This software and related documentation are provided under a license agreement containing restrictions on use and disclosure and are protected by intellectual property laws. Except as expressly permitted in your license agreement or allowed by law, you may not use, copy, reproduce, translate, broadcast, modify, license, transmit, distribute, exhibit, perform, publish, or display any part, in any form, or by any means. Reverse engineering, disassembly, or decompilation of this software, unless required by law for interoperability, is prohibited.

The information contained herein is subject to change without notice and is not warranted to be error-free. If you find any errors, please report them to us in writing.

If this is software or related software documentation that is delivered to the U.S. Government or anyone licensing it on behalf of the U.S. Government, the following notice is applicable:

U.S. GOVERNMENT RIGHTS Programs, software, databases, and related documentation and technical data delivered to U.S. Government customers are "commercial computer software" or "commercial technical data" pursuant to the applicable Federal Acquisition Regulation and agency-specific supplemental regulations. As such, the use, duplication, disclosure, modification, and adaptation shall be subject to the restrictions and license terms set forth in the applicable Government contract, and, to the extent applicable by the terms of the Government contract, the additional rights set forth in FAR 52.227-19, Commercial Computer Software License (December 2007). Oracle America, Inc., 500 Oracle Parkway, Redwood City, CA 94065.

This software or hardware is developed for general use in a variety of information management applications. It is not developed or intended for use in any inherently dangerous applications, including applications which may create a risk of personal injury. If you use this software or hardware in dangerous applications, then you shall be responsible to take all appropriate fail-safe, backup, redundancy, and other measures to ensure its safe use. Oracle Corporation and its affiliates disclaim any liability for any damages caused by use of this software or hardware in dangerous applications.

Oracle and Java are registered trademarks of Oracle and/or its affiliates. Other names may be trademarks of their respective owners.

AMD, Opteron, the AMD logo, and the AMD Opteron logo are trademarks or registered trademarks of Advanced Micro Devices. Intel and Intel Xeon are trademarks or registered trademarks of Intel Corporation. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. UNIX is a registered trademark licensed through X/Open Company, Ltd.

This software or hardware and documentation may provide access to or information on content, products, and services from third parties. Oracle Corporation and its affiliates are not responsible for and expressly disclaim all warranties of any kind with respect to third-party content, products, and services. Oracle Corporation and its affiliates will not be responsible for any loss, costs, or damages incurred due to your access to or use of third-party content, products, or services.

Preface

Both novice users and those familiar with the SunOS operating system can use online man pages to obtain information about the system and its features. A man page is intended to answer concisely the question “What does it do?” The man pages in general comprise a reference manual. They are not intended to be a tutorial.

Overview

The following contains a brief description of each man page section and the information it references:

- Section 1 describes, in alphabetical order, commands available with the operating system.
- Section 1M describes, in alphabetical order, commands that are used chiefly for system maintenance and administration purposes.
- Section 2 describes all of the system calls. Most of these calls have one or more error returns. An error condition is indicated by an otherwise impossible returned value.
- Section 3 describes functions found in various libraries, other than those functions that directly invoke UNIX system primitives, which are described in Section 2.
- Section 4 outlines the formats of various files. The C structure declarations for the file formats are given where applicable.
- Section 5 contains miscellaneous documentation such as character-set tables.
- Section 7 describes various special files that refer to specific hardware peripherals and device drivers. STREAMS software drivers, modules and the STREAMS-generic set of system calls are also described.
- Section 9E describes the DDI (Device Driver Interface)/DKI (Driver/Kernel Interface), DDI-only, and DKI-only entry-point routines a developer can include in a device driver.
- Section 9F describes the kernel functions available for use by device drivers.
- Section 9S describes the data structures used by drivers to share information between the driver and the kernel.

Below is a generic format for man pages. The man pages of each manual section generally follow this order, but include only needed headings. For example, if there are no bugs to report,

there is no BUGS section. See the intro pages for more information and detail about each section, and [man\(1\)](#) for more information about man pages in general.

NAME	This section gives the names of the commands or functions documented, followed by a brief description of what they do.
SYNOPSIS	<p>This section shows the syntax of commands or functions. When a command or file does not exist in the standard path, its full path name is shown. Options and arguments are alphabetized, with single letter arguments first, and options with arguments next, unless a different argument order is required.</p> <p>The following special characters are used in this section:</p> <ul style="list-style-type: none">[] Brackets. The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.. . . Ellipses. Several values can be provided for the previous argument, or the previous argument can be specified multiple times, for example, "filename . . .". Separator. Only one of the arguments separated by this character can be specified at a time.{ } Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.
PROTOCOL	This section occurs only in subsection 3R to indicate the protocol description file.
DESCRIPTION	This section defines the functionality and behavior of the service. Thus it describes concisely what the command does. It does not discuss OPTIONS or cite EXAMPLES. Interactive commands, subcommands, requests, macros, and functions are described under USAGE.
IOCTL	This section appears on pages in Section 7 only. Only the device class that supplies appropriate parameters to the ioctl(2) system call is called <code>ioctl</code> and generates its own heading. <code>ioctl</code> calls for a specific device are listed alphabetically (on the man page for that specific device).

	<p><code>ioctl</code> calls are used for a particular class of devices all of which have an <code>io</code> ending, such as <code>mtio(7I)</code>.</p>
OPTIONS	<p>This section lists the command options with a concise summary of what each option does. The options are listed literally and in the order they appear in the SYNOPSIS section. Possible arguments to options are discussed under the option, and where appropriate, default values are supplied.</p>
OPERANDS	<p>This section lists the command operands and describes how they affect the actions of the command.</p>
OUTPUT	<p>This section describes the output – standard output, standard error, or output files – generated by the command.</p>
RETURN VALUES	<p>If the man page documents functions that return values, this section lists these values and describes the conditions under which they are returned. If a function can return only constant values, such as 0 or -1, these values are listed in tagged paragraphs. Otherwise, a single paragraph describes the return values of each function. Functions declared void do not return values, so they are not discussed in RETURN VALUES.</p>
ERRORS	<p>On failure, most functions place an error code in the global variable <code>errno</code> indicating why they failed. This section lists alphabetically all error codes a function can generate and describes the conditions that cause each error. When more than one condition can cause the same error, each condition is described in a separate paragraph under the error code.</p>
USAGE	<p>This section lists special rules, features, and commands that require in-depth explanations. The subsections listed here are used to explain built-in functionality:</p> <ul style="list-style-type: none">CommandsModifiersVariablesExpressionsInput Grammar
EXAMPLES	<p>This section provides examples of usage or of how to use a command or function. Wherever possible a complete</p>

	<p>example including command-line entry and machine response is shown. Whenever an example is given, the prompt is shown as <code>example%</code>, or if the user must be superuser, <code>example#</code>. Examples are followed by explanations, variable substitution rules, or returned values. Most examples illustrate concepts from the SYNOPSIS, DESCRIPTION, OPTIONS, and USAGE sections.</p>
ENVIRONMENT VARIABLES	<p>This section lists any environment variables that the command or function affects, followed by a brief description of the effect.</p>
EXIT STATUS	<p>This section lists the values the command returns to the calling program or shell and the conditions that cause these values to be returned. Usually, zero is returned for successful completion, and values other than zero for various error conditions.</p>
FILES	<p>This section lists all file names referred to by the man page, files of interest, and files created or required by commands. Each is followed by a descriptive summary or explanation.</p>
ATTRIBUTES	<p>This section lists characteristics of commands, utilities, and device drivers by defining the attribute type and its corresponding value. See attributes(5) for more information.</p>
SEE ALSO	<p>This section lists references to other man pages, in-house documentation, and outside publications.</p>
DIAGNOSTICS	<p>This section lists diagnostic messages with a brief explanation of the condition causing the error.</p>
WARNINGS	<p>This section lists warnings about special conditions which could seriously affect your working conditions. This is not a list of diagnostics.</p>
NOTES	<p>This section lists additional information that does not belong anywhere else on the page. It takes the form of an aside to the user, covering points of special interest. Critical information is never covered here.</p>
BUGS	<p>This section describes known bugs and, wherever possible, suggests workarounds.</p>

R E F E R E N C E

Introduction

Name Intro – introduction to maintenance commands and application programs

Description This section describes, in alphabetical order, commands that are used chiefly for system maintenance and administration purposes.

Because of command restructuring for the Virtual File System architecture, there are several instances of multiple manual pages that begin with the same name. For example, the `mount`, pages – `mount(1M)`, `mount_cachefs(1M)`, `mount_hsf(1M)`, `mount_nfs(1M)`, `mount_tmpfs(1M)`, and `mount_ufs(1M)`. In each such case the first of the multiple pages describes the syntax and options of the generic command, that is, those options applicable to all FSTypes (file system types). The succeeding pages describe the functionality of the FSType-specific modules of the command. These pages list the command followed by an underscore (`_`) and the FSType to which they pertain. Note that the administrator should not attempt to call these modules directly. The generic command provides a common interface to all of them. Thus the FSType-specific manual pages should not be viewed as describing distinct commands, but rather as detailing those aspects of a command that are specific to a particular FSType.

Command Syntax Unless otherwise noted, commands described in this section accept options and other arguments according to the following syntax:

name [*option*(*s*)] [*cmdarg*(*s*)]

where:

name The name of an executable file.

option – *noargletter*(*s*) or,
 – *argletter*< >*optarg*

where < > is optional white space.

noargletter A single letter representing an option without an argument.

argletter A single letter representing an option requiring an argument.

optarg Argument (character string) satisfying preceding *argletter*.

cmdarg Pathname (or other command argument) *not* beginning with – or, – by itself indicating the standard input.

Attributes See `attributes(5)` for a discussion of the attributes listed in this section.

Acknowledgments Sun Microsystems, Inc. gratefully acknowledges The Open Group for permission to reproduce portions of its copyrighted documentation. Original documentation from The Open Group can be obtained online at <http://www.opengroup.org/bookstore/>.

The Institute of Electrical and Electronics Engineers and The Open Group, have given us permission to reprint portions of their documentation.

In the following statement, the phrase "this text" refers to portions of the system documentation.

Portions of this text are reprinted and reproduced in electronic form in the SunOS Reference Manual, from IEEE Std 1003.1, 2004 Edition, Standard for Information Technology -- Portable Operating System Interface (POSIX), The Open Group Base Specifications Issue 6, Copyright (C) 2001-2004 by the Institute of Electrical and Electronics Engineers, Inc and The Open Group. In the event of any discrepancy between these versions and the original IEEE and The Open Group Standard, the original IEEE and The Open Group Standard is the referee document. The original Standard can be obtained online at <http://www.opengroup.org/unix/online.html>.

This notice shall appear on any product containing this material.

See Also [getopt\(1\)](#), [getopt\(3C\)](#), [attributes\(5\)](#)

Diagnostics Upon termination, each command returns 0 for normal termination and non-zero to indicate troubles such as erroneous parameters, bad or inaccessible data, or other inability to cope with the task at hand. It is called variously "exit code," "exit status," or "return code," and is described only where special conventions are involved.

Notes Unfortunately, not all commands adhere to the standard syntax.

REFERENCE

System Administration Commands - Part 1

Name 6to4relay – administer configuration for 6to4 relay router communication

Synopsis /usr/sbin/6to4relay

/usr/sbin/6to4relay [-e] [-a *addr*]

/usr/sbin/6to4relay [-d]

/usr/sbin/6to4relay [-h]

Description The `6to4relay` command is used to configure 6to4 relay router communication. Relay router communication support is enabled by setting the value of a variable that stores an IPv4 address within the `tun` module. This variable is global to all tunnels and defines the policy for communication with relay routers. By default, the address is set to `INADDR_ANY (0.0.0.0)`, and the kernel interprets the value to indicate that support for relay router communication is disabled. Otherwise, support is enabled, and the specified address is used as the IPv4 destination address when packets destined for native IPv6 (non-6to4) hosts are sent through the 6to4 tunnel interface. The `6to4relay` command uses a project private `ioctl` to set the variable.

`6to4relay` used without any options outputs the current, in-kernel, configuration status. Use the `-a` option to send packets to a specific relay router's unicast address instead of the default anycast address. The address specified with the `-a` option does not specify the policy for receiving traffic from relay routers. The source relay router on a received packet is non-deterministic, since a different relay router may be chosen for each sending native IPv6 end-point.

Configuration changes made by using the `6to4relay` are not persistent across reboot. The changes will persist in the kernel only until you take the tunnel down

Options The `6to4relay` command supports the following options:

`-a addr` Use the specified address, *addr*.

`-e` Enable support for relay router. Use `-a addr` if it is specified. Otherwise, use the default anycast address, 192.88.99.1.

`-d` Disable support for the relay router.

`-h` Help

Operands The following operands are supported:

addr A specific relay router's unicast address. *addr* must be specified as a dotted decimal representation of an IPv4 address. Otherwise, an error will occur, and the command will fail.

Examples EXAMPLE 1 Printing the In-Kernel Configuration Status

Use `/usr/sbin/6to4relay` without any options to print the in-kernel configuration status.

example# **/usr/sbin/6to4relay**

EXAMPLE 1 Printing the In-Kernel Configuration Status (Continued)

If 6to4 relay router communication is disabled, the administrator will see the following message:

```
6to4relay: 6to4 Relay Router communication support is disabled.
```

If 6to4 router communication is enabled, the user will see this message:

```
6to4relay: 6to4 Relay Router communication support is enabled.
IPv4 destination address of Relay Router = 192.88.99.1
```

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Files /usr/sbin/6to4relay The default installation root

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs
Interface Stability	Committed

See Also [ifconfig\(1M\)](#), [attributes\(5\)](#)

Huitema, C. *RFC 3068, An Anycast Prefix for 6to4 Relay Routers*. Network Working Group. June, 2001.

Carpenter, B. and Moore, K. *RFC 3056, Connection of IPv6 Domains via IPv4 Clouds*. Network Working Group. February, 2001.

Diagnostics The 6to4relay reports the following messages:

```
6to4relay: input (0.0.0.0) is not a valid IPv4 unicast address
```

Example: The following example provides an incorrect unicast address.

```
example# 6to4relay -e -a 0.0.0.0
```

Description: The address specified with the -a option must be a valid unicast address.

```
6to4relay: option requires an argument -a
```

usage:

```
6to4relay
```

```
6to4relay -e [-a <addr>]
```

```
6to4relay -d
```

```
6to4relay -h
```

Example: The following example does not include an argument for the `-a` option.

```
example# 6to4relay -e -a
```

Description: The `-a` option requires an argument.

usage:

```
6to4relay
```

```
6to4relay -e [-a <addr>]
```

```
6to4relay -d
```

```
6to4relay -h
```

Example: The following example specifies options that are not permitted.

```
example# 6to4relay -e -d
```

Description: The options specified are not permitted. A usage message is output to the screen.

usage:

```
6to4relay
```

```
6to4relay -e [-a <addr>]
```

```
6to4relay -d
```

```
6to4relay -h
```

Example: The following example specifies the `-a` option without specifying the `-e` option.

```
example# 6to4relay -a 1.2.3.4
```

Description: The `-e` option is required in conjunction with the `-a` option. A usage message is output to the screen.

6to4relay: ioctl (I_STR) : Invalid argument

Example: The following example specifies an invalid address.

```
example# 6to4relay -e -a 239.255.255.255
```

Description: The address specified with the `-a` option must not be a class d *addr*.

- Name** accept, reject – accept or reject print requests
- Synopsis** accept *destination* . . .
 reject [-r *reason*] *destination* . . .
- Description** accept allows the queuing of print requests for the named destinations.
 reject prevents queuing of print requests for the named destinations.
 Use `lpstat -a` to check if destinations are accepting or rejecting print requests.
 Generally, accept and reject are run on the print server to control local print queues. Under some configurations, accept and reject are run on client systems when IPP is being used to communicate between client and server.
- Options** The following options are supported for reject:
- r *reason* Assigns a reason for rejection of print requests for *destination*.
reason is reported by `lpstat -a`. By default, *reason* is unknown reason for existing destinations, and new printer for destinations added to the system but not yet accepting requests. Enclose *reason* in quotes if it contains blanks.
- Operands** The following operands are supported:
- destination* The name of the destination accepting or rejecting print requests. Destination specifies the name of a printer or class of printers (see [lpadmin\(1M\)](#)). Specify *destination* using atomic name or URI-style (scheme://endpoint) names. See [printers.conf\(4\)](#) for information regarding the naming conventions for destinations.
- Exit Status** The following exit values are returned:
- 0 Successful completion.
 non-zero An error occurred.
- Files**
- | | |
|----------------------|---------------------------------------|
| /etc/printers.conf | System printer configuration database |
| \$HOME/.printers | User-configurable printer database |
| ou=printers | LDAP version of /etc/printers.conf |
| printers.conf.byname | NIS version of /etc/printers.conf |
- Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWlp-cmds

ATTRIBUTE TYPE	ATTRIBUTE VALUE
CSI	Enabled. See NOTES.
Interface Stability	Obsolete

See Also [enable\(1\)](#), [lp\(1\)](#), [lpstat\(1\)](#), [lpadmin\(1M\)](#), [lpsched\(1M\)](#), [printers.conf\(4\)](#), [attributes\(5\)](#)

Notes `accept` and `reject` affect only queuing on the print server's spooling system. Requests made from a client system remain queued in the client system's queuing mechanism until they are cancelled or accepted by the print server's spooling system.

`accept` is CSI-enabled except for the *destination* name.

When IPP is in use, the user is prompted for a passphrase if the remote print service is configured to require authentication.

- Name** acct, acctdisk, acctdusg, accton, acctwtmp, closewtmp, utmp2wtmp – overview of accounting and miscellaneous accounting commands
- Synopsis** /usr/lib/acct/acctdisk
 /usr/lib/acct/acctdusg [-u *filename*] [-p *filename*]
 /usr/lib/acct/accton [*filename*]
 /usr/lib/acct/acctwtmp *reason filename*
 /usr/lib/acct/closewtmp
 /usr/lib/acct/utmp2wtmp
- Description** Accounting software is structured as a set of tools (consisting of both C programs and shell procedures) that can be used to build accounting systems. [acctsh\(1M\)](#) describes the set of shell procedures built on top of the C programs.
- Connect time accounting is handled by various programs that write records into /var/adm/wtmpx, as described in [utmpx\(4\)](#). The programs described in [acctcon\(1M\)](#) convert this file into session and charging records, which are then summarized by [acctmerg\(1M\)](#).
- Process accounting is performed by the system kernel. Upon termination of a process, one record per process is written to a file (normally /var/adm/pacct). The programs in [acctprc\(1M\)](#) summarize this data for charging purposes; [acctcms\(1M\)](#) is used to summarize command usage. Current process data may be examined using [acctcom\(1\)](#).
- Process accounting records and connect time accounting records (or any accounting records in the tacct format described in [acct.h\(3HEAD\)](#)) can be merged and summarized into total accounting records by acctmerg (see tacct format in [acct.h\(3HEAD\)](#)). prtacct (see [acctsh\(1M\)](#)) is used to format any or all accounting records.
- acctdisk reads lines that contain user ID, login name, and number of disk blocks and converts them to total accounting records that can be merged with other accounting records. acctdisk returns an error if the input file is corrupt or improperly formatted.
- acctdusg reads its standard input (usually from find / -print) and computes disk resource consumption (including indirect blocks) by login.
- accton without arguments turns process accounting off. If *filename* is given, it must be the name of an existing file, to which the kernel appends process accounting records (see [acct\(2\)](#) and [acct.h\(3HEAD\)](#)).
- acctwtmp writes a [utmpx\(4\)](#) record to *filename*. The record contains the current time and a string of characters that describe the *reason*. A record type of ACCOUNTING is assigned (see [utmpx\(4\)](#)) *reason* must be a string of 11 or fewer characters, numbers, \$, or spaces. For example, the following are suggestions for use in reboot and shutdown procedures, respectively:
- ```
acctwtmp "acctg on" /var/adm/wtmpx
acctwtmp "acctg off" /var/adm/wtmpx
```

For each user currently logged on, `closewtmp` puts a false `DEAD_PROCESS` record in the `/var/adm/wtmpx` file. `runacct` (see [runacct\(1M\)](#)) uses this false `DEAD_PROCESS` record so that the connect accounting procedures can track the time used by users logged on before `runacct` was invoked.

For each user currently logged on, `runacct` uses `utmp2wtmp` to create an entry in the file `/var/adm/wtmpx`, created by `runacct`. Entries in `/var/adm/wtmpx` enable subsequent invocations of `runacct` to account for connect times of users currently logged in.

**Options** The following options are supported:

- u *filename* Places in *filename* records consisting of those filenames for which `acctdusg` charges no one (a potential source for finding users trying to avoid disk charges).
- p *filename* Specifies a password file, *filename*. This option is not needed if the password file is `/etc/passwd`.

**Environment Variables** If any of the `LC_*` variables (`LC_TYPE`, `LC_MESSAGES`, `LC_TIME`, `LC_COLLATE`, `LC_NUMERIC`, and `LC_MONETARY`) (see [environ\(5\)](#)) are not set in the environment, the operational behavior of `acct` for each corresponding locale category is determined by the value of the `LANG` environment variable. If `LC_ALL` is set, its contents are used to override both the `LANG` and the other `LC_*` variables. If none of the above variables are set in the environment, the "C" (U.S. style) locale determines how `acct` behaves.

`LC_CTYPE` Determines how `acct` handles characters. When `LC_CTYPE` is set to a valid value, `acct` can display and handle text and filenames containing valid characters for that locale. `acct` can display and handle Extended Unix Code (EUC) characters where any character can be 1, 2, or 3 bytes wide. `acct` can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

`LC_TIME` Determines how `acct` handles date and time formats. In the "C" locale, date and time handling follows the U.S. rules.

- Files**
- `/etc/passwd` Used for login name to user ID conversions.
  - `/usr/lib/acct` Holds all accounting commands listed in sub-class 1M of this manual.
  - `/var/adm/pacct` Current process accounting file.
  - `/var/adm/wtmpx` History of user access and administration information..

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE           |
|---------------|--------------------------|
| Availability  | system/accounting/legacy |

**See Also** acctcom(1), acctcms(1M), acctcon(1M), acctmerg(1M), acctprc(1M), acctsh(1M), fwtmp(1M), runacct(1M), acct(2), acct.h(3HEAD), passwd(4), utmpx(4), attributes(5), environ(5)

*System Administration Guide: Basic Administration*

**Name** acctadm – configure extended accounting facility

**Synopsis** /usr/sbin/acctadm [-DEsrux] [-d *resource\_list*]  
[-e *resource\_list*] [-f *filename*]  
[task | process | flow | net]

**Description** acctadm configures various attributes of the extended accounting facility. Without arguments, acctadm displays the current status of the extended accounting facility.

**Options** The following options are supported:

-d *resource\_list*

Disable reporting of resource usage for resource. Specify *resource\_list* as a comma-separated list of resources or resource groups.

This option requires an operand. See OPERANDS.

-D

Disable accounting of the given operand type without closing the accounting file. This option can be used to temporarily stop writing accounting records to the accounting file without closing it. To close the file use the -x option. See -x.

-e *resource\_list*

Enable reporting of resource usage for resource. Specify *resource\_list* as a comma-separated list of resources or resource groups.

This option requires an operand. See OPERANDS.

-E

Enable accounting of the given operand type without sending the accounting output to a file. This option requires an operand. See OPERANDS.

-f *filename*

Send the accounting output for the given operand type to *filename*. If *filename* exists, its contents must be of the given accounting type.

This option requires an operand. See OPERANDS.

-r

Display available resource groups.

When this option is used with an operand, it displays resource groups available for a given accounting type. When no operand is specified, this option displays resource groups for all available accounting types. See OPERANDS.

-s

Start method for the `smf(5)` instance. This option is used to restore the extended accounting configuration at boot.

-x

Deactivate accounting of the given operand type. This option also closes the accounting file for the given accounting type if it is currently open.

This option requires an operand. See OPERANDS.

**Operands** The -d, -D, -e, -E, -f, and -x options require an operand.

The following operands are supported:

process

Run acctadm on the process accounting components of the extended accounting facility.

task

Run acctadm on the task accounting components of the extended accounting facility.

flow

Run acctadm on the IPQoS accounting components of the extended accounting facility.

net

Run acctadm on links and flows administered by `dladm(1M)` and `flowadm(1M)`, respectively. Basic network accounting relates only to links, while extended network accounting includes both link and flow accounting.

The optional final parameter to `acctadm` represents whether the command should act on the process, system task, IPQoS, or network accounting components of the extended accounting facility.

**Examples** **EXAMPLE 1** Displaying the Current Status

The following command displays the current status. In this example, system task accounting is active and tracking only CPU resources. Process and flow accounting are not active.

```
$ acctadm
 Task accounting: active
 Task accounting file: /var/adm/exacct/task
 Tracked task resources: extended
 Untracked task resources: host
 Process accounting: inactive
 Process accounting file: none
 Tracked process resources: none
 Untracked process resources: extended,host
 Flow accounting: inactive
 Flow accounting file: none
 Tracked flow resources: none
 Untracked flow resources: extended
 Net accounting: inactive
 Net accounting file: none
 Tracked Net resources: none
 Untracked Net resources: extended
```

**EXAMPLE 2** Activating Basic Process Accounting

The following command activates basic process accounting:

```
$ acctadm -e basic -f /var/adm/exacct/proc process
```

**EXAMPLE 3** Displaying Available Resource Groups

The following command displays available resource groups:

```
$ acctadm -r
process:
extended pid,uid,gid,cpu,time,command,tty,projid, \
taskid,ancpid,wait-status,zone,flag,memory,mstate
basic pid,uid,gid,cpu,time,command,tty,flag
task:
extended taskid,projid,cpu,time,host,mstate,anctaskid,zone
basic taskid,projid,cpu,time
flow:
extended saddr,daddr,sport,dport,proto,dsfield,nbytes,npkts, \
action,ctime,lseen,projid,uid
basic saddr,daddr,sport,dport,proto,nbytes,npkts,action
net:
extended name,devname,edest,vlan_tpid,vlan_tci,sap,cpuid, \
priority,bwlimit,curtime,ibytes,obytes,ipkts,opks,ierrpkts \
oerrpkts,saddr,daddr,sport,dport,protocol,dsfield
basic name,devname,edest,vlan_tpid,vlan_tci,sap,cpuid, \
priority,bwlimit,curtime,ibytes,obytes,ipkts,opks,ierrpkts \
oerrpkts
```

In the output above, the lines beginning with `extended` are shown with a backslash character. In actual `acctadm` output, these lines are displayed as unbroken, long lines.

**EXAMPLE 4** Displaying Resource Groups for Task Accounting

The following command displays resource groups for task accounting:

```
$ acctadm -r task
extended taskid,projid,cpu,time,host,mstate,anctaskid,zone
basic taskid,projid,cpu,time
```

**Exit Status** The following exit values are returned:

0

Successful completion.

The modifications to the current configuration were valid and made successfully.

1

An error occurred.

A fatal error occurred either in obtaining or modifying the accounting configuration.

2

Invalid command line options were specified.

95

A fatal, non-configuration error occurred during the start of the `smf(5)` service instance.

96

A fatal configuration error occurred during the start of the `smf(5)` service instance.

**Attributes** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcs          |
| Interface Stability | Committed       |

**See Also** `dladm(1M)`, `flowadm(1M)`, `acct(2)`, `attributes(5)`, `smf(5)`, `ipqos(7ipp)`

**Notes** Both extended accounting and regular accounting can be active.

Available resources can vary from system to system, and from platform to platform.

Extended accounting configuration is stored in the service management facility (`smf(5)`) repository. The configuration is restored at boot by a transient service instance, one per accounting type:

```

svc:/system/extended-accounting:flow Flow accounting
svc:/system/extended-accounting:process Process accounting
svc:/system/extended-accounting:task Task accounting
svc:/system/extended-accounting:net Network accounting

```

The instances are enabled or disabled by `acctadm` as needed. Configuration changes are made using `acctadm`; service properties should not be modified directly using `svccfg(1M)`.

Users can manage extended accounting (start accounting, stop accounting, change accounting configuration parameters) if they have the appropriate RBAC Rights profile for the accounting type to be managed:

- Extended Accounting Flow Management
- Extended Accounting Process Management
- Extended Accounting Task Management
- Extended Accounting Network Management

The preceding profiles are for, respectively, flow accounting, process accounting, task accounting, and network accounting.

**Name** acctcms – command summary from process accounting records

**Synopsis** /usr/lib/acct/acctcms [-a [-o] [-p]] [-c] [-j] [-n] [-s]  
[-t] *filename...*

**Description** acctcms reads one or more *filenames*, normally in the form described in [acct.h\(3HEAD\)](#). It adds all records for processes that executed identically named commands, sorts them, and writes them to the standard output, normally using an internal summary format.

**Options** -a Print output in ASCII rather than in the internal summary format. The output includes command name, number of times executed, total kcore-minutes, total CPU minutes, total real minutes, mean size (in K), mean CPU minutes per invocation, "hog factor," characters transferred, and blocks read and written, as in [acctcom\(1\)](#). Output is normally sorted by total kcore-minutes.

Use the following options only with the -a option:

-o Output a (non-prime) offshift-time-only command summary.

-p Output a prime-time-only command summary.

When -o and -p are used together, a combination prime-time and non-prime-time report is produced. All the output summaries are total usage except number of times executed, CPU minutes, and real minutes, which are split into prime and non-prime.

-c Sort by total CPU time, rather than total kcore-minutes.

-j Combine all commands invoked only once under "\*\*\*other".

-n Sort by number of command invocations.

-s Any file names encountered hereafter are already in internal summary format.

-t Process all records as total accounting records. The default internal summary format splits each field into prime and non-prime-time parts. This option combines the prime and non-prime time parts into a single field that is the total of both, and provides upward compatibility with old style acctcms internal summary format records.

**Examples** EXAMPLE 1 Using the acctcms command.

A typical sequence for performing daily command accounting and for maintaining a running total is:

```
example% acctcms filename ... > today
example% cp total previous total
example% acctcms -s today previous total > total
example% acctcms -a -s today
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

---

| ATTRIBUTE TYPE | ATTRIBUTE VALUE          |
|----------------|--------------------------|
| Availability   | system/accounting/legacy |

**See Also** `acctcom(1)`, `acct(1M)`, `acctcon(1M)`, `acctmerg(1M)`, `acctprc(1M)`, `acctsh(1M)`, `fwtmp(1M)`, `runacct(1M)`, `acct(2)`, `acct.h(3HEAD)`, `utmpx(4)`, `attributes(5)`

**Notes** Unpredictable output results if `-t` is used on new style internal summary format files, or if it is not used with old style internal summary format files.

**Name** acctcon, acctcon1, acctcon2 – connect-time accounting

**Synopsis** /usr/lib/acct/acctcon [-l *lineuse*] [-o *reboot*]  
/usr/lib/acct/acctcon1 [-p] [-t] [-l *lineuse*] [-o *reboot*]  
/usr/lib/acct/acctcon2

**Description** acctcon converts a sequence of login/logoff records to total accounting records (see the tacct format in [acct.h\(3HEAD\)](#)). The login/logoff records are read from standard input. The file /var/adm/wtmpx is usually the source of the login/logoff records; however, because it might contain corrupted records or system date changes, it should first be fixed using wtmpfix. The fixed version of file /var/adm/wtmpx can then be redirected to acctcon. The tacct records are written to standard output.

acctcon is a combination of the programs acctcon1 and acctcon2. acctcon1 converts login/logoff records, taken from the fixed /var/adm/wtmpx file, to ASCII output. acctcon2 reads the ASCII records produced by acctcon1 and converts them to tacct records. acctcon1 can be used with the -l and -o options, described below, as well as with the -p and -t options.

**Options**

- p Print input only, showing line name, login name, and time (in both numeric and date/time formats).
- t acctcon1 maintains a list of lines on which users are logged in. When it reaches the end of its input, it emits a session record for each line that still appears to be active. It normally assumes that its input is a current file, so that it uses the current time as the ending time for each session still in progress. The -t flag causes it to use, instead, the last time found in its input, thus assuring reasonable and repeatable numbers for non-current files.
- l *lineuse* *lineuse* is created to contain a summary of line usage showing line name, number of minutes used, percentage of total elapsed time used, number of sessions charged, number of logins, and number of logoffs. This file helps track line usage, identify bad lines, and find software and hardware oddities. Hangup, termination of [login\(1\)](#) and termination of the login shell each generate logoff records, so that the number of logoffs is often three to four times the number of sessions. See [init\(1M\)](#) and [utmpx\(4\)](#).
- o *reboot* reboot is filled with an overall record for the accounting period, giving starting time, ending time, number of reboots, and number of date changes.

**Examples** EXAMPLE 1 Using the acctcon command.

The acctcon command is typically used as follows:

```
example% acctcon -l lineuse -o reboots < tmpwtmp > ctacct
```

The acctcon1 and acctcon2 commands are typically used as follows:

**EXAMPLE 1** Using the `acctcon` command. *(Continued)*

```
example% acctcon1 -l lineuse -o reboots < tmpwtmp | sort +1n +2 > ctmp
example% acctcon2 < ctmp > ctacct
```

**Files** `/var/adm/wtmpx` History of user access and administration information

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE          |
|----------------|--------------------------|
| Availability   | system/accounting/legacy |

**See Also** [acctcom\(1\)](#), [login\(1\)](#), [acct\(1M\)](#), [acctcms\(1M\)](#), [acctmerg\(1M\)](#), [acctprc\(1M\)](#), [acctsh\(1M\)](#), [fwtmp\(1M\)](#), [init\(1M\)](#), [runacct\(1M\)](#), [acct\(2\)](#), [acct.h\(3HEAD\)](#), [utmpx\(4\)](#), [attributes\(5\)](#)

*System Administration Guide: Basic Administration*

**Notes** The line usage report is confused by date changes. Use `wtmpfix` (see [fwtmp\(1M\)](#)), with the `/var/adm/wtmpx` file as an argument, to correct this situation.

During a single invocation of any given command, the `acctcon`, `acctcon1`, and `acctcon2` commands can process a maximum of:

- 6000 distinct session
- 1000 distinct terminal lines
- 2000 distinct login names

If at some point the actual number of any one of these items exceeds the maximum, the command will not succeed.

**Name** acctmerg – merge or add total accounting files

**Synopsis** /usr/lib/acct/acctmerg [-a] [-i] [-p] [-t] [-u] [-v]  
[filename] ...

**Description** acctmerg reads its standard input and up to nine additional files, all in the tacct format (see [acct.h\(3HEAD\)](#)) or an ASCII version thereof. It merges these inputs by adding records whose keys (normally user ID and name) are identical, and expects the inputs to be sorted on those keys.

**Options**

- a Produce output in ASCII version of tacct.
- i Produce input in ASCII version of tacct.
- p Print input with no processing.
- t Produce a single record that totals all input.
- u Summarize by user ID, rather than by user ID and name.
- v Produce output in verbose ASCII format, with more precise notation for floating-point numbers.

**Examples** EXAMPLE 1 Using the acctmerg command.

The following sequence is useful for making "repairs" to any file kept in this format:

```
example% acctmerg -v <filename1 >filename2
```

Edit *filename2* as you want:

```
example% acctmerg -i <filename2 >filename1
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE          |
|----------------|--------------------------|
| Availability   | system/accounting/legacy |

**See Also** [acctcom\(1\)](#), [acct\(1M\)](#), [acctcms\(1M\)](#), [acctcon\(1M\)](#), [acctprc\(1M\)](#), [acctsh\(1M\)](#), [fwtmp\(1M\)](#), [runacct\(1M\)](#), [acct\(2\)](#), [acct.h\(3HEAD\)](#), [utmpx\(4\)](#), [attributes\(5\)](#)

*System Administration Guide: Basic Administration*

**Name** acctprc, acctprc1, acctprc2 – process accounting

**Synopsis** /usr/lib/acct/acctprc  
 /usr/lib/acct/acctprc1 [*ctmp*]  
 /usr/lib/acct/acctprc2

**Description** acctprc reads the standard input and converts it to total accounting records (see the tacct record in [acct.h\(3HEAD\)](#)). acctprc divides CPU time into prime time and non-prime time and determines mean memory size (in memory segment units). acctprc then summarizes the tacct records, according to user IDs, and adds login names corresponding to the user IDs. The summarized records are then written to the standard output. acctprc1 reads input in the form described by [acct.h\(3HEAD\)](#), adds login names corresponding to user IDs, then writes for each process an ASCII line giving user ID, login name, prime CPU time (tics), non-prime CPU time (tics), and mean memory size (in memory segment units). If *ctmp* is given, it should contain a list of login sessions sorted by user ID and login name. If this file is not supplied, it obtains login names from the password file, just as acctprc does. The information in *ctmp* helps it distinguish between different login names that share the same user ID.

From the standard input, acctprc2 reads records in the form written by acctprc1, summarizes them according to user ID and name, then writes the sorted summaries to the standard output as total accounting records.

**Examples** EXAMPLE 1 Examples of acctprc.

The acctprc command is typically used as shown below:

```
example% acctprc < /var/adm/pacct > ptacct
```

The acctprc1 and acctprc2s commands are typically used as shown below:

```
example% acctprc1 ctmp </var/adm/pacct
example% acctprc2 > ptacct
```

**Files** /etc/passwd system password file

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE          |
|----------------|--------------------------|
| Availability   | system/accounting/legacy |

**See Also** [acctcom\(1\)](#), [acct\(1M\)](#), [acctcms\(1M\)](#), [acctcon\(1M\)](#), [acctmerge\(1M\)](#), [acctsh\(1M\)](#), [cron\(1M\)](#), [fwtmp\(1M\)](#), [runacct\(1M\)](#), [acct\(2\)](#), [acct.h\(3HEAD\)](#), [utmpx\(4\)](#), [attributes\(5\)](#)

**Notes** Although it is possible for acctprc1 to distinguish among login names that share user IDs for commands run from a command line, it is difficult for acctprc1 to make this distinction for commands invoked in other ways. A command run from [cron\(1M\)](#) is an example of where

acctprc1 might have difficulty. A more precise conversion can be done using the acctwtmp program in [acct\(1M\)](#). acctprc does not distinguish between users with identical user IDs.

A memory segment of the mean memory size is a unit of measure for the number of bytes in a logical memory segment on a particular processor.

During a single invocation of any given command, the acctprc, acctprc1, and acctprc2 commands can process a maximum of

- 6000 distinct sessions
- 1000 distinct terminal lines
- 2000 distinct login names

If at some point the actual number of any one of these items exceeds the maximum, the command will not succeed.

**Name** acctsh, chargefee, ckpacct, dodisk, lastlogin, monacct, nulladm, prctmp, prdaily, prtacct, shutacct, startup, turnacct – shell procedures for accounting

**Synopsis** /usr/lib/acct/chargefee *login-name number*  
 /usr/lib/acct/ckpacct [*blocks*]  
 /usr/lib/acct/dodisk [-o] [*filename*]...  
 /usr/lib/acct/lastlogin  
 /usr/lib/acct/monacct *number*  
 /usr/lib/acct/nulladm *filename*...  
 /usr/lib/acct/prctmp *filename*  
 /usr/lib/acct/prdaily [-c] [-l] [*mmdd*]  
 /usr/lib/acct/prtacct *filename* [*' heading '*]  
 /usr/lib/acct/shutacct [*' reason '*]  
 /usr/lib/acct/startup  
 /usr/lib/acct/turnacct on | off | switch

## Description

- chargefee Command** chargefee can be invoked to charge a *number* of units to *login-name*. A record is written to /var/adm/fee, to be merged with other accounting records by [runacct\(1M\)](#).
- ckpacct Command** ckpacct should be initiated using [cron\(1M\)](#) to periodically check the size of /var/adm/pacct. If the size exceeds *blocks*, 500 by default, turnacct will be invoked with argument switch. To avoid a conflict with turnacct switch execution in runacct, do not run ckpacct and runacct simultaneously. If the number of free disk blocks in the /var file system falls below 500, ckpacct will automatically turn off the collection of process accounting records via the off argument to turnacct. When at least 500 blocks are restored, the accounting will be activated again on the next invocation of ckpacct. This feature is sensitive to the frequency at which ckpacct is executed, usually by the [cron\(1M\)](#) command.
- dodisk Command** dodisk should be invoked by cron(1M) to perform the disk accounting functions.
- lastlogin Command** lastlogin is invoked by [runacct\(1M\)](#) to update /var/adm/acct/sum/loginlog, which shows the last date on which each person logged in.
- monacct Command** monacct should be invoked once each month or each accounting period. *number* indicates which month or period it is. If *number* is not given, it defaults to the current month (01–12). This default is useful if monacct is to be executed using [cron\(1M\)](#) on the first day of each month. monacct creates summary files in /var/adm/acct/fiscal and restarts the summary files in /var/adm/acct/sum.

- nulladm Command** `nulladm` creates *filename* with mode 664 and ensures that owner and group are `adm`. It is called by various accounting shell procedures.
- prctmp Command** `prctmp` can be used to print the session record file (normally `/var/adm/acct/nite/ctmp` created by `acctcon1` (see [acctcon\(1M\)](#)).
- prdaily Command** `prdaily` is invoked by [runacct\(1M\)](#) to format a report of the previous day's accounting data. The report resides in `/var/adm/acct/sum/rprt/mddd` where *mddd* is the month and day of the report. The current daily accounting reports may be printed by typing `prdaily`. Previous days' accounting reports can be printed by using the *mddd* option and specifying the exact report date desired.
- prtacct Command** `prtacct` can be used to format and print any total accounting (`tacct`) file.
- shutacct Command** `shutacct` is invoked during a system shutdown to turn process accounting off and append a *reason* record to `/var/adm/wtmpx`.
- startup Command** `startup` can be invoked when the system is brought to a multi-user state to turn process accounting on.
- turnacct Command** `turnacct` is an interface to `accton` (see [acct\(1M\)](#)) to turn process accounting on or off. The `switch` argument moves the current `/var/adm/pacct` to the next free name in `/var/adm/pacct.incr` (where *incr* is a number starting with 0 and incrementing by one for each additional `pacct` file), then turns accounting back on again. This procedure is called by `ckpacct` and thus can be taken care of by the [cron\(1M\)](#) command and used to keep `pacct` to a reasonable size. `shutacct` uses `turnacct` to stop process accounting. `startup` uses `turnacct` to start process accounting.

**Options** The following options are supported:

- c This option prints a report of exceptional resource usage by command, and may be used on current day's accounting data only.
- l This option prints a report of exceptional usage by login id for the specified date. Previous daily reports are cleaned up and therefore inaccessible after each invocation of `monacct`.
- o This option uses `acctdusg` (see [acct\(1M\)](#)) to do a slower version of disk accounting by login directory. *filenames* specifies the one or more filesystem names where disk accounting will be done. If *filenames* are used, disk accounting will be done on these filesystems only. If the `-o` option is used, *filenames* should be mount points of mounted filesystems. If the `-o` option is omitted, *filenames* should be the special file names of mountable filesystems.

| <code>/var/adm/acct/sum</code>          | Summary directory that contains information for monacct                                  |
| <code>/var/adm/acct/sum/loginlog</code> | File updated by last login                                                               |
| <code>/var/adm/fee</code>               | Accumulator for fees                                                                     |
| <code>/var/adm/pacct</code>             | Current file for per-process accounting                                                  |
| <code>/var/adm/pacctincr</code>         | Used if <code>pacct</code> gets large and during execution of daily accounting procedure |
| <code>/var/adm/wtmpx</code>             | History of user access and administration information                                    |

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE           |
|---------------|--------------------------|
| Availability  | system/accounting/legacy |

**See Also** [acctcom\(1\)](#), [acct\(1M\)](#), [acctcms\(1M\)](#), [acctcon\(1M\)](#), [acctmerg\(1M\)](#), [acctprc\(1M\)](#), [cron\(1M\)](#), [fwtmp\(1M\)](#), [logadm\(1M\)](#), [runacct\(1M\)](#), [acct\(2\)](#), [acct.h\(3HEAD\)](#), [utmpx\(4\)](#), [attributes\(5\)](#)

**Notes** See [runacct\(1M\)](#) for the main daily accounting shell script, which performs the accumulation of connect, process, fee, and disk accounting on a daily basis. It also creates summaries of command usage.

**Name** acpihpd – ACPI hot plug daemon

**Synopsis** /usr/platform/i86pc/lib/acpihpd

**Description** The ACPI hot plug daemon, `acpihpd`, is a daemon process that runs on x86 platforms. The daemon is started by the service management facility. It communicates with the [syseventd\(1M\)](#) and [cfgadm\(1M\)](#) subsystems to handle ACPI events from hotpluggable devices.

The service FMRI for `acpihpd` is:

```
svc:/platform/i86pc/acpihpd:default
```

Note that `acpihpd` is a private interface.

**Options** The `acpihpd` daemon does not support any options.

**Errors** `acpihpd` uses [syslog\(3C\)](#) to report status and error messages. All of the messages are logged with the LOG\_DAEMON facility.

Error messages are logged with the LOG\_ERR and LOG\_NOTICE priorities, and informational messages are logged with the LOG\_DEBUG priority. The default entries in the `/etc/syslog.conf` file log all of the error messages to the `/var/adm/messages` log.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE                             |
|---------------------|---------------------------------------------|
| Availability        | system/kernel/dynamic-reconfiguration/i86pc |
| Interface Stability | Private                                     |

**See Also** [svcs\(1\)](#), [cfgadm\(1M\)](#), [inetadm\(1M\)](#), [svcadm\(1M\)](#), [syseventd\(1M\)](#), [syslog\(3C\)](#), [syslog.conf\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

**Notes** The `acpihpd` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/platform/i86pc/acpihpd:default
```

**Name** adbggen – generate adb script

**Synopsis** /usr/lib/adb/adbggen [-m *model*] *filename.adb* . . .

**Description** adbggen makes it possible to write [adb\(1\)](#) scripts that do not contain hard-coded dependencies on structure member offsets. The input to adbggen is a file named *filename.adb* that contains header information, then a null line, then the name of a structure, and finally an adb script. adbggen only deals with one structure per file; all member names are assumed to be in this structure. The output of adbggen is an adb script in *filename.adb*. adbggen operates by generating a C program which determines structure member offsets and sizes, which in turn generate the adb script.

The header lines, up to the null line, are copied verbatim into the generated C program. Typically, these are `#include` statements, which include the headers containing the relevant structure declarations.

The adb script part may contain any valid adb commands (see [adb\(1\)](#)), and may also contain adbggen requests, each enclosed in braces ( `{ }` ). Request types are:

- Print a structure member. The request form is `{member, format}`. *member* is a member name of the *structure* given earlier, and *format* is any valid adb format request or any of the adbggen format specifiers (such as `{POINTER}`) listed below. For example, to print the `p_pid` field of the *proc* structure as a decimal number, you would write `{p_pid, d}`.
- Print the appropriate adb format character for the given adbggen format specifier. This action takes the data model into consideration. The request form is `{format specifier}`. The valid adbggen format specifiers are:

|                         |                                    |
|-------------------------|------------------------------------|
| <code>{POINTER}</code>  | pointer value in hexadecimal       |
| <code>{LONGDEC}</code>  | long value in decimal              |
| <code>{ULONGDEC}</code> | unsigned long value in decimal     |
| <code>{ULONGHEX}</code> | unsigned long value in hexadecimal |
| <code>{LONGOCT}</code>  | long value in octal                |
| <code>{ULONGOCT}</code> | unsigned long value in octal       |

- Reference a structure member. The request form is `{*member, base}`. *member* is the member name whose value is desired, and *base* is an adb register name which contains the base address of the structure. For example, to get the `p_pid` field of the *proc* structure, you would get the *proc* structure address in an adb register, for example `<f`, and write `{*p_pid, <f}`.
- Tell adbggen that the offset is valid. The request form is `{OFFSETOK}`. This is useful after invoking another adb script which moves the adb *dot*.
- Get the size of the *structure*. The request form is `{SIZEOF}`. adbggen replaces this request with the size of the structure. This is useful in incrementing a pointer to step through an array of structures.

- Calculate an arbitrary C expression. The request form is {EXPR, *expression*}. adbgen replaces this request with the value of the expression. This is useful when more than one structure is involved in the script.
- Get the offset to the end of the structure. The request form is {END}. This is useful at the end of the structure to get adb to align the *dot* for printing the next structure member.

adbgen keeps track of the movement of the adb *dot* and generates adb code to move forward or backward as necessary before printing any structure member in a script. adbgen's model of the behavior of adb's *dot* is simple: it is assumed that the first line of the script is of the form *struct\_address/adb text* and that subsequent lines are of the form *+/adb text*. The adb *dot* then moves in a sane fashion. adbgen does not check the script to ensure that these limitations are met. adbgen also checks the size of the structure member against the size of the adb format code and warns if they are not equal.

**Options** The following option is supported:

*-m model* Specifies the data type model to be used by adbgen for the macro. This affects the outcome of the {*format specifier*} requests described under DESCRIPTION and the offsets and sizes of data types. *model* can be *i1p32* or *lp64*. If the *-m* option is not given, the data type model defaults to *i1p32*.

**Operands** The following operand is supported:

*filename.adb* Input file that contains header information, followed by a null line, the name of the structure, and finally an adb script.

**Examples** EXAMPLE 1 A sample adbgen file.

For an include file *x.h* which contained

```
struct x {
 char *x_cp;
 char x_c;
 int x_i;
};
```

then, an adbgen file (call it *script.adb*) to print the file *x.h* would be:

```
#include "x.h"
x
./"x_cp"16t"x_c"8t"x_i"n{x_cp,{POINTER}}{x_c,C}{x_i,D}
```

After running adbgen as follows,

```
% /usr/lib/adb/adbgen script.adb
```

the output file *script* contains:

```
./"x_cp"16t"x_c"8t"x_i"nXC3+D
```

**EXAMPLE 1** A sample adbggen file. (Continued)

For a macro generated for a 64-bit program using the lp64 data model as follows,

```
% /usr/lib/adb/adbggen/ -m lp64 script.adb
```

the output file `script` would contain:

```
./"x_cp"16t"x_c"8t"x_i"nJC3+D
```

To invoke the script, type:

```
example% adb program
x$<script
```

**Files** `/usr/platform/platform-name/lib/adb/*`  
platform-specific adb scripts for debugging the 32-bit kernel

`/usr/platform/platform-name/lib/adb/sparcv9/*`  
platform-specific adb scripts for debugging the 64-bit SPARC V9 kernel

`/usr/lib/adb/*`  
adb scripts for debugging the 32-bit kernel

`/usr/lib/adb/sparcv9/*`  
adb scripts for debugging the 64-bit SPARC V9 kernel

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE                  |
|----------------|----------------------------------|
| Availability   | system/extended-system-utilities |

**See Also** [adb\(1\)](#), [kmdb\(1\)](#), [uname\(1\)](#), [attributes\(5\)](#)

**Diagnosics** Warnings are given about structure member sizes not equal to adb format items and about badly formatted requests. The C compiler complains if a structure member that does not exist is referenced. It also complains about an ampersand before array names; these complaints may be ignored.

**Notes** *platform-name* can be found using the `-i` option of [uname\(1\)](#).

**Bugs** adb syntax is ugly; there should be a higher level interface for generating scripts.

Structure members which are bit fields cannot be handled because C will not give the address of a bit field. The address is needed to determine the offset.

**Name** add\_allocatable – add entries to allocation databases

**Synopsis** /usr/sbin/add\_allocatable [-f] [-s] [-d] -n *name* -t *type* -l *device-list*  
[-a *authorization*] [-c *clean*] [-o *key=value*]

**Description** add\_allocatable creates new entries for user allocatable devices that are to be managed by the device allocation mechanism. add\_allocatable can also be used to update existing entries of such devices.

add\_allocatable can also create and update entries for non-allocatable devices, such as printers, whose label range is managed by the device allocation mechanism.

add\_allocatable can be used in shell scripts, such as installation scripts for driver packages, to automate the administrative work of setting up a new device.

Use [list\\_devices\(1\)](#) to see the names and types of allocatable devices, their attributes, and device paths.

**Options**

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -f                      | Force an update of an already-existing entry with the specified information. add_allocatable exits with an error if this option is not specified when an entry with the specified device name already exists.                                                                                                                                                                                                                                                                                                                            |
| -s                      | Turn on silent mode. add_allocatable does not print any error or warning messages.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| -d                      | If this option is present, add_allocatable updates the system-supplied default attributes of the device type specified with -t.                                                                                                                                                                                                                                                                                                                                                                                                          |
| -n <i>name</i>          | Adds or updates an entry for device that is specified by <i>name</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| -t <i>type</i>          | Adds or updates device entries that are of a type that are specified by <i>type</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| -l <i>device-list</i>   | Adds or updates device paths to the device that is specified with -n. Multiple paths in <i>device-list</i> must be separated by white spaces and the list must be quoted.                                                                                                                                                                                                                                                                                                                                                                |
| -a <i>authorization</i> | Adds or updates the authorization that is associated with either the device that is specified with -n or with devices of the type that is specified with -t. When more than one authorization is specified, the list must be separated by commas and must be quoted. When the device is not allocatable, <i>authorization</i> is specified with an asterisk (*) and must be quoted. When the device is allocatable by any user, <i>authorization</i> is specified with the at sign (@) and must be quoted. Default authorization is '@'. |
| -c <i>clean</i>         | Specifies the <a href="#">device_clean(5)</a> program <i>clean</i> to be used with the device that is specified with -n or with devices of the type that is specified with -t. The default clean program is /bin/true.                                                                                                                                                                                                                                                                                                                   |

|                           |                                                                                                                                                                                                                                                 |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-o key=value</code> | Accepts a string of colon-separated <i>key=value</i> pairs for a device that is specified with <code>-n</code> or with devices of the type that is specified with <code>-t</code> . The following keys are currently interpreted by the system: |
| <code>minlabel</code>     | The minimum label at which the device can be used.                                                                                                                                                                                              |
| <code>maxlabel</code>     | The maximum label at which the device can be used.                                                                                                                                                                                              |
| <code>class</code>        | Specifies a logical grouping of devices. For example, all Sun Ray devices of all device types is a logical grouping. The <code>class</code> keyword has no default value.                                                                       |
| <code>xdpi</code>         | Specifies the display name of the X session. This keyword is used to identify devices that are associated with the X session. The <code>xdpi</code> keyword has no default value.                                                               |

**Exit Status** When successful, `add_allocatable` returns an exit status of 0 (true). `add_allocatable` returns a nonzero exit status in the event of an error. The exit codes are as follows:

- 1 Invocation syntax error
- 2 Unknown system error
- 3 An entry already exists for the specified device. This error occurs only when the `-f` option is not specified.
- 4 Permission denied. User does not have DAC or MAC access record updates.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | system/trusted  |
| Interface Stability | See below.      |

The invocation is Uncommitted. The options are Uncommitted. The output is Not-an-Interface.

**See Also** [allocate\(1\)](#), [deallocate\(1\)](#), [list\\_devices\(1\)](#), [remove\\_allocatable\(1M\)](#), [attributes\(5\)](#), [device\\_clean\(5\)](#)

**Notes** The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

**Name** addbadsec – map out defective disk blocks

**Synopsis** addbadsec [-p] [-a *blkno* [*blkno*...]] [-f *filename*] *raw\_device*

**Description** addbadsec is used by the system administrator to map out bad disk blocks. Normally, these blocks are identified during surface analysis, but occasionally the disk subsystem reports unrecoverable data errors indicating a bad block. A block number reported in this way can be fed directly into addbadsec, and the block will be remapped. addbadsec will first attempt hardware remapping. This is supported on SCSI drives and takes place at the disk hardware level. If the target is an IDE drive, then software remapping is used. In order for software remapping to succeed, the partition must contain an alternate slice and there must be room in this slice to perform the mapping.

It should be understood that bad blocks lead to data loss. Remapping a defective block does not repair a damaged file. If a bad block occurs to a disk-resident file system structure such as a superblock, the entire slice might have to be recovered from a backup.

**Options** The following options are supported:

- a Adds the specified blocks to the hardware or software map. If more than one block number is specified, the entire list should be quoted and block numbers should be separated by white space.
- f Adds the specified blocks to the hardware or software map. The bad blocks are listed, one per line, in the specified file.
- p Causes addbadsec to print the current software map. The output shows the defective block and the assigned alternate. This option cannot be used to print the hardware map.

**Operands** The following operand is supported:

*raw\_device* The address of the disk drive (see FILES).

**Files** The raw device should be `/dev/rdisk/c?[t?]d?p0`. See [disks\(1M\)](#) for an explanation of SCSI and IDE device naming conventions.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Architecture   | x86             |
| Availability   | SUNWcs          |

**See Also** [disks\(1M\)](#), [diskscan\(1M\)](#), [fdisk\(1M\)](#), [fmthard\(1M\)](#), [format\(1M\)](#), [attributes\(5\)](#)

**Notes** The `format(1M)` utility is available to format, label, analyze, and repair SCSI disks. This utility is included with the `addbadsec`, `diskscan(1M)`, `fdisk(1M)`, and `fmthard(1M)` commands available for x86. To format an IDE disk, use the DOS "format" utility; however, to label, analyze, or repair IDE disks on x86 systems, use the Solaris `format(1M)` utility.

**Name** add\_drv – add a new device driver to the system

**Synopsis** add\_drv [-b *basedir*] [-c *class\_name*]  
 [-i '*identify\_name...*'] [-m '*permission', '...*']  
 [-p '*policy*'] [-P *privilege*] [-n] [-f] [-u] [-v] *device\_driver*

**Description** The add\_drv command is used to inform the system about newly installed device drivers.

Each device on the system has a name associated with it. This name is represented by the name property for the device. Similarly, the device may also have a list of driver names associated with it. This list is represented by the compatible property for the device.

The system determines which devices will be managed by the driver being added by examining the contents of the name property and the compatible property (if it exists) on each device. If the value in the name property does not match the driver being added, each entry in the compatible property is tried, in order, until either a match occurs or there are no more entries in the compatible property.

In some cases, adding a new driver may require a reconfiguration boot. See the NOTES section.

Aliases might require quoting (with double-quotes) if they contain numbers. See EXAMPLES.

The /etc/minor\_perm File add\_drv and [update\\_drv\(1M\)](#) read the /etc/minor\_perm file to obtain permission information. The permission specified is applied to matching minor nodes created when a device bound to the driver is attached. A minor node's permission may be manually changed by [chmod\(1\)](#). For such nodes, the specified permissions apply, overriding the default permissions specified via add\_drv or [update\\_drv\(1M\)](#).

The format of the /etc/minor\_perm file is as follows:

```
name:minor_name permissions owner group
```

*minor\_name* may be the actual name of the minor node, or contain shell metacharacters to represent several minor nodes (see [sh\(1\)](#)).

For example:

```
sd:* 0640 root sys
zs:[a-z],cu 0600 uucp uucp
mm:kmem 0640 root bin
```

The first line sets all devices exported by the sd node to 0640 permissions, owned by root, with group sys. In the second line, devices such as a, cu and z, cu exported by the zs driver are set to 0600 permission, owned by uucp, with group uucp. In the third line the kmem device exported by the mm driver is set to 0640 permission, owned by root, with group bin.

Running add\_drv from a postinstall Script When running add\_drv from within the context of a package's postinstall script, you must consider whether the package is being added to a system image or to a running system. When a package is being installed on a system image, such as occurs with the Live Upgrade or flash

features (see [live\\_upgrade\(5\)](#) and [flarcreate\(1M\)](#)), the `BASEDIR` variable refers to the image's base directory. In this situation, `add_drv` should be invoked with `-b $BASEDIR`. This causes `add_drv` only to update the image's system files; a reboot of the system or client would be required to make the driver operational.

When a package is being installed on the running system itself, the system files need to be updated, as in the case above. However, the running kernel can be informed of the existence of the new driver without requiring a reboot. To accomplish this, the `postinstall` script must invoke `add_drv` without the `-b` option. Accordingly, `postinstall` scripts invoking `add_drv` should be written thusly:

```
if ["${BASEDIR:=/}" = "/"]
then
 ADD_DRV="add_drv"
else
 ADD_DRV="add_drv -b ${BASEDIR}"
fi
$ADD_DRV [options] <driver>
```

...or, alternatively:

```
if ["${BASEDIR:=/}" != "/"]
then
 BASEDIR_OPT="-b $BASEDIR"
fi
add_drv $BASEDIR_OPT [options] <driver>
```

The `-b` option is described below.

#### Options `-b basedir`

Installs the driver on the system with a root directory of *basedir* rather than installing on the system executing `add_drv`. This option is typically used in package post-installation scripts when the package is not being installed on the system executing the `pkgadd` command. The system using *basedir* as its root directory must reboot to complete the driver installation.

**Note** – The root file system of any non-global zones must not be referenced with the `-b` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).

#### `-c class_name`

The driver being added to the system exports the class *class\_name*.

#### `-f`

Normally if a reconfiguration boot is required to complete the configuration of the driver into the system, `add_drv` will not add the driver. The force flag forces `add_drv` to add the driver even if a reconfiguration boot is required. See the `-v` flag.

-i '*identify\_name*'

A white-space separated list of aliases for the driver *device\_driver*.

-m '*permission*'

Specify the file system permissions for device nodes created by the system on behalf of *device\_driver*.

-n

Do not try to load and attach *device\_driver*, just modify the system configuration files for the *device\_driver*.

-p '*policy*'

Specify an additional device security policy.

The device security policy consists of several whitespace separated tokens:

*minorspec* {token=value}+)+

*minorspec* is a simple wildcard pattern for a minor device. A single \* matches all minor devices. Only one \* is allowed in the pattern.

Patterns are matched in the following order:

- entries without a wildcard
- entries with wildcards, longest wildcard first

The following tokens are defined: *read\_priv\_set* and *write\_priv\_set*. *read\_priv\_set* defines the privileges that need to be asserted in the effective set of the calling process when opening a device for reading. *write\_priv\_set* defines the privileges that need to be asserted in the effective set of the calling process when opening a device for writing. See [privileges\(5\)](#).

A missing minor spec is interpreted as a \*.

-P '*privilege*'

Specify additional, comma separated, privileges used by the driver. You can also use specific privileges in the device's policy.

-u

Add the driver to the system, leaving it in an inactive state for later configuration with [devfsadm\(1M\)](#) -u. The -u behavior differs from -n in that -n only updates the system files, requiring a reboot to attach the driver. Drivers added with -u can be attached by running [devfsadm](#) -u without rebooting. Driver writers should verify their driver with this behavior. See NOTES for additional considerations. The -u option cannot be used together with -n or -b.

-v

The verbose flag causes [add\\_drv](#) to provide additional information regarding the success or failure of a driver's configuration into the system. See the EXAMPLES section.

**Examples** EXAMPLE 1 Adding SUNW Example Driver to the System

The following example adds the SUNW,example driver to a 32-bit system, with an alias name of SUNW,alias. It assumes the driver has already been copied to /usr/kernel/drv.

```
example# add_drv -m '* 0666 bin bin', 'a 0644 root sys' \
 -p 'a write_priv_set=sys_config * write_priv_set=none' \
 -i 'SUNW,alias' SUNW,example
```

Every minor node created by the system for the SUNW,example driver will have the permission 0666, and be owned by user bin in the group bin, except for the minor device a, which will be owned by root, group sys, and have a permission of 0644. The specified device policy requires no additional privileges to open all minor nodes, except minor device a, which requires the sys\_config privilege when opening the device for writing.

## EXAMPLE 2 Adding Driver to the Client /export/root/sun1

The following example adds the driver to the client /export/root/sun1. The driver is installed and loaded when the client machine, sun1, is rebooted. This second example produces the same result as the first, except the changes are on the diskless client, sun1, and the client must be rebooted for the driver to be installed.

```
example# add_drv -m '* 0666 bin bin', 'a 0644 root sys' \
 -i 'SUNW,alias' -b /export/root/sun1 \
 SUNW,example
```

See the note in the description of the -b option, above, specifying the caveat regarding the use of this option with the Solaris zones feature.

## EXAMPLE 3 Adding Driver for a Device Already Managed by an Existing Driver

The following example illustrates the case where a new driver is added for a device that is already managed by an existing driver. Consider a device that is currently managed by the driver dumb\_framebuffer. The name and compatible properties for this device are as follows:

```
name="display"
compatible="whizzy_framebuffer", "dumb_framebuffer"
```

If add\_drv is used to add the whizzy\_framebuffer driver, the following will result.

```
example# add_drv whizzy_framebuffer
Error: Could not install driver (whizzy_framebuffer)
Device managed by another driver.
```

If the -v flag is specified, the following will result.

```
example# add_drv -v whizzy_framebuffer
Error: Could not install driver (whizzy_framebuffer)
Device managed by another driver.
Driver installation failed because the following
entries in /devices would be affected:
```

**EXAMPLE 3** Adding Driver for a Device Already Managed by an Existing Driver *(Continued)*

```
/devices/iommu@f,e0000000/sbus@f,e0001000/display[:*]
(Device currently managed by driver "dumb_framebuffer")
```

The following entries in /dev would be affected:

```
/dev/fbs/dumb_framebuffer0
```

If the -v and -f flags are specified, the driver will be added resulting in the following.

```
example# add_drv -vf whizzy_framebuffer
A reconfiguration boot must be performed to complete the
installation of this driver.
```

The following entries in /devices will be affected:

```
/devices/iommu@f,e0000000/sbus@f,e0001000/display[:*]
(Device currently managed by driver "dumb_framebuffer")
```

The following entries in /dev will be affected:

```
/dev/fbs/dumb_framebuffer0
```

The above example is currently only relevant to devices exporting a generic device name.

**EXAMPLE 4** Use of Double Quotes in Specifying Driver Alias

The following example shows the use of double quotes in specifying a driver alias that contains numbers.

```
example# add_drv -i "pci10c5,25" smc
```

**Exit Status** add\_drv returns 0 on success and 1 on failure.

**Files**

- /kernel/drv
  - 32-bit boot device drivers
- /kernel/drv/sparcv9
  - 64-bit SPARC boot device drivers
- /kernel/drv/amd64

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcs          |

**See Also** [boot\(1M\)](#), [chmod\(1\)](#), [devfsadm\(1M\)](#), [flarccreate\(1M\)](#), [kernel\(1M\)](#), [modinfo\(1M\)](#), [rem\\_drv\(1M\)](#), [update\\_drv\(1M\)](#), [driver.conf\(4\)](#), [system\(4\)](#), [attributes\(5\)](#), [live\\_upgrade\(5\)](#), [privileges\(5\)](#), [devfs\(7FS\)](#), [ddi\\_create\\_minor\\_node\(9F\)](#)

### *Writing Device Drivers*

**Notes** It is possible to add a driver for a device already being managed by a different driver, where the driver being added appears in the device's `compatible` list before the current driver. In such cases, a reconfiguration boot is required (see [boot\(1M\)](#) and [kernel\(1M\)](#)). After the reconfiguration boot, device links in `/dev` and references to these files may no longer be valid (see the `-v` flag). If a reconfiguration boot would be required to complete the driver installation, `add_drv` will fail unless the `-f` option is specified. See Example 3 in the EXAMPLES section.

With the introduction of the device policy several drivers have had their minor permissions changed and a device policy instated. The typical network driver should use the following device policy:

```
add_drv -p 'read_priv_set=net_rawaccess\
 write_priv_set=net_rawaccess' -m '* 666 root sys'\
 mynet
```

This document does not constitute an API. `/etc/minor_perm`, `/etc/name_to_major`, `/etc/driver_classes`, and `/devices` may not exist or may have different contents or interpretations in a future release. The existence of this notice does not imply that any other documentation that lacks this notice constitutes an API.

`/etc/minor_perm` can only be updated by `add_drv(1M)`, `rem_drv(1M)` or `update_drv(1M)`.

In the current version of `add_drv`, the use of double quotes to specify an alias is optional when used from the command line. However, when using `add_drv` from packaging scripts, you should continue to use double quotes to specify an alias.

Some drivers should not be added and configured on the system directly, but should only be configured as the system boots. The reasons for this restriction include, but are not limited to, a driver dependency on configuration early during boot or a dependency on some kernel component being installed or updated at the same time as the driver is being added. Such drivers should only be added to the system with the `-n` flag, so the driver is only loaded and configured when the system is rebooted, thus assuring an environment in which the driver can be configured properly.

**Bugs** Previous versions of `add_drv` accepted a pathname for `device_driver`. This feature is no longer supported and results in failure.

**Name** afbconfig, SUNWafb\_config – configure the AFB Graphics Accelerator

**Synopsis** /usr/sbin/afbconfig [-dev *device-filename*]  
 [-res *video-mode* [now | try] [noconfirm | nocheck]]  
 [-file machine | system] [-deflinear true | false]  
 [-defoverlay true | false]  
 [-overlayorder first | last]  
 [-expvis enable | disable] [-sov enable | disable]  
 [-maxwinds *n*] [-extovl enable | disable]  
 [-g *gamma-correction-value*]  
 [-gfile *gamma-correction-file*] [-propt] [-prconf]  
 [-defaults]  
  
 /usr/sbin/afbconfig [-propt] [-prconf]  
 /usr/sbin/afbconfig [-help] [-res ?]

**Description** afbconfig configures the AFB Graphics Accelerator and some of the X11 window system defaults for AFB.

The following form of afbconfig stores the specified options in the OWconfig file:

```
/usr/sbin/afbconfig [-devdevice-filename]

 [-res video-mode [now | try] [noconfirm | nocheck]]

 [-file machine | system] [-deflinear true | false]

 [-defoverlay true | false]

 [-overlayorderfirst | last] [-expvisenable | disable]

 [-sov enable | disable] [-maxwindsn]

 [-extovl enable | disable] [-ggamma-correction-value]

 [-gfilegamma-correction-file] [-propt] [-prconf]

 [-defaults]
```

The options are used to initialize the AFB device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots.

The following forms of the afbconfig command invoke only the -prconf, -propt, -help, and -res ? options. None of these options update the OWconfig file.

```
/usr/sbin/afbconfig [-propt] [-prconf]

 /usr/sbin/afbconfig [-help] [-res ?]
```

Additionally, the following invocation of afbconfig ignores all other options:

```
/usr/sbin/afbconfig [-help] [-res ?]
```

You can only specify options for one AFB device at a time. Specifying options for multiple AFB devices requires multiple invocations of the afbconfig command.

Only AFB-specific options can be specified through afbconfig. The normal window system options for specifying default depth, visual class and so forth are still specified as device modifiers on the openwin command line.

You can also specify the `OWconfig` file that is to be updated. By default, the machine-specific file in the `/etc/openwin` directory tree is updated. The `-file` option can be used to specify an alternate file to use. For example, the system-global `OWconfig` file in the `/usr/openwin` directory tree can be updated instead.

Both of these standard `OWconfig` files can only be written by root. Consequently, the `afbconfig` program, which is owned by the root user, always runs with `setuid root` permission.

**Option Defaults** For a given invocation of an `afbconfig` command line if an option does not appear on the command line, the corresponding `OWconfig` option is not updated; it retains its previous value. When the window system is run, if an AFB option has never been specified by way of `afbconfig`, a default value is used. The option defaults are as follows:

|                            |                            |
|----------------------------|----------------------------|
| <code>-dev</code>          | <code>/dev/fbs/afb0</code> |
| <code>-file</code>         | <code>machine</code>       |
| <code>-res</code>          | <code>none</code>          |
| <code>-deflinear</code>    | <code>false</code>         |
| <code>-defoverlay</code>   | <code>false</code>         |
| <code>-linearorder</code>  | <code>last</code>          |
| <code>-overlayorder</code> | <code>last</code>          |
| <code>-expvis</code>       | <code>enabled</code>       |
| <code>-sov</code>          | <code>enabled</code>       |
| <code>-maxwids</code>      | <code>32</code>            |
| <code>-extovl</code>       | <code>enabled</code>       |
| <code>-g</code>            | <code>2.22</code>          |

The default for the `-res` option of `none` means that when the window system is run the screen resolution is the video mode currently programmed in the device.

This provides compatibility for users who are used to specifying the device resolution through the PROM. On some devices (for example, GX) this is the only way of specifying the video mode. This means that the PROM ultimately determines the default AFB video mode.

**Options** The following options are supported:

`-defaults`  
Resets all option values to their default values.

`-deflinear true | false`

AFB possesses two types of visuals: linear and nonlinear. Linear visuals are gamma corrected and nonlinear visuals are not. There are two visuals that have both linear and nonlinear versions: 24-bit TrueColor and 8-bit StaticGray.

If `true`, the default visual is set to the linear visual that satisfies other specified default visual selection options (specifically, the Xsun(1) `defdepth` and `defclass` options described in the OpenWindows Reference Manual).

If `false`, or if there is no linear visual that satisfies the other default visual selection options, the non-linear visual specified by these other options are chosen as the default. This option cannot be used when the `-defoverlay` option is present, because AFB doesn't possess a linear overlay visual.

`-defoverlay true | false`

The AFB provides an 8-bit PseudoColor visual whose pixels are disjoint from the rest of the AFB visuals. This is called the overlay visual. Windows created in this visual do not damage windows created in other visuals. The converse, however, is not true. Windows created in other visuals damage overlay windows.

The number of colors available to the windows created using this visual depends on the settings for the `-extovl` option. If the `-extovl` is enabled, extended overlay with 256 opaque color values is available. See `-extovl`. If `-extovl` is disabled, extended overlay is not available and the visual has 256 `-maxwids`) number of opaque color values. See `-maxwids`.

If the value of `-defoverlay` is `true`, the overlay visual is made the default visual. If the value of `-defoverlay` is `false`, the nonoverlay visual that satisfies the other default visual selection options, such as `def`, `depth`, and `defclass`, are chosen as the default visual. See the OpenWindows Reference Manual.

Whenever the `defoverlay true` option is used, the default depth and class specified on the `openwin` command line must be 8-bit PseudoColor. If not, a warning message is printed and the `-defoverlay` option is treated as `false`.

The `-defoverlay` option can not be used when the `-deflinear` option specified, because AFB doesn't possess a linear overlay visual.

`-dev device-filename`

Specifies the AFB special file. The default is `/dev/fbs/afb0`.

`-expvis enable | disable`

If enabled, activates OpenGL Visual Expansion. Multiple instances of selected visual groups (8-bit PseudoColor, 24-bit TrueColor and so forth) are in the screen visual list.

`-extovl enable | disable`

If enabled, makes extended overlay available. The overlay visuals have 256 opaque colors. The SOV visuals have 255 opaque colors and 1 transparent color.

This option also enables hardware supported transparency, thus provides better performance for windows using the SOV visuals.

**-file** *machine* | *system*

Specifies which OWconfig file to update. If *machine* is specified, the machine-specific OWconfig file in the `/etc/openwin` directory tree is updated. If *system* is specified, the global OWconfig file in the `/usr/openwin` directory tree is updated. If the specified file does not exist, it is created. This option has no effect unless other options are specified. The default is *machine*.

**-g** *gamma-correction value*

Allows changing the gamma correction value. All linear visuals provide gamma correction. By default, the *gamma-correction-value* is 2.22. Any value less than 0 is illegal. The gamma correction value is applied to the linear visual, which then has an effective gamma value of 1.0, which is the value returned by `XSolarisGetVisualGamma(3)`. See `XSolarisGetVisualGamma(3)` for a description of that function.

This option can be used while the window system is running. Changing the gamma correction value affects all the windows being displayed using the linear visuals.

**-gfile** *gamma-correction-file*

Loads the gamma correction table from the specified file (*gamma-correction-file*). This file should be formatted to provide the gamma correction values for R, G and B channels on each line. Each of these values should be in hexadecimal format and separated from each other by at least one space. *gamma-correction-file* should also provide 256 such triplets.

An example of a *gamma-correction-file* follows.

```
0x00 0x00 0x00
0x01 0x01 0x01

0xff 0xff 0xff
```

Using this option, the gamma correction table can be loaded while the window system is running. The new gamma correction affects all the windows being displayed using the linear visuals. When gamma correction is being done using user specified table, the gamma correction value is undefined. By default, the window system assumes a gamma correction value of 2.22 and loads the gamma table it creates corresponding to this value.

**-help**

Prints a list of the afbconfig command line options, along with a brief explanation of each.

**-linearorder** *first* | *last*

If *first*, linear visuals come before their non-linear counterparts on the X11 screen visual list for the AFB screen. If *last*, the nonlinear visuals come before the linear ones.

**-maxwids *n***

Specifies the maximum number of AFB X channel pixel values that are reserved for use as window IDs (WIDs). The remainder of the pixel values in overlay colormaps are used for normal X11 opaque color pixels. The reserved WIDs are allocated on a first-come first-serve basis by 3D graphics windows (such as XGL), MBX windows, and windows that have a non-default visual. The X channel codes 0 to (255 - *n*) are opaque color pixels. The X channel codes (255 - *n* + 1) to 255 are reserved for use as WIDs. Legal values are 1, 2, 4, 8, 16, 32, and 64.

This option is available only if the `-extovl` is disabled.

**-overlayorder first | last**

If `first`, the depth 8 PseudoColor Overlay visual comes before the non-overlay visual on the X11 screen visual list for the AFB screen. If `last`, the non-overlay visual comes before the overlay one.

**-propt**

Prints the current values of all AFB options in the `OWconfig` file specified by the `-file` option for the device specified by the `-dev` option. Prints the values of options as they will be in the `OWconfig` file after the call to `afbconfig` completes.

The following is a typical display:

```
--- OpenWindows Configuration for /dev/fbs/afb0 ---
OWconfig: machine
Video Mode: 1280x1024x76
Default Visual: Non-Linear Normal Visual
Visual Ordering: Linear Visuals are last
 Overlay Visuals are last
OpenGL Visual Expansion: enabled
Server Overlay Visuals: enabled
Extended Overlay: enabled
Underlay WIDs: 64 (not configurable)
Overlay WIDs: 4 (not configurable)
Gamma Correction Value: 2.220
Gamma Correction Table: Available
```

**-prconf**

Prints the AFB hardware configuration.

The following is a typical display:

```
--- Hardware Configuration for /dev/fbs/afb0 ---
Type: double-buffered AFB with Z-buffer
Board: rev 0 (Horizontal)
Number of Floats: 6
PROM Information: @(#)afb.fth x.xx xx/xx/xx
AFB ID: 0x101df06d
DAC: Brooktree 9070, version 1 (Pac2)
```

```

3DRAM: Mitsubishi 130a, version x
EDID Data: Available - EDID version 1 revision x
Monitor Sense ID: 4 (Sun 37x29cm RGB color monitor)
Monitor possible resolutions: 1024x768x77, 1024x800x84, 1
 1152x900x76, 1280x1024x67, 1280x1024x76, 960x680xx108s
Current resolution setting: 1280x1024x76

```

-sov enable | disable

If enabled, the root window's SERVER\_OVERLAY\_VISUALS property are advertised. SOV visuals are exported and their transparent types, values and layers can be retrieved through this property. If disabled, the SERVER\_OVERLAY\_VISUALS property are not defined and SOV visuals are not exported.

-res *video-mode* [ now | try [ noconfirm | nocheck ] ]

Specifies the video mode used to drive the monitor connected to the specified AFB device.

The format of these built-in video modes is: *widthxheightxrate*, where *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh.

The s suffix of 960x680x112s and 960x680x108s means that these are stereo video modes. The i suffix of 640x480x60i and 768x575x50i designates interlaced video timing. If absent, non-interlaced timing is used.

As a convenience, the -res also accepts formats with an at sign (@) in front of the refresh rate instead of *n*, (1280x1024@76). Some video-modes, supported by AFB, may not be supported by the monitor. The list of video-modes supported by the AFB device and the monitor can be obtained by running afbconfig with the -res ? option (the third form shown SYNOPSIS).

A list of all possible video-modes supported on AFB follows:

```

1024x768x60
1024x768x70
1024x768x75
1024x768x77
1024x800x84
1152x900x66
1152x900x76
1280x800x76
1280x1024x60
1280x1024x67
1280x1024x76
960x680x112s (Stereo)
960x680x108s (Stereo)
640x480x60
640x480x60i (Interlaced)
768x575x50i (Interlaced)

```

For convenience, some of the video-modes supported on the AFB have *symbolic names* defined for them. Instead of the form *widthxheightxrate*, one of these names may be supplied as the argument to the `-res` option. The meaning of the symbolic name `none` is that when the window system is run, the screen resolution is the video mode that is currently programmed in the device.

A list of symbolic names for video-modes supported on AFB follows:

| Name                | Corresponding Video Mode  |
|---------------------|---------------------------|
| <code>svga</code>   | <code>1024x768x60</code>  |
| <code>1152</code>   | <code>1152x900x76</code>  |
| <code>1280</code>   | <code>1280x1024x76</code> |
| <code>stereo</code> | <code>960x680x112s</code> |
| <code>ntsc</code>   | <code>640x480x60i</code>  |
| <code>pal</code>    | <code>768x575x50i</code>  |
| <code>none</code>   | (see text above)          |

The `-res` option also accepts the additional, optional arguments immediately following the video mode specification. Any or all of the following arguments can be specified:

- `noconfirm` Using the `-res` option, the user could potentially put the system into an unusable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this, the default behavior of `afbconfig` is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. The `noconfirm` option instructs `afbconfig` to bypass this confirmation and to program the requested video mode anyway. This option is useful when `afbconfig` is being run from a shell script.
- `nocheck` If present, the normal error checking based on the monitor sense code is suspended. The video mode specified by the user is accepted regardless of whether it is appropriate for the currently attached monitor. (This option is useful if a different monitor is to be connected to the AFB device). Use of this option implies `noconfirm` well.
- `now` Updates the video mode in the `0Wconfig` file, and immediately programs the AFB device to display this video mode. This is useful for changing the video mode before starting the window system.

This argument should not be used with `afbconfig` while the configured device is being used (for example, while running the window system); unpredictable results may occur. To run `afbconfig` with the `now` argument, first bring the window system down. If the `now` argument is used within a window system session, the video mode is changed immediately, but the width and height of the affected screen won't change until the window system is exited and re-entered again. In addition, the system may not recognize changes in stereo mode. Consequently, this usage is strongly discouraged.

**try** If present, the specified video mode is programmed on a trial basis. The user is asked to confirm the video mode by typing `y` within 10 seconds. Or the user may terminate the trial before 10 seconds are up by typing any character. Any character other than `y` or Return is considered a `no`. The previous video mode is restored and `afbconfig` does not change the video mode in the `OWconfig` file (other options specified still take effect). If a Return is typed, the user is prompted for a `yes` or `no` answer on whether to keep the new video mode.

This sub-option should not be used with `afbconfig` while the configured device is being used (for example, while running the window system) as unpredictable results may occur. To run `afbconfig` with the `try` sub-option, the window system should be brought down first.

**Examples** **EXAMPLE 1** Switching the monitor type

The following example switches the monitor type to a resolution of 1280 x 1024 at 76 Hz:

```
example% /usr/sbin/afbconfig -res 1280x1024x76
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| <code>/var/apache/htdocs</code>  | Default document root.<br><br>This can be changed by altering the <code>httpd.conf</code> file and restarting the server.                                                                                                                                    |

|                                |                                                                                                                                                                                                                                                              |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/var/apache/icons</code> | Icons used by the server.<br><br>This normally shouldn't need to be changed.                                                                                                                                                                                 |
| <code>/var/apache/logs</code>  | Contains server log files.<br><br>The formats, names, and locations of the files in this directory can be altered by various configuration directives in the <code>httpd.conf</code> file.                                                                   |
| <code>/var/apache/proxy</code> | Directory used to cache pages if the caching feature of <code>mod_proxy</code> is enabled in the <code>httpd.conf</code> file.<br><br>The location of the cache can also be changed by changing the proxy configuration in the <code>httpd.conf</code> file. |

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE                                                                    |
|----------------|------------------------------------------------------------------------------------|
| Availability   | web/server/apache-13<br>web/server/apache-13<br>web/server/apache-13/documentation |

**See Also** [attributes\(5\)](#)

<http://www.apache.org>

**Notes** In addition to the documentation and man pages included with Solaris, more information is available at <http://www.apache.org>

The Apache man pages are provided with the programming modules. To view the manual pages for the Apache modules with the `man` command, add `/usr/apache/man` to the `MANPATH` environment variable. See [man\(1\)](#) for more information. Running [catman\(1M\)](#) on the Apache manual pages is not supported.

**Name** arp – address resolution display and control

**Synopsis** arp *hostname*

arp -a [-n]

arp -d *hostname*

arp -f *filename*

arp -s *hostname ether\_address* [temp] [pub] [trail]  
[permanent]

**Description** The arp program displays and modifies the Internet-to-MAC address translation tables used by the address resolution protocol (see [arp\(7P\)](#)).

With no flags, the program displays the current ARP entry for *hostname*. The host may be specified by name or by number, using Internet dot notation.

Options that modify the ARP translation tables (-d, -f, and -s) can be used only when the invoked command is granted the `sys_net_config` privilege. See [privileges\(5\)](#).

- Options**
- a Display all of the current ARP entries. The definition for the flags in the table are:
    - d Unverified; this is a local IP address that is currently undergoing Duplicate Address Detection. ARP will not respond to requests for this address until Duplicate Address Detection completes.
    - o Old; this entry is aging away. If IP requests it again, a new ARP query will be generated. This state is used for detecting peer address changes.
    - y Delayed; periodic address defense and conflict detection was unable to send a packet due to internal network use limits for non-traffic-related messages (100 packets per hour per interface). This occurs only on interfaces with very large numbers of aliases.
    - A Authority; this machine is authoritative for this IP address. ARP will not accept updates from other machines for this entry.
    - L Local; this is a local IP address configured on one of the machine's logical interfaces. ARP will defend this address if another node attempts to claim it.
    - M Mapping; only used for the multicast entry for 224.0.0.0
    - P Publish; includes IP address for the machine and the addresses that have explicitly been added by the -s option. ARP will respond to ARP requests for this address.
    - S Static; entry cannot be changed by learned information. This indicates that the permanent flag was used when creating the entry.
    - U Unresolved; waiting for ARP response.

You can use the `-n` option with the `-a` option to disable the automatic numeric IP address-to-name translation. Use `arp -an` or `arp -na` to display numeric IP addresses. The `arp -a` option is equivalent to:

```
netstat -p -f inet
```

...and `-an` and `-na` are equivalent to:

```
netstat -pn -f inet
```

- d Delete an entry for the host called *hostname*.

Note that ARP entries for IPMP (IP Network Multipathing) data and test addresses are managed by the kernel and thus cannot be deleted.

- f Read the file named *filename* and set multiple entries in the ARP tables. Entries in the file should be of the form:

```
hostname MACaddress [temp] [pub] [trail] [permanent]
```

See the `-s` option for argument definitions.

- s Create an ARP entry for the host called *hostname* with the MAC address *MACaddress*. For example, an Ethernet address is given as six hexadecimal bytes separated by colons. The entry will not be subject to deletion by aging unless the word *temp* is specified in the command. If the word *pub* is specified, the entry will be published, which means that this system will respond to ARP requests for *hostname* even though the *hostname* is not its own. The word *permanent* indicates that the system will not accept MAC address changes for *hostname* from the network.

Solaris does not implement trailer encapsulation, and the word *trail* is accepted on entries for compatibility only.

`arp -s` can be used for a limited form of proxy ARP when a host on one of the directly attached networks is not physically present on a subnet. Another machine can then be configured to respond to ARP requests using `arp -s`. This is useful in certain SLIP configurations.

Non-temporary proxy ARP entries for an IPMP (IP Network Multipathing) group are automatically managed by the kernel. Specifically, if the hardware address in an entry matches the hardware address of an IP interface in an IPMP group, and the IP address is not local to the system, this will be regarded as an IPMP proxy ARP entry. This entry will have its hardware address automatically adjusted in order to keep the IP address reachable so long as the IPMP group has not entirely failed.

ARP entries must be consistent across an IPMP group. Therefore, ARP entries cannot be associated with individual underlying IP interfaces in an IPMP group, and must instead be associated with the corresponding IPMP IP interface.

Note that ARP entries for IPMP data and test addresses are managed by the kernel and thus cannot be changed.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

**Name** atohexlabel – convert a human readable label to its internal text equivalent

**Synopsis** /usr/sbin/atohexlabel [*human-readable-sensitivity-label*]  
 /usr/sbin/atohexlabel -c [*human-readable-clearance*]

**Description** atohexlabel converts a human readable label into an internal text representation that is safe for storing in a public object. If no option is supplied, the label is assumed to be a sensitivity label.

Internal conversions can later be parsed to their same value. This internal form is often hexadecimal. The converted label is written to the standard output file. If no human readable label is specified, the label is read from the standard input file. The expected use of this command is emergency repair of labels that are stored in internal databases.

**Options** -c Identifies the human readable label as a clearance.

**Exit Status** The following exit values are returned:

0 On success.  
 1 On failure, and writes diagnostics to the standard error file.

**Files** /etc/security/tsol/label\_encodings  
 The label encodings file contains the classification names, words, constraints, and values for the defined labels of this system.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | system/trusted  |
| Interface Stability | See below.      |

The command output is Committed for systems with the same label\_encodings file. The command invocation is Committed for systems that implement the DIA MAC policy.

**See Also** [hextoalabel\(1M\)](#), [label\\_to\\_str\(3TSOL\)](#), [str\\_to\\_label\(3TSOL\)](#), [label\\_encodings\(4\)](#), [attributes\(5\)](#)

“How to Obtain the Hexadecimal Equivalent for a Label” in *Oracle Solaris Trusted Extensions Configuration and Administration*

**Notes** The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

This file is part of the Defense Intelligence Agency (DIA) Mandatory Access Control (MAC) policy. This file might not be applicable to other MAC policies that might be developed for future releases of Solaris Trusted Extensions software.

**Name** audit – control the behavior of the audit daemon

**Synopsis** audit -n | -s | -t | -v

**Description** The `audit` command is the system administrator's interface to start, stop, and refresh the audit service `auditd(1M)`. Refreshing the audit service rereads the system and plugin configuration.

**Options**

- n Notify the audit service `audit_binfile` plugin to close the current audit file and open a new audit file in the current audit directory.
- s Start (enable) the audit service if it is not running, or refresh the audit service, if it is currently running.
- t Terminate (disable) the audit service. The audit service will close out the active plugins, stop auditing and exit. Use `-s` to restart auditing.
- v Verify that at least one plugin is active. Verify the directory parameters of `audit_binfile(5)`.

**Diagnostics** The `audit` command will exit with 0 upon success and a positive integer upon failure.

**Attributes** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | Committed       |

**See Also** `auditconfig(1M)`, `auditd(1M)`, `attributes(5)`, `audit_binfile(5)`

See the section on Solaris Auditing in *System Administration Guide: Security Services*.

**Notes** The `audit` command does not modify a process's preselection mask. Its functions are limited to performing control actions of the auditing subsystem. See `auditconfig(1M)` for configuration.

The `-s` option validates the audit plugin configuration. If it is not valid an error message is displayed and the audit service is not started or refreshed. The `-v` option may be used to validate the audit plugin configuration before using the `-s` option to start or refresh the audit service.

All options are valid in the global zone. Unless per-zone is enabled, only the `-v` option is valid in a local zone. See `auditconfig(1M)` for per-zone audit configuration.

**Name** auditconfig – configure auditing

**Synopsis** auditconfig *subcommand*...

**Description** auditconfig provides a command line interface to get and set kernel audit parameters.

Except for getting or setting the persistent audit service values, this functionality is available only if the Solaris Auditing feature has been enabled.

A zero (0) queue value indicates that the system default is in effect.

The setting of the perzone policy determines the scope of the audit setting controlled by auditconfig. If perzone is set, then the values reflect the local zone except as noted. Otherwise, the settings are for the entire system. Any restriction based on the perzone setting is noted for each option to which it applies.

A non-global zone administrator can set all audit policy options except perzone and ahlt. perzone and ahlt apply only to the global zone; setting these policies requires the privileges of a global zone administrator. perzone and ahlt are described under the -setpolicy option, below.

This command is available to administrators who have been granted the Audit Control Rights Profile.

**Options** The following option is supported:

-t

Display or set the values on the running system in addition to the persistent values of the audit service.

This option is available only for the subcommands that list it below.

**Sub-commands** -aconf

Set the configured non-attributable audit mask. For example:

```
auditconfig -aconf
Configured non-attributable event mask.
```

-audit event *sofretval string*

This command constructs an audit record for audit event *event* using the process's audit characteristics containing a text token *string*. The return token is constructed from the *sof* (success/failure flag) and the *retval* (return value). The event is type *char\**, the *sof* is 0/1 for success/failure, *retval* is an *errno* value, *string* is type *\*char*. This command is useful for constructing an audit record with a shell script. An example of this option:

```
auditconfig -audit AUE_ftpd 0 0 "test string"
#
```

audit record from audit trail:

```
header,76,2,ftp access,,Fri Dec 08 08:44:02 2000, + 669 msec
```

```

subject,abc,root,other,root,other,104449,102336,235 197121 elbow
text,test string
return,success,0

```

**-chkaconf**

Checks the configuration of the non-attributable events set in the kernel against the entries configured in the audit service (-setnaflags). If the active class mask of a kernel audit event does not match the configured class mask, a mismatch is reported.

**-chkconf**

Check the configuration of kernel audit event to class mappings. If the runtime class mask of a kernel audit event does not match the configured class mask, a mismatch is reported.

**-conf**

Configure kernel audit event to class mappings. Runtime class mappings are changed to match those in the audit event to class database file.

**-getasid**

Prints the audit session ID of the current process. For example:

```

auditconfig -getasid
audit session id = 102336

```

**-getaudit**

Returns the audit characteristics of the current process.

```

auditconfig -getaudit
audit id = abc(666)
process preselection mask = lo(0x1000,0x1000)
terminal id (maj,min,host) = 235,197121,elbow(172.146.89.77)
audit session id = 102336

```

**-getauid**

Prints the audit ID of the current process. For example:

```

auditconfig -getauid
audit id = abc(666)

```

**-getcar**

Prints current active root location (anchored from root [or local zone root] at system boot). For example:

```

auditconfig -getcar
current active root = /

```

**-getclass *event***

Display the preselection mask associated with the specified kernel audit event. *event* is the kernel event number or event name.

**-getcond**

Display the kernel audit condition. The condition displayed is the literal string `auditing` meaning auditing is enabled and turned on (the kernel audit module is constructing and

queuing audit records); `noaudit`, meaning auditing is enabled but turned off (the kernel audit module is not constructing and queuing audit records); `disabled`, meaning that the audit module has not been enabled; or `nospace`, meaning there is no space for saving audit records. See `auditon(2)` and `auditd(1M)` for further information.

**-getestate *event***

For the specified event (string or event number), print out classes *event* has been assigned. For example:

```
auditconfig -getestate 20
audit class mask for event AUE_REBOOT(20) = 0x800
auditconfig -getestate AUE_RENAME
audit class mask for event AUE_RENAME(42) = 0x30
```

**-getflags**

Display the user default audit preselection flags.

**-getkaudit**

Get audit characteristics of the current zone. For example:

```
auditconfig -getkaudit
audit id = unknown(-2)
process preselection mask = lo,na(0x1400,0x1400)
terminal id (maj,min,host) = 0,0,(0.0.0.0)
audit session id = 0
```

If the audit policy `perzone` is not set, the terminal id is that of the global zone. Otherwise, it is the terminal id of the local zone.

**-getkmask**

Get non-attributable pre-selection mask for the current zone. For example:

```
auditconfig -getkmask
audit flags for non-attributable events = lo,na(0x1400,0x1400)
```

If the audit policy `perzone` is not set, the kernel mask is that of the global zone. Otherwise, it is that of the local zone.

**-getnaflags**

Display the non-attributable audit flags.

**-getpinfo *pid***

Display the audit ID, preselection mask, terminal ID, and audit session ID for the specified process.

**-getplugin [*name*]**

Display information about the plugin name. If *name* is not specified, display all plugins.

**[-t] -getpolicy**

Display the kernel audit policy. The `audit` and `perzone` policies reflect the settings from the global zone. If `perzone` is set, all other policies reflect the local zone's settings. If `perzone` is not set, the policies are machine-wide.

**-getcwd**

Prints current working directory (anchored from zone root at system boot). For example:

```
cd /usr/tmp
auditconfig -getcwd
current working directory = /var/tmp
```

**[-t] -getqbufsz**

Get audit queue write buffer size. For example:

```
auditconfig -getqbufsz
no configured audit queue size
audit queue buffer size (bytes) = 1024
```

**[-t] -getqctrl**

Get audit queue write buffer size, audit queue hiwater mark, audit queue lowater mark, audit queue prod interval (ticks).

```
auditconfig -getqctrl
no configured audit queue lowater mark
no configured audit queue hiwater mark
no configured audit queue size
no configured audit queue delay
audit queue hiwater mark (records) = 100
audit queue lowater mark (records) = 10
audit queue buffer size (bytes) = 1024
audit queue delay (ticks) = 20

auditconfig -setqbufsz 8192
auditconfig -t -setqbufsz 12288
auditconfig -setqdelay 20
auditconfig -t -setqdelay 25
auditconfig -getqctrl
no configured audit queue lowater mark
no configured audit queue hiwater mark
configured audit queue buffer size (bytes) = 8192
configured audit queue delay (ticks) = 20
active audit queue hiwater mark (records) = 100
active audit queue lowater mark (records) = 10
active audit queue buffer size (bytes) = 12288
active audit queue delay (ticks) = 25
```

**[-t] -getqdelay**

Get interval at which audit queue is prodded to start output. For example:

```
auditconfig -getqdelay
no configured audit queue delay
audit queue delay (ticks) = 20
```

**[-t] -getqhiwater**

Get high water point in undelivered audit records when audit generation will block. For example:

```
./auditconfig -getqhiwater
no configured audit queue hiwater mark
audit queue hiwater mark (records) = 100
```

**[-t] -getqlowater**

Get low water point in undelivered audit records where blocked processes will resume. For example:

```
auditconfig -getqlowater
no configured audit queue lowater mark
audit queue lowater mark (records) = 10
```

**-getstat**

Print current audit statistics information. For example:

```
auditconfig -getstat
gen nona kern aud ctl enq wrtn wblk rblk drop tot mem
910 1 725 184 0 910 910 0 231 0 88 48
```

See [auditstat\(1M\)](#) for a description of the headings in `-getstat` output.

**-gettid**

Print audit terminal ID for current process. For example:

```
auditconfig -gettid
terminal id (maj,min,host) = 235,197121,elbow(172.146.89.77)
```

**-lsevent**

Display the currently configured (runtime) kernel and user level audit event information.

**-lspolicy**

Display the kernel audit policies with a description of each policy.

**-setasid *session-ID* [*cmd*]**

Execute shell or *cmd* with specified *session-ID*. For example:

```
./auditconfig -setasid 2000 /bin/ksh
#
./auditconfig -getpinfo 104485
audit id = abc(666)
process preselection mask = lo(0x1000,0x1000)
terminal id (maj,min,host) = 235,197121,elbow(172.146.89.77)
audit session id = 2000
```

**-setaudit *audit-ID* *preselect\_flags* *term-ID* *session-ID* [*cmd*]**

Execute shell or *cmd* with the specified audit characteristics.

**-setaudit *audit-ID* [*cmd*]**

Execute shell or *cmd* with the specified *audit-ID*.

- setclass *event audit\_flag[,audit\_flag...]*  
Map the kernel event *event* to the classes specified by *audit\_flag* list. *event* is an event number or name. An *audit\_flag* is a character string representing an audit class. See [audit\\_flags\(5\)](#) for further information. If *perzone* is not set, this option is valid only in the global zone.
- setflags *audit\_flags*  
Set the default user audit preselection flags; see [audit\\_flags\(5\)](#). The default preselection flags are combined with the user's specific audit flags to form the user's audit preselection mask.
- setkaudit *IP-address\_type IP\_address*  
Set IP address of machine to specified values. *IP-address\_type* is *ipv6* or *ipv4*.  
  
If *perzone* is not set, this option is valid only in the global zone.
- setkmask *audit\_flags*  
Set non-attributable preselection flags of machine.  
  
If *perzone* is not set, this option is valid only in the global zone.
- setnaflags *audit\_flags*  
Set the non-attributable audit flags; see [audit\\_flags\(5\)](#). Non-attributable audit flags define which classes of events are to be audited when the action cannot be attributed to an authenticated user. Failed login is an example of an event that is non-attributable.
- setpmask *pid flags*  
Set the preselection mask of the specified process. *flags* is the ASCII representation of the flags similar to that in [audit\\_flags\(5\)](#).  
  
If *perzone* is not set, this option is valid only in the global zone.
- setplugin *name active | inactive [attributes [qsize]]*  
Configure the plugin name to be *active* or *inactive*. Optionally configure the attributes and number of unprocessed audit records to queue for the plugin. See the relevant audit plugin man pages and [auditd\(1M\)](#).
- [-t] -setpolicy [+|-]*policy\_flag[,policy\_flag...]*  
Set the kernel audit policy. A policy *policy\_flag* is literal strings that denotes an audit policy. A prefix of + adds the policies specified to the current audit policies. A prefix of - removes the policies specified from the current audit policies. No policies can be set from a local zone unless the *perzone* policy is first set from the global zone. The following are the valid policy flag strings (`auditconfig -lspolicy` also lists the current valid audit policy flag strings):
 

|      |                                                                                                                                                                                                              |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| all  | Include all policies that apply to the current zone.                                                                                                                                                         |
| ahlt | Panic is called and the system dumps core if an asynchronous audit event occurs that cannot be delivered because the audit queue has reached the high-water mark or because there are insufficient resources |

|              |                                                                                                                                                                                                                                           |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|              | to construct an audit record. By default, records are dropped and a count is kept of the number of dropped records.                                                                                                                       |
| arge         | Include the <code>execv(2)</code> system call environment arguments to the audit record. This information is not included by default.                                                                                                     |
| argv         | Include the <code>execv(2)</code> system call parameter arguments to the audit record. This information is not included by default.                                                                                                       |
| cnt          | Do not suspend processes when audit resources are exhausted. Instead, drop audit records and keep a count of the number of records dropped. By default, process are suspended until audit resources become available.                     |
| group        | Include the supplementary group token in audit records. By default, the group token is not included.                                                                                                                                      |
| none         | Include no policies. If used in other than the global zone, the <code>ahlt</code> and <code>perzone</code> policies are not changed.                                                                                                      |
| path         | Add secondary path tokens to audit record. These are typically the pathnames of dynamically linked shared libraries or command interpreters for shell scripts. By default, they are not included.                                         |
| perzone      | Maintain separate configuration, queues, and logs for each zone and execute a separate version of <code>auditd(1M)</code> for each zone.                                                                                                  |
| public       | Audit public files. By default, read-type operations are not audited for certain files which meet <i>public</i> characteristics: owned by root, readable by all, and not writable by all.                                                 |
| trail        | Include the trailer token in every audit record. By default, the trailer token is not included.                                                                                                                                           |
| seq          | Include the sequence token as part of every audit record. By default, the sequence token is not included. The sequence token attaches a sequence number to every audit record.                                                            |
| windata_down | Include in an audit record any downgraded data moved between windows. This policy is available only if the system is configured with Trusted Extensions. By default, this information is not included.                                    |
| windata_up   | Include in an audit record any upgraded data moved between windows. This policy is available only if the system is configured with Trusted Extensions. By default, this information is not included.                                      |
| zonename     | Include the <code>zonename</code> token as part of every audit record. By default, the <code>zonename</code> token is not included. The <code>zonename</code> token gives the name of the zone from which the audit record was generated. |

- [-t] -setqbufsz *buffer\_size***  
Set the audit queue write buffer size (bytes). Zero (0), indicates reset to no configured value.
- [-t] -setqctrl *hiwater lowater bufsz interval***  
Set the audit queue write buffer size (bytes), hiwater audit record count, lowater audit record count, and wakeup interval (ticks). Valid within a local zone only if perzone is set. Zero (0), indicates reset to no configured value.
- [-t] -setqdelay *interval***  
Set the audit queue wakeup interval (ticks). This determines the interval at which the kernel pokes the audit queue, to write audit records to the audit trail. Valid within a local zone only if perzone is set. Zero (0), indicates reset to no configured value.
- [-t] -setqhiwater *hiwater***  
Set the number of undelivered audit records in the audit queue at which audit record generation blocks. Valid within a local zone only if perzone is set. Zero (0), indicates reset to no configured value.
- [-t] -setqlowater *lowater***  
Set the number of undelivered audit records in the audit queue at which blocked auditing processes unblock. Valid within a local zone only if perzone is set. Zero (0), indicates reset to no configured value.
- setsmask *asid flags***  
Set the preselection mask of all processes with the specified audit session ID. Valid within a local zone only if perzone is set.
- setstat**  
Reset audit statistics counters. Valid within a local zone only if perzone is set.
- setumask *asid flags***  
Set the preselection mask of all processes with the specified audit ID. Valid within a local zone only if perzone is set.

### Examples EXAMPLE 1 Using auditconfig

The following is an example of an auditconfig command:

```
#
map kernel audit event number 10 to the "fr" audit class
#
% auditconfig -setclass 10 fr

#
turn on inclusion of exec arguments in exec audit records
#
% auditconfig -setpolicy +argv
```

**EXAMPLE 2** Setting Only the Number of Unprocessed Audit Records

The following sequence of commands sets only the number of unprocessed audit records to queue for the `audit_binfile` plugin:

```
#
see if audit_binfile is active
#
% auditconfig -getplugin audit_binfile

#
set to queue 20 unprocessed audit records
#
% auditconfig -setplugin active "" 20
```

**Exit Status** 0 Successful completion.  
1 An error occurred.

**Files** `/etc/security/audit_event` Stores event definitions used in the audit system.  
`/etc/security/audit_class` Stores class definitions used in the audit system.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE       | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcs          |
| Interface Stability | Committed       |

**See Also** [audit\(1M\)](#), [auditd\(1M\)](#), [auditstat\(1M\)](#), [praudit\(1M\)](#), [auditon\(2\)](#), [execv\(2\)](#), [au\\_user\\_mask\(3BSM\)](#), [audit\\_class\(4\)](#), [audit\\_event\(4\)](#), [attributes\(5\)](#), [audit\\_binfile\(5\)](#), [audit\\_flags\(5\)](#), [audit\\_remote\(5\)](#), [audit\\_syslog\(5\)](#)

See the section on Solaris Auditing in *System Administration Guide: Security Services*.

**Notes** If plugin output is selected using the `-setplugin` option, the behavior of the system with respect to the `-setpolicy +cnt` and the `-setqhiwater` options is modified slightly. If `-setpolicy +cnt` is set, data will continue to be sent to the selected plugin, even though output of the `audit_binary` plugin is stopped, pending the freeing of disk space. If `-setpolicy -cnt` is used, the blocking behavior is as described under **SUBCOMMANDS**, above. The queue high water mark value is used within `auditd` as the upper bound for its queue limits unless overridden by means of the `qsize` attribute, as described in the explanation of the `-setplugin` option, above.

The `auditconfig` options that modify or display process-based information are not affected by the `perzone` policy. Those that modify system audit data such as the terminal id and audit

queue parameters are valid only in the global zone, unless the perzone policy is set. The display of a system audit reflects the local zone if perzone is set. Otherwise, it reflects the settings of the global zone.

The change to plugins (`-setplugin`) settings do not take effect (such as becoming active or inactive, or changing the active attribute or queue size values) until the audit service is refreshed. Use [audit\(1M\)](#) to refresh the audit service.

**Name** auditd – audit daemon

**Synopsis** /usr/sbin/auditd

**Description** The audit daemon, `auditd`, controls the generation and location of audit trail files and the generation of `syslog` messages based on its configuration (see [auditconfig\(1M\)](#)). If auditing is enabled, `auditd` reads its configuration to do the following:

- Configure audit policy.
- Configure the audit queue control parameters.
- Configure the event-to-class mappings.
- Set the default audit masks.
- Load one or more plugins.

Solaris provides three plugins. `audit_binfile(5)` writes binary audit data to a file. `audit_remote(5)` sends binary audit data to an authenticated server with privacy and integrity protection. `audit_syslog(5)` sends text summaries of audit records to the `syslog` daemon.

- Read audit data from the kernel and pass that data to each of the active plugins.
- Execute the `audit_warn(1M)` script to warn of various conditions.

`audit(1M)` is used to control `auditd`. It can cause `auditd` to:

- Close the current audit file and open a new one.
- Start and refresh the service based on the current properties.
- Close the audit trail and terminate auditing.

`auditconfig(1M)` is used to configure `auditd`. It can configure the active and permanent:

- audit policy
- audit queue control parameters
- default audit masks
- which plugins are to be loaded
- plugin attributes

**Audit Record Queue** The maximum number of records to queue for audit data sent to the plugin is specified by the `qsize` parameter specified for the plugin. If omitted, the current `hiwater` mark is used. See the `-getqctrl` option in [auditconfig\(1M\)](#). When this maximum is reached, `auditd` will either block processes or discard data, depending on the `cnt` audit policy as described in [auditconfig\(1M\)](#).

**Auditing Conditions** The audit daemon and audit plugins invoke the program `audit_warn(1M)` under certain conditions. See [audit\\_warn\(1M\)](#) for more information.

- Files**
- `etc/security/audit/audit_class`
  - `etc/security/audit/audit_event`

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcs          |
| Interface Stability | Committed       |

**See Also** [audit\(1M\)](#), [audit\\_warn\(1M\)](#), [auditconfig\(1M\)](#), [praudit\(1M\)](#), [auditon\(2\)](#), [audit\\_class\(4\)](#), [audit\\_class\(4\)](#), [audit\\_event\(4\)](#), [attributes\(5\)](#), [audit\\_binfile\(5\)](#), [audit\\_flags\(5\)](#), [audit\\_remote\(5\)](#), [audit\\_syslog\(5\)](#), [smf\(5\)](#)

See the section on Solaris Auditing in *System Administration Guide: Security Services*.

**Notes** The functionality described in this man page is available only if the Solaris Auditing Service has been enabled by [audit\(1M\)](#).

`auditd` is loaded in the global zone at boot time if auditing is enabled.

If the audit policy `perzone` is set, `auditd` runs in each zone, starting automatically when the local zone boots. If a zone is running when the `perzone` policy is set, auditing must be started manually in local zones. It is not necessary to reboot the system or the local zone to start auditing in a local zone. `auditd` can be started with `audit -s` and will start automatically with future boots of the zone.

When `auditd` runs in a local zone, the configuration is taken from the local zone's [smf\(5\)](#) repository and the `/etc/security` directory's files: `audit_class`, `user_attr`, and `audit_event`.

Configuration changes do not affect audit sessions that are currently running, as the changes do not modify a process's preselection mask. To change the preselection mask on a running process, use the `-setpmask` option of the `auditconfig` command (see [auditconfig\(1M\)](#)). If the user logs out and logs back in, the new configuration changes will be reflected in the next audit session.

The audit service FMRI is `svc:/system/auditd:default`.

**Name** auditrecord – display Solaris audit record formats

**Synopsis** /usr/sbin/auditrecord [-d] [ [-a] | [-e *string*] | [-c *class*] |  
[-i *id*] | [-p *programname*] | [-s *systemcall*] | [-h]]

**Description** The `auditrecord` utility displays the event ID, audit class and selection mask, and record format for audit record event types defined in `audit_event(4)`. You can use `auditrecord` to generate a list of all audit record formats, or to select audit record formats based on event class, event name, generating program name, system call name, or event ID.

There are two output formats. The default format is intended for display in a terminal window; the optional HTML format is intended for viewing with a web browser.

Tokens contained in square brackets ( [ ] ) are optional and might not be present in every record.

**Options** The following options are supported:

-a

List all audit records.

-c *class*

List all audit records selected by *class*. *class* is one of the two-character class codes from the file `/etc/security/audit_class`.

-d

Debug mode. Display number of audit records that are defined in `audit_event`, the number of classes defined in `audit_class`, any mismatches between the two files, and report which defined events do not have format information available to `auditrecord`.

-e *string*

List all audit records for which the event ID label contains the string *string*. The match is case insensitive.

-h

Generate the output in HTML format.

-i *id*

List the audit records having the numeric event ID *id*.

-p *programname*

List all audit records generated by the program *programname*, for example, audit records generated by a user-space program.

-s *systemcall*

List all audit records generated by the system call *systemcall*, for example, audit records generated by a system call.

The `-p` and `-s` options are different names for the same thing and are mutually exclusive. The `-a` option is ignored if any of `-c`, `-e`, `-i`, `-p`, or `-s` are given. Combinations of `-c`, `-e`, `-i`, and either `-p` or `-s` are ANDed together.

**Examples** EXAMPLE 1 Displaying an Audit Record with a Specified Event ID

The following example shows how to display the contents of a specified audit record.

```
% auditrecord -i 6152
terminal login
program /usr/sbin/login see login(1)
 /usr/dt/bin/dtlogin See dtlogin
event ID 6152 AUE_login
class lo (0x00001000)
 header
 subject
 [text] error message
 return
```

**EXAMPLE 2** Displaying an Audit Record with an Event ID Label that Contains a Specified String

The following example shows how to display the contents of a audit record with an event ID label that contains the string login.

```
auditrecord -e login
terminal login
program /usr/sbin/login see login(1)
 /usr/dt/bin/dtlogin See dtlogin
event ID 6152 AUE_login
class lo (0x00001000)
 header
 subject
 [text] error message
 return

rlogin
program /usr/sbin/login see login(1) - rlogin
event ID 6155 AUE_rlogin
class lo (0x00001000)
 header
 subject
 [text] error message
 return
```

**Exit Status** 0

Successful operation

non-zero

Error

**Files** /etc/security/audit\_class

Provides the list of valid classes and the associated audit mask.

/etc/security/audit\_event

Provides the numeric event ID, the literal event name, and the name of the associated system call or program.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE       | ATTRIBUTEVALUE |
|---------------------|----------------|
| Availability        | SUNWcs         |
| CSI                 | Enabled        |
| Interface Stability | Uncommitted    |

**See Also** [auditconfig\(1M\)](#), [praudit\(1M\)](#), [audit.log\(4\)](#), [audit\\_class\(4\)](#), [audit\\_event\(4\)](#), [attributes\(5\)](#)

See the section on Solaris Auditing in *System Administration Guide: Security Services*.

**Diagnostics** If unable to read either of its input files or to write its output file, `auditrecord` shows the name of the file on which it failed and exits with a non-zero return.

If no options are provided, if an invalid option is provided, or if both `-s` and `-p` are provided, an error message is displayed and `auditrecord` displays a usage message then exits with a non-zero return.

**Notes** This command was formerly known as `bsmrecord`.

If `/etc/security/audit_event` has been modified to add user-defined audit events, `auditrecord` displays the record format as undefined.

The audit records displayed by `auditrecord` are the core of the record that can be produced. Various audit policies and optional tokens, such as those shown below, might also be present.

The following is a list of [praudit\(1M\)](#) token names with their descriptions.

`group`

Present if the `group` audit policy is set.

`sensitivity label`

Present when Trusted Extensions is enabled and represents the label of the subject or object with which it is associated. The `mandatory_label` token is noted in the basic audit record where a label is explicitly part of the record.

`sequence`

Present when the `seq` audit policy is set.

`trailer`

Present when the `trail` audit policy is set.

**zone**

The name of the zone generating the record when the zonename audit policy is set. The zonename token is noted in the basic audit record where a zone name is explicitly part of the record.

**Name** auditreduce – merge and select audit records from audit trail files

**Synopsis** auditreduce [*options*] [*audit-trail-file*]. . .

**Description** auditreduce allows you to select or merge records from audit trail files. Audit files can be from one or more machines.

The merge function merges together audit records from one or more input audit trail files into a single output file. The records in an audit trail file are assumed to be sorted in chronological order (oldest first) and this order is maintained by auditreduce in the output file.

Unless instructed otherwise, auditreduce will merge the entire audit trail, which consists of all the audit trail files in the directory structure *audit\_root\_dir*/\*/files (see *audit\_log(4)* for details of the structure of the audit root). Unless specified with the *-R* or *-S* option, *audit\_root\_dir* defaults to */etc/security/audit*. By using the file selection options it is possible to select some subset of these files, or files from another directory, or files named explicitly on the command line.

The select function allows audit records to be selected on the basis of numerous criteria relating to the record's content (see *audit\_log(4)* for details of record content). A record must meet all of the *record-selection-option* criteria to be selected.

**Audit Trail Filename Format** Any audit trail file not named on the command line must conform to the audit trail filename format. Files produced by the audit system already have this format. Output file names produced by auditreduce are in this format. It is:

*start-time . end-time . suffix*

where *start-time* is the 14-character timestamp of when the file was opened, *end-time* is the 14-character timestamp of when the file was closed, and *suffix* is the name of the machine which generated the audit trail file, or some other meaningful suffix (for example, *all*, if the file contains a combined group of records from many machines). The *end-time* can be the literal string *not\_terminated*, to indicate that the file is still being written to by the audit system. Timestamps are of the form *yyyymmddhhmmss* (year, month, day, hour, minute, second). The timestamps are in Greenwich Mean Time (GMT).

## Options

**File Selection Options** The file selection options indicate which files are to be processed and certain types of special treatment.

*-A*

All of the records from the input files will be selected regardless of their timestamp. This option effectively disables the *-a*, *-b*, and *-d* options. This is useful in preventing the loss of records if the *-D* option is used to delete the input files after they are processed. Note, however, that if a record is *not* selected due to another option, then *-A* will not override that.

- C  
Only process complete files. Files whose filename *end-time* timestamp is not `_terminated` are not processed (such a file is currently being written to by the audit system). This is useful in preventing the loss of records if `-D` is used to delete the input files after they are processed. It does not apply to files specified on the command line.
- D *suffix*  
Delete input files after they are read if the entire run is successful. If `auditreduce` detects an error while reading a file, then that file is not deleted. If `-D` is specified, `-A`, `-C` and `-O` are also implied. *suffix* is given to the `-O` option. This helps prevent the loss of audit records by ensuring that all of the records are written, only complete files are processed, and the records are written to a file before being deleted. Note that if both `-D` and `-O` are specified in the command line, the order of specification is significant. The *suffix* associated with the latter specification is in effect.
- M *machine*  
Allows selection of records from files with *machine* as the filename suffix. If `-M` is not specified, all files are processed regardless of suffix. `-M` can also be used to allow selection of records from files that contain combined records from many machines and have a common suffix (such as `all`).
- N  
Select objects in *new mode*. This flag is off by default, thus retaining backward compatibility. In the existing, *old mode*, specifying the `-e`, `-f`, `-g`, `-r`, or `-u` flags would select not only actions taken with those IDs, but also certain objects owned by those IDs. When running in *new mode*, only actions are selected. In order to select objects, the `-o` option must be used.
- O *suffix*  
Direct output stream to a file in the current `audit_root_dir` with the indicated suffix. *suffix* can alternatively contain a full pathname, in which case the last component is taken as the suffix, ahead of which the timestamps will be placed, ahead of which the remainder of the pathname will be placed. If the `-O` option is not specified, the output is sent to the standard output. When `auditreduce` places timestamps in the filename, it uses the times of the first and last records in the merge as the *start-time* and *end-time*.
- Q  
Quiet. Suppress notification about errors with input files.
- R *pathname*  
Specify the pathname of an alternate audit root directory `audit_root_dir` to be *pathname*. Therefore, rather than using `/etc/security/audit/*/files` by default, `pathname/*/files` will be examined instead.
- Note** – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).

**-S *server***

This option causes `audit reduce` to read audit trail files from a specific location (`server` directory). `server` is normally interpreted as the name of a subdirectory of the audit root, therefore `audit reduce` will look in `audit_root_dir/server/files` for the audit trail files. But if `server` contains any `'/'` characters, it is the name of a specific directory not necessarily contained in the audit root. In this case, `server/files` will be consulted. This option allows archived files to be manipulated easily, without requiring that they be physically located in a directory structure like that of `/etc/security/audit`.

**-V**

Verbose. Display the name of each file as it is opened, and how many records total were written to the output stream.

Record Selection Options The record selection options listed below are used to indicate which records are written to the output file produced by `audit reduce`.

Multiple arguments of the same type are not permitted.

**-a *date-time***

Select records that occurred at or after *date-time*. The *date-time* argument is described under Option Arguments, below. *date-time* is in local time. The `-a` and `-b` options can be used together to form a range.

**-b *date-time***

Select records that occurred before *date-time*.

**-c *audit-classes***

Select records by audit class. Records with events that are mapped to the audit classes specified by *audit-classes* are selected. Audit class names are defined in `audit_class(4)`. The *audit-classes* can be a comma separated list of `audit flags` like those described in `audit_flags(5)`. Using the `audit flags`, one can select records based upon success and failure criteria.

**-d *date-time***

Select records that occurred on a specific day (a 24-hour period beginning at 00:00:00 of the day specified and ending at 23:59:59). The day specified is in local time. The time portion of the argument, if supplied, is ignored. Any records with timestamps during that day are selected. If any hours, minutes, or seconds are given in *time*, they are ignored. `-d` can not be used with `-a` or `-b`.

**-e *effective-user***

Select records with the specified *effective-user*.

**-f *effective-group***

Select records with the specified *effective-group*.

**-g *real-group***

Select records with the specified *real-group*.

- 
- j *subject-ID*  
Select records with the specified *subject-ID* where *subject-ID* is a process ID.
  - l *label*  
Select records with the specified label (or label range), as explained under “Option Arguments,” below. This option is available only if the system is configured with Trusted Extensions.
  - m *event*  
Select records with the indicated *event*. The *event* is the literal string or the *event* number.
  - o *object\_type=objectID\_value*  
Select records by object type. A match occurs when the record contains the information describing the specified *object\_type* and the object ID equals the value specified by *objectID\_value*. The allowable object types and values are as follows:
    - file=pathname*  
Select records containing file system objects with the specified pathname, where pathname is a comma separated list of regular expressions. If a regular expression is preceded by a tilde (~), files matching the expression are excluded from the output. For example, the option *file=~ /usr/openwin, /usr, /etc* would select all files in */usr* or */etc* except those in */usr/openwin*. The order of the regular expressions is important because auditreduce processes them from left to right, and stops when a file is known to be either selected or excluded. Thus the option *file= /usr, /etc, ~ /usr/openwin* would select all files in */usr* and all files in */etc*. Files in */usr/openwin* are not excluded because the regular expression */usr* is matched first. Care should be given in surrounding the *pathname* with quotes so as to prevent the shell from expanding any tildes.
    - filegroup=group*  
Select records containing file system objects with *group* as the owning group.
    - fileowner=user*  
Select records containing file system objects with *user* as the owning user.
    - fmri=service\_instance*  
Select records containing fault management resource identifier (FMRI) objects with the specified *service instance*. See [smf\(5\)](#).
    - msgqid=ID*  
Select records containing message queue objects with the specified *ID* where *ID* is a message queue ID.
    - msgqgroup=group*  
Select records containing message queue objects with *group* as the owning or creating group.
    - msgqowner=user*  
Select records containing message queue objects with *user* as the owning or creating user.

*pid=ID*

Select records containing process objects with the specified *ID* where *ID* is a process ID. Process are objects when they are receivers of signals.

*procgroup=group*

Select records containing process objects with *group* as the real or effective group.

*procowner=user*

Select records containing process objects with *user* as the real or effective user.

*semid=ID*

Select records containing semaphore objects with the specified *ID* where *ID* is a semaphore ID.

*semgroup=group*

Select records containing semaphore objects with *group* as the owning or creating group.

*semowner=user*

Select records containing semaphore objects with *user* as the owning or creating user.

*shmid=ID*

Select records containing shared memory objects with the specified *ID* where *ID* is a shared memory ID.

*shmgroup=group*

Select records containing shared memory objects with *group* as the owning or creating group.

*shmowner=user*

Select records containing shared memory objects with *user* as the owning or creating user.

*sock=port\_number|machine*

Select records containing socket objects with the specified *port\_number* or the specified *machine* where *machine* is a machine name as defined in [hosts\(4\)](#).

*user=user\_name*

Select records containing the user object whose name is specified. User objects are generally specified for administrative actions on a user.

*-r real-user*

Select records with the specified *real-user*.

*-s session-id*

Select audit records with the specified *session-id*.

*-u audit-user*

Select records with the specified *audit-user*.

*-z zone-name*

Select records from the specified zone name. The zone name selection is case-sensitive.

When one or more *filename* arguments appear on the command line, only the named files are processed. Files specified in this way need not conform to the audit trail filename format. However, -M, -S, and -R must not be used when processing named files. If the *filename* is "-" then the input is taken from the standard input.

Option Arguments *audit-trail-file*

An audit trail file as defined in [audit.log\(4\)](#). An audit trail file not named on the command line must conform to the audit trail file name format. Audit trail files produced as output of `auditreduce` are in this format as well. The format is:

*start-time . end-time . suffix*

*start-time* is the 14 character time stamp denoting when the file was opened. *end-time* is the 14 character time stamp denoting when the file was closed. *end-time* can also be the literal string `not_terminated`, indicating the file is still be written to by the audit daemon or the file was not closed properly (a system crash or abrupt halt occurred). *suffix* is the name of the machine that generated the audit trail file (or some other meaningful suffix; for example, `all` would be a good suffix if the audit trail file contains a combined group of records from many machines).

*date-time*

The *date-time* argument to -a, -b, and -d can be of two forms: An absolute *date-time* takes the form:

`yyyymmdd [ hh [ mm [ ss ] ] ]`

where *yyyy* specifies a year (with 1970 as the earliest value), *mm* is the month (01-12), *dd* is the day (01-31), *hh* is the hour (00-23), *mm* is the minute (00-59), and *ss* is the second (00-59). The default is 00 for *hh*, *mm* and *ss*.

An offset can be specified as: `+n d|h|m|s` where *n* is a number of units, and the tags *d*, *h*, *m*, and *s* stand for days, hours, minutes and seconds, respectively. An offset is relative to the starting time. Thus, this form can only be used with the -b option.

*event*

The literal string or ordinal event number as found in [audit\\_event\(4\)](#). If *event* is not found in the `audit_event` file it is considered invalid.

*group*

The literal string or ordinal group ID number as found in [group\(4\)](#). If *group* is not found in the `group` file it is considered invalid. *group* can be negative.

*label*

The literal string representation of a MAC label or a range of two valid MAC labels. To specify a range, use `x;y` where *x* and *y* are valid MAC labels. Only those records that are fully bounded by *x* and *y* will be selected. If *x* or *y* is omitted, the default uses `ADMIN_LOW` or `ADMIN_HIGH` respectively. Notice that quotes must be used when specifying a range.

*pathname*

A regular expression describing a pathname.

*user*

The literal username or ordinal user ID number as found in [passwd\(4\)](#). If the username is not found in the `passwd` file it is considered invalid. *user* can be negative.

**Examples** **EXAMPLE 1** The `auditreduce` command

`praudit(1M)` is available to display audit records in a human-readable form.

This will display the entire audit trail in a human-readable form:

```
% auditreduce | praudit
```

If all the audit trail files are being combined into one large file, then deleting the original files could be desirable to prevent the records from appearing twice:

```
% auditreduce -V -D /etc/security/audit/combined/all
```

This displays what user `milner` did on April 13, 1988. The output is displayed in a human-readable form to the standard output:

```
% auditreduce -d 19880413 -u milner | praudit
```

The above example might produce a large volume of data if `milner` has been busy. Perhaps looking at only login and logout times would be simpler. The `-c` option will select records from a specified class:

```
% auditreduce -d 19880413 -u milner -c lo | praudit
```

To see `milner`'s login/logout activity for April 13, 14, and 15, the following is used. The results are saved to a file in the current working directory. Notice that the name of the output file will have `milnerlo` as the *suffix*, with the appropriate timestamp prefixes. Notice also that the long form of the name is used for the `-c` option:

```
% auditreduce -a 19880413 -b +3d -u milner -c login_logout -O milnerlo
```

To follow `milner`'s movement about the file system on April 13, 14, and 15 the `chdir` record types could be viewed. Notice that in order to get the same time range as the above example we needed to specify the `-b` time as the day *after* our range. This is because `19880416` defaults to midnight of that day, and records before that fall on `0415`, the end-day of the range.

```
% auditreduce -a 19880413 -b 19880416 -u milner -m AUE_CHDIR | praudit
```

In this example, the audit records are being collected in summary form (the login/logout records only). The records are being written to a summary file in a different directory than the normal audit root to prevent the selected records from existing twice in the audit root.

```
% auditreduce -d 19880330 -c lo -O /etc/security/audit_summary/logins
```

**EXAMPLE 1** The `auditreduce` command (Continued)

If activity for user ID 9944 has been observed, but that user is not known to the system administrator, then the command in the following example searches the entire audit trail for any records generated by that user. `auditreduce` queries the system about the current validity of ID 9944 and displays a warning message if it is not currently active:

```
% auditreduce -O /etc/security/audit_suspect/user9944 -u 9944
```

To get an audit log of only the global zone:

```
% auditreduce -z global
```

**Files** `/etc/security/audit/server/files/*` location of audit trails, when stored

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | See below.      |

The command invocation is Stable. The binary file format is Stable. The binary file contents is Unstable.

**See Also** [praudit\(1M\)](#), [audit.log\(4\)](#), [audit\\_class\(4\)](#), [group\(4\)](#), [hosts\(4\)](#), [passwd\(4\)](#), [attributes\(5\)](#), [audit\\_flags\(5\)](#), [smf\(5\)](#)

See the section on Solaris Auditing in *System Administration Guide: Security Services*.

**Diagnostics** `auditreduce` displays error messages if there are command line errors and then exits. If there are fatal errors during the run, `auditreduce` displays an explanatory message and exits. In this case, the output file might be in an inconsistent state (no trailer or partially written record) and `auditreduce` displays a warning message before exiting. Successful invocation returns 0 and unsuccessful invocation returns 1.

Since `auditreduce` might be processing a large number of input files, it is possible that the machine-wide limit on open files will be exceeded. If this happens, `auditreduce` displays a message to that effect, give information on how many file there are, and exit.

If `auditreduce` displays a record's timestamp in a diagnostic message, that time is in local time. However, when filenames are displayed, their timestamps are in GMT.

**Bugs** Conjunction, disjunction, negation, and grouping of record selection options should be allowed.

**Notes** The functionality described in this man page is available only if the Solaris Auditing has been enabled.

The -z option should be used only if the audit policy zonename is set. If there is no zonename token, then no records will be selected.

**Name** auditstat – display kernel audit statistics

**Synopsis** auditstat [-c *count*] [-h *numlines*] [-i *interval*] [-n]  
[-T u | d ] [-v]

**Description** auditstat displays kernel audit statistics. The fields displayed are as follows:

|      |                                                                                                                                                                          |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| aud  | The total number of audit records processed by the audit(2) system call.                                                                                                 |
| ctl  | This field is obsolete.                                                                                                                                                  |
| drop | The total number of audit records that have been dropped. Records are dropped according to the kernel audit policy. See auditon(2), AUDIT_CNT policy for details.        |
| enq  | The total number of audit records put on the kernel audit queue.                                                                                                         |
| gen  | The total number of audit records that have been constructed (not the number written).                                                                                   |
| kern | The total number of audit records produced by user processes (as a result of system calls).                                                                              |
| mem  | The total number of Kbytes of memory currently in use by the kernel audit module.                                                                                        |
| nona | The total number of non-attributable audit records that have been constructed. These are audit records that are not attributable to any particular user.                 |
| rb1k | The total number of times that the audit queue has blocked waiting to process audit data.                                                                                |
| tot  | The total number of Kbytes of audit data written to the audit trail.                                                                                                     |
| wb1k | The total number of times that user processes blocked on the audit queue at the high water mark.                                                                         |
| wrtn | The total number of audit records written. The difference between enq and wrtn is the number of outstanding audit records on the audit queue that have not been written. |

|                |                    |                                                                                                                                                                                            |
|----------------|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Options</b> | -c <i>count</i>    | Display the statistics a total of <i>count</i> times. If <i>count</i> is equal to zero, statistics are displayed indefinitely. A time interval must be specified.                          |
|                | -h <i>numlines</i> | Display a header for every <i>numlines</i> of statistics printed. The default is to display the header every 20 lines. If <i>numlines</i> is equal to zero, the header is never displayed. |
|                | -i <i>interval</i> | Display the statistics every <i>interval</i> where <i>interval</i> is the number of seconds to sleep between each collection.                                                              |
|                | -n                 | Display the number of kernel audit events currently configured.                                                                                                                            |
|                | -T u   d           | Display a time stamp.                                                                                                                                                                      |

Specify `u` for a printed representation of the internal representation of time. See [time\(2\)](#). Specify `d` for standard date format. See [date\(1\)](#).

`-v` Display the version number of the kernel audit module software.

**Exit Status** `auditstat` returns 0 upon success and 1 upon failure.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcs          |

**See Also** [auditconfig\(1M\)](#), [praudit\(1M\)](#), [audit\(2\)](#), [auditon\(2\)](#), [attributes\(5\)](#)

**Notes** The functionality described in this man page is available only if Solaris Auditing has been enabled.

**Name** audit\_warn – audit daemon warning script

**Synopsis** /etc/security/audit\_warn [*option* [*arguments*]]

**Description** The audit\_warn utility processes warning or error messages from the audit daemon. When a problem is encountered, the audit daemon, [auditd\(1M\)](#) calls audit\_warn with the appropriate arguments. The *option* argument specifies the error type.

The system administrator can specify a list of mail recipients to be notified when an audit\_warn situation arises by defining a mail alias called audit\_warn in [aliases\(4\)](#). The users that make up the audit\_warn alias are typically the audit and root users.

**Options** The following options are supported:

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| allhard <i>count</i> | Indicates that the hard limit for all filesystems has been exceeded <i>count</i> times. The default action for this option is to send mail to the audit_warn alias only if the <i>count</i> is 1, and to write a message to the machine console every time. It is recommended that mail <i>not</i> be sent every time as this could result in a the saturation of the file system that contains the mail spool directory. |
| allsoft              | Indicates that the soft limit for all filesystems has been exceeded. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console.                                                                                                                                                                                                                            |
| auditoff             | Indicates that someone other than the audit daemon changed the system audit state to something other than AUC_AUDITING. The audit daemon will have exited in this case. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console.                                                                                                                         |
| ebusy                | Indicates that the audit daemon is already running. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console.                                                                                                                                                                                                                                             |
| hard <i>filename</i> | Indicates that the hard limit for the file has been exceeded. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console.                                                                                                                                                                                                                                   |
| nostart              | Indicates that auditing could not be started. The default action for this option is to send mail to the audit_warn alias and to write a message to the machine console. Some                                                                                                                                                                                                                                              |

administrators may prefer to modify `audit_warn` to reboot the system when this error occurs.

`plugin name error count text`

Indicates that an error occurred during execution of the `auditd` plugin *name*. The default action for this option is to send mail to the `audit_warn` alias only if *count* is 1, and to write a message to the machine console every time. (Separate counts are kept for each error type.) It is recommended that mail not be sent every time as this could result in the saturation of the file system that contains the mail spool directory. The *text* field provides the detailed error message passed from the plug-in. The *error* field is one of the following strings:

|                           |                                                                                                                                                                                                                                                                                         |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>load_error</code>   | Unable to load the plugin <i>name</i> .                                                                                                                                                                                                                                                 |
| <code>sys_error</code>    | The plugin <i>name</i> is not executing due to a system error such as a lack of resources.                                                                                                                                                                                              |
| <code>config_error</code> | No plug-ins loaded (including the binary file plug-in, <code>audit_binfile(5)</code> ) due to configuration errors (see the <code>-setplugin</code> option of the <code>auditconfig(1M)</code> command). The name string is <code>--</code> , to indicate that no plug-in name applies. |
| <code>retry</code>        | The plugin <i>name</i> reports it has encountered a temporary failure. For example, the <code>audit_binfree.so</code> plugin uses <code>retry</code> to indicate that all directories are full.                                                                                         |
| <code>no_memory</code>    | The plugin <i>name</i> reports a failure due to lack of memory.                                                                                                                                                                                                                         |
| <code>invalid</code>      | The plugin <i>name</i> reports it received an invalid input.                                                                                                                                                                                                                            |
| <code>failure</code>      | The plugin <i>name</i> has reported an error as described in <i>text</i> .                                                                                                                                                                                                              |

`postsigterm`

Indicates that an error occurred during the orderly shutdown of the audit daemon. The default action for this option is to send mail to the `audit_warn` alias and to write a message to the machine console.

|                            |                                                                                                                                                                                                                         |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>soft filename</code> | Indicates that the soft limit for <i>filename</i> has been exceeded. The default action for this option is to send mail to the <code>audit_warn</code> alias and to write a message to the machine console.             |
| <code>tmpfile</code>       | Indicates that the temporary audit file already exists indicating a fatal error. The default action for this option is to send mail to the <code>audit_warn</code> alias and to write a message to the machine console. |

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE       | ATTRIBUTEVALUE |
|---------------------|----------------|
| Availability        | SUNWcs         |
| Interface Stability | Committed      |

The interface stability is evolving. The file content is unstable.

**See Also** [audit\(1M\)](#), [auditconfig\(1M\)](#), [auditd\(1M\)](#), [aliases\(4\)](#), [audit.log\(4\)](#), [attributes\(5\)](#)

See the section on Solaris Auditing in *System Administration Guide: Security Services*.

**Notes** This functionality is available only if the Solaris Auditing feature has been enabled.

If the audit policy `perzone` is set, the `/etc/security/audit_warn` script for the local zone is used for notifications from the local zone's instance of `auditd`. If the `perzone` policy is not set, all `auditd` errors are generated by the global zone's copy of `/etc/security/audit_warn`.

**Name** automount – install automatic mount points

**Synopsis** /usr/sbin/automount [-t *duration*] [-v]

**Description** The automount utility installs `autofs` mount points and associates an automount map with each mount point. It starts the `automountd(1M)` daemon if it finds any non-trivial entries in either local or distributed automount maps and if the daemon is not already running. The `autofs` file system monitors attempts to access directories within it and notifies the `automountd(1M)` daemon. The daemon uses the map to locate a file system, which it then mounts at the point of reference within the `autofs` file system. A map can be assigned to an `autofs` mount using an entry in the `/etc/auto_master` map or a direct map.

If the file system is not accessed within an appropriate interval (10 minutes by default), the `automountd` daemon unmounts the file system.

The file `/etc/auto_master` determines the locations of all `autofs` mount points. By default, this file contains three entries:

```
Master map for automounter
#
+auto_master
/net -hosts -nosuid
/home auto_home
```

The `+auto_master` entry is a reference to an external NIS master map. If one exists, then its entries are read as if they occurred in place of the `+auto_master` entry. The remaining entries in the master file specify a directory on which an `autofs` mount will be made followed by the automounter map to be associated with it. Optional mount options may be supplied as an optional third field in the each entry. These options are used for any entries in the map that do not specify mount options explicitly. The `automount` command is usually run without arguments. It compares the entries `/etc/auto_master` with the current list of `autofs` mounts in `/etc/mnttab` and adds, removes or updates `autofs` mounts to bring the `/etc/mnttab` up to date with the `/etc/auto_master`. At boot time it installs all `autofs` mounts from the master map. Subsequently, it may be run to install `autofs` mounts for new entries in the master map or the direct map, or to perform unmounts for entries that have been removed from these maps.

**SMF Management** The automount service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/system/filesystem/autofs:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

Startup `autofs` SMF parameters for `automount` can be manipulated using `sharectl(1M)`. Refer to `sharectl(1M)` for instructions for viewing and updating these parameters. Supported parameters are:

`timeout=num`

Specifies a duration, in seconds, that a file system is to remain mounted when not in use. The default value is 600 (10 minutes). Equivalent to the `-t` option in `automount`.

`automount_verbose=TRUE | FALSE`

Verbose mode. Causes you to be notified of non-critical events, such as `autofs` mounts and unmounts. The default value is `FALSE`. Equivalent to the `-v` option in `automount`.

Automount with  
Solaris Trusted  
Extensions

If a system is configured with Solaris Trusted Extensions, additional processing is performed to facilitate multilevel home directory access. A list of zones whose labels are dominated by the current zone is generated and default `auto_home` automount maps are generated if they do not currently exist. These automount maps are named `auto_home_<zonenumber>`, where `<zonenumber>` is the name of each zone's lower-level zone. An `autofs` mount of each such `auto_home` map is then performed, regardless of whether it is explicitly or implicitly listed in the master map. Instead of `autofs` mounting the standard `auto_home` map, the zone uses an `auto_home` file appended with its own zone name. Each zone's `auto_home` map is uniquely named so that it can be maintained and shared by all zones using a common name server.

By default, the home directories of lower-level zones are mounted read-only under `/zone/<zonenumber>/export/home` when each zone is booted. The default `auto_home_<zonenumber>` automount map specifies that path as the source directory for an `lofs` remount onto `/zone/<zonenumber>/home/<username>`. For example, the file `auto_home_public`, as generated from a higher level zone would contain:

```
+auto_home_public
```

```
* -fstype=lofs :/zone/public/export/home/&
```

When a home directory is referenced and the name does not match any other keys in the `auto_home_public` map, it will match this loopback mount specification. If this loopback match occurs and the name corresponds to a valid user whose home directory does not exist in the public zone, the directory is automatically created on behalf of the user.

**Options** The following options are supported:

- `-t duration` Specifies a *duration*, in seconds, that a file system is to remain mounted when not in use. The default is 10 minutes.
- `-v` Verbose mode. Notifies of `autofs` mounts, unmounts, or other non-essential information.

## Usage

Map Entry Format A simple map entry (mapping) takes the form:

```
key [-mount-options] location . . .
```

where `key` is the full pathname of the directory to mount when used in a direct map, or the simple name of a subdirectory in an indirect map. *mount-options* is a comma-separated list of

mount options, and *location* specifies a file system from which the directory may be mounted. In the case of a simple NFS mount, the options that can be used are as specified in [mount\\_nfs\(1M\)](#), and *location* takes the form:

*host*: *pathname*

*host* is the name of the host from which to mount the file system, and *pathname* is the absolute pathname of the directory to mount.

Options to other file systems are documented on the other `mount_*` reference manual pages, for example, [mount\\_cachefs\(1M\)](#).

**Replicated File Systems** Multiple *location* fields can be specified for replicated NFS file systems, in which case `automount` and the kernel will each try to use that information to increase availability. If the read-only flag is set in the map entry, `automountd` mounts a list of locations that the kernel may use, sorted by several criteria. Only locations available at mount time will be mounted, and thus be available to the kernel. When a server does not respond, the kernel will switch to an alternate server. The sort ordering of `automount` is used to determine how the next server is chosen. If the read-only flag is not set, `automount` will mount the best single location, chosen by the same sort ordering, and new servers will only be chosen when an unmount has been possible, and a remount is done. Servers on the same local subnet are given the strongest preference, and servers on the local net are given the second strongest preference. Among servers equally far away, response times will determine the order if no weighting factors (see below) are used.

If the list includes server locations using both the NFS Version 2 Protocol and the NFS Version 3 Protocol, `automount` will choose only a subset of the server locations on the list, so that all entries will be the same protocol. It will choose servers with the NFS Version 3 Protocol so long as an NFS Version 2 Protocol server on a local subnet will not be ignored. See the [System Administration Guide: IP Services](#) for additional details.

If each *location* in the list shares the same *pathname* then a single *location* may be used with a comma-separated list of hostnames:

*hostname*,*hostname* . . . : *pathname*

Requests for a server may be weighted, with the weighting factor appended to the server name as an integer in parentheses. Servers without a weighting are assumed to have a value of zero (most likely to be selected). Progressively higher values decrease the chance of being selected. In the example,

```
man -ro alpha,bravo,charlie(1),delta(4) : /usr/man
```

hosts `alpha` and `bravo` have the highest priority; host `delta` has the lowest.

Server proximity takes priority in the selection process. In the example above, if the server `delta` is on the same network segment as the client, but the others are on different network

segments, then `delta` will be selected; the weighting value is ignored. The weighting has effect only when selecting between servers with the same network proximity. The automounter always selects the localhost over other servers on the same network segment, regardless of weighting.

In cases where each server has a different export point, the weighting can still be applied. For example:

```
man -ro alpha:/usr/man bravo,charlie(1):/usr/share/man
 delta(3):/export/man
```

A mapping can be continued across input lines by escaping the NEWLINE with a backslash (`\`). Comments begin with a number sign (`#`) and end at the subsequent NEWLINE.

**Map Key Substitution** The ampersand (`&`) character is expanded to the value of the key field for the entry in which it occurs. In this case:

```
jane sparcsrver : /home/&
```

the `&` expands to `jane`.

**Wildcard Key** The asterisk (`*`) character, when supplied as the key field, is recognized as the catch-all entry. Such an entry will match any key not previously matched. For instance, if the following entry appeared in the indirect map for `/config`:

```
* & : /export/config/&
```

this would allow automatic mounts in `/config` of any remote file system whose location could be specified as:

```
hostname : /export/config/hostname
```

Note that the wildcard key does not work in conjunction with the `-browse` option.

**Variable Substitution** Client specific variables can be used within an automount map. For instance, if `$HOST` appeared within a map, automount would expand it to its current value for the client's host name. Supported variables are:

|      |                                     |                                                                                        |
|------|-------------------------------------|----------------------------------------------------------------------------------------|
| ARCH | The output of <code>arch</code>     | The architecture name. For example, <code>sun4</code> on a <code>sun4u</code> machine. |
| CPU  | The output of <code>uname -p</code> | The processor type.<br>For example, "sparc"                                            |
| HOST | The output of <code>uname -n</code> | The host name.<br>For example, <code>myhost</code> .                                   |

---

|          |                                                             |                                                                                          |
|----------|-------------------------------------------------------------|------------------------------------------------------------------------------------------|
| KARCH    | The output of <code>arch -k</code> or <code>uname -m</code> | The kernel architecture name or machine hardware name. For example, <code>sun4u</code> . |
| OSNAME   | The output of <code>uname -s</code>                         | The OS name.<br>For example, “SunOS”                                                     |
| OSREL    | The output of <code>uname -r</code>                         | The OS release name.<br>For example “5.3”                                                |
| OSVERS   | The output of <code>uname -v</code>                         | The OS version.<br>For example, “beta1.0”                                                |
| NATISA   | The output of <code>isainfo -n</code>                       | The native instruction set architecture for the system.<br>For example, “sparcv9”        |
| PLATFORM | The output of <code>uname -i</code>                         | The platform name. For example, <code>SUNW,Sun-Fire-V240</code> .                        |

---

If a reference needs to be protected from affixed characters, you can surround the variable name with curly braces ( `{ }` ).

**Multiple Mounts** A multiple mount entry takes the form:

```
key [-mount-options] [[mountpoint] [-mount-options] location. . .] . . .
```

The initial `/[mountpoint]` is optional for the first mount and mandatory for all subsequent mounts. The optional *mountpoint* is taken as a pathname relative to the directory named by *key*. If *mountpoint* is omitted in the first occurrence, a *mountpoint* of `/` (root) is implied.

Given an entry in the indirect map for `/src`

```
beta -ro\
/ svr1,svr2:/export/src/beta \
/1.0 svr1,svr2:/export/src/beta/1.0 \
/1.0/man svr1,svr2:/export/src/beta/1.0/man
```

All offsets must exist on the server under `beta`. `automount` will automatically mount `/src/beta`, `/src/beta/1.0`, and `/src/beta/1.0/man`, as needed, from either `svr1` or `svr2`, whichever host is nearest and responds first.

**Other File System Types** The automounter assumes NFS mounts as a default file system type. Other file system types can be described using the `fstype` mount option. Other mount options specific to this file system type can be combined with the `fstype` option. The location field must contain information specific to the file system type. If the location field begins with a slash, a colon character must be prepended, for instance, to mount a CD file system:

```
cdrom -fstype=hsfs,ro : /dev/sr0
```

or to perform an `autofs` mount:

```
src -fstype=autofs auto_src
```

Use this procedure only if you are not using Volume Manager.

Mounts using CacheFS are most useful when applied to an entire map as map defaults. The following entry in the master map describes cached home directory mounts. It assumes the default location of the cache directory, `/cache`.

```
/home auto_home -fstype =cachefs,backfstype=nfs
```

See the NOTES section for information on option inheritance.

**Indirect Maps** An indirect map allows you to specify mappings for the subdirectories you wish to mount under the `directory` indicated on the command line. In an indirect map, each key consists of a simple name that refers to one or more file systems that are to be mounted as needed.

**Direct Maps** Entries in a direct map are associated directly with `autofs` mount points. Each *key* is the full pathname of an `autofs` mount point. The direct map as a whole is not associated with any single directory.

Direct maps are distinguished from indirect maps by the `/-` key. For example:

```
Master map for automounter
#
+auto_master
/net -hosts -nosuid,nobrowse
/home auto_home -nobrowse
/- auto_direct
```

**Included Maps** The contents of another map can be included within a map with an entry of the form

```
+mapname
```

If *mapname* begins with a slash, it is assumed to be the pathname of a local file. Otherwise, the location of the map is determined by the policy of the name service switch according to the entry for the automounter in `/etc/nsswitch.conf`, such as

```
automount: files nis
```

If the name service is `files`, then the name is assumed to be that of a local file in `/etc`. If the key being searched for is not found in the included map, the search continues with the next entry.

**Special Maps** There are two special maps available: `-hosts` and `-null`. The `-hosts` map is used with the `/net` directory and assumes that the map key is the hostname of an NFS server. The `automountd` daemon dynamically constructs a map entry from the server's list of exported file systems. References to a directory under `/net/hermes` will refer to the corresponding directory relative to `hermes` root.

The `-null` map cancels a previous map for the directory indicated. This is most useful in the `/etc/auto_master` for cancelling entries that would otherwise be inherited from the `+auto_master` include entry. To be effective, the `-null` entries must be inserted before the included map entry.

**Executable Maps** Local maps that have the execute bit set in their file permissions will be executed by the automounter and provided with a key to be looked up as an argument. The executable map is expected to return the content of an automounter map entry on its stdout or no output if the entry cannot be determined. A direct map cannot be made executable.

**Configuration and the auto\_master Map** When initiated without arguments, `automount` consults the master map for a list of `auto`fs mount points and their maps. It mounts any `auto`fs mounts that are not already mounted, and unmounts `auto`fs mounts that have been removed from the master map or direct map.

The master map is assumed to be called `auto_master` and its location is determined by the name service switch policy. Normally the master map is located initially as a local file `/etc/auto_master`.

**Browsing** The `automount` daemon supports browsability of indirect maps. This allows all of the potential mount points to be visible, whether or not they are mounted. The `-nobrowse` option can be added to any indirect `auto`fs map to disable browsing. For example:

```
/net -hosts -nosuid,nobrowse
/home auto_home
```

In this case, any *hostnames* would only be visible in `/net` after they are mounted, but all potential mount points would be visible under `/home`. The `-browse` option enables browsability of `auto`fs file systems. This is the default for all indirect maps.

The `-browse` option does not work in conjunction with the wildcard key.

**Restricting Mount Maps** Options specified for a map are used as the default options for all the entries in that map. They are ignored when map entries specify their own mount options.

In some cases, however, it is desirable to force `nosuid`, `nodevices`, `nosetuid`, or `noexec` for a complete mount map and its submounts. This can be done by specifying the additional mount option, `-restrict`.

```
/home auto_home -restrict,nosuid,hard
```

The `-restrict` option forces the inheritance of all the restrictive options `nosuid`, `nodevices`, `nosetuid`, and `noexec` as well as the `restrict` option itself. In this particular example, the

nosuid and restrict option are inherited but the hard option is not. The restrict option also prevents the execution of “executable maps” and is enforced for auto mounts established by programs with fewer than all privileges available in their zone.

**Exit Status** The following exit values are returned:

0 Successful completion.

1 An error occurred.

**Files**

*System Administration Guide: Network Services*

**Notes** auto fs mount points must not be hierarchically related. automount does not allow an auto fs mount point to be created within another auto fs mount.

Since each direct map entry results in a new auto fs mount such maps should be kept short.

Entries in both direct and indirect maps can be modified at any time. The new information is used when automountd next uses the map entry to do a mount.

New entries added to a master map or direct map will not be useful until the automount command is run to install them as new auto fs mount points. New entries added to an indirect map may be used immediately.

As of the Solaris 2.6 release, a listing (see [ls\(1\)](#)) of the auto fs directory associated with an indirect map shows all potential mountable entries. The attributes associated with the potential mountable entries are temporary. The real file system attributes will only be shown once the file system has been mounted.

Default mount options can be assigned to an entire map when specified as an optional third field in the master map. These options apply only to map entries that have no mount options. Note that map entities with options override the default options, as at this time, the options do not concatenate. The concatenation feature is planned for a future release.

When operating on a map that invokes an NFS mount, the default number of retries for the automounter is 0, that is, a single mount attempt, with no retries. Note that this is significantly different from the default (10000) for the `mount_nfs(1M)` utility.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Name</b>        | automountd – autofs mount/unmount daemon                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Synopsis</b>    | automountd [-Tvn] [-D <i>name=value</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>automountd is an RPC server that answers file system mount and unmount requests from the autofs file system. It uses local files or name service maps to locate file systems to be mounted. These maps are described with the <a href="#">automount(1M)</a> command.</p> <p>If automount finds any non-trivial entries in either the local or distributed automount maps and if the daemon is not running already, the automountd daemon is automatically invoked by <a href="#">automount(1M)</a>. automountd enables the <code>svc:/network/nfs/nlockmgr</code> service (<a href="#">lockd(1M)</a>), and the <code>svc:/network/nfs/status</code> service (<a href="#">statd(1M)</a>), if NFS mounts need to be done.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| SMF Management     | <p>The automountd service is managed by the service management facility, <a href="#">smf(5)</a>, under the service identifier:</p> <pre>svc:/system/filesystem/autofs</pre> <p>Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using <a href="#">svcadm(1M)</a>. The service's status can be queried using <a href="#">svcs(1)</a>. If it is disabled, it is enabled by <a href="#">automount(1M)</a> unless the <code>application/auto_enable</code> property is set to <code>false</code>.</p> <p>Values for parameters for automountd are stored in SMF and manipulated using <a href="#">sharectl(1M)</a>. The following are the supported parameters.</p> <p><code>automountd_verbose=TRUE   FALSE</code><br/>     Verbose mode. Causes status messages to be logged to:<br/> <pre>/var/svc/log/system-filesystem-autofs:default.log</pre>     See <a href="#">smf(5)</a>. The default value is FALSE. Equivalent to the <code>-v</code> option.</p> <p><code>nobrowse=ON   OFF</code><br/>     Turn on or off browsing for all autofs mount points. The default value is OFF. Equivalent to the <code>-n</code> option.</p> <p><code>trace=num</code><br/>     Expands each RPC call and logs it to:<br/> <pre>/var/svc/log/system-filesystem-autofs:default.log</pre>     See <a href="#">smf(5)</a>. The default value, 0, turns off such tracing. Starting with 1, with each higher value, the verbosity of trace output increases. This property is equivalent to the <code>-T</code> option.</p> <p><code>environment=name=value</code><br/>     Environment variables. You can specify multiple <code>name=value</code> pairs with a comma separator. If there is more than one value for a name, use the double forward slash to indicate that. See EXAMPLES. There are no environment variable settings supplied. This property is equivalent to the <code>-D</code> option.</p> <p>All the above parameters can be changed using the <a href="#">sharectl(1M)</a> command.</p> |

**Options** The following options are supported:

- D *name=value* Assign *value* to the indicated automount map substitution variable. These assignments cannot be used to substitute variables in the master map `auto_master`.
- n Turn off browsing for all `autofs` mount points. This option overrides the `-browse autofs` map option on the local host.
- T Trace. Expand each RPC call and display it on the standard output.
- v Verbose. Log status messages to the console.

**Usage** See [largefile\(5\)](#) for the description of the behavior of `automountd` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**Examples** EXAMPLE 1 Setting Verbose Mode

The following command turns on verbose mode, causing status messages to be logged to the location specified in “SMF Management,” above. See that section for a description of the properties specified in this and following examples.

```
sharectl set -p automountd_verbose=true autofs
```

EXAMPLE 2 Turning on Browsing for Mount Points

The following command turns on browsing for all `autofs` mount points.

```
sharectl set -p nobrowse=off autofs
```

EXAMPLE 3 Specifying and Displaying Environment Variables

The following commands set and display the value for an environment variable named `DAY`.

```
sharectl set -p environment=DAY=TUES autofs
% sharectl get -p environment autofs
environment=DAY=TUES
```

The following command sets multiple parameters for an environment variable. The subsequent command displays the result.

```
sharectl set -p environment=DAY=TUES,TIME=NOON autofs
% sharectl get -p environment autofs
environment=DAY=TUES,TIME=NOON
```

The following command set multiple values for name that is assigned to an environment variable. The subsequent command displays the result.

```
sharectl set -p environment=DAY=MON\\,TUE,TIME=NOON autofs
% sharectl get -p environment autofs
environment=DAY=MON\\,TUE,TIME=NOON
```

**Files** /etc/auto\_master    Master map for automounter.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcs          |

**See Also** [svcs\(1\)](#), [automount\(1M\)](#), [sharectl\(1M\)](#), [svcadm\(1M\)](#), [attributes\(5\)](#), [largefile\(5\)](#), [smf\(5\)](#)

**Name** autopush – configures lists of automatically pushed STREAMS modules

**Synopsis** autopush -f *filename*  
autopush -g -M *major* -m *minor*  
autopush -r -M *major* -m *minor*

**Description** The autopush command configures the list of modules to be automatically pushed onto the stream when a device is opened. It can also be used to remove a previous setting or get information on a setting.

**Options** The following options are supported:

-f *filename*

Sets up the autopush configuration for each driver according to the information stored in *filename*. An autopush file consists of lines of four or more fields, separated by spaces as shown below:

```
major minor last-minor module1 module2 . . . module8
```

The first field is a string that specifies the *major* device name, as listed in the `/kernel/drv` directory. The next two fields are integers that specify the *minor* device number and *last-minor* device number. The fields following represent the names of modules. If *minor* is `-1`, then all minor devices of a major driver specified by *major* are configured, and the value for *last-minor* is ignored. If *last-minor* is `0`, then only a single minor device is configured. To configure a range of minor devices for a particular major, *minor* must be less than *last-minor*.

The remaining fields list the names of modules to be automatically pushed onto the stream when opened, along with the position of an optional anchor. The maximum number of modules that can be pushed is eight. The modules are pushed in the order they are specified. The optional special character sequence `[anchor]` indicates that a STREAMS anchor should be placed on the stream at the module previously specified in the list; it is an error to specify more than one anchor or to have an anchor first in the list.

A nonzero exit status indicates that one or more of the lines in the specified file failed to complete successfully.

-g

Gets the current configuration setting of a particular *major* and *minor* device number specified with the -M and -m options respectively and displays the autopush modules associated with it. It will also return the starting minor device number if the request corresponds to a setting of a range (as described with the -f option).

-m *minor*

Specifies the minor device number.

-M *major*

Specifies the major device number.

-r

Removes the previous configuration setting of the particular *major* and *minor* device number specified with the -M and -m options respectively. If the values of *major* and *minor* correspond to a previously established setting of a range of minor devices, where *minor* matches the first minor device number in the range, the configuration would be removed for the entire range.

**Exit Status** The following exit values are returned:

0

Successful completion.

non-zero

An error occurred.

**Examples** **EXAMPLE 1** Using the autopush command.

The following example gets the current configuration settings for the *major* and *minor* device numbers as indicated and displays the autopush modules associated with them for the character-special device /dev/term/a:

```
example# autopush -g -M 29 -m 0
Major Minor Lastminor Modules
 29 0 1 ldterm ttcompat
```

**Files** /etc/iu.ap

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcs          |

**See Also** [dladm\(1M\)](#), [ttymon\(1M\)](#), [attributes\(5\)](#), [ldterm\(7M\)](#), [sad\(7D\)](#), [streamio\(7I\)](#), [ttcompat\(7M\)](#)

*STREAMS Programming Guide*

**Notes** The use of the autopush command is obsolete for networking data-links. The preferred method of configuring a list of automatically pushed STREAMS modules on a given networking data-link interface is the [dladm\(1M\)](#) autopush link property.

Because network devices are self-cloning, the autopush command is inadequate for networking devices. The granularity of the autopush command's configuration is driver-wide, and not per-interface as one might expect. Another reason not to use autopush is that administrators are more familiar with the names of their network interfaces than with device major and minor numbers. The [dladm\(1M\)](#) command allows the configuration using data-link interface names.

**Name** bart – basic audit reporting tool

**Synopsis** /usr/bin/bart create [ -n ] [-R *root\_directory*]  
          [-r *rules\_file* | -]  
  
          /usr/bin/bart create [-n] [-R *root\_directory*] -I  
          [*file\_name*]...  
  
          /usr/bin/bart compare [-i *attribute* ] [-p]  
          [-r *rules\_file* | -] *control-manifest test-manifest*

**Description** bart(1M) is a tool that performs a file-level check of the software contents of a system.

You can also specify the files to track and the types of discrepancies to flag by means of a rules file, *bart\_rules*. See *bart\_rules(4)*.

The bart utility performs two basic functions:

**bart create**       The manifest generator tool takes a file-level *snapshot* of a system. The output is a catalog of file attributes referred to as a *manifest*. See *bart\_manifest(4)*.

You can specify that the list of files be cataloged in three ways. Use *bart create* with no options, specify the files by name on the command line, or create a rules file with directives that specify which the files to monitor. See *bart\_rules(4)*.

By default, the manifest generator catalogs all attributes of all files in the root (/) file system. File systems mounted on the root file system are cataloged only if they are of the same type as the root file system.

For example, /, /usr, and /opt are separate UFS file systems. /usr and /opt are mounted on /. Therefore, all three file systems are cataloged. However, /tmp, also mounted on /, is not cataloged because it is a TMPFS file system. Mounted CD-ROMs are not cataloged since they are HSFS file systems.

**bart compare**     The report tool compares two manifests. The output is a list of per-file attribute discrepancies. These discrepancies are the differences between two manifests: a control manifest and a test manifest.

A discrepancy is a change to any attribute for a given file cataloged by both manifests. A new file or a deleted file in a manifest is reported as a discrepancy.

The reporting mechanism provides two types of output: verbose and programmatic. Verbose output is localized and presented on multiple lines, while programmatic output is more easily parsable by other programs. See OUTPUT.

By default, the report tool generates verbose output where all discrepancies are reported except for modified directory timestamps (`dirmtime` attribute).

To ensure consistent and accurate comparison results, *control-manifest* and *test-manifest* must be built with the same rules file.

Use the rules file to ignore specified files or subtrees when you generate a manifest or compare two manifests. Users can compare manifests from different perspectives by re-running the `bart compare` command with different rules files.

**Options** The following options are supported:

- i *attribute ...*      Specify the file attributes to be ignored globally. Specify attributes as a comma separated list.  
  
This option produces the same behavior as supplying the file attributes to a global IGNORE keyword in the rules file. See `bart_rules(4)`.
- I [*file\_name...*]    Specify the input list of files. The file list can be specified at the command line or read from standard input.
- n                      Prevent computation of content signatures for all regular files in the file list.
- p                      Display manifest comparison output in “programmatic mode,” which is suitable for programmatic parsing. The output is not localized.
- r *rules\_file*        Use *rules\_file* to specify which files and directories to catalog, and to define which file attribute discrepancies to flag. If *rules\_file* is -, then the rules are read from standard input. See `bart_rules(4)` for the definition of the syntax.
- R *root\_directory*    Specify the root directory for the manifest. All paths specified by the rules, and all paths reported in the manifest, are relative to *root\_directory*.

**Note** – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).

**Operands** `bart` allows quoting of operands. This is particularly important for white-space appearing in subtree and subtree modifier specifications.

The following operands are supported:

- control-manifest*    Specify the manifest created by `bart create` on the control system.
- test-manifest*        Specify the manifest created by `bart create` on the test system.

**Output** The `bart create` and `bart compare` commands write output to standard output, and write error messages to standard error.

The `bart create` command generates a system manifest. See `bart_manifest(4)`.

When the `bart compare` command compares two system manifests, it generates a list of file differences. By default, the comparison output is localized. However, if the `-p` option is specified, the output is generated in a form that is suitable for programmatic manipulation.

Default Format *filename*

*attribute control:xxxx test:yyyy*

*filename* Name of the file that differs between *control-manifest* and *test-manifest*. For file names that contain embedded whitespace or newline characters, see `bart_manifest(4)`.

*attribute* The name of the file attribute that differs between the manifests that are compared. *xxxx* is the attribute value from *control-manifest*, and *yyyy* is the attribute value from *test-manifest*. When discrepancies for multiple attributes occur for the same file, each difference is noted on a separate line.

The following attributes are supported:

|                       |                                                                                                                                                                                                  |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>acl</code>      | ACL attributes for the file. For a file with ACL attributes, this field contains the output from <code>acltotext()</code> .                                                                      |
| <code>all</code>      | All attributes.                                                                                                                                                                                  |
| <code>contents</code> | Checksum value of the file. This attribute is only specified for regular files. If you turn off context checking or if checksums cannot be computed, the value of this field is <code>-</code> . |
| <code>dest</code>     | Destination of a symbolic link.                                                                                                                                                                  |
| <code>devnode</code>  | Value of the device node. This attribute is for character device files and block device files only.                                                                                              |
| <code>dirmtime</code> | Modification time in seconds since 00:00:00 UTC, January 1, 1970 for directories.                                                                                                                |
| <code>gid</code>      | Numerical group ID of the owner of this entry.                                                                                                                                                   |
| <code>lnmtime</code>  | Creation time for links.                                                                                                                                                                         |
| <code>mode</code>     | Octal number that represents the permissions of the file.                                                                                                                                        |
| <code>mtime</code>    | Modification time in seconds since 00:00:00 UTC, January 1, 1970 for files.                                                                                                                      |
| <code>size</code>     | File size in bytes.                                                                                                                                                                              |
| <code>type</code>     | Type of file.                                                                                                                                                                                    |

**uid** Numerical user ID of the owner of this entry.

The following default output shows the attribute differences for the `/etc/passwd` file. The output indicates that the `size`, `mtime`, and `contents` attributes have changed.

```
/etc/passwd:
 size control:74 test:81
 mtime control:3c165879 test:3c165979
 contents control:daca28ae0de97afd7a6b91fde8d57afa
test:84b2b32c4165887355317207b48a6ec7
```

Programmatic Format *filename attribute control-val test-val [attribute control-val test-val]\**

*filename* Same as *filename* in the default format.

*attribute control-val test-val* A description of the file attributes that differ between the control and test manifests for each file. Each entry includes the attribute value from each manifest. See `bart_manifest(4)` for the definition of the attributes.

Each line of the programmatic output describes all attribute differences for a single file.

The following programmatic output shows the attribute differences for the `/etc/passwd` file. The output indicates that the `size`, `mtime`, and `contents` attributes have changed.

```
/etc/passwd size 74 81 mtime 3c165879 3c165979
contents daca28ae0de97afd7a6b91fde8d57afa 84b2b32c4165887355317207b48a6ec7
```

## Exit Status

Manifest Generator The manifest generator returns the following exit values:

- 0 Success
- 1 Non-fatal error when processing files; for example, permission problems
- >1 Fatal error; for example, invalid command-line options

Report Tool The report tool returns the following exit values:

- 0 No discrepancies reported
- 1 Discrepancies found
- >1 Fatal error executing comparison

## Examples

**EXAMPLE 1** Creating a Default Manifest Without Computing Checksums

The following command line creates a default manifest, which consists of all files in the `/` file system. The `-n` option prevents computation of checksums, which causes the manifest to be generated more quickly.

**EXAMPLE 1** Creating a Default Manifest Without Computing Checksums *(Continued)*

```
bart create -n
```

**EXAMPLE 2** Creating a Manifest for a Specified Subtree

The following command line creates a manifest that contains all files in the `/home/nickiso` subtree.

```
bart create -R /home/nickiso
```

**EXAMPLE 3** Creating a Manifest by Using Standard Input

The following command line uses output from the `find(1)` command to generate the list of files to be cataloged. The `find` output is used as input to the `bart create` command that specifies the `-I` option.

```
find /home/nickiso -print | bart create -I
```

**EXAMPLE 4** Creating a Manifest by Using a Rules File

The following command line uses a rules file, `rules`, to specify the files to be cataloged.

```
bart create -r rules
```

**EXAMPLE 5** Comparing Two Manifests and Generating Programmatic Output

The following command line compares two manifests and produces output suitable for parsing by a program.

```
bart compare -p manifest1 manifest2
```

**EXAMPLE 6** Comparing Two Manifests and Specifying Attributes to Ignore

The following command line compares two manifests. The `dirmtime`, `lnmtime`, and `mtime` attributes are not compared.

```
bart compare -i dirmtime,lnmtime,mtime manifest1 manifest2
```

**EXAMPLE 7** Comparing Two Manifests by Using a Rules File

The following command line uses a rules file, `rules`, to compare two manifests.

```
bart compare -r rules manifest1 manifest2
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | security/bart   |

---

| ATTRIBUTETYPE       | ATTRIBUTEVALUE |
|---------------------|----------------|
| Interface Stability | Committed      |

**See Also** [cksum\(1\)](#), [digest\(1\)](#), [find\(1\)](#), [bart\\_manifest\(4\)](#), [bart\\_rules\(4\)](#), [attributes\(5\)](#)

**Notes** The file attributes of certain system libraries can be temporarily altered by the system as it boots. To avoid triggering false warnings, you should compare manifests only if they were both created with the system in the same state; that is, if both were created in single-user or both in multi-user.

**Name** beadm – manage ZFS boot environments

**Synopsis** beadm create [-a] [-d *description*]  
          [-e *non-activeBeName* | *beName@snapshot*]  
          [-o *property=value*] ... [-p *zpool*] *beName*  
  
beadm create *beName@snapshot*  
  
beadm destroy [-fF] *beName* | *beName@snapshot*  
  
beadm list [-a | -ds] [-H] [*beName*]  
  
beadm mount *beName mountpoint*  
  
beadm unmount [-f] *beName*  
  
beadm rename *beName newBeName*  
  
beadm activate *beName*

**Description** The beadm command is the user interface for managing ZFS Boot Environments (BEs). This utility is intended to be used by system administrators who want to manage multiple Oracle Solaris instances on a single system.

Using beadm, you can do the following:

- Create a new BE, based on the active BE.
- Create a new BE, based on an inactive BE.
- Create a snapshot of an existing BE.
- Create a new BE, based on an existing snapshot.
- Create a new BE, and copy it to a different zpool.
- Activate an existing, inactive BE.
- Mount a BE.
- Unmount a BE.
- Destroy a BE.
- Destroy a snapshot of a BE.
- Rename an existing, inactive BE.
- Display information about your snapshots and datasets.

**Sub-commands** The beadm command has the subcommands and options listed below. Usage of many of these subcommands and options is illustrated in EXAMPLES, below.

beadm (*no arguments*)

Displays command usage.

beadm create [-a] [-d *description*] [-e *non-activeBeName* | *beName@snapshot*] [-o *property=value*] ... [-p *zpool*] *beName*

Creates a new boot environment named *beName*. If the -e option is not provided, the new boot environment will be created as a clone of the currently running boot environment. If the -d option is provided, then the description is also used as the title for the BE's entry in the GRUB menu for x86 systems or in the boot menu for SPARC systems. If the -d option is not provided, *beName* will be used as the title.

- a  
Activate the newly created BE upon creation. The default is to not activate the newly created BE.
- d *description*  
Create a new BE with a description associated with it.
- e *non-activeBeName*  
Create a new BE from an existing inactive BE.
- e *beName@snapshot*  
Create a new BE from an existing snapshot of the BE named *beName*.
- o *property=value*  
Create the datasets for a new BE with specific ZFS properties. Multiple -o options can be specified. See [zfs\(1M\)](#) for more information on the -o option.
- p *zpool*  
Create the new BE in the specified *zpool*. If this is not provided, the default behavior is to create the new BE in the same pool as the origin BE.

`beadm create beName@snapshot`  
Creates a snapshot of the existing BE named *beName*.

`beadm destroy [-fF] beName | beName@snapshot`  
Destroys the boot environment named *beName* or destroys an existing snapshot of the boot environment named *beName@snapshot*. Destroying a boot environment will also destroy all snapshots of that boot environment. Use this command with caution.

- f  
Forcefully unmount the boot environment if it is currently mounted.
- F  
Force the action without prompting to verify the destruction of the boot environment.

`beadm list [-a | -ds] [-H] [beName]`  
Lists information about the existing boot environment named *beName*, or lists information for all boot environments if *beName* is not provided. The **A**ctive field indicates whether the boot environment is active now, represented by **N**; active on reboot, represented by **R**; or both, represented by **NR**.

Each line in the machine-parsable output has the boot environment name as the first field. The **S**pace field is displayed in bytes and the **C**reated field is displayed in UTC format. The -H option used with no other options gives the boot environment's UUID in the second field. This field will be blank if the boot environment does not have a UUID. See the **EXAMPLES** section.

- a  
Lists all available information about the boot environment. This includes subordinate file systems and snapshots.

- d  
Lists information about all subordinate file systems belonging to the boot environment.
- s  
Lists information about the snapshots of the boot environment.
- H  
Do not list header information. Each field in the list information is separated by a semicolon.

**beadm mount** *beName mountpoint*

Mounts a boot environment named *beName* at *mountpoint*. *mountpoint* must be an already existing empty directory.

**beadm unmount** [-f] *beName*

Unmounts a boot environment named *beName*.

-f

Forcefully unmount the boot environment even if it is currently busy.

**beadm rename** *beName newBeName*

Renames the boot environment named *beName* to *newBeName*.

**beadm activate** *beName*

Makes *beName* the active BE on next reboot.

#### **Examples** EXAMPLE 1 Creating a New BE Using Active BE

The following command creates a new BE, BE1, by cloning the current BE.

```
beadm create BE1
```

#### EXAMPLE 2 Creating a New BE Using Inactive BE

The following command creates a new BE, BE2, by cloning the existing inactive BE named BE1.

```
beadm beadm create -e BE1 BE2
```

#### EXAMPLE 3 Creating a Snapshot of Existing BE

The following command creates a snapshot named now of the existing BE named BE1.

```
beadm create BE1@now
```

#### EXAMPLE 4 Cloning a Snapshot to Create a New BE

The following command creates a new BE named BE3, by cloning an existing snapshot of BE1.

```
beadm create -e BE1@now BE3
```

#### EXAMPLE 5 Creating a New BE in Specified zpool

The following command creates a new BE named BE4, based on the currently running BE. The command creates the new BE in the zpool rpool2.

---

**EXAMPLE 5** Creating a New BE in Specified zpool *(Continued)*

```
beadm create -p rpool2 BE4
```

**EXAMPLE 6** Creating a New BE in Specified zpool with Compression Enabled

The following command creates a new BE named BE5, based on the currently running BE. The command creates the new BE in the zpool rpool2 and creates its datasets with compression turned on.

```
beadm create -p rpool2 -o compression=on BE5
```

**EXAMPLE 7** Creating a New BE and Providing a Description

The following command creates a new BE named BE6, based on the currently running BE, and provides a description for it.

```
beadm create -d "BE6 used as test environment" BE6
```

**EXAMPLE 8** Activating a BE

The following command activates an existing, inactive BE named BE3.

```
beadm activate BE3
```

**EXAMPLE 9** Mounting a BE

The following command mounts the BE named BE3 at /mnt.

```
beadm mount BE3 /mnt
```

**EXAMPLE 10** Unmounting a BE

The following command unmounts the BE named BE3.

```
beadm unmount BE3
```

**EXAMPLE 11** Destroying a BE

The following command destroys the BE named BE3 without asking for confirmation.

```
beadm destroy -F BE3
```

**EXAMPLE 12** Destroying a Snapshot

The following command destroys the snapshot named now of BE1.

```
beadm destroy BE1@now
```

**EXAMPLE 13** Renaming a BE

The following command renames the existing, inactive BE named BE1 to BE3.

```
beadm rename BE1 BE3
```

**EXAMPLE 14** Listing All BEs

The following command lists all existing BEs.

```
beadm list
BE Active Mountpoint Space Policy Created

BE2 - - 72.0K static 2008-05-21 12:26
BE3 - - 332.0K static 2008-08-26 10:28
BE4 - - 15.78M static 2008-09-05 18:20
BE5 NR / 7.25G static 2008-09-09 16:53
```

**EXAMPLE 15** Listing All BEs with Dataset and Snapshot Info

The following command lists all existing BEs and list all dataset and snapshot information about those boot environments.

```
beadm list -d -s
BE/Dataset/Snapshot Active Mountpoint Space Policy Created

BE2
 p/ROOT/BE2 - - 36.0K static 2008-05-21 12:26
 p/ROOT/BE2/opt - - 18.0K static 2008-05-21 16:26
 p/ROOT/BE2/opt@now - - 0 static 2008-09-08 22:43
 p/ROOT/BE2@now - - 0 static 2008-09-08 22:43
BE3
 p/ROOT/BE3 - - 192.0K static 2008-08-26 10:28

 p/ROOT/BE3/opt/local - - 36.0K static 2008-08-28 10:58
BE4
 p/ROOT/BE4 - - 15.78M static 2008-09-05 18:20
BE5
 p/ROOT/BE5 NR / 6.10G static 2008-09-09 16:53
 p/ROOT/BE5/opt - /opt 24.55M static 2008-09-09 16:53
 p/ROOT/BE5/opt@bar - - 18.38M static 2008-09-10 00:59
 p/ROOT/BE5/opt@foo - - 18.38M static 2008-06-10 16:37
 p/ROOT/BE5@bar - - 139.44M static 2008-09-10 00:59
 p/ROOT/BE5@foo - - 912.85M static 2008-06-10 16:37
```

**EXAMPLE 16** Listing Dataset and Snapshot Info for a BE

The following command lists all dataset and snapshot information about BE5.

```
beadm list -a BE5
BE/Dataset/Snapshot Active Mountpoint Space Policy Created

BE5
 p/ROOT/BE5 NR / 6.10G static 2008-09-09 16:53
 p/ROOT/BE5/opt - /opt 24.55M static 2008-09-09 16:53
 p/ROOT/BE5/opt@bar - - 18.38M static 2008-09-10 00:59
 p/ROOT/BE5/opt@foo - - 18.38M static 2008-06-10 16:37
```

**EXAMPLE 16** Listing Dataset and Snapshot Info for a BE *(Continued)*

```
p/ROOT/BE5@bar - - 139.44M static 2008-09-10 00:59
p/ROOT/BE5@foo - - 912.85M static 2008-06-10 16:37
```

**EXAMPLE 17** Listing in Machine-Parseable Format

The following command lists information about all BEs in machine-parseable format.

```
beadm list -H
BE2;;;55296;static;1211397974
BE3;;;339968;static;1219771706
BE4;;;16541696;static;1220664051
BE5;215b8387-4968-627c-d2d0-f4a011414bab;NR;/;7786206208;static;1221004384
```

**Exit Status** 0

Success.

>0

Failure.

**Files** /var/log/beadm/beName/create.log.yyyymmdd\_hhmmss

Log used for capturing beadm create output. The time designation portion of the file name is explained as follows.

- *yyymmdd\_hhmmss* — for example, 20071130\_140558.
- *yyyy* — year, 2007
- *mm* — month, 11
- *dd* — day, 30
- *hh* — hour, 14
- *mm* — minute, 05
- *ss* — second, 58

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | install/beadm   |
| Interface Stability | Committed       |

**See Also** [zfs\(1M\)](#), [attributes\(5\)](#)

**Name** boot – start the system kernel or a standalone program

### Synopsis

```
SPARC boot [OBP names] [file] [-aLV] [-F object] [-D default-file]
 [-Z dataset] [boot-flags] [—] [client-program-args]

x86 kernel$ /platform/i86pc/kernel/$ISADIR/unix [boot-args]
 [-B prop=val [,val...]]
```

**Description** Bootstrapping is the process of loading and executing a standalone program. For the purpose of this discussion, bootstrapping means the process of loading and executing the bootable operating system. Typically, the standalone program is the operating system kernel (see [kernel\(1M\)](#)), but any standalone program can be booted instead. On a SPARC-based system, the diagnostic monitor for a machine is a good example of a standalone program other than the operating system that can be booted.

If the standalone is identified as a dynamically-linked executable, boot will load the interpreter (linker/loader) as indicated by the executable format and then transfer control to the interpreter. If the standalone is statically-linked, it will jump directly to the standalone.

Once the kernel is loaded, it starts the UNIX system, mounts the necessary file systems (see [vfstab\(4\)](#)), and runs `/sbin/init` to bring the system to the “initdefault” state specified in `/etc/inittab`. See [inittab\(4\)](#).

**SPARC Bootstrap Procedure** On SPARC based systems, the bootstrap procedure on most machines consists of the following basic phases.

After the machine is turned on, the system firmware (in PROM) executes power-on self-test (POST). The form and scope of these tests depends on the version of the firmware in your system.

After the tests have been completed successfully, the firmware attempts to autoboot if the appropriate flag has been set in the non-volatile storage area used by the firmware. The name of the file to load, and the device to load it from can also be manipulated.

These flags and names can be set using the [eeprom\(1M\)](#) command from the shell, or by using PROM commands from the ok prompt after the system has been halted.

The second level program is either a filesystem-specific boot block (when booting from a disk), or `inetboot` or `wanboot` (when booting across the network).

### Network Booting

Network booting occurs in two steps: the client first obtains an IP address and any other parameters necessary to permit it to load the second-stage booter. The second-stage booter in turn loads the boot archive from the boot device.

An IP address can be obtained in one of three ways: RARP, DHCP, or manual configuration, depending on the functions available in and configuration of the PROM. Machines of the sun4u and sun4v kernel architectures have DHCP-capable PROMs.

The boot command syntax for specifying the two methods of network booting are:

```
boot net:rarp
boot net:dhcp
```

The command:

```
boot net
```

without a `rarp` or `dhcp` specifier, invokes the default method for network booting over the network interface for which `net` is an alias.

The sequence of events for network booting using RARP/`bootparams` is described in the following paragraphs. The sequence for DHCP follows the RARP/`bootparams` description.

When booting over the network using RARP/`bootparams`, the PROM begins by broadcasting a reverse ARP request until it receives a reply. When a reply is received, the PROM then broadcasts a TFTP request to fetch the first block of `inetboot`. Subsequent requests will be sent to the server that initially answered the first block request. After loading, `inetboot` will also use reverse ARP to fetch its IP address, then broadcast `bootparams` RPC calls (see [bootparams\(4\)](#)) to locate configuration information and its root file system. `inetboot` then loads the boot archive by means of NFS and transfers control to that archive.

When booting over the network using DHCP, the PROM broadcasts the hardware address and kernel architecture and requests an IP address, boot parameters, and network configuration information. After a DHCP server responds and is selected (from among potentially multiple servers), that server sends to the client an IP address and all other information needed to boot the client. After receipt of this information, the client PROM examines the name of the file to be loaded, and will behave in one of two ways, depending on whether the file's name appears to be an HTTP URL. If it does not, the PROM downloads `inetboot`, loads that file into memory, and executes it. `inetboot` loads the boot archive, which takes over the machine and releases `inetboot`. Startup scripts then initiate the DHCP agent (see [dhcagent\(1M\)](#)), which implements further DHCP activities.

If the file to be loaded is an HTTP URL, the PROM will use HTTP to load the referenced file. If the client has been configured with an HMAC SHA-1 key, it will check the integrity of the loaded file before proceeding to execute it. The file is expected to be the `wanboot` binary. The WAN boot process can be configured to use either DHCP or NVRAM properties to discover the install server and router and the proxies needed to connect to it. When `wanboot` begins executing, it determines whether sufficient information is available to it to allow it to proceed. If any necessary information is missing, it will either exit with an appropriate error or bring up a command interpreter and prompt for further configuration information. Once `wanboot` has obtained the necessary information, it loads the boot loader into memory by means of HTTP.

If an encryption key has been installed on the client, wanboot will verify the boot loader's signature and its accompanying hash. Presence of an encryption key but no hashing key is an error.

The wanboot boot loader can communicate with the client using either HTTP or secure HTTP. If the former, and if the client has been configured with an HMAC SHA-1 key, the boot loader will perform an integrity check of the root file system. Once the root file system has been loaded into memory (and possibly had an integrity check performed), the boot archive is transferred from the server. If provided with a `boot_logger` URL by means of the `wanboot.conf(4)` file, wanboot will periodically log its progress.

Not all PROMs are capable of consuming URLs. You can determine whether a client is so capable using the `list-security-keys` OBP command (see [monitor\(1M\)](#)).

WAN booting is not currently available on the x86 platform.

The wanboot Command Line

When the client program is wanboot, it accepts `client-program-args` of the form:

```
boot ... -o opt1[,opt2[,...]]
```

where each option may be an action:

`dhcp`

Require wanboot to obtain configuration parameters by means of DHCP.

`prompt`

Cause wanboot to enter its command interpreter.

`<cmd>`

One of the interpreter commands listed below.

...or an assignment, using the interpreter's parameter names listed below.

The wanboot Command Interpreter

The wanboot command interpreter is invoked by supplying a `client-program-args` of “`-o prompt`” when booting. Input consists of single commands or assignments, or a comma-separated list of commands or assignments. The configuration parameters are:

`host-ip`

IP address of the client (in dotted-decimal notation)

`router-ip`

IP address of the default router (in dotted-decimal notation)

`subnet-mask`

subnet mask (in dotted-decimal notation)

`client-id`

DHCP client identifier (a quoted ASCII string or hex ASCII)

`hostname`  
hostname to request in DHCP transactions (ASCII)

`http-proxy`  
HTTP proxy server specification (IPADDR[:PORT])

The key names are:

`3des`  
the triple DES encryption key (48 hex ASCII characters)

`aes`  
the AES encryption key (32 hex ASCII characters)

`sha1`  
the HMAC SHA-1 signature key (40 hex ASCII characters)

Finally, the URL or the WAN boot CGI is referred to by means of:

`bootserver`  
URL of WAN boot's CGI (the equivalent of OBP's `file` parameter)

The interpreter accepts the following commands:

`help`  
Print a brief description of the available commands

`var=val`  
Assign *val* to *var*, where *var* is one of the configuration parameter names, the key names, or `bootserver`.

`var=`  
Unset parameter *var*.

`list`  
List all parameters and their values (key values retrieved by means of OBP are never shown).

`prompt`  
Prompt for values for unset parameters. The name of each parameter and its current value (if any) is printed, and the user can accept this value (press Return) or enter a new value.

`go`  
Once the user is satisfied that all values have been entered, leave the interpreter and continue booting.

`exit`  
Quit the boot interpreter and return to OBP's ok prompt.

Any of these assignments or commands can be passed on the command line as part of the `-o` options, subject to the OBP limit of 128 bytes for boot arguments. For example, `-o list,go` would simply list current (default) values of the parameters and then continue booting.

iSCSI Boot iSCSI boot is supported on both x86 and SPARC.

### **iSCSI Boot on x86**

For iSCSI boot on x86, the host being booted must be equipped with NIC(s) capable of iBFT (iSCSI Boot Firmware Table) or have the mainboard's BIOS be iBFT-capable. iBFT, defined in the Advanced Configuration and Power Interface (ACPI) 3.0b specification, specifies a block of information that contains various parameters that are useful to the iSCSI Boot process.

Firmware implementing iBFT presents an iSCSI disk in the BIOS during startup as a bootable device by establishing the connection to the iSCSI target. The rest of the process of iSCSI booting is the same as booting from a local disk.

To configure the iBFT properly, users need to refer to the documentation from their hardware vendors.

### **iSCSI Boot on SPARC**

iSCSI boot on SPARC is supported with OpenBoot level 4.31 and above, and does not require a specific NIC.

The boot command in OpenBoot takes a series of keywords to identify the destination iSCSI target, following the *keyword=value* format. The complete form of the iSCSI boot command is:

```
boot net:iscsi-target-ip=t-ip,iscsi-target-name=name
 host-ip=h-ip[,router-ip=r-ip]
 [,subnet-mask=m-ip]
 [,iscsi-port=port]
 [,iscsi-lun=lun]
 [,iscsi-partition=partition]
```

The descriptions of the preceding keywords are as follows:

|                                |                                         |
|--------------------------------|-----------------------------------------|
| <code>host-ip</code>           | IP address of booting host.             |
| <code>router-ip</code>         | IP address of routing gateway.          |
| <code>subnet-mask</code>       | Subnet mask of <code>host-ip</code> .   |
| <code>iscsi-target-ip</code>   | IP address of iSCSI target storing OS.  |
| <code>iscsi-target-name</code> | Name of iSCSI target storing OS.        |
| <code>iscsi-partition</code>   | Partition containing the bootable root. |
| <code>iscsi-port</code>        | IP port of the target.                  |
| <code>iscsi-lun</code>         | LUN to be booted off on target.         |

The values of `iscsi-target-ip`, `route-ip`, and `subnet-mask` are in standard, IPv4 dotted-decimal format; for example, 255.255.255.0 for `subnet-mask`. IPv6 is not supported in the current OpenBoot implementation.

The value of `iscsi-port`, a decimal number, is in the range of 1 to 65535.

The value of `iscsi-lun` is in the format of a dashed hexadecimal LUN, `fff-fff-fff-fff`. Please refer to section 5 of RFC 4173 for details. Leading zeroes and trailing dashes can be excluded, thus, 3, for example, is equivalent to `0003-0000-0000-0000`.

The value of `iscsi-partition` is one ASCII character, used to specify the root partition. Most commonly, it is a.

The value of `iscsi-target-name` is in the format of a string, as specified by RFC 3720 and RFC 3722.

Two security keys are added to provide CHAP authentication on the target side. These are:

```
chap-user CHAP name
chap-password CHAP secret
```

Currently these two keys can be set with the command `set-ascii-security-key` at the Open Boot PROM (ok) prompt. For example:

```
ok set-ascii-security-key chap-user chap name
ok set-ascii-security-key chap-password chap password
```

Bi-directional authentication is not yet supported. These two variables can be changed only under the Open Boot PROM prompt.

RFC 4173 is supported, to retrieve iSCSI boot information from a DHCP server. The DHCP server must specify the Root Path option for the booting client, after which the client can do an iSCSI boot by means of the simple command:

```
boot net:dhcp
```

Currently the key `boot-device` is used to retrieve the physical boot device path during iSCSI boot. This key is setup during the Solaris installation. A manually modified key value might break iSCSI boot.

**Booting from Disk** When booting from disk, the OpenBoot PROM firmware reads the boot blocks from blocks 1 to 15 of the partition specified as the boot device. This standalone booter usually contains a file system-specific reader capable of reading the boot archive.

If the pathname to the standalone is relative (does not begin with a slash), the second level boot will look for the standalone in a platform-dependent search path. This path is guaranteed to contain `/platform/platform-name`. Many SPARC platforms next search the platform-specific path entry `/platform/hardware-class-name`. See [filesystem\(5\)](#). If the pathname is absolute, boot will use the specified path. The boot program then loads the standalone at the appropriate address, and then transfers control.

Once the boot archive has been transferred from the boot device, Solaris can initialize and take over control of the machine. This process is further described in the “Boot Archive Phase,” below, and is identical on all platforms.

If the filename is not given on the command line or otherwise specified, for example, by the `boot-file` NVRAM variable, `boot` chooses an appropriate default file to load based on what software is installed on the system and the capabilities of the hardware and firmware.

The path to the kernel must not contain any whitespace.

**Booting from ZFS** Booting from ZFS differs from booting from UFS in that, with ZFS, a device specifier identifies a storage pool, not a single root file system. A storage pool can contain multiple bootable datasets (that is, root file systems). Therefore, when booting from ZFS, it is not sufficient to specify a boot device. One must also identify a root file system within the pool that was identified by the boot device. By default, the dataset selected for booting is the one identified by the pool's `boot fs` property. This default selection can be overridden by specifying an alternate bootable dataset with the `-Z` option.

**Boot Archive Phase** The boot archive contains a file system image that is mounted using an in-memory disk. The image is self-describing, specifically containing a file system reader in the boot block. This file system reader mounts and opens the RAM disk image, then reads and executes the kernel contained within it. By default, this kernel is in:

```
/platform/'uname -i'/kernel/unix
```

If booting from ZFS, the pathnames of both the archive and the kernel file are resolved in the root file system (that is, dataset) selected for booting as described in the previous section.

The initialization of the kernel continues by loading necessary drivers and modules from the in-memory filesystem until I/O can be turned on and the root filesystem mounted. Once the root filesystem is mounted, the in-memory filesystem is no longer needed and is discarded.

**OpenBoot PROM boot Command Behavior** The OpenBoot boot command takes arguments of the following form:

```
ok boot [device-specifier] [arguments]
```

The default boot command has no arguments:

```
ok boot
```

If no *device-specifier* is given on the boot command line, OpenBoot typically uses the *boot-device* or *diag-device* NVRAM variable. If no optional *arguments* are given on the command line, OpenBoot typically uses the *boot-file* or *diag-file* NVRAM variable as default boot arguments. (If the system is in diagnostics mode, *diag-device* and *diag-file* are used instead of *boot-device* and *boot-file*).

*arguments* may include more than one string. All *argument* strings are passed to the secondary booter; they are not interpreted by OpenBoot.

If any *arguments* are specified on the boot command line, then neither the *boot-file* nor the *diag-file* NVRAM variable is used. The contents of the NVRAM variables are not merged with command line arguments. For example, the command:

```
ok boot -s
```

ignores the settings in both *boot-file* and *diag-file*; it interprets the string "-s" as *arguments*. boot will not use the contents of *boot-file* or *diag-file*.

With older PROMs, the command:

```
ok boot net
```

took no arguments, using instead the settings in *boot-file* or *diag-file* (if set) as the default file name and arguments to pass to boot. In most cases, it is best to allow the boot command to choose an appropriate default based upon the system type, system hardware and firmware, and upon what is installed on the root file system. Changing *boot-file* or *diag-file* can generate unexpected results in certain circumstances.

This behavior is found on most OpenBoot 2.x and 3.x based systems. Note that differences may occur on some platforms.

The command:

```
ok boot cdrom
```

...also normally takes no arguments. Accordingly, if *boot-file* is set to the 64-bit kernel filename and you attempt to boot the installation CD or DVD with boot cdrom, boot will fail if the installation media contains only a 32-bit kernel.

Because the contents of *boot-file* or *diag-file* can be ignored depending on the form of the boot command used, reliance upon *boot-file* should be discouraged for most production systems.

When executing a WAN boot from a local (CD or DVD) copy of wanboot, one must use:

```
ok boot cdrom -F wanboot - install
```

Modern PROMs have enhanced the network boot support package to support the following syntax for arguments to be processed by the package:

```
[protocol,] [key=value,]*
```

All arguments are optional and can appear in any order. Commas are required unless the argument is at the end of the list. If specified, an argument takes precedence over any default values, or, if booting using DHCP, over configuration information provided by a DHCP server for those parameters.

*protocol*, above, specifies the address discovery protocol to be used.

Configuration parameters, listed below, are specified as *key=value* attribute pairs.

`tftp-server`

IP address of the TFTP server

`file`

file to download using TFTP or URL for WAN boot

`host-ip`

IP address of the client (in dotted-decimal notation)

`router-ip`

IP address of the default router

`subnet-mask`

subnet mask (in dotted-decimal notation)

`client-id`

DHCP client identifier

`hostname`

hostname to use in DHCP transactions

`http-proxy`

HTTP proxy server specification (IPADDR[:PORT])

`tftp-retries`

maximum number of TFTP retries

`dhcp-retries`

maximum number of DHCP retries

The list of arguments to be processed by the network boot support package is specified in one of two ways:

- As arguments passed to the package's open method, or
- arguments listed in the NVRAM variable `network-boot-arguments`.

Arguments specified in `network-boot-arguments` will be processed only if there are no arguments passed to the package's open method.

#### Argument Values

*protocol* specifies the address discovery protocol to be used. If present, the possible values are `rarp` or `dhcp`.

If other configuration parameters are specified in the new syntax and style specified by this document, absence of the *protocol* parameter implies manual configuration.

---

If no other configuration parameters are specified, or if those arguments are specified in the positional parameter syntax currently supported, the absence of the *protocol* parameter causes the network boot support package to use the platform-specific default address discovery protocol.

Manual configuration requires that the client be provided its IP address, the name of the boot file, and the address of the server providing the boot file image. Depending on the network configuration, it might be required that `subnet - mask` and `router - ip` also be specified.

If the *protocol* argument is not specified, the network boot support package uses the platform-specific default address discovery protocol.

`tftp-server` is the IP address (in standard IPv4 dotted-decimal notation) of the TFTP server that provides the file to download if using TFTP.

When using DHCP, the value, if specified, overrides the value of the TFTP server specified in the DHCP response.

The TFTP RRQ is unicast to the server if one is specified as an argument or in the DHCP response. Otherwise, the TFTP RRQ is broadcast.

*file* specifies the file to be loaded by TFTP from the TFTP server, or the URL if using HTTP. The use of HTTP is triggered if the file name is a URL, that is, the file name starts with `http:` (case-insensitive).

When using RARP and TFTP, the default file name is the ASCII hexadecimal representation of the IP address of the client, as documented in a preceding section of this document.

When using DHCP, this argument, if specified, overrides the name of the boot file specified in the DHCP response.

When using DHCP and TFTP, the default file name is constructed from the root node's name property, with commas (,) replaced by periods (.).

When specified on the command line, the filename must not contain slashes (/).

The format of URLs is described in RFC 2396. The HTTP server must be specified as an IP address (in standard IPv4 dotted-decimal notation). The optional port number is specified in decimal. If a port is not specified, port 80 (decimal) is implied.

The URL presented must be “safe-encoded”, that is, the package does not apply escape encodings to the URL presented. URLs containing commas must be presented as a quoted string. Quoting URLs is optional otherwise.

`host-ip` specifies the IP address (in standard IPv4 dotted-decimal notation) of the client, the system being booted. If using RARP as the address discovery protocol, specifying this argument makes use of RARP unnecessary.

If DHCP is used, specifying the `host - ip` argument causes the client to follow the steps required of a client with an “Externally Configured Network Address”, as specified in RFC 2131.

`router - ip` is the IP address (in standard IPv4 dotted-decimal notation) of a router on a directly connected network. The router will be used as the first hop for communications spanning networks. If this argument is supplied, the router specified here takes precedence over the preferred router specified in the DHCP response.

`subnet - mask` (specified in standard IPv4 dotted-decimal notation) is the subnet mask on the client's network. If the subnet mask is not provided (either by means of this argument or in the DHCP response), the default mask appropriate to the network class (Class A, B, or C) of the address assigned to the booting client will be assumed.

`client - id` specifies the unique identifier for the client. The DHCP client identifier is derived from this value. Client identifiers can be specified as:

- The ASCII hexadecimal representation of the identifier, or
- a quoted string

Thus, `client - id="openboot"` and `client - id=6f70656e626f6f74` both represent a DHCP client identifier of 6F70656E626F6F74.

Identifiers specified on the command line must not include slash (/) or spaces.

The maximum length of the DHCP client identifier is 32 bytes, or 64 characters representing 32 bytes if using the ASCII hexadecimal form. If the latter form is used, the number of characters in the identifier must be an even number. Valid characters are 0-9, a-f, and A-F.

For correct identification of clients, the client identifier must be unique among the client identifiers used on the subnet to which the client is attached. System administrators are responsible for choosing identifiers that meet this requirement.

Specifying a client identifier on a command line takes precedence over any other DHCP mechanism of specifying identifiers.

`hostname` (specified as a string) specifies the hostname to be used in DHCP transactions. The name might or might not be qualified with the local domain name. The maximum length of the hostname is 255 characters.

**Note** – The `hostname` parameter can be used in service environments that require that the client provide the desired hostname to the DHCP server. Clients provide the desired hostname to the DHCP server, which can then register the hostname and IP address assigned to the client with DNS.

`http - proxy` is specified in the following standard notation for a host:

```
host [":" port]
```

...where *host* is specified as an IP address (in standard IPv4 dotted-decimal notation) and the optional *port* is specified in decimal. If a port is not specified, port 8080 (decimal) is implied.

`tftp-retries` is the maximum number of retries (specified in decimal) attempted before the TFTP process is determined to have failed. Defaults to using infinite retries.

`dhcp-retries` is the maximum number of retries (specified in decimal) attempted before the DHCP process is determined to have failed. Defaults to using infinite retries.

#### x86 Bootstrap Procedure

On x86 based systems, the bootstrapping process consists of two conceptually distinct phases, kernel loading and kernel initialization. Kernel loading is implemented in GRUB (GRand Unified Bootloader) using the BIOS ROM on the system board, and BIOS extensions in ROMs on peripheral boards. The BIOS loads GRUB, starting with the first physical sector from a hard disk, DVD, or CD. If supported by the ROM on the network adapter, the BIOS can also download the `pxegrub` binary from a network boot server. Once GRUB is located, it executes a command in a menu to load the `unix` kernel and a pre-constructed boot archive containing kernel modules and data.

If the device identified by GRUB as the boot device contains a ZFS storage pool, the `menu.lst` file used to create the GRUB menu will be found in the dataset at the root of the pool's dataset hierarchy. This is the dataset with the same name as the pool itself. There is always exactly one such dataset in a pool, and so this dataset is well-suited for pool-wide data such as the `menu.lst` file. After the system is booted, this dataset is mounted at `/poolname` in the root file system.

There can be multiple bootable datasets (that is, root file systems) within a pool. By default, the file system in which file name entries in a `menu.lst` file are resolved is the one identified by the pool's `bootfs` property (see [zpool\(1M\)](#)). However, a `menu.lst` entry can contain a `bootfs` command, which specifies an alternate dataset in the pool. In this way, the `menu.lst` file can contain entries for multiple root file systems within the pool.

Kernel initialization starts when GRUB finishes loading the boot archive and hands control over to the `unix` binary. At this point, GRUB becomes inactive and no more I/O occurs with the boot device. The Unix operating system initializes, links in the necessary modules from the boot archive and mounts the root file system on the real root device. At this point, the kernel regains storage I/O, mounts additional file systems (see [vfstab\(4\)](#)), and starts various operating system services (see [smf\(5\)](#)).

#### Enabling Automatic Rebooting (x86)

The Solaris operating system supports an [smf\(5\)](#) property that enables a system to automatically reboot from the current boot device, to recover from conditions such as an out-of-date boot archive.

The service `svc:/system/boot-config:default` contains the boolean property `auto-reboot-safe`, which is set to `false` by default. Setting it to `true` communicates that both the system's BIOS and default GRUB menu entry are set to boot from the current boot device. The value of this property can be changed using [svccfg\(1M\)](#) and [svcadm\(1M\)](#). For example, to set `auto-reboot-safe` to enable automatic rebooting, enter a command such as:

```
example# svccfg -s svc:/system/boot-config:default \
 setprop config/auto-reboot-safe = true
```

Most systems are configured for automatic reboot from the current boot device. However, in some instances, automatic rebooting to an unknown operating system might produce undesirable results. For these instances, the `auto-reboot-safe` property allows you to specify the behavior you want.

**Failsafe Mode** A requirement of booting from a root filesystem image built into a boot archive then remounting root onto the actual root device is that the contents of the boot archive and the root filesystem must be consistent. Otherwise, the proper operation and integrity of the machine cannot be guaranteed.

The term “consistent” means that all files and modules in the root filesystem are also present in the boot archive and have identical contents. Since the boot strategy requires first reading and mounting the boot archive as the first-stage root image, all unloadable kernel modules and initialization derived from the contents of the boot archive are required to match the real root filesystem. Without such consistency, it is possible that the system could be running with a kernel module or parameter setting applied to the root device before reboot, but not yet updated in the root archive. This inconsistency could result in system instability or data loss.

Once the root filesystem is mounted, and before relinquishing the in-memory filesystem, Solaris performs a consistency verification against the two file systems. If an inconsistency is detected, Solaris suspends the normal boot sequence and falls back to failsafe mode. Correcting this state requires the administrator take one of two steps. The recommended procedure is to reboot to the failsafe archive and rebuild the boot archive. This ensures that a known kernel is booted and functioning for the archive rebuild process. Alternatively, the administrator can elect to clear the inconsistent boot archive service state and continue system bring-up if the inconsistency is such that correct system operation will not be impaired. See [svcadm\(1M\)](#).

If the boot archive service is cleared and system bring-up is continued (the second alternative above), the system may be running with unloadable kernel drivers or other modules that are out-of-date with respect to the root filesystem. As such, correct system operation may be compromised.

To ensure that the boot archive is consistent, the normal system shutdown process, as initiated by [reboot\(1M\)](#) and [shutdown\(1M\)](#), checks for and applies updates to the boot archive at the conclusion of the [umountall\(1M\)](#) milestone.

An update to any kernel file, driver, module or driver configuration file that needs to be included in the boot archive after the `umountall` service is complete will result in a failed boot archive consistency check during the next boot. To avoid this, it is recommended to always shut down a machine cleanly.

If an update is required to the kernel after completion of the `umountall` service, the administrator may elect to rebuild the archive by invoking:

**# bootadm update-archive**

Failsafe Boot Archive The failsafe archive can be used to boot the machine at any time for maintenance or troubleshooting. The failsafe boot archive is installed on the machine, sourced from the miniroot archive. Booting the failsafe archive causes the machine to boot using the in-memory filesystem as the root device.

**SPARC**

The SPARC failsafe archive is:

```
/platform/`uname -i`/failsafe
```

...and can be booted as follows:

```
ok boot [device-specifier] -F failsafe
```

If a user wishes to boot a failsafe archive from a particular ZFS bootable dataset, this can be done as follows:

```
ok boot [device-specifier] -Z dataset -F failsafe
```

**x86**

The x86 failsafe archive is:

```
/boot/x86.miniroot-safe
```

...and can be booted by selecting the Solaris failsafe item from the GRUB menu.

**Options**

SPARC The following SPARC options are supported:

-a

The boot program interprets this flag to mean ask me, and so it prompts for the name of the standalone. The '-a' flag is then passed to the standalone program.

-D *default-file*

Explicitly specify the *default-file*. On some systems, boot chooses a dynamic default file, used when none is otherwise specified. This option allows the *default-file* to be explicitly set and can be useful when booting [kmdb\(1\)](#) since, by default, kmdb loads the default-file as exported by the boot program.

-F *object*

Boot using the named object. The object must be either an ELF executable or bootable object containing a boot block. The primary use is to boot the failsafe or wanboot boot archive.

-L

List the bootable datasets within a ZFS pool. You can select one of the bootable datasets in the list, after which detailed instructions for booting that dataset are displayed. Boot the selected dataset by following the instructions. This option is supported only when the boot device contains a ZFS storage pool.

-V

Display verbose debugging information.

*boot-flags*

The boot program passes all *boot-flags* to *file*. They are not interpreted by boot. See the [kernel\(1M\)](#) and [kmdb\(1\)](#) manual pages for information about the options available with the default standalone program.

*client-program-args*

The boot program passes all *client-program-args* to *file*. They are not interpreted by boot.

*file*

Name of a standalone program to boot. If a filename is not explicitly specified, either on the boot command line or in the *boot-file* NVRAM variable, boot chooses an appropriate default filename.

*OBP names*

Specify the open boot prom designations. For example, on Desktop SPARC based systems, the designation `/sbus/esp@0,800000/sd@3,0:a` indicates a SCSI disk (sd) at target 3, lun0 on the SCSI bus, with the esp host adapter plugged into slot 0.

-Z *dataset*

Boot from the root file system in the specified ZFS dataset.

x86 The following x86 options are supported:

-B *prop=val...*

One or more property-value pairs to be passed to the kernel. Multiple property-value pairs must be separated by a comma. Use of this option is the equivalent of the command: `eeeprom prop=val`. See [eeeprom\(1M\)](#) for available properties and valid values.

If the root file system corresponding to this menu entry is a ZFS dataset, the menu entry needs the following option added:

-B \$ZFS-BOOTFS

*boot-args*

The boot program passes all *boot-args* to *file*. They are not interpreted by boot. See [kernel\(1M\)](#) and [kmdb\(1\)](#) for information about the options available with the kernel.

*/platform/i86pc/kernel/\$ISADIR/unix*

Name of the kernel to boot. When using the `kernel$` token, `$ISADIR` expands to `amd64` on 64-bit machines, and a null string on other machines. As a result of this dereferencing, this path expands to the proper kernel for the machine.

**x86 Boot Sequence Details** After a PC-compatible machine is turned on, the system firmware in the BIOS ROM executes a power-on self test (POST), runs BIOS extensions in peripheral board ROMs, and invokes software interrupt INT 19h, Bootstrap. The INT 19h handler typically performs the standard PC-compatible boot, which consists of trying to read the first physical sector from the first diskette drive, or, if that fails, from the first hard disk. The processor then jumps to the first byte of the sector image in memory.

**x86 Primary Boot** The first sector on a floppy disk contains the master boot block (GRUB stage1). The stage 1 is responsible for loading GRUB stage2. Now GRUB is fully functional. It reads and executes the menu file `/boot/grub/menu.lst`. A similar sequence occurs for DVD or CD boot, but the master boot block location and contents are dictated by the El Torito specification. The El Torito boot also leads to `strap.com`, which in turn loads `boot.bin`.

The first sector on a hard disk contains the master boot block, which contains the master boot program and the FDISK table, named for the PC program that maintains it. The master boot finds the active partition in the FDISK table, loads its first sector (GRUB stage1), and jumps to its first byte in memory. This completes the standard PC-compatible hard disk boot sequence. If GRUB stage1 is installed on the master boot block (see the `-m` option of [installgrub\(1M\)](#)), then stage2 is loaded directly from the Solaris FDISK partition regardless of the active partition.

An x86 FDISK partition for the Solaris software begins with a one-cylinder boot slice, which contains GRUB stage1 in the first sector, the standard Solaris disk label and volume table of contents (VTOC) in the second and third sectors, and GRUB stage2 in the fiftieth and subsequent sectors. The area from sector 4 to 49 might contain boot blocks for older versions of Solaris. This makes it possible for multiple Solaris releases on the same FDISK to coexist. When the FDISK partition for the Solaris software is the active partition, the master boot program (`mboot`) reads the partition boot program in the first sector into memory and jumps to it. It in turn reads GRUB stage2 program into memory and jumps to it. Once the GRUB menu is displayed, the user can choose to boot an operating system on a different partition, a different disk, or possibly from the network.

For network booting, the supported method is Intel's Preboot eXecution Environment (PXE) standard. When booting from the network using PXE, the system or network adapter BIOS uses DHCP to locate a network bootstrap program (`pxegrub`) on a boot server and reads it using Trivial File Transfer Protocol (TFTP). The BIOS executes the `pxegrub` by jumping to its first byte in memory. The `pxegrub` program downloads a menu file and presents the entries to user.

**x86 Kernel Startup** The kernel startup process is independent of the kernel loading process. During kernel startup, console I/O goes to the device specified by the `console` property.

When booting from UFS, the root device is specified by the `bootpath` property, and the root file system type is specified by the `fstype` property. These properties should be setup by the Solaris Install/Upgrade process in `/boot/solaris/bootenv.rc` and can be overridden with the `-B` option, described above (see the [eeprom\(1M\)](#) man page).

When booting from ZFS, the root device is specified by a boot parameter specified by the `-B $ZFS-BOOTFS` parameter on either the `kernel` or `module` line in the GRUB menu entry. This value (as with all parameters specified by the `-B` option) is passed by GRUB to the kernel.

If the console properties are not present, console I/O defaults to `screen` and `keyboard`. The root device defaults to `ramdisk` and the file system defaults to `ufs`.

## Examples

### SPARC EXAMPLE 1 To Boot the Default Kernel In Single-User Interactive Mode

To boot the default kernel in single-user interactive mode, respond to the `ok` prompt with one of the following:

```
boot -as
```

```
boot disk3 -as
```

### EXAMPLE 2 Network Booting with WAN Boot-Capable PROMs

To illustrate some of the subtle repercussions of various boot command line invocations, assume that the `network-boot-arguments` are set and that `net` is devaliased as shown in the commands below.

In the following command, device arguments in the device alias are processed by the device driver. The network boot support package processes arguments in `network-boot-arguments`.

```
boot net
```

The command below results in no device arguments. The network boot support package processes arguments in `network-boot-arguments`.

```
boot net:
```

The command below results in no device arguments. `rarp` is the only network boot support package argument. `network-boot-arguments` is ignored.

```
boot net:rarp
```

In the command below, the specified device arguments are honored. The network boot support package processes arguments in `network-boot-arguments`.

```
boot net:speed=100,duplex=full
```

### EXAMPLE 3 Using wanboot with Older PROMs

The command below results in the `wanboot` binary being loaded from DVD or CD, at which time `wanboot` will perform DHCP and then drop into its command interpreter to allow the user to enter keys and any other necessary configuration.

```
boot cdrom -F wanboot -o dhcp,prompt
```

x86 (32-bit) **EXAMPLE 4** To Boot the Default Kernel In 32-bit Single-User Interactive Mode

To boot the default kernel in single-user interactive mode, edit the GRUB kernel command line to read:

```
kernel /platform/i86pc/kernel/unix -as
```

x86 (64-bit Only) **EXAMPLE 5** To Boot the Default Kernel In 64-bit Single-User Interactive Mode

To boot the default kernel in single-user interactive mode, edit the GRUB kernel command line to read:

```
kernel /platform/i86pc/kernel/amd64/unix -as
```

**EXAMPLE 6** Switching Between 32-bit and 64-bit Kernels on 64-bit x86 Platform

To be able to boot both 32-bit and 64-bit kernels, add entries for both kernels to `/boot/grub/menu.lst`, and use the `set -menu` subcommand of [bootadm\(1M\)](#) to switch. See [bootadm\(1M\)](#) for an example of the `bootadm set -menu`.

**Files** `/platform/platform-name/ufsboot`  
Second-level program to boot from a disk, DVD, or CD

`/etc/inittab`  
Table in which the `initdefault` state is specified

`/sbin/init`  
Program that brings the system to the `initdefault` state

64-bit SPARC Only `/platform/platform-name/kernel/sparcv9/unix`  
Default program to boot system.

x86 Only `/boot`  
Directory containing boot-related files.

`/boot/grub/menu.lst`  
Menu of bootable operating systems displayed by GRUB.

`/platform/i86pc/kernel/unix`  
32-bit kernel.

64-bit x86 Only `/platform/i86pc/kernel/amd64/unix`  
64-bit kernel.

*OpenBoot Command Reference Manual*

**Warnings** The boot utility is unable to determine which files can be used as bootable programs. If the booting of a file that is not bootable is requested, the boot utility loads it and branches to it. What happens after that is unpredictable.

**Notes** *platform-name* can be found using the -i option of `uname(1)`. *hardware-class-name* can be found using the -m option of `uname(1)`.

The current release of the Solaris operating system does not support machines running an UltraSPARC-I CPU.

**Name** bootadm – manage bootability of GRUB-enabled operating system

**Synopsis** /sbin/bootadm update-archive [-vn] [-R *alroot* [-p *platform*]]  
 /sbin/bootadm list-archive [-vn] [-R *alroot* [-p *platform*]]  
 x86 only  
 /sbin/bootadm set-menu [-R *alroot* [-p *platform*]] *key=value*  
 /sbin/bootadm list-menu [-R *alroot* [-p *platform*]]

**Description** The bootadm command manages the boot archive and, with x86 boot environments, the GRUB (GRand Unified Bootloader) menu. The update-archive option provides a way for user to update the boot archive as a preventative measure or as part of a recovery procedure. The set-menu subcommand allows you to switch the auto-boot timeout and default boot entry in the GRUB menu.

The list-menu subcommand displays the location of the GRUB menu and the current GRUB menu entries. While the typical location of the GRUB menu is /boot/grub/menu.lst, depending on the install method used the active GRUB menu might be located somewhere else. Use the list-menu subcommand to locate the active GRUB menu. For example, if a system was installed using Live Upgrade, the GRUB menu might not be located in the current boot environment. See the EXAMPLES section for typical output from the list-menu option.

Note that OpenBoot PROM (OBP)-based machines, such as SPARC systems, do not use GRUB and have no boot menu manageable by bootadm.

The bootadm command determines dynamically the options supported by the image to be managed, so that bootadm invoked on one platform can be used to manage diskless clients of a different platform type.

**Subcommands** The bootadm command has the following subcommands:

update-archive

Updates current boot archive if required. Applies to both SPARC and x86 platforms.

list-archive

Lists the files and directories to be included in the boot archive. Applies to both SPARC and x86 platforms.

set-menu

Maintain the GRUB menu. The current GRUB menu is boot/grub/menu.lst, relative to root. Do not depend on this location, because it is subject to change. Applies to x86 platforms only.

list-menu

Lists the location of the active GRUB menu, as well as the current GRUB menu entries. This includes the autoboot-timeout, the default entry number, and the title of each entry. Applies to x86 platforms only.

**Options** The bootadm command has the following options:

-v

In an update-archive operation, stale files are displayed on stderr.

-n

In an update-archive operation, archive content is checked but not updated.

-p *platform*

The platform, or machine hardware class, of the client. The platform type can only be specified together with -R, and is generally useful only for managing a diskless client where the client is of a different platform class than the server. Platform must be one of i86pc, sun4u, or sun4v.

-R *altroot*

Operation is applied to an alternate root path.

**Note** – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).

*key=value*

Possible values are:

*default=entrynum*

The item number (for example, 0, 1, or 2) in the GRUB menu designating the operating system to boot when the timer expires.

*timeout=seconds*

The number of seconds before the operating system designated by the default item number is booted. If the value is -1, auto boot is disabled.

### Examples EXAMPLE 1 Updating the Current Boot Archive

The following command updates the current boot archive:

```
bootadm update-archive
```

### EXAMPLE 2 Updating the Boot Archive on an Alternate Root

The following command updates the boot archive on an alternate root:

```
bootadm update-archive -R /a
```

### EXAMPLE 3 Listing Installed OS Instances

The following command lists the installed operating system instances in a GRUB menu:

```
bootadm list-menu
```

```
default=0
timeout=10
(0) Solaris10
```

**EXAMPLE 3** Listing Installed OS Instances (Continued)

- (1) Solaris10 Failsafe
- (2) Linux

**EXAMPLE 4** Switching Default Boot Entry

The following command refers to the menu displayed in the previous example. The user selects Linux (item 2).

```
bootadm set-menu default=2
```

**EXAMPLE 5** Listing GRUB Menu Entries and Location of GRUB Menu

The following command lists the GRUB menu entries and the location of the GRUB menu:

```
bootadm list-menu
The location for the active GRUB menu is: /stubboot/boot/grub/menu.lst
default 0
timeout 10
0 Solaris10
1 Solaris10 failsafe
2 Linux
```

**EXAMPLE 6** Displaying Location of GRUB Menu

The following command displays the location of the GRUB menu:

```
bootadm list-menu
The location for the active GRUB menu is: /dev/dsk/c0t1d0s0 (not mounted)
The filesystem type of the menu device is <ufs>
default 2
timeout 10
0 c0t1d0s3
1 c0t1d0s3 failsafe
2 Solaris10
3 Solaris10 failsafe
```

In this example, the active GRUB menu is located on a device which is *not* mounted. To access the GRUB menu, mount the device and access the GRUB menu at `<mountpoint>/boot/grub/menu.lst`.

**Exit Status** The following exit values are returned:

- 0  
The command completed successfully.
- 1  
The command exited due to an error.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcs          |
| Interface Stability | Committed       |

**See Also** [boot\(1M\)](#), [installgrub\(1M\)](#), [attributes\(5\)](#)

Consult the GRUB home page, under:

<http://www.gnu.org/>

**Name** bootconfchk – verify the integrity of a network boot configuration file

**Synopsis** /usr/sbin/bootconfchk [*bootconf-file*]

**Description** The `bootconfchk` command checks that the file specified is a valid network boot configuration file as described in [wanboot.conf\(4\)](#).

Any discrepancies are reported on standard error.

**Exit Status** 0 Successful completion.

1 An error occurred.

2 Usage error.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE     |
|---------------------|---------------------|
| Availability        | system/boot/wanboot |
| Interface Stability | Committed           |

**See Also** [wanboot.conf\(4\)](#), [attributes\(5\)](#)

**Name** busstat – report bus-related performance statistics

**Synopsis** busstat -e *device-inst* | -h | -l

```
busstat [-a] [-n]
 [-w device-inst [,pic0=event,picn=event]]. . .
 [-r device-inst]. . . [interval [count]]
```

**Description** busstat provides access to the bus-related performance counters in the system. These performance counters allow for the measurement of statistics like hardware clock cycles, bus statistics including DMA and cache coherency transactions on a multiprocessor system. Each bus device that supports these counters can be programmed to count a number of events from a specified list. Each device supports one or more Performance Instrumentation Counters (PIC) that are capable of counting events independently of each other.

Separate events can be selected for each PIC on each instance of these devices. busstat summarizes the counts over the last interval seconds, repeating forever. If a count is given, the statistics are repeated count times.

Only root users can program these counters. Non-root users have the option of reading the counters that have been programmed by a root user.

The default value for the *interval* argument is 1 second, and the default *count* is unlimited.

The devices that export these counters are highly platform-dependent and the data may be difficult to interpret without an in-depth understanding of the operation of the components that are being measured and of the system they reside in.

**Options** The following options are supported:

- |                       |                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -a                    | Display absolute counter values. The default is delta values.                                                                                                                                                                                                                                                                                                        |
| -e <i>device-inst</i> | Display the list of events that the specified device supports for each pic.<br><br>Specify <i>device-inst</i> as device (name) followed by an optional instance number. If an instance number is specified, the events for that instance are displayed. If no instance number is specified, the events for the first instance of the specