- Use `maximal` to produce multiple error definitions for duplicate accesses.
- Use `unbiased` to create unbiased error definitions.
- Use `onebyte`, `twobyte`, `fourbyte`, or `eightbyte` to select errdefs corresponding to 1, 2, 4 or 8 byte accesses (if chosen, the `-xr` option is enforced in order to ensure that `ddi_rep_*()` calls are decomposed into *multiple single accesses*).
- Use `multibyte` to create error definitions for multibyte accesses performed using `ddi_rep_get*()` and `ddi_rep_put*()`.

Policies can be combined by adding together these options. See the NOTES section for further information.

-x *flags*

Applicable when the *acc_types* option includes `log`. The *flags* parameter modifies the way in which the `bofi` driver logs accesses. It is specified as a string containing any combination of the following letters:

`w` Continuous logging (that is, the log will wrap when full).

`t` Timestamp each log entry (access times are in seconds).

`r` Log repeated I/O as individual accesses (for example, a `ddi_rep_get16(9F)` call which has a repcount of *N* is logged *N* times with each transaction logged as size 2 bytes. Without this option, the default logging behavior is to log this access once only, with a transaction size of twice the *repcount*).

-C *comment_string*

Applicable when the *acc_types* option includes `log`. It provides a comment string to be placed in any generated test scripts. The string must be enclosed in double quotes.

-e *fixup_script* [*args*]

Applicable when the *acc_types* option includes `log`. The output of a logging errdefs is to generate a test script for each driver access handle. Use this option to embed a command in the resulting script before the errors are injected. The generated test scripts will take an instance offline and bring it back online before injecting errors in order to bring the instance into a known fault–free state. The executable *fixup_script* will be called twice with the set of optional *args*— once just before the instance is taken offline and again after the instance has been brought online. The following variables are passed into the environment of the called executable:

`DRIVER_PATH` Identifies the device path of the instance.

`DRIVER_INSTANCE` Identifies the instance number of the device.

`DRIVER_UNCONFIGURE`	Has the value 1 when the instance is about to be taken offline.
`DRIVER_CONFIGURE`	Has the value 1 when the instance has just been brought online.

Typically, the executable ensures that the device under test is in a suitable state to be taken offline (unconfigured) or in a suitable state for error injection (for example configured, error free and servicing a workload). A minimal script for a network driver could be:

```
#!/bin/ksh

driver=xyznetdriver
ifnum=$driver$DRIVER_INSTANCE

if [[ $DRIVER_CONFIGURE = 1 ]]; then
    ifconfig $ifnum plumb
    ifconfig $ifnum ...
    ifworkload start $ifnum
elif [[ $DRIVER_UNCONFIGURE = 1 ]]; then
    ifworkload stop $ifnum
    ifconfig $ifnum down
    ifconfig $ifnum unplumb
fi
exit $?
```

The `-e` option must be the last option on the command line.

If the `-a log` option is selected but the `-e` option is not given, a default script is used. This script repeatedly attempts to detach and then re-attach the device instance under test.

Examples

Examples of Error Definitions

```
th_define -n foo -i 1 -a log
```

Logs all accesses to all handles used by instance 1 of the `foo` driver while running the default workload (attaching and detaching the instance). Then generates a set of test scripts to inject appropriate errdefs while running that default workload.

```
th_define -n foo -i 1 -a log pio
```

Logs PIO accesses to each PIO handle used by instance 1 of the `foo` driver while running the default workload (attaching and detaching the instance). Then generates a set of test scripts to inject appropriate errdefs while running that default workload.

```
th_define -n foo -i 1 -p onebyte median -e fixup arg -now
```

Logs all accesses to all handles used by instance 1 of the `foo` driver while running the workload defined in the fixup script `fixup` with arguments `arg` and `-now`. Then generates a set of test scripts to inject appropriate errdefs while running that workload. The resulting error definitions are requested to focus upon single byte accesses to locations that are accessed a *median* number of times with respect to frequency of access to I/O addresses.

```
th_define -n se -l 0x20 1 -a pio_r -o OR 0x4 -c 10 1000
```

Simulates a stuck serial chip command by forcing 1000 consecutive read accesses made by any instance of the `se` driver to its command status register, thereby returning status busy.

```
th_define -n foo -i 3 -r 1 -a pio_r -c 0 1 -f 1 -o OR 0x100
```

Causes 0x100 to be ORed into the next physical I/O read access from any register in register set 1 of instance 3 of the `foo` driver. Subsequent calls in the driver to `ddi_check_acc_handle()` return `DDI_FAILURE`.

```
th_define -n foo -i 3 -r 1 -a pio_r -c 0 1 -o OR 0x0
```

Causes 0x0 to be ORed into the next physical I/O read access from any register in register set 1 of instance 3 of the `foo` driver. This is of course a no-op.

```
th_define -n foo -i 3 -r 1 -l 0x8100 1 -a pio_r -c 0 10 -o EQ 0x70003
```

Causes the next ten next physical I/O reads from the register at offset 0x8100 in register set 1 of instance 3 of the `foo` driver to return 0x70003.

```
th_define -n foo -i 3 -r 1 -l 0x8100 1 -a pio_w -c 100 3 -o AND
0xfffffffffffefff
```

The next 100 physical I/O writes to the register at offset 0x8100 in register set 1 of instance 3 of the `foo` driver take place as normal. However, on each of the three subsequent accesses, the 0x1000 bit will be cleared.

```
th_define -n foo -i 3 -r 1 -l 0x8100 0x10 -a pio_r -c 0 1 -f 1 -o XOR 7
```

Causes the bottom three bits to have their values toggled for the next physical I/O read access to registers with offsets in the range 0x8100 to 0x8110 in register set 1 of instance 3 of the `foo` driver. Subsequent calls in the driver to `ddi_check_acc_handle()` return `DDI_FAILURE`.

```
th_define -n foo -i 3 -a pio_w -c 0 1 -o NO 0
```

Prevents the next physical I/O write access to any register in any register set of instance 3 of the `foo` driver from going out on the bus.

```
th_define -n foo -i 3 -l 0 8192 -a dma_r -c 0 1 -o OR 7
```

Causes 0x7 to be ORed into each `long long` in the first 8192 bytes of the next DMA read, using any DMA handle for instance 3 of the `foo` driver.

```
th_define -n foo -i 3 -r 2 -l 0 8 -a dma_r -c 0 1 -o OR 0x7070707070707070
```

Causes 0x70 to be ORed into each byte of the first `long long` of the next DMA read, using the DMA handle with sequential allocation number 2 for instance 3 of the `foo` driver.

```
th_define -n foo -i 3 -l 256 256 -a dma_w -c 0 1 -f 2 -o OR 7
```

Causes 0x7 to be ORed into each `long long` in the range from offset 256 to offset 512 of the next DMA write, using any DMA handle for instance 3 of the `foo` driver. Subsequent calls in the driver to `ddi_check_dma_handle()` return `DDI_FAILURE`.

```
th_define -n foo -i 3 -r 0 -l 0 8 -a dma_w -c 100 3 -o AND 0xfffffffffffefff
```

The next 100 DMA writes using the DMA handle with sequential allocation number 0 for instance 3 of the `foo` driver take place as normal. However, on each of the three subsequent accesses, the 0x1000 bit will be cleared in the first `long long` of the transfer.

```
th_define -n foo -i 3 -a intr -c 0 6 -o LOSE 0
```

Causes the next six interrupts for instance 3 of the `foo` driver to be lost.

```
th_define -n foo -i 3 -a intr -c 30 1 -o EXTRA 10
```

When the thirty-first subsequent interrupt for instance 3 of the `foo` driver occurs, a further ten interrupts are also generated.

```
th_define -n foo -i 3 -a intr -c 0 1 -o DELAY 1024
```

Causes the next interrupt for instance 3 of the `foo` driver to be delayed by 1024 microseconds.

Notes The policy option in the `th_define -p` syntax determines how a set of logged accesses will be converted into the set of error definitions. Each logged access will be matched against the chosen policies to determine whether an error definition should be created based on the access.

Any number of policy options can be combined to modify the generated error definitions.

Bytewise Policies These select particular I/O transfer sizes. Specifing a byte policy will exclude other byte policies that have not been chosen. If none of the byte type policies is selected, all transfer sizes are treated equally. Otherwise, only those specified transfer sizes will be selected.

`onebyte`	Create errdefs for one byte accesses (`ddi_get8()`)
`twobyte`	Create errdefs for two byte accesses (`ddi_get16()`)
`fourbyte`	Create errdefs for four byte accesses (`ddi_get32()`)
`eightbyte`	Create errdefs for eight byte accesses (`ddi_get64()`)
`multibyte`	Create errdefs for repeated byte accesses (`ddi_rep_get*()`)

Frequency of Access Policies

The frequency of access to a location is determined according to the access type, location and transfer size (for example, a two-byte read access to address A is considered distinct from a four-byte read access to address A). The algorithm is to count the number of accesses (of a given type and size) to a given location, and find the locations that were most and least accessed (let *maxa* and *mina* be the number of times these locations were accessed, and *mean* the total number of accesses divided by total number of locations that were accessed). Then a rare access is a location that was accessed less than

(mean - mina) / 3 + mina

times. Similarly for the definition of common accesses:

maxa - (maxa - mean) / 3

A location whose access patterns lies within these cutoffs is regarded as a location that is accessed with median frequency.

`rare`	Create errdefs for locations that are rarely accessed.
`common`	Create errdefs for locations that are commonly accessed.
`median`	Create errdefs for locations that are accessed a median frequency.

Policies for Minimizing errdefs

If a transaction is duplicated, either a single or multiple errdefs will be written to the test scripts, depending upon the following two policies:

`maximal`	Create multiple errdefs for locations that are repeatedly accessed.
`unbiased`	Create a single errdef for locations that are repeatedly accessed.
`operators`	For each location, a default operator and operand is typically applied. For maximal test coverage, this default may be modified using the `operators` policy so that a separate errdef is created for each of the possible corruption operators.

See Also `kill(1)`, `th_manage(1M)`, `alarm(2)`, `ddi_check_acc_handle(9F)`, `ddi_check_dma_handle(9F)`

Name th_manage – manage the fault injection test harness

Synopsis

```
th_manage name instance command

th_manage path command
```

Description `th_manage` applies the action specified by *command* to the instance specified by *instance* of the driver specified by *name* (or the driver instance specified by *path*). The driver instance must be running fault injection specifications (errdefs) defined by `th_define(1M)`.

`th_manage` supports several commands that operate on the driver instance specified by *name* and *instance* (or *path*). The commands are:

`broadcast`	Awaken all `th_define` processes, causing them to display their current status and exit if the errdef is now defunct (that is, if *count*, *failcount* , and *acc_chk* are all zero).
`clear_acc_chk`	Awaken all `th_define` processes. If *count* and *failcount* are already zero, then set *acc_chk* to zero, so that `th_define` exits once it has displayed its status.
`clear_errdefs`	Awaken all `th_define processes`. *count*, *failcount* and *acc_chk* are all set to zero so that all `th_define` commands exit once they have displayed their status.
`clear_errors`	Awaken all `th_define` processes. If *count* is already zero, set *failcount* and *acc_chk* to zero, so that `th_define` exits once it has displayed its status.
`get_handles`	List all the access handles.
`start`	Begin or resume execution of all errdefs.
`stop`	Suspend all errdefs for this *name* and *instance* (or *path).*

Examples **EXAMPLE 1** Useful Commands

To begin the tests, enter:

```
# th_manage foo 0 start
```

To check the status of the errdefs, enter:

```
# th_manage foo 0 broadcast
```

This causes each `th_define` process to print out its current status.

If the driver has reported a fatal error, you can take the driver offline using `libdevice`, clear the error condition by entering:

```
# th_manage foo 0 clear_acc_chk
```

EXAMPLE 1 Useful Commands *(Continued)*

or

```
# th_manage foo 0 clear_errors
```

and bring the driver online again using `libdevice`.

To terminate testing, enter:

```
# th_manage foo 0 clear_errdefs
```

See Also `th_define(1M)`

Name tic – terminfo compiler

Synopsis `tic [-v [n]] [-c] file`

Description The command `tic` translates a `terminfo` file from the source format into the compiled format. The results are placed in the directory `/usr/share/lib/terminfo`. The compiled format is necessary for use with the library routines in `curses(3CURSES)`.

If the environment variable `TERMINFO` is set, the compiled results are placed there instead of `/usr/share/lib/terminfo`.

Total compiled entries cannot exceed 4096 bytes. The name field cannot exceed 128 bytes. Terminal names exceeding 14 characters will be truncated to 14 characters and a warning message will be printed.

Options The following options are supported:

`-c` Specifies to check only `file` for errors. Errors in `use=` links are not detected.

`-v`[*n*] Specify that (verbose) output be written to standard error trace information showing `tic`'s progress. The optional integer *n* is a number from 1 to 10, indicating the desired level of detail of information. If *n* is omitted, the default level is 1. If *n* is specified and greater than 1, the level of detail is increased.

Operands `file` Contains one or more `terminfo` terminal descriptions in source format [see `terminfo(4)`]. Each description in the file describes the capabilities of a particular terminal. When a `use=`*entry-name* field is discovered in a terminal entry currently being compiled, `tic` reads in the binary from `/usr/share/lib/terminfo` to complete the entry. (Entries created from `file` will be used first. If the environment variable `TERMINFO` is set, that directory is searched instead of `/usr/share/lib/terminfo`.) `tic` duplicates the capabilities in *entry-name* for the current entry, with the exception of those capabilities that are explicitly defined in the current entry.

Files `/usr/share/lib/terminfo/?/*` Compiled terminal description database

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `captoinfo(1M)`, `infocmp(1M)`, `curses(3CURSES)`, `terminfo(4)`, `attributes(5)`

Notes When an entry, for example, `entry_name_1`, contains a `use=`*entry_name_2* field, any canceled capabilities in *entry_name_2* must also appear in `entry_name_1` before `use=` for these capabilities to be canceled in `entry_name_1`.

Name tnchkdb – check file syntax of trusted network databases

Synopsis

```
/usr/sbin/tnchkdb  [-h path] [-t path] [-z path]
```

Description `tnchkdb` checks the syntax of the `tnrhtp`, `tnrhdb`, and `tnzonecfg` databases. By default, the *path* for each file is:

- `/etc/security/tsol/tnrhtp`
- `/etc/security/tsol/tnrhdb`
- `/etc/security/tsol/tnzonecfg`

You can specify an alternate path for any or all of the files by specifying that path on the command line by using the `-h` (`tnrhdb`), `-t` (`tnrhtp`) and `-z` (`tnzonecfg`) options. The options are useful when testing a set of modified files before installing the files as new system databases.

All three database files are checked for integrity. `tnchkdb` returns an exit status of `0` if all of the files are syntactically and, to the extent possible, semantically correct. If one or more files have errors, then an exit status of `1` is returned. If there are command line problems, such as an unreadable file, an exit status of `2` is returned. Errors are written to standard error.

To avoid cascading errors, when there are errors in `tnrhtp`, the template names in `tnrhdb` are not validated.

`tnchkdb` can be run at any label, but the standard `/etc/security/tsol` files are visible only in the global zone.

Options

`-h` [*path*] Check *path* for proper `tnrhdb` syntax. If *path* is not specified, then check `/etc/security/tsol/tnrhdb`.

`-t` [*path*] Check *path* for proper `tnrhtp` syntax. If *path* is not specified, then check `/etc/security/tsol/tnrhtp`.

`-z` [*path*] Check *path* for proper `tnzonecfg` syntax. If *path* is not specified, then check `/etc/security/tsol/tnzonecfg`.

Examples **EXAMPLE 1** Sample Error Message

The `tnchkdb` command checks for CIPSO errors. In this example, the `admin_low` template has an incorrect value of `ADMIN_HIGH` for its default label.

```
# tnchkdb
checking /etc/security/tsol/tnrhtp ...
tnchkdb: def_label classification 7fff is invalid for cipso labels:
line 14 entry admin_low
tnchkdb: def_label compartments 241-256 must be zero for cipso labels:
line 14 entry admin_low
checking /etc/security/tsol/tnrhdb ...
checking /etc/security/tsol/tnzonecfg ...
```

The command line is Committed. The output is Uncommitted.

See Also `tnd(1M)`, `tnctl(1M)`, `attributes(5)`

"How to Check the Syntax of Trusted Network Databases" in *Oracle Solaris Trusted Extensions Administrator's Procedures*

Notes The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

It is possible to have inconsistent but valid configurations of `tnrhtp` and `tnrhdb` when LDAP is used to supply missing templates.

Name tnctl – configure Trusted Extensions network parameters

Synopsis

```
/usr/sbin/tnctl [-dfv] [-h host [/prefix] [:template]]
     [-m zone:mlp:shared-mlp][-t template [:key=val [;key=val]]]
     [-HTz] file]
```

Description `tnctl` provides an interface to manipulate trusted network parameters in the Solaris kernel.

As part of Solaris Trusted Extensions initialization, `tnctl` is run in the global zone by an `smf(5)` script during system boot. The `tnctl` command is not intended to be used during normal system administration. Instead, if a local trusted networking database file is modified without using the Solaris Management Console, the administrator first issues `tnchkdb(1M)` to check the syntax, and then refreshes the kernel copy with this command:

```
# svcadm restart svc:/network/tnctl
```

See `WARNINGS` about the risks of changing remote host and template information on a running system.

Options

`-d`
Delete matching entries from the kernel. The default is to add new entries.

When deleting MLPs, the MLP range must match exactly. MLPs are specified in the form:

port`[-`*port*`]/`*protocol*

Where *port* can be a number in the range 1 to 65535. or any known service (see `services(4)`), and protocol can be a number in the range 1 to 255, or any known protocol (see `protocols(4)`).

`-f`
Flush all kernel entries before loading the entries that are specified on the command line. The flush does not take place unless at least one entry parsed successfully.

`-v`
Turn on verbose mode.

`-h` *host*[/*prefix*][:*template*]
Update the kernel remote-host cache on the local host for the specified *host* or, if a template name is given, change the kernel's cache to use the specified *template*. If *prefix* is not specified, then an implied prefix length is determined according to the rules used for interpreting the `tnrhdb`. If `-d` is specified, then a template name cannot be specified.

`-m` *zone*:*mlp*:*shared-mlp*
Modify the kernel's multilevel port (MLP) configuration cache for the specified *zone*. *zone* specifies the zone to be updated. *mlp* and *shared-mlp* specify the MLPs for the zone-specific and shared IP addresses. The *shared-mlp* field is effective in the global zone only.

`-t` *template*[*key=val*[;*key=val*]]
Update the kernel template cache for *template* or, if a list of *key=val* pairs is given, change the kernel's cache to use the specified entry. If `-d` is specified, then *key=val* pairs cannot be specified.

`-T` *file*
Load all template entries in *file* into the kernel cache.

`-H` *file*
Load all remote host entries in *file* into the kernel cache.

`-z` *file*
Load just the global zone's MLPs from *file* into the kernel cache. To reload MLPs for a non-global zone, reboot the zone:

```
# zoneadm -z non-global zone reboot
```

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWtsu
Interface Stability	Uncommitted

"How to Synchronize the Kernel Cache With Trusted Network Databases" in *Oracle Solaris Trusted Extensions Administrator's Procedures*

Warnings

Changing a template while the network is up can change the security view of an undetermined number of hosts.

Notes

The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

The `tnctl` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/tnctl
```

The service's status can be queried by using svcs(1). Administrative actions on this service, such as refreshing the kernel cache, can be performed using svcadm(1M), as in:

```
svcadm refresh svc:/network/tnctl
```

Name tnd – trusted network daemon

Synopsis `/usr/sbin/tnd [-p` *poll-interval*`]`

Description The `tnd` (trusted network daemon) initializes the kernel with trusted network databases and also reloads the databases on demand from an LDAP server and local files. `tnd` follows the order specified in the `nsswitch.conf(4)` file when loading configuration databases. `tnd` is started at the beginning of the boot process.

`tnd` loads two databases into the kernel: the remote host database, `tnrhdb` and the remote-host template database, `tnrhtp`. These databases and their effect on the trusted network are described in their respective man pages. When the associated LDAP database or local databases are changed, `tnd` also updates the local kernel cache at the predetermined interval.

If a local trusted networking database file is modified, the administrator should run `tnchkdb(1M)` to check the syntax, and should also run `svcadm refresh svc:/network/tnd` to initiate an immediate database scan by `tnd`.

`tnd` is intended to be started from an `smf(5)` script and to run in the global zone. The following signals cause specific `svcadm` actions:

`SIGHUP` Causes `svcadm refresh svc:/network/tnd` to be run.

Initiates a rescan of the local and LDAP `tnrhdb` and `tnrhtp` databases. `tnd` updates the kernel database with any changes found.

`SIGTERM` Causes `svcadm disable svc:/network/tnd` to be run.

Terminates the `tnd` daemon. No changes are made to the kernel database.

Running `tnd` in debug mode is determined by the value of the following service management facility (SMF) property:

```
tnd/debug_level = 0
```

A value of `0`, as above, prevents debug information from being collected; `1` turns on debugging. The default value is `0`. Debug output is sent to the `/var/tsol/tndlog` log file.

Options `-p` *poll-interval* Set poll interval to *poll-interval* seconds. The default *poll-interval* is 1800 seconds (30 minutes).

Examples **EXAMPLE 1** Changing the Poll Interval

The following command changes the polling interval to one hour, and puts this interval in the SMF repository. At the next boot, the `tnd` poll interval will be one hour.

```
# svccfg -s network/tnd setprop tnd/poll_interval=3600
```

The following command changes the polling interval, but does not update the repository. At the next boot, the `tnd` poll interval remains the default, 30 minutes.

EXAMPLE 1 Changing the Poll Interval *(Continued)*

```
# tnd -p 3600
```

Name tninfo – print kernel-level network information and statistics

Synopsis `/usr/sbin/tninfo [-h` *hostname*`] [-m` *zone-name*`] [-t` *template*`]`

Description `tninfo` provides an interface to retrieve and display kernel-level network information and statistics.

Options

`-h` *hostname*	Display the security structure for the specified host in the remote-host cache. The output should reflect what is specified in the `tnrhdb` database.
`-m` *zone-name*	Display the MLP configuration associated with the specified zone. The output should reflect what is specified in the `tnzonecfg` database.
`-t` *template*	Display the structure associated with the specified *template*. The output should reflect what is specified in the `tnrhtp` database.

Examples

EXAMPLE 1 Displaying Remote Host Structures Cached in the Kernel

This example shows the remote host structures cached in the kernel. The output reflects the definition in the `tnrhdb` database.

```
# tninfo -h machine1
   IP address= 192.168.8.61
   Template = cipso
```

EXAMPLE 2 Displaying Multilevel Ports for the Global Zone

This example shows the kernel-cached MLPs for the global zone. The output reflects the definition in the `tnzonecfg` database, plus any dynamically allocated MLPs. `private` indicates zone-specific MLPs.

```
# tninfo -m global
private:23/tcp;111/tcp;111/udp;515/tcp;2049/tcp;6000-6003/tcp;
        32812/tcp;36698/ip;38634/tcp;64365/ip
shared: 6000-6003/tcp
```

EXAMPLE 3 Displaying the `cipso` Template Definition

This example shows the kernel-cached `cipso` template definition. The output reflects the definition in the `tnrhtp` database.

```
# tninfo -t cipso
====================================
   Remote Host Template Table Entries:

   ___________________________
   template: cipso
   host_type: CIPSO
   doi: 1
   min_sl: ADMIN_LOW
   hex: ADMIN_LOW
   max_sl: ADMIN_HIGH
```

EXAMPLE 3 Displaying the `cipso` Template Definition *(Continued)*

```
    hex: ADMIN_HIGH
```

"How to Synchronize the Kernel Cache With Trusted Network Databases" in *Oracle Solaris Trusted Extensions Administrator's Procedures*

Notes The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

Name traceroute – print the route packets take to network host

Synopsis

```
traceroute [-adFIlnSvx] [-A addr_family] [-c traffic_class]
     [-f first_hop] [-g gateway [-g gateway...] | -r]
     [-i iface] [-L flow_label] [-m max_hop]
     [-P pause_sec] [-p port] [-Q max_timeout]
     [-q nqueries] [-s src_addr] [-t tos] [-w wait_time] host
     [packetlen]
```

Description The Internet is a large and complex aggregation of network hardware, connected by gateways. Tracking the route a packet follows can be difficult. The utility `traceroute` traces the route that an IP packet follows to another internet host.

The `traceroute` utility utilizes the both the IPv4 and IPv6 protocols. Use the `-A` option to override the default behavior. `traceroute` uses the IPv4 protocol *ttl* (time to live) field or the IPv6 field *hop limit*. It attempts to elicit an ICMP or ICMP6 `TIME_EXCEEDED` response from each *gateway* along the path, and a `PORT_UNREACHABLE`(or `ECHO_REPLY` if `-I` is used) response from the destination host. It starts by sending probes with a *ttl* or *hop limit* of `1` and increases by `1` until it either gets to the host, or it hits the maximum *max_hop*. The default maximum *max_hop* is 30 hops, but this can be set by the `-m` option.

Three probes are sent at each *ttl* (*hop limit*) setting, and a line is printed showing the *ttl* (*hop limit*), the hostname and the address of the gateway, and the *rtt* (round trip time) of each probe. The number of probes may be specifically set using the `-q` option. If the probe answers come from different gateways, the hostname and the address of each responding system will be printed. If there is no response within a 5 second timeout interval, an asterisk (`*`) is displayed for that probe. The `-w` option may be used to set the timeout interval. Other possible annotations that may appear after the time are:

`!`
: the *ttl* (*hop limit*) value in the received packet is `<= 1`.

`!H`
: host unreachable.

`!X`
: communication administratively prohibited.

`<!N>`
: ICMP (ICMP6) unreachable code N.

The following annotations appear only for IPv4:

`!F`
: fragmentation needed. This should never occur. If this is seen, the associated gateway is broken.

`!N`
: network unreachable.

`!P`
protocol unreachable.

`!S`
source route failed. It is likely that the gateway does not support source routing.

`!T`
unreachable for the specified tos (type-of-service).

`!U`
source host isolated or precedence problem.

The following annotations appear only for IPv6:

`!A`
host unreachable for a reason other than lack of an entry in the routing table.

`!B`
packet too big.

`!E`
destination is not a neighbor.

`!R`
unrecognized next header.

If almost all the probes result in some kind of unreachable code, then `traceroute` gives up and exits.

The destination *host* is not supposed to process the UDP probe packets, so the destination *port* default is set to an unlikely value. However, if some application on the destination is using that value, the value of *port* can be changed with the `-p` option.

The only mandatory parameter is the destination *host* name or IP number. The default probe datagram length is 40 bytes (60 bytes for IPv6), but this may be increased by specifying a packet length (in bytes) after the destination *host* name.

All integer arguments to `traceroute` can be specified in either decimal or hexadecimal notation. For example, *packetlen* can be specified either as `256` or `0x100`.

Options `-A` *addr_family*
Specify the address family of the target host. *addr_family* can be either `inet` or `inet6`. Address family determines which protocol to use. For an argument of `inet`, IPv4 is used. For `inet6`, IPv6 is used.

By default, if the name of a host is provided, not the literal IP address, and a valid IPv6 address exists in the name service database, `traceroute` will use this address. Otherwise, if the name service database contains an IPv4 address, it will try the IPv4 address.

Specify the address family `inet` or `inet6` to override the default behavior. If the argument specified is `inet`, `traceroute` will use the IPv4 address associated with the hostname. If none exists, `traceroute` will state that the host is unknown and exit. It will not try to determine if an IPv6 address exists in the name service database.

If the specified argument is `inet6`, `traceroute` will use the IPv6 address that is associated with the hostname. If none exists, `traceroute` will state that the host is unknown and exit.

`-a`
Probe all of the addresses of a multi-homed destination. The output looks like `traceroute` has been run once for each IP address of the destination. If this option is used together with `-A`, `traceroute` probes only the addresses that are of the specified address family. While probing one of the addresses of the destination, user can skip to the next address by sending a `SIGINT`, or exit `traceroute` by sending a `SIGQUIT` signal. See `signal(3C)`

`-c` *traffic_class*
Specify the traffic class of probe packets. The value must be an integer in the range from 0 to 255. Gateways along the path may route the probe packet differently depending upon the value of *traffic_class* set in the probe packet. This option is valid only on IPv6.

`-d`
Set the `SO_DEBUG` socket option.

`-F`
Set the "don't fragment" bit. This option is valid only on IPv4. When specified from within a shared-IP zone, this option has no effect as the "don't fragment" bit is always set in this case.

`-f` *first_hop*
Set the starting *ttl* (*hop limit*) value to *first_hop*, to override the default value `1`. `traceroute` skips processing for those intermediate gateways which are less than *first_hop* hops away.

`-g` *gateway*
Specify a loose source route *gateway*. The user can specify more than one *gateway* by using `-g` for each gateway. The maximum number of gateways is 8 for IPv4 and 127 for IPv6. Note that some factors such as the link MTU can further limit the number of gateways for IPv6. This option cannot be used with the `-r` option.

Only users with the `{PRIV_NET_RAWACCESS}` privilege can specify a loose source route with this option.

`-I`
Use ICMP (ICMP6) `ECHO` instead of UDP datagrams.

`-i` *iface*
For IPv4, this option specifies a network interface to obtain the source IP address. This is normally only useful on a multi-homed host. The `-s` option is also another way to do this.

For IPv6, it specifies the network interface on which probe packets are transmitted. The argument can be either an interface index, for example, `1`, `2`, or an interface name, for example, `eri0`, `hme0`.

`-L` *flow_label*
Specify the flow label of probe packets. The value must be an integer in the range from 0 to 1048575. This option is valid only on IPv6.

`-l`
Print the value of the *ttl* (*hop limit*) field in each packet received.

`-m` *max_hop*
Set the maximum *ttl* (*hop limit*) used in outgoing probe packets. The default is 30 hops, which is the same default used for TCP connections.

`-n`
Print hop addresses numerically rather than symbolically and numerically. This saves a nameserver address-to-name lookup for each gateway found on the path.

`-P` *pause_sec*
Specify a delay, in seconds, to pause between probe packets. This may be necessary if the final destination does not accept undeliverable packets in bursts. By default, `traceroute` sends the next probe as soon as it has received a reply. Note that *pause_sec* is a real number.

`-p` *port*
Set the base UDP *port* number used in probes.The default is 33434. `traceroute` hopes that nothing is listening on UDP *ports* `(base+(nhops-1)*nqueries)` to `(base+(nhops*nqueries)-1)` at the destination host, so that an ICMP (ICMP6) `PORT_UNREACHABLE` message will be returned to terminate the route tracing. If something is listening on a *port* in the default range, this option can be used to select an unused *port* range. `nhops` is defined as the number of hops between the source and the destination.

`-Q` *max_timeout*
Stop probing this hop after *max_timeout* consecutive timeouts are detected. The default value is 5. Useful in combination with the `-q` option if you have specified a large *nqueries* probe count.

`-q` *nqueries*
Set the desired number of probe queries. The default is 3.

`-r`
Bypass the normal routing tables and send directly to a host on an attached network. If the host is not on a directly-attached network, an error is returned. This option can be used to send probes to a local host through an interface that has been dropped by the router deamon. See `in.routed(1M)`. You cannot use this option if the `-g` option is used.

`-S`
Display a summary of how many probes were not answered for each hop.

`-s` *src_addr*
Use the following address, which usually is given as a literal IP address, not a hostname, as the source address in outgoing probe packets. On multi-homed hosts, those with more than one IP address, this option can be used to force the source address to be something other than the IP address `traceroute` picks by default. If the IP address is not one of this machine's interface addresses, an error is returned and nothing is sent. For IPv4, when used together with the `-i` option, the given IP address should be configured on the specified interface. Otherwise, an error will be returned. In the case of IPv6, the interface name and the source address do not have to match.

`-t` *tos*
Set the *tos*(type-of-service) in probe packets to the specified value. The default is zero. The value must be an integer in the range from 0 to 255. Gateways along the path may route the probe packet differently depending upon the *tos* value set in the probe packet. This option is valid only on IPv4.

`-v`
Verbose output. For each hop, the size and the destination of the response packets is displayed. Also ICMP (ICMP6) packets received other than `TIME_EXCEEDED` and `UNREACHABLE` are listed as well.

`-w` *waittime*
Set the time, in seconds, to wait for a response to a probe. The default is 5 seconds.

`-x`
Prevent `traceroute` from calculating checksums. Checksums are usually required for the last hop when using ICMP `ECHO` probes. This option is valid only on IPv4. See the `-I` option.

When specified from within a shared-IP zone, this option has no effect as the checksum is always calculated by the operating system in this case.

Operands

The following operands are supported:

host
The network host.

Examples

EXAMPLE 1 Sample Output From the `traceroute` Utility

Some sample output from the `traceroute` utility might be:

```
istanbul% traceroute london
traceroute: Warning: london has multiple addresses;  \
  using 4::114:a00:20ff:ab3d:83ed
traceroute: Warning: Multiple interfaces found; \
  using 4::56:a00:20ff:fe93:8dde @ eri0:2
traceroute to london (4::114:a00:20ff:ab3d:83ed), 30 hops max, \
  60 byte packets
1  frbldg7c-86 (4::56:a00:20ff:fe1f:65a1)  1.786 ms  1.544 ms  1.719 ms
```

EXAMPLE 1 Sample Output From the `traceroute` Utility *(Continued)*

```
2  frbldg7b-77 (4::255:0:0:c0a8:517)  2.587 ms 3.001 ms  2.988 ms
3  london (4::114:a00:20ff:ab3d:83ed)  3.122 ms  2.744 ms  3.356 ms
```

The target host, london, has both IPv4 and IPv6 addresses in the name service database. According to the default behavior, `traceroute` uses IPv6 address of the destination host.

EXAMPLE 2 Using the `traceroute` Utility For a Host Which has Only IPv4 Addresses

In the following examples, `traceroute` is tracking the route to host sanfrancisco, which has only IPv4 addresses in the name service database. Therefore traceroute uses only IPv4 addresses. The following shows the 7-hop path that a packet would follow from the host istanbul to the host sanfrancisco.

```
istanbul% traceroute sanfrancisco
traceroute: Warning: Multiple interfaces found; using 172.31.86.247 @eri0
traceroute to sanfrancisco (172.29.64.39), 30 hops max, 40 byte packets
1  frbldg7c-86 (172.31.86.1)  1.516 ms  1.283 ms  1.362 ms
2  bldg1a-001 (172.31.1.211)  2.277 ms  1.773 ms  2.186 ms
3  bldg4-bldg1 (172.30.4.42)  1.978 ms  1.986 ms  13.996 ms
4  bldg6-bldg4 (172.30.4.49)  2.655 ms  3.042 ms  2.344 ms
5  ferbldg11a-001 (172.29.1.236)  2.636 ms  3.432 ms  3.830 ms
6  frbldg12b-153 (172.29.153.72)  3.452 ms  3.146 ms  2.962 ms
7  sanfrancisco (172.29.64.39)  3.430 ms  3.312 ms  3.451 ms
```

EXAMPLE 3 Using the `traceroute` Utility With Source Routing

The following example shows the path of a packet that goes from istanbul to sanfrancisco through the hosts cairo and paris, as specified by the `-g` option. The `-I` option makes `traceroute` send ICMP `ECHO` probes to the host sanfrancisco. The `-i` options sets the source address to the IP address configured on the interface `qe0`.

```
istanbul% traceroute -g cairo -g paris -i qe0 -q 1 -I sanfrancisco
traceroute to sanfrancisco (172.29.64.39), 30 hops max, 56 byte packets
1  frbldg7c-86 (172.31.86.1)  2.012 ms
2  flrbldg7u (172.31.17.131)  4.960 ms
3  cairo (192.168.163.175) 4.894 ms
4  flrbldg7u (172.31.17.131)  3.475 ms
5  frbldg7c-017 (172.31.17.83)  4.126 ms
6  paris (172.31.86.31) 4.086 ms
7  frbldg7b-82 (172.31.82.1)  6.454 ms
8  bldg1a-001 (172.31.1.211)  6.541 ms
9  bldg6-bldg4 (172.30.4.49)  6.518 ms
10  ferbldg11a-001 (172.29.1.236)  9.108 ms
11  frbldg12b-153 (172.29.153.72)  9.634 ms
12  sanfrancisco (172.29.64.39)  14.631 ms
```

Exit Status The following exit values are returned:

`0`
Successful operation.

`>0`
An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `netstat(1M)`, `signal(3C)`, `ping(1M)`, `attributes(5)`, `privileges(5)`, `zones(5)`

Warnings This utility is intended for use in network testing, measurement and management. It should be used primarily for manual fault isolation. Because of the load it could impose on the network, it is unwise to use `traceroute`(1M) during normal operations or from automated scripts.

Name trapstat – report trap statistics

Synopsis

```
/usr/sbin/trapstat [-t | -T | -e entry]
     [-C processor_set_id | -c cpulist] [-P] [-a]
     [-r rate] [ [interval [count]] | command | [args]]

/usr/sbin/trapstat -l
```

Description The `trapstat` utility gathers and displays run-time trap statistics on UltraSPARC-based systems. The default output is a table of trap types and CPU IDs, with each row of the table denoting a trap type and each column of the table denoting a CPU. If standard output is a terminal, the table contains as many columns of data as can fit within the terminal width; if standard output is not a terminal, the table contains at most six columns of data. By default, data is gathered and and displayed for all CPUs; if the data cannot fit in a single table, it is printed across multiple tables. The set of CPUs for which data is gathered and displayed can be optionally specified with the `-c` or `-C` option.

Unless the `-r` option or the `-a` option is specified, the value displayed in each entry of the table corresponds to the number of traps per second. If the `-r` option is specified, the value corresponds to the number of traps over the interval implied by the specified sampling rate; if the `-a` option is specified, the value corresponds to the accumulated number of traps since the invocation of `trapstat`.

By default, `trapstat` displays data once per second, and runs indefinitely; both of these behaviors can be optionally controlled with the *interval* and *count* parameters, respectively. The *interval* is specified in seconds; the *count* indicates the number of intervals to be executed before exiting. Alternatively, `command` can be specified, in which case `trapstat` executes the provided command and continues to run until the command exits. A positive integer is assumed to be an *interval*; if the desired *command* cannot be distinguished from an integer, the full path of *command* must be specified.

UltraSPARC I (obsolete), II, and III handle translation lookaside buffer (TLB) misses by trapping to the operating system. TLB miss traps can be a significant component of overall system performance for some workloads; the `-t` option provides in-depth information on these traps. When run with this option, `trapstat` displays both the rate of TLB miss traps and the percentage of time spent processing those traps. Additionally, TLB misses that hit in the translation storage buffer (TSB) are differentiated from TLB misses that further miss in the TSB. (The TSB is a software structure used as a translation entry cache to allow the TLB to be quickly filled; it is discussed in detail in the *UltraSPARC II User's Manual*.) The TLB and TSB miss information is further broken down into user- and kernel-mode misses.

Workloads with working sets that exceed the TLB reach may spend a significant amount of time missing in the TLB. To accommodate such workloads, the operating system supports multiple page sizes: larger page sizes increase the effective TLB reach and thereby reduce the number of TLB misses. To provide insight into the relationship between page size and TLB miss rate, `trapstat` optionally provides in-depth TLB miss information broken down by page size using the `-T` option. The information provided by the `-T` option is a superset of that provided by the `-t` option; only one of `-t` and `-T` can be specified.

Options The following options are supported:

`-a` Displays the number of traps as accumulating, monotonically increasing values instead of per-second or per-interval rates.

`-c` *cpulist* Enables `trapstat` only on the CPUs specified by *cpulist*.

cpulist can be a single processor ID (for example, `4`), a range of processor IDs (for example, `4-6`), or a comma separated list of processor IDs or processor ID ranges (for example, `4,5,6` or `4,6-8`).

`-C` *processor_set_id* Enables `trapstat` only on the CPUs in the processor set specified by *processor_set_id*.

`trapstat` modifies its output to always reflect the CPUs in the specified processor set. If a CPU is added to the set, `trapstat` modifies its output to include the added CPU; if a CPU is removed from the set, `trapstat` modifies its output to exclude the removed CPU. At most one processor set can be specified.

`-e` *entrylist* Enables `trapstat` only for the trap table entry or entries specified by *entrylist*. A trap table entry can be specified by trap number or by trap name (for example, the level–10 trap can be specified as `74`, `0x4A`, `0x4a`, or `level-10`).

entrylist can be a single trap table entry or a comma separated list of trap table entries. If the specified trap table entry is not valid, `trapstat` prints a table of all valid trap table entries and values. A list of valid trap table entries is also found in *The SPARC Architecture Manual, Version 9* and the *Sun Microelectronics UltraSPARC II User's Manual*. If the parsable option (`-P`) is specified in addition to the `-e` option, the format of the data is as follows:

Field	Contents
1	Timestamp (nanoseconds since start)
2	CPU ID
3	Trap number (in hexadecimal)
4	Trap name
5	Trap rate per interval

Each field is separated with whitespace. If the format is modified, it will be modified by adding potentially new fields beginning with field 6; exant fields will remain unchanged.

`-l` Lists trap table entries. By default, a table is displayed containing all valid trap numbers, their names and a brief description. The trap name is used in both the default output and in the *entrylist* parameter for the `-e` argument. If the parsable option (`-P`) is specified in addition to the `-l` option, the format of the data is as follows:

Field	Contents
1	Trap number in hexadecimal
2	Trap number in decimal
3	Trap name
Remaining	Trap description

`-P` Generates parsable output. When run without other data gathering modifying options (that is, `-e`, `-t` or `-T`), `trapstat`'s the parsable output has the following format:

Field	Contents
1	Timestamp (nanoseconds since start)
2	CPU ID
3	Trap number (in hexadecimal)
4	Trap name
5	Trap rate per interval

Each field is separated with whitespace. If the format is modified, it will be modified by adding potentially new fields beginning with field 6; extant fields will remain unchanged.

`-r` *rate* Explicitly sets the sampling rate to be *rate* samples per second. If this option is specified, `trapstat`'s output changes from a traps-per-second to traps-per-sampling-interval.

`-t` Enables TLB statistics.

A table is displayed with four principal columns of data: *itlb-miss*, *itsb-miss*, *dtlb-miss*, and *dtsb-miss*. The columns contain both the rate of the corresponding event and the percentage of CPU time spent processing the event. The percentage of CPU time is given only in terms of a single CPU. The rows of the table correspond to CPUs,

with each CPU consuming two rows: one row for user-mode events (denoted with `u`) and one row for kernel-mode events (denoted with `k`). For each row, the percentage of CPU time is totalled and displayed in the rightmost column. The CPUs are delineated with a solid line. If the parsable option (`-P`) is specified in addition to the `-t` option, the format of the data is as follows:

Field	Contents
1	Timestamp (nanoseconds since start)
2	CPU ID
3	Mode (`k` denotes kernel, `u` denotes user)
4	I-TLB misses
5	Percentage of time in I-TLB miss handler
6	I-TSB misses
7	Percentage of time in I-TSB miss handler
8	D-TLB misses
9	Percentage of time in D-TLB miss handler
10	D-TSB misses
11	Percentage of time in D-TSB miss handler

Each field is separated with whitespace. If the format is modified, it will be modified by adding potentially new fields beginning with field 12; extant fields will remain unchanged.

`-T` Enables TLB statistics, with page size information. As with the `-t` option, a table is displayed with four principal columns of data: *itlb-miss*, *itsb-miss*, *dtlb-miss*, and *dtsb-miss*. The columns contain both the absolute number of the corresponding event, and the percentage of CPU time spent processing the event. The percentage of CPU time is given only in terms of a single CPU. The rows of the table correspond to CPUs, with each CPU consuming two sets of rows: one set for user-level events (denoted with `u`) and one set for kernel-level events (denoted with `k`). Each set, in turn, contains as many rows as

there are page sizes supported (see `getpagesizes(3C)`). For each row, the percentage of CPU time is totalled and displayed in the right-most column. The two sets are delineated with a dashed line; CPUs are delineated with a solid line. If the parsable option (`-P`) is specified in addition to the `-T` option, the format of the data is as follows:

Field	Contents
1	Timestamp (nanoseconds since start)
2	CPU ID
3	Mode `k` denotes kernel, `u` denotes user)
4	Page size, in decimal
5	I-TLB misses
6	Percentage of time in I-TLB miss handler
7	I-TSB misses
8	Percentage of time in I-TSB miss handler
9	D-TLB misses
10	Percentage of time in D-TLB miss handler
11	D-TSB misses
12	Percentage of time in D-TSB miss handler

Each field is separated with whitespace. If the format is modified, it will be modified by adding potentially new fields beginning with field 13; extant fields will remain unchanged.

Examples

EXAMPLE 1 Using `trapstat` Without Options

When run without options, `trapstat` displays a table of trap types and CPUs. At most six columns can fit in the default terminal width; if (as in this example) there are more than six CPUs, multiple tables are displayed:

```
example# trapstat
vct  name                |     cpu0     cpu1     cpu4     cpu5     cpu8     cpu9
-----------------------+-------------------------------------------------------
 24 cleanwin             |     6446     4837     6368     2153     2623     1321
 41 level-1              |      100        0        0        0        1        0
```

EXAMPLE 1 Using `trapstat` Without Options *(Continued)*

```
 44 level-4             |        0        1        1        1        0        0
 45 level-5             |        0        0        0        0        0        0
 47 level-7             |        0        0        0        0        9        0
 49 level-9             |      100      100      100      100      100      100
 4a level-10            |      100        0        0        0        0        0
 4d level-13            |        6       10        7       16       13       11
 4e level-14            |      100        0        0        0        1        0

EXAMPLE 2 Using `trapset` with CPU Filtering

The `-c` option can be used to limit the CPUs on which `trapstat` is enabled. This example limits `CPU` 1 and CPUs 12 through 15.

```
example# trapstat -c 1,12-15
```

```
vct  name                |     cpu1    cpu12    cpu13    cpu14    cpu15
-------------------------+-----------------------------------------------
 24 cleanwin             |     6923     3072     2500     3518     2261
 44 level-4              |        3        0        0        1        1
 49 level-9              |      100      100      100      100      100
 4d level-13             |       23        8       14       19       14
 60 int-vec              |     2559     2699     2752     2688     2792

```

EXAMPLE 3 Using `trapstat` with TLB Statistics

The `-t` option displays in-depth TLB statistics, including the amount of time spent performing TLB miss processing. The following example shows that the machine is spending 14.1 percent of its time just handling D-TLB misses:

```
example# trapstat -t
cpu m| itlb-miss %tim itsb-miss %tim | dtlb-miss %tim dtsb-miss %tim |%tim
-----+-------------------------------+-------------------------------+----
  0 u|      2571  0.3         0  0.0 |     10802  1.3         0  0.0 | 1.6
  0 k|         0  0.0         0  0.0 |    106420 13.4       184  0.1 |13.6
-----+-------------------------------+-------------------------------+----
  1 u|      3069  0.3         0  0.0 |     10983  1.2       100  0.0 | 1.6
  1 k|        27  0.0         0  0.0 |    106974 12.6        19  0.0 |12.7
-----+-------------------------------+-------------------------------+----

  4 k|        31  0.0         0  0.0 |    107977 13.0       236  0.1 |13.1
=====+===============================+===============================+====
 ttl |     14816  0.3         0  0.0 |    585937 14.1      1009  0.0 |14.5
```

EXAMPLE 4 Using `trapstat` with TLB Statistics and Page Size Information

By specifying the `-T` option, `trapstat` shows TLB misses broken down by page size. In this example, CPU 0 is spending 7.9 percent of its time handling user-mode TLB misses on 8K pages, and another 2.3 percent of its time handling user-mode TLB misses on 64K pages.

```
example# trapstat -T -c 0
cpu m size| itlb-miss %tim itsb-miss %tim | dtlb-miss %tim dtsb-miss %tim |%tim
----------+-------------------------------+-------------------------------+----
  0 u   8k|      1300  0.1        15  0.0 |    104897  7.9        90  0.0 | 8.0
  0 u  64k|         0  0.0         0  0.0 |     29935  2.3         7  0.0 | 2.3
  0 u 512k|         0  0.0         0  0.0 |      3569  0.2         2  0.0 | 0.2
  0 u   4m|         0  0.0         0  0.0 |       233  0.0         2  0.0 | 0.0

```

EXAMPLE 5 Using `trapstat` with Entry Filtering

By specifying the `-e` option, `trapstat` displays statistics for only specific trap types. Using this option minimizes the probe effect when seeking specific data. This example yields statistics for only the *dtlb-prot* and *syscall-32* traps on CPUs 12 through 15:

```
example# trapstat -e dtlb-prot,syscall-32 -c 12-15
vct  name                |    cpu12    cpu13    cpu14    cpu15
-------------------------+-----------------------------------
 6c dtlb-prot            |      817      754     1018      560
108 syscall-32           |     1426     1647     2186     1142

vct  name                |    cpu12    cpu13    cpu14    cpu15
-------------------------+-----------------------------------
 6c dtlb-prot            |     1085      996      800      707
108 syscall-32           |     2578     2167     1638     1452
```

EXAMPLE 6 Using `trapstat` with a Higher Sampling Rate

The following example uses the `-r` option to specify a sampling rate of 1000 samples per second, and filter only for the level-10 trap. Additionally, specifying the `-P` option yields parsable output.

Notice the timestamp difference between the level-10 events: 9,998,000 nanoseconds and 10,007,000 nanoseconds. These level-10 events correspond to the system clock, which by default ticks at 100 hertz (that is, every 10,000,000 nanoseconds).

```
example# trapstat -e level-10 -P -r 1000
1070400 0 4a level-10 0
2048600 0 4a level-10 0
3030400 0 4a level-10 1
4035800 0 4a level-10 0
5027200 0 4a level-10 0
6027200 0 4a level-10 0
7027400 0 4a level-10 0
8028200 0 4a level-10 0
9026400 0 4a level-10 0
10029600 0 4a level-10 0
11028600 0 4a level-10 0
12024000 0 4a level-10 0
13028400 0 4a level-10 1
14031200 0 4a level-10 0
15027200 0 4a level-10 0
16027600 0 4a level-10 0
17025000 0 4a level-10 0
18026000 0 4a level-10 0
19027800 0 4a level-10 0
20025600 0 4a level-10 0
21025200 0 4a level-10 0
22025000 0 4a level-10 0
```

EXAMPLE 6 Using `trapstat` with a Higher Sampling Rate *(Continued)*

```
23035400 0 4a level-10 1
24027400 0 4a level-10 0
25026000 0 4a level-10 0
26027000 0 4a level-10 0
```

The SPARC Architecture Manual, Version 9, 1994, Prentice-Hall.

Notes

When enabled, `trapstat` induces a varying probe effect, depending on the type of information collected. While the precise probe effect depends upon the specifics of the hardware, the following table can be used as a rough guide:

Option	Approximate probe effect
default	3-5% per trap
`-e`	3-5% per specified trap
`-t`, `-T`	40-45% per TLB miss trap hitting in the TSB, 25-30% per TLB miss trap missing in the TSB

These probe effects are *per trap* not for the system as a whole. For example, running `trapstat` with the default options on a system that spends 7% of total time handling traps induces a performance degradation of less than one half of one percent; running `trapstat` with the `-t` or `-T` option on a system spending 5% of total time processing TLB misses induce a performance degradation of no more than 2.5%.

When run with the `-t` or `-T` option, `trapstat` accounts for its probe effect when calculating the *%tim* fields. This assures that the *%tim* fields are a reasonably accurate indicator of the time a given workload is spending handling TLB misses — regardless of the perturbing presence of `trapstat`.

While the *%tim* fields include the explicit cost of executing the TLB miss handler, they do *not* include the implicit costs of TLB miss traps (for example, pipeline effects, cache pollution, etc). These implicit costs become more significant as the trap rate grows; if high *%tim* values are reported (greater than 50%), you can accurately infer that much of the balance of time is being spent on the implicit costs of the TLB miss traps.

Due to the potential system wide degradation induced, only the super-user can run `trapstat`.

Due to the limitation of the underlying statistics gathering methodology, only one instance of `trapstat` can run at a time.

Name ttyadm – format and output port monitor-specific information

Synopsis

```
/usr/sbin/ttyadm [-b] [-c] [-h] [-I] [-r count] [-i msg]
     [-m modules] [-p prompt] [-t timeout] [-S y | n]
     [-T termtype] -d device -l ttylabel -s service

/usr/sbin/ttyadm -V
```

Description The `ttyadm` command is an administrative command that formats `ttymon`(1M)-specific information and writes it to standard output. The Service Access Facility (SAF) requires each port monitor to provide such a command. Note that the port monitor administrative file is updated by the Service Access Controller's administrative commands, `sacadm`(1M) and `pmadm`(1M). `ttyadm` provides a means of presenting formatted port monitor-specific (`ttymon`-specific) data to these commands.

Options The following options are supported:

`-b` Set the "bi-directional port" flag. When this flag is set, the line can be used in both directions. `ttymon` will allow users to connect to the service associated with the port, but if the port is free, `uucico`(1M), `cu`(1C), or `ct`(1C) can use it for dialing out.

`-c` Set the connect-on-carrier flag for the port. If the `-c` flag is set, `ttymon` will invoke the port's associated service immediately when a connect indication is received (that is, no prompt is printed and no baud-rate searching is done).

`-d` *device* *device* is the full pathname of the device file for the TTY port.

`-h` Set the hangup flag for the port. If the `-h` flag is not set, `ttymon` will force a hangup on the line by setting the speed to `0` before setting the speed to the default or specified value.

`-i` *message* Specify the inactive (disabled) response message. This message will be sent to the TTY port if the port is disabled or the `ttymon` monitoring the port is disabled.

`-I` Initialize only. If the `-I` option is used, `ttymon` will invoke the service only once. This can be used to configure a particular device without actually monitoring it, as with software carrier.

`-l` *ttylabel* Specify which *ttylabel* in the `/etc/ttydefs` file to use as the starting point when searching for the proper baud rate.

`-m` *modules* Specify a list of pushable STREAMS modules. The modules will be pushed in the order in which they are specified before the service is invoked. *modules* must be a comma-separated list of modules, with no white space included. Any modules currently on the stream will be popped before these modules are pushed.

`-p` *prompt* Specify the prompt message, for example, "`login:`".

`-r` *count* — When the `-r` option is invoked, `ttymon` will wait until it receives data from the port before it displays a prompt. If *count* is `0`, `ttymon` will wait until it receives any character. If *count* is greater than `0`, `ttymon` will wait until *count* newlines have been received.

`-s` *service* — *service* is the full pathname of the service to be invoked when a connection request is received. If arguments are required, the command and its arguments must be enclosed in double quotes (" ").

`-S y|n` — Set the software carrier value. `y` will turn software carrier on. `n` will turn software carrier off.

`-t` *timeout* — Specify that `ttymon` should close a port if the open on the port succeeds, and no input data is received in *timeout* seconds.

`-T` *termtype* — Set the terminal type. The `TERM` environment variable will be set to *termtype*.

`-V` — Display the version number of the current `/usr/lib/saf/ttymon` command.

Output If successful, `ttyadm` will generate the requested information, write it to standard output, and exit with a status of `0`. If `ttyadm` is invoked with an invalid number of arguments or invalid arguments, or if an incomplete option is specified, an error message will be written to standard error and `ttymon` will exit with a non-zero status.

System Administration Guide: Basic Administration

Name ttymon – port monitor for terminal ports

Synopsis

```
/usr/lib/saf/ttymon

/usr/lib/saf/ttymon  -g [-d device] [-h] [-t timeout]
 [-l ttylabel] [-p prompt] [-m modules] [-T termtype]
```

Description `ttymon` is a STREAMS-based TTY port monitor. Its function is to monitor ports, to set terminal modes, baud rates, and line disciplines for the ports, and to connect users or applications to services associated with the ports. Normally, `ttymon` is configured to run under the Service Access Controller, `sac(1M)`, as part of the Service Access Facility (SAF). It is configured using the `sacadm(1M)` command. Each instance of `ttymon` can monitor multiple ports. The ports monitored by an instance of `ttymon` are specified in the port monitor's administrative file. The administrative file is configured using the `pmadm(1M)` and `ttyadm(1M)` commands. When an instance of `ttymon` is invoked by the `sac` command, it starts to monitor its ports. For each port, `ttymon` first initializes the line disciplines, if they are specified, and the speed and terminal settings. For ports with entries in `/etc/logindevperm`, device owner, group and permissions are set. (See `logindevperm(4)`.) The values used for initialization are taken from the appropriate entry in the TTY settings file. This file is maintained by the `sttydefs(1M)` command. Default line disciplines on ports are usually set up by the `autopush(1M)` command of the Autopush Facility.

`ttymon` then writes the prompt and waits for user input. If the user indicates that the speed is inappropriate by pressing the BREAK key, `ttymon` tries the next speed and writes the prompt again. When valid input is received, `ttymon` interprets the per-service configuration file for the port, if one exists, creates a `utmpx` entry if required (see `utmpx(4)`), establishes the service environment, and then invokes the service associated with the port. Valid input consists of a string of at least one non-newline character, terminated by a carriage return. After the service terminates, `ttymon` cleans up the `utmpx` entry, if one exists, and returns the port to its initial state.

If *autobaud* is enabled for a port, `ttymon` will try to determine the baud rate on the port automatically. Users must enter a carriage return before `ttymon` can recognize the baud rate and print the prompt. Currently, the baud rates that can be determined by *autobaud* are `110`, `1200`, `2400`, `4800`, and `9600`.

If a port is configured as a bidirectional port, `ttymon` will allow users to connect to a service, and, if the port is free, will allow `uucico(1M)`, `cu(1C)`, or `ct(1C)` to use it for dialing out. If a port is bidirectional, `ttymon` will wait to read a character before it prints a prompt.

If the *connect-on-carrier* flag is set for a port, `ttymon` will immediately invoke the port's associated service when a connection request is received. The prompt message will not be sent.

If a port is disabled, `ttymon` will not start any service on that port. If a disabled message is specified, `ttymon` will send out the disabled message when a connection request is received. If `ttymon` is disabled, all ports under that instance of `ttymon` will also be disabled.

Service Invocation

The service `ttymon` invokes for a port is specified in the `ttymon` administrative file. `ttymon` will scan the character string giving the service to be invoked for this port, looking for a `%d` or a `%%` two-character sequence. If `%d` is found, `ttymon` will modify the service command to be executed by replacing those two characters by the full path name of this port (the device name). If `%%` is found, they will be replaced by a single `%`. When the service is invoked, file descriptor `0`, `1`, and `2` are opened to the port device for reading and writing. The service is invoked with the user ID, group ID and current home directory set to that of the user name under which the service was registered with `ttymon`. Two environment variables, `HOME` and `TTYPROMPT`, are added to the service's environment by `ttymon`. `HOME` is set to the home directory of the user name under which the service is invoked. `TTYPROMPT` is set to the prompt string configured for the service on the port. This is provided so that a service invoked by `ttymon` has a means of determining if a prompt was actually issued by `ttymon` and, if so, what that prompt actually was.

See `ttyadm(1M)` for options that can be set for ports monitored by `ttymon` under the Service Access Controller.

System Console Invocation

The invocation of ttymon on the system console is managed under `smf(5)` by the service `svc:/system/console-login`. It provides a number of properties within the property group `ttymon` to control the invocation, as follows:

```
NAME                 TYPE              TTYMON OPTION
-------------------------------------------------------------
device               astring           [-d device]
nohangup             boolean           [-h]
label                astring           [-l label]
modules              astring           [-m module1,module2]
prompt               astring           [-p prompt]
timeout              count             [-t timeout]
terminal_type        astring           [-T termtype]
```

If any value is the empty string or an integer set to zero, then the option is not passed to the ttymon invocation. The `-g` option is always specified for this invocation. The `-d` option always defaults to `/dev/console` if it is not set.

See `EXAMPLES`.

Security

`ttymon` uses `pam(3PAM)` for session management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the modules to be used for `ttymon`. Here is a partial `pam.conf` file with entries for `ttymon` using the UNIX session management module.

```
ttymon session  required /usr/lib/security/pam_unix_session.so.1
```

If there are no entries for the `ttymon` service, then the entries for the "other" service will be used.

Options The following options are supported:

`-g` A special invocation of `ttymon` is provided with the `-g` option. This form of the command should only be called by applications that need to set the correct baud rate and terminal settings on a port and then connect to `login` service, but that cannot be pre-configured under the SAC. The following combinations of options can be used with `-g`:

`-d`*device* *device* is the full path name of the port to which `ttymon` is to attach. If this option is not specified, file descriptor `0` must be set up by the invoking process to a TTY port.

`-h` If the -h flag is not set, `ttymon` will force a hangup on the line by setting the speed to zero before setting the speed to the default or specified speed.

`-l`*ttylabel* *ttylabel* is a link to a speed and TTY definition in the `ttydefs` file. This definition tells `ttymon` at what speed to run initially, what the initial TTY settings are, and what speed to try next if the user indicates that the speed is inappropriate by pressing the BREAK key. The default speed is 9600 baud.

`-m`*modules* When initializing the port, `ttymon` will pop all modules on the port, and then push *modules* in the order specified. *modules* is a comma-separated list of pushable modules. Default modules on the ports are usually set up by the Autopush Facility.

`-p`*prompt* Allows the user to specify a prompt string. The default prompt is `Login:`.

`-t`*timeout* Specifies that `ttymon` should exit if no one types anything in *timeout* seconds after the prompt is sent.

`-T`*termtype* Sets the `TERM` environment variable to *termtype*.

Examples **EXAMPLE 1** Setting the Terminal Type

The following example sets the value of the terminal type (`-T`) option for the system console `ttymon` invocation:

```
svccfg -s svc:/system/console-login setprop \
    ttymon/terminal_type = "xterm"
svcadm refresh svc:/system/console-login:default
```

Environment Variables If any of the `LC_*` variables (`LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `LC_COLLATE`, `LC_NUMERIC`, and `LC_MONETARY`) (see `environ(5)`) are not set in the environment, the operational behavior of `ttymon` for each corresponding locale category is determined by the value of the `LANG` environment variable. If `LC_ALL` is set, its contents are used to override both the `LANG` and the other `LC_*` variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how `ttymon` behaves.

`LC_CTYPE` Determines how `ttymon` handles characters. When `LC_CTYPE` is set to a valid value, `ttymon` can display and handle text and filenames containing valid characters for that locale. `ttymon` can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. `ttymon` can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

Files `/etc/logindevperm`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Stability	See below.

The command-line syntax is Stable. The SMF properties are Evolving.

See Also `ct(1C)`, `cu(1C)`, `autopush(1M)`, `pmadm(1M)`, `sac(1M)`, `sacadm(1M)`, `sttydefs(1M)`, `ttyadm(1M)`, `uucico(1M)`, `pam(3PAM)`, `logindevperm(4)`, `pam.conf(4)`, `utmpx(4)`, `attributes(5)`, `environ(5)`, `pam_authtok_check(5)`, `pam_authtok_get(5)`, `pam_authtok_store(5)`, `pam_dhkeys(5)`, `pam_passwd_auth(5)`, `pam_unix_account(5)`, `pam_unix_auth(5)`, `pam_unix_session(5)`, `smf(5)`

System Administration Guide: Basic Administration

Notes If a port is monitored by more than one `ttymon`, it is possible for the `ttymons` to send out prompt messages in such a way that they compete for input.

The `pam_unix`(5) module is no longer supported. Similar functionality is provided by `pam_authtok_check(5)`, `pam_authtok_get(5)`, `pam_authtok_store(5)`, `pam_dhkeys(5)`, `pam_passwd_auth(5)`, `pam_unix_account(5)`, `pam_unix_auth(5)`, and `pam_unix_session(5)`.

Name tunefs – tune an existing UFS file system

Synopsis

```
tunefs [-a maxcontig] [-d rotdelay] [-e maxbpg]
     [-m minfree] [-o space | time] special | filesystem
```

Description `tunefs` is designed to change the dynamic parameters of a file system that affect the layout policies. When using `tunefs` with *filesystem*, *filesystem* must be in `/etc/vfstab`. The parameters that can be changed are indicated by the options given below.

Options The following options are supported:

`-a` *maxcontig* The maximum number of logical blocks, belonging to one file, that is allocated contiguously. The default is calculated as follows:

`maxcontig =` *disk drive maximum transfer size / disk block size*

If the disk drive's maximum transfer size cannot be determined, the default value for `maxcontig` is calculated from kernel parameters as follows:

If `maxphys` is less than `ufs_maxmaxphys`, which is 1 Mbyte, then `maxcontig` is set to `maxphys`. Otherwise, `maxcontig` is set to `ufs_maxmaxphys`.

You can set `maxcontig` to any positive integer value.

The actual value will be the lesser of what has been specified and what the hardware supports.

`-d` *rotdelay* This parameter is obsolete as of the Solaris 10 release. The value is always set to `0`, regardless of the input value.

`-e` *maxbpg* Indicates the maximum number of contiguous logical blocks any single file can allocate from a cylinder group before it is forced to begin allocating blocks from another cylinder group. Typically this value is set to approximately one quarter of the total contiguous logical blocks in a cylinder group. The intent is to prevent any single file from using up all the blocks in a single cylinder group, thus degrading access times for all files subsequently allocated in that cylinder group.

The effect of this limit is to cause big files to do long seeks more frequently than if they were allowed to allocate all the blocks in a cylinder group before seeking elsewhere. For file systems with exclusively large files, this parameter should be set higher.

`-m` *minfree* Specifies the minimum free space threshold, or the percentage of space held back from normal users. This value can be set to `0`. However, up to a factor of three in throughput will be lost over the performance obtained at a 10% threshold. *Note:* If the value is raised above the current usage level, users will be unable to allocate files until enough files have been deleted to get under the higher threshold.

-o *space* | *time* The file system can either be instructed to try to minimize the *time* spent allocating blocks, or to try to minimize the *space* fragmentation on the disk. The default is *time*.

Generally, you should optimize for time unless the file system is over 90% full.

Usage See `largefile(5)` for the description of the behavior of `tunefs` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `mkfs_ufs(1M)`, `newfs(1M)`, `attributes(5)`, `largefile(5)`

Name txzonemgr – Trusted Extensions Zone Manager Configuration Utility

Synopsis

```
/usr/sbin/txzonemgr
```

Description The `txzonemgr` shell script provides a simple menu-based GUI wizard for creating, installing, initializing, and booting labeled zones on a system where Trusted Extensions is enabled. The script provides contextual menus with appropriate choices.

`txzonemgr` is run by roles granted in the Zone Management Rights Profile, or by root in the global zone. It takes no options and returns no values.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Command Interface Stability	Committed
Interactive Dialogue	Not an Interface

See Also `zenity`(1), `ifconfig(1M)`, `zoneadm(1M)`, `zonecfg(1M)`, `attributes(5)`, `rbac(5)`, `zones(5)`

Solaris Trusted Extensions Administrator's Procedures

Notes If administering zones from JDS, use `txzonemgr` rather than CDE actions.

`txzonemgr` uses the `zenity` command. For details, see the `zenity`(1) man page.

Name tzreload – notify timezone update

Synopsis

```
/usr/sbin/tzreload [-a]
```

Description The `tzreload` command notifies active (running) processes to reread timezone information. The timezone information is cached in each process, absent a `tzreload` command, is never reread until a process is restarted. In response to a `tzreload` command, active processes reread the current timezone information at the next call to `ctime(3C)` and `mktime(3C)`. By default, the `tzreload` notification is sent to the processes within the current zone.

In addition to notifying active processes, the `tzreload` command also notifies cron(1M), to reinitialize the job scheduler with the new timezone information.

Options The following options are supported:

`-a`
Notify processes in all zones.

Files `/usr/share/lib/zoneinfo`
Standard zone information directory.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs
Interface Stability	Committed

See Also `cron(1M)`, `zdump(1M)`, `zic(1M)`, `zoneadm(1M)`, `ctime(3C)`, `mktime(3C)`, `attributes(5)`

`rpc.cmsd(1M)`, part of the CDE man page set.

Notes Although `tzreload` reinitializes `cron(1M)`, applications that are affected by timezone changes still need to be restarted or reinitialized if they do not reread the new timezone information before timezone changes take place.

Name tzselect – select a time zone

Synopsis

```
/usr/bin/tzselect
```

Description The `tzselect` program asks you a series of questions about the current location and outputs the resulting time zone description to standard output. The output is suitable as a value for the `TZ` environment variable.

All user interaction is through standard input and standard error.

Options The `tzselect` command has no options.

Exit Status The following exit values are returned:

`0` Timezone information was successfully obtained.

`>0` An error occurred.

Files `/usr/share/lib/zoneinfo` directory containing timezone data files

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Stability	Evolving

See Also `zdump(1M)`, `zic(1M)`, `ctime(3C)`, `attributes(5)`

Name uadmin – administrative control

Synopsis

```
/usr/sbin/uadmin cmd fcn [mdep]

/sbin/uadmin cmd fcn [mdep]
```

Description The `uadmin` command provides control for basic administrative functions. This command is tightly coupled to the system administration procedures and is not intended for general use. It may be invoked only by the super-user.

Both the *cmd* (command) and *fcn* (function) arguments are converted to integers and passed to the `uadmin` system call. The optional *mdep* (machine dependent) argument is only available for the *cmd* values of `1` (`A_REBOOT`), `2` (`A_SHUTDOWN`), or `5` (`A_DUMP`). For any other *cmd* value, no *mdep* command-line argument is allowed.

When passing an *mdep* value that contains whitespaces, the string must be grouped together as a single argument enclosed within quotes, for example:

```
uadmin 1 1 “-s kernel/unix”
```

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `halt(1M)`, `reboot(1M)`, `uadmin(2)`, `attributes(5)`

Warnings Shutting down or halting the system by means of `uadmin` does not update the boot archive. Avoid using this command after

- editing of files such as `/etc/system`
- installing new driver binaries or kernel binaries
- updating existing driver binaries or kernel binaries.

Use `reboot(1M)` or `halt(1M)` instead.

Name ucodeadm – update processor microcode

Synopsis

```
/usr/sbin/ucodeadm -v

/usr/sbin/ucodeadm -umicrocode-text-file

/usr/sbin/ucodeadm -i [-R path] microcode-text-file
```

Description The `ucodeadm` utility can be used to report running microcode revision on the processors, update microcode, or install microcode on the target system to be used during the boot process.

The *microcode-text-file* can be obtained from processor vendors.

Options

`-v` Report microcode revision.

`-u` *microcode-text-file* Update microcode on all cross-call interrupt ready processors.

`-i` *microcode-text-file* Install microcode files on target system to be used during the next boot cycle. The text file name must have the vendor name prefix, such as "`intel`" or "`amd`".

By default the microcode files will be installed at:

```
/platform/i86pc/ucode/$VENDORSTR/
```

where `VENDORSTR` is either "`GenuineIntel`" or "`AuthenticAMD`".

`-R` *alternate path* Install *microcode* path in the *alternate path*.

Examples

EXAMPLE 1 Reporting the Microcode Revision

The following example displays the microcode revision that is currently running:

```
# ucodeadm -v
```

EXAMPLE 2 Updating the Processor Microcode

The following example updates the processor microcode to `intel-ucode.txt`:

```
# ucodeadm -u intel-ucode.txt
```

EXAMPLE 3 Installing the Microcode on the Target System

The following example installs the microcode on the target system, `/export/ucode-path`:

```
# ucodeadm -i -R /export/ucode-path intel-ucode.txt
```

If an alternate path is used when installing the microcode on the target system, the installed microcode file is not used on the next boot cycle.

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Stable

See Also psradm(1M), psrinfo(1M), attributes(5)

Name ufsdump – incremental file system dump

Synopsis `/usr/sbin/ufsdump [`*options*`] [`*arguments*`]` *files_to_dump*

Description `ufsdump` backs up all files specified by *files_to_dump* (usually either a whole file system or files within a file sytem changed after a certain date) to magnetic tape, diskette, or disk file.

The `ufsdump` command can only be used on unmounted file systems, or those mounted read-only. Attempting to dump a mounted, read-write file system might result in a system disruption or the inability to restore files from the dump. Consider using the `fssnap(1M)` command to create a file system snapshot if you need a point-in-time image of a file system that is mounted.

If a filesystem was mounted with the logging option, it is strongly recommended that you run `ufsdump` as the root user. Running the command as a non-root user might result in the creation of an inconsistent dump.

options is a single string of one-letter `ufsdump` options.

arguments may be multiple strings whose association with the options is determined by order. That is, the first argument goes with the first option that takes an argument; the second argument goes with the second option that takes an argument, and so on.

files_to_dump is required and must be the last argument on the command line. See `OPERANDS` for more information.

With most devices `ufsdump` can automatically detect the end-of-media. Consequently, the `d`, `s`, and `t` options are not necessary for multi-volume dumps, unless `ufsdump` does not understand the way the device detects the end-of-media, or the files are to be restored on a system with an older version of the `restore` command.

Options The following options are supported:

`0`–`9`
The "dump level." All files specified by *files_to_dump* that have been modified since the last `ufsdump` at a lower dump level are copied to the *dump_file* destination (normally a magnetic tape device). For instance, if a "level `2`" dump was done on Monday, followed by a "level `4`" dump on Tuesday, a subsequent "level `3`" dump on Wednesday would contain all files modified or added since the "level `2`" (Monday) backup. A "level `0`" dump copies the entire file system to the *dump_file*.

`a` *archive_file*
Archive file. Archive a dump table-of-contents in the specified *archive_file* to be used by `ufsrestore(1M)` to determine whether a file is in the dump file that is being restored.

`b` *factor*
Blocking factor. Specify the blocking factor for tape writes. The default is 20 blocks per write for tapes of density less than 6250BPI (bytes-per-inch). The default blocking factor for tapes of density 6250BPI and greater is 64. The default blocking factor for cartridge

tapes (c option) is 126. The highest blocking factor available with most tape drives is 126. Note: the blocking factor is specified in terms of 512-byte blocks, for compatibility with tar(1).

c

Cartridge. Set the defaults for cartridge instead of the standard half-inch reel. This sets the density to 1000BPI and the blocking factor to 126. Since ufsdump can automatically detect the end-of-media, only the blocking parameter normally has an effect. When cartridge tapes are used, and this option is *not* specified, ufsdump will slightly miscompute the size of the tape. If the b, d, s or t options are specified with this option, their values will override the defaults set by this option.

d *bpi*

Tape density. Not normally required, as ufsdump can detect end-of-media. This parameter can be used to keep a running tab on the amount of tape used per reel. The default density is 6250BPI except when the c option is used for cartridge tape, in which case it is assumed to be 1000BPI per track. Typical values for tape devices are:

1/2 inch tape
6250 BPI

1/4 inch cartridge
1000 BPI The tape densities and other options are documented in the st(7D) man page.

D

Diskette. Dump to diskette.

f *dump_file*

Dump file. Use *dump_file* as the file to dump to, instead of /dev/rmt/0. If *dump_file* is specified as –, dump to standard output.

If the name of the file is of the form *machine*:*device,* the dump is done from the specified machine over the network using rmt(1M). Since ufsdump is normally run by root, the name of the local machine must appear in the /.rhosts file of the remote machine. If the file is specified as *user*@*machine*:*device,* ufsdump will attempt to execute as the specified user on the remote machine. The specified user must have a .rhosts file on the remote machine that allows the user invoking the command from the local machine to access the remote machine.

l

Autoload. When the end-of-tape is reached before the dump is complete, take the drive offline and wait up to two minutes for the tape drive to be ready again. This gives autoloading (stackloader) tape drives a chance to load a new tape. If the drive is ready within two minutes, continue. If it is not, prompt for another tape and wait.

L *string*

Sets the tape label to *string*, instead of the default `none`. *string* may be no more than sixteen characters long. If it is longer, it is truncated and a warning printed; the dump will still be done. The tape label is specific to the `ufsdump` tape format, and bears no resemblance to IBM or ANSI-standard tape labels.

n

Notify all operators in the `sys` group that `ufsdump` requires attention by sending messages to their terminals, in a manner similar to that used by the `wall(1M)` command. Otherwise, such messages are sent only to the terminals (such as the console) on which the user running `ufsdump` is logged in.

N *device_name*

Use *device_name* when recording information in `/etc/dumpdates` (see the `u` option) and when comparing against information in `/etc/dumpdates` for incremental dumps. The *device_name* provided can contain no white space as defined in `scanf(3C)` and is case-sensitive.

o

Offline. Take the drive offline when the dump is complete or the end-of-media is reached and rewind the tape, or eject the diskette. In the case of some autoloading 8mm drives, the tape is removed from the drive automatically. This prevents another process which rushes in to use the drive, from inadvertently overwriting the media.

s *size*

Specify the *size* of the volume being dumped to. Not normally required, as `ufsdump` can detect end-of-media. When the specified size is reached, `ufsdump` waits for you to change the volume. `ufsdump` interprets the specified size as the length in feet for tapes and cartridges, and as the number of 1024-byte blocks for diskettes. The values should be a little smaller than the actual physical size of the media (for example, 425 for a 450-foot cartridge). Typical values for tape devices depend on the `c` option, for cartridge devices, and the `D` option for diskettes:

1/2 inch tape
: 2300 feet

60-Mbyte 1/4 inch cartridge
: 425 feet

150-Mbyte 1/4 inch cartridge
: 700 feet

diskette
: 1422 blocks (Corresponds to a 1.44-Mbyte diskette, with one cylinder reserved for bad block information.)

S
Size estimate. Determine the amount of space that is needed to perform the dump without actually doing it, and display the estimated number of bytes it will take. This is useful with incremental dumps to determine how many volumes of media will be needed.

t *tracks*
Specify the number of tracks for a cartridge tape. Not normally required, as `ufsdump` can detect end-of-media. The default is 9 tracks. The `t` option is not compatible with the `D` option. Values for Sun-supported tape devices are:

60-Mbyte 1/4 inch cartridge
9 tracks

150-Mbyte 1/4 inch cartridge
18 tracks

T *time_wait*[hms]
Sets the amount of time to wait for an `autoload` command to complete. This option is ignored unless the `l` option has also been specified. The default time period to wait is two minutes. Specify time units with a trailing `h` (for hours), `m` (for minutes), or `s` (for seconds). The default unit is minutes.

u
Update the dump record. Add an entry to the file `/etc/dumpdates`, for each file system successfully dumped that includes the file system name (or *device_name* as specified with the `N` option), date, and dump level.

v
Verify. After each tape or diskette is written, verify the contents of the media against the source file system. If any discrepancies occur, prompt for new media, then repeat the dump/verification process. The file system *must* be unmounted. This option cannot be used to verify a dump to standard output.

w
Warning. List the file systems that have not been backed up within a day. This information is gleaned from the files `/etc/dumpdates` and `/etc/vfstab`. When the `w` option is used, all other options are ignored. After reporting, `ufsdump` exits immediately.

W
Warning with highlight. Similar to the `w` option, except that the `W` option includes all file systems that appear in `/etc/dumpdates`, along with information about their most recent dump dates and levels. File systems that have not been backed up within a day are highlighted.

Operands The following operand is supported:

files_to_dump
Specifies the files to dump. Usually it identifies a whole file system by its raw device name (for example, `/dev/rdsk/c0t3d0s6`). Incremental dumps (levels `1` to `9`) of files changed

after a certain date only apply to a whole file system. Alternatively, *files_to_dump* can identify individual files or directories. All named directories that may be examined by the user running `ufsdump`, as well as any explicitly-named files, are dumped. This dump is equivalent to a level `0` dump of the indicated portions of the filesystem, except that `/etc/dumpdates` is not updated even if the `-u` option has been specified. In all cases, the files must be contained in the same file system, and the file system must be local to the system where `ufsdump` is being run.

files_to_dump is required and must be the last argument on the command line.

If no *options* are given, the default is `9uf /dev/rmt/0` *files_to_dump*.

Usage See `largefile(5)` for the description of the behavior of `ufsdump` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples **EXAMPLE 1** Using `ufsdump`

The following command makes a full dump of a root file system on `c0t3d0`, on a 150-MByte cartridge tape unit `0`:

```
example# ufsdump 0cfu /dev/rmt/0 /dev/rdsk/c0t3d0s0
```

The following command makes and verifies an incremental dump at level `5` of the `usr` partition of `c0t3d0`, on a 1/2 inch reel tape unit `1,`:

```
example# ufsdump 5fuv /dev/rmt/1 /dev/rdsk/c0t3d0s6
```

Exit Status While running, `ufsdump` emits many verbose messages. `ufsdump` returns the following exit values:

`0`
Normal exit.

`1`
Startup errors encountered.

`3`
Abort – no checkpoint attempted.

Files `/dev/rmt/0`
default unit to dump to

`/etc/dumpdates`
dump date record

`/etc/group`
to find group `sys`

`/etc/hosts`
to gain access to remote system with drive

`/etc/vfstab`
list of file systems

Attributes See `attributes(5)` for descriptions of the following attributes:

Availability	SUNWcsu

See Also `cpio(1)`, `tar(1)`, `dd(1M)`, `devnm(1M)`, `fssnap(1M)`, `prtvtoc(1M)`, `rmt(1M)`, `shutdown(1M)`, `ufsrestore(1M)`, `volcopy(1M)`, `wall(1M)`, `scanf(3C)`, `ufsdump(4)`, `attributes(5)`, `largefile(5)`, `st(7D)`

Notes

Read Errors Fewer than 32 read errors on the file system are ignored.

Process Per Reel Because each reel requires a new process, parent processes for reels that are already written hang around until the entire tape is written.

Operator Intervention `ufsdump` requires operator intervention on these conditions: end of volume, end of dump, volume write error, volume open error or disk read error (if there are more than a threshold of 32). In addition to alerting all operators implied by the `n` option, `ufsdump` interacts with the operator on `ufsdump`'s control terminal at times when `ufsdump` can no longer proceed, or if something is grossly wrong. All questions `ufsdump` poses *must* be answered by typing `yes` or `no`, as appropriate.

Since backing up a disk can involve a lot of time and effort, `ufsdump` checkpoints at the start of each volume. If writing that volume fails for some reason, `ufsdump` will, with operator permission, restart itself from the checkpoint after a defective volume has been replaced.

Suggested Dump Schedule It is vital to perform full, "level `0`", dumps at regular intervals. When performing a full dump, bring the machine down to single-user mode using `shutdown(1M)`. While preparing for a full dump, it is a good idea to clean the tape drive and heads. Incremental dumps should be performed with the system running in single-user mode.

Incremental dumps allow for convenient backup and recovery of active files on a more frequent basis, with a minimum of media and time. However, there are some tradeoffs. First, the interval between backups should be kept to a minimum (once a day at least). To guard against data loss as a result of a media failure (a rare, but possible occurrence), capture active files on (at least) two sets of dump volumes. Another consideration is the desire to keep unnecessary duplication of files to a minimum to save both operator time and media storage. A third consideration is the ease with which a particular backed-up version of a file can be located and restored. The following four-week schedule offers a reasonable tradeoff between these goals.

```
           Sun     Mon     Tue     Wed     Thu     Fri
Week 1:    Full    5       5       5       5       3
Week 2:            5       5       5       5       3
Week 3:            5       5       5       5       3
Week 4:            5       5       5       5       3
```

Although the Tuesday through Friday incrementals contain “extra copies” of files from Monday, this scheme assures that any file modified during the week can be recovered from the previous day's incremental dump.

Process Priority of ufsdump

`ufsdump` uses multiple processes to allow it to read from the disk and write to the media concurrently. Due to the way it synchronizes between these processes, any attempt to run dump with a `nice` (process priority) of ‘–5' or better will likely make `ufsdump` run *slower* instead of faster.

Overlapping Partitions

Most disks contain one or more overlapping slices because slice 2 covers the entire disk. The other slices are of various sizes and usually do not overlap. For example, a common configuration places `root` on slice 0, `swap` on slice 1, `/opt` on slice 5 and `/usr` on slice 6.

It should be emphasized that `ufsdump` dumps one `ufs` file system at a time. Given the above scenario where slice 0 and slice 2 have the same starting offset, executing `ufsdump` on slice 2 with the intent of dumping the entire disk would instead dump only the `root` file system on slice 0. To dump the entire disk, the user must dump the file systems on each slice separately.

Bugs

The `/etc/vfstab` file does not allow the desired frequency of backup for file systems to be specified (as `/etc/fstab` did). Consequently, the `w` and `W` options assume file systems should be backed up daily, which limits the usefulness of these options.

Name ufsrestore – incremental file system restore

Synopsis

```
/usr/sbin/ufsrestore i | r | R | t | x [abcdfhlmostvyLT]
     [archive_file] [factor] [dumpfile] [n] [label]
     [timeout] [filename]...
```

Description The `ufsrestore` utility restores files from backup media created with the `ufsdump` command. `ufsrestores`'s actions are controlled by the *key* argument. The *key* is exactly one `function` *letter* (`i`, `r`, `R`, `t`, or `x`) and zero or more *function modifiers* (letters). The *key* string contains no SPACE characters. Function modifier arguments are listed on the command line in the same order as their corresponding function modifiers appear in the *key* string.

filename arguments which appear on the command line, or as arguments to an interactive command, are treated as shell `glob` patterns by the `x` and `t` functions; any files or directories matching the patterns are selected. The metacharacters `*`, `?`, and `[ ]` must be protected from the shell if they appear on the command line. There is no way to quote these metacharacters to explicitly match them in a filename.

The temporary files `rstdir*` and `rstmode*` are placed in `/tmp` by default. If the environment variable `TMPDIR` is defined with a non-empty value, that location is used instead of `/tmp`.

Options

Function Letters You must specify one (and only one) of the function letters listed below. Note that `i`, `x`, and `r` are intended to restore files into an empty directory. The `R` function is intended for restoring into a populated directory.

`i` Interactive. After reading in the directory information from the media, `ufsrestore` invokes a shell-like interface that allows you to browse through the dump file's directory hierarchy and select individual files to be extracted. Restoration has the same semantics as `x` (see below). See `Interactive Commands`, below, for a description of available commands.

`r` Recursive. Starting with an empty directory and a level 0 dump, the `r` function recreates the filesystem relative to the current working directory, exactly as it appeared when the dump was made. Information used to restore incremental dumps on top of the full dump (for example, `restoresymtable`) is also included. Several `ufsrestore` runs are typical, one for each higher level of dump (0, 1, ..., 9). Files that were deleted between the level 0 and a subsequent incremental dump will not exist after the final restore. To completely restore a file system, use the `r` function restore the level 0 dump, and again for each incremental dump. Although this function letter is intended for a complete restore onto a new file system (one just created with `newfs(1M)`), if the file system contains files not on the backup media, they are preserved.

`R` Resume restoring. If an `r`-mode `ufsrestore` was interrupted, this function prompts for the volume from which to resume restoring and continues the restoration from where it was left off. Otherwise identical to `r`.

t Table of contents. List each *filename* that appears on the media. If no *filename* argument is given, the root directory is listed. This results in a list of all files on the media, unless the `h` function modifier is in effect. The table of contents is taken from the media or from the specified archive file, when the `a` function modifier is used. The `a` function modifier is mutually exclusive with the `x` and `r` function letters.

x Extract the named files from the media. Files are restored to the same relative locations that they had in the original file system.

If the *filename* argument matches a directory whose contents were written onto the media, and the `h` modifier is not in effect, the directory is recursively extracted, relative to the current directory, which is expected to be empty. For each file, the owner, modification time, and mode are restored (if possible).

If you omit the *filename* argument or specify `.`, the root directory is extracted. This results in the entire tape being extracted, unless the `h` modifier is in effect. . With the `x` function, existing files are overwritten and `ufsrestore` displays the names of the overwritten files. Overwriting a currently-running executable can have unfortunate consequences.

Use the `x` option to restore partial file system dumps, as they are (by definition) not entire file systems.

Function Modifiers

a *archive_file* Read the table of contents from *archive_file* instead of the media. This function modifier can be used in combination with the `t`, `i`, or `x` function letters, making it possible to check whether files are on the media without having to mount the media. When used with the `x` and interactive (`i`) function letters, it prompts for the volume containing the file(s) before extracting them.

b *factor* Blocking factor. Specify the blocking factor for tape reads. For variable length SCSI tape devices, unless the data was written with the default blocking factor, a blocking factor at least as great as that used to write the tape must be used; otherwise, an error will be generated. Note that a tape block is 512 bytes. Refer to the man page for your specific tape driver for the maximum blocking factor.

c Convert the contents of the media in 4.1BSD format to the new `ufs` file system format.

d Debug. Turn on debugging output.

f *dump_file* Use *dump_file* instead of `/dev/rmt/0` as the file to restore from. Typically *dump_file* specifies a tape or diskette drive. If *dump_file* is specified as '–', `ufsrestore` reads from the standard input. This allows `ufsdump(1M)` and `ufsrestore` to be used in a pipeline to copy a file system:

```
example# ufsdump 0f - /dev/rdsk/c0t0d0s7 \
 | (cd /home;ufsrestore xf -)
```

If the name of the file is of the form *machine*:*device*, the restore is done from the specified machine over the network using `rmt(1M)`. Since `ufsrestore` is normally run by root, the name of the local machine must appear in the `/.rhosts` file of the remote machine. If the file is specified as *user*`@`*machine*:*device*, `ufsrestore` will attempt to execute as the specified user on the remote machine. The specified user must have a `.rhosts` file on the remote machine that allows the user invoking the command from the local machine to access the remote machine.

h — Extract or list the actual directory, rather than the files that it references. This prevents hierarchical restoration of complete subtrees from the tape.

l — Autoload. When the end-of-tape is reached before the restore is complete, take the drive off-line and wait up to two minutes (the default, see the `T` function modifier) for the tape drive to be ready again. This gives autoloading (stackloader) tape drives a chance to load a new tape. If the drive is ready within two minutes, continue. If it is not, prompt for another tape and wait.

L *label* — The label that should appear in the header of the dump file. If the labels do not match, `ufsrestore` issues a diagnostic and exits. The tape label is specific to the `ufsdump` tape format, and bears no resemblance to IBM or ANSI-standard tape labels.

m — Extract by inode numbers rather than by filename to avoid regenerating complete pathnames. Regardless of where the files are located in the dump hierarchy, they are restored into the current directory and renamed with their inode number. This is useful if only a few files are being extracted.

o — Offline. Take the drive off-line when the restore is complete or the end-of-media is reached and rewind the tape, or eject the diskette. In the case of some autoloading 8mm drives, the tape is removed from the drive automatically.

s *n* — Skip to the *n*th file when there are multiple dump files on the same tape. For example, the command:

```
example# ufsrestore xfs /dev/rmt/0hn 5
```

would position you to the fifth file on the tape when reading volume 1 of the dump. If a dump extends over more than one volume, all volumes except the first are assumed to start at position 0, no matter what "`s` *n*" value is specified.

If "`s` *n*" is specified, the backup media must be at BOT (beginning of tape). Otherwise, the initial positioning to read the table of contents will fail, as it is performed by skipping the tape forward *n*`-1` files rather than by using absolute positioning. This is because on some devices absolute positioning is very time consuming.

T timeout [hms] — Sets the amount of time to wait for an autoload command to complete. This function modifier is ignored unless the `l` function modifier has also been specified. The default timeout period is two minutes. The time units may be specified as a trailing `h` (hours), `m` (minutes), or `s` (seconds). The default unit is minutes.

v — Verbose. `ufsrestore` displays the name and inode number of each file it restores, preceded by its file type.

y — Do not ask whether to abort the restore in the event of tape errors. `ufsrestore` tries to skip over the bad tape block(s) and continue as best it can.

Interactive Commands

`ufsrestore` enters interactive mode when invoked with the `i` function letters. Interactive commands are reminiscent of the shell. For those commands that accept an argument, the default is the current directory. The interactive options are:

add [*filename*] — Add the named file or directory to the list of files to extract. If a directory is specified, add that directory and its files (recursively) to the extraction list (unless the `h` modifier is in effect).

cd *directory* — Change to *directory* (within the dump file).

delete [*filename*] — Delete the current directory, or the named file or directory from the list of files to extract. If a directory is specified, delete that directory and all its descendents from the extraction list (unless the `h` modifier is in effect). The most expedient way to extract a majority of files from a directory is to add that directory to the extraction list, and then delete specific files to omit.

extract — Extract all files on the extraction list from the dump media. `ufsrestore` asks which volume the user wishes to mount. The fastest way to extract a small number of files is to start with the last volume and work toward the first. If "`s` *n*" is given on the command line, volume 1 will automatically be positioned to file *n* when it is read.

help — Display a summary of the available commands.

ls [*directory*] — List files in *directory* or the current directory, represented by a '`.`' (period). Directories are appended with a '`/`' (slash). Entries marked for extraction are prefixed with a '`*`' (asterisk). If the verbose option is in effect, inode numbers are also listed.

marked [*directory*]	Like `ls`, except only files marked for extraction are listed.
pager	Toggle the pagination of the output from the `ls` and `marked` commands. The pager used is that defined by the `PAGER` environment variable, or more(1) if that envar is not defined. The `PAGER` envar may include white-space-separated arguments for the pagination program.
pwd	Print the full pathname of the current working directory.
quit	`ufsrestore` exits immediately, even if the extraction list is not empty.
setmodes	Prompts: `set owner/mode for '.'` (period). Type `y` for yes to set the mode (permissions, owner, times) of the current directory '.' (period) into which files are being restored equal to the mode of the root directory of the file system from which they were dumped. Normally, this is what you want when restoring a whole file system, or restoring individual files into the same locations from which they were dumped. Type `n` for no, to leave the mode of the current directory unchanged. Normally, this is what you want when restoring part of a dump to a directory other than the one from which the files were dumped.
setpager *command*	Sets the command to use for paginating output instead of the default or that inherited from the environment. The *command* string may include arguments in addition to the command itself.
verbose	Toggle the status of the `v` modifier. While `v` is in effect, the `ls` command lists the inode numbers of all entries, and `ufsrestore` displays information about each file as it is extracted.
what	Display the dump header on the media.

Operands The following operands are supported.

filename Specifies the pathname of files (or directories) to be restored to disk. Unless the `h` function modifier is also used, a directory name refers to the files it contains, and (recursively) its subdirectories and the files they contain. *filename* is associated with either the `x` or `t` function letters, and must come last.

Usage See `largefile(5)` for the description of the behavior of `ufsrestore` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Exit Status The following exit values are returned:

`0` Successful completion.

`1` An error occurred. Verbose messages are displayed.

Environment Variables PAGER The command to use as a filter for paginating output. This can also be used to specify the options to be used. Default is `more(1)`.

TMPDIR Selects the directory for temporary files. Defaults to `/tmp` if not defined in the environment.

Files

`/dev/rmt/0`	the default tape drive
`$TMPDIR/rstdir*`	file containing directories on the tape
`$TMPDIR/rstmode*`	owner, mode, and timestamps for directories
`./restoresymtable`	information passed between incremental restores

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `more(1)`, `mkfs(1M)`, `mount(1M)`, `rmt(1M)`, `ufsdump(1M)`, `ufsdump(4)`, `attributes(5)`, `largefile(5)`

Diagnostics `ufsrestore` complains about bad option characters.

Read errors result in complaints. If `y` has been specified, or the user responds `y`, `ufsrestore` will attempt to continue.

If the dump extends over more than one tape, `ufsrestore` asks the user to change tapes. If the `x` or `i` function letter has been specified, `ufsrestore` also asks which volume the user wishes to mount. If the `s` modifier has been specified, and volume 1 is mounted, it is automatically positioned to the indicated file.

There are numerous consistency checks that can be listed by `ufsrestore`. Most checks are self-explanatory or can "never happen". Common errors are given below.

`Converting to new file system format`
A dump tape created from the old file system has been loaded. It is automatically converted to the new file system format.

filename`: not found on tape`
The specified file name was listed in the tape directory, but was not found on the tape. This is caused by tape read errors while looking for the file, using a dump tape created on an active file system, or restoring a partial dump with the `r` function.

`expected next file` *inumber*`, got` *inumber*
A file that was not listed in the directory showed up. This can occur when using a dump tape created on an active file system.

`Incremental tape too low`
When doing an incremental restore, a tape that was written before the previous incremental tape, or that has too low an incremental level has been loaded.

`Incremental tape too high`
When doing incremental restore, a tape that does not begin its coverage where the previous incremental tape left off, or one that has too high an incremental level has been loaded.

`media read error: invalid argument`
Blocking factor specified for read is smaller than the blocking factor used to write data.

`Tape read error while restoring`
`Tape read error while skipping over inode inumber`
`Tape read error while trying to resynchronize`
`A tape read error has occurred`
If a file name is specified, then its contents are probably partially wrong. If an inode is being skipped or the tape is trying to resynchronize, then no extracted files have been corrupted, though files may not be found on the tape.

`resync ufsrestore, skipped` *num*
After a tape read error, `ufsrestore` may have to resynchronize itself. This message lists the number of blocks that were skipped over.

`Incorrect tape label. Expected 'foo', got 'bar'.`
The `L` option was specified, and its value did not match what was recorded in the header of the dump file.

Notes `ufsrestore` can get confused when doing incremental restores from dump tapes that were made on active file systems.

A `level 0` dump must be done after a full restore. Because `ufsrestore` runs in user mode, it has no control over inode allocation. This means that `ufsrestore` repositions the files, although it does not change their contents. Thus, a full dump must be done to get a new set of directories reflecting the new file positions, so that later incremental dumps will be correct.

Name unshare – make local resource unavailable for mounting by remote systems

Synopsis

```
unshare [-F FSType] [-o specific_options]
      [pathname | resourcename]
```

Description The `unshare` command makes a shared local resource unavailable as file system type *FSType*. If the option `-F`*FSType* is omitted, then the first file system type listed in file `/etc/dfs/fstypes` will be used as the default. *Specific_options*, as well as the semantics of *resourcename*, are specific to particular distributed file systems.

Options

`-F` *FSType* Specify the file system type.

`-o` *specific_options* Specify options specific to the file system provided by the `-F` option.

Files

`/etc/dfs/fstypes`

`/etc/dfs/sharetab`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `share(1M)`, `shareall(1M)`, `attributes(5)`

Notes If *pathname* or *resourcename* is not found in the shared information, an error message will be sent to standard error.

When an `unshare` command completes successfully, a client mounting a file system specified in that `unshare` command no longer has access to that file system.

Name unshare_nfs – make local NFS file systems unavailable for mounting by remote systems

Synopsis

```
unshare [-F nfs] pathname
```

Description The `unshare` command makes local file systems unavailable for mounting by remote systems. The shared file system must correspond to a line with NFS as the *FSType* in the file `/etc/dfs/sharetab`.

Options The following options are supported:

`-F` This option may be omitted if NFS is the first file system type listed in the file `/etc/dfs/fstypes`.

Files

`/etc/dfs/fstypes`

`/etc/dfs/sharetab`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnfssu

See Also `nfsd(1M)`, `share(1M)`, `attributes(5)`

Notes If the file system being unshared is a symbolic link to a valid pathname, the canonical path (the path which the symbolic link follows) will be unshared.

For example, if `/export/foo` is a symbolic link to `/export/bar` (`/export/foo -> /export/bar`), the following `unshare` command will result in `/export/bar` as the unshared pathname (and not `/export/foo`):

```
example#  unshare -F nfs /export/foo
```

For file systems that are accessed by NFS Version 4 clients, once the unshare is complete, all NFS Version 4 state (open files and file locks) are released and unrecoverable by the clients. If the intent is to share the file system after some administrative action, the NFS daemon (`nfsd`) should first be stopped and then the file system unshared. After the administrative action is complete, the file system would then be shared and the NFS daemon restarted. See `nfsd(1M)`

Name update_drv – modify device driver attributes

Synopsis

```
update_drv [-f | -v] driver_module

update_drv [-b basedir] [-f | -v] -a [-m 'permission']
     [-i 'identify-name'] [-P 'privilege'] [-p 'policy'] driver_module

update_drv [-b basedir] [-f | -v] -d [-m 'permission']
     [-i 'identify-name'] [-P 'privilege'] [-p 'policy'] driver_module
```

Description The `update_drv` command informs the system about attribute changes to an installed device driver. It can be used to re-read the `driver.conf(4)` file, or to add, modify, or delete a driver's minor node permissions or aliases.

Without options, `update_drv` reloads the `driver.conf` file.

Upon successfully updating the aliases, the driver binding takes effect upon reconfig boot or hotplug of the device.

Upon successfully updating the permissions, only the new driver minor nodes get created with the modified set of file permissions. Existing driver minor nodes do not get modified.

Options The following options are supported:

`-a` Add a *permission*, *aliases*, *privilege* or *policy* entry.

With the `-a` option specified, a permission entry (using the `-m` option), or a driver's aliases entry (using the `-i` option), a device privilege (using the `-P` option) or a a device policy (using the `-p` option), can be added or updated. If a matching minor node permissions entry is encountered (having the same driver name and the minor node), it is replaced. If a matching aliases entry is encountered (having a different driver name and the same alias), an error is reported.

The `-a` and `-d` options are mutually exclusive.

`-b` *basedir* Installs or modifies the driver on the system with a root directory of basedir rather than installing on the system executing `update_drv`.

Note – The root file system of any non-global zones must not be referenced with the `-b` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.

`-d` Delete a *permission*, *aliases*, *privilege* or *policy* entry.

The `-m` *permission*, `-i` *identify-name*, `-P` *privilege* or the `-p` *policy* option needs to be specified with the `-d` option.

The `-d` and `-a` options are mutually exclusive.

	If the entry doesn't exist `update_drv` returns an error.
`-f`	Force the system to reread the `driver.conf` file even if the driver module cannot be unloaded. See `NOTES` section for details.
`-i` '*identify-name*'	A white-space separated list of aliases for the driver. If `-a` or `-d` option is not specified then this option is ignored. The *identify-name* string is mandatory. If all aliases need to be removed, `rem_drv(1M)` is recommended.
`-m` '*permission*'	Specify a white-space separated list of file system permissions for the device node of the device driver. If `-a` or `-d` option is not specified then, this option is ignored. The permission string is mandatory.
`-p` '*policy*'	With the `-a` option, policy is a white-space separated list of complete device policies. For the `-d` option, policy is a white space separated list of minor device specifications. The minor device specifications are matched exactly against the entries in `/etc/security/device_policy`, that is., no wildcard matching is performed.
`-P` '*privilege*'	With the `-a` option, privilege is a comma separated list of additional driver privileges. For the `-d` option, privilege is a single privilege. The privileges are added to or removed from the `/etc/security/extra_privs` file.
`-v`	Verbose.

Examples

EXAMPLE 1 Adding or Modifying an Existing Minor Permissions Entry

The following command adds or modifies the exisitng minor permissions entry of the `clone` driver:

```
example# update_drv -a -m 'llc1 777 joe staff' clone
```

EXAMPLE 2 Removing All Minor Permissions Entries

The following command removes all minor permission entries of the `usbprn` driver, the USB printer driver:

```
example# update_drv -d -m '* 0666 root sys' usbprn
```

EXAMPLE 3 Adding a Driver Aliases Entry

The following command adds a driver aliases entry of the `ugen` driver with the identity string of `usb459,20`:

```
example# update_drv -a -i '"usb459,20"' ugen
```

EXAMPLE 4 Re-reading the `driver.conf` File For the `ohci` Driver

The following command re-reads the `driver.conf`(4) file.

```
example# update_drv ohci
```

EXAMPLE 5 Requiring a Self-defined Privilege to Open a tcp Socket

The following command requires a self-defined privilege to open a tcp socket:

```
example#   update_drv -a -P net_tcp -p \
     'write_priv_set=net_tcp read_priv_set=net_tcp' tcp
```

EXAMPLE 6 Establishing a Path-oriented Alias

The following command establishes a path-oriented alias to force a specific driver, `qlt`, to be used for a particular device path:

```
example#   update_drv -a -i '"/pci@8,600000/SUNW,qlc@4"' qlt
```

Exit Status

The following exit values are returned:

`0` Successful completion.

>`0` An error occurred.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also

`add_drv`(1M), `modunload`(1M), `rem_drv`(1M), `driver.conf`(4), `attributes`(5), `privileges`(5)

Notes

If `-a` or `-d` options are specified, `update_drv` does not re-read the `driver.conf` file.

A forced update of the `driver.conf` file reloads the `driver.conf` file without reloading the driver binary module. In this case, devices which can not be detached reference driver global properties from the old `driver.conf` file, while the remaining driver instances reference global properties in the new `driver.conf` file.

It is possible to add an alias , which changes the driver binding of a device already being managed by a different driver. A force update with the `-a` option tries to bind to the new driver and report error if it cannot. If you specify more than one of the `-m`, `-i`, `-P` or `-p` options, a force flag tries to modify aliases or permissions. This is done even if the other operation fails and vice-versa. A force update with the `-d` option tries to delete entries and report the error if it cannot.

Name updatehome – update the home directory copy and link files for the current label

Synopsis

```
/usr/bin/updatehome  [-cirs]
```

Description `updatehome` reads the user's minimum-label copy and link-control files (`.copy_files` and `.link_files`). These files contain a list of files to be copied and symbolically linked from the user's minimum-label home directory to the user's home directory at the current label.

The Solaris Trusted Extensions `dtsession` program performs an `updatehome` whenever a newly labeled workspace is created so that the user's favorite files are available for use. For example, the user probably wants a symbolic link to such files as `.profile`, `.login`, `.cshrc`, `.exrc`, `.mailrc`, and `~/bin`. The `updatehome` command provides a convenient mechanism for accomplishing this symlink. The user can add files to those to be copied (`.copy_files`) and to those to be symbolically linked (`.link_files`).

Options

`-c` Replace existing home-directory copies at the current label. The default is to skip over existing copies.

`-i` Ignore errors encountered. The default aborts on error.

`-r` Replace existing home-directory copies or symbolic links at the current label. This option implies options `-c` and `-s`. The default is to skip over existing copies or symbolic links.

`-s` Replace existing home-directory symbolic links at the current label. The default is to skip over existing symbolic links.

Exit Status Upon success, `updatehome` returns `0`. Upon failure, `updatehome` returns `1` and writes diagnostic messages to standard error.

Examples

EXAMPLE 1 A Sample `.copy_files` File

The files that are listed in `.copy_files` can be modified at every user's label.

```
.cshrc
.mailrc
.mozilla/bookmarks.html
```

EXAMPLE 2 A Sample `.link_files` File

The files that are listed in `.link_files` can be modified at the lowest label. The changes propagate to the other labels that are available to the user.

```
~/bin
.mozilla/preferences
.xrc
.rhosts
```

EXAMPLE 3 Updating the Linked and Copied Files

The `.copy_files` and `.link_files` were updated by the user at the minimum label. At a higher label, the user refreshes the copies and the links. No privileges are required to run the command.

```
% updatehome -r
```

Files

`$HOME/.copy_files`	List of files to be copied
`$HOME/.link_files`	List of files to be symbolically linked

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWtsu
Interface Stability	Committed

See Also `attributes(5)`

"`.copy_files` and `.link_files` Files" in *Oracle Solaris Trusted Extensions Administrator's Procedures*

Notes The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

Name updatemanager – start the Sun Update Manager application

Synopsis

```
updatemanager
```

Description The `updatemanager` command starts the Sun Update Manager application. The Sun Update Manager is a graphical user interface (GUI) that you can use to manage updates and patches on your Solaris system.

For more information about using this application, see the *Sun Update Manager 1.0 Administration Guide* in the *Sun Update Connection, System Edition Collection* on `docs.sun.com`.

You can also manage updates and patches on the command line by using the `smpatch` command. See the `smpatch(1M)` man page.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWupdatemgru
Interface Stability	Unstable

See Also `smpatch(1M)`, `attributes(5)`

Name updatemedia – modify Solaris media with patches and packages

Synopsis

```
/usr/bin/updatemedia  -d media-root [-v] [-o iso] [-l label]
     pkg_or_patch [pkg_or_patch ...]
```

Description The `updatemedia` utility takes a list of patches and packages as input and updates the install miniroot in *media-root* (the root directory of an on-disk image of a Solaris installation media) to include the specified patches and packages. These patches and packages are also placed in a subdirectory called `DU` under the Solaris install image. For example:

media-root`/Solaris_10/DU`

When booting a system from the updated media, the patches and packages will be part of the booted Solaris image. They will also be applied to the target system being installed at the end of the installation process.

If `-o` is specified, a bootable ISO image is created in the file `media.iso` that contains the Solaris install media. The ISO image can then be burned onto a CD/DVD with utilities such as `cdrw(1)` or `cdrecord(1)`. (The latter is not a SunOS man page.)

Options The following options are supported:

`-d` *media-root*
Top-level directory of on-disk image of Solaris installation media. This is option must be specified.

`-o` *iso*
Create a Solaris ISO image of *media-root*.

`-l` *label*
Label/volume name of the ISO image (if `-o` option is specified). If `-o` is not specified, the name of Solaris directory under *media-root*, for example, `Solaris_10`, will be used.

`-v`
Verbose. Multiple `-v` options increase verbosity.

Operands The following operands are supported:

pkg_or_patch [*pkg_or_patch* ...]
One or more patches or packages (you can have both patches and packages in a single command) with which the Solaris installation media *media-root* will be updated.

Examples **EXAMPLE 1** Updating a Solaris Install Image with Patch and Package

The following command updates the Solaris install image in `s10u1` by adding patch `123456-07` and package `SUNWfoo`.

```
# /usr/bin/updatemedia -d s10u1 SUNWfoo 123456-07
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Committed

See Also cdrw(1), mkbootmedia(1M), attributes(5)

mkisofs(8), (/usr/share/man/man8/mkisofs.8), in the SUNWfsman package (not a SunOS man page)

Name useradd – administer a new user login on the system

Synopsis

```
useradd [-c comment] [-d dir] [-e expire] [-f inactive]
 [-g group] [-G group [, group...]] [-m [-k skel_dir]]
 [-u uid [-o]] [-s shell] [-A authorization [,authorization...]]
 [-P profile [,profile...]] [-R role [,role...]]
 [-p projname] [-K key=value] login

useradd -D [-b base_dir] [-e expire] [-f inactive]
 [-g group] [-A authorization [,authorization...]]
 [-P profile [,profile...]] [-R role [,role...]]
 [-p projname] [-K key=value]
```

Description `useradd` adds a new user to the `/etc/passwd` and `/etc/shadow` and `/etc/user_attr` files. The `-A` and `-P` options respectively assign authorizations and profiles to the user. The `-R` option assigns roles to a user. The `-p` option associates a project with a user. The `-K` option adds a *key=value* pair to `/etc/user_attr` for the user. Multiple *key=value* pairs may be added with multiple `-K` options.

`useradd` also creates supplementary group memberships for the user (`-G` option) and creates the home directory (`-m` option) for the user if requested. The new login remains locked until the `passwd(1)` command is executed.

Specifying `useradd -D` with the `-g`, `-b`, `-f`, `-e`, `-A`, `-P`, `-p`, `-R`, or `-K` option (or any combination of these options) sets the default values for the respective fields. See the `-D` option, below. Subsequent `useradd` commands without the `-D` option use these arguments.

The system file entries created with this command have a limit of 2048 characters per line. Specifying long arguments to several options can exceed this limit.

`useradd` requires that usernames be in the format described in `passwd(4)`. A warning message is displayed if these restrictions are not met. See `passwd(4)` for the requirements for usernames.

Options The following options are supported:

`-A` *authorization*
: One or more comma separated authorizations defined in `auth_attr(4)`. Only a user or role who has `grant` rights to the authorization can assign it to an account.

`-b` *base_dir*
: The default base directory for the system if `-d` *dir* is not specified. *base_dir* is concatenated with the account name to define the home directory. If the `-m` option is not used, *base_dir* must exist.

`-c` *comment*
: Any text string. It is generally a short description of the login, and is currently used as the field for the user's full name. This information is stored in the user's `/etc/passwd` entry.

`-d` *dir*
The home directory of the new user. It defaults to *base_dir*/*account_name*, where *base_dir* is the base directory for new login home directories and *account_name* is the new login name.

`-D`
Display the default values for `group`, `base_dir`, `skel_dir`, `shell`, `inactive`, `expire`, `proj`, `projname` and `key=value` pairs. When used with the `-g`, `-b`, `-f`, `-e`, `-A`, `-P`, `-p`, `-R`, or `-K` options, the `-D` option sets the default values for the specified fields. The default values are:

group	`other` (GID of 1)
base_dir	`/home`
skel_dir	`/etc/skel`
shell	`/bin/sh`
inactive	`0`
expire	null
auths	null
profiles	null
proj	`3`
projname	`default`
key=value (pairs defined in `user_attr(4)`	not present
roles	null

`-e` *expire*
Specify the expiration date for a login. After this date, no user will be able to access this login. The expire option argument is a date entered using one of the date formats included in the template file `/etc/datemsk`. See `getdate(3C)`.

If the date format that you choose includes spaces, it must be quoted. For example, you can enter `10/6/90` or "`October 6, 1990`". A null value ("") defeats the status of the expired date. This option is useful for creating temporary logins.

`-f` *inactive*
The maximum number of days allowed between uses of a login ID before that ID is declared invalid. Normal values are positive integers. A value of `0` defeats the status.

`-g` *group*
An existing group's integer ID or character-string name. Without the `-D` option, it defines the new user's primary group membership and defaults to the default group. You can reset this default value by invoking `useradd -D -g` *group*. GIDs 0-99 are reserved for allocation by the Solaris Operating System.

`-G` *group*
An existing group's integer ID or character-string name. It defines the new user's supplementary group membership. Duplicates between *group* with the `-g` and `-G` options are ignored. No more than `NGROUPS_MAX` groups can be specified. GIDs 0-99 are reserved for allocation by the Solaris Operating System.

`-K` *key=value*
A *key=value* pair to add to the user's attributes. Multiple `-K` options may be used to add multiple *key=value* pairs. The generic `-K` option with the appropriate key may be used instead of the specific implied key options (`-A`, `-P`, `-R`, `-p`). See `user_attr(4)` for a list of valid *key=value* pairs. The "type" key is not a valid key for this option. Keys may not be repeated.

`-k` *skel_dir*
A directory that contains skeleton information (such as `.profile`) that can be copied into a new user's home directory. This directory must already exist. The system provides the `/etc/skel` directory that can be used for this purpose.

`-m`
Create the new user's home directory if it does not already exist. If the directory already exists, it must have read, write, and execute permissions by *group*, where *group* is the user's primary group.

`-o`
This option allows a UID to be duplicated (non-unique).

`-P` *profile*
One or more comma-separated execution profiles defined in `prof_attr(4)`.

`-p` *projname*
Name of the project with which the added user is associated. See the *projname* field as defined in `project(4)`.

`-R` *role*
One or more comma-separated execution profiles defined in `user_attr(4)`. Roles cannot be assigned to other roles.

`-s` *shell*
Full pathname of the program used as the user's shell on login. It defaults to an empty field causing the system to use `/bin/sh` as the default. The value of *shell* must be a valid executable file.

`-u` *uid*
The UID of the new user. This UID must be a non-negative decimal integer below `MAXUID` as defined in `<sys/param.h>`. The UID defaults to the next available (unique) number above the highest number currently assigned. For example, if UIDs 100, 105, and 200 are assigned, the next default UID number will be 201. UIDs `0-99` are reserved for allocation by the Solaris Operating System.

Files

`/etc/datemsk`

`/etc/passwd`

`/etc/shadow`

`/etc/group`

`/etc/skel`

`/usr/include/limits.h`

`/etc/user_attr`

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Evolving

See Also

`passwd(1)`, `profiles(1)`, `roles(1)`, `users(1B)`, `groupadd(1M)`, `groupdel(1M)`, `groupmod(1M)`, `grpck(1M)`, `logins(1M)`, `pwck(1M)`, `userdel(1M)`, `usermod(1M)`, `getdate(3C)`, `auth_attr(4)`, `passwd(4)`, `prof_attr(4)`, `project(4)`, `user_attr(4)`, `attributes(5)`

Diagnostics

In case of an error, `useradd` prints an error message and exits with a non-zero status.

The following indicates that `login` specified is already in use:

```
UX: useradd: ERROR: login is already in use. Choose another.
```

The following indicates that the *uid* specified with the `-u` option is not unique:

```
UX: useradd: ERROR: uid uid is already in use. Choose another.
```

The following indicates that the *group* specified with the `-g` option is already in use:

```
UX: useradd: ERROR: group group does not exist. Choose another.
```

The following indicates that the *uid* specified with the `-u` option is in the range of reserved UIDs (from `0-99`):

```
UX: useradd: WARNING: uid uid is reserved.
```

The following indicates that the *uid* specified with the `-u` option exceeds `MAXUID` as defined in `<sys/param.h>`:

```
UX: useradd: ERROR: uid uid is too big. Choose another.
```

The following indicates that the `/etc/passwd` or `/etc/shadow` files do not exist:

```
UX: useradd: ERROR: Cannot update system files - login cannot be created.
```

Notes The `useradd` utility adds definitions to only the local `/etc/group`, `etc/passwd`, `/etc/passwd`, `/etc/shadow`, `/etc/project`, and `/etc/user_attr` files. If a network name service such as NIS or NIS+ is being used to supplement the local `/etc/passwd` file with additional entries, `useradd` cannot change information supplied by the network name service. However `useradd` will verify the uniqueness of the user name (or role) and user id and the existence of any group names specified against the external name service.

Name userdel – delete a user's login from the system

Synopsis

```
userdel [-r] login
```

Description The `userdel` utility deletes a user account from the system and makes the appropriate account-related changes to the system file and file system.

Options The following options are supported:

`-r` Remove the user's home directory from the system. This directory must exist. The files and directories under the home directory will no longer be accessible following successful execution of the command.

Operands The following operands are supported:

login An existing login name to be deleted.

Exit Status The following exit values are returned:

`0` Successful completion.

`2` Invalid command syntax. A usage message for the `userdel` command is displayed.

`6` The account to be removed does not exist.

`8` The account to be removed is in use.

`10` Cannot update the `/etc/group` or `/etc/user_attr` file but the login is removed from the `/etc/passwd` file.

`12` Cannot remove or otherwise modify the home directory.

Files

`/etc/passwd`	system password file
`/etc/shadow`	system file contain users' encrypted passwords and related information
`/etc/group`	system file containing group definitions
`/etc/user_attr`	system file containing additional user attributes

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `auths(1)`, `passwd(1)`, `profiles(1)`, `roles(1)`, `users(1B)`, `groupadd(1M)`, `groupdel(1M)`, `groupmod(1M)`, `logins(1M)`, `roleadd(1M)`, `rolemod(1M)`, `useradd(1M)`, `userdel(1M)`, `usermod(1M)`, `passwd(4)`, `prof_attr(4)`, `user_attr(4)`, `attributes(5)`

Notes The `userdel` utility only deletes an account definition that is in the local `/etc/group`, `/etc/passwd`, `/etc/shadow`, and `/etc/user_attr` file. file. If a network name service such as NIS or NIS+ is being used to supplement the local `/etc/passwd` file with additional entries, `userdel` cannot change information supplied by the network name service.

Name usermod – modify a user's login information on the system

Synopsis

```
usermod [-u uid [-o]] [-g group] [-G group [, group...]]
     [-d dir [-m]] [-s shell] [-c comment] [-l new_name]
     [-f inactive] [-e expire]
     [-A authorization [, authorization]]
     [-P profile [, profile]] [-R role [, role]]
     [-K key=value] login
```

Description The `usermod` utility modifies a user's login definition on the system. It changes the definition of the specified login and makes the appropriate login-related system file and file system changes.

The system file entries created with this command have a limit of 512 characters per line. Specifying long arguments to several options might exceed this limit.

Options The following options are supported:

`-A` *authorization*
: One or more comma separated authorizations as defined in `auth_attr(4)`. Only a user or role who has `grant` rights to the `authorization` can assign it to an account. This replaces any existing authorization setting. If no authorization list is specified, the existing setting is removed.

`-c` *comment*
: Specify a comment string. *comment* can be any text string. It is generally a short description of the login, and is currently used as the field for the user's full name. This information is stored in the user's `/etc/passwd` entry.

`-d` *dir*
: Specify the new home directory of the user. It defaults to *base_dir/login*, where *base_dir* is the base directory for new login home directories, and `login` is the new login.

`-e` *expire*
: Specify the expiration date for a login. After this date, no user will be able to access this login. The expire option argument is a date entered using one of the date formats included in the template file `/etc/datemsk`. See `getdate(3C)`.

  For example, you may enter `10/6/90` or `October 6, 1990`. A value of "`''` defeats the status of the expired date.

`-f` *inactive*
: Specify the maximum number of days allowed between uses of a login ID before that login ID is declared invalid. Normal values are positive integers. A value of `0` defeats the status.

`-g` *group*
: Specify an existing group's integer ID or character-string name. It redefines the user's primary group membership.

`-G` *group*
Specify an existing group's integer "ID" "," or character string name. It redefines the user's supplementary group membership. Duplicates between *group* with the `-g` and `-G` options are ignored. No more than `NGROUPS_UMAX` groups may be specified as defined in `<param.h>`.

`-K` *key=value*
Replace existing or add to a user's *key=value* pair attributes. Multiple `-K` options can be used to replace or add multiple *key=value* pairs. However, keys must not be repeated. The generic `-K` option with the appropriate key can be used instead of the specific implied key options (`-A`, `-P`, `-R`, `-p`). See `user_attr(4)` for a list of valid *key*s. Values for these keys are usually found in man pages or other sources related to those keys. For example, see `project(4)` for guidance on values for the `project` key. Use the command `ppriv(1)` with the `-v` and `-l` options for a list of values for the keys `defaultpriv` and `limitpriv`.

The keyword `type` can be specified with the value `role` or the value `normal`. When using the value `role`, the account changes from a normal user to a role; using the value `normal` keeps the account a normal user.

As a `role` account, no roles (`-R` or *roles=value*) can be present.

`-l` *new_logname*
Specify the new login name for the user. See `passwd(4)` for the requirements for usernames.

`-m`
Move the user's home directory to the new directory specified with the `-d` option. If the directory already exists, it must have permissions read/write/execute by *group*, where *group* is the user's primary group.

`-o`
This option allows the specified UID to be duplicated (non-unique).

`-P` *profile*
One or more comma-separated rights profiles defined in `prof_attr(4)`. This replaces any existing profile setting in `user_attr(4)`. If an empty profile list is specified, the existing setting is removed.

`-R` *role*
One or more comma-separated roles (see `roleadd(1M)`). This replaces any existing role setting. If no role list is specified, the existing setting is removed.

`-s` *shell*
Specify the full pathname of the program that is used as the user's shell on login. The value of *shell* must be a valid executable file.

`-u` *uid*
Specify a new UID for the user. It must be a non-negative decimal integer less than `MAXUID` as defined in `<param.h>`. The UID associated with the user's home directory is not modified with this option; a user will not have access to their home directory until the UID is manually reassigned using `chown(1)`.

Operands The following operands are supported:

`login`
An existing login name to be modified.

Examples

EXAMPLE 1 Assigning Privileges to a User

The following command adds the privilege that affects high resolution times to a user's initial, inheritable set of privileges.

```
# usermod -K defaultpriv=basic,proc_clock_highres jdoe
```

This command results in the following entry in `user_attr`:

```
jdoe::::type=normal;defaultpriv=basic,proc_clock_highres
```

EXAMPLE 2 Removing a Privilege from a User's Limit Set

The following command removes the privilege that allows the specified user to create hard links to directories and to unlink directories.

```
# usermod -K limitpriv=all,!sys_linkdir jdoe
```

This command results in the following entry in `user_attr`:

```
jdoe::::type=normal;defaultpriv=basic,limitpriv=all,!sys_linkdir
```

EXAMPLE 3 Removing a Privilege from a User's Basic Set

The following command removes the privilege that allows the specified user to examine processes outside the user's session.

```
# usermod -K defaultpriv=basic,!proc_session jdoe
```

This command results in the following entry in `user_attr`:

```
jdoe::::type=normal;defaultpriv=basic,!proc_session;limitpriv=all
```

EXAMPLE 4 Assigning a Role to a User

The following command assigns a role to a user. The role must have been created prior to this command, either through use of the Solaris Management Console GUI or through `roleadd(1M)`.

```
# usermod -R mailadm jdoe
```

This command results in the following entry in `user_attr`:

```
jdoe::::type=normal;roles=mailadm;defaultpriv=basic;limitpriv=all
```

EXAMPLE 5 Removing All Profiles from a User

The following command removes all profiles that were granted to a user directly. The user will still have any rights profiles that are granted by means of the `PROFS_GRANTED` key in `policy.conf(4)`.

EXAMPLE 5 Removing All Profiles from a User *(Continued)*

```
# usermod -P "" jdoe
```

Exit Status In case of an error, `usermod` prints an error message and exits with one of the following values:

`2`
The command syntax was invalid. A usage message for the `usermod` command is displayed.

`3`
An invalid argument was provided to an option.

`4`
The *uid* given with the `-u` option is already in use.

`5`
The password files contain an error. `pwconv(1M)` can be used to correct possible errors. See `passwd(4)`.

`6`
The login to be modified does not exist, the *group* does not exist, or the login shell does not exist.

`8`
The login to be modified is in use.

`9`
The *new_logname* is already in use.

`10`
Cannot update the `/etc/group` or `/etc/user_attr` file. Other update requests will be implemented.

`11`
Insufficient space to move the home directory (`-m` option). Other update requests will be implemented.

`12`
Unable to complete the move of the home directory to the new home directory.

Files `/etc/group`
system file containing group definitions

`/etc/datemsk`
system file of date formats

`/etc/passwd`
system password file

`/etc/shadow`
system file containing users' encrypted passwords and related information

`/etc/user_attr`
system file containing additional user and role attributes

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Committed

See Also `chown(1)`, `passwd(1)`, `users(1B)`, `groupadd(1M)`, `groupdel(1M)`, `groupmod(1M)`, `logins(1M)`, `pwconv(1M)`, `roleadd(1M)`, `roledel(1M)`, `rolemod(1M)`, `useradd(1M)`, `userdel(1M)`, `getdate(3C)`, `auth_attr(4)`, `passwd(4)`, `policy.conf(4)`, `prof_attr(4)`, `user_attr(4)`, `attributes(5)`

Notes The `usermod` utility modifies `passwd` definitions only in the local `/etc/passwd` and `/etc/shadow` files. If a network nameservice such as `NIS` or `NIS+` is being used to supplement the local files with additional entries, `usermod` cannot change information supplied by the network nameservice. However `usermod` will verify the uniqueness of user name and user ID against the external nameservice.

The `usermod` utility uses the `/etc/datemsk` file, available with SUNWaccr, for date formatting.

Name utmpd – utmpx monitoring daemon

Synopsis

```
utmpd [-debug]
```

Description The `utmpd` daemon monitors the `/var/adm/utmpx` file. See `utmpx(4)` (and `utmp(4)` for historical information).

`utmpd` receives requests from `pututxline(3C)` by way of a named pipe. It maintains a table of processes and uses `poll(2)` on `/proc` files to detect process termination. When `utmpd` detects that a process has terminated, it checks that the process has removed its `utmpx` entry from `/var/adm/utmpx`. If the process' `utmpx` entry has not been removed, `utmpd` removes the entry. By periodically scanning the `/var/adm/utmpx` file, `utmpd` also monitors processes that are not in its table.

Options

`-debug`
: Run in debug mode, leaving the process connected to the controlling terminal. Write debugging information to standard output.

Exit Status The following exit values are returned:

`0`
: Successful completion.

`>0`
: An error occurred.

Files

`/etc/default/utmpd`
: You can set default values for the flags listed below. For example: `SCAN_PERIOD=600`

  `SCAN_PERIOD`
  : The number of seconds that `utmpd` sleeps between checks of `/proc` to see if monitored processes are still alive. The default is 300.

  `MAX_FDS`
  : The maximum number of processes that `utmpd` attempts to monitor. The default value is 4096.

  `WTMPX_UPDATE_FREQ`
  : The number of seconds that `utmpd` sleeps between read accesses of the `wtmpx` file. The `wtmpx` file's last access time is used by `init(1M)` on reboot to determine when the operating system became unavailable. The default is 60.

`/var/adm/utmpx`
: File containing user and accounting information for commands such as `who(1)`, `write(1)`, and `login(1)`.

`/proc`
: Directory containing files for processes whose `utmpx` entries are being monitored.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also svcs(1), init(1M), svcadm(1M), poll(2), pututxline(3C), proc(4), utmp(4), utmpx(4), attributes(5), smf(5)

Notes If the filesystem holding /var/adm/wtmpx is mounted with options which inhibit or defer access time updates, an unknown amount of error will be introduced into the utmp DOWN_TIME record's timestamp in the event of an uncontrolled shutdown (for example, a crash or loss of power). Controlled shutdowns will update the modify time of /var/adm/wtmpx, which will be used on the next boot to determine when the previous shutdown ocurred, regardless of access time deferral or inhibition.

The utmpd service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/system/utmp:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name uucheck – check the uucp directories and permissions file

Synopsis

```
/usr/lib/uucp/uucheck [-v] [-x debug-level]
```

Description `uucheck` checks for the presence of the `uucp` system required files and directories. `uucheck` also does error checking of the `Permissions` file (`/etc/uucp/Permissions`).

`uucheck` is executed during package installation. `uucheck` can only be used by the super-user or `uucp`.

Options The following options are supported:

`-v` Give a detailed (verbose) explanation of how the `uucp` programs will interpret the `Permissions` file.

`-x` *debug-level* Produce debugging output on the standard output. *debug-level* is a number from `0` to `9`. Higher numbers give more detailed debugging information.

Files

`/etc/uucp/Devices`

`/etc/uucp/Limits`

`/etc/uucp/Permissions`

`/etc/uucp/Systems`

`/var/spool/locks/*`

`/var/spool/uucp/*`

`/var/spool/uucppublic/*`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbnuu

See Also `uucp(1C)`, `uustat(1C)`, `uux(1C)`, `uucico(1M)`, `uusched(1M)`, `attributes(5)`

Bugs The program does not check file/directory modes or some errors in the `Permissions` file such as duplicate login or machine name.

Name uucico – file transport program for the uucp system

Synopsis
```
/usr/lib/uucp/uucico [-f] [-c type] [-d spool-directory]
     [-i interface] [-r role-number] [-s system-name]
     [-x debug-level]
```

Description `uucico` is the file transport program for `uucp` work file transfers.

Options The following options are supported:

`-f` This option is used to "force execution" of `uucico` by ignoring the limit on the maximum number of uucicos defined in the `/etc/uucp/Limits` file.

`-c` *type* The first field in the `Devices` file is the "Type" field. The `-c` option forces `uucico` to only use entries in the "Type" field that match the user specified `type`. The specified `type` is usually the name of a local area network.

`-d` *spool-directory* This option specifies the directory *spool-directory* that contains the `uucp` work files to be transferred. The default spool directory is `/var/spool/uucp`.

`-i` *interface* This option defines the *interface* used with `uucico`. The interface only affects slave mode. Known interfaces are UNIX (default), TLI (basic Transport Layer Interface), and TLIS (Transport Layer Interface with Streams modules, read/write).

`-r` *role-number* The *role-number* `1` is used for master mode. *role-number* `0` is used for slave mode (default). When `uucico` is started by a program or `cron`, *role-number* `1` should be used for master mode.

`-s` *system-name* The `-s` option defines the remote system (*system-name*) that `uucico` will try to contact. It is required when the role is master; *system-name* must be defined in the `Systems` file.

`-x` *debug-level* Both `uux` and `uucp` queue jobs that will be transferred by `uucico`. These jobs are normally started by the `uusched` scheduler, for debugging purposes, and can be started manually. For example, the shell `Uutry` starts `uucico` with debugging turned on. The *debug-level* is a number between `0` and `9`. Higher numbers give more detailed debugging information.

Files `/etc/uucp/Devconfig`

`/etc/uucp/Devices`

`/etc/uucp/Limits`

`/etc/uucp/Permissions`

`/etc/uucp/Sysfiles`

`/etc/uucp/Systems`

`/var/spool/locks/*`

`/var/spool/uucp/*`

`/var/spool/uucppublic/*`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbnuu

Name uucleanup – uucp spool directory clean-up

Synopsis

```
/usr/lib/uucp/uucleanup [-Ctime] [-Dtime] [-mstring]
     [-otime] [-ssystem] [-Wtime] [-xdebug-level] [-Xtime]
```

Description `uucleanup` will scan the spool directories for old files and take appropriate action to remove them in a useful way:

- Inform the requester of send/receive requests for systems that can not be reached.
- Return undeliverable mail to the sender.
- Deliver `rnews` files addressed to the local system.
- Remove all other files.

In addition, there is a provision to warn users of requests that have been waiting for a given number of days (default 1 day). Note: `uucleanup` will process as if all option `times` were specified to the default values unless `time` is specifically set.

This program is typically started by the shell `uudemon.cleanup`, which should be started by `cron(1M)`.

Options

`-Ctime`	Remove any `C.` files greater or equal to `time` days old and send appropriate information to the requester (default 7 days).
`-Dtime`	Remove any `D.` files greater or equal to `time` days old, make an attempt to deliver mail messages, and execute `rnews` when appropriate (default 7 days).
`-m`*string*	Include *string* in the warning message generated by the `-W` option. The default line is "See your local administrator to locate the problem".
`-otime`	Delete other files whose age is more than `time` days (default 2 days).
`-s`*system*	Execute for *system* spool directory only.
`-Wtime`	Any `C.` files equal to `time` days old will cause a mail message to be sent to the requester warning about the delay in contacting the remote. The message includes the *JOBID*, and in the case of mail, the mail message. The administrator may include a message line telling whom to call to check the problem (`-m` option) (default 1 day).
`-x`*debug-level*	Produce debugging output on standard ouput. *debug-level* is a single digit between 0 and 9; higher numbers give more detailed debugging information. (This option may not be available on all systems.)
`-Xtime`	Any `X.` files greater or equal to `time` days old will be removed. The `D.` files are probably not present (if they were, the `X.` could get executed). But if there are `D.` files, they will be taken care of by D. processing (default 2 days).

Files

`/usr/lib/uucp`	directory with commands used by `uucleanup` internally
`/var/spool/uucp`	spool directory

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbnuu

See Also `uucp(1C)`, `uux(1C)`, `cron(1M)`, `attributes(5)`

Name uusched – uucp file transport program scheduler

Synopsis

```
/usr/lib/uucp/uusched [-u debug-level] [-x debug-level]
```

Description `uusched` is the `uucp(1C)` file transport scheduler. It is usually started by the daemon *uudemon.hour* that is started by `cron(1M)` from an entry in user `uucp`'s crontab file:

```
11,41 * * * * /etc/uucp/uucp/uudemon.hour
```

Options The options are for debugging purposes only. *debug-level* is a number between `0` and `9`. Higher numbers give more detailed debugging information:

The following options are supported:

`-u` *debug-level* Passes the `-u` *debug-level* option `uucico(1M)` as `-x` *debug-level*.

`-x` *debug-level* Outputs debugging messages from `uusched`.

Files

```
/etc/uucp/Devices
/etc/uucp/Permissions
/etc/uucp/Systems
/var/spool/locks/*
/var/spool/uucp/*
/var/spool/uucppublic/*
```

Name Uutry, uutry – attempt to contact remote system with debugging on

Synopsis `/usr/lib/uucp/Uutry [-r] [-c` *type*`] [-x` *debug-level*`]` *system-name*

Description `Uutry` is a shell script that is used to invoke `uucico`(1M) to call a remote site. Debugging is initially turned on and is set to the default value of `5`. The debugging output is put in file `/tmp/`*system-name*.

Options The following options are supported:

`-r` This option overrides the retry time that is set in file `/var/uucp/.Status/`*system-name*.

`-c` *type* The first field in the `Devices` file is the "Type" field. The `-c` option forces `uucico` to use only entries in the "Type" field that match the user-specified `type`. The specified `type` is usually the name of a local area network.

`-x` *debug-level* *debug-level* is a number from `0` to `9`. Higher numbers give more detailed debugging information.

Files `/etc/uucp/Devices`

Name uuxqt – execute remote command requests

Synopsis `/usr/lib/uucp/uuxqt [-s system] [-x debug-level]`

Description `uuxqt` is the program that executes remote job requests from remote systems generated by the use of the `uux` command. (`mail` uses `uux` for remote mail requests). `uuxqt` searches the spool directories looking for execution requests. For each request, `uuxqt` checks to see if all the required data files are available, accessible, and the requested commands are permitted for the requesting system. The `Permissions` file is used to validate file accessibility and command execution permission.

There are two environment variables that are set before the `uuxqt` command is executed:

- `UU_MACHINE` is the machine that sent the job (the previous one).
- `UU_USER` is the user that sent the job.

These can be used in writing commands that remote systems can execute to provide information, auditing, or restrictions.

Options The following options are supported:

`-s` *system* Specifies the remote *system* name.

`-x` *debug-level* *debug-level* is a number from `0` to `9`. Higher numbers give more detailed debugging information.

Files

`/etc/uucp/Limits`

`/etc/uucp/Permissions`

`/var/spool/locks/*`

`/var/spool/uucp/*`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

See Also `mail(1)`, `uucp(1C)`, `uustat(1C)`, `uux(1C)`, `uucico(1M)`, `attributes(5)`

Name vmstat – report virtual memory statistics

Synopsis

```
vmstat [-cipqsS] [disks] [interval [count]]
```

Description `vmstat` reports virtual memory statistics regarding kernel thread, virtual memory, disk, trap, and CPU activity.

On MP (multi-processor) systems, `vmstat` averages the number of CPUs into the output. For per-processor statistics, see `mpstat(1M)`.

`vmstat` only supports statistics for certain devices. For more general system statistics, use `sar(1)`, `iostat(1M)`, or `sar(1M)`.

Without options, `vmstat` displays a one-line summary of the virtual memory activity since the system was booted.

During execution of the kernel status command, the `state` of the system can change. If relevant, a state change message is included in the `vmstat` output, in one of the following forms:

```
<<device added: sd0>>
<<device removed: sd0>>
<<processors added: 1, 3>>
<<processors removed: 1, 3>>
```

See *System Administration Guide: Advanced Administration* for device naming conventions for disks.

Options The following options are supported:

`-c` Report cache flushing statistics. This option is obsolete, and no longer meaningful. This option might be removed in a future version of Solaris.

`-i` Report the number of interrupts per device. *count* and *interval* does not apply to the `-i` option.

`-p` Report paging activity in details. This option will display the following, respectively:

- epi Executable page-ins.
- epo Executable page-outs.
- epf Executable page-frees.
- api Anonymous page-ins.
- apo Anonymous page-outs.
- apf Anonymous page-frees.
- fpi File system page-ins.
- fpo File system page-outs.

fpf File system page-frees.

When executed in a zone and if the pools facility is active, all of the above only report actitivity on the processors in the processor set of the zone's pool.

`-q` Suppress messages related to state changes.

`-s` Display the total number of various system events since boot. *count* and *interval* does not apply to the `-s` option.

`-S` Report on swapping rather than paging activity. This option will change two fields in `vmstat`'s "paging" display: rather than the "re" and "mf" fields, `vmstat` will report "si" (swap-ins) and "so" (swap-outs).

Operands The following operands are supported:

count Specifies the number of times that the statistics are repeated. *count* does not apply to the `-i` and `-s` options.

disks Specifies which disks are to be given priority in the output (only four disks fit on a line). Common disk names are `id`, `sd`, `xd`, or `xy,` followed by a number (for example, `sd2`, `xd0`, and so forth).

interval Specifies the last number of seconds over which `vmstat` summarizes activity. This number of seconds repeats forever. *interval* does not apply to the `-i` and `-s` options.

Examples **EXAMPLE 1** Using `vmstat`

The following command displays a summary of what the system is doing every five seconds.

```
example% vmstat 5

kthr   memory          page             disk      faults        cpu

example%
```

The fields of `vmstat`'s display are

EXAMPLE 1 Using `vmstat` *(Continued)*

`kthr` Report the number of kernel threads in each of the three following states:

- `r` the number of kernel threads in run queue
- `b` the number of blocked kernel threads that are waiting for resources I/O, paging, and so forth
- `w` the number of swapped out lightweight processes (LWPs) that are waiting for processing resources to finish.

`memory` Report on usage of virtual and real memory.

- `swap` available swap space (Kbytes)
- `free` size of the free list (Kbytes)

`page` Report information about page faults and paging activity. The information on each of the following activities is given in units per second.

- `re` page reclaims — but see the `-S` option for how this field is modified.
- `mf` minor faults — but see the `-S` option for how this field is modified.
- `pi` kilobytes paged in
- `po` kilobytes paged out
- `fr` kilobytes freed
- `de` anticipated short-term memory shortfall (Kbytes)
- `sr` pages scanned by clock algorithm

When executed in a `zone` and if the pools facility is active, all of the above (except for "de") only report activity on the processors in the processor set of the `zone`'s pool.

`disk` Report the number of disk operations per second. There are slots for up to four disks, labeled with a single letter and number. The letter indicates the type of disk (s = SCSI, i = IPI, and so forth); the number is the logical unit number.

`faults` Report the trap/interrupt rates (per second).

- `in` interrupts
- `sy` system calls
- `cs` CPU context switches

When executed in a `zone` and if the pools facility is active, all of the above only report actitivity on the processors in the processor set of the `zone`'s pool.

EXAMPLE 1 Using `vmstat` *(Continued)*

`cpu` Give a breakdown of percentage usage of CPU time. On MP systems, this is an average across all processors.

`us` user time

`sy` system time

`id` idle time

When executed in a `zone` and if the pools facility is active, all of the above only report actitivity on the processors in the processor set of the `zone`'s pool.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	See below.

Invocation is evolving. Human readable output is unstable.

`sar(1)`, `iostat(1M)`, `mpstat(1M)`, `sar(1M)`, `attributes(5)`

System Administration Guide: Basic Administration

System Administration Guide: Advanced Administration

Notes

The sum of CPU utilization might vary slightly from 100 because of rounding errors in the production of a percentage figure.

The `-c` option (Report cache flushing statistics) is not supported in this release.

Name vntsd – virtual network terminal server daemon for Logical Domains

Synopsis

```
/usr/lib/ldoms/vntsd
```

Description The `vntsd` daemon is a server that supports connections to the Logical Domains (LDoms) console by using `telnet(1)`. When a `telnet` session starts, `vntsd` sends `telnet` options to the client indicating a willingness to remotely echo characters and to suppress go ahead.

Consoles are organized into groups by the LDoms Manager. Each console group is assigned a unique group name and TCP port number. `vntsd` uses the group's port number to export access to the consoles within that group. To establish a connection with a console or console group, a user starts a `telnet(1)` session with the corresponding group's port number. Depending on the number of consoles within that group, `vntsd` does one of two things:

- If there is only one console in the group, `vntsd` connects a session to that LDoms console.
- If there are multiple consoles in the group, `vntsd` prompts the user to select the console to which they would like to connect, as shown in "Multiple-Console Options," below.

For each console, `vntsd` provides write access only to the first user connecting to the console. Subsequent users connecting to the console are allowed only to read from the console and wait for write access. When the first user disconnects, write privileges are transferred to the next user waiting in the queue. If a user who does not have write privileges attempts to write to a console, the `vntsd` displays the following message:

```
You do not have write access
```

A user who has no write access can acquire write access forcibly by using the `~w` special console command, described in "Special Console Commands," below.

`vntsd` can be invoked only with superuser privileges or by someone in the Primary Administrator role.

Options The options for `vntsd` are divided into multiple-console options and console commands.

Multiple-Console Options

The options listed below are supported when there are multiple LDoms consoles in a group. The syntax for the use of these options is:

<*hostname*>`-vnts-`<*group-name*>`:` <*option*>

For example:

```
myhost-vnts-salesgroup: h
```

The `h` option invokes help, as described below.

`h`

Display the following help text:

```
h -- this help
l -- list of consoles
q -- quit
c{id}, n{name} -- connect to console of domain {id} or domain name
```

`l`
List all consoles in the group. For example:

```
DOMAIN ID       DOMAIN NAME     DOMAIN STATE
0               ldg1            online
1               ldg2            connected
...             ...             ...
```

The two domain states and their meanings are:

`online`
No one is connected to the console.

`connected`
At least one user is already connected to the console.

`q`
Disconnect from `vntsd`.

c*{id}*, n*{name}*
Connect to specified console. Upon connection, the following message is displayed:

```
Connecting to console <domain-name> in group <group-name>
Press ~? for control options ....
```

Special Console Commands

A tilde (~) appearing as the first character of a line is an escape signal that directs `vntsd` to perform a special console command. The tilde-tilde (~~) sequence outputs a tilde. In conjunction with the initial tilde, `vntsd` accepts the following special console commands:

`~.`
Disconnect from the console or console group.

`~w`
Force write access to the console.

`~p`
Disconnect from this console, and connect to the console that precedes this console in the list of consoles.

`~n`
Disconnect from this console, and connect to the console that follows this console in the list of consoles.

`~#`
Send break.

`~^B`
Send alternate break.

`~?`
Display `vntsd` help, as follows:

```
~# - Send break
~^B - Send alternate break
~. - Exit from this console
~w - Force write access
~n - Console next
~p - Console previous
~? - Help
```

Files `/usr/lib/ldoms/vntsd`
Binary executable `vntsd` file.

`/usr/lib/ldoms/vntsd.xml`
Service management facility (`smf(5)`) manifest file for `vntsd`.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWldoms
Interface Stability	Evolving

See Also `telnet(1)`, `svccfg(1M)`, `usermod(1M)`, `auth_attr(4)`, `attributes(5)`, `smf(5)`

Notes The `vntsd` is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/ldoms/vntsd
```

You can change the following properties using the `svccfg(1M)` command:

`vntsd/vcc_device`
Set an instance of the virtual console concentrator (`vcc`) driver to which `vntsd` is connected.

`vntsd/listen_addr`
Set the IP address to which `vntsd` listens, using the following syntax:

```
vntsd/listen_addr:"xxx.xxx.xxx.xxx"
```

...where *xxx.xxx.xxx.xxx* is a valid IP address. The default value of this property is to listen on IP address 127.0.0.1. Users can connect to a guest console over a network if the value is set to the IP address of the control domain.

Note – Enabling network access to a console has security implications. Any user can connect to a console and for this reason it is disabled by default.

`vntsd/timeout_minutes`
Set timeout in minutes. `vntsd` will timeout (close) `telnet` connection if there is no activity (input or output) on the console. The default value is 0, which disables timeout.

`vntsd/authorization`

Enable the authorization checking of users and roles for the domain console or consoles that are being accessed. The default value of this property is `false` to maintain backward compatibility. To enable authorization checking, use the `svccfg(1M)` command to set the property value to `true`. While this option is enabled, `vntsd` listens and accepts connections on `localhost`. If the `listen_addr` property specifies an alternate IP address when this option is enabled, `vntsd` ignores the alternate IP address and continues to listen on `localhost`. Connections that are initiated from other hosts will also fail. Authorizations are available to access all consoles or console groups, or to access specific consoles or console groups. When the `vntsd` service is enabled, the following authorization is added to the authorization description database, `auth_attr(4)`:

```
solaris.vntsd.consoles:::Access All LDoms Guest Consoles::
```

Add any fine-grained authorizations based on the name of the console group. For example, if the name of the console group to be authorized is `ldg1`, add the following entry to the `auth_attr(4)` file:

```
solaris.vntsd.console-ldg1:::Access Specific LDoms Guest Console::
```

By default, the authorization to access all consoles is assigned to the root user or role. The Primary Administrator (superuser) can use the `usermod(1M)` command to assign the required authorization or authorizations to other users or roles.

The following example gives user `user1` the authorization to access all domain consoles:

```
# usermod -A "solaris.vntsd.consoles" user1
```

The following example gives user `user1` the authorization to access the console group named `ldg1`:

```
# usermod -A "solaris.vntsd.console-ldg1" user1
```

Name volcopy – make an image copy of file system

Synopsis

```
volcopy [-F FSType] [-V] [generic_options]
     [-o FSType-specific_options] operands
```

Description `volcopy` makes a literal copy of the file system. This command may not be supported for all *FSTypes*.

Options The following options are supported:

`-F` *FSType* — Specify the *FSType* on which to operate. The *FSType* should either be specified here or be determinable from `/etc/vfstab` by matching the *operands* with an entry in the table. Otherwise, the default file system type specified in `/etc/default/fs` will be used.

`-V` — Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from `/etc/vfstab`. This option should be used to verify and validate the command line.

generic_options — Options that are commonly supported by most *FSType*-specific command modules. The following options are available:

- `-a` Require the operator to respond "yes" or "no" instead of simply waiting ten seconds before the copy is made.
- `-s` (Default) Invoke the DEL if wrong verification sequence.

`-o` *FSType-specific_options* — Specify *FSType*-specific options in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the *FSType*-specific module of the command.

Operands The following operands are supported:

operands — generally include the device and volume names and are file system specific. A detailed description of the *operands* can be found on the *FSType*-specific man pages of `volcopy`.

Exit Status The following exit values are returned:

- `0` Successful file system copy
- `1` An error has occurred.

Files

`/etc/vfstab`	list of default parameters for each file system
`/etc/default/fs`	default local file system type. Default values can be set for the following flags in `/etc/default/fs`. For example: `LOCAL=ufs`.
`LOCAL:`	The default partition for a command if no *FSType* is specified.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `labelit(1M)`, `vfstab(4)`, `attributes(5)` Manual pages for the *FSType*-specific modules of `volcopy`.

Name volcopy_ufs – make an image copy of a ufs file system

Synopsis `volcopy [-F ufs] [`*generic_options*`] `*fsname srcdevice volname1 destdevice volname2*

Description `volcopy` makes a literal copy of the `ufs` file system using a blocksize matched to the device.

Options The following option is supported:

generic_options options supported by the generic `volcopy` command. See `volcopy(1M)`.

Operands The following operands are supported:

fsname represents the mount point (for example, `root`, `u1`, etc.) of the file system being copied.

srcdevice or *destdevice* the disk partition specified using the raw device (for example, `/dev/rdsk/cld0s8`, `/dev/rdsk/cld1s8`, etc.).

srcdevice and *volname1* the device and physical volume from which the copy of the file system is being extracted.

destdevice and *volname2* the target device and physical volume.

fsname and *volname* are limited to six or fewer characters and recorded in the superblock. *volname* may be '–' to use the existing volume name.

Exit Status The following exit values are returned:

`0` Successful file system copy.

non-zero An error has occurred.

Files `/var/adm/filesave.log` a record of file systems/volumes copied

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `cpio(1)`, `dd(1M)`, `labelit(1M)`, `volcopy(1M)`, `attributes(5)`, `ufs(7FS)`

Notes `volcopy` does not support copying to tape devices. Use `dd(1M)` for copying to and from tape devices.

Name vold – Volume Management daemon to manage removable media devices

Synopsis

```
/usr/sbin/vold  [-n] [-t] [-v] [-f config-file] [-l log-file]
 [-d root-dir] [-L debug-level]
```

Description The Volume Management daemon, `vold`, creates and maintains a file system image rooted at *root-dir* that contains symbolic names for removable media devices. These devices include CD-R, CD-RW, floppies, DVD, and USB and 1394 mass storage devices. The default *root-dir* is set to `/vol` if no directory is specified by the `-d` option.

`vold` reads the `/etc/vold.conf` configuration file upon startup. If the configuration file is modified later, `vold` must be told to reread the `/etc/vold.conf` file. Accomplish this rereading by entering:

```
example# svcadm refresh volfs
```

To tell `vold` to clean up and exit, enter:

```
example# svcadm disable volfs
```

To reenable:

```
example# svcadm enable volfs
```

To specify options (see OPTIONS):

```
example# svccfg
svc:> select volfs
svc:/system/filesystem/volfs> listprop vold/*
vold/config_file            astring
vold/log_debuglevel         count    0
vold/log_file               astring
vold/log_nfs_trace          boolean  false
vold/log_verbose            boolean  false
vold/never_writeback_label  boolean  false
vold/root_dir               astring
svc:/system/filesystem/volfs> setprop vold/never_writeback_label=true
svc:/system/filesystem/volfs> exit

# svcadm disable volfs
# svcadm enable volfs
```

`vold` is hotplug-aware for USB and 1394 mass storage devices, thus there is no need for stopping and restarting `vold`. It is recommended to `eject(1)` the "media" before hot-removing a device. The `eject` command unmounts any filesystems mounted from the media, making it safe to remove the device. (Note that all USB and 1394 devices, regardless of whether they contain removable media, are treated like removable media devices).

Options The following options are supported:

`-n`	Never writeback. Volume Management updates media labels with unique information if labels are not unique. This flag keeps Volume Management from changing your media. The default setting is FALSE.
`-t`	Dump NFS trace information to the log file. The default setting is FALSE.
`-v`	Provide lots of status information to the log file. The default setting is FALSE (do not provide status info to log file).
`-d` *root-dir*	Specify an alternate root directory. The default location is `/vol`. Setting this will also cause other Volume Management utilities to use this as the default root directory.
`-f` *config-file*	Specify an alternate configuration file. The default file is `/etc/vold.conf`.
`-l` *log-file*	Specify an alternate log file. The default log file is `/var/adm/vold.log`.
`-L` *debug-level*	Change the level (verbosity) of debug messages sent to the log file. The range is `0` to `99` where `0` is nothing and `99` is everything. The default level is `0`.

Environment Variables `vold` sets the following environment variables to aid programs which are called when events such as `insert`, `notify`, and `eject` occur:

`VOLUME_ACTION`	Event that caused this program to be executed.
`VOLUME_PATH`	Pathname of the matched *regex* from the `vold.conf` file.
`VOLUME_DEVICE`	Device (in `/vol/dev`) that applies to the media.
`VOLUME_NAME`	Name of the volume in question.
`VOLUME_USER`	User ID of the user causing the event to occur.
`VOLUME_SYMNAME`	Symbolic name of a device containing the volume.
`VOLUME_MEDIATYPE`	Name of the type of media (CD-ROM, floppy or rmdisk)

Files

`/etc/vold.conf`	Volume Management daemon configuration file. Directs the Volume Management daemon to control certain devices, and causes events to occur when specific criteria are met.
`/usr/lib/vold/*.so.1`	Shared objects called by Volume Management daemon when certain actions occur.
`/var/adm/vold.log`	the default log file location (see the `-l` option for a description).
`/vol`	the default Volume Management root directory.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWvolu, SUNWvolr

See Also volcancel(1), volcheck(1), volmissing(1), rmmount(1M), rpc.smserverd(1M), rmmount.conf(4), vold.conf(4), attributes(5), smf(5), volfs(7FS), usb(7D), scsa1394(7D)

System Administration Guide: Basic Administration

Notes The Volume Management daemon and associated commands might not be included in a future Solaris release.

Name wall – write to all users

Synopsis `/usr/sbin/wall [-a] [-g grpname] [filename]`

Description `wall` reads its standard input until an end-of-file. It then sends this message to all currently logged-in users preceded by:

```
Broadcast Message from . . .
```

If *filename* is given, then the message is read in from that file. Normally, pseudo-terminals that do not correspond to rlogin sessions are ignored. Thus, when using a window system, the message appears only on the console window. However, `-a` will send the message even to such pseudo-terminals.

It is used to warn all users, typically prior to shutting down the system.

The sender must be superuser to override any protections the users may have invoked See `mesg(1)`.

`wall` runs `setgid()` to the group ID `tty`, in order to have write permissions on other user's terminals. See `setuid(2)`.

`wall` will detect non-printable characters before sending them to the user's terminal. Control characters will appear as a " ^ " followed by the appropriate ASCII character; characters with the high-order bit set will appear in "meta" notation. For example, '`\003`' is displayed as '`^C`' and '`\372`' as '`M–z`'.

Options The following options are supported:

`-a` Broadcast message to the console and pseudo-terminals.

`-g` *grpname* Broadcast to the users in a specified group only, per the group database (see `group(4)`).

Environment Variables If the `LC_*` variables (`LC_CTYPE`, `LC_TIME`, `LC_COLLATE`, `LC_NUMERIC`, and `LC_MONETARY`) are not set in the environment, the operational behavior of `wall` for each corresponding locale category is determined by the value of the `LANG` environment variable. See `environ(5)`. If `LC_ALL` is set, its contents are used to override both the `LANG` and the other `LC_*` variables. If none of the above variables are set in the environment, the "C" (U.S. style) locale determines how `wall` behaves.

Files `/dev/tty*`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also mesg(1), write(1), setuid(2), attributes(5), environ(5)

Notes wall displays "Cannot send to . . ." when the open on a user's tty file fails.

Name wanboot_keygen – create and display client and server keys for WAN booting

Synopsis

```
/usr/lib/inet/wanboot/keygen -c -o net=a.b.c.d ,cid=client_ID,type=3des

/usr/lib/inet/wanboot/keygen -c -o net=a.b.c.d ,cid=client_ID,type=aes

/usr/lib/inet/wanboot/keygen -m

/usr/lib/inet/wanboot/keygen -c -o net=a.b.c.d ,cid=client_ID,type=sha1

/usr/lib/inet/wanboot/keygen -d -m

/usr/lib/inet/wanboot/keygen -c -o net=a.b.c.d ,cid=client_ID,type=keytype
```

Description The keygen utility has three purposes:

- Using the `-c` flag, to generate and store per-client 3DES/AES encryption keys, avoiding any DES weak keys.
- Using the `-m` flag, to generate and store a "master" HMAC SHA-1 key for WAN install, and to derive from the master key per-client HMAC SHA-1 hashing keys, in a manner described in RFC 3118, Appendix A.
- Using the `-d` flag along with either the `-c` or `-m` flag to indicate the key repository, to display a key of type specified by *keytype*, which must be one of `3des`, `aes`, or `sha1`.

The `net` and `cid` arguments are used to identify a specific client. Both arguments are optional. If the `cid` option is not provided, the key being created or displayed will have a per-network scope. If the `net` option is not provided, then the key will have a global scope. Default net and code values are used to derive an HMAC SHA-1 key if the values are not provided by the user.

Options The following options are supported:

`-c` Generate and store per-client 3DES/AES encryption keys, avoiding any DES weak keys. Also generates and stores per-client HMAC SHA-1 keys. Used in conjunction with `-o`.

`-d` Display a key of type specified by *keytype*, which must be one of `3des`, `aes`, or `sha1`. Use `-d` with `-m` or with `-c` and `-o`.

`-m` Generate and store a "master" HMAC SHA-1 key for WAN install.

`-o` Specifies the WANboot client and/or keytype.

Examples

EXAMPLE 1 Generate a Master HMAC SHA-1 Key

```
# keygen -m
```

EXAMPLE 2 Generate and Then Display a Client-Specific Master HMAC SHA-1 Key

```
# keygen -c -o net=172.16.174.0,cid=010003BA0E6A36,type=sha1
# keygen -d -c -o net=172.16.174.0,cid=010003BA0E6A36,type=sha1
```

EXAMPLE 3 Generate and Display a 3DES Key with a Per-Network Scope

```
# keygen -c -o net=172.16.174.0,type=3des
# keygen -d -o net=172.16.174.0,type=3des
```

Exit Status

`0` Successful operation.

`>0` An error occurred.

Attributes

See `attributes(5)` for descriptions of the following attributes:

Name wanboot_keymgmt – insert and extract keys

Synopsis

```
/usr/lib/inet/wanboot/keymgmt -i -k key_file -s keystore -o type=keytype

/usr/lib/inet/wanboot/keymgmt -x -f outfile -s keystore -o type=keytype
```

Description The `keymgmt` utility has two purposes:

- To take a raw key, stored in *key_file*, and insert it in the repository specified by *keystore*.
- To extract a key of a specified type from the repository specified by *keystore*, depositing it in *outfile*.

outfile will be created if it does not already exist. The type of key being added or extracted is specified by *keytype* and may have one of four values: `3des`, `aes`, `rsa`, or `sha1` (the last used by HMAC SHA-1). When extracting a key, the first key with an OID matching the supplied type is used.

Arguments The following arguments are supported:

`-i`	Used in conjunction with `-k` to insert a raw key in *keystore*.
`-f` *outfile*	Used to specify a file to receive an extracted key.
`-k` *key_file*	Used in conjunction with `-i` to specify the file in which a raw key is stored. This key will be inserted in *keystore*.
`-o` type=*keytype*	Specifies the type of key being inserted or extracted. Must be one of `3des`, `aes`, `rsa`, or `sha1`.
`-s` *keystore*	Specifies a repository in which a key will be inserted or from which a key will be extracted.
`-x`	Used in conjunction with `-f` to extract a key of a specified type and deposit it in *outfile*.

Exit Status

`0`	Successful operation.
`>0`	An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWwbsup
Interface Stability	Obsolete

See Also `attributes(5)`

ITU-T Recommendation X.208

Name wanboot_p12split – split a PKCS #12 file into separate certificate and key files

Synopsis

```
/usr/lib/inet/wanboot/p12split -i p12file -c out_cert -k out_key
     [-t out_trust -l id -v]
```

Description The `p12split` utility extracts a certificate and private key from the repository specified by *p12file*, depositing the certificate in *out_cert* and the key in *out_key*. If supplied, the `-l` option specifies the value for the `LocalKeyId` that will be used in the new certificate and key files. `p12split` can optionally extract a trust certificate into the *out_trust* file if the `-t` option is specified. Use the `-v` option to get a verbose description of the split displayed to standard output.

Options The following arguments and options are supported:

`-c` *out_cert* Specifies a repository that receives a extracted certificate.

`-i` *p12file* Specifies a repository from which a certificate and private key is extracted.

`-k` *out_key* Specifies a repository that receives a extracted private key.

`-l` *id* Specifies the value for the `LocalKeyId` that will be used in the new certificate and key files.

`-t` *out_trust* Specifies a file for receiving an extracted trust certificate.

`-v` Displays a verbose description of the split to sdtout.

Exit Status

`0` Successful operation.

`>0` An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWwbsup
Interface Stability	Unstable

See Also `attributes(5)`

Name wanbootutil – manage keys and certificates for WAN booting

Synopsis

```
wanbootutil [keygen] [option_specific_arguments]

wanbootutil [keymgmt] [option_specific_arguments]

wanbootutil [p12split] [option_specific_arguments]
```

Description The `wanbootutil` command creates and manages WANboot encyrption and hashing keys and manipulates PKCS #12 files for use by WAN boot.

`wanbootutil` has three subcommands, each covered in a separate man page:

`wanboot_keygen(1M)`	Generates encryption and hashing keys.
`wanboot_keymgmt(1M)`	Inserts and extracts keys from WAN boot key repositories.
`wanboot_p12split(1M)`	Splits a PKCS #12 file into separate certificate and key files for use by WAN boot.

Options The options are supported for `wanbootutil` are the use of `keygen`, `keymgmt`, or `p12split`. The options for these subcommands are described in their respective man pages.

Examples

EXAMPLE 1 Generate a 3DES Client Key

```
# wanbootutil keygen -c -o net=172.16.174.0,cid=010003BA0E6A36,type=3des
```

EXAMPLE 2 Insert an RSA Private Client Key

```
wanbootutil keymgmt -i -k keyfile \
  -s /etc/netboot/172.16.174.0/010003BA0E6A36/keystore -o type=rsa
```

EXAMPLE 3 Split a PKCS #12 File into Certificate and Key Components

```
# wanbootutil p12split -i p12file -c out_cert -k out_key
```

Exit Status

`0`	Successful operation.
`non-zero`	An error occurred. Writes an appropriate error message to standard error.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWwbsup
Interface Stability	Obsolete

Name wbemadmin – start Sun WBEM User Manager

Synopsis

```
/usr/sadm/bin/wbemadmin
```

Description The `wbemadmin` utility starts Sun WBEM User Manager, a graphical user interface that enables you to add and delete authorized WBEM users and to set their access privileges. Use this application to manage access to groups of managed resources, such as disks and installed software, in the Solaris operating environment.

The `wbemadmin` utility allows you to perform the following tasks:

Manage user access rights	Use the `wbemadmin` utility to add, delete, or modify an individual user's access rights to a namespace on a WBEM-enabled system.
Manage namespace access rights	Use the `wbemadmin` utility to add, delete, or modify access rights for all users to a namespace.

The Sun WBEM User Manager displays a Login dialog box. You must log in as root or a user with write access to the `root\security` namespace to grant access rights to users. By default, Solaris users have guest privileges, which grants them read access to the default namespaces.

Managed resources are described using a standard information model called Common Information Model (CIM). A CIM object is a computer representation, or model, of a managed resource, such as a printer, disk drive, or CPU. CIM objects can be shared by any WBEM-enabled system, device, or application. CIM objects are grouped into meaningful collections called schema. One or more schemas can be stored in directory-like structures called namespaces.

All programming operations are performed within a namespace. Two namespaces are created by default during installation:

- `root\cimv2` — Contains the default CIM classes that represent objects on your system.
- `root\security` — Contains the security classes used by the CIM Object Manager to represent access rights for users and namespaces.

When a WBEM client application connects to the CIM Object Manager in a particular namespace, all subsequent operations occur within that namespace. When you connect to a namespace, you can access the classes and instances in that namespace (if they exist) and in any namespaces contained in that namespace.

When a WBEM client application accesses CIM data, the WBEM system validates the user's login information on the current host. By default, a validated WBEM user is granted read access to the Common Information Model (CIM) Schema. The CIM Schema describes managed objects on your system in a standard format that all WBEM-enabled systems and applications can interpret.

You can set access privileges on individual namespaces or for a user-namespace combination. When you add a user and select a namespace, by default the user is granted read access to CIM objects in the selected namespace. An effective way to combine user and namespace access rights is to first restrict access to a namespace. Then grant individual users read, read and write, or write access to that namespace.

You cannot set access rights on individual managed objects. However you can set access rights for all managed objects in a namespace as well as on a per-user basis.

If you log in to the root account, you can set the following types of access to CIM objects:

- Read Only — Allows read-only access to CIM Schema objects. Users with this privilege can retrieve instances and classes, but cannot create, delete, or modify CIM objects.
- Read/Write — Allows full read, write, and delete access to all CIM classes and instances.
- Write — Allows write and delete, but not read access to all CIM classes and instances.
- None — Allows no access to CIM classes and instances.

Context help is displayed in the left side of the `wbemadmin` dialog boxes. When you click on a field, the help content changes to describe the selected field. No context help is available on the main User Manager window.

The `wbemadmin` security administration tool updates the following Java classes in the `root\security` namespace:

- `Solaris_UserAcl` — Updated when access rights are granted or changed for a user.
- `Solaris_namespaceAcl` — Updated when access rights are granted or changed for a namespace.

Usage The `wbemadmin` utility is not the tool for a distributed environment. It is used for local administration on the machine on which the CIM Object Manager is running.

Exit Status The `wbemadmin` utility terminates with exit status `0`.

Warning The `root\security` namespace stores access privileges. If you grant other users access to the `root\security` namespace, those users can grant themselves or other users rights to all other namespaces.

Name wbemconfig – convert a JavaSpaces datastore to the newer Reliable Log datastore format

Synopsis

```
/usr/sadm/lib/wbem/wbemconfig convert
```

Description A Reliable Log directory is created that contains the converted data. This directory is named `/var/sadm/wbem/logr`.

The `convert` argument is the only supported option of this command. You should only run this command after stopping WBEM (CIM Object Manager) with the `init.wbem stop` command. Otherwise your data may be corrupted.

This command successfully converts any proprietary custom MOFs you have created in the datastore, but not any CIM or Solaris MOFs you have modified. These will be destroyed. To recompile any modified CIM or Solaris MOFs into the new datastore, run the `mofcomp` command on the MOF files containing the class definitions.

Because the `wbemconfig convert` command invokes the JVM (Java Virtual Machine) to perform conversion of the JavaSpaces datastore, you must be running the same version of the JVM as when the original JavaSpaces storage was created. After the `wbemconfig convert` command is completed, you can change to any version of the JVM you want.

To see what version of the JVM you are running, issue the `java -version` command.

Options The following options are supported:

convert Convert a JavaSpaces datastore to the newer Reliable Log datastore format.

Attributes See `attributes(5)` for descriptions of the following attributes:

Name wbemlogviewer – start WBEM Log Viewer

Synopsis

```
/usr/sadm/bin/wbemlogviewer
```

Description The `wbemlogviewer` utility starts the WBEM Log Viewer graphical user interface, which enables administrators to view and maintain log records created by WBEM clients and providers. The WBEM Log Viewer displays a Login dialog box. You must log in as root or a user with write access to the `root\cimv2` namespace to view and maintain log files. Namespaces are described in `wbemadmin(1M)`.

Log events can have three severity levels.

- Errors
- Warnings
- Informational

The WBEM log file is created in the `/var/sadm/wbem/log` directory, with the name `wbem_log`. The first time the log file is backed up, it is renamed `wbem_log.1`, and a new `wbem_log` file is created. Each succeeding time the `wbem_log` file is backed up, the file extension number of each backup log file is increased by 1, and the oldest backup log file is removed *if* the limit, which in turn is specified in the log service settings, on the number of logfiles is exceeded. Older backup files have higher file extension numbers than more recent backup files.

The log file is renamed with a `.1` file extension and saved when one of the following two conditions occur:

- The current file reaches the specified file size limit.
- A WBEM client application uses the `clearLog()` method in the `Solaris_LogService` class to clear the current log file.
- A WBEM client application uses the `clearLog()` method in the Solaris_LogService class to clear the current log file.
- A user chooses Action->Back Up Now in the Log Viewer application.

Help is displayed in the left panel of each dialog box. Context help is not displayed in the main Log Viewer window.

Usage The WBEM Log Viewer is not the tool for a distributed environment. It is used for local administration.

The WBEM Log Viewer allows you to perform the following tasks:

View the logs

Set properties of log files	Click Action->Log File Settings to specify log file parameters and the log file directory.
Back up a log file	Click Action->Back Up Now to back up and close the current log file and start a new log file.

Open historical log files	Click Action->Open Log File to open a backed-up log file.
Delete an old log file	Open the file and then click Action->Delete Log File. You can only delete backed-up log files.
View log record details	Double-click a log entry or click View->Log Entry Details to display the details of a log record.
Sort the logs	Click View->Sort By to sort displayed entries. You can also click any column heading to sort the list. By default, the log entries are displayed in reverse chronological order (new logs first).

Exit Status The `wbemlogviewer` utility terminates with exit status `0`.

Files `/var/sadm/wbem/log/wbem_log` WBEM log file

Name wcadmin – manage the configuration of the Sun Java Web Console

Synopsis

```
/usr/sbin/wcadmin subcommand options
/usr/sbin/wcadmin [-h| --help]
/usr/sbin/wcadmin [-V | --version]
```

Description `wcadmin` is a Command Line Interface (CLI) — based tool for managing the configuration of the Sun Java Web Console.

Subcommands The following subcommands are supported:

add — The `wcadmin add` subcommand adds a new shared jar file, a new JAAS login module, or a new shared service property to the console configuration. An optional identifier may be specified; if omitted, the identifier is derived from the resource name. The resource is added when the console is next started.

The format of the `add` subcommand is:

add `-l -a` *appname* [`-n` *id*] *jarpath*

add `-m -a` *appname* [`-n` *id*] `-b` *behavior* `-s` *service* [`-o` *name=value*] *classname*

add `-p -a` *appname name=value* [... *name=value*]

deploy — The `wcadmin deploy` subcommand deploys the specified web application into the console's web server instance. Applications are deployed directly from their installation directories.

The format of the `deploy` subcommand is:

deploy [`-D`] `-a` *appname* `-x` *context app_path*

disable — The `wcadmin disable` subcommand disables access to the specified web application in the console's web server instance.

The format of the `disable` subcommand is:

disable `-x` *context*

enable — The `wcadmin enable` subcommand enables access to the specified web application in the console's web server instance.

The format of the `enable` subcommand is:

enable `-x` *context*

list — The `wcadmin list` subcommand lists the resources currently configured for the console; including deployed web applications, shared jar files, login modules, and shared service properties. If no option is specified, all resources are listed.

The format of the `list` subcommand is:

list [`-a`] [`-d`] [`-l`] [`-m`] [`-p`]

password — The `wcadmin password` subcommand manages the administrator and security keystore passwords for the console. Keystore passwords should not be changed while the console is running.

The format of the `password` subcommand is:

password [`-a`] [`-k`] [`-t`]

password `-f` *password_file*

reload — The `wcadmin reload` subcommand unloads the specified web application from the console's web server instance and reloads the application from its original installation directory.

The format of the `reload` subcommand is:

reload `-x` *context*

remove — The `wcadmin remove` subcommand removes a shared jar file, a login module, or a shared service property from the console configuration. The resource may be specified by its identifier or by its full jarpath or classname. The resource is removed when the console is next started.

The format of the `remove` subcommand is:

remove `-l -a` *appname* [`-n` *id*] *jarpath*

remove `-m -a` *appname* [`-n` *id*] *classname*

remove `-p -a` *appname property* [...]

undeploy — The `wcadmin undeploy` subcommand undeploys the specified web application from the console's web server instance.

The format of the `undeploy` subcommand is:

undeploy [`-D`] `-a` *appname* `-x` *context*

Options The following options are supported:

`-h` | `--help` | `-?` — Display runtime help.

`-V` | `--version` — Display console version information.

`-D` | `--defer` — When used with the deploy and undeploy subcommands, defers the deployment or undeployment until the next console restart.

The operation is deferred by simply adding or removing the corresponding resource registration notification file. If defer is not specified, a runtime deployment or undeployment is performed, so that the application becomes available or unavailable in the running console. If the console instance is not currently running, the operation is automatically deferred.

`-a|--adminpassword` Specify that the administrator password should be changed, when used with password subcommand. You are prompted for a new password, which must be 8 to 32 characters.

`-a|--application` Specify the application name, when used with subcommands other than password subcommand.

`-d|--detail` Specify that configuration details of each resource should be displayed.

`-f` Specify the fully qualified path name to a file containing one or more password property values. See the description of the password_file argument.

`-k|--keypassword` Specify that the keystore password should be changed. You are prompted for a new password, which must be 8 to 32 characters.

`-l|--library` Specify that the resource is a shared jar file.

`-m|--module` Specify that the resource is a JAAS login module.

`-n|--name` Specify the short-hand identifier name for the resource. If omitted, the identifier name is derived from the full resource name.

`-o|--option` Specify the name and value of a login module option property, separated by the equals character.

`-p|--property` Specify that the resource is one or more shared service properties.

`-s|--service` Specify the name of the JAAS login service definition. If omitted, the default console login service definition is assumed.

`-t|--trustpassword` Specify that the truststore password should be changed. You are prompted for a new password, which must be 8 to 32 characters.

`-x|--context` Specify the web application context path name under which the application is deployed.

Arguments

app_path The fully qualified file system path to the web application installation directory.

appname The application name. The name must be unique among all web applications registered with the console. It is also used as the name of the subdirectory under the console's pre-registration directory which contains

all the resource registration notification files for that application. Typically, the application package name, plugin identifier, or context path name is specified for the application name.

behavior The JAAS login module control flag behavior. Must be one of "optional", "required", "requisite", or "sufficient".

classname The fully qualified Java package class name of the JAAS login module. The specified class must be included in a shared jar file added to the console.

context The web application context path name under which the application is deployed. With the .reg suffix, the context forms the file name of the registration notification file for that application.

id The short-hand identifier name for a jar file or login module resource to be added or removed. The identifier name must be unique among the resources shared for a given application name. With the .reg suffix, it forms the file name of the registration notfication file for that resource.

jarpath The fully qualified file system path to the jar file resource. When the resource is added to the console, its path is included in the classpath of the console's shared class loader.

option The JAAS login module option property name.

property The shared service property name.

password_file The fully qualified path to a password text file that contains the new administrator, keystore, and truststore passwords in property file format. The administrator password is specified using the "adminpassword" property. The keystore password is specified using the "keypassword" property. The truststore password is specified using the "trustpasswd" property. At least one password property must be contained in the password file.

value The login module option or shared service property value. If the value contains white space, it must be quoted.

Examples The following command adds a jar file to be shared in the console:

```
wcadmin add -l -a myapp_1.0 -n wbem /usr/sadm/lib/wbem.jar
```

The following command deploys a new web application:

```
wcadmin deploy -a myapp_1.0 -x myapp /opt/SUNWmyapp/myapp
```

The following command reloads an existing web application:

```
wcadmin reload -x myapp
```

The following command undeploys a web application at the next server restart:

```
wcadmin undeploy -D -a myapp_1.0 -x myapp
```

The following command lists all the deployed web applications in the console. If the status field is "running", the web application is available. If the status field is "stopped", the web application is disabled and is not available. If all web applications are "stopped", this typically indicates the console web server instance is not running.

```
wcadmin list -a
```

The following command removes a shared jar file:

```
wcadmin remove -l -a myapp_1.0 -n wbem
```

The following command changes passwords that are specified in a file:

```
wcadmin password -f /home/mydir/console-passwords
```

Exit Status The following exit values are returned:

`0` Subcommand succeeded without error

1 Usage error: missing or malformed arguments

2 Fatal error: subcommand failed with one or more errors

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmcon
Interface Stability	Stable

See Also `smcwebserver(1M)`, `smreg(1M)`, `attributes(5)`, `environ(5)`

Name whodo – who is doing what

Synopsis

```
/usr/sbin/whodo [-h] [-l] [user]
```

Description The `whodo` command produces formatted and dated output from information in the `/var/adm/utmpx` and `/proc/pid` files.

The display is headed by the date, time, and machine name. For each user logged in, device name, user-ID and login time is shown, followed by a list of active processes associated with the user-ID. The list includes the device name, process-ID, CPU minutes and seconds used, and process name.

If *user* is specified, output is restricted to all sessions pertaining to that user.

Options The following options are supported:

`-h` Suppress the heading.

`-l` Produce a long form of output. The fields displayed are: the user's login name, the name of the tty the user is on, the time of day the user logged in (in *hours*:*minutes*), the idle time — that is, the time since the user last typed anything (in *hours*:*minutes*), the CPU time used by all processes and their children on that terminal (in *minutes*:*seconds*), the CPU time used by the currently active processes (in *minutes*:*seconds*), and the name and arguments of the current process.

Examples **EXAMPLE 1** Using the whodo Command

The command:

```
example% whodo
```

produces a display like this:

```
Tue Mar 12 15:48:03 1985
bailey
tty09    mcn       8:51
    tty09   28158    0:29 sh

tty52    bdr      15:23
    tty52   21688    0:05 sh
    tty52   22788    0:01 whodo
    tty52   22017    0:03 vi
    tty52   22549    0:01 sh

xt162    lee      10:20
    tty08    6748    0:01 layers
    xt162    6751    0:01 sh
    xt163    6761    0:05 sh
    tty08    6536    0:05 sh
```

Environment Variables If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of tar(1) for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the C (U.S. style) locale determines how whodo behaves.

LC_CTYPE — Determines how whodo handles characters. When LC_CTYPE is set to a valid value, whodo can display and handle text and filenames containing valid characters for that locale. The whodo command can display and handle Extended Unix code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. whodo can also handle EUC characters of 1, 2, or more column widths. In the C locale, only characters from ISO 8859-1 are valid.

LC_MESSAGES — Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the C locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

LC_TIME — Determines how whodo handles date and time formats. In the C locale, date and time handling follow the U.S. rules.

Exit Status The following exit values are returned:

0 — Successful completion.

non-zero — An error occurred.

Files

/etc/passwd — System password file

/var/adm/utmpx — User access and administration information

/proc/pid — PID information for individual users

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also ps(1), who(1), attributes(5), environ(5)

Name wracct – write extended accounting records for active processes and tasks

Synopsis

```
/usr/sbin/wracct -i id_list [-t record_type]
     {process | task}
```

Description The `wracct` utility allows the administrator to invoke the extended accounting system, if active, to write intermediate records representing the resource usage of a selected set of processes or tasks. For tasks, a *record_type* option is also supported, allowing the administrator to request the writing of:

- an interval record, which reflects task usage since a previous interval record (or since task creation if there is no interval record), or
- a partial record, which reflects usage since task creation.

Options The following options are supported:

`-i` *id_list* Select the IDs of the tasks or processes to write records for. Specify *id_list* as a comma- or space-separated list of IDs, presented as a single argument. For some shells, this requires appropriate quoting of the argument.

`-t` *record_type* Select type of record to write for the selected task or process. For tasks, *record_type* can be `partial` or `interval`. `partial` is the default type, and the only type available for process records.

Operands The following operands are supported:

`process` Treat the given ID as a process ID for the purposes of constructing and writing an extended accounting record.

`task` Treat the given ID as a task ID for the purposes of constructing and writing an extended accounting record.

Examples **EXAMPLE 1** Writing a Partial Record

Write a partial record for all active `sendmail` processes.

```
# /usr/sbin/wracct -i "‘pgrep sendmail‘" process
```

EXAMPLE 2 Writing an Interval Record

Write an interval record for the task with `ID 182`.

```
# /usr/sbin/wracct -t interval -i 182 task
```

Exit Status The following exit values are returned:

`0` Successful completion.

`1` An error occurred.

`2` Invalid command line options were specified.

3 Pertinent components of extended accounting facility are not active.

Files `/var/adm/exacct/task`

`/var/adm/exacct/proc` Extended accounting data files.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

See Also `acctadm(1M)`, `attributes(5)`

Name wrsmconf – manage WCI RSM controller configurations

Synopsis

```
/usr/platform/sun4u/sbin/wrsmconf create -c controller_id -f config_file

wrsmconf initial -f config_file [-c controller_id]

wrsmconf remove [-c controller_id]

wrsmconf topology [-c controller_id]

wrsmconf dump -c controller_id -f config_file
```

Description `wrsmconf` provides a means to create, install, retrieve, and remove configurations for WCI remote shared memory (RSM) controllers.

Options The following options are supported:

`create -c` *controller_id* `-f` *config_file*

Create a set of per-node configurations for the specified controller and store them to the file *config_file*. The created file contains a per-node configuration for each node specified in the input for the specified controller. The file has a checksum on it and cannot be modified directly. This file can be used in a `wrsmconf initial` call on each node to install the node's configuration into the local driver.

A list of nodes and WCI devices connected to those nodes is read from standard input. For each connected pair of links, specify the nodename (`uname -n`), safari port id, and link number on both sides of the connection. The format of the information looks like this:

```
<nodename>.<wrsm-portid>.<linkno>=<nodename>.<wrsm-portid>.<linkno>
<nodename>.<wrsm-portid>.<linkno>=<nodename>.<wrsm-portid>.<linkno>
```

This interface is intended for installing configurations for testing (such as for SunVTS). Only direct-connect, non-striped configurations for 1 to 3 nodes can be specified. FM node ids and RSM hardware addresses are assigned to the specified nodes contiguously and in order starting from 0.

`initial -f` *config_file* [`-c` *controller_id*]

Install the configuration for the local node stored in the file *config_file* into the driver as the initial configuration for the specified controller. This command fails under the following circumstances:

- If *controller_id* is specified and the configuration in the file is not for the specified controller.
- If the file does not contain a valid configuration for the local node or if the checksum in the file shows it has been modified.
- If a configuration has already been installed for the controller. If this happens, use `wrsmconf remove` to remove the existing configuration.

`remove` [`-c` *controller_id*]

Disable communication through the installed configuration for all controllers or the specified controller and remove the configuration(s) from the driver.

`topology -c` *controller_id*

For each installed controller (or for the specified controller), print to stdout the set of nodes this controller is configured to reach, including the nodename, FM node id, and RSM hardware address for each node. The following is example output:

```
FM Node ID   Node Name  Controller Instance    Controller HW Addr
0            hpc00              0                    101
0            hpc00              1                    333
1            hpc01              0                    102
1            hpc01              1                    54
1            hpc01              2                    34
2            hpc03              0                    103
2            hpc03              1                    103
2            hpc03              2                    103
```

`dump -c` *controller-id* `-f` *config_file*

Fetch the installed configuration for the specified controller from the driver and store it into the file *config_file* along with a checksum to protect the data. This configuration can later be installed with the command `wrsmconf initial`.

Exit Status This command returns 0 on successful completion, and a non-zero value if an error occured.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWwrsm

See Also kstat(1M), wrsmstat(1M), attributes(5)

Name wrsmstat – report WCI RSM driver statistics

Synopsis

```
/usr/platform/sun4u/sbin/wrsmstat controller
     [-c controller_id]

wrsmstat wrsm [-i wrsm_instance_num] [-v]

wrsmstat route [-c controller_id]
     [-h node_hostname]

wrsmstat set [-i wrsm_instance_num] -c cmmu -s start -e end
```

Description The `wrsmstat` command provides statistics on remote shared memory (RSM) controllers, routes to nodes, and WCI interfaces managed by the WCI RSM driver (`wrsm`). It also provides an interface for setting extended performance counter control registers that constrain the `wrsm` counters available through `busstat(1M)`.

Options The following options are supported:

`controller` [`-c` *controller_id*]
Displays information describing the state of the specified controller, or of all controllers if none is specified. The following is sample output:

$ wrsmstat controller -c 5 Controller 5 ---------- Controller state: up Local RSM Hardware address: 0x4 Exported segments: 0 # published: 0 # connections: 0 total bound memory: 0 Imported segments: 0 Send Queues: 0 Registered Handlers: 0 Assigned WCIs: 4 Available WCIs: 2

`wrsm` [`-i` *wrsm_instance_num*] [`-v`]
Displays information describing the state of the specified RSM WCI, or of all RSM WCIs if none is specified. The following is sample output:

```
$ wrsmstat wrsm -i 2
    WCI instance 2
    --------------
    Portid: 5
    Controller ID: 0
    Config Version: 5
    Link Error Shutdown Trigger: 40000
    Link #0 is not present.
    Link #1
        Link Enabled: yes
        Link State: up
        Remote RSM HW addr: 1
        Remote wnode ID: 1
        Remote link num: 1
        Remote WCI port ID: 3
        Error takedowns: 0
        Bad Config takedowns: 0
        Failed bringups: 0
```

```
        Total link errors: 0
        Maximum link errors: 0
        Average link errors: 0
        Auto shutdown enabled: yes
    Link #2 is not present.
```

If you specify the `-v` option, the following additional information is displayed:

```
Cluster Error Count:        0
Uncorrectable SRAM ECC error:   no
Maximum SRAM ECC errors:    0
Average SRAM ECC errors:    0
```

`route` [`-c` *controller_id*] [`-h` *nodename*]
Displays the route to the specified node through the specified controller. If no node is specified, displays the routes to all nodes. If no controller is specified, displays the specified node's route through all controllers. If neither is specified, displays the routes to all nodes through all controllers. The following is sample output:

```
$ wrsmstat -c 3 -h fred
Controller 3 - Route to fred
----------------------------
Config Version: 1
FM node id: 0x345543
RSM hardware address: 0x9
Route Changes: 3
Route Type: Passthrough
Number of WCIs: 2
Stripes: 4
WCI #0
    Port ID: 3
    Instance: 0
    Num of hops: 2
    Num of links: 2
        link# 1, first hop RSM HW addr: 0x4
        link# 2, first hop RSM HW addr: 0x2
WCI #1
    Port ID: 13
    Instance: 1
    Num of hops: 2
    Num of links: 2
        link# 0, first hop RSM HW addr: 0x4
        link# 2, first hop RSM HW addr: 0x2
```

`set` [`-i` *wrsm_instance_num*] `-c cmmu -s` <*start*> `-e` <*end*>
For the specified WCI (or for each RSM WCI if none specified), configure the specified range of CMMU entries so that transactions through them are counted by *wrsm* `busstat kstats`. Each call will cause transactions to be counted through the new ranges of `cmmu` entries in addition to the previously specified ranges. To count transactions through all CMMUs, specify a start value of 0 and end value of 0. To clear all ranges (and not count

transactions through any `cmmu` entries), specify a start value of 0 and end value of -1.

Exit Status This command returns 0 on successful completion, and a non-zero value if an error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

Name xntpd – Network Time Protocol daemon

Synopsis

```
/usr/lib/inet/xntpd [-aAbdm] [-c conffile] [-e authdelay]
     [-f driftfile] [-k keyfile] [-l logfile] [-p pidfile]
     [-r broadcastdelay] [-s statsdir] [-t trustedkey]
     [-v variable] [-V variable]
```

Description `xntpd` is a daemon which sets and maintains a UNIX system time-of-day in agreement with Internet standard time servers. `xntpd` is a complete implementation of the Network Time Protocol (NTP) version 3 standard, as defined by *RFC 1305*. It also retains compatibility with version 1 and 2 servers as defined by *RFC 1059* and *RFC 1119*, respectively. The computations done in the protocol and clock adjustment code are carried out with high precision and with attention to the details which might introduce systematic bias into the computations. This is done to try to maintain an accuracy suitable for synchronizing with even the most precise external time source.

Ordinarily, `xntpd` reads its configuration from a configuration file at startup time. The default configuration file name is `/etc/inet/ntp.conf`, although this may be overridden from the command line. It is also possible to specify a working, although limited, `xntpd` configuration entirely on the command line, obviating the need for a configuration file. This may be particularly appropriate when `xntpd` is to be configured as a broadcast or multicast client, with all peers being determined by listening to broadcasts at run time. Through the use of the `ntpq(1M)` program, various internal `xntpd` variables can be displayed and configuration options altered while the daemon is running.

The daemon can operate in any of several modes, including symmetric active/passive, client/server and broadcast/multicast. A broadcast/multicast client can automatically discover remote servers, compute one-way delay correction factors and configure itself automatically. This makes it possible to deploy a fleet of workstations without specifying a configuration file or configuration details specific to its environment.

Options The following command line arguments are understood by `xntpd`. See `Configuration Commands` for a more complete functional description:

`-a`	Run in authentication mode.
`-A`	Disable authentication mode.
`-b`	Listen for broadcast NTP and sync to this if available.
`-c` *conffile*	Specify an alternate configuration file.
`-d`	Specify debugging mode. This flag may occur multiple times, with each occurrence indicating greater detail of display.
`-e` *authdelay*	Specify the time (in seconds) it takes to compute the NTP encryption field on this computer.
`-f` *driftfile*	Specify the location of the drift file.

`-k` *keyfile*	Specify the location of the file which contains the NTP authentication keys.
`-l` *logfile*	Specify a log file instead of logging to syslog.
`-m`	Listen for multicast messages and synchronize to them if available (requires multicast kernel).
`-p` *pidfile*	Specify the name of the file to record the daemon's process id.
`-r` *broadcast*	Ordinarily, the daemon automatically compensates for the network delay between the broadcast/multicast server and the client; if the calibration procedure fails, use the specified default delay (in seconds).
`-s` *statsdir*	Specify the directory to be used for creating statistics files.
`-t` *trustedkey*	Add a key number to the trusted key list.
`-v` *variable*	Add a system variable.
`-V` *variable*	Add a system variable listed by default.

Usage `xntpd`'s configuration file format is similar to other Unix configuration files. Comments begin with a '#' character and extend to the end of the line. Blank lines are ignored. Configuration commands consist of an initial keyword followed by a list of arguments, separated by whitespace. Some arguments may be optional. These commands may not be continued over multiple lines. Arguments may be host names, host addresses written in dotted–decimal, integers, floating point numbers (when specifying times in seconds) and text strings.

Configuration Commands

In the following descriptions, optional arguments are delimited by '[ ]', while alternatives are separated by '|'. The first three commands specify various time servers to be used and time services to be provided.

`peer` *host_address* [`key` #] [`version` #][`prefer`]

Specifies that the local server is to operate in "symmetric active" mode with the remote server *host_address* named in the command. In this mode, the local server can be synchronized to the remote server. In addition, the remote server can be synchronized by the local server. This is useful in a network of servers where, depending on various failure scenarios, either the local or remote server host may be the better source of time. The `peer` command, and the `server` and `broadcast` commands that follow, can take the following arguments:

`key`	Indicates that all packets sent to the address are to include authentication fields, encrypted using the specified key number. The range of this number is that of an unsigned 32 bit integer. By default, an encryption field is not included.
`version`	Specifies the version number to be used for outgoing NTP packets. Versions 1, 2, and 3 are the choices; version 3 is the default.
`prefer`	Marks the host as a preferred host. This host will be preferred for synchronization over other comparable hosts.

server *host_address* [key #] [version f1#] [prefer] [mode f1#] server	Specifies that the local server is to operate in "client" mode with the remote server named in the command. In this mode the local server can be synchronized to the remote server, but the remote server can never be synchronized to the local server.
broadcast *host_address* [key #] [version #] [ttl #]	Specifies that the local server is to operate in "broadcast" mode where the local server sends periodic broadcast messages to a client population at the broadcast/multicast address named in the command. Ordinarily, this specification applies only to the local server operating as a transmitter. For operation as a broadcast client, see `broadcastclient` or `multicastclient` commands elsewhere in this document. In

broadcast mode the *host_address* is usually the broadcast address on a local network or a multicast address assigned to NTP. The IANA has assigned the network, 224.0.1.1 to NTP. This is presently the only network that should be used. The following option is used only with the broadcast mode:

`ttl` Specifies the time-to-live (TTL) to use on multicast packets. Selection of the proper value, which defaults to 127, is something of a black art and must be coordinated with the network administrator(s).

`broadcastclient` Directs the local server to listen for broadcast messages on the local network, in order to discover other servers on the same subnet. Upon hearing a broadcast message for the first time, the local server measures the nominal network delay using a brief client/server exchange with the remote server. Then the server enters the "broadcastclient" mode, in which it listens for and synchronizes to succeeding broadcast messages. In order to avoid accidental or malicious disruption in this mode, both the local and remote servers must operate using authentication, with the same trusted key and key identifier.

`multicastclient` [*IP address* . . .] Used in the same way as the `broadcastclient` command, but operates using IP multicasting. Support for this command requires the use of authentication. If one or more IP addresses are given, the server joins the respective multicast group(s).

If none are given, the IP address assigned to NTP (224.0.1.1) is assumed.

`driftfile` *filename*

Specifies the name of the file used to record the frequency offset of the local clock oscillator. If the file exists, it is read at startup in order to set the initial frequency offset. Then the file is updated once per hour with the current offset computed by the daemon. If the file does not exist or this command is not given, the initial frequency offset is assumed to be zero. In this case, it may take some hours for the frequency to stabilize and the residual timing errors to subside. The file contains a single floating point value equal to the offset in parts-per-million (ppm). The file is updated by first writing the current drift value into a temporary file and then using `rename(2)` to replace the old version. This implies that `xntpd` must have write permission for the directory the drift file is located in, and that file system links, symbolic or otherwise, should probably be avoided.

`enable`
`auth | bclient | pll | monitor | stats [...]`
`disable`
`auth | bclient | pll | monitor | stats`
`[...]`

Provides a way to enable or disable various server options. To do so, execute a two word command, where the first word is `enable` or `disable` and the second is the flag. Flags not mentioned are unaffected. Flags that can be changed are described below, along with their default values.

Flag	Default	Description
auth	disable	Causes the server to synchronize with unconfigured peers only if the peer has been correctly authenticated using a trusted key and key identifier.
bclient	disable	Causes the server to listen for a message from a broadcast or multicast server. After this occurs, an association is automatically instantiated for that server. default for this flag is disable (off).
pll	enable	Enables the server to adjust its local clock. If not set, the local clock free-runs at its intrinsic time and frequency offset. This flag is useful in case the local clock is controlled by some other device or protocol and NTP is used only to provide synchronization to other clients.
monitor	disable	Enables the monitoring facility (see elsewhere).
stats	enable	Enables statistics facility filegen (see `Monitoring Commands` below).

`slewalways` [`yes`|`no`] Force `xntpd` to always slew the time.

Authentication Commands

`keys` *filename* Specifies the name of a file which contains the encryption keys and key identifiers used by `xntpd` when operating in authenticated mode. The format of this file is described later in this document.

`trustedkey` # [# . . .] Specifies the encryption key identifiers which are trusted for the purposes of authenticating peers suitable for synchronization. The

authentication procedures require that both the local and remote servers share the same key and key identifier, defined to be used for this purpose. However, different keys can be used with different servers. The arguments are 32 bit unsigned integers. Note, however, that key `0` is fixed and globally known. If meaningful authentication is to be performed, the `0` key should not be trusted.

`controlkey #` Specifies the key identifier to use with the `ntpq`(1M) program, which is useful to diagnose and repair problems that affect `xntpd` operation. The operation of the `ntpq` program and `xntpd` conform to those specified in *RFC 1305*. Requests from a remote `ntpq` program which affect the state of the local server must be authenticated. This requires that both the remote program and local server share a common key and key identifier. The argument to this command is a 32 bit unsigned integer. If no `controlkey` command is included in the configuration file, or if the keys don't match. These requests are ignored.

Access Control Commands

`restrict` *address* [`mask` *numeric_mask*] [*flag*] [. . .]

`xntpd` implements a general purpose address–and–mask based restriction list. The list is sorted by IP address and mask, and the list is searched in this order for matches, with the last match found defining the restriction flags associated with the incoming packets. The source address of incoming packets is used for the match, with the 32 bit address being logically and'ed with the mask associated with the restriction entry and then compared with the entry's address (which has also been and'ed with the mask) to look for a match. The "mask" argument defaults to 255.255.255.255, meaning that the "address" is treated as the address of an individual host. A default entry (address 0.0.0.0, mask 0.0.0.0) is always included and, given the sort algorithm, is always the first entry in the list. Note that, while "address" is normally given in dotted–quad format, the text string "default", with no mask option, may be used to indicate the default entry.

In the current implementation, flags always restrict access, i.e., an entry with no flags indicates that free access to the server is to be given. The flags are not orthogonal, in that more restrictive flags often make less restrictive ones redundant. The flags can generally be classed into two categories, those which restrict time service and those which restrict informational queries and attempts to do run time reconfiguration of the server.

One or more of the following flags may be specified:

`ignore` Ignore all packets from hosts which match this entry. If this flag is specified neither queries nor time server polls will be responded to.

`noquery` Ignore all NTP mode 7 packets (i.e., information queries and configuration requests) from the source. Time service is not affected.

`nomodify`	Ignore all NTP mode 7 packets which attempt to modify the state of the server (i.e., run time reconfiguration). Queries which return information are permitted.
`notrap`	Decline to provide mode 6 control message trap service to matching hosts. The trap service is a subsystem of the mode 6 control message protocol which is intended for use by remote event logging programs.
`lowpriotrap`	Declare traps set by matching hosts to be low priority. The number of traps a server can maintain is limited. The current limit is 3. Traps are usually assigned on a first come, first served basis, with later trap requestors being denied service. This flag modifies the assignment algorithm by allowing low priority traps to be overridden by later requests for normal priority traps.
`noserve`	Ignore NTP packets whose mode is other than 7. In effect, time service is denied, though queries may still be permitted.
`nopeer`	Provide stateless time service to polling hosts, but do not allocate peer memory resources to these hosts even if they otherwise might be considered useful as future synchronization partners.
`notrust`	Treat these hosts normally in other respects, but never use them as synchronization sources.
`limited`	These hosts are subject to a limitation on number of clients from the same net that will be accepted. Net in this context refers to the IP notion of net (class A, class B, class C, etc.). Only the first *client_limit* hosts that have shown up at the server and that have been active during the last *client_limit_period* seconds are accepted. Requests from other clients from the same net are rejected. Only time request packets are taken into account. "Private", "control", and "broadcast" packets are not subject to client limitation and therefore do not contribute to client count. A history of clients is kept using the monitoring capability of `xntpd`. Thus, monitoring is active as long as there is a restriction entry with the `limited` flag. The default value for *client_limit* is 3. The default value for *client_limit_period* is 3600 seconds. Currently both variables are not runtime configurable.
`ntpport`	This is actually a match algorithm modifier, rather than a restriction flag. Its presence causes the restriction entry to be matched only if the source port in the packet is the standard

NTP UDP port (123). Both `ntpport` and `non–ntpport` may be specified. The `ntpport` is considered more specific and is sorted later in the list.

Default restriction list entries, with the flags, `ignore`, `ntpport`, for each of the local host's interface addresses are inserted into the table at startup to prevent the server from attempting to synchronize to its own time. A default entry is also always present, though if it is otherwise unconfigured no flags are associated with the default entry (i.e., everything besides your own NTP server is unrestricted).

The restriction facility was added to allow the current access policies of the time servers running on the NSF net backbone to be implemented with `xntpd` as well. This facility may be useful for keeping unwanted or broken remote time servers from affecting your own. However, it should not be considered an alternative to the standard NTP authentication facility.

`clientlimit limit` Sets *client_limit* to `limit`; allows configuration of client limitation policy. This variable defines the number of clients from the same network that are allowed to use the server.

`clientperiod period` Sets *client_limit_period*; allows configuration of client limitation policy. This variable specifies the number of seconds after which a client is considered inactive and thus no longer is counted for client limit restriction.

Monitoring Commands `statsdir` */directory path/*

Indicates the full path of a directory where statistics files should be created (see below). This keyword allows the (otherwise constant) filegen filename prefix to be modified for file generation sets used for handling statistics logs (see `filegen` statement below).

`statistics` *name . . .*

Enables writing of statistics records. Currently, three kinds of statistics are supported. Each type is described below by giving its *name*, a sample line of data, and an explanation of each field:

`loopstats` enables recording of loop filter statistics information. Each update of the local clock outputs a line of the following form to the file generation set named “loopstats”:

```
48773  10847.650  0.0001307  17.3478  2
```

`Field No.`	`Description`
1	The date (Modified Julian day)
2	The time (seconds and fraction past UTC midnight)

3	Time offset in seconds
4	Frequency offset in parts-per-million
5	Time constant of the clock-discipline algorithm at each update of the clock

`peerstats` enables recording of peer statistics information. This includes statistics records of all peers of a NTP server and of the 1-pps signal, where present and configured. Each valid update appends a line similar to the one below, to the current element of a file generation set named "peerstats":

```
48773  10847.650  127.127.4.1  9714  -0.001605  \
     0.00000  0.00142
```

`Field No.`	`Description`
1	The date (Modified Julian Day)
2	The time (seconds and fraction past UTC midnight)
3	The peer address in dotted-quad notation
4	peer status. The status field is encoded in hex in the format described in Appendix B.2.2 of the NTP specification, *RFC 1305*.
5	Offset in seconds
6	Delay in seconds
7	Dispersion in seconds

`clockstats` enables recording of clock driver statistics information. Each update received from a clock driver outputs a line of the following form to the file generation set named "clockstats":

```
49213  525.624  127.127.4.1  93  226  \
   00:08:29.606  D
```

`Field No.`	`Description`
1	The date (Modified Julian Day)
2	The time (seconds and fraction past UTC midnight)
3	The clock address in dotted-quad notation
4	The last timecode received from the clock in decoded ASCII format, where meaningful

In some clock drivers a good deal of additional information can be gathered and displayed as well.

Statistic files are managed using file generation sets (see `filegen` below). The information obtained by enabling statistics recording allows analysis

of temporal properties of a `xntpd` server. It is usually only useful to primary servers or maybe main campus servers.

`filegen` *name* [`file` *filename*] [`type` *typename*][`flag` *flagval*] [`link` | `nolink`] [enable | disable]

Configures setting of generation file set *name*. Generation file sets provide a means for handling files that are continuously growing during the lifetime of a server. Server statistics are a typical example for such files. Generation file sets provide access to a set of files used to store the actual data. At any time at most one element of the set is being written to. The `type` given specifies when and how data will be directed to a new element of the set. This way, information stored in elements of a file set that are currently unused are available for administrational operations without the risk of disturbing the operation of `xntpd`. (Most important: they can be removed to free space for new data produced.)

Filenames of set members are built from three elements:

prefix This is a constant filename path. It is not subject to modifications via the `filegen` statement. It is defined by the server, usually specified as a compile time constant. It may, however, be configurable for individual file generation sets via other commands. For example, the prefix used with "loopstats" and "peerstats" filegens can be configured using the `statsdir` statement explained above.

filename This string is directly concatenated to the *prefix* mentioned above (no intervening '/' (slash)). This can be modified using the `file` argument to the `filegen` statement. No '. .' elements are allowed in this component to prevent filenames referring to parts outside the filesystem hierarchy denoted by *prefix*.

suffix This part is reflects individual elements of a file set. It is generated according to the `type` of a file set as explained below.

A file generation set is characterized by its type. The following types are supported:

`none` The file set is actually a single plain file.

`pid` One element of file set is used per incarnation of a `xntpd` server. This type does not perform any changes to file set members during runtime. However it provides an easy way of separating files belonging to different `xntpd` server incarnations. The set member filename is built by appending a '.' (dot) to concatenated *prefix* and *filename* strings, and appending the decimal representation of the process id of the `xntpd` server process.

`day` One file generation set element is created per day. The term *day* is based on UTC . A day is defined as the period between 00:00 and 24:00 UTC . The file set member suffix consists of a '.' (dot) and a day specification in the form, *YYYYMMDD*. *YYYY* is a 4 digit year number (e.g., 1992). *MM* is a two digit month number. *DD* is a two digit day number. Thus, all information written at December 10th, 1992 would end up in a file named, *PrefixFilename*.19921210.

`week` Any file set member contains data related to a certain week of a year. The term *week* is defined by computing "day of year" modulo 7. Elements of such a file generation set are distinguished by appending the following suffix to the file set filename base: a dot, a four digit year number, the letter 'W', and a two digit week number. For example, information from January, 5th 1992 would end up in a file with suffix ".1992W1".

`month` One generation file set element is generated per month. The file name suffix consists of a dot, a four digit year number, and a two digit month.

`year` One generation file elment is generated per year. The filename suffix consists of a dot and a 4 digit year number.

`age` This type of file generation sets changes to a new element of the file set every 24 hours of server operation. The filename suffix consists of a dot, the letter 'a', and an eight digit number. This number is taken to be the number of seconds the server is running at the start of the corresponding 24 hour period.

Information is only written to a file generation set when this set is `enabled`. Output is prevented by specifying, `disabled`.

It is convenient to be able to access the current element of a file generation set by a fixed name. This feature is enabled by specifying `link` and disabled using `nolink`. If `link` is specified, a hard link from the current file set element to a file without suffix is created. When there is already a file with this name and the number of links of this file is one, it is renamed appending a dot, the letter, 'C', and the pid of the `xntpd` server process. When the number of links is greater than one, the file is unlinked. This allows the current file to be accessed by a constant name.

Miscellaneous Commands

`broadcastdelay` *seconds*

The broadcast and multicast modes require a special calibration to determine the network delay between the local and remote servers. Ordinarily, this is done automatically by the initial protocol exchanges between the local and remote servers. In some cases, the calibration procedure may fail due to, for example, network or server access controls. This command specifies the default delay to be used under these circumstances. Typically (for Ethernet), a number between 0.003 and 0.007 is appropriate for *seconds*. When this command is not used, the default is 0.004 seconds.

`trap` *host_address* [`port` *port_number*] [`interface` *interface_address*]

Configures a trap receiver at the given *host_address* and *port_number* for sending

messages with the specified local *interface_address*. If the port number is unspecified, a value of 18447 is used. If the interface address is not specified, the message is sent with the source address of the local interface the message is sent through. On a multi-homed host, the interface used may change with routing changes.

C information from the server in a log file. While such monitor programs may also request their own trap dynamically, configuring a trap receiver ensures that no messages are lost when the server is started.

`setvar` *variable* [*default*]

This command adds an additional system variable. Variables like this can be used to distribute additional information such as the access policy. If the variable of the form, *variable_name=value* is followed by the *default* keyword, the variable will be listed as one of the default system variables (see the `ntpq`(1M) command). Additional variables serve informational purposes only. They can be listed; but they are not related to the protocol. The known protocol variables always override any variables defined via the `setvar` mechanism.

Three special variables contain the names of all variable of the same group. *sys_var_list* holds the names of all system variables. *peer_var_list* holds the names of all peer variables. And *clock_var_list* hold the names of the reference clock variables.

`monitor` [`yes` | `no`]
`authenticate` [`yes` | `no`]

These commands have been superseded by the `enable` and `disable` commands. They are listed here for historical purposes.

`logconfig` *configkeyword*

Controls the amount of output written to syslog or the logfile. By default all output is turned on. *configkeyword* is formed by concatenating the message class with the event class. It is permissible to use the prefix, `all`, instead of a message class. A message class may also be

followed by the keyword, `all`, meaning to enable/disable all of the respective message class. All *configkeywords* can be prefixed with the symbols, '=', '+' and '–' . Here, '=' sets the syslogmask, '+' adds messages, and '–' removes messages. Syslog messages can be controlled in four classes: *sys*, *peer*, *clock*, `sync`. Within these classes four types of messages can be controlled. Each is described below, along with its `configkeyword`:

`Configkeyword`	`Message type`
`info`	Informational messages control configuration information.
`events`	Event messages control logging of events (reachability, synchronization, alarm conditions).
`statistics`	Statistical messages control statistical output.
`status`	Status messages describe mainly the synchronization status.

A minimal log configuration might look like this:

```
logconfig =syncstatus +sysevents
```

A configuration like this lists, just the synchronization state of `xntp` and the major system events. For a simple reference server, the following minimum message configuration could be useful:

```
logconfig =syncall +clockall
```

This configuration lists all clock information and synchronization information. All other events and messages about peers, system events and so on, is suppressed.

Authentication Key File Format

The NTP standard specifies an extension to allow verification of the authenticity of received NTP packets, and to provide an indication of authenticity in outgoing packets. This is implemented in `xntpd` using the DES or MD5 algorithms to compute a digital signature, or message-digest. The specification allows any one of possibly 4 billion keys, numbered with 32 bit key identifiers, to be used to authenticate an association. The servers involved in an association must agree on the key and key identifier used to authenticate their data. However they must each learn the key and key identifier independently. In the case of DES, the keys are 56 bits long with, depending on type, a parity check on each byte. In the case of MD5, the keys are 64 bits (8 bytes). `xntpd` reads its keys from a file specified using the `-k` command line option or the `keys` statement in the configuration file. While key number 0 is fixed by the NTP standard (as 56 zero bits) and may not be changed, one or more of the keys numbered 1 through 15 may be arbitrarily set in the keys file.

The key file uses the same comment conventions as the configuration file. Key entries use a fixed format of the form, *keyno type key*. Here, *keyno* is a positive integer, `type` is a single character which defines the format the key is given in, and *key* is the key itself.

The *key* may be given in one of several different formats, controlled by the `type` character. The different key types, and corresponding formats, are described below:

`Key:` S

`Format:` A 64 bit hexadecimal number in DES format

In this format, the high order 7 bits of each octet are used to form the 56 bit key while the low order bit of each octet is given a value such that odd parity is maintained for the octet. Leading zeroes must be specified (i.e., the key must be exactly 16 hex digits long) and odd parity must be maintained. Hence a zero key, in standard format, would be given as: 0101010101010101.

`Key:` N

`Format:` A 64 bit hexadecimal number in NTP format

This format is the same as the DES format except the bits in each octet have been rotated one bit right so that the parity bit is now the high order bit of the octet. Leading zeroes must be specified and odd parity must be maintained. A zero key in NTP format would be specified as: `8080808080808080`.

`Key:` A

`Format:` A 1–to–8 character ASCII string

A key is formed from this by using the lower order 7 bits of the ASCII representation of each character in the string. Zeroes are added on the right when necessary to form a full width 56 bit key.

`Key:` M

`Format:` A 1–to–8 character ASCII string, using the MD5 authentication scheme.

Note that both the keys and the authentication schemes (DES or MD5) must be identical between a set of peers sharing the same key number.

Primary Clock Support

`xntpd` has been built to be compatible with all supported types of reference clocks. A reference clock is generally (though not always) a radio timecode receiver which is synchronized to a source of standard time such as the services offered by the NRC in Canada and NIST in the U.S. The interface between the computer and the timecode receiver is device dependent and will vary, but it is often a serial port.

For the purposes of configuration, `xntpd` treats reference clocks in a manner analogous to normal NTP peers as much as possible. Reference clocks are referred to by address, much as a normal peer is. However, an invalid IP address is used to distinguish them from normal peers. Reference clock addresses are of the form *127.127.t.u* where *t* is an integer denoting the clock type and *u* indicates the type–specific unit number. Reference clocks are configured using a `server` statement in the configuration file where the *host_address* is the clock address. The `key`, `version` and `ttl` options are not used for reference clock support. Some reference clocks require a `mode` option to further specify their operation. The `prefer` option can be useful to persuade the server to cherish a reference clock with somewhat more enthusiasm than other reference clocks or peers. Clock addresses may generally be used anywhere in the configuration file that a normal IP address can be used. For example, they can be used in `restrict` statements, although such use would normally be considered strange.

Reference clock support provides the `fudge` command, which can be used to configure reference clocks in special ways. The generic format that applies to this command is,

```
fudge 127.127.t.u [  time1 secs ] [  time2 secs ]\
     [  stratum int ] [  refid int ] \
     [  flag1 0 | 1 ] [  flag2 0 | 1 ] [  flag3 0 | 1 ] [  flag4  0 | 1 ]
```

with options described as follows:

time1
time2 Are specified in fixed point seconds and used in some clock drivers as calibration constants. By convention, and unless indicated otherwise, `time1` is used as a calibration constant to adjust the nominal time offset of a particular clock to agree with an external standard, such as a precision PPS signal. The specified offset is in addition to the propagation delay provided by other means, such as internal DIP switches.

stratum Is a number in the range zero to 15 and is used to assign a nonstandard operating stratum to the clock.

refid Is an ASCII string in the range one to four characters and is used to assign a nonstandard reference identifier to the clock.

flag1
flag2
flag3
flag4

Are binary flags used for customizing the clock driver. The interpretation of these values, and whether they are used at all, is a function of the needs of the particular clock driver. However, by convention, and unless indicated otherwise, *flag3* invokes the TIOCSPPS ioctl, while *flag4* is used to enable recording verbose monitoring data to the clockstats file configured with the `filegen` command.

Ordinarily, the stratum of a reference clock is zero, by default. Since the `xntpd` daemon adds one to the stratum of each peer, a primary server ordinarily displays stratum one. In order to provide engineered backups, it is often useful to specify the reference clock stratum as greater than zero. The `stratum` option is used for this purpose. Also, in cases involving both a reference clock and a 1-pps discipline signal, it is useful to specify the reference clock identifier as other than the default, depending on the driver. The *refid* option is used for this purpose. Except where noted, these options apply to all clock drivers.

`xntpd` on Unix machines currently supports several different types of clock hardware. It also supports a special pseudo–clock used for backup or when no other clock source is available. In the case of most of the clock drivers, support for a 1-pps precision timing signal is available as described in the `README` file in the `./doc directory of the xntp3` program distribution. The clock drivers, and the addresses used to configure them, are described in the file, `README.refclocks`, in the doc directory of the current program distribution.

Variables

Most variables used by the NTP protocol can be examined with `ntpq` (mode 6 messages). Currently very few variables can be modified via mode 6 messages. These variables are either created with the `setvar` directive or the leap warning variables. The leap warning bits that can be set in the *leapwarning* variable (up to one month ahead). Both, the *leapwarning* and in the *leapindication* variable, have a slightly different encoding than the usual `leap` bits interpretation:

`00` The daemon passes the leap bits of its synchronization source (usual mode of operation).

`01/10` A leap second is added/deleted (operator forced leap second).

`11` Leap information from the synchronization source is ignored (thus LEAP_NOWARNING is passed on).

Files

`/etc/inet/ntp.conf`	Default name of the configuration file
`/etc/ntp/ntp.drift`	Conventional name of the drift file
`/etc/inet/ntp.keys`	Conventional name of the key file
`/etc/inet/ntp.server`	Sample server configuration file

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWntpu

See Also svcs(1), ntpdate(1M), ntpq(1M), ntptrace(1M), svcadm(1M), xntpdc(1M), rename(2), attributes(5), smf(5)

Notes The xntpd service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/network/ntp:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name xntpdc – special NTP query program

Synopsis `xntpdc [-ilnps] [-c` *command*`] [`*host*`] [...]`

Description `xntpdc` queries the `xntpd` daemon about its current state and requests changes in that state. You can run `xntpdc` in interactive mode or in controlled using command line arguments.

Extensive state and statistics information is available through the `xntpdc` interface. In addition, nearly all the configuration options which can be specified at start up using `xntpd`'s configuration file may also be specified at run time using xntpdc.

If one or more request options is included on the command line when `xntpdc` is executed, each of the requests is sent to the NTP servers running on each of the hosts given as command line arguments, or on the local host by default. If no request options are given, `xntpdc` attempts to read commands from the standard input and execute these on the NTP server running on the first host specified on the command line, again defaulting to the local host when no other host is specified. `xntpdc` prompts for commands if the standard input is a terminal device.

`xntpdc` uses NTP `mode 7` packets to communicate with the NTP server, and can be used to query any compatable server on the network which permits it. As NTP is a UDP protocol, this communication is somewhat unreliable, especially over large distances. `xntpdc` does not attempt to re-transmit requests, and times requests out if the remote host is not heard from within a suitable timeout time.

The operation of `xntpdc` is specific to the particular implementation of the `xntpd` daemon. You can expect `xntpdc` to work only with this and maybe some previous versions of the daemon. Requests from a remote `xntpdc` program that affect the state of the local server must be authenticated. This requires that both the remote program and local server share a common key and key identifier.

Options `xntpdc` reads interactive format commands from the standard input. If you specify the `-c`, `-l`, `-p` or `-s` option, the specified queries are sent to the hosts immediately.

The following command line options are supported:

`-c` *command*`-...` Add *command* to the list of commands to execute on the specified hosts. *command* is interpreted as an interactive format command.

Multiple `-c` options may be specified.

`-i` Force `xntpdc` to operate in interactive mode.

Prompts are written to the standard output. Commands are read from the standard input.

`-l` Obtain a list of peers which are known to the servers.

This option is equivalent to `-c listpeers`. See `listpeers` in `Control Message Commands`.

`-n`	Output all host addresses in dotted-quad numeric format rather than converting to the canonical host names.
`-p`	Print a list of the peers known to the server as well as a summary of their state. This option is equivalent to `-c peers`. See `peers` in `Control Message Commands`.
`-s`	Print a list of the peers known to the server as well as a summary of their state, but in a slightly different format than the `-p` option. This option is equivalent to `-c dmpeers`. See `dmpeers` in `Control Message Commands`.

Operands The following operands are supported:

Usage

Interactive Commands The interactive commands consist of a keyword (*command_keyword*) followed by zero to four arguments. You need to entry only enough characters of the *command_keyword* to uniquely identify it. The output of an interactive command is sent to the standard output by default. You can send the output of an interactive command to a file by appending a <, followed by a file name, to the command line.

A number of interactive format commands are executed entirely within the `xntpdc` program itself and do not result in NTP mode.

The following interactive commands are supported:

`?` [*command_keyword*]	Without an argument, print a list of `ntpq` command keywords. If *command_keyword* is specified, print function and usage information about the *command_keyword*.
delay *milliseconds*	Specify a time interval to add to timestamps included in requests which require authentication. This enables (unreliable) server reconfiguration over long delay network paths or between machines whose clocks are unsynchronized. Because the server no longer requires timestamps in authenticated requests, this command may be obsolete.
help [*command_keyword*]	Without an argument, print a list of `ntpq` command keywords. If *command_keyword* is specified, print function and usage information about the *command_keyword*.
host *hostname*	Set the host (*hostname*) to which future queries are sent. Specify *hostname* as a host name or a numeric address.

hostnames [`yes` | `no`]	Print hostnames or numeric addresses in information displays. Specify `yes` to print host names. Specify `no` to print numeric addresses. The default is `yes`, unless the `-n` command line option is specified.
keyid *keyid*	Enable specification of a key number (*keyid*) to authenticate configuration requests. *keyid* must correspond to a key number the server has been configured to use for this purpose.
passwd	Allow the user to specify a password at the command line to authenticate configuration requests. The password is not displayed, and must correspond to the key configured for use by the NTP server for this purpose. If the password does not correspond to the key configured for use by the NTP server, requests are not successful.
quit	Exit `xntpdc`.
timeout *millseconds*	Specify a timeout period for responses to server queries. The default is approximately `8000` milliseconds. As `xntpdc` retries each query once after a timeout, the total waiting time for a timeout is twice the timeout value set.

Control Message Commands

Query commands result in `NTP` mode 7 packets containing requests for information being sent to the server. These control message commands are read-only commands in that they make no modification of the server configuration state.

The following control message commands are supported:

clkbug	Obtain debugging information for a reference clock driver. This information is provided only by some clock drivers.
clockinfo *clock_peer_address* [...]	Obtain and print information concerning a peer clock. The values obtained provide information on the setting of fudge factors and other clock performance information.
dmpeers	Obtain a list of peers for which the sserver is maintaining state, along with a summary of that state.

	The peer summary list is identical to the output of the `peers` command, except for the character in the leftmost column. Characters only appear beside peers which were included in the final stage of the clock selection algorithm. A `.` indicates that this peer was cast off in the falseticker detection, while a + indicates that the peer made it through. A * denotes the peer with which the server is currently synchronizing.
iostats	Print statistics counters maintained in the input-output module.
kerninfo	Obtain and print kernel phase-lock loop operating parameters. This information is available only if the kernel has been specially modified for a precision timekeeping function.
listpeers	Obtain and print a brief list of the peers for which the server is maintaining state. These should include all configured peer associations as well as those peers whose stratum is such that they are considered by the server to be possible future synchonization candidates. candidates.
loopinfo [oneline | multiline]	Print the values of selected loop filter variables. The loop filter is the part of NTP which deals with adjusting the local system clock. The `oneline` and `multiline` options specify the format in which this information is printed. `multiline` is the default. The offset is the last offset given to the loop filter by the packet processing code. The frequency is the frequency error of the local clock in parts-per-million (ppm). The `time_const` controls the stiffness of the phase-lock loop and thus the speed at which it can adapt to oscillator drift. The watchdog timer value is the number of seconds which have elapsed since the last sample offset was given to the loop filter.
memstats	Print statistics counters related to memory allocation code.

monlist [version]

Obtain and print traffic counts collected and maintained by the monitor facility. The version number should not normally need to be specified.

peers

Obtain a list of peers for which the server is maintaining state, along with a summary of that state.

The following summary information is included:

- Address of the remote peer.
- Local interface address. If a local address has yet to be determined it is `0.0.0.0`.
- Stratum of the remote peer. A stratum of `16` indicates the remote peer is unsynchronized.
- Polling interval, in seconds.
- Reachability register, in octal.
- Current estimated delay, offset and dispersion of the peer, in seconds.
- Mode in which the peer entry is operating.

  This is represented by the character in the left margin. A + denotes symmetric active, a - indicates symmetric passive, a = means the remote server is being polled in client mode, a ^ indicates that the server is broadcasting to this address, a ~ denotes that the remote peer is sending broadcasts and a * marks the peer the server is currently synchonizing to.
- Host.

  This field may contain a host name, an IP address, a reference clock implementation name with its parameter or `REFCLK` (implementation number, parameter). On hostnames no only IP-addresses is displayed.

pstats *peer_address* [...]

Show the per-peer statistic counters associated with the specified peers.

reslist

Obtain and print the server's restriction list.

Generally, this list is printed in sorted order.

showpeer *peer_address* [...]	Show a detailed display of the current peer variables for one or more peers. Most of these values are described in the NTP Version 2 specification.
sysinfo	Print a variety of system state variables that are related to the local server. The output from `sysinfo` is described in NTP Version 3 specification, RFC-1305. All except the last four lines are described in the NTP Version 3 specification, RFC-1305. The `system flags` show various system flags, some of which can be set and cleared by the `enable` and `disable` configuration commands, respectively. These are the `auth`, `bclient`, `monitor`, `pll`, `pps` and `stats` flags. See the xntpd documentation for the meaning of these flags. There are two additional flags which are read only, the `kernel_pll` and `kernel_pps`. These flags indicate the synchronization status when the precision time kernel modifications are in use. The `kernel_pll` indicates that the local clock is being disciplined by the kernel, while the `kernel_pps` indicates the kernel discipline is provided by the `PPS` signal. The stability is the residual frequency error remaining after the system frequency correction is applied and is intended for maintenance and debugging. In most architectures, this value initially decreases from as high as `500` ppm to a nominal value in the range `.01` to `0.1` ppm. If it remains high for some time after starting the daemon, something may be wrong with the local clock, or the value of the kernel variable tick may be incorrect. The `broadcastdelay` shows the default broadcast delay, as set by the `broadcastdelay` configuration command. The `authdelay` shows the default authentication delay, as set by the `authdelay` configuration command.
sysstats	Print statistics counters maintained in the protocol module.
timerstats	Print statistics counters maintained in the timer/event queue support code.

Runtime Configuration Requests

The server authenticates all requests that cause state changes in the server. The server uses a configured NTP key to accomplish this. This facility can also be disabled by the server by not configuring a key).

You must make the key number and the corresponding key known to `xtnpdc`. Use the `keyid` or `passwd` commands to do so.

The `passwd` command prompts users for a password to use as the encryption key. It also prompts automatically for both the key number and password the first time a command which would result in an authenticated request to the server is given. Authentication provides verification that the requester has permission to make such changes. It also gives an extra degree of protection against transmission errors.

Authenticated requests always include a time stamp in the packet data. The time stamp is included in the computation of the authentication code. This timestamp is compared by the server to its receive time stamp. If the time stamps differ by more than a small amount the request is rejected.

Time stamps are rejected for two reasons. First, it makes simple replay attacks on the server, by someone who might be able to overhear traffic on your LAN, much more difficult. Second, it makes it more difficult to request configuration changes to your server from topologically remote hosts.

While the reconfiguration facility works well with a server on the local host, and may work adequately between time-synchronized hosts on the same LAN, it works very poorly for more distant hosts. If reasonable passwords are chosen, care is taken in the distribution and protection of keys and appropriate source address restrictions are applied, the run time reconfiguration facility should provide an adequate level of security.

The following commands make authenticated requests.

addpeer *peer_address* [*keyid*] [*version*] [*prefer*]
: Add a configured peer association at the given address and operating in symmetric active mode. An existing association with the same peer may be deleted when this command is executed, or may simply be converted to conform to the new configuration, as appropriate.

  If the optional *keyid* is a non-zero integer, all outgoing packets to the remote server will have an authentication field attached encrypted with this key. If the *keyid* is `0` or omitted, no authentication is done.

  Specify *version* as `1`, `2` or `3`. The default is `3`.

  The *prefer* keyword indicates a preferred peer. This keyword is used primarily for clock synchronisation if possible. The preferred peer also determines the validity of the PPS signal - if the preferred peer is suitable for synchronisation so is the PPS signal.

addserver *peer_address* [*keyid*] [*version*] [*prefer*]
: Identical to the `addpeer` command, except that the operating mode is client.

addtrap [*address* [*port*] [*interface*]
: Set a trap for asynchronous messages.

authinfo
Return information concerning the authentication module, including known keys and counts of encryptions and decryptions which have been done.

broadcast *peer_address* [*keyid*] [*version*] [*prefer*]
Identical to the `addpeer` command, except that the operating mode is `broadcast`. In this case a valid key identifier and key are required. The `peer_address` parameter can be the broadcast address of the local network or a multicast group address assigned to NTP. If a multicast address, a multicast-capable kernel is required.

clrtrap [*address* [*port*] [*interface*]
Clear a trap for asynchronous messages.

delrestrict *address mask* [*ntpport*]
Delete the matching entry from the restrict list.

fudge *peer_address* [*time1*] [*time2*] [*stratum*] [*refid*]
Provide a way to set certain data for a reference clock.

readkeys
Cause the current set of authentication keys to be purged and a new set to be obtained by re-reading the `keys` file. The `keys` file must have been specified in the `xntpd` configuration file. This enables encryption keys to be changed without restarting the server.

restrict *address mask flag* [*flag*]
This command operates in the same way as the restrict configuration file commands of `xntpd`.

reset
Clear the statistics counters in various modules of the server.

traps
Display the traps set in the server.

trustkey *keyid* [...]
untrustkey *keyid* [...]
These commands operate in the same way as the `trustedkey` and `untrustkey` configuration file commands of `xntpd`.

unconfig *peer_address* [...]
Cause the configured bit to be removed from the specified peers. In many cases this causes the peer association to be deleted. When appropriate, however, the association may persist in an unconfigured mode if the remote peer is willing to continue on in this fashion.

unrestrict *address mask flag* [*flag*]
Unrestrict the matching entry from the restrict list.

Attributes See `attributes(5)` for descriptions of the following attributes:

Name ypbind – NIS binder process

Synopsis

```
/usr/lib/netsvc/yp/ypbind [-broadcast | -ypset | -ypsetme]
```

Description NIS provides a simple network lookup service consisting of databases and processes. The databases are stored at the machine that runs an NIS server process. The programmatic interface to NIS is described in `ypclnt(3NSL)`. Administrative tools are described in `ypinit(1M)`, `ypwhich(1)`, and `ypset(1M)`. Tools to see the contents of NIS maps are described in `ypcat(1)`, and `ypmatch(1)`.

`ypbind` is a daemon process that is activated at system startup time from the `svc:/network/nis/client:default` service. By default, it is invoked as `ypbind -broadcast`. `ypbind` runs on all client machines that are set up to use NIS. See `sysidtool(1M)`. The function of `ypbind` is to remember information that lets all NIS client processes on a node communicate with some NIS server process. `ypbind` must run on every machine which has NIS client processes. The NIS server may or may not be running on the same node, but must be running somewhere on the network. If the NIS server is a NIS+ server in NIS (YP) compatibility mode, see the `NOTES` section of the `ypfiles(4)`man page for more information.

The information `ypbind` remembers is called a *binding* — the association of a domain name with a NIS server. The process of binding is driven by client requests. As a request for an unbound domain comes in, if started with the `-broadcast` option, the `ypbind` process broadcasts on the net trying to find an NIS server, either a `ypserv` process serving the domain or an `rpc.nisd` process in "YP-compatibility mode" serving NIS+ directory with name the same as (case sensitive) the domain in the client request. Since the binding is established by broadcasting, there must be at least one NIS server on the net. If started without the `-broadcast` option, `ypbind` process steps through the list of NIS servers that was created by `ypinit -c` for the requested domain. There must be an NIS server process on at least one of the hosts in the NIS servers file. All the hosts in the NIS servers file must be listed in the `/etc/hosts` file along with their IP addresses. Once a domain is bound by `ypbind`, that same binding is given to every client process on the node. The `ypbind` process on the local node or a remote node may be queried for the binding of a particular domain by using the `ypwhich(1)` command.

If `ypbind` is unable to speak to the NIS server process it is bound to, it marks the domain as unbound, tells the client process that the domain is unbound, and tries to bind the domain once again. Requests received for an unbound domain will wait until the requested domain is bound. In general, a bound domain is marked as unbound when the node running the NIS server crashes or gets overloaded. In such a case, `ypbind` will try to bind to another NIS server using the process described above.`ypbind` also accepts requests to set its binding for a particular domain. The request is usually generated by the `ypset(1M)` command. In order for `ypset` to work, `ypbind` must have been invoked with flags `-ypset` or `-ypsetme`.

Options

`-broadcast` Send a broadcast datagram using UDP/IP that requests the information needed to bind to a specific NIS server. This option is analogous to `ypbind` with no options in earlier Sun releases and is recommended for ease of use.

`-ypset` Allow users from any remote machine to change the binding by means of the `ypset` command. By default, no one can change the binding. This option is insecure.

`-ypsetme` Only allow `root` on the local machine to change the binding to a desired server by means of the `ypset` command. `ypbind` can verify the caller is indeed a `root` user by accepting such requests only on the loopback transport. By default, no external process can change the binding.

Files `/var/yp/binding/`*ypdomain*`/ypservers`

`/etc/inet/hosts`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

See Also `svcs(1)`, `ypcat(1)`, `ypmatch(1)`, `ypwhich(1)`, `ifconfig(1M)`, `rpc.nisd(1M)`, `svcadm(1M)`, `ypinit(1M)`, `ypset(1M)`, `ypclnt(3NSL)`, `hosts(4)`, `ypfiles(4)`, `attributes(5)`, `smf(5)`

Notes `ypbind` supports multiple domains. The `ypbind` process can maintain bindings to several domains and their servers, the default domain is the one specified by the `domainname(1M)` command at startup time.

The `-broadcast` option works only on the UDP transport. It is insecure since it trusts “any” machine on the net that responds to the broadcast request and poses itself as an NIS server.

The `ypbind` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/nis/client:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

Name ypinit – set up NIS client

Synopsis

```
/usr/sbin/ypinit [-c] [-m] [-s master_server]
```

Description `ypinit` can be used to set up an NIS client system. You must be the superuser to run this command. This script need not be used at all if `ypbind`(1M) is started with the `-broadcast` option (it is invoked with this option from the `svc:/network/nis/client:default service`).

Normally, `ypinit` is run only once after installing the system. It may be run whenever a new NIS server is added to the network or an existing one is decommissioned.

`ypinit` prompts for a list of NIS servers to bind the client to; this list should be ordered from the closest to the furthest server. Each of these NIS servers must be listed in the `/etc/hosts` file along with its IP address. `ypinit` stores the list in file `/var/yp/binding/`*domain*`/ypservers`. This file is used by `ypbind` when run without the `-broadcast` option.

Options

`-c`	Set up a `ypclient` system.
`-m`	Build a master `ypserver` data base.
`-s` *master_server*	Slave data base. *master_server* must be the same master configured in the YP maps and returned by the `ypwhich -m` command.

Files

`/etc/hosts`

`/var/yp/binding/`*domain*`/ypservers`

Attributes See `attributes`(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

See Also `svcs`(1), `svcadm`(1M), `ypbind`(1M), `sysinfo`(2), `hosts`(4), `attributes`(5), `smf`(5)

Notes The `NIS client` service is managed by the service management facility, `smf`(5), under the service identifier:

```
svc:/network/nis/client:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm`(1M). The service's status can be queried using the `svcs`(1) command.

Bugs `ypinit` sets up the list of NIS servers only for the current domain on the system when it is run, that is, the domain returned by the `SI_SRPC_DOMAIN` command to `sysinfo`(2). Care should be taken to ensure that this is the same as the desired domain for NIS client processes.

Name ypmake – rebuild NIS database

Synopsis

```
cd /var/yp ; make [map]
```

Description The file called `Makefile` in `/var/yp` is used by `make(1S)` to build the Network Information Service (NIS) database. With no arguments, `make` creates `dbm` databases for any NIS maps that are out-of-date, and then executes `yppush(1M)` to notify slave databases that there has been a change.

If you supply a *map* on the command line, `make` will update that map only. Typing `make passwd` will create and `yppush` the password database (assuming it is out of date). Likewise, `make ipnodes` and `make networks` will create and `yppush` the `ipnodes` and `network` files, `$(INETDIR)/ipnodes` and `$(DIR)/networks`.

There are four special variables used by `make`: `DIR`, which gives the directory of the source files; `NOPUSH`, which when non-null inhibits doing a `yppush` of the new database files; `INETDIR`, which gives the directory of the `ipnodes` source file; and `DOM`, which is used to construct a domain other than the master's default domain. The default for `DIR` is `/etc`, and the default for `INETDIR` is `/etc/inet`. The default for `NOPUSH` is the null string.

Refer to `ypfiles(4)` and `ypserv(1M)` for an overview of the NIS service.

If a NIS to LDAP (N2L) configuration file, `/var/yp/NISLDAPmapping`, is present, the NIS server components run in N2L mode. In N2L mode, the server components use a new set of map files with an LDAP-prefix, based on the LDAP DIT. In N2L mode, authoritative NIS information is obtained from the DIT. The NIS source files and `ypmake` have no role, and they should not be used. If `ypmake` is accidentally run, then the server components will detect this, and will log a warning message. For additional information, see `ypfiles(4)`.

Files

`/var/yp`	Directory containing NIS configuration files.
`/etc/inet/hosts`	System hosts file.
`/etc`	Default directory for source files.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWypu
Interface Stability	Evolving

See Also `make(1S)`, `NIS+(1)`, `makedbm(1M)`, `rpc.nisd(1M)`, `ypbind(1M)`, `yppush(1M)`, `ypserv(1M)`, `ypclnt(3NSL)`, `NISLDAPmapping(4)`, `ypfiles(4)`, `ypserv(4)`

Notes The NIS makefile is only used when running the ypserv(1M) server to provide NIS services. If these are being provided by the NIS+ server running in NIS compatibility mode, see rpc.nisd(1M); this makefile is not relevant. See ypfiles(4) for more details.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same. Only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications plc, and may not be used without permission.

Name ypmap2src – convert NIS maps to NIS source files

Synopsis

```
/usr/lib/netsvc/yp/ypmap2src [-t]
     [ [-c custom-map-name]]... [-d domain] -o output-directory
     [ [ source-file]]...
```

Description Use the `ypmap2src` utility to convert standard NIS maps to approximations of the equivalent NIS source files. This utility functions like the reverse of `ypmake(1M)`.

The primary use for `ypmap2src` is to convert from a NIS server that uses the NIS to LDAP(N2L) transition mechanism, which does not use NIS source files, to traditional NIS, where source files are required. The `ypmap2src` utility is also used by NIS administrators who wish to discover the contents of NIS maps for which the sources are not available.

Generally, this operation is not necessary. More often, administrators will switch from traditional NIS to N2L in anticipation of the eventual transition to LDAP naming. When this switch is made, authoritative information is moved into the LDAP DIT, and the NIS sources have no further role. N2L supports NIS clients until such time as they can be converted to LDAP, and the NIS service suspended.

The `ypmap2src` utility does not guarantee that the files that are generated are identical to the original NIS source files. Some information might have been thrown away by `ypmake` and cannot be recovered. N2L also might have updated the maps to reflect changes made by LDAP clients. It is essential that the sources generated are checked to confirm no problems have occurred.

Per entry comment fields, from existing source files, are not merged into source files generated by `ypmap2src`. If a user wishes N2L to maintain comment information, then the `NISLDAPmapping` configuration file should be modified so that the comment fields are mapped into LDAP. This will ensure that the comments are visible to native LDAP clients and present in the N2L map files.

When `ypmap2src` is run, it will take up-to-date comments from the map file and insert them into the NIS source file generated.

Handling Custom Maps `ypmap2src` only knows about the standard NIS maps and standard source to map conversion. If an advanced user has changed these, that is, the user has modified the NIS makefile, the equivalent changes must also be made to the `ypmap2src` script.

Options `ypmap2src` supports the following options:

`-c` Specifies that *custom-map-name* should be converted to a source file by running `makedbm -u` on it. This is a short cut so that simple custom maps can be handled without editing `ypmap2src`.

`-d` *domain-name* Specifies the domain to convert. The *domain-name* can be a fully qualified file path, such as `/var/yp/a.b.c`, or just a domain name, a.b.c. In the latter case, `ypmaptosrc` looks in `/var/yp` for the domain directory.

`-o` *dest* — Specifies the destination directory for the converted files. A directory other than `/etc` should be specified. The maps generated are copied to the correct location, `/etc`, `/etc/security` or other source directory, as appropriate.

`-t` — Specifies that traditional NIS maps, without N2L's `LDAP_` prefix, should be converted. By default, maps with the `LDAP_` prefix are converted.

Operands `ypmap2src` supports the following operands:

source-file — Lists the standard source files to convert. If this option is not given, then all the standard source files, plus any custom files pecified by the `-c` option, are converted.

Attributes See `attributes(5)` for descriptions of the following attributes:

System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)

Name yppoll – return current version of a NIS map at a NIS server host

Synopsis

```
/usr/sbin/yppoll [-d ypdomain] [-h host] mapname
```

Description The `yppoll` command asks a `ypserv( )` process what the order number is, and which host is the master NIS server for the named map.

Options

`-d` *ypdomain* Use *ypdomain* instead of the default domain.

`-h` *host* Ask the `ypserv` process at *host* about the map parameters. If *host* is not specified, the NIS server for the local host is used. That is, the default host is the one returned by `ypwhich(1)`.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWnisu

See Also `ypwhich(1)`, `ypfiles(4)`, `attributes(5)`

Name yppush – force propagation of changed NIS map

Synopsis

```
/usr/lib/netsvc/yp/yppush [-v] [-h host] [-d domain]
     [-p #parallel-xfrs] mapname
```

Description `yppush` copies a new version of a Network Information Service (NIS) map from the master NIS server to the slave NIS servers. It is normally run only on the master NIS server by the `Makefile` in `/var/yp` after the master databases are changed. It first constructs a list of NIS server hosts by reading the NIS `ypservers` map within the *domain*. Keys within the `ypservers` map are the ASCII names of the machines on which the NIS servers run.

A "transfer map" request is sent to the NIS server at each host, along with the information needed by the transfer agent (the program that actually moves the map) to call back the `yppush`. When the attempt has completed (successfully or not), and the transfer agent has sent `yppush` a status message, the results can be printed to `stdout`. Messages are also printed when a transfer is not possible, for instance, when the request message is undeliverable, or when the timeout period on responses has expired.

Refer to `ypfiles(4)` and `ypserv(1M)` for an overview of the NIS service.

Options The following options are supported:

`-d` *domain*	Specifies a *domain*.
`-h` *host*	Propagates only to the named *host*.
`-p` *#parallel-xfrs*	Allows the specified number of map transfers to occur in parallel.
`-v`	Verbose. This prints messages when each server is called, and for each response. If this flag is omitted, only error messages are printed.

Files

`/var/yp`	Directory where NIS configuration files reside.
`/var/yp/`*domain*`/ypservers.` `{`*dir*`,` *pag* `}`	Map containing list of NIS servers to bind to when running in server mode.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWypu

See Also `ypserv(1M)`, `ypxfr(1M)`, `ypfiles(4)`, `attributes(5)`

Notes The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and must not be used without permission.

Bugs In the current implementation (version 2 NIS protocol), the transfer agent is `ypxfr(1M)`, which is started by the `ypserv` program. If `yppush` detects that it is speaking to a version 1 NIS protocol server, it uses the older protocol, sending a version 1 `YPPROC_GET` request and issues a message to that effect. Unfortunately, there is no way of knowing if or when the map transfer is performed for version 1 servers. `yppush` prints a message saying that an "old-style" message has been sent. The system administrator should later check to see that the transfer has actually taken place.

Name ypserv, ypxfrd – NIS server and binder processes

Synopsis

```
/usr/lib/netsvc/yp/ypserv [-dv] [-i | -I] [-r | -R]

/usr/lib/netsvc/yp/ypxfrd
```

Description The Network Information Service (NIS) provides a simple network lookup service consisting of databases and processes. The databases are `ndbm` files in a directory tree rooted at `/var/yp`. See `ndbm(3C)`. These files are described in `ypfiles(4)`. The processes are `/usr/lib/netsvc/yp/ypserv`, the NIS database lookup server, and `/usr/lib/netsvc/yp/ypbind`, the NIS binder. The programmatic interface to the NIS service is described in `ypclnt(3NSL)`. Administrative tools are described in `yppoll(1M)`, `yppush(1M)`, `ypset(1M)`, `ypxfr(1M)`, and `ypwhich(1)`. Tools to see the contents of NIS maps are described in `ypcat(1)`, and `ypmatch(1)`. Database generation and maintenance tools are described in `ypinit(1M)`, `ypmake(1M)`, and `makedbm(1M)`.

The `ypserv` utility is a daemon process typically activated at system startup from `svc:/network/nis/server:default`. Alternatively, you can, as the root user, start NIS services using `ypstart(1M)` from the command-line. `ypserv` runs only on NIS server machines with a complete NIS database. You can halt all NIS services using the `ypstop(1M)` command.

The `ypxfrd` utility transfers entire NIS maps in an efficient manner. For systems that use this daemon, map transfers are 10 to 100 times faster, depending on the map. To use this daemon, be sure `ypxfrd` is running on the master server. See `/usr/lib/netsvc/yp/ypstart`. `ypxfr` attempts to use `ypxfrd` first. If that fails, it prints a warning, then uses the older transfer method.

The `ypserv` daemon's primary function is to look up information in its local database of NIS maps.

The operations performed by `ypserv` are defined for the implementor by the *YP Protocol Specification*, and for the programmer by the header file <`rpcsvc/yp_prot.h`>.

Communication to and from `ypserv` is by means of RPC calls. Lookup functions are described in `ypclnt(3NSL)`, and are supplied as C-callable functions in the `libnsl(3LIB)` library. There are four lookup functions, all of which are performed on a specified map within some NIS domain: `yp_match(3NSL)`, `yp_first(3NSL)`, `yp_next(3NSL)`, and `yp_all(3NSL)`. The `yp_match` operation takes a key, and returns the associated value. The `yp_first` operation returns the first key-value pair from the map, and `yp_next` can be used to enumerate the remainder. `yp_all` ships the entire map to the requester as the response to a single RPC request.

A number of special keys in the DBM files can alter the way in which `ypserv` operates. The keys of interest are:

`YP_INTERDOMAIN` The presence of this key causes `ypserv` to forward to a DNS server host lookups that cannot be satisfied by the DBM files.

`YP_SECURE`	This key causes `ypserv` to answer only questions coming from clients on reserved ports.
`YP_MULTI_`*hostname*	This is a special key in the form, `YP_MULTI_`*hostname addr1,...,addrN*. A client looking for *hostname* receives the closest address.

Two other functions supply information about the map, rather than map entries: `yp_order(3NSL)`, and `yp_master(3NSL)`. In fact, both order number and master name exist in the map as key-value pairs, but the server will not return either through the normal lookup functions. If you examine the map with `makedbm(1M)`, however, they are visible. Other functions are used within the NIS service subsystem itself, and are not of general interest to NIS clients. These functions include `do_you_serve_this_domain?`, `transfer_map`, and `reinitialize_internal_state`.

On start up, `ypserv` checks for the existence of the NIS to LDAP (N2L) configuration file `/var/yp/NISLDAPmapping`. If it is present then a master server starts in N2L mode. If the file is not present it starts in "traditional" (non N2L) mode. Slave servers always start in traditional mode.

In N2L mode, a new set of map files, with an `LDAP_` prefix, are generated, based on the contents of the LDAP DIT. The old map files, NIS source files and `ypmake(1M)` are not used.

It is possible that `ypmake(1M)` can be accidentally run in N2L mode. If the occurs, the old style map files are overwritten. That the map files are overwritten is harmless. However, any resulting `yppush(1M)` operation will push information based on the DIT rather than the source files. The user may not expect information based on the DIT. `ypserv` keeps track of the last modification date of the old style map files. If the map files have been updated, a warning is logged that suggests that the user call `yppush` directly instead of `ypmake`.

If a server attempts to run in N2L mode and a LDAP server cannot be contacted, it behaves as follows:

1. When `ypserv` is started, a warning will be logged.
2. When a NIS read access is made and the TTL entry has expired, a warning is logged.Information that is returned from the cache has not been updated.
3. When a NIS write access is made, a warning is logged. The cache will not be updated, and a NIS failure will be returned.

If `ypxfrd` is running in N2L mode and is asked to transfer a map, `ypxfrd` first checks whether the map is out of date. If the map is out of date, `ypxfrd` initiates an update from the DIT. `ypxfrd` cannot wait for the update to complete. If `ypxfrd` waited, the client end `ypxfr` operation could time out. To prevent `ypxfrd` from timing out, the existing map is transferred from the cache. The most up to date map will be transferred on subsequent `ypxfrd` operations.

Options

ypserv `-d` The NIS service should go to the DNS for more host information. This requires the existence of a correct `/etc/resolv.conf` file pointing to a DNS server. This option turns on DNS forwarding regardless of whether or not the `YP_INTERDOMAIN` flag is set in the `hosts` maps. See makedbm(1M). In the absence of an `/etc/resolv.conf` file, `ypserv` complains, but ignores the `-d` option.

`-i` If in N2L mode, initialize the NIS related parts of the `DIT` based on the current, non `LDAP_` prefixed, map files. The `LDAP_` prefixed maps are not created or updated. If you require that `LDAP_` prefixed maps be updated or created, then use the `-ir` option.

The `-i` option does not attempt to create any NIS domain or container objects. If any NIS domain or container objects have not already been created, then errors will occur, as entries are written to nonexistent containers.

`-I` Identical to `-i`, except that any missing domain and container objects are created.

`-r` If in N2L mode, then refresh the `LDAP_` prefixed map files based on the contents of the `DIT`.

`-ir` If both `-i` and `-r` are specified in N2L mode, then the `DIT` will first be initialized from the current non `LDAP_` prefixed map files. A new set of `LDAP_` prefixed maps will then be generated from the contents of the `DIT`. A new set of `LDAP_` prefixed maps is required when moving from traditional NIS to N2L mode NIS.

`-Ir` Identical to `-ir`, except that any missing domain and container objects are created.

`-v` Operate in the verbose mode, printing diagnostic messages to stderr.

When run with the `-i`, `-r`, `-I`, `-ir` or `-Ir` options, the `ypserv` command runs in the foreground and exits once map initialization has been completed. Once the `ypserv` command exits, the user knows the maps are ready and can restart `ypserv` and the other `yp` daemons by running ypstart(1M).

If there is a requirement to initialize the `DIT` from the NIS source files, which may have been modified since the maps were last remade, run `ypmake` before running `ypserv -i` or `ypserv -ir`. `ypmake` regenerated old style NIS maps. Then `ypserv -ir` dumps them into the `DIT`. When the `-ir` option is used, the `LDAP_` prefixe maps are also generated or updated. Since these maps will be more recent than the old style maps, `ypmake` will not be reported as erroneous when it is run.

Files

`/var/yp/securenets` Defines the hosts and networks that are granted access to information in the served domain. It is read at startup time by both `ypserv` and `ypxfrd`.

`/var/yp/ypserv.log`	If the `/var/yp/ypserv.log` file exists when `ypserv` starts up, log information is written to it when error conditions arise.
`/var/yp/binding/domainname/ypservers`	Lists the NIS server hosts that `ypbind` can bind to.

Network Interface Guide

System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)

Notes `ypserv` supports multiple domains. The `ypserv` process determines the domains it serves by looking for directories of the same name in the directory `/var/yp`. It replies to all broadcasts requesting yp service for that domain.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and must not be used without permission.

NIS uses `ndbm()` files to store maps. Therefore, it is subject to the 1024 byte limitations described in the USAGE and NOTES sections of the `ndbm(3C)` man page.

The NIS server service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/nis/server:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

Name ypset – point ypbind at a particular server

Synopsis

```
/usr/sbin/ypset [-d ypdomain] [-h host] server
```

Description In order to run `ypset`, `ypbind` must be initiated with the –`ypset` or –`ypsetme` options. See `ypbind(1M)`. `ypset` tells `ypbind` to get NIS services for the specified *ypdomain* from the `ypserv` process running on *server*. If *server* is down, or is not running `ypserv`, this might not be discovered until an NIS client process tries to obtain a binding for the domain. At this point, the binding set by `ypset` is tested by `ypbind`. If the binding is invalid, `ypbind` attempts to rebind for the same domain.

`ypset` is useful for binding a client node that is not on a broadcast net, or is on a broadcast net that is not running an NIS server host. It is also useful for debugging NIS client applications, for instance, where an NIS map exists only at a single NIS server host.

Where several hosts on the local net are supplying NIS services, `ypbind` can rebind to another host, even while you attempt to find out if the `ypset` operation succeeded. For example, if you enter the `ypset` command below, you might get the subsequent response from `ypwhich`:

```
example% ypset host1
example% ypwhich
host2
```

The sequence shown above is a function of the NIS subsystem's attempt to load-balance among the available NIS servers, and occurs when `host1` does not respond to `ypbind` because it is not running `ypserv` (or is overloaded), and `host2`, running `ypserv`, obtains the binding.

server indicates which NIS server to bind to, and must be specified as a name or an IP address. This works only if the node has a current valid binding for the domain in question and `ypbind` has been set to allow use of `ypset`. In most cases, *server* should be specified as an IP address.

`ypset` tries to bind over a connectionless transport. The NIS library call, `yp_all()`, uses connection-oriented transport and derives the NIS server's address based on the connectionless address supplied by `ypset`.

Refer to `ypfiles(4)` for an overview of the NIS name service.

Options

`-d` *ypdomain* Use *ypdomain*, instead of the default domain.

`-h` *host* Set `ypbind`'s binding on *host*, instead of locally. Specify *host* as a name.

Name ypstart, ypstop – Start and stop NIS services

Synopsis

```
/usr/lib/netsvc/yp/ypstart

/usr/lib/netsvc/yp/ypstop
```

Description The `ypstart` command is used to start the Network Information Service (NIS). After the host has been configured using the `ypinit(1M)` command, `ypstart` automatically determines the NIS status of the machine and starts the appropriate daemons.

The `ypstop` command is used to stop the Network Information Service (NIS).

Attributes See `attributes(5)` for descriptions of the following attributes:

System Administration Guide: Basic Administration

Notes The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two services remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and must not be used without permission.

Name ypxfr, ypxfr_1perday, ypxfr_1perhour, ypxfr_2perday – transfer NIS map from a NIS server to host

Synopsis

```
/usr/lib/netsvc/yp/ypxfr [-c] [-f] [-C tid prog server]
     [-d ypdomain] [-h host] [-s ypdomain] mapname
```

Description The `ypxfr` command moves an NIS map in the default domain for the local host to the local host by making use of normal NIS services. It creates a temporary map in the directory `/var/yp/`*ypdomain* (this directory must already exist; *ypdomain* is the default domain for the local host), fills it by enumerating the map's entries, fetches the map parameters (master and order number), and loads them. It then deletes any old versions of the map and moves the temporary map to the real *name*.

If run interactively, `ypxfr` writes its output to the terminal. However, if it is started without a controlling terminal, and if the log file `/var/yp/ypxfr.log` exists, it appends all its output to that file. Since `ypxfr` is most often run from the privileged user's `crontab` file, or by `ypserv`, the log file can retain a record of what was attempted, and what the results were.

For consistency between servers, `ypxfr` should be run periodically for every map in the NIS data base. Different maps change at different rates: a map might not change for months at a time, for instance, and can therefore be checked only once a day. Some maps might change several times per day. In such a case, you might want to check hourly for updates. A `crontab(1)` entry can be used to automatically perform periodic updates. Rather than having a separate `crontab` entry for each map, you can group commands to update several maps in a shell script. Examples (mnemonically named) are in `/usr/sbin/yp`: `ypxfr_1perday`, `ypxfr_2perday`, and `ypxfr_1perhour`.

Refer to `ypfiles(4)` for an overview of the NIS name service.

Options

`-c`	Do not send a “Clear current map” request to the local `ypserv` process. Use this flag if `ypserv` is not running locally at the time you are running `ypxfr`. Otherwise, `ypxfr` complains that it cannot communicate with the local `ypserv`, and the transfer fails.
`-f`	Force the transfer to occur even if the version at the master is not more recent than the local version.
`-C` *tid prog server*	This option is for use *only* by `ypserv`. When `ypserv` starts `ypxfr`, it specifies that `ypxfr` should call back a `yppush` process at the host *server*, registered as program number *prog*, and waiting for a response to transaction *tid*.
`-d` *ypdomain*	Specify a domain other than the default domain.
`-h` *host*	Get the map from *host*, regardless of the master. If *host* is not specified, `ypxfr` asks the NIS service for the name of the master, and tries to get the map from there. *host* must be a valid host name.

`-s` *ypdomain*	Specify a source domain from which to transfer a map that should be the same across domains.

Files

`/var/yp/ypxfr.log`	Log file
`/usr/lib/netsvc/yp/ypxfr_1perday`	Script to run one transfer per day, for use with `cron`(1M)

Name zdb – ZFS debugger

Synopsis `zdb` *pool*

Description The `zdb` command is used by support engineers to diagnose failures and gather statistics. Since the ZFS file system is always consistent on disk and is self-repairing, `zdb` should only be run under the direction by a support engineer.

If no arguments are specified, `zdb`, performs basic consistency checks on the pool and associated datasets, and report any problems detected.

Any options supported by this command are internal to Sun and subject to change at any time.

Exit Status The following exit values are returned:

`0` The pool is consistent.

`1` An error was detected.

`2` Invalid command line options were specified.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWzfsu
Interface Stability	Unstable

See Also `zfs(1M)`, `zpool(1M)`, `attributes(5)`

Name zdump – time zone dumper

Synopsis

```
zdump [--version] [-v] [-c [loyear,]hiyear] [zonename]...
```

Description The `zdump` command prints the current time for each time zone (*zonename*) listed on the command line. Specify *zonename* as the name of the time zone database file relative to `/usr/share/lib/zoneinfo`.

Specifying an invalid time zone (*zonename*) to `zdump` does not return an error, rather `zdump` uses GMTO. This is consistent with the behavior of the library calls; `zdump` reflects the same behavior of the time routines in `libc`. See `ctime(3C)` and `mktime(3C)`.

Options The following options are supported:

`--`*version* Outputs version information and exits.

`-v` Displays the entire contents of the time zone database file for *zonename*. Prints the time at the lowest possible time value; the time one day after the lowest possible time value; the times both one second before and exactly at each time at which the rules for computing local time change; the time at the highest possible time value; and the time at one day less than the highest possible time value. See `mktime(3C)` and `ctime(3C)` for information regarding time value (`time_t`). Each line of output ends with `isdst=1` if the given time is Daylight Saving Time, or `isdst=0` otherwise.

`-c` [*loyear*],*hiyear* Cuts off the verbose output near the start of the given year(s) . By default, the program cuts off verbose output near the start of the years -500 and 2500.

Exit Status The following exit values are returned:

`0` Successful completion.

`1` An error occurred.

Files `/usr/share/lib/zoneinfo` Standard zone information directory

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Name zfs – configures ZFS file systems

Synopsis

```
zfs [-?]

zfs create [-p] [-o property=value] ... filesystem

zfs create [-ps] [-b blocksize] [-o property=value] ... -V size volume

zfs destroy [-rRf] filesystem|volume

zfs destroy [-rRd] snapshot

zfs snapshot [-r] [-o property=value]...
      filesystem@snapname|volume@snapname

zfs rollback [-rRf] snapshot

zfs clone [-p] [-o property=value] ... snapshot filesystem|volume

zfs promote clone-filesystem

zfs rename filesystem|volume|snapshot
     filesystem|volume|snapshot

zfs rename [-p] filesystem|volume filesystem|volume

zfs rename -r snapshot snapshot

zfs list [-r|-d depth][-H][-o property[,...]] [-t type[,...]]
     [-s property] ... [-S property] ... [filesystem|volume|snapshot] ...

zfs set property=value filesystem|volume|snapshot ...

zfs get [-r|-d depth][-Hp][-o all | field[,...]] [-s source[,...]]
     all | property[,...] filesystem|volume|snapshot ...

zfs inherit [-rS] property filesystem|volume|snapshot ...

zfs upgrade

zfs upgrade -v

zfs upgrade [-r] [-V version] -a | filesystem

zfs userspace [-niHp] [-o field[,...]] [-sS field] ...
     [-t type [,...]] filesystem|snapshot

zfs groupspace [-niHp] [-o field[,...]] [-sS field] ...
     [-t type [,...]] filesystem|snapshot

zfs mount

zfs mount [-vO] [-o options] -a | filesystem

zfs unmount [-f] -a | filesystem|mountpoint

zfs share -a | filesystem

zfs unshare -a filesystem|mountpoint

zfs send [-DvRp] [-[iI] snapshot] snapshot
```

```
zfs receive [-vnFu] filesystem|volume|snapshot

zfs receive [-vnFu] [-d | -e] filesystem

zfs allow filesystem|volume

zfs allow [-ldug] everyone|user|group[,...] perm|@setname[,...]
     filesystem|volume

zfs allow [-ld] -e perm|@setname[,...] filesystem|volume

zfs allow -c perm|@setname[,...] filesystem|volume

zfs allow -s @setname perm|@setname[,...] filesystem|volume

zfs unallow [-rldug] everyone|user|group[,...] [perm|@setname[,... ]]
     filesystem|volume

zfs unallow [-rld] -e [perm|@setname[,... ]] filesystem|volume

zfs unallow [-r] -c [perm|@setname[ ... ]] filesystem|volume

zfs unallow [-r] -s @setname [perm|@setname[,... ]] filesystem|volume

zfs hold [-r] tag snapshot...

zfs holds [-r] snapshot...

zfs release [-r] tag snapshot...
```

Description The `zfs` command configures ZFS datasets within a ZFS storage pool, as described in `zpool(1M)`. A dataset is identified by a unique path within the ZFS namespace. For example:

```
pool/{filesystem,volume,snapshot}
```

where the maximum length of a dataset name is `MAXNAMELEN` (256 bytes).

A dataset can be one of the following:

file system
A ZFS dataset of type `filesystem` can be mounted within the standard system namespace and behaves like other file systems. While ZFS file systems are designed to be POSIX compliant, known issues exist that prevent compliance in some cases. Applications that depend on standards conformance might fail due to nonstandard behavior when checking file system free space.

volume
A logical volume exported as a raw or block device. This type of dataset should only be used under special circumstances. File systems are typically used in most environments.

snapshot
A read-only version of a file system or volume at a given point in time. It is specified as *filesystem@name* or *volume@name*.

ZFS File System Hierarchy

A ZFS storage pool is a logical collection of devices that provide space for datasets. A storage pool is also the root of the ZFS file system hierarchy.

The root of the pool can be accessed as a file system, such as mounting and unmounting, taking snapshots, and setting properties. The physical storage characteristics, however, are managed by the `zpool(1M)` command.

See `zpool(1M)` for more information on creating and administering pools.

Snapshots

A snapshot is a read-only copy of a file system or volume. Snapshots can be created extremely quickly, and initially consume no additional space within the pool. As data within the active dataset changes, the snapshot consumes more data than would otherwise be shared with the active dataset.

Snapshots can have arbitrary names. Snapshots of volumes can be cloned or rolled back, but cannot be accessed independently.

File system snapshots can be accessed under the `.zfs/snapshot` directory in the root of the file system. Snapshots are automatically mounted on demand and may be unmounted at regular intervals. The visibility of the `.zfs` directory can be controlled by the `snapdir` property.

Clones

A clone is a writable volume or file system whose initial contents are the same as the original dataset. As with snapshots, creating a clone is nearly instantaneous, and initially consumes no additional space.

Clones can only be created from a snapshot. When a snapshot is cloned, it creates an implicit dependency between the parent and child. Even though the clone is created somewhere else in the dataset hierarchy, the original snapshot cannot be destroyed as long as a clone exists. The `origin` property exposes this dependency, and the `zfs destroy` command lists any such dependencies, if they exist.

The clone parent-child dependency relationship can be reversed by using the `promote` subcommand. This causes the *origin* file system to become a clone of the specified file system, which makes it possible to destroy the file system that the clone was created from.

Mount Points

Creating a ZFS file system is a simple operation, so the number of file systems per system is likely to be numerous. To cope with this, ZFS automatically manages mounting and unmounting file systems without the need to edit the `/etc/vfstab` file. All automatically managed file systems are mounted by ZFS at boot time.

By default, file systems are mounted under */path*, where *path* is the name of the file system in the ZFS namespace. Directories are created and destroyed as needed.

A file system can also have a mount point set in the `mountpoint` property. This directory is created as needed, and ZFS automatically mounts the file system when the `zfs mount -a` command is invoked (without editing `/etc/vfstab`). The `mountpoint` property can be inherited, so if `pool/home` has a mount point of `/export/stuff`, then `pool/home/user` automatically inherits a mount point of `/export/stuff/user`.

A file system `mountpoint` property of `none` prevents the file system from being mounted.

If needed, ZFS file systems can also be managed with traditional tools (`mount`, `umount`, `/etc/vfstab`). If a file system's mount point is set to `legacy`, ZFS makes no attempt to manage the file system, and the administrator is responsible for mounting and unmounting the file system.

Zones

A ZFS file system can be added to a non-global zone by using the `zonecfg add fs` subcommand. A ZFS file system that is added to a non-global zone must have its `mountpoint` property set to `legacy`.

The physical properties of an added file system are controlled by the global administrator. However, the zone administrator can create, modify, or destroy files within the added file system, depending on how the file system is mounted.

A dataset can also be delegated to a non-global zone by using the `zonecfg add dataset` subcommand. You cannot delegate a dataset to one zone and the children of the same dataset to another zone. The zone administrator can change properties of the dataset or any of its children. However, the `quota` property is controlled by the global administrator.

A ZFS volume can be added as a device to a non-global zone by using the `zonecfg add device` subcommand. However, its physical properties can be modified only by the global administrator.

For more information about `zonecfg` syntax, see `zonecfg(1M)`.

After a dataset is delegated to a non-global zone, the `zoned` property is automatically set. A zoned file system cannot be mounted in the global zone, since the zone administrator might have to set the mount point to an unacceptable value.

The global administrator can forcibly clear the `zoned` property, though this should be done with extreme care. The global administrator should verify that all the mount points are acceptable before clearing the property.

Native Properties

Properties are divided into two types, native properties and user-defined (or *user*) properties. Native properties either export internal statistics or control ZFS behavior. In addition, native properties are either editable or read-only. User properties have no effect on ZFS behavior, but you can use them to annotate datasets in a way that is meaningful in your environment. For more information about user properties, see the "User Properties" section, below.

Every dataset has a set of properties that export statistics about the dataset as well as control various behaviors. Properties are inherited from the parent unless overridden by the child. Some properties apply only to certain types of datasets (file systems, volumes, or snapshots).

The values of numeric properties can be specified using human-readable suffixes (for example, `k`, `KB`, `M`, `Gb`, and so forth, up to `Z` for zettabyte). The following are all valid (and equal) specifications:

```
1536M, 1.5g, 1.50GB
```

The values of non-numeric properties are case sensitive and must be lowercase, except for `mountpoint`, `sharenfs`, and `sharesmb`.

The following native properties consist of read-only statistics about the dataset. These properties can be neither set, nor inherited. Native properties apply to all dataset types unless otherwise noted.

`available`
The amount of space available to the dataset and all its children, assuming no other activity in the pool. Because space is shared within a pool, availability can be limited by any number of factors, including physical pool size, quotas, reservations, or other datasets within the pool.

This property can also be referred to by its shortened column name, `avail`.

`compressratio`
The compression ratio achieved for this dataset, expressed as a multiplier. Compression can be turned on by running: `zfs set compression=on` *dataset*. The default value is `off`.

`creation`
The time this dataset was created.

`defer_destroy`
This property is `on` if the snapshot has been marked for deferred destroy by using the `zfs destroy -d` command. Otherwise, the property is `off`.

`mounted`
For file systems, indicates whether the file system is currently mounted. This property can be either `yes` or `no`.

`origin`
For cloned file systems or volumes, the snapshot from which the clone was created. The origin cannot be destroyed (even with the `-r` or `-f` options) so long as a clone exists.

`referenced`
The amount of data that is accessible by this dataset, which may or may not be shared with other datasets in the pool. When a snapshot or clone is created, it initially references the same amount of space as the file system or snapshot it was created from, since its contents are identical.

This property can also be referred to by its shortened column name, `refer`.

`type`
The type of dataset: `filesystem`, `volume`, or `snapshot`.

`used`
The amount of space consumed by this dataset and all its descendents. This is the value that is checked against this dataset's quota and reservation. The space used does not include this

dataset's reservation, but does take into account the reservations of any descendent datasets. The amount of space that a dataset consumes from its parent, as well as the amount of space that is freed if this dataset is recursively destroyed, is the greater of its space used and its reservation.

When snapshots (see the "Snapshots" section) are created, their space is initially shared between the snapshot and the file system, and possibly with previous snapshots. As the file system changes, space that was previously shared becomes unique to the snapshot, and counted in the snapshot's space used. Additionally, deleting snapshots can increase the amount of space unique to (and used by) other snapshots.

The amount of space used, available, or referenced does not take into account pending changes. Pending changes are generally accounted for within a few seconds. Committing a change to a disk using `fsync(3C)` or `O_SYNC` does not necessarily guarantee that the space usage information is updated immediately.

`usedby*`
The `usedby*` properties decompose the `used` properties into the various reasons that space is used. Specifically, `used` = `usedbychildren` + `usedbydataset` + `usedbyrefreservation` +, `usedbysnapshots`. These properties are only available for datasets created on version 13 pools.

`usedbychildren`
The amount of space used by children of this dataset, which would be freed if all the dataset's children were destroyed.

`usedbydataset`
The amount of space used by this dataset itself, which would be freed if the dataset were destroyed (after first removing any `refreservation` and destroying any necessary snapshots or descendents).

`usedbyrefreservation`
The amount of space used by a `refreservation` set on this dataset, which would be freed if the `refreservation` was removed.

`usedbysnapshots`
The amount of space consumed by snapshots of this dataset. In particular, it is the amount of space that would be freed if all of this dataset's snapshots were destroyed. Note that this is not simply the sum of the snapshots' `used` properties because space can be shared by multiple snapshots.

`userused@`*user*
The amount of space consumed by the specified user in this dataset. Space is charged to the owner of each file, as displayed by `ls -l`. The amount of space charged is displayed by `du` and `ls -s`. See the `zfs userspace` subcommand for more information.

Unprivileged users can access only their own space usage. The root user, or a user who has been granted the `userused` privilege with `zfs allow`, can access everyone's usage.

The `userused@...` properties are not displayed by `zfs get all`. The user's name must be appended after the `@` symbol, using one of the following forms:

- *POSIX name* (for example, `joe`)
- *POSIX numeric ID* (for example, `789`)
- *SID name* (for example, `joe.smith@mydomain`)
- *SID numeric ID* (for example, `S-1-123-456-789`)

`userrefs`
This property is set to the number of user holds on this snapshot. User holds are set by using the `zfs hold` command.

`groupused@`*group*
The amount of space consumed by the specified group in this dataset. Space is charged to the group of each file, as displayed by `ls -l`. See the `userused@`*user* property for more information.

Unprivileged users can only access their own groups' space usage. The root user, or a user who has been granted the `groupused` privilege with `zfs allow`, can access all groups' usage.

`volblocksize=`*blocksize*
For volumes, specifies the block size of the volume. The `blocksize` cannot be changed once the volume has been written, so it should be set at volume creation time. The default `blocksize` for volumes is 8 KB. Any power of 2 from 512 bytes to 128 KB is valid.

This property can also be referred to by its shortened column name, `volblock`.

The following native properties can be used to change the behavior of a ZFS dataset.

`aclinherit=discard` | `noallow` | `restricted` | `passthrough` | `passthrough-x`
Controls how ACL entries are inherited when files and directories are created. A file system with an `aclinherit` property of `discard` does not inherit any ACL entries. A file system with an `aclinherit` property value of `noallow` only inherits inheritable ACL entries that specify deny permissions. The property value `restricted` (the default) removes the `write_acl` and `write_owner` permissions when the ACL entry is inherited. A file system with an `aclinherit` property value of `passthrough` inherits all inheritable ACL entries without any modifications made to the ACL entries when they are inherited. A file system with an `aclinherit` property value of `passthrough-x` has the same meaning as `passthrough`, except that the `owner@`, `group@`, and `everyone@` ACEs inherit the execute permission only if the file creation mode also requests the execute bit.

When the property value is set to `passthrough`, files are created with a mode determined by the inheritable ACEs. If no inheritable ACEs exist that affect the mode, then the mode is set in accordance to the requested mode from the application.

`aclmode=discard` | `groupmask` | `passthrough`
Controls how an ACL is modified during chmod(2). A file system with an `aclmode` property of `discard` deletes all ACL entries that do not represent the mode of the file. An `aclmode` property of `groupmask` (the default) reduces user or group permissions. The permissions

are reduced, such that they are no greater than the group permission bits, unless it is a user entry that has the same UID as the owner of the file or directory. In this case, the ACL permissions are reduced so that they are no greater than owner permission bits. A file system with an `aclmode` property of `passthrough` indicates that no changes are made to the ACL other than generating the necessary ACL entries to represent the new mode of the file or directory.

`atime=on | off`
Controls whether the access time for files is updated when they are read. Turning this property off avoids producing write traffic when reading files and can result in significant performance gains, though it might confuse mailers and other similar utilities. The default value is `on`.

`canmount=on | off | noauto`
If this property is set to `off`, the file system cannot be mounted, and is ignored by `zfs mount -a`. Setting this property to `off` is similar to setting the `mountpoint` property to `none`, except that the dataset still has a normal `mountpoint` property, which can be inherited. Setting this property to `off` allows datasets to be used solely as a mechanism to inherit properties. One example of setting `canmount=off` is to have two datasets with the same `mountpoint`, so that the children of both datasets appear in the same directory, but might have different inherited characteristics.

When the `noauto` option is set, a dataset can only be mounted and unmounted explicitly. The dataset is not mounted automatically when the dataset is created or imported, nor is it mounted by the `zfs mount -a` command or unmounted by the `zfs unmount -a` command.

This property is not inherited.

`checksum=on | off | fletcher2, | fletcher4 | sha256`
Controls the checksum used to verify data integrity. The default value is `on`, which automatically selects the `fletcher4` algorithm. The value `off` disables integrity checking on user data. Disabling checksums is *NOT* a recommended practice.

Changing this property affects only newly-written data.

`compression=on | off | lzjb | gzip | gzip-`*N*` | zle`
Controls the compression algorithm used for this dataset. The `lzjb` compression algorithm is optimized for performance while providing decent data compression. Setting compression to `on` uses the `lzjb` compression algorithm. The `gzip` compression algorithm uses the same compression as the `gzip`(1) command. You can specify the `gzip` level by using the value `gzip-`*N* where *N* is an integer from 1 (fastest) to 9 (best compression ratio). Currently, `gzip` is equivalent to `gzip-6` (which is also the default for `gzip`(1)).

This property can also be referred to by its shortened column name `compress`. Changing this property affects only newly-written data.

`copies=1 | 2 | 3`
Controls the number of copies of data stored for this dataset. These copies are in addition to any redundancy provided by the pool, for example, mirroring or RAID-Z. The copies are stored on different disks, if possible. The space used by multiple copies is charged to the associated file and dataset, changing the `used` property and counting against quotas and reservations.

Changing this property only affects newly-written data. Therefore, set this property at file system creation time by using the `-o copies=`*N* option.

`devices=on | off`
Controls whether device nodes can be opened on this file system. The default value is `on`.

`exec=on | off`
Controls whether processes can be executed from within this file system. The default value is `on`.

`mountpoint=`*path* `| none | legacy`
Controls the mount point used for this file system. See the "Mount Points" section for more information on how this property is used.

When the `mountpoint` property is changed for a file system, the file system and any children that inherit the mount point are unmounted. If the new value is `legacy`, then they remain unmounted. Otherwise, they are automatically remounted in the new location if the property was previously `legacy` or `none`, or if they were mounted before the property was changed. In addition, any shared file systems are unshared and shared in the new location.

`nbmand=on | off`
Controls whether the file system should be mounted with `nbmand` (Non Blocking mandatory locks). This is used for SMB clients. Changes to this property only take effect when the file system is umounted and remounted. See `mount(1M)` for more information on `nbmand` mounts.

This SMB related property is not fully functional in the Oracle Solaris 10 release because the Oracle Solaris SMB server is not supported in the Oracle Solaris 10 release.

`primarycache=all | none | metadata`
Controls what is cached in the primary cache (ARC). If this property is set to `all`, then both user data and metadata is cached. If this property is set to `none`, then neither user data nor metadata is cached. If this property is set to `metadata`, then only metadata is cached. The default value is `all`.

`quota=`*size* `| none`
Limits the amount of space a dataset and its descendents can consume. This property enforces a hard limit on the amount of space used. This includes all space consumed by

descendents, including file systems and snapshots. Setting a quota on a descendent of a dataset that already has a quota does not override the ancestor's quota, but rather imposes an additional limit.

Quotas cannot be set on volumes, as the `volsize` property acts as an implicit quota.

`userquota@`*user*`=`*size*`|none`
Limits the amount of space consumed by the specified user. Similar to the `refquota` property, the `userquota` space calculation does not include space that is used by descendent datasets, such as snapshots and clones. User space consumption is identified by the `userspace@`*user* property.

Enforcement of user quotas may be delayed by several seconds. This delay means that a user might exceed her quota before the system notices that she is over quota. The system would then begin to refuse additional writes and displays the `EDQUOT` error message. See the `zfs userspace` subcommand for more information.

Unprivileged users can only access their own groups' space usage. The root user, or a user who has been granted the `userquota` privilege with `zfs allow`, can get and set everyone's quota.

This property is not available on volumes, on file systems before version 4, or on pools before version 15. The `userquota@...` properties are not displayed by `zfs get all`. The user's name must be appended after the `@` symbol, using one of the following forms:

- *POSIX name* (for example, `joe`)
- *POSIX numeric ID* (for example, `789`)
- *SID name* (for example, `joe.smith@mydomain`)
- *SID numeric ID* (for example, `S-1-123-456-789`)

`groupquota@`*group*`=`*size*`|none`
Limits the amount of space consumed by the specified group. Group space consumption is identified by the `userquota@`*user* property.

Unprivileged users can access only their own groups' space usage. The root user, or a user who has been granted the `groupquota` privilege with `zfs allow`, can get and set all groups' quotas.

`readonly=on|off`
Controls whether this dataset can be modified. The default value is `off`.

This property can also be referred to by its shortened column name, `rdonly`.

`recordsize=`*size*
Specifies a suggested block size for files in the file system. This property is designed solely for use with database workloads that access files in fixed-size records. ZFS automatically tunes block sizes according to internal algorithms optimized for typical access patterns.

For databases that create very large files but access them in small random chunks, these algorithms may be suboptimal. Specifying a `recordsize` greater than or equal to the record size of the database can result in significant performance gains. Use of this property for general purpose file systems is strongly discouraged, and may adversely affect performance.

The size specified must be a power of two greater than or equal to 512 and less than or equal to 128 Kbytes.

Changing the file system's `recordsize` affects only files created afterward; existing files are unaffected.

This property can also be referred to by its shortened column name, `recsize`.

`refquota=`*size* | `none`
Limits the amount of space a dataset can consume. This property enforces a hard limit on the amount of space used. This hard limit does not include space used by descendents, including file systems and snapshots.

`refreservation=`*size* | `none`
The minimum amount of space guaranteed to a dataset, not including its descendents. When the amount of space used is below this value, the dataset is treated as if it were taking up the amount of space specified by `refreservation`. The `refreservation` reservation is accounted for in the parent datasets' space used, and counts against the parent datasets' quotas and reservations.

If `refreservation` is set, a snapshot is only allowed if there is enough free pool space outside of this reservation to accommodate the current number of referenced bytes in the dataset.

This property can also be referred to by its shortened column name, `refreserv`.

`reservation=`*size* | `none`
The minimum amount of space guaranteed to a dataset and its descendents. When the amount of space used is below this value, the dataset is treated as if it were taking up the amount of space specified by its reservation. Reservations are accounted for in the parent datasets' space used, and count against the parent datasets' quotas and reservations.

This property can also be referred to by its shortened column name, `reserv`.

`secondarycache=all` | `none` | `metadata`
Controls what is cached in the secondary cache (L2ARC). If this property is set to `all`, then both user data and metadata is cached. If this property is set to `none`, then neither user data nor metadata is cached. If this property is set to `metadata`, then only metadata is cached. The default value is `all`.

`setuid=on` | `off`
Controls whether the set-UID bit is enabled for the file system. The default value is `on`.

`shareiscsi=on | off`
Like the `sharenfs` property, `shareiscsi` indicates whether a ZFS volume is shared as an iSCSI target. The acceptable values for this property are `on`, `off`, and `type=disk`. The default value is `off`.

You might want to set `shareiscsi=on` for a file system so that all ZFS volumes within the file system are shared by default. However, setting this property on a file system has no direct effect.

`sharesmb=on | off |` *opts*
Controls whether the file system is shared by using the Oracle Solaris SMB service, and what options are to be used. A file system with the `sharesmb` property set to `off` is managed through traditional UNIX tools. Otherwise, the file system is automatically shared and unshared with the `zfs share` and `zfs unshare` commands.

Because SMB shares requires a resource name, a unique resource name is constructed from the dataset name. The constructed name is a copy of the dataset name except that the characters in the dataset name, which would be illegal in the resource name, are replaced with underscore (_) characters. A pseudo property `name` is also supported that allows you to replace the data set name with a specified name. The specified name is then used to replace the prefix dataset in the case of inheritance. For example, if the dataset `data/home/john` is set to `name=john`, then `data/home/john` has a resource name of `john`. If a child dataset of `data/home/john/backups`, it has a resource name of `john_backups`.

When SMB shares are created, the SMB share name appears as an entry in the `.zfs/shares` directory. You can use the `ls` or `chmod` command to display the share-level ACLs on the entries in this directory.

When the `sharesmb` property is changed for a dataset, the dataset and any children inheriting the property are re-shared with the new options, only if the property was previously set to `off`, or if they were shared before the property was changed. If the new property is set to `off`, the file systems are unshared.

Note that the Oracle Solaris SMB service is not supported in the Oracle Solaris 10 release.

`sharenfs=on | off |` *opts*
Controls whether the file system is shared over NFS, and what options are used. A file system with a `sharenfs` property of `off` is managed through traditional tools such as `share(1M)`, `unshare(1M)`, and `dfstab(4)`. Otherwise, the file system is automatically shared and unshared with the `zfs share` and `zfs unshare` commands. If the property is set to `on`, the `share(1M)` command is invoked with no options. Otherwise, the `share(1M)` command is invoked with options equivalent to the contents of this property.

When the `sharenfs` property is changed for a dataset, the dataset and any children inheriting the property are re-shared with the new options, only if the property was previously `off`, or if they were shared before the property was changed. If the new property is `off`, the file systems are unshared.

`logbias` = `latency` | `throughput`
Provides a hint to ZFS about handling of synchronous requests in this dataset. If `logbias` is set to `latency` (the default), ZFS uses the pool's log devices (if configured) to handle the requests at low latency. If `logbias` is set to `throughput`, ZFS does not use the configured pool log devices. Instead, ZFS optimizes synchronous operations for global pool throughput and efficient use of resources.

`snapdir=hidden` | `visible`
Controls whether the `.zfs` directory is hidden or visible in the root of the file system as discussed in the "Snapshots" section. The default value is `hidden`.

`version=`*version* | `current`
The on-disk version of this file system, which is independent of the pool version. This property can only be set to later supported versions. See the `zfs upgrade` command.

`volsize=`*size*
For volumes, specifies the logical size of the volume. By default, creating a volume establishes a reservation of equal size. For storage pools with a version number of 9 or higher, a `refreservation` is set instead. Any changes to `volsize` are reflected in an equivalent change to the reservation (or `refreservation`). The `volsize` can only be set to a multiple of `volblocksize`, and cannot be zero.

The reservation is kept equal to the volume's logical size to prevent unexpected behavior for consumers. The reservation size corresponds to the volume's logical size, increased by ZFS implementation overhead. Without the reservation, the volume could run out of space, resulting in undefined behavior or data corruption, depending on how the volume is used. These effects can also occur when the volume size is changed while it is in use (particularly when shrinking the size). Extreme care should be used when adjusting the volume size.

Though not recommended, a *sparse volume* (also known as *thin provisioning*) can be created by specifying the `-s` option to the `zfs create -V` command, or by changing the reservation after the volume has been created. A sparse volume is a volume where the reservation is less then the volume size. Consequently, writes to a sparse volume can fail with the `ENOSPC` message when the pool is low on space. For a sparse volume, changes to `volsize` are not reflected in the reservation.

`vscan=on` | `off`
Controls whether regular files should be scanned for viruses when a file is opened and closed. In addition to enabling this property, the virus scan service must also be enabled for virus scanning to occur. The default value is `off`.

This SMB related property is not fully functional in the Oracle Solaris 10 release because the Oracle Solaris SMB server is not supported in the Oracle Solaris 10 release.

`xattr=on` | `off`
Controls whether extended attributes are enabled for this file system. The default value is `on`.

`zoned=on | off`
Controls whether the dataset is managed from a non-global zone. See the "Zones" section for more information. The default value is `off`.

The following three properties cannot be changed after the file system is created, and therefore, should be set when the file system is created. If the properties are not set with the `zfs create` or `zpool create` commands, these properties are inherited from the parent dataset. If the parent dataset lacks these properties due to having been created prior to these features being supported, the new file system will have the default values for these properties.

`casesensitivity=sensitive | insensitive | mixed`
Indicates whether the file name matching algorithm used by the file system should be case-sensitive, case-insensitive, or allow a combination of both styles of matching. The default value for the `casesensitivity` property is `sensitive`. Traditionally, UNIX and POSIX file systems have case-sensitive file names.

The `mixed` value for the `casesensitivity` property indicates that the file system can support requests for both case-sensitive and case-insensitive matching behavior. Currently, case-insensitive matching behavior on a file system that supports mixed behavior is limited to the Oracle Solaris SMB server product, which is not supported in the Oracle Solaris 10 release. For more information about the `mixed` value behavior, see the *Oracle Solaris ZFS Administration Guide*.

This SMB related property is not fully functional in the Oracle Solaris 10 release because the Oracle Solaris SMB server is not supported in the Oracle Solaris 10 release.

`normalization = none | formC | formD | formKC | formKD`
Indicates whether the file system should perform a `unicode` normalization of file names whenever two file names are compared, and which normalization algorithm should be used. File names are always stored unmodified, names are normalized as part of any comparison process. If this property is set to a legal value other than `none`, and the `utf8only` property was left unspecified, the `utf8only` property is automatically set to `on`. The default value of the `normalization` property is `none`. This property cannot be changed after the file system is created.

This SMB related property is not fully functional in the Oracle Solaris 10 release because the Oracle Solaris SMB server is not supported in the Oracle Solaris 10 release.

`utf8only=on | off`
Indicates whether the file system should reject file names that include characters that are not present in the UTF-8 character code set. If this property is explicitly set to `off`, the normalization property must either not be explicitly set or be set to `none`. The default value for the `utf8only` property is `off`. This property cannot be changed after the file system is created.

This SMB related property is not fully functional in the Oracle Solaris 10 release because the Oracle Solaris SMB server is not supported in the Oracle Solaris 10 release.

Temporary Mount Point Properties

When a file system is mounted, either through mount(1M) for legacy mounts or the `zfs mount` command for normal file systems, its mount options are set according to its properties. The correlation between properties and mount options is as follows:

PROPERTY	MOUNT OPTION
devices	devices/nodevices
exec	exec/noexec
readonly	ro/rw
setuid	setuid/nosetuid
xattr	xattr/noxattr

In addition, these options can be set on a per-mount basis using the `-o` option, without affecting the property that is stored on disk. The values specified on the command line override the values stored in the dataset. The `-nosuid` option is an alias for `nodevices,nosetuid`. These properties are reported as *temporary* by the `zfs get` command. If the properties are changed while the dataset is mounted, the new setting overrides any temporary settings.

User Properties

In addition to the standard native properties, ZFS supports arbitrary user properties. User properties have no effect on ZFS behavior, but applications or administrators can use them to annotate datasets (file systems, volumes, and snapshots).

User property names must contain a colon (`:`) character to distinguish them from native properties. They may contain lowercase letters, numbers, and the following punctuation characters: colon (`:`), dash (`-`), period (`.`), and underscore (`_`). The expected convention is that the property name is divided into two portions such as *module*`:`*property*, but this namespace is not enforced by ZFS. User property names can be at most 256 characters, and cannot begin with a dash (`-`).

When making programmatic use of user properties, it is strongly suggested to use a reversed DNS domain name for the *module* component of property names to reduce the chance that two independently-developed packages use the same property name for different purposes. Property names beginning with `com.sun.` are reserved for use by Sun Microsystems.

The values of user properties are arbitrary strings, are always inherited, and are never validated. All of the commands that operate on properties (`zfs list`, `zfs get`, `zfs set`, and so forth) can be used to manipulate both native properties and user properties. Use the `zfs inherit` command to clear a user property . If the property is not defined in any parent dataset, it is removed entirely. Property values are limited to 1024 characters.

ZFS Volumes as Swap or Dump Devices

During an initial installation or a live upgrade from a UFS file system, a swap device and dump device are created on ZFS volumes in the ZFS root pool. By default, the swap area size is based on 1/2 the size of physical memory up to 2 GB. The size of the dump device depends on the kernel's requirements at installation time. Separate ZFS volumes must be used for the swap area and dump devices. Do not swap to a file on a ZFS file system. A ZFS swap file configuration is not supported.

If you need to change your swap area or dump device after the system is installed or upgraded, use the swap(1M) and dumpadm(1M) commands. If you need to change the size of your swap area or dump device, see the *Oracle Solaris ZFS Administration Guide*

Subcommands All subcommands that modify state are logged persistently to the pool in their original form.

`zfs ?`
Displays a help message.

`zfs create` [`-p`] [`-o` *property=value*] ... *filesystem*
Creates a new ZFS file system. The file system is automatically mounted according to the `mountpoint` property inherited from the parent.

`-p`
Creates the non-existing parent datasets. Datasets created in this manner are automatically mounted according to the `mountpoint` property inherited from their parent. Any property specified on the command line using the `-o` option is ignored. If the target filesystem already exists, the operation completes successfully.

`-o` *property=value*
Sets the specified property as if the command `zfs set` *property=value* was invoked at the same time the dataset was created. Any editable ZFS property can also be set at creation time. Multiple `-o` options can be specified. An error results if the same property is specified in multiple `-o` options.

`zfs create` [`-ps`] [`-b` *blocksize*] [`-o` *property=value*] ... `-V` *size volume*
Creates a volume of the given size. The volume is exported as a block device in `/dev/zvol/{dsk,rdsk}/`*path*, where *path* is the name of the volume in the ZFS namespace. The size represents the logical size as exported by the device. By default, a reservation of equal size is created.

size is automatically rounded up to the nearest 128 KB to ensure that the volume has an integral number of blocks regardless of *blocksize*.

`-p`
Creates the non-existing parent datasets. Datasets created in this manner are automatically mounted according to the `mountpoint` property inherited from their parent. Any property specified on the command line using the `-o` option is ignored. If the target file system already exists, the operation completes successfully.

`-s`
Creates a sparse volume with no reservation. See `volsize` in the "Native Properties" section for more information about sparse volumes.

`-o` *property=value*
Sets the specified property as if the `zfs set` *property=value* command was invoked at the same time the dataset was created. Any editable ZFS property can also be set at creation time. Multiple `-o` options can be specified. An error results if the same property is specified in multiple `-o` options.

`-b` *blocksize*
Equivalent to `-o volblocksize=`*blocksize*. If this option is specified in conjunction with `-o volblocksize`, the resulting behavior is undefined.

`zfs destroy` [`-rRf`] *filesystem*|*volume*
Destroys the given dataset. By default, the command unshares any file systems that are currently shared, unmounts any file systems that are currently mounted, and refuses to destroy a dataset that has active dependents (children or clones).

`-r`
Recursively destroy all children.

`-R`
Recursively destroy all dependents, including cloned file systems outside the target hierarchy.

`-f`
Force an unmount of any file systems using the `unmount -f` command. This option has no effect on non-file systems or unmounted file systems.

Extreme care should be taken when applying either the `-r` or the `-f` options, as they can destroy large portions of a pool and cause unexpected behavior for mounted file systems in use.

`zfs destroy` [`-rRd`] *snapshot*
The given snapshot is destroyed immediately if and only if the `zfs destroy` command without the `-d` option would have destroyed it. Such immediate destruction would occur, for example, if the snapshot had no clones and the user-initiated reference count were zero.

If the snapshot does not qualify for immediate destruction, it is marked for deferred deletion. In this state, it exists as a usable, visible snapshot until both of the preconditions listed above are met, at which point it is destroyed.

`-d`
Defer snapshot deletion.

`-r`
Destroy (or mark for deferred deletion) all snapshots with this name in descendent file systems.

`-R`
Recursively destroy all dependents.

`zfs snapshot` [`-r`] [`-o` *property=value*] ... *filesystem@snapname*|*volume@snapname*
Creates a snapshot with the given name. All previous modifications by successful system calls to the file system are part of the snapshot. See the "Snapshots" section for details.

`-r`
Recursively create snapshots of all descendent datasets. Snapshots are taken atomically, so that all recursive snapshots correspond to the same moment in time.

`-o` *property=value*
Sets the specified property; see `zfs create` for details.

`zfs rollback` [`-rRf`] *snapshot*
Roll back the given dataset to a previous snapshot. When a dataset is rolled back, all data that has changed since the snapshot is discarded, and the dataset reverts to the state at the time of the snapshot. By default, the command refuses to roll back to a snapshot other than the most recent one. In order to do so, all intermediate snapshots must be destroyed by specifying the `-r` option.

The `-rR` options do not recursively destroy the child snapshots of a recursive snapshot. Only the top-level recursive snapshot is destroyed by either of these options. To completely roll back a recursive snapshot, you must rollback the individual child snapshots.

`-r`
Recursively destroy any snapshots more recent than the one specified.

`-R`
Recursively destroy any more recent snapshots, as well as any clones of those snapshots.

`-f`
Used with the `-R` option to force an unmount of any clone file systems that are to be destroyed.

`zfs clone` [`-p`] [`-o` *property=value*] ... *snapshot filesystem|volume*
Creates a clone of the given snapshot. See the "Clones" section for details. The target dataset can be located anywhere in the ZFS hierarchy, and is created as the same type as the original.

`-p`
Creates the non-existing parent datasets. Datasets created in this manner are automatically mounted according to the `mountpoint` property inherited from their parent. If the target filesystem or volume already exists, the operation completes successfully.

`-o` *property=value*
Sets the specified property; see `zfs create` for details.

`zfs promote` *clone-filesystem*
Promotes a clone file system to no longer be dependent on its "origin" snapshot. This makes it possible to destroy the file system that the clone was created from. The clone parent-child dependency relationship is reversed, so that the origin file system becomes a clone of the specified *filesystem*.

The snapshot that was cloned, and any snapshots previous to this snapshot, are now owned by the promoted clone. The space they use moves from the origin file system to the promoted clone, so enough space must be available to accommodate these snapshots. No new space is consumed by this operation, but the space accounting is adjusted. The

promoted clone must not have any conflicting snapshot names of its own. The `rename` subcommand can be used to rename any conflicting snapshots.

`zfs rename` *filesystem*|*volume*|*snapshot*
filesystem|*volume*|*snapshot*
`zfs rename` [`-p`] *filesystem*|*volume filesystem*|*volume*

Renames the given dataset. The new target can be located anywhere in the ZFS hierarchy, with the exception of snapshots. Snapshots can only be renamed within the parent file system or volume. When renaming a snapshot, the parent file system of the snapshot does not need to be specified as part of the second argument. Renamed file systems can inherit new mount points, in which case they are unmounted and remounted at the new mount point.

`-p`

Creates the nonexistent parent datasets. Datasets created in this manner are automatically mounted according to the `mountpoint` property inherited from their parent.

`zfs rename -r` *snapshot snapshot*

Recursively rename the snapshots of all descendent datasets. Snapshots are the only dataset that can be renamed recursively.

`zfs list` [`-r`|`-d` *depth*] [`-H`] [`-o` *property*[,...]] [`-t` *type*[,...]] [`-s` *property*] ... [`-S` *property*] ... [*filesystem*|*volume*|*snapshot*] ...

Lists the property information for the given datasets in tabular form. If specified, you can list property information by the absolute pathname or the relative pathname. By default, all file systems and volumes are displayed. Snapshots are displayed if the `listsnaps` property is `on` (the default is `off`) . The following fields are displayed, `name,used,available,referenced,mountpoint`.

`-H`

Used for scripting mode. Do not print headers and separate fields by a single tab instead of arbitrary white space.

`-r`

Recursively display any children of the dataset on the command line.

`-d` *depth*

Recursively display any children of the dataset, limiting the recursion to *depth*. A depth of `1` will display only the dataset and its direct children.

`-o` *property*

A comma-separated list of properties to display. The property must be:

- One of the properties described in the "Native Properties" section
- A user property
- The value `name` to display the dataset name

- The value `space` to display space usage properties on file systems and volumes. This is a shortcut for specifying
  `-o name,avail,used,usedsnap,usedds,usedrefreserv,usedchild`
  `-t filesystem,volume` syntax.

`-s` *property*
A property for sorting the output by column in ascending order based on the value of the property. The property must be one of the properties described in the "Properties" section, or the special value `name` to sort by the dataset name. Multiple properties can be specified at one time using multiple `-s` property options. Multiple `-s` options are evaluated from left to right in decreasing order of importance.

The following is a list of sorting criteria:

- Numeric types sort in numeric order.
- String types sort in alphabetical order.
- Types inappropriate for a row sort that row to the literal bottom, regardless of the specified ordering.
- If no sorting options are specified the existing behavior of `zfs list` is preserved.

`-S` *property*
Same as the `-s` option, but sorts by property in descending order.

`-t` *type*
A comma-separated list of types to display, where *type* is one of `filesystem`, `snapshot`, `volume`, or `all`. For example, specifying `-t snapshot` displays only snapshots.

`zfs set` *property=value filesystem*|*volume*|*snapshot* ...
Sets the property to the given value for each dataset. Only some properties can be edited. See the "Properties" section for more information on what properties can be set and acceptable values. Numeric values can be specified as exact values, or in a human-readable form with a suffix of `B`, `K`, `M`, `G`, `T`, `P`, `E`, `Z` (for bytes, kilobytes, megabytes, gigabytes, terabytes, petabytes, exabytes, or zettabytes, respectively). User properties can be set on snapshots. For more information, see the "User Properties" section.

`zfs get` [`-r`|`-d` *depth*] [`-Hp`] [`-o all` | *field*[,...] [`-s` *source*[,...]] `all` | *property*[,...] *filesystem*|*volume*|*snapshot* ...
Displays properties for the given datasets. If no datasets are specified, then the command displays properties for all datasets on the system. For each property, the following columns are displayed:

```
name      Dataset name
property  Property name
value     Property value
source    Property source. Can either be local, default,
          temporary, inherited, or none (-).
```

All columns except the `RECEIVED` column are displayed by default; specify particular or all columns, using the `-o` option. This command takes a comma-separated list of properties as described in the "Native Properties" and "User Properties" sections.

The special value `all` can be used to display all properties that apply to the given dataset's type (file system, volume, or snapshot).

`-r`
Recursively display properties for any children.

`-d` *depth*
Recursively display any children of the dataset, limiting the recursion to *depth*. A depth of `1` will display only the dataset and its direct children.

`-H`
Display output in a form more easily parsed by scripts. Any headers are omitted, and fields are explicitly separated by a single tab instead of an arbitrary amount of space.

`-o` *field*
Set of fields to display. One or more of:

```
name,property,value,received,source
```

Present multiple fields as a comma-separated list. The default value is:

```
name,property,value,source
```

The keyword `all` specifies all sources.

`-s` *source*
A comma-separated list of sources to display. Those properties coming from a source other than those in this list are ignored. Each source must be one of the following:

```
local,default,inherited,temporary,received,none
```

The default value is all sources.

`-p`
Display numbers in parseable (exact) values.

`zfs inherit` [`-rS`] *property filesystem*|*volume*|*snapshot* ...
Clears the specified property, causing it to be inherited from an ancestor. If no ancestor has the property set, then the default value is used. See the "Properties" section for a listing of default values, and details on which properties can be inherited.

`-r`
Recursively inherit the given property for all children.

`-S`
Revert to the received property value, if any. If the property does not have a received value, the behavior of `zfs inherit -S` is the same as `zfs inherit` without `-S`. If the property does have a received value, `zfs inherit` masks the received value with the

inherited value until `zfs inherit -S` reverts to the received value.

`zfs upgrade`
Identifies a file system version, which determines available file system features in the currently running software release. You can continue to use older file system versions, but some features might not be available. A file system can be upgraded by using the `zfs upgrade -a` command. You will not be able to access a file system of a later version on a system that runs an earlier software version.

`zfs upgrade -v`
Displays ZFS file system versions that are supported by the current software. The current ZFS file system version and all previously supported versions are displayed, along with a pithy explanation of the features provided with each version.

`zfs upgrade` [`-r`] [`-V` *version*] [`-a` | *filesystem*]
Upgrades a file system to a new on-disk version. Upgrading a file system means that it will no longer be accessible on a system running an older software version. A `zfs send` stream that is generated from a new file system snapshot cannot be accessed on a system that runs an older software version.

In general, the file system version is independent of the pool version. See `zpool(1M)` for information on the `zpool upgrade` command.

In some cases, the file system version and the pool version are interrelated and the pool version must be upgraded before the file system version can be upgraded.

`-a`
Upgrade all file systems on all imported pools.

filesystem
Upgrade the specified *filesystem*.

`-r`
Upgrade the specified *filesystem* and all descendent file systems.

`-V` *version*
Upgrade to the specified *version*. If the `-V` flag is not specified, this command upgrades to the most recent version. This option can only be used to increase the version number, and only up to the most recent version supported by this software.

`zfs userspace` [`-niHp`] [`-o` *field*[,...]] [`-sS` *field*]... [`-t` *type* [,...]] *filesystem* | *snapshot*
Displays space consumed by, and quotas on, each user in the specified *filesystem* or *snapshot*. This corresponds to the `userused@`*user* and `userquota@`*user* properties.

`-n`
Print numeric ID instead of user/group name.

`-H`
Do not print headers, use tab-delimited output.

`-p`
Use exact (parseable) numeric output.

`-o` *field*[,...]
Display only the specified fields from the following set, `type,name,used,quota`.The default is to display all fields.

`-s` *field*
Sort output by this field. The *s* and *S* flags may be specified multiple times to sort first by one field, then by another. The default is `-s type -s name`.

`-S` *field*
Sort by this field in reverse order. See `-s`.

`-t` *type*[,...]
Print only the specified types from the following set, `all,posixuser,smbuser,posixgroup,smbgroup`.

The default is `-t posixuser,smbuser`

The default can be changed to include group types.

`-i`
Translate SID to POSIX ID. The POSIX ID may be ephemeral if no mapping exists. Normal POSIX interfaces (for example, `stat(2)`, `ls -l`) perform this translation, so the `-i` option allows the output from `zfs userspace` to be compared directly with those utilities. However, `-i` may lead to confusion if some files were created by an SMB user before a SMB-to-POSIX name mapping was established. In such a case, some files are owned by the SMB entity and some by the POSIX entity. However, the `-i` option will report that the POSIX entity has the total usage and quota for both.

`zfs groupspace` [`-niHp`] [`-o` *field*[,...]] [`-sS` *field*]... [`-t` *type* [,...]] *filesystem* | *snapshot*
Displays space consumed by, and quotas on, each group in the specified *filesystem* or *snapshot*. This subcommand is identical to `zfs userspace`, except that the default types to display are `-t posixgroup,smbgroup`.

`-`

`zfs mount`
Displays all ZFS file systems currently mounted.

`zfs mount` [`-vO`] [`-o` *options*] `-a` | *filesystem*
Mounts ZFS file systems. Invoked automatically as part of the boot process.

`-o` *options*
An optional, comma-separated list of mount options to use temporarily for the duration of the mount. See the "Temporary Mount Point Properties" section for details.

`-O`
Perform an overlay mount. See `mount(1M)` for more information.

`-v`
Report mount progress.

`-a`
Mount all available ZFS file systems. Invoked automatically as part of the boot process.

filesystem
Mount the specified *filesystem*.

`zfs unmount` [`-f`] `-a` | *filesystem*|*mountpoint*
Unmounts currently mounted ZFS file systems. Invoked automatically as part of the shutdown process.

`-f`
Forcefully unmount the file system, even if it is currently in use.

`-a`
Unmount all available ZFS file systems. Invoked automatically as part of the boot process.

filesystem|*mountpoint*
Unmount the specified *filesystem*. The command can also be given a path to a ZFS file system mount point on the system.

`zfs share -a` | *filesystem*
Shares ZFS file systems that have the `sharenfs` or `sharesmb` property set. Sharing a file system with the NFS or SMB protocol means that the file system data is available over the network. ZFS file systems that have the `sharenfs` or `sharesmb` property set are automatically shared when a system is booted. For information about sharing a ZFS volume as an iSCSI target, see the `shareiscsi` property description.

Note that the Oracle Solaris SMB service is not supported in the Oracle Solaris 10 release.

`-a`
Shares all ZFS file systems that have the `sharenfs` or `sharesmb` property set and according to the `share` property values.

filesystem
Shares the specified *filesystem* that has the `sharenfs` or `sharesmb` property set and according to the `share` property values.

`zfs unshare -a` | *filesystem*|*mountpoint*
Unshares currently shared ZFS file systems that have the `sharenfs` or `sharesmb` property set. File systems that have the `sharenfs` or `sharesmb` property set are automatically unshared when a system is shutdown.

`-a`
Unshares all ZFS file systems that have the `sharenfs` or `sharesmb` property set.

filesystem|*mountpoint*
Unshares the specified *filesystem*. This command can also be given a path to a ZFS file system shared on the system.

`zfs send` [`-vRp`] [`-`[`iI`] *snapshot*] *snapshot*
Creates a stream representation of the second *snapshot*, which is written to standard output. The output can be redirected to a file or to a different system (for example, using `ssh(1)`. By default, a full stream is generated.

`-i` *snapshot*
Generate an incremental stream from the first *snapshot* to the second *snapshot*. The incremental source (the first *snapshot*) can be specified as the last component of the snapshot name (for example, the part after the `@`), and it is assumed to be from the same file system as the second *snapshot*.

If the destination is a clone, the source may be the origin snapshot, which must be fully specified (for example, `pool/fs@origin`, not just `@origin`).

`-I` *snapshot*
Generate a stream package that sends all intermediary snapshots from the first snapshot to the second snapshot. For example, `-I @a fs@d` is similar to `-i @a fs@b; -i @b fs@c; -i @c fs@d`. The incremental source snapshot may be specified as with the `-i` option.

`-R`
Generate a replication stream package to replicate the specified *filesystem* and all descendent file systems, up to the named snapshot. When received, all properties, snapshots, descendent file systems, and clones are preserved.

If the `-i` or `-I` flags are used in conjunction with the `-R` flag, an incremental replication stream is generated. The current values of properties, and current snapshot and file system names are set when the stream is received. If the `-F` flag is specified when this stream is received, snapshots and file systems that do not exist on the sending side are destroyed.

`-p`
Send properties.

`-v`
Print verbose information about the stream package generated.

The format of the stream is committed. You will be able to receive your streams on future versions of ZFS.

`zfs receive` [`-vnFu`] *filesystem*|*volume*|*snapshot*
`zfs receive` [`-vnFu`] [`-d` | `-e`] *filesystem*

Creates a snapshot whose contents are as specified in the stream provided on standard input. If a full stream is received, then a new file system is created as well. Streams are created using the `zfs send` subcommand, which by default creates a full stream. `zfs recv` can be used as an alias for `zfs receive`.

If an incremental stream is received, then the destination file system must already exist, and its most recent snapshot must match the incremental stream's source. For ZFS volumes, the destination device link is destroyed and recreated, which means the volume cannot be accessed during the `receive` operation.

When a snapshot replication package stream that is generated by using the `zfs send -R` command is received, any snapshots that do not exist on the sending location are destroyed by using the `zfs destroy -d` command.

The name of the snapshot (and file system, if a full stream is received) that this subcommand creates depends on the argument type and the `-d` or `-e` option.

If the argument is a snapshot name, the specified *snapshot* is created. If the argument is a file system or volume name, a snapshot with the same name as the sent snapshot is created within the specified *filesystem* or *volume*. If the `-d` or `-e` option is specified, the snapshot name is determined by appending the sent snapshot's name to the specified filesystem. If the `-d` option is specified, all but the pool name of the sent snapshot path is appended (for example, `b/c@1` appended from sent snapshot `a/b/c@1`), and if the `-e` option is specified, only the tail of the sent snapshot path is appended (for example, `c@1` appended from sent snapshot `a/b/c@1`). In the case of `-d`, any file systems needed to replicate the path of the sent snapshot are created within the specified *filesystem*.

`-d`
: Use all but the first element of the sent snapshot path (all but the pool name) to determine the name of the new snapshot as described in the paragraph above.

`-e`
: Use the last element of the sent snapshot path to determine the name of the new snapshot as described in the paragraph above.

`-u`
: File system that is associated with the received stream is not mounted.

`-v`
: Print verbose information about the stream and the time required to perform the receive operation.

`-n`
: Do not actually receive the stream. This can be useful in conjunction with the `-v` option to verify the name the receive operation would use.

`-F`
: Force a rollback of the file system to the most recent snapshot before performing the receive operation. If receiving an incremental replication stream (for example, one

generated by `zfs send -R -[iI]`), destroy snapshots and file systems that do not exist on the sending side.

`zfs allow` *filesystem* | *volume*
Displays permissions that have been delegated on the specified *filesystem* or *volume*. See the other forms of `zfs allow` for more information.

`zfs allow` [`-ldug`] `everyone`|*user*|*group*[,...] *perm*|*@setname*[,...] *filesystem*| *volume*
`zfs allow` [`-ld`] `-e` *perm*|*@setname*[,...] *filesystem* | *volume*
Delegates ZFS administration permission for the file systems to non-privileged users.

[`-ug`] `everyone`|*user*|*group*[,...]
Specifies to whom the permissions are delegated. Multiple entities can be specified as a comma-separated list. If neither of the `-ug` options are specified, then the argument is interpreted preferentially as the keyword `everyone`, then as a user name, and lastly as a group name. To specify a user or group named `everyone`, use the `-u` or `-g` options. To specify a group with the same name as a user, use the `-g` options.

[`-e`] *perm*|*@setname*[,...]
Specifies that the permissions be delegated to `everyone`. Multiple permissions may be specified as a comma-separated list. Permission names are the same as ZFS subcommand and property names. See the property list below. Property set names, which begin with an at sign (`@`) , may be specified. See the `-s` form below for details.

[`-ld`] *filesystem*|*volume*
Specifies where the permissions are delegated. If neither of the `-ld` options are specified, or both are, then the permissions are allowed for the file system or volume, and all of its descendents. If only the `-l` option is used, then is allowed `locally` only for the specified *filesystem*. If only the `-d` option is used, then is allowed only for the descendent file systems.

Permissions are generally the ability to use a ZFS subcommand or change a ZFS property. The following permissions are available:

```
NAME            TYPE           NOTES
allow           subcommand     Must also have the permission that is
                               being allowed
clone           subcommand     Must also have the 'create' ability and
                               'mount' ability in the origin file system
create          subcommand     Must also have the 'mount' ability
destroy         subcommand     Must also have the 'mount' ability
hold            subcommand     Allows adding a user hold to a snapshot
mount           subcommand     Allows mount/umount of ZFS datasets
promote         subcommand     Must also have the 'mount' and 'promote'
                               ability in the origin file system
receive         subcommand     Must also have the 'mount' and 'create'
                               ability
release         subcommand     Allows releasing a user hold which
                               might destroy the snapshot
```

```
rename          subcommand     Must also have the 'mount' and 'create'

```

`zfs allow -c` *perm* | *@setname*[,...] *filesystem*|*volume*
Sets create time permissions. These permissions are granted (locally) to the creator of any newly-created descendent file system.

`zfs allow -s` *@setname perm*|*@setname*[,...] *filesystem*|*volume*
Defines or adds permissions to a permission set. The set can be used by other `zfs allow` commands for the specified *filesystem* and its descendents. Sets are evaluated dynamically, so changes to a set are immediately reflected. Permission sets follow the same naming restrictions as ZFS file systems, but the name must begin with an at sign (`@`), and can be no more than 64 characters long.

`zfs unallow` [`-rldug`] `everyone`|*user*|*group*[,...] [*perm*|*@setname*[, ...]] *filesystem*|*volume*
`zfs unallow` [`-rld`] `-e` [*perm*|*@setname* [,...]] *filesystem*|*volume*
`zfs unallow` [`-r`] `-c` [*perm*|*@setname*[,...]]
filesystem|*volume*
Removes permissions that were granted with the `zfs allow` command. No permissions are explicitly denied, so other permissions granted are still in effect. For example, if the permission is granted by an ancestor. If no permissions are specified, then all permissions for the specified *user*, *group*, or `everyone` are removed. Specifying `everyone` (or using the `-e` option) only removes the permissions that were granted to `everyone`, not all permissions for every user and group. See the `zfs allow` command for a description of the `-ldugec` options.

`-r`
Recursively remove the permissions from this file system and all descendents.

`zfs unallow` [`-r`] `-s` *@setname* [*perm*|*@setname*[,...]]
filesystem|*volume*
Removes permissions from a permission set. If no permissions are specified, then all permissions are removed, thus removing the set entirely.

`zfs hold` [`-r`] *tag snapshot*...
Adds a single reference, named with the *tag* argument, to the specified snapshot or snapshots. Each snapshot has its own tag namespace, and tags must be unique within that space.

If a hold exists on a snapshot, attempts to destroy that snapshot by using the `zfs destroy` command return `EBUSY`.

`-r`
Specifies that a hold with the given tag is applied recursively to the snapshots of all descendent file systems.

`zfs holds` [`-r`] *snapshot*...
Lists all existing user references for the given snapshot or snapshots.

`-r`
Lists the holds that are set on the named descendent snapshots, in addition to listing the holds on the named snapshot.

`zfs release` [`-r`] *tag snapshot...*

Removes a single reference, named with the *tag* argument, from the specified snapshot or snapshots. The tag must already exist for each snapshot.

If a hold exists on a snapshot, attempts to destroy that snapshot by using the `zfs destroy` command return `EBUSY`.

`-r`

Recursively releases a hold with the given tag on the snapshots of all descendent file systems.

Examples

EXAMPLE 1 Creating a ZFS File System Hierarchy

The following commands create a file system named `pool/home` and a file system named `pool/home/bob`. The mount point `/export/home` is set for the parent file system, and is automatically inherited by the child file system.

```
# zfs create pool/home
# zfs set mountpoint=/export/home pool/home
# zfs create pool/home/bob
```

EXAMPLE 2 Creating a ZFS Snapshot

The following command creates a snapshot named `yesterday`. This snapshot is mounted on demand in the `.zfs/snapshot` directory at the root of the `pool/home/bob` file system.

```
# zfs snapshot pool/home/bob@yesterday
```

EXAMPLE 3 Creating and Destroying Multiple Snapshots

The following command creates snapshots named `yesterday` of `pool/home` and all of its descendent file systems. Each snapshot is mounted on demand in the `.zfs/snapshot` directory at the root of its file system. The second command destroys the newly created snapshots.

```
# zfs snapshot -r pool/home@yesterday
# zfs destroy -r pool/home@yesterday
```

EXAMPLE 4 Disabling and Enabling File System Compression

The following command disables the `compression` property for all file systems under `pool/home`. The next command explicitly enables `compression` for `pool/home/anne`.

```
# zfs set compression=off pool/home
# zfs set compression=on pool/home/anne
```

EXAMPLE 5 Listing ZFS Datasets

The following command lists all active file systems and volumes in the system. Snapshots are displayed if the pool's `listsnaps` property is `on`. The default is `on`. See `zpool(1M)` for more information on pool properties.

EXAMPLE 5 Listing ZFS Datasets *(Continued)*

```
# zfs list
   NAME                    USED  AVAIL  REFER  MOUNTPOINT
   pool                    450K   457G    18K  /pool
   pool/home               315K   457G    21K  /export/home
   pool/home/anne           18K   457G    18K  /export/home/anne
   pool/home/bob           276K   457G   276K  /export/home/bob
```

EXAMPLE 6 Setting a Quota on a ZFS File System

The following command sets a quota of 50 Gbytes for `pool/home/bob`.

```
# zfs set quota=50G pool/home/bob
```

EXAMPLE 7 Listing ZFS Properties

The following command lists all properties for `pool/home/bob`.

```
# zfs get all pool/home/bob
NAME           PROPERTY              VALUE                  SOURCE
pool/home/bob  type                  filesystem             -
pool/home/bob  creation              Wed May  5 13:09 2010  -
pool/home/bob  used                  21K                    -
pool/home/bob  available             50.0G                  -
pool/home/bob  referenced            21K                    -
pool/home/bob  compressratio         1.00x                  -
pool/home/bob  mounted               yes                    -
pool/home/bob  quota                 50G                    local
pool/home/bob  reservation           none                   default
pool/home/bob  recordsize            128K                   default
pool/home/bob  mountpoint            /pool/home/bob         default
pool/home/bob  sharenfs              off                    default
pool/home/bob  checksum              on                     default
pool/home/bob  compression           off                    default
pool/home/bob  atime                 on                     default
pool/home/bob  devices               on                     default
pool/home/bob  exec                  on                     default
pool/home/bob  setuid                on                     default
pool/home/bob  readonly              off                    default
pool/home/bob  zoned                 off                    default
pool/home/bob  snapdir               hidden                 default
pool/home/bob  aclmode               groupmask              default
pool/home/bob  aclinherit            restricted             default
pool/home/bob  canmount              on                     default
pool/home/bob  shareiscsi            off                    default
pool/home/bob  xattr                 on                     default
pool/home/bob  copies                1                      default
pool/home/bob  version               4                      -
pool/home/bob  utf8only              off                    -
```

EXAMPLE 7 Listing ZFS Properties *(Continued)*

```
pool/home/bob  normalization         none                  -
pool/home/bob  casesensitivity       sensitive             -
pool/home/bob  vscan                 off                   default
pool/home/bob  nbmand                off                   default
pool/home/bob  sharesmb              off                   default
pool/home/bob  refquota              none                  default
pool/home/bob  refreservation        none                  default
pool/home/bob  primarycache          all                   default
pool/home/bob  secondarycache        all                   default
pool/home/bob  usedbysnapshots       0                     -
pool/home/bob  usedbydataset         21K                   -
pool/home/bob  usedbychildren        0                     -
pool/home/bob  usedbyrefreservation  0                     -
pool/home/bob  logbias               latency               default
```

The following command gets a single property value.

```
# zfs get -H -o value compression pool/home/bob
on
```

The following command lists all properties with local settings for `pool/home/bob`.

```
# zfs get -r -s local -o name,property,value all pool/home/bob
NAME           PROPERTY              VALUE
pool/home/bob  quota                 20G
pool/home/bob  compression           on
```

EXAMPLE 8 Rolling Back a ZFS File System

The following command reverts the contents of `pool/home/anne` to the snapshot named `yesterday`, deleting all intermediate snapshots.

```
# zfs rollback -r pool/home/anne@yesterday
```

EXAMPLE 9 Creating a ZFS Clone

The following command creates a writable file system whose initial contents are the same as `pool/home/bob@yesterday`.

```
# zfs clone pool/home/bob@yesterday pool/clone
```

EXAMPLE 10 Promoting a ZFS Clone

The following commands illustrate how to test out changes to a file system, and then replace the original file system with the changed one, using clones, clone promotion, and renaming:

```
# zfs create pool/project/production
  populate /pool/project/production with data
# zfs snapshot pool/project/production@today
```

EXAMPLE 10 Promoting a ZFS Clone *(Continued)*

```
# zfs clone pool/project/production@today pool/project/beta
make changes to /pool/project/beta and test them
# zfs promote pool/project/beta
# zfs rename pool/project/production pool/project/legacy
# zfs rename pool/project/beta pool/project/production
once the legacy version is no longer needed, it can be destroyed
# zfs destroy pool/project/legacy
```

EXAMPLE 11 Inheriting ZFS Properties

The following command causes `pool/home/bob` and `pool/home/anne` to inherit the `checksum` property from their parent.

```
# zfs inherit checksum pool/home/bob pool/home/anne
```

EXAMPLE 12 Remotely Replicating ZFS Data

The following commands send a full stream and then an incremental stream to a remote machine, restoring them into `poolB/received/fs@a`and `poolB/received/fs@b`, respectively. `poolB` must contain the file system `poolB/received`, and must not initially contain `poolB/received/fs`.

```
# zfs send pool/fs@a | \
   ssh host zfs receive poolB/received/fs@a
# zfs send -i a pool/fs@b | ssh host \
   zfs receive poolB/received/fs
```

EXAMPLE 13 Using the `zfs receive -d` Option

The following command sends a full stream of `poolA/fsA/fsB@snap` to a remote machine, receiving it into `poolB/received/fsA/fsB@snap`. The `fsA/fsB@snap` portion of the received snapshot's name is determined from the name of the sent snapshot. `poolB` must contain the file system `poolB/received`. If `poolB/received/fsA` does not exist, it is created as an empty file system.

```
# zfs send poolA/fsA/fsB@snap | \
   ssh host zfs receive -d poolB/received
```

EXAMPLE 14 Setting User Properties

The following example sets the user–defined `com.example:department` property for a dataset.

```
# zfs set com.example:department=12345 tank/accounting
```

EXAMPLE 15 Creating a ZFS Volume as an iSCSI Target Device

The following example shows how to create a ZFS volume as an iSCSI target.

```
# zfs create -V 2g pool/volumes/vol1
# zfs set shareiscsi=on pool/volumes/vol1
```

EXAMPLE 15 Creating a ZFS Volume as an iSCSI Target Device *(Continued)*

```
# iscsitadm list target
Target: pool/volumes/vol1
 iSCSI Name:
 iqn.1986-03.com.sun:02:7b4b02a6-3277-eb1b-e686-a24762c52a8c
 Connections: 0
```

After the iSCSI target is created, set up the iSCSI initiator. For more information about the Solaris iSCSI initiator, see `iscsitadm(1M)`.

EXAMPLE 16 Performing a Rolling Snapshot

The following example shows how to maintain a history of snapshots with a consistent naming scheme. To keep a week's worth of snapshots, the user destroys the oldest snapshot, renames the remaining snapshots, and then creates a new snapshot, as follows:

```
# zfs destroy -r pool/users@7daysago
# zfs rename -r pool/users@6daysago @7daysago
# zfs rename -r pool/users@5daysago @6daysago
# zfs rename -r pool/users@yesterday @5daysago
# zfs rename -r pool/users@yesterday @4daysago
# zfs rename -r pool/users@yesterday @3daysago
# zfs rename -r pool/users@yesterday @2daysago
# zfs rename -r pool/users@today @yesterday
# zfs snapshot -r pool/users@today
```

EXAMPLE 17 Setting `sharenfs` Property Options on a ZFS File System

The following commands show how to set `sharenfs` property options to enable `rw` access for a set of IP addresses and to enable root access for system `neo` on the `tank/home` file system.

```
# zfs set sharenfs='rw=@123.123.0.0/16,root=neo' tank/home
```

If you are using DNS for host name resolution, specify the fully qualified hostname.

EXAMPLE 18 Delegating ZFS Administration Permissions on a ZFS Dataset

The following example shows how to set permissions so that user `cindys` can create, destroy, mount, and take snapshots on `tank/cindys`. The permissions on `tank/cindys` are also displayed.

```
# zfs allow cindys create,destroy,mount,snapshot tank/cindys
# zfs allow tank/cindys
-------------------------------------------------------------
Local+Descendent permissions on (tank/cindys)
          user cindys create,destroy,mount,snapshot
-------------------------------------------------------------
```

Because the `tank/cindys` mount point permission is set to 755 by default, user `cindys` will be unable to mount file systems under `tank/cindys`. Set an ACL similar to the following syntax to provide mount point access:

```
# chmod A+user:cindys:add_subdirectory:allow /tank/cindys
```

EXAMPLE 19 Delegating Create Time Permissions on a ZFS Dataset

The following example shows how to grant anyone in the group `staff` to create file systems in `tank/users`. This syntax also allows staff members to destroy their own file systems, but not destroy anyone else's file system. The permissions on `tank/users` are also displayed.

```
# zfs allow staff create,mount tank/users
# zfs allow -c destroy tank/users
# zfs allow tank/users
-------------------------------------------------------------
Create time permissions on (tank/users)
          create,destroy
Local+Descendent permissions on (tank/users)
          group staff create,mount
-------------------------------------------------------------
```

EXAMPLE 20 Defining and Granting a Permission Set on a ZFS Dataset

The following example shows how to define and grant a permission set on the `tank/users` file system. The permissions on `tank/users` are also displayed.

```
# zfs allow -s @pset create,destroy,snapshot,mount tank/users
# zfs allow staff @pset tank/users
# zfs allow tank/users
-------------------------------------------------------------
Permission sets on (tank/users)
        @pset create,destroy,mount,snapshot
Create time permissions on (tank/users)
        create,destroy
Local+Descendent permissions on (tank/users)
        group staff @pset,create,mount
-------------------------------------------------------------
```

EXAMPLE 21 Delegating Property Permissions on a ZFS Dataset

The following example shows to grant the ability to set quotas and reservations on the `users/home` file system. The permissions on `users/home` are also displayed.

```
# zfs allow cindys quota,reservation users/home
# zfs allow users/home
-------------------------------------------------------------
Local+Descendent permissions on (users/home)
        user cindys quota,reservation
-------------------------------------------------------------
cindys% zfs set quota=10G users/home/marks
```

EXAMPLE 21 Delegating Property Permissions on a ZFS Dataset *(Continued)*

```
cindys% zfs get quota users/home/marks
NAME              PROPERTY  VALUE             SOURCE
users/home/marks  quota     10G               local
```

EXAMPLE 22 Removing ZFS Delegated Permissions on a ZFS Dataset

The following example shows how to remove the snapshot permission from the `staff` group on the `tank/users` file system. The permissions on `tank/users` are also displayed.

```
# zfs unallow staff snapshot tank/users
# zfs allow tank/users
-------------------------------------------------------------
Permission sets on (tank/users)
        @pset create,destroy,mount,snapshot
Create time permissions on (tank/users)
        create,destroy
Local+Descendent permissions on (tank/users)
        group staff @pset,create,mount
-------------------------------------------------------------
```

Exit Status

The following exit values are returned:

`0`
Successful completion.

`1`
An error occurred.

`2`
Invalid command line options were specified.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Notes The ZFS deduplication feature is not available in the Oracle Solaris 10 release.

Name zic – time zone compiler

Synopsis

```
zic [--version] [-s] [-v] [-l localtime] [-p posixrules]
    [-d directory] [-y yearistype] [filename]...
```

Description `zic` reads text from the file(s) named on the command line and creates the time conversion information files specified in this input. If a *filename* is '–', the standard input is read.

Input lines are made up of fields. Fields are separated by any number of white space characters. Leading and trailing white space on input lines is ignored. A pound sign (#) indicates a comment that extends to the end of the line. White space characters and pound signs can be enclosed within double quotes (" ") if they are to be used as part of a field. Any line that is blank (after comment stripping) is ignored. Non-blank lines are expected to be of one of three types: rule lines, zone lines, or link lines.

Rule A rule line has the form:

For example:

```
Rule   NAME  FROM  TO  TYPE  IN   ON     AT   SAVE  LETTER/S
```

The fields that make up a rule line are:

```
Rule   USA   1969  1973   -  Apr lastSun 2:00  1:00   D
```

`NAME` Gives the (arbitrary) name of the set of rules this rule is part of.

`FROM` Gives the first year in which the rule applies. The word `minimum` (or an abbreviation) means the minimum year with a representable time value. The word `maximum` (or an abbreviation) means the maximum year with a representable time value.

`TO` Gives the final year in which the rule applies. In addition to `minimum` and `maximum` (as above), the word `only` (or an abbreviation) can be used to repeat the value of the `FROM` field.

`TYPE` Gives the type of year in which the rule applies. If `TYPE` is:

- '–' The rule applies in all years between `FROM` and `TO`, inclusive.
- `uspres` The rule applies in U.S. Presidential election years.
- `nonpres` The rule applies in years other than U.S. Presidential election years.
- `even` The rule applies to even-numbered years.
- `odd` The rule applies to odd-numbered years.

If `TYPE` is something else, then `zic` will attempt to execute the command

`yearistype` *year* `type`

to check the type of a year: an exit status of `0` means that the year is of the given type; an exit status of `1` means that the year is not of the given type. The `yearistype` command is not currently provided in the Solaris environment.

`IN` Names the month in the rule takes effect. Month names can be abbreviated.

`ON` Gives the day on which the rule takes effect. Recognized forms include:

`5`	the fifth day of the month
`lastSun`	The last Sunday in the month
`lastMon`	The last Monday in the month
`Sun>=8`	First Sunday on or after the eighth
`Sun<=25`	Last Sunday on or before the 25th

Names of days of the week can be abbreviated or spelled out in full. Note: There cannot be spaces within the `ON` field.

`AT` Gives the time of day at which the rule takes effect. Recognized forms include:

`2`	Time in hours
`2:00`	Time in hours and minutes
`15:00`	24-hour format time (for times after noon)
`1:28:14`	Time in hours, minutes, and seconds, where hour 0 is midnight at the start of the day and hour 24 is midnight at the end of the day.

Any of these forms can be followed by the letter `w` if the given time is local "wall clock" time; `s` if the given time is local "standard" time; or `u` (or `g` or `z`) if the given time is universal time. In the absence of an indicator, wall clock time is assumed.

`SAVE` Gives the amount of time to be added to local standard time when the rule is in effect. This field has the same format as the `AT` field (without the `w` and `s` suffixes).

`LETTER/S` Gives the "variable part" (for example, the "S" or "D" in "EST" or "EDT" of time zone abbreviations to be used when this rule is in effect. If this field is '–', the variable part is null.

`Zone` A zone line has the form:

```
Zone  NAME                GMTOFF  RULES/SAVE   FORMAT  [UNTIL]
```

For example:

```
Zone Australia/SouthWest   9:30        -         CST    1992 Mar 15 12:00
                           8:30      Aus         CST
```

The fields that make up a zone line are:

NAME — The name of the time zone. This is the name used in creating the time conversion information file for the zone.

GMTOFF — The amount of time to add to UTC to get standard time in this zone. This field has the same format as the AT and SAVE fields of rule lines; begin the field with a minus sign to subtract time from UTC.

RULES/SAVE — The name of the rule(s) that apply in the time zone or, alternately, an amount of time to add to local standard time. If this field is '–', then standard time always applies in the time zone.

FORMAT — The format for time zone abbreviations in this time zone. The pair of characters %s is used to show where the "variable part" of the time zone abbreviation goes. Alternately, a slash (/) separates standard and daylight abbreviations.

UNTIL — The time at which the UTC offset or the rule(s) change for a location. It is specified as a year, a month, a day, and a time of day. The time of day has the same format as the AT field of rule lines. If this is specified, the time zone information is generated from the given UTC offset and rule change until the time specified.

The month, day, and time of day have the same format as the IN, ON, and AT columns of a rule; trailing columns can be omitted, and default to the earliest possible value for the missing columns.

The next line must be a "continuation" line. This line has the same form as a zone line except that the string "Zone" and the name are omitted. The continuation line places information starting at the time specified as the UNTIL field in the previous line in the file used by the previous line. Continuation lines can contain an UNTIL field, just as zone lines do, indicating that the next line is a further continuation.

Link — A link line has the form:

```
Link   LINK-FROM   LINK-TO
```

For example:

```
Link   Europe/Istanbul Asia/Istanbul
```

The LINK-FROM field should appear as the NAME field in some zone line; the LINK-TO field is used as an alternate name for that zone.

Except for continuation lines, lines can appear in any order in the input.

Options

`--`*version* Outputs version information and exits.

`-d` *directory* Creates time conversion information files in the directory *directory* rather than in the standard directory `/usr/share/lib/zoneinfo`.

`-l` *localtime* Uses the given time zone as local time *localtime*. `zic` acts as if the file contained a link line of the form:

```
Link localtime localtime
```

`-p` *posixrules* Uses the rules of the given time zone *posixrules* when handling POSIX-format time zone environment variables. `zic` acts as if the input contained a link line of the form:

```
Link    posixrules posixrules
```

This option is not used by `ctime(3C)` and `mktime(3C)` in the Solaris environment.

`-s` Limits time values stored in output files to values that are the same whether they are taken to be signed or unsigned. You can use this option to generate SVVS-compatible files.

This option is obsolete and may be removed in a future release.

`-v` Complains if a year that appears in a data file is outside the range of years representable by system time values (`0:00:00 a.m. UTC, January 1, 1970`, to `3:14:07 a.m. UTC, January 19, 2038`). This option also complains if a time of 24:00 (which cannot be handled by pre-1998 versions of `zic`) appears in the input.

`-y` *yearistype* Uses the given command *yearistype* rather than `yearistype` when checking year types (see `Rules` under `DESCRIPTION`).

Operands

filename A file containing input lines that specify the time conversion information files to be created. If a *filename* is '–', the standard input is read.

Files

`/usr/share/lib/zoneinfo` Standard directory used for created files

`/usr/share/lib/zoneinfo/src` Directory containing source files

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Committed*

* The `-s` option is obsolete.

See Also `time(1)`, `zdump(1M)`, `ctime(3C)`, `mktime(3C)`, `attributes(5)`

Notes For areas with more than two types of local time, you might need to use local standard time in the `AT` field of the earliest transition time's rule to ensure that the earliest transition time recorded in the compiled file is correct.

If the current *timezone* file is edited and compiled using the "`zic`" command, the changes will only be reflected in any new processes that are running. The most accurate way to reflect the changes for the whole system would be a reboot.

Name zoneadm – administer zones

Synopsis

```
zoneadm -z zonename [-u uuid-match] subcommand
     [subcommand_options]

zoneadm [-R root] [-z zonename] [-u uuid-match] list
     [list_options]

zoneadm [-R root] -z zonename [-u uuid-match] mark incomplete
```

Description The `zoneadm` utility is used to administer system zones. A zone is an application container that is maintained by the operating system runtime.

Security Once a process has been placed in a zone other than zone `0`, the process or any of its children cannot change zones.

Options The following options are supported:

`-R` *root*
Specify an alternate root (boot environment). This option can only be used in conjunction with the "`list`" and "`mark`" subcommands.

`-u` *uuid-match*
Unique identifier for a zone, as assigned by `libuuid(3LIB)`. If this option is present and the argument is a non-empty string, then the zone matching the UUID is selected instead of the one named by the `-z` option, if such a zone is present.

`-z` *zonename*
String identifier for a zone.

Subcommands Subcommands which can result in destructive actions or loss of work have a `-F` flag to force the action. If input is from a terminal device, the user is prompted if such a command is given without the `-F` flag; otherwise, if such a command is given without the `-F` flag, the action is disallowed, with a diagnostic message written to standard error. If a zone installation or uninstallation is interrupted, the zone is left in the incomplete state. Use uninstall to reset such a zone back to the configured state.

The following subcommands are supported:

`attach` [`-u` | `-U`] [`-b` *patchid*]... [`-F`] [`-n` *path*] [*brand-specific options*]
The `attach` subcommand takes a zone that has been detached from one system and attaches the zone onto a new system. Therefore, it is advised (though not required) that the `detach` subcommand should be run before the "attach" takes place. Once you have the new zone in the configured state, use the `attach` subcommand to set up the zone root instead of installing the zone as a new zone.

For native zones, `zoneadm` checks package and patch levels on the machine to which the zone is to be attached. If the packages/patches that the zone depends on from the global zone are different (have different revision numbers) from the dependent packages/patches on the source machine, `zoneadm` reports these conflicts and does not perform the attach. If

the destination system has only newer dependent packages/patches (higher revision numbers) than those on the source system, you can use the `-u` or `-U` options. The `-u` option updates the minimum number of packages within the attached zone to match the higher-revision packages and patches that exist on the new system. The `-U` option updates all packages in the attached zone that are also installed in the global zone. With `-u` or `-U`, as in the default behavior, `zoneadm` does not perform an attach if outdated packages/patches are found on the target system.

For native zones, one or more `-b` options can be used to specify a patch ID for a patch installed in the zone. These patches will be backed out before the zone is attached or, if `-u` was also specified, updated.

The `-F` option can be used to force the zone into the "installed" state with no validation. This option should be used with care since it can leave the zone in an unsupportable state if it was moved from a source system to a target system that is unable to properly host the zone. The `-n` option can be used to perform a "dry run" of the `attach` subcommand. It uses the output of the "`detach -n`" subcommand as input and is useful to identify any conflicting issues, such as the network device being incompatible, and can also determine whether the host is capable of supporting the zone. The path can be "`-`", to read the input from standard input.

The zone's brand may include additional options that govern how the zone will be attached. See `brands(5)` for specific brand information.

The zone being attached must first be configured using the `zonecfg` (see `zonecfg(1M)`) command. This does not apply when running "`attach -n`".

Use the following command to attach a zone:

```
# zoneadm -z my-zone attach
```

Use the following command to attach and update a zone:

```
# zoneadm -z my-zone attach -u (or -U)
```

In the absence of `-n` (as above), the source zone must be halted before this subcommand can be used.

`-n` *path*
: Read the zone manifest and verify that the target machine has the correct configuration to host the zone without actually performing an attach. The zone on the target system does not have to be configured on the new host before doing a trial-run attach.

`-u` or `-U`
: Update the attached zone as described above.

`boot` [`--` *boot_options*]
: Boot (or activate) the specified zones.

The following *boot_options* are supported:

`-i` *altinit*
Select an alternative executable to be the primordial Process. *altinit* is a valid path to an executable. The default primordial process is `init(1M)`.

`-m` *smf_options*
The *smf_options* include two categories of options to control booting behavior of the service management facility: recovery options and messages options.

Message options determine the type and amount of messages that `smf(5)` displays during boot. Service options determine the services which are used to boot the system. See `kernel(1M)` for a listing of the `-m` suboptions.

`-s`
Boots only to milestone `svc:/milestone/single-user:default`. This milestone is equivalent to init level `s`. See `svc.startd(1M)` and `init(1M)`.

`clone` [`-m` *copy*] [`-s` *zfs_snapshot*] *source_zone*
Install a zone by copying an existing installed zone. This subcommand is an alternative way to install the zone.

`-m` *copy*
Force the clone to be a copy, even if a "ZFS clone" is possible.

`-s` *zfs_snapshot*
Specify the name of a ZFS snapshot to use as the source of the clone. The *snapshot* must be a *snapshot* of the source zone taken from a previous "`zoneadm` clone" installation.

The source zone must be halted before this subcommand can be used.

`detach` [`-n`]
Detach the specified zone. Detaching a zone is the first step in moving a zone from one system to another. The full procedure to migrate a zone is that the zone is detached, the *zonepath* directory is moved to the new host, and then the zone is attached on the new host. Once the zone is detached, it is left in the configured state. If you try to install or clone to a configured zone that has been detached, you will receive an error message and the `install` or `clone` subcommand will not be allowed to proceed. The `-n` option can be used to perform a "dry run" of the `detach` subcommand. This generates the information needed for running the "`attach -n`" subcommand, which is useful to identify any conflicting issues, such as the network device being incompatible or if the host is capable of supporting the zone. The information is sent to standard output and can be saved to a file or piped to the "`attach -n`" subcommand.

Use the following command to detach a zone:

```
# zoneadm -z my-zone detach
```

Unless the `-n` option is used, the source zone must be halted before this subcommand can be used.

`-n`
Generate a zone manifest on a running zone without actually detaching the zone. The state of the zone on the originating system is not changed. The zone manifest is sent to `stdout`. The global administrator can direct this output to a file or pipe it to a remote command to be immediately validated on the target host.

`halt`
Halt the specified zones. `halt` bypasses running the shutdown scripts inside the zone. It also removes run time resources of the zone.

Use:

```
zlogin zone shutdown
```

to cleanly shutdown the zone by running the shutdown scripts.

`help` [*subcommand*]
Display general help. If you specify *subcommand*, displays help on *subcommand*.

`install` [`-x` *nodataset*] [*brand-specific options*]
Install the specified zone on the system. This subcommand automatically attempts to verify first. It refuses to install if the verify step fails. See the `verify` subcommand.

The zone's brand may include additional options that govern how the software will be installed in the zone. See `brands(5)` for specific brand information.

`-x` *nodataset*
Do not create a ZFS file system.

`list` [*list_options*]
Display the name of the current zones, or the specified zone if indicated.

By default, all running zones are listed. If you use this subcommand with the `zoneadm -z` *zonename* option, it lists only the specified zone, regardless of its state. In this case, the `-i` and `-c` options are disallowed.

If neither the `-i` or `-c` options are given, all running zones are listed.

The following *list_options* are supported:

`-c`
Display all configured zones. This option overides the `-i` option.

`-i`
Expand the display to all installed zones.

`-p`
Request machine parsable output. The output format is a list of lines, one per zone, with colon- delimited fields. These fields are:

```
zoneid:zonename:state:zonepath:uuid:brand:ip-type
```

If the `zonepath` contains embedded colons, they can be escaped by a backslash ("\:"), which is parsable by using the shell `read(1)` function with the environmental variable IFS. The *uuid* value is assigned by `libuuid(3LIB)` when the zone is installed, and is useful for identifying the same zone when present (or renamed) on alternate boot environments. Any software that parses the output of the "`zoneadm list -p`" command must be able to handle any fields that may be added in the future.

The `-v` and `-p` options are mutually exclusive. If neither `-v` nor `-p` is used, just the zone name is listed.

`-v`

Display verbose information, including zone name, id, current state, root directory, brand type, ip-type, and options.

The `-v` and `-p` options are mutually exclusive. If neither `-v` nor `-p` is used, just the zone name is listed.

`mark incomplete`

Change the state of an installed zone to "incomplete." This command may be useful in cases where administrative changes on the system have rendered a zone unusable or inconsistent. This change cannot be undone (except by uninstalling the zone).

`move` *new_zonepath*

Move the *zonepath* to *new_zonepath*. The zone must be halted before this subcommand can be used. The *new_zonepath* must be a local file system and normal restrictions for *zonepath* apply.

`ready`

Prepares a zone for running applications but does not start any user processes in the zone.

`reboot`

Restart the zones. This is equivalent to a `halt boot` sequence. This subcommand fails if the specified zones are not active.

`uninstall [-F]`

Uninstall the specified zone from the system. Use this subcommand with caution. It removes all of the files under the *zonepath* of the zone in question. You can use the `-F` flag to force the action.

`verify`

Check to make sure the configuration of the specified zone can safely be installed on the machine. Following is a break-down of the checks by `resource/property` type:

`zonepath`

`zonepath` and its parent directory exist and are owned by root with appropriate modes . The appropriate modes are that `zonepath` is `700`, its parent is not `group` or `world-writable` and so forth. `zonepath` is not over an NFS mount. A sub-directory of the `zonepath` named "root" does not exist.

If `zonepath` does not exist, the `verify` does not fail, but merely warns that a subsequent install will attempt to create it with proper permissions. A `verify` subsequent to that might fail should anything go wrong.

`zonepath` cannot be a symbolic link.

`fs`
Any `fs` resources have their *type* value checked. An error is reported if the value is one of `proc`, `mntfs`, `autofs`, `cachefs`, or `nfs` or the filesystem does not have an associated mount binary at `/usr/lib/fs/`<*fstype*>`/mount`.

It is an error for the *directory* to be a relative path.

It is an error for the path specified by `raw` to be a relative path or if there is no `fsck` binary for a given filesystem type at `/usr/lib/fs/`<*fstype*>`/fsck`. It is also an error if a corresponding `fsck` binary exists but a `raw` path is not specified.

`net`
All physical network interfaces exist. All network address resources are one of:

- a valid IPv4 address, optionally followed by "/" and a prefix length;
- a valid IPv6 address, which must be followed by "/" and a prefix length;
- a host name which resolves to an IPv4 address.

Note that hostnames that resolve to IPv6 addresses are not supported.

The physical interface name is the network interface name.

A zone can be configured to be either exclusive-IP or shared-IP. For a shared-IP zone, both the physical and address properties must be set. For an exclusive-IP zone, the physical property must be set and the address property cannot be set.

`rctl`
It also verifies that any defined resource control values are valid on the current machine. This means that the privilege level is `privileged`, the limit is lower than the currently defined system value, and that the defined action agrees with the actions that are valid for the given resource control.

Examples

EXAMPLE 1 Using the `-m` Option

The following command illustrates the use of the `-m` option.

```
# zoneadm boot -- -m verbose
```

EXAMPLE 2 Using the `-i` Option

The following command illustrates the use of the `-i` option.

```
# zoneadm boot -- -i /sbin/init
```

EXAMPLE 3 Using the -s Option

The following command illustrates the use of the -s option.

```
# zoneadm boot -- -s
```

Exit Status

The following exit values are returned:

`0`
Successful completion.

`1`
An error occurred.

`2`
Invalid usage.

Attributes

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/zones
Interface Stability	Committed

See Also

`read(1)`, `svcs(1)`, `zlogin(1)`, `zonename(1)`, `init(1M)`, `kernel(1M)`, `svcadm(1M)`, `svc.startd(1M)`, `svc.startd(1M)`, `zonecfg(1M)`, `libuuid(3LIB)`, `attributes(5)`, `brands(5)`, `smf(5)`, `zones(5)`

Notes

The `zones(5)` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/system/zones:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

The act of installing a new non-global zone is a fresh installation of the Solaris operating system. A new installation of Solaris must not require interaction with the user (that is, it must be “hands off”). Because of this, packages installed in the global zone and all non-global zones cannot contain request scripts (see `pkgask(1M)`). If a package did have a request script, then the creation of a non-global zone could not be done without user intervention. Any package that contains a request script is added to the global zone only. See `pkgadd(1M)`.

Name zoneadmd – zone administration daemon

Synopsis

```
/usr/lib/zones/zoneadmd
```

Description `zoneadmd` is a system daemon that is started when the system needs to manage a particular zone. Because each instance of the `zoneadmd` daemon manages a particular zone, it is not unexpected to see multiple `zoneadmd` daemons running.

This daemon is started automatically by the zone management software and should not be invoked directly. The daemon shuts down automatically when no longer in use. It does not constitute a programming interface, but is classified as a private interface.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWzoneu
Interface Stability	Private

See Also `svcs(1)`, `zlogin(1)`, `svcadm(1M)`, `zoneadm(1M)`, `attributes(5)`, `smf(5)`, `zones(5)`

Notes The `zones(5)` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/system/zones:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

Name zonecfg – set up zone configuration

Synopsis

```
zonecfg -z zonename
zonecfg -z zonename subcommand
zonecfg -z zonename -f command_file
zonecfg help
```

Description The `zonecfg` utility creates and modifies the configuration of a zone. Zone configuration consists of a number of resources and properties.

To simplify the user interface, `zonecfg` uses the concept of a scope. The default scope is global.

The following synopsis of the `zonecfg` command is for interactive usage:

```
zonecfg -z zonename subcommand
```

Parameters changed through `zonecfg` do not affect a running zone. The zone must be rebooted for the changes to take effect.

In addition to creating and modifying a zone, the `zonecfg` utility can also be used to persistently specify the resource management settings for the global zone.

In the following text, "rctl" is used as an abbreviation for "resource control". See `resource_controls(5)`.

Every zone is configured with an associated brand. The brand determines the user-level environment used within the zone, as well as various behaviors for the zone when it is installed, boots, or is shutdown. Once a zone has been installed the brand cannot be changed. The default brand is determined by the installed distribution in the global zone. Some brands do not support all of the `zonecfg` properties and resources. See the brand-specific man page for more details on each brand. For an overview of brands, see the `brands(5)` man page.

Resources The following resource types are supported:

`attr`
Generic attribute.

`capped-cpu`
Limits for CPU usage.

`capped-memory`
Limits for physical, swap, and locked memory.

`dataset`
ZFS dataset.

`dedicated-cpu`
Subset of the system's processors dedicated to this zone while it is running.

`device`
Device.

`fs`
file-system

`inherit-pkg-dir`
Directory inherited from the global zone. Used for sparse root zones (see the discussion of "Sparse and Whole Root Non-Global Zones," below). Software packages whose contents have been transferred into that directory are inherited in read-only mode by the non-global zone and the non-global zone's packaging database is updated to reflect those packages. Such resources are not modifiable or removable once a zone has been installed with `zoneadm`.

`net`
Network interface.

`rctl`
Resource control.

Sparse and Whole Root Non-Global Zones

In the administration of zones, it is useful to distinguish between the global zone and non-global zones. Within non-global zones, there are two zone root file system models: sparse and whole root. The sparse root zone model optimizes the sharing of objects. The whole root zone model provides the maximum configurability. Note that not all brands support the sparse zone model.

Sparse Root Zones

Non-global zones that have `inherit-pkg-dir` resources are called sparse root zones.

The sparse root zone model optimizes the sharing of objects in the following ways:

- Only a subset of the packages installed in the global zone are installed directly into the non-global zone.
- Read-only loopback file systems, identified as `inherit-pkg-dir` resources, are used to gain access to other files.

In this model, all packages appear to be installed in the non-global zone. Packages that do not deliver content into read-only loopback mount file systems are fully installed. There is no need to install content delivered into read-only loopback mounted file systems since that content is inherited (and visible) from the global zone.

- As a general guideline, a zone requires about 100 megabytes of free disk space per zone when the global zone has been installed with all of the standard Solaris packages.
- By default, any additional packages installed in the global zone also populate the non-global zones. The amount of disk space required might be increased accordingly, depending on whether the additional packages deliver files that reside in the `inherit-pkg-dir` resource space.

An additional 40 megabytes of RAM per zone are suggested, but not required on a machine with sufficient swap space.

A sparse zone inherits the following directories:

```
/lib
/platform
/sbin
/usr
```

Although `zonecfg` allows you to remove one of these as an inherited directory, you should not do so. You should either follow the whole-root model or the sparse model; a subset of the sparse model is not tested and you might encounter unexpected problems.

Adding an additional `inherit-pkg-dir` directory, such as `/opt`, to a sparse root zone is acceptable.

Whole Root Zones

The whole root zone model provides the maximum configurability. All of the required and any selected optional Solaris packages are installed into the private file systems of the zone. The advantages of this model include the capability for global administrators to customize their zones file system layout. This would be done, for example, to add arbitrary unbundled or third-party packages.

The disk requirements for this model are determined by the disk space used by the packages currently installed in the global zone.

Note – If you create a sparse root zone that contains the following `inherit-pkg-dir` directories, you must remove these directories from the non-global zone's configuration before the zone is installed to have a whole root zone:

- `/lib`
- `/platform`
- `/sbin`
- `/usr`

Properties Each resource type has one or more properties. There are also some global properties, that is, properties of the configuration as a whole, rather than of some particular resource.

The following properties are supported:

(global)
`zonename`

(global)
`zonepath`

(global)
`autoboot`

(global)
bootargs

(global)
pool

(global)
limitpriv

(global)
brand

(global)
cpu-shares

(global)
hostid

(global)
max-lwps

(global)
max-msg-ids

(global)
max-sem-ids

(global)
max-shm-ids

(global)
max-shm-memory

(global)
scheduling-class

fs
dir, special, raw, type, options

inherit-pkg-dir
dir

net
address, physical, defrouter

device
match

rctl
name, value

attr
name, type, value

```
dataset
   name

dedicated-cpu
   ncpus, importance

capped-memory
   physical, swap, locked

capped-cpu
   ncpus
```

As for the property values which are paired with these names, they are either simple, complex, or lists. The type allowed is property-specific. Simple values are strings, optionally enclosed within quotation marks. Complex values have the syntax:

(*<name>*=*<value>*,*<name>*=*<value>*, . . .)

where each *<value>* is simple, and the *<name>* strings are unique within a given property. Lists have the syntax:

[*<value>*, . . .]

where each *<value>* is either simple or complex. A list of a single value (either simple or complex) is equivalent to specifying that value without the list syntax. That is, "foo" is equivalent to "[foo]". A list can be empty (denoted by "[]").

In interpreting property values, `zonecfg` accepts regular expressions as specified in `fnmatch(5)`. See `EXAMPLES`.

The property types are described as follows:

global: `zonename`
The name of the zone.

global: `zonepath`
Path to zone's file system.

global: `autoboot`
Boolean indicating that a zone should be booted automatically at system boot. Note that if the zones service is disabled, the zone will not autoboot, regardless of the setting of this property. You enable the zones service with a `svcadm` command, such as:

```
# svcadm enable svc:/system/zones:default
```

Replace `enable` with `disable` to disable the zones service. See `svcadm(1M)`.

global: `bootargs`
Arguments (options) to be passed to the zone bootup, unless options are supplied to the "`zoneadm boot`" command, in which case those take precedence. The valid arguments are described in `zoneadm(1M)`.

global: `pool`
Name of the resource pool that this zone must be bound to when booted. This property is incompatible with the `dedicated-cpu` resource.

global: `limitpriv`
The maximum set of privileges any process in this zone can obtain. The property should consist of a comma-separated privilege set specification as described in `priv_str_to_set(3C)`. Privileges can be excluded from the resulting set by preceding their names with a dash (-) or an exclamation point (!). The special privilege string "zone" is not supported in this context. If the special string "default" occurs as the first token in the property, it expands into a safe set of privileges that preserve the resource and security isolation described in `zones(5)`. A missing or empty property is equivalent to this same set of safe privileges.

The system administrator must take extreme care when configuring privileges for a zone. Some privileges cannot be excluded through this mechanism as they are required in order to boot a zone. In addition, there are certain privileges which cannot be given to a zone as doing so would allow processes inside a zone to unduly affect processes in other zones. `zoneadm(1M)` indicates when an invalid privilege has been added or removed from a zone's privilege set when an attempt is made to either "boot" or "ready" the zone.

See `privileges(5)` for a description of privileges. The command "`ppriv -l`" (see `ppriv(1)`) produces a list of all Solaris privileges. You can specify privileges as they are displayed by `ppriv`. In `privileges(5)`, privileges are listed in the form PRIV_*privilege_name*. For example, the privilege *sys_time*, as you would specify it in this property, is listed in `privileges(5)` as `PRIV_SYS_TIME`.

global: `brand`
The zone's brand type.

global: `ip-type`
A zone can either share the IP instance with the global zone, which is the default, or have its own exclusive instance of IP.

This property takes the values `shared` and `exclusive`.

global: `hostid`
A zone can emulate a 32-bit host identifier to ease system consolidation. A zone's `hostid` property is empty by default, meaning that the zone does not emulate a host identifier. Zone host identifiers must be hexadecimal values between 0 and FFFFFFFE. A `0x` or `0X` prefix is optional. Both uppercase and lowercase hexadecimal digits are acceptable.

`fs`: dir, special, raw, type, options
Values needed to determine how, where, and so forth to mount file systems. See `mount(1M)`, `mount(2)`, `fsck(1M)`, and `vfstab(4)`.

`inherit-pkg-dir`: dir
The directory path.

`net`: address, physical, defrouter
The network address and physical interface name of the network interface. The network address is one of:

- a valid IPv4 address, optionally followed by "`/`" and a prefix length;
- a valid IPv6 address, which must be followed by "`/`" and a prefix length;
- a host name which resolves to an IPv4 address.

Note that host names that resolve to IPv6 addresses are not supported.

The physical interface name is the network interface name.

The value for the optional default router is specified similarly to the network address except that it must not be followed by a `/` (slash) and a network prefix length. To enable correct use of the `defrouter` functionality, the zones that use the property must be on a different subnet from the subnet on which the global zone resides. Also, each zone (or set of zones) that uses a different `defrouter` setting must be on a different subnet.

A zone can be configured to be either exclusive-IP or shared-IP. For a shared-IP zone, you must set both the physical and address properties; setting the default router is optional. The interface specified in the physical property must be plumbed in the global zone prior to booting the non-global zone. However, if the interface is not used by the global zone, it should be configured `down` in the global zone, and the default router for the interface should be specified here.

For an exclusive-IP zone, the physical property must be set and the address and default router properties cannot be set. Note that a single datalink cannot be shared among multiple exclusive-IP zones.

`device`: match
Device name to match.

`rctl`: name, value
The name and *priv*/*limit*/*action* triple of a resource control. See `prctl(1)` and `rctladm(1M)`. The preferred way to set rctl values is to use the global property name associated with a specific rctl.

`attr`: name, type, value
The name, type and value of a generic attribute. The `type` must be one of `int`, `uint`, `boolean` or `string`, and the value must be of that type. `uint` means unsigned , that is, a non-negative integer.

`dataset`: name
The name of a ZFS dataset to be accessed from within the zone. See `zfs(1M)`.

global: `cpu-shares`
The number of Fair Share Scheduler (FSS) shares to allocate to this zone. This property is incompatible with the `dedicated-cpu` resource. This property is the preferred way to set the `zone.cpu-shares` rctl.

global: `max-lwps`
The maximum number of LWPs simultaneously available to this zone. This property is the preferred way to set the `zone.max-lwps` rctl.

global: `max-msg-ids`
The maximum number of message queue IDs allowed for this zone. This property is the preferred way to set the `zone.max-msg-ids` rctl.

global: `max-sem-ids`
The maximum number of semaphore IDs allowed for this zone. This property is the preferred way to set the `zone.max-sem-ids` rctl.

global: `max-shm-ids`
The maximum number of shared memory IDs allowed for this zone. This property is the preferred way to set the `zone.max-shm-ids` rctl.

global: `max-shm-memory`
The maximum amount of shared memory allowed for this zone. This property is the preferred way to set the `zone.max-shm-memory` rctl. A scale (K, M, G, T) can be applied to the value for this number (for example, 1M is one megabyte).

global: `scheduling-class`
Specifies the scheduling class used for processes running in a zone. When this property is not specified, the scheduling class is established as follows:

- If the `cpu-shares` property or equivalent rctl is set, the scheduling class FSS is used.
- If neither `cpu-shares` nor the equivalent rctl is set and the zone's pool property references a pool that has a default scheduling class, that class is used.
- Under any other conditions, the system default scheduling class is used.

`dedicated-cpu`: ncpus, importance
The number of CPUs that should be assigned for this zone's exclusive use. The zone will create a pool and processor set when it boots. See `pooladm(1M)` and `poolcfg(1M)` for more information on resource pools. The `ncpu` property can specify a single value or a range (for example, 1-4) of processors. The `importance` property is optional; if set, it will specify the `pset.importance` value for use by `poold(1M)`. If this resource is used, there must be enough free processors to allocate to this zone when it boots or the zone will not boot. The processors assigned to this zone will not be available for the use of the global zone or other zones. This resource is incompatible with both the `pool` and `cpu-shares` properties. Only a single instance of this resource can be added to the zone.

`capped-memory`: physical, swap, locked
The caps on the memory that can be used by this zone. A scale (K, M, G, T) can be applied to the value for each of these numbers (for example, 1M is one megabyte). Each of these properties is optional but at least one property must be set when adding this resource. Only a single instance of this resource can be added to the zone. The `physical` property sets the `max-rss` for this zone. This will be enforced by `rcapd(1M)` running in the global zone. The

swap property is the preferred way to set the zone.max-swap rctl. The locked property is the preferred way to set the zone.max-locked-memory rctl.

capped-cpu: ncpus
Sets a limit on the amount of CPU time that can be used by a zone. The unit used translates to the percentage of a single CPU that can be used by all user threads in a zone, expressed as a fraction (for example, .75) or a mixed number (whole number and fraction, for example, 1.25). An ncpu value of 1 means 100% of a CPU, a value of 1.25 means 125%, .75 mean 75%, and so forth. When projects within a capped zone have their own caps, the minimum value takes precedence.

The capped-cpu property is an alias for zone.cpu-cap resource control and is related to the zone.cpu-cap resource control. See resource_controls(5).

The following table summarizes resources, property-names, and types:

```
resource          property-name   type
(global)          zonename        simple
(global)          zonepath        simple
(global)          autoboot        simple
(global)          bootargs        simple
(global)          pool            simple
(global)          limitpriv       simple
(global)          brand           simple
(global)          ip-type         simple
(global)          hostid          simple
(global)          cpu-shares      simple
(global)          max-lwps        simple
(global)          max-msg-ids     simple
(global)          max-sem-ids     simple
(global)          max-shm-ids     simple
(global)          max-shm-memory  simple
(global)          scheduling-class simple
fs                dir             simple
                   special         simple
                   raw             simple
                   type            simple
                   options         list of simple
inherit-pkg-dir   dir             simple
net               address         simple
                   physical        simple
device            match           simple
rctl              name            simple
                   value           list of complex
attr              name            simple
                   type            simple
                   value           simple
dataset           name            simple
dedicated-cpu     ncpus           simple or range
```

```
                    importance      simple

capped-memory      physical        simple with scale
                    swap            simple with scale
                    locked          simple with scale

capped-cpu         ncpus           simple
```

To further specify things, the breakdown of the complex property "value" of the "rctl" resource type, it consists of three name/value pairs, the names being "priv", "limit" and "action", each of which takes a simple value. The "name" property of an "attr" resource is syntactically restricted in a fashion similar but not identical to zone names: it must begin with an alphanumeric, and can contain alphanumerics plus the hyphen (-), underscore (_), and dot (.) characters. Attribute names beginning with "zone" are reserved for use by the system. Finally, the "autoboot" global property must have a value of "true" or "false".

Using Kernel Statistics to Monitor CPU Caps

Using the kernel statistics (kstat(3KSTAT)) module caps, the system maintains information for all capped projects and zones. You can access this information by reading kernel statistics (kstat(3KSTAT)), specifying caps as the kstat module name. The following command displays kernel statistics for all active CPU caps:

```
# kstat caps::'/cpucaps/'
```

A kstat(1M) command running in a zone displays only CPU caps relevant for that zone and for projects in that zone. See EXAMPLES.

The following are cap-related arguments for use with kstat(1M):

caps
: The kstat module.

project_caps or zone_caps
: kstat class, for use with the kstat -c option.

cpucaps_project_*id* or cpucaps_zone_*id*
: kstat name, for use with the kstat -n option. *id* is the project or zone identifier.

The following fields are displayed in response to a kstat(1M) command requesting statistics for all CPU caps.

module
: In this usage of kstat, this field will have the value caps.

name
: As described above, cpucaps_project_*id* or cpucaps_zone_*id*

above_sec
: Total time, in seconds, spent above the cap.

below_sec
: Total time, in seconds, spent below the cap.

`maxusage`
Maximum observed CPU usage.

`nwait`
Number of threads on cap wait queue.

`usage`
Current aggregated CPU usage for all threads belonging to a capped project or zone, in terms of a percentage of a single CPU.

`value`
The cap value, in terms of a percentage of a single CPU.

`zonename`
Name of the zone for which statistics are displayed.

See `EXAMPLES` for sample output from a `kstat` command.

Options The following options are supported:

`-f` *command_file*
Specify the name of `zonecfg` command file. *command_file* is a text file of `zonecfg` subcommands, one per line.

`-z` *zonename*
Specify the name of a zone. Zone names are case sensitive. Zone names must begin with an alphanumeric character and can contain alphanumeric characters, the underscore (`_`) the hyphen (`-`), and the dot (`.`). The name `global` and all names beginning with `SUNW` are reserved and cannot be used.

Subcommands You can use the `add` and `select` subcommands to select a specific resource, at which point the scope changes to that resource. The `end` and `cancel` subcommands are used to complete the resource specification, at which time the scope is reverted back to global. Certain subcommands, such as `add`, `remove` and `set`, have different semantics in each scope.

`zonecfg` supports a semicolon-separated list of subcommands. For example:

```
# zonecfg -z myzone "add net; set physical=myvnic; end"
```

Subcommands which can result in destructive actions or loss of work have an `-F` option to force the action. If input is from a terminal device, the user is prompted when appropriate if such a command is given without the `-F` option otherwise, if such a command is given without the `-F` option, the action is disallowed, with a diagnostic message written to standard error.

The following subcommands are supported:

`add` *resource-type* (global scope)
`add` *property-name property-value* (resource scope)
In the global scope, begin the specification for a given resource type. The scope is changed to that resource type.

In the resource scope, add a property of the given name with the given value. The syntax for property values varies with different property types. In general, it is a simple value or a list of simple values enclosed in square brackets, separated by commas (`[foo,bar,baz]`). See `PROPERTIES`.

`cancel`
End the resource specification and reset scope to global. Abandons any partially specified resources. `cancel` is only applicable in the resource scope.

`clear` *property-name*
Clear the value for the property.

`commit`
Commit the current configuration from memory to stable storage. The configuration must be committed to be used by `zoneadm`. Until the in-memory configuration is committed, you can remove changes with the `revert` subcommand. The `commit` operation is attempted automatically upon completion of a `zonecfg` session. Since a configuration must be correct to be committed, this operation automatically does a verify.

`create [-F] [ -a` *path* `|-b | -t` *template*`]`
Create an in-memory configuration for the specified zone. Use `create` to begin to configure a new zone. See `commit` for saving this to stable storage.

If you are overwriting an existing configuration, specify the `-F` option to force the action. Specify the `-t` *template* option to create a configuration identical to *template*, where *template* is the name of a configured zone.

Use the `-a` *path* option to facilitate configuring a detached zone on a new host. The *path* parameter is the zonepath location of a detached zone that has been moved on to this new host. Once the detached zone is configured, it should be installed using the "`zoneadm attach`" command (see `zoneadm(1M)`). All validation of the new zone happens during the `attach` process, not during zone configuration.

Use the `-b` option to create a blank configuration. Without arguments, `create` applies the Sun default settings.

`delete [-F]`
Delete the specified configuration from memory and stable storage. This action is instantaneous, no commit is necessary. A deleted configuration cannot be reverted.

Specify the `-F` option to force the action.

`end`
End the resource specification. This subcommand is only applicable in the resource scope. `zonecfg` checks to make sure the current resource is completely specified. If so, it is added to the in-memory configuration (see `commit` for saving this to stable storage) and the scope reverts to global. If the specification is incomplete, it issues an appropriate error message.

`export [-f` *output-file*`]`
Print configuration to standard output. Use the `-f` option to print the configuration to *output-file*. This option produces output in a form suitable for use in a command file.

`help [usage] [`*subcommand*`] [syntax] [`*command-name*`]`
Print general help or help about given topic.

`info zonename | zonepath | autoboot | brand | pool | limitpriv`
`info [`*resource-type* `[`*property-name*`=`*property-value*`]*]`
Display information about the current configuration. If *resource-type* is specified, displays only information about resources of the relevant type. If any *property-name* value pairs are specified, displays only information about resources meeting the given criteria. In the resource scope, any arguments are ignored, and `info` displays information about the resource which is currently being added or modified.

`remove` *resource-type*{*property-name*=*property-value*}(global scope)
In the global scope, removes the specified resource. The `[]` syntax means 0 or more of whatever is inside the square braces. If you want only to remove a single instance of the resource, you must specify enough property name-value pairs for the resource to be uniquely identified. If no property name-value pairs are specified, all instances will be removed. If there is more than one pair is specified, a confirmation is required, unless you use the `-F` option.

`select` *resource-type* {*property-name*=*property-value*}
Select the resource of the given type which matches the given *property-name property-value* pair criteria, for modification. This subcommand is applicable only in the global scope. The scope is changed to that resource type. The `{}` syntax means 1 or more of whatever is inside the curly braces. You must specify enough *property -name property-value* pairs for the resource to be uniquely identified.

`set` *property-name*=*property- value*
Set a given property name to the given value. Some properties (for example, `zonename` and `zonepath`) are global while others are resource-specific. This subcommand is applicable in both the global and resource scopes.

`verify`
Verify the current configuration for correctness:

- All resources have all of their required properties specified.
- A `zonepath` is specified.

`revert [-F]`
Revert the configuration back to the last committed state. The `-F` option can be used to force the action.

`exit [-F]`
Exit the `zonecfg` session. A commit is automatically attempted if needed. You can also use an EOF character to exit `zonecfg`. The `-F` option can be used to force the action.

Examples

EXAMPLE 1 Creating the Environment for a New Zone

In the following example, `zonecfg` creates the environment for a new zone. `/usr/local` is loopback mounted from the global zone into `/opt/local`. `/opt/sfw` is loopback mounted from the global zone, three logical network interfaces are added, and a limit on the number of fair-share scheduler (FSS) CPU shares for a zone is set using the `rctl` resource type. The example also shows how to select a given resource for modification.

```
example# zonecfg -z myzone3
my-zone3: No such zone configured
Use 'create' to begin configuring a new zone.
zonecfg:myzone3> create
zonecfg:myzone3> set zonepath=/export/home/my-zone3
zonecfg:myzone3> set autoboot=true
zonecfg:myzone3> add fs
zonecfg:myzone3:fs> set dir=/usr/local
zonecfg:myzone3:fs> set special=/opt/local
zonecfg:myzone3:fs> set type=lofs
zonecfg:myzone3:fs> add options [ro,nodevices]
zonecfg:myzone3:fs> end
zonecfg:myzone3> add fs
zonecfg:myzone3:fs> set dir=/mnt
zonecfg:myzone3:fs> set special=/dev/dsk/c0t0d0s7
zonecfg:myzone3:fs> set raw=/dev/rdsk/c0t0d0s7
zonecfg:myzone3:fs> set type=ufs
zonecfg:myzone3:fs> end
zonecfg:myzone3> add inherit-pkg-dir
zonecfg:myzone3:inherit-pkg-dir> set dir=/opt/sfw
zonecfg:myzone3:inherit-pkg-dir> end
zonecfg:myzone3> add net
zonecfg:myzone3:net> set address=192.168.0.1/24
zonecfg:myzone3:net> set physical=eri0
zonecfg:myzone3:net> end
zonecfg:myzone3> add net
zonecfg:myzone3:net> set address=192.168.1.2/24
zonecfg:myzone3:net> set physical=eri0
zonecfg:myzone3:net> end
zonecfg:myzone3> add net
zonecfg:myzone3:net> set address=192.168.2.3/24
zonecfg:myzone3:net> set physical=eri0
zonecfg:myzone3:net> end
zonecfg:my-zone3> set cpu-shares=5
zonecfg:my-zone3> add capped-memory
zonecfg:my-zone3:capped-memory> set physical=50m
zonecfg:my-zone3:capped-memory> set swap=100m
zonecfg:my-zone3:capped-memory> end
zonecfg:myzone3> exit
```

EXAMPLE 2 Creating a Non-Native Zone

The following example creates a new Linux zone:

```
example# zonecfg -z lxzone
lxzone: No such zone configured
Use 'create' to begin configuring a new zone
zonecfg:lxzone> create -t SUNWlx
zonecfg:lxzone> set zonepath=/export/zones/lxzone
zonecfg:lxzone> set autoboot=true
zonecfg:lxzone> exit
```

EXAMPLE 3 Creating an Exclusive-IP Zone

The following example creates a zone that is granted exclusive access to `bge1` and `bge33000` and that is isolated at the IP layer from the other zones configured on the system.

The IP addresses and routing is configured inside the new zone using `sysidtool(1M)`.

```
example# zonecfg -z excl
excl: No such zone configured
Use 'create' to begin configuring a new zone
zonecfg:excl> create
zonecfg:excl> set zonepath=/export/zones/excl
zonecfg:excl> set ip-type=exclusive
zonecfg:excl> add net
zonecfg:excl:net> set physical=bge1
zonecfg:excl:net> end
zonecfg:excl> add net
zonecfg:excl:net> set physical=bge33000
zonecfg:excl:net> end
zonecfg:excl> exit
```

EXAMPLE 4 Associating a Zone with a Resource Pool

The following example shows how to associate an existing zone with an existing resource pool:

```
example# zonecfg -z myzone
zonecfg:myzone> set pool=mypool
zonecfg:myzone> exit
```

For more information about resource pools, see `pooladm(1M)` and `poolcfg(1M)`.

EXAMPLE 5 Changing the Name of a Zone

The following example shows how to change the name of an existing zone:

```
example# zonecfg -z myzone
zonecfg:myzone> set zonename=myzone2
zonecfg:myzone2> exit
```

EXAMPLE 6 Changing the Privilege Set of a Zone

The following example shows how to change the set of privileges an existing zone's processes will be limited to the next time the zone is booted. In this particular case, the privilege set will be the standard safe set of privileges a zone normally has along with the privilege to change the system date and time:

```
example# zonecfg -z myzone
zonecfg:myzone> set limitpriv="default,sys_time"
zonecfg:myzone2> exit
```

EXAMPLE 7 Setting the `zone.cpu-shares` Property for the Global Zone

The following command sets the `zone.cpu-shares` property for the global zone:

```
example# zonecfg -z global
zonecfg:global> set cpu-shares=5
zonecfg:global> exit
```

EXAMPLE 8 Using Pattern Matching

The following commands illustrate `zonecfg` support for pattern matching. In the zone `flexlm`, enter:

```
zonecfg:flexlm> add device
zonecfg:flexlm:device> set match="/dev/cua/a00[2-5]"
zonecfg:flexlm:device> end
```

In the global zone, enter:

```
global# ls /dev/cua
a     a000  a001  a002  a003  a004  a005  a006  a007  b
```

In the zone `flexlm`, enter:

```
flexlm# ls /dev/cua
a002  a003  a004  a005
```

EXAMPLE 9 Setting a Cap for a Zone to Three CPUs

The following sequence uses the `zonecfg` command to set the CPU cap for a zone to three CPUs.

```
zonecfg:myzone> add capped-cpu
zonecfg:myzone>capped-cpu> set ncpus=3
zonecfg:myzone>capped-cpu>capped-cpu> end
```

The preceding sequence, which uses the capped-cpu property, is equivalent to the following sequence, which makes use of the `zone.cpu-cap` resource control.

```
zonecfg:myzone> add rctl
zonecfg:myzone:rctl> set name=zone.cpu-cap
zonecfg:myzone:rctl> add value (priv=privileged,limit=300,action=none)
```

EXAMPLE 9 Setting a Cap for a Zone to Three CPUs *(Continued)*

```
zonecfg:myzone:rctl> end
```

EXAMPLE 10 Using `kstat` to Monitor CPU Caps

The following command displays information about all CPU caps.

```
# kstat -n /cpucaps/
module: caps                            instance: 0
name:   cpucaps_project_0               class:    project_caps
        above_sec                       0
        below_sec                       2157
        crtime                          821.048183159
        maxusage                        2
        nwait                           0
        snaptime                        235885.637253027
        usage                           0
        value                           18446743151372347932
        zonename                        global

module: caps                            instance: 0
name:   cpucaps_project_1               class:    project_caps
        above_sec                       0
        below_sec                       0
        crtime                          225339.192787265

```

EXAMPLE 11 Displaying CPU Caps for a Specific Zone or Project

Using the `kstat -c` and `-i` options, you can display CPU caps for a specific zone or project, as below. The first command produces a display for a specific project, the second for the same project within zone 1.

```
# kstat -c project_caps

# kstat -c project_caps -i 1
```

Exit Status

The following exit values are returned:

`0`
: Successful completion.

`1`
: An error occurred.

`2`
: Invalid usage.

Attributes

See `attributes(5)` for descriptions of the following attributes:

Name zpool – configures ZFS storage pools

Synopsis

```
zpool [-?]

zpool add [-fn] pool vdev ...

zpool attach [-f] pool device new_device

zpool clear [-F [-n]] pool [device]

zpool create [-fn] [-o property=value] ... [-O file-system-property=value]
     ... [-m mountpoint] [-R root] pool vdev ...

zpool destroy [-f] pool

zpool detach pool device

zpool export [-f] pool ...

zpool get all | property[,...] pool ...

zpool history [-il] [pool] ...

zpool import [-d dir] [-D]

zpool import [-o mntopts] [-o property=value] ... [-d dir | -c cachefile]
     [-D] [-f] [-R root] [-F [-n]] -a

zpool import [-o mntopts] [-o property=value] ... [-d dir | -c cachefile]
     [-D] [-f] [-R root] [-F [-n]] pool |id [newpool]

zpool iostat [-v] [pool] ... [interval[count]]

zpool list [-H] [-o property[,...]] [pool] ...

zpool offline [-t] pool device ...

zpool online pool device ...

zpool remove pool device ...

zpool replace [-f] pool device [new_device]

zpool scrub [-s] pool ...

zpool set property=value pool

zpool split [-R altroot] [-n] [-o mntopts] [-o property=value] pool
     newpool [device ...]

zpool status [-xv] [pool] ...

zpool upgrade

zpool upgrade -v

zpool upgrade [-V version] -a | pool ...
```

Description The `zpool` command configures ZFS storage pools. A storage pool is a collection of devices that provides physical storage and data replication for ZFS datasets.

All datasets within a storage pool share the same space. See `zfs(1M)` for information on managing datasets.

Virtual Devices (`vdevs`) A *virtual device* describes a single device or a collection of devices organized according to certain performance and fault characteristics. The following virtual devices are supported:

`disk`
A block device, typically located under `/dev/dsk`. ZFS can use individual slices or partitions, though the recommended mode of operation is to use whole disks. A disk can be specified by a full path, or it can be a shorthand name (the relative portion of the path under `/dev/dsk`). A whole disk can be specified by omitting the slice or partition designation. When given a whole disk, ZFS automatically labels the disk, if necessary.

`file`
A regular file. The use of files as a backing store is strongly discouraged. It is designed primarily for experimental purposes, as the fault tolerance of a file is only as good as the file system of which it is a part. A file must be specified by a full path.

`mirror`
A mirror of two or more devices. Data is replicated in an identical fashion across all components of a mirror. A mirror with *N* disks of size *X* can hold *X* bytes and can withstand (*N-1*) devices failing before data integrity is compromised.

`raidz`
`raidz1`
`raidz2`
`raidz3`
A variation on RAID-5 that allows for better distribution of parity and eliminates the "RAID-5 write hole" (in which data and parity become inconsistent after a power loss). Data and parity is striped across all disks within a raidz group.

A raidz group can have single-, double- , or triple parity, meaning that the raidz group can sustain one, two, or three failures, respectively, without losing any data. The raidz1 `vdev` type specifies a single-parity raidz group; the raidz2 `vdev` type specifies a double-parity raidz group; and the raidz3 `vdev` type specifies a triple-parity raidz group. The raidz `vdev` type is an alias for raidz1.

A raidz group with *N* disks of size *X* with *P* parity disks can hold approximately (*N-P*)***X* bytes and can withstand *P* device(s) failing before data integrity is compromised. The minimum number of devices in a raidz group is one more than the number of parity disks. The recommended number of devices is between 3 and 9, to help increase performance.

`spare`
A special pseudo-`vdev` that identifies an available hot spare for a pool. For more information, see the "Hot Spares" section.

`log`
A separate-intent log device. If more than one log device is specified, then writes are load-balanced between devices. Log devices can be mirrored. However, raidz `vdev` types are not supported for the intent log. For more information, see the "Intent Log" section.

`cache`
A device used to cache storage pool data. A cache device cannot be configured as a mirror or `raidz` group. For more information, see the "Cache Devices" section.

Virtual devices cannot be nested, so a mirror or raidz virtual device can only contain files or disks. Mirrors of mirrors (or other combinations) are not allowed.

A pool can have any number of virtual devices at the top of the configuration (known as *top-level vdevs*). Data is dynamically distributed across all top-level devices to balance data among devices. As new virtual devices are added, ZFS automatically places data on the newly available devices.

Virtual devices are specified one at a time on the command line, separated by whitespace. The keywords `mirror` and `raidz` are used to distinguish where a group ends and another begins. For example, the following creates two top-level vdevs, each a mirror of two disks:

```
# zpool create mypool mirror c0t0d0 c0t1d0 mirror c1t0d0 c1t1d0
```

Device Failure and Recovery

ZFS supports a rich set of mechanisms for handling device failure and data corruption. All metadata and data is checksummed, and ZFS automatically repairs bad data from a good copy when corruption is detected.

In order to take advantage of these features, a pool must make use of some form of redundancy, using either mirrored or raidz groups. While ZFS supports running in a non-redundant configuration, where each top-level vdev is simply a disk or file, this is strongly discouraged. A single case of bit corruption can render some or all of your data unavailable.

A pool's health status is described by one of three states: online, degraded, or faulted. An online pool has all devices operating normally. A degraded pool is one in which one or more devices have failed, but the data is still available due to a redundant configuration. A faulted pool has corrupted metadata, or one or more faulted devices, and insufficient replicas to continue functioning.

The health of the top-level vdev, such as mirror or raidz device, is potentially impacted by the state of its associated vdevs, or component devices. A top-level vdev or component device is in one of the following states:

`DEGRADED`
One or more top-level vdevs is in the degraded state because one or more component devices are offline. Sufficient replicas exist to continue functioning.

One or more component devices is in the degraded or faulted state, but sufficient replicas exist to continue functioning. The underlying conditions are as follows:

- The number of checksum errors exceeds acceptable levels and the device is degraded as an indication that something may be wrong. ZFS continues to use the device as necessary.
- The number of I/O errors exceeds acceptable levels. The device could not be marked as faulted because there are insufficient replicas to continue functioning.

`FAULTED`
One or more top-level vdevs is in the faulted state because one or more component devices are offline. Insufficient replicas exist to continue functioning.

One or more component devices is in the faulted state, and insufficient replicas exist to continue functioning. The underlying conditions are as follows:

- The device could be opened, but the contents did not match expected values.
- The number of I/O errors exceeds acceptable levels and the device is faulted to prevent further use of the device.

`OFFLINE`
The device was explicitly taken offline by the "`zpool offline`" command.

`ONLINE`
The device is online and functioning.

`REMOVED`
The device was physically removed while the system was running. Device removal detection is hardware-dependent and may not be supported on all platforms.

`UNAVAIL`
The device could not be opened. If a pool is imported when a device was unavailable, then the device will be identified by a unique identifier instead of its path since the path was never correct in the first place.

If a device is removed and later reattached to the system, ZFS attempts to put the device online automatically. Device attachment detection is hardware-dependent and might not be supported on all platforms.

Hot Spares ZFS allows devices to be associated with pools as *hot spares*. These devices are not actively used in the pool, but when an active device fails, it is automatically replaced by a hot spare. To create a pool with hot spares, specify a `spare` vdev with any number of devices. For example,

```
# zpool create pool mirror c0d0 c1d0 spare c2d0 c3d0
```

Spares can be shared across multiple pools, and can be added with the `zpool add` command and removed with the `zpool remove` command. When a spare replacement is initiated, a new `spare` vdev is created within the configuration that will remain there until the original device is replaced. At this point, the hot spare becomes available again if another device fails.

If a pool has a shared spare that is currently being used, the pool can not be exported since other pools may use this shared spare, which may lead to potential data corruption.

An in-progress spare replacement can be cancelled by detaching the hot spare. If the original faulted device is detached, then the hot spare assumes its place in the configuration, and is removed from the spare list of all active pools.

Spares cannot replace log devices.

Intent Log

The ZFS Intent Log (ZIL) satisfies POSIX requirements for synchronous transactions. For instance, databases often require their transactions to be on stable storage devices when returning from a system call. NFS and other applications can also use `fsync()` to ensure data stability. By default, the intent log is allocated from blocks within the main pool. However, it might be possible to get better performance using separate intent log devices such as NVRAM or a dedicated disk. For example:

```
# zpool create pool c0d0 c1d0 log c2d0
```

Multiple log devices can also be specified, and they can be mirrored. See the "EXAMPLES" section for an example of mirroring multiple log devices.

Log devices can be added, replaced, attached, detached, and imported and exported as part of the larger pool. Mirrored log devices can be removed by specifying the top-level mirror for the log.

Cache Devices

Devices can be added to a storage pool as *cache devices*. These devices provide an additional layer of caching between main memory and disk. For read-heavy workloads, where the working set size is much larger than what can be cached in main memory, using cache devices allow much more of this working set to be served from low latency media. Using cache devices provides the greatest performance improvement for random read-workloads of mostly static content.

To create a pool with cache devices, specify a `cache` vdev with any number of devices. For example:

```
# zpool create pool c0d0 c1d0 cache c2d0 c3d0
```

Cache devices cannot be mirrored or part of a RAID-2 configuration. If a read error is encountered on a cache device, that read I/O is reissued to the original storage pool device, which might be part of a mirrored or RAID-2 configuration.

The content of the cache devices is considered volatile, as is the case with other system caches.

Processes

Each imported pool has an associated process, named `zpool-`*poolname*. The threads in this process are the pool's I/O processing threads, which handle the compression, checksumming, and other tasks for all I/O associated with the pool. This process exists to provides visibility into the CPU utilization of the system's storage pools. The existence of this process is an unstable interface.

Properties Each pool has several properties associated with it. Some properties are read-only statistics while others are configurable and change the behavior of the pool. The following are read-only properties:

`allocated`
Amount of storage space within the pool that has been physically allocated. This property can also be referred to by its shortened column name, `alloc`.

`capacity`
Percentage of pool space used. This property can also be referred to by its shortened column name, `cap`.

`free`
Number of blocks within the pool that are not allocated.

`guid`
A unique identifier for the pool.

`health`
The current health of the pool. Health can be `ONLINE`, `DEGRADED`, `FAULTED`, `OFFLINE`, `REMOVED`, or `UNAVAIL`.

`size`
Total size of the storage pool.

These space usage properties report actual physical space available to the storage pool. The physical space can be different from the total amount of space that any contained datasets can actually use. The amount of space used in a raidz configuration depends on the characteristics of the data being written. In addition, ZFS reserves some space for internal accounting that the `zfs(1M)` command takes into account, but the `zpool` command does not. For non-full pools of a reasonable size, these effects should be invisible. For small pools, or pools that are close to being completely full, these discrepancies may become more noticeable.

The following property can be set at creation time and import time:

`altroot`
Alternate root directory. If set, this directory is prepended to any mount points within the pool. This can be used when examining an unknown pool where the mount points cannot be trusted, or in an alternate boot environment, where the typical paths are not valid. `altroot` is not a persistent property. It is valid only while the system is up. Setting `altroot` defaults to using `cachefile=none`, though this value may be overridden using an explicit setting.

The following properties can be set at creation time and import time, and later changed with the `zpool set` command:

`autoexpand=on | off`
Controls automatic pool expansion when the underlying LUN is grown. If set to `on`, the pool is resized according to the size of the expanded device. If the device is part of a `mirror`

or `raidz` configuration, then all devices within that `mirror` or`raidz` group must be expanded before the new space is made available to the pool. The default behavior is `off`. This property can also be referred to by its shortened column name, `expand`.

`autoreplace=on | off`
Controls automatic device replacement. If set to `off`, device replacement must be initiated by the administrator by using the `zpool replace` command. If set to `on`, any new device, found in the same physical location as a device that previously belonged to the pool, is automatically formatted and replaced. The default behavior is `off`. This property can also be referred to by its shortened column name, `replace`.

`bootfs=`*pool*`/`*dataset*
Identifies the default bootable dataset for the root pool. This property is expected to be set mainly by the installation and upgrade programs.

`cachefile=`*path* | `none`
Controls the location of where the pool configuration is cached. Discovering all pools on system startup requires a cached copy of the configuration data that is stored on the root file system. All pools in this cache are automatically imported when the system boots. Some environments, such as install and clustering, need to cache this information in a different location so that pools are not automatically imported. Setting this property caches the pool configuration in a different location that can later be imported with `zpool import -c`. Setting it to the special value `none` creates a temporary pool that is never cached, and the special value `''` (empty string) uses the default location.

Multiple pools can share the same cache file. Because the kernel destroys and recreates this file when pools are added and removed, care should be taken when attempting to access this file. When the last pool using a `cachefile` is exported or destroyed, the file is removed.

`delegation=on | off`
Controls whether a non-privileged user is granted access based on the dataset permissions defined on the dataset. See `zfs(1M)` for more information on ZFS delegated administration.

`failmode=wait | continue | panic`
Controls the system behavior in the event of catastrophic pool failure. This condition is typically a result of a loss of connectivity to the underlying storage device(s) or a failure of all devices within the pool. The behavior of such an event is determined as follows:

`wait`
Blocks all I/O access to the pool until the device connectivity is recovered and the errors are cleared. A pool remains in the wait state until the device issue is resolved. This is the default behavior.

`continue`
Returns `EIO` to any new write I/O requests but allows reads to any of the remaining healthy devices. Any write requests that have yet to be committed to disk would be blocked.

`panic`
Prints out a message to the console and generates a system crash dump.

`listsnaps`=on | off
Controls whether information about snapshots associated with this pool is output when `zfs list` is run without the `-t` option. The default value is `on`.

`version`=*version*
The current on-disk version of the pool. The pool version can be increased, but never decreased. The preferred method of updating pools is with the `zpool upgrade` command, though this property can be used when a specific version is needed for backwards compatibility. This property can be any number between 1 and the current version reported by `zpool upgrade -v`.

Subcommands

All subcommands that modify state are logged persistently to the pool in their original form.

The `zpool` command provides subcommands to create and destroy storage pools, add capacity to storage pools, and provide information about the storage pools. The following subcommands are supported:

`zpool -?`
Displays a help message.

`zpool add` [`-fn`] *pool vdev ...*
Adds the specified virtual devices to the given pool. The *vdev* specification is described in the "Virtual Devices" section. The behavior of the `-f` option, and the device checks performed are described in the zpool create subcommand.

`-f`
Forces use of *vdevs*, even if they appear in use or specify a conflicting replication level. Not all devices can be overridden in this manner.

`-n`
Displays the configuration that would be used without actually adding the *vdev*s. The actual pool creation can still fail due to insufficient privileges or device sharing.

Do not add a disk that is currently configured as a quorum device to a storage pool. After a disk is in the pool, that disk can then be configured as a quorum device.

`zpool attach` [`-f`] *pool device new_device*
Attaches *new_device* to an existing `zpool` device. The existing device cannot be part of a raidz configuration. If *device* is not currently part of a mirrored configuration, *device* automatically transforms into a two-way mirror of *device* and *new_device*. If *device* is part of a two-way mirror, attaching *new_device* creates a three-way mirror, and so on. In either case, *new_device* begins to resilver immediately.

`-f`
Forces use of *new_device*, even if its appears to be in use. Not all devices can be overridden in this manner.

`zpool clear` [`-F` [`-n`]] *pool* [*device*] ...
Clears device errors in a pool. If no arguments are specified, all device errors within the pool are cleared. If one or more devices is specified, only those errors associated with the specified device or devices are cleared.

`-F`
Initiates recovery mode for an unopenable pool. Attempts to discard the last few transactions in the pool to return it to an openable state. Not all damaged pools can be recovered by using this option. If successful, the data from the discarded transactions is irretrievably lost.

`-n`
Used in combination with the `-F` flag. Check whether discarding transactions would make the pool openable, but do not actually discard any transactions.

`zpool create` [`-fn`] [`-o` *property=value*] ... [`-O` *file-system-property=value*] ... [`-m` *mountpoint*] [`-R` *root*] *pool vdev* ...
Creates a new storage pool containing the virtual devices specified on the command line. The pool name must begin with a letter, and can only contain alphanumeric characters as well as underscore (_), dash (-), and period (“.”). The pool names `mirror`, `raidz`, `raidz1`, `raidz2`, `raidz3`, `spare`, and `log` are reserved, as are names beginning with the pattern `c[0-9]`. The *vdev* specification is described in the “Virtual Devices” section.

The command verifies that each device specified is accessible and not currently in use by another subsystem. There are some uses, such as being currently mounted, or specified as the dedicated dump device, that prevents a device from ever being used by ZFS. Other uses, such as having a preexisting UFS file system, can be overridden with the `-f` option.

The command also checks that the replication strategy for the pool is consistent. An attempt to combine redundant and non-redundant storage in a single pool, or to mix disks and files, results in an error unless `-f` is specified. The use of differently sized devices within a single `raidz` or `mirror` group is also flagged as an error unless `-f` is specified.

Unless the `-R` option is specified, the default mount point is */pool*. The mount point must not exist or must be empty, or else the root dataset cannot be mounted. This can be overridden with the `-m` option.

`-f`
Forces use of *vdev*s, even if they appear in use or specify a conflicting replication level. Not all devices can be overridden in this manner.

`-n`
Displays the configuration that would be used without actually creating the pool. The actual pool creation can still fail due to insufficient privileges or device sharing.

`-o` *property=value* [`-o` *property=value*] ...
Sets the given pool properties. See the “Properties” section for a list of valid properties that can be set.

`-O` *file-system-property=value*
[`-O` *file-system-property=value*] ...
Sets the given file system properties in the root file system of the pool. See the "Properties" section of `zfs(1M)` for a list of valid properties that can be set.

`-R` *root*
Equivalent to `-o cachefile=none,altroot=`*root*

`-m` *mountpoint*
Sets the mount point for the root dataset. The default mount point is /*pool* or `altroot`/*pool* if `altroot` is specified. The mount point must be an absolute path, `legacy`, or `none`. For more information on dataset mount points, see `zfs(1M)`.

`zpool destroy` [`-f`] *pool*
Destroys the given pool, freeing up any devices for other use. This command tries to unmount any active datasets before destroying the pool.

`-f`
Forces any active datasets contained within the pool to be unmounted.

`zpool detach` *pool device*
Detaches *device* from a mirror. The operation is refused if there are no other valid replicas of the data.

`zpool export` [`-f`] *pool* ...
Exports the given pools from the system. All devices are marked as exported, but are still considered in use by other subsystems. The devices can be moved between systems (even those of different endianness) and imported as long as a sufficient number of devices are present.

Before exporting the pool, all datasets within the pool are unmounted. A pool can not be exported if it has a shared spare that is currently being used.

For pools to be portable, they must be created with whole disks, not just slices, so that ZFS can label the disks with portable EFI labels. Otherwise, disk drivers on platforms of different endianness will not recognize the disks.

`-f`
Forcefully unmount all datasets, using the `unmount -f` command.

This command will forcefully export the pool even if it has a shared spare that is currently being used. This may lead to potential data corruption.

`zpool get all` | *property*[,...] *pool* ...
Retrieves the given list of properties (or all properties if `all` is used) for the specified storage pool(s). These properties are displayed with the following fields:

```
name          Name of storage pool
 property      Property name
 value         Property value
```

```
source        Property source, either 'default' or 'local'.
```

See the "Properties" section for more information on available pool properties.

`zpool history` [`-il`] [*pool*] ...
Displays the command history of the specified pools or all pools if no pool is specified.

`-i`
Displays internally logged ZFS events in addition to user initiated events.

`-l`
Displays log records in long format, which in addition to standard format includes, the user name, the hostname, and the zone in which the operation was performed.

`zpool import` [`-d` *dir* | `-c` *cachefile*] [`-D`]
Lists pools available to import. If the `-d` option is not specified, this command searches for devices in `/dev/dsk`. The `-d` option can be specified multiple times, and all directories are searched. If the device appears to be part of an exported pool, this command displays a summary of the pool with the name of the pool, a numeric identifier, as well as the *vdev* layout and current health of the device for each device or file. Destroyed pools, pools that were previously destroyed with the `zpool destroy` command, are not listed unless the `-D` option is specified.

The numeric identifier is unique, and can be used instead of the pool name when multiple exported pools of the same name are available.

`-c` *cachefile*
Reads the pool configuration information from the given `cachefile` that was created with the `cachefile` pool property. This `cachefile` is used instead of searching for devices.

`-d` *dir*
Searches for devices or files in *dir*. The `-d` option can be specified multiple times.

`-D`
Lists destroyed pools only.

`zpool import` [`-o` *mntopts*] [`-o` *property*=*value*] ... [`-d` *dir* | `-c` *cachefile*] [`-D`] [`-f`] [`-R` *root*] [`-F` [`-n`]] `-a`
Imports all pools found in the search directories. Identical to the previous command, except that all pools with a sufficient number of devices available are imported. Destroyed pools, pools that were previously destroyed with the `zpool destroy` command, will not be imported unless the `-D` option is specified.

`-o` *mntopts*
Comma-separated list of mount options to use when mounting datasets within the pool. See `zfs(1M)` for a description of dataset properties and mount options.

`-o` *property=value*
Sets the specified property on the imported pool. See the "Properties" section for more information on available pool properties.

`-c` *cachefile*
Reads the pool configuration information from the given `cachefile` that was created with the "`cachefile`" pool property. This `cachefile` is used instead of searching for devices.

`-d` *dir*
Searches for devices or files in *dir*. The `-d` option can be specified multiple times. This option is incompatible with the `-c` option.

`-D`
Imports destroyed pools only.

`-f`
Forces import, even if the pool appears to be potentially active.

`-F`
Recovery mode for a non-importable pool. Attempts to return the pool to an importable state by discarding the last few transactions. Not all damaged pools can be recovered by using this option. If successful, the data from the discarded transactions is irretrievably lost. This option is ignored if the pool is importable or already imported.

`-a`
Searches for and imports all pools found.

`-R` *root*
Sets the `cachefile` property to `none` and the *altroot* property to *root*.

`-n`
Used with the `-F` recovery option. Determines whether a non-importable pool can be made importable again, but does not actually perform the pool recovery. For more details about pool recovery mode, see the `-F` option, above.

`zpool import` [`-o` *mntopts*] [`-o` *property=value*] ... [`-d` *dir* | `-c` *cachefile*] [`-D`] [`-f`] [`-R` *root*] [`-F` [`-n`]] *pool* | *id* [*newpool*]
Imports a specific pool. A pool can be identified by its name or by the numeric identifier. If *newpool* is specified, the pool is imported using the name *newpool*. Otherwise, it is imported with the same name as its exported name.

If a device is removed from a system without running `zpool export` first, the device appears as potentially active. It cannot be determined if this was a failed export, or whether the device is really in use from another host. To import a pool in this state, the `-f` option is required.

`-o` *mntopts*
Comma-separated list of mount options to use when mounting datasets within the pool. See `zfs(1M)` for a description of dataset properties and mount options.

`-o` *property=value*
Sets the specified property on the imported pool. See the "Properties" section for more information on available pool properties.

`-c` *cachefile*
Reads configuration from the given `cachefile` that was created with the `cachefile` pool property. This `cachefile` is used instead of searching for devices.

`-d` *dir*
Searches for devices or files in *dir*. The `-d` option can be specified multiple times. This option is incompatible with the `-c` option.

`-D`
Imports destroyed pool. The `-f` option is also required.

`-f`
Forces import, even if the pool appears to be potentially active.

`-F`
Recovery mode for a non-importable pool. Attempts to return the pool to an importable state by discarding the last few transactions. Not all damaged pools can be recovered by using this option. If successful, the data from the discarded transactions is irretrievably lost. This option is ignored if the pool is importable or already imported.

`-R` *root*
Sets the `cachefile` property to `none` and the *altroot* property to *root*.

`-n`
Used with the `-F` recovery option. Determines whether a non-importable pool can be made importable again, but does not actually perform the pool recovery. For more details about pool recovery mode, see the `-F` option, above.

`zpool iostat` [`-v`] [*pool*] ... [*interval*[*count*]]
Displays I/O statistics for the given pools. When given an interval, the statistics are printed every *interval* seconds until `Ctrl-C` is pressed. If no *pools* are specified, statistics for every pool in the system is shown. If *count* is specified, the command exits after *count* reports are printed.

`-v`
Verbose statistics. Reports usage statistics for individual *vdevs* within the pool, in addition to the pool-wide statistics.

`zpool list` [`-H`] [`-o` *props*[,...]] [*pool*] ...
Lists pool health status and space usage. The default list of properties displayed is `name`, `size`, `allocated`, `free`, `capacity`, `health`, and `altroot`. With no arguments, all pools in the system are listed.

`-H`
Scripted mode. Do not display headers, and separate fields by a single tab instead of arbitrary space.

`-o` *props*
Comma-separated list of properties to display. See the "Properties" section for a list of valid properties.

`zpool offline` [`-t`] *pool device* ...
Takes the specified physical device offline. While the *device* is offline, no attempt is made to read or write to the device.

This command is not applicable to spares or cache devices.

`-t`
Temporary. Upon reboot, the specified physical device reverts to its previous state.

`zpool online` [`-e`] *pool device*...
Brings the specified physical device online.

This command is not applicable to spares or cache devices.

`-e`
Expand the device to use all available space. If the device is part of a mirrored RAID-2 configuration, then all devices must be expanded before the new space is made available to the pool.

`zpool remove` *pool device* ...
Removes the specified device from the pool. This command currently only supports removing hot spares, cache, and log devices. A mirrored log device can be removed by specifying the top-level mirror for the log. Non-log devices that are part of a mirrored configuration can be removed using the `zpool detach` command. Non-redundant and raidz devices cannot be removed from a pool.

`zpool replace` [`-f`] *pool old_device* [*new_device*]
Replaces *old_device* with *new_device*. This is equivalent to attaching *new_device*, waiting for it to resilver, and then detaching *old_device*.

The size of *new_device* must be greater than or equal to the minimum size of all the devices in a mirror or raidz configuration.

new_device is required if the pool is not redundant. If *new_device* is not specified, it defaults to *old_device*. This form of replacement is useful after an existing disk has failed and has been physically replaced. In this case, the new disk may have the same `/dev/dsk` path as the old device, even though it is actually a different disk. ZFS recognizes this.

`-f`
Forces use of *new_device*, even if its appears to be in use. Not all devices can be overridden in this manner.

`zpool scrub` [`-s`] *pool* ...
Begins a scrub. The scrub examines all data in the specified pools to verify that it checksums correctly. For replicated (`mirror` or `raidz`) devices, ZFS automatically repairs

any damage discovered during the scrub. The `zpool status` command reports the progress of the scrub and summarizes the results of the scrub upon completion.

Scrubbing and resilvering are very similar operations. The difference is that resilvering only examines data that ZFS knows to be out of date (for example, when attaching a new device to a mirror or replacing an existing device), whereas scrubbing examines all data to discover silent errors due to hardware faults or disk failure.

Because scrubbing and resilvering are I/O-intensive operations, ZFS only allows one at a time. If a scrub is already in progress, the "`zpool scrub`" command terminates it and starts a new scrub. If a resilver is in progress, ZFS does not allow a scrub to be started until the resilver completes.

`-s`
Stop scrubbing.

`zpool set` *property=value pool*
Sets the given property on the specified pool. See the "Properties" section for more information on what properties can be set and acceptable values.

`zpool split` [`-R` *altroot*] [`-n`] [`-o` *mntopts*] [`-o` *property=value*] *pool newpool* [*device* ...]
Splits off one disk from each mirrored top-level vdev in a pool and creates a new pool from the split-off disks. The original pool must be made up of one or more mirrors and must not be in the process of resilvering. The `split` subcommand chooses the last device in each mirror vdev unless overridden by a device specification on the command line.

When using a *device* argument, `split` includes the specified device(s) in a new pool and, should any devices remain unspecified, assigns the last device in each mirror vdev to that pool, as it does normally. If you are uncertain about the outcome of a `split` command, use the `-n` (*dry-run*) option to confirm the intended command syntax.

`-R` *altroot*
Automatically import the newly created pool after splitting, using the specified *altroot* parameter for the new pool's alternate root. See the `altroot` description in the "Properties" section, above.

`-n`
Displays the configuration that would be created without actually splitting the pool. The actual pool split could still fail due to insufficient privileges or device status.

`-o` *mntopts*
Comma-separated list of mount options to use when mounting datasets within the pool. See `zfs(1M)` for a description of dataset properties and mount options. Valid only in conjunction with the `-R` option.

`-o` *property=value*
Sets the specified property on the new pool. See the "Properties" section, above, for more information on available pool properties.

`zpool status` [`-xv`] [*pool*] ...
Displays the detailed health status for the given pools. If no *pool* is specified, then the status of each pool in the system is displayed. For more information on pool and device health, see the "Device Failure and Recovery" section.

If a scrub or resilver is in progress, this command reports the percentage done and the estimated time to completion. Both of these are only approximate, because the amount of data in the pool and the other workloads on the system can change.

`-x`
Only display status for pools that are exhibiting errors or are otherwise unavailable.

`-v`
Displays verbose data error information, printing out a complete list of all data errors since the last complete pool scrub.

`zpool upgrade`
Identifies a pool's on-disk version, which determines available pool features in the currently running software release. You can continue to use older pool versions, but some features may not be available. A pool can be upgraded by using the `zpool upgrade -a` command. You will not be able to access a pool of a later version on a system that runs an earlier software version.

`zpool upgrade -v`
Displays ZFS versions supported by the current software. The current ZFS pool versions and all previous supported versions are displayed, along with an explanation of the features provided with each version.

`zpool upgrade` [`-V` *version*] `-a` | *pool* ...
Upgrades the given pool to the latest on-disk version. If this command identifies that a pool is out-of-date, then it can be upgraded by using the `zpool upgrade -a` command. A pool that is upgraded will not be accessible on a system that runs an earlier software release.

`-a`
Upgrades all pools.

`-V` *version*
Upgrade to the specified version. If the `-V` flag is not specified, the pool is upgraded to the most recent version. This option can only be used to increase the version number, and only up to the most recent version supported by this software.

Examples

EXAMPLE 1 Creating a RAID-Z Storage Pool

The following command creates a pool with a single raidz root *vdev* that consists of six disks.

```
# zpool create tank raidz c0t0d0 c0t1d0 c0t2d0 c0t3d0 c0t4d0 c0t5d0
```

EXAMPLE 2 Creating a Mirrored Storage Pool

The following command creates a pool with two mirrors, where each mirror contains two disks.

```
# zpool create tank mirror c0t0d0 c0t1d0 mirror c0t2d0 c0t3d0
```

EXAMPLE 3 Adding a Mirror to a ZFS Storage Pool

The following command adds two mirrored disks to the pool *tank*, assuming the pool is already made up of two-way mirrors. The additional space is immediately available to any datasets within the pool.

```
# zpool add tank mirror c1t0d0 c1t1d0
```

EXAMPLE 4 Listing Available ZFS Storage Pools

The following command lists all available pools on the system.

```
# zpool list
NAME    SIZE  ALLOC   FREE    CAP  HEALTH  ALTROOT
pool    136G  95.5K   136G     0%  ONLINE  -
rpool    93G   111K  93.0G     0%  ONLINE  -
```

EXAMPLE 5 Listing All Properties for a Pool

The following command lists all the properties for a pool.

```
% zpool get all pool
NAME  PROPERTY       VALUE       SOURCE
pool  size           136G        -
pool  capacity       0%          -
pool  altroot        -           default
pool  health         ONLINE      -
pool  guid           4898854009727303489  default
pool  version        22          default
pool  bootfs         -           default
pool  delegation     on          default
pool  autoreplace    off         default
pool  cachefile      -           default
pool  failmode       wait        default
pool  listsnapshots  off         default
pool  autoexpand     off         default
pool  free           136G        -
pool  allocated      76.5K       -
```

EXAMPLE 6 Destroying a ZFS Storage Pool

The following command destroys the pool `tank` and any datasets contained within.

```
# zpool destroy -f tank
```

EXAMPLE 7 Exporting a ZFS Storage Pool

The following command exports the devices in pool `tank` so that they can be relocated or later imported.

```
# zpool export tank
```

EXAMPLE 8 Importing a ZFS Storage Pool

The following command displays available pools, and then imports the pool `tank` for use on the system.

The results from this command are similar to the following:

```
# zpool import
  pool: tank
    id: 7678868315469843843
 state: ONLINE
action: The pool can be imported using its name or numeric identifier.
config:

        tank        ONLINE
          mirror-0  ONLINE
            c1t2d0  ONLINE
            c1t3d0  ONLINE

# zpool import tank
```

EXAMPLE 9 Upgrading All ZFS Storage Pools to the Current Version

The following command upgrades all ZFS Storage pools to the current version of the software.

```
# zpool upgrade -a
This system is currently running ZFS pool version 22.

All pools are formatted using this version.
```

EXAMPLE 10 Managing Hot Spares

The following command creates a new pool with an available hot spare:

```
# zpool create tank mirror c0t0d0 c0t1d0 spare c0t2d0
```

If one of the disks were to fail, the pool would be reduced to the degraded state. The failed device can be replaced using the following command:

```
# zpool replace tank c0t0d0 c0t3d0
```

After the device has been resilvered, the spare is automatically detached and is made available should another device fail. The hot spare can be permanently removed from the pool using the following command:

```
# zpool remove tank c0t2d0
```

EXAMPLE 11 Creating a ZFS Pool with Mirrored Separate Intent Logs

The following command creates a ZFS storage pool consisting of two, two-way mirrors and mirrored log devices:

```
# zpool create pool mirror c0d0 c1d0 mirror c2d0 c3d0 log mirror \
   c4d0 c5d0
```

EXAMPLE 12 Adding Cache Devices to a ZFS Pool

The following command adds two disks for use as cache devices to a ZFS storage pool:

```
# zpool add pool cache c2d0 c3d0
```

Once added, the cache devices gradually fill with content from main memory. Depending on the size of your cache devices, it could take over an hour for them to fill. Capacity and reads can be monitored using the `iostat` option as follows:

```
# zpool iostat -v pool 5
```

EXAMPLE 13 Removing a Mirrored Log Device

The following command removes the mirrored log device `mirror-2`.

Given this configuration:

```
   pool: tank
  state: ONLINE
  scrub: none requested
config:

        NAME        STATE     READ WRITE CKSUM
        tank        ONLINE       0     0     0
          mirror-0  ONLINE       0     0     0
            c6t0d0  ONLINE       0     0     0
            c6t1d0  ONLINE       0     0     0
          mirror-1  ONLINE       0     0     0
            c6t2d0  ONLINE       0     0     0
            c6t3d0  ONLINE       0     0     0
        logs
          mirror-2  ONLINE       0     0     0
            c4t0d0  ONLINE       0     0     0
            c4t1d0  ONLINE       0     0     0
```

The command to remove the mirrored log `mirror-2` is:

```
# zpool remove tank mirror-2
```

EXAMPLE 14 Recovering a Faulted ZFS Pool

If a pool is faulted but recoverable, a message indicating this state is provided by `zpool status` if the pool was cached (see `cachefile` above), or as part of the error output from a failed `zpool import` of the pool.

EXAMPLE 14 Recovering a Faulted ZFS Pool *(Continued)*

Recover a cached pool with the `zpool clear` command:

```
# zpool clear -F data
Pool data returned to its state as of Tue Sep 08 13:23:35 2009.
Discarded approximately 29 seconds of transactions.
```

If the pool configuration was not cached, use `zpool import` with the recovery mode flag:

```
# zpool import -F data
Pool data returned to its state as of Tue Sep 08 13:23:35 2009.
Discarded approximately 29 seconds of transactions.
```

Exit Status

The following exit values are returned:

`0`
: Successful completion.

`1`
: An error occurred.

`2`
: Invalid command line options were specified.

Attributes

Name zuludaemon – load microcode for Sun XVR-4000 Graphics Accelerator device

Synopsis

```
/usr/sbin/zuludaemon [-dev zulu_device]
```

Description The `zuludaemon` is a daemon, started and stopped from a script in `/etc/init.d`, that loads the microcode and provides other support functions for the Sun XVR-4000 Graphics Accelerator device. Do not kill this process. This deamon is essential to the `zulu(7d)` driver.

The `zuludaemon` process is not configurable.

Options

`-dev` *zulu_device* name of the Sun XVR-4000 Graphics Accelerator device

Files

`/usr/sbin/zuludaemon` daemon executable

`/usr/lib/zulu.ucode` file containing microcode used by `zuludaemon`

`/etc/init.d/zuluinit` startup/kill script for `zuludaemon`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWzuluc
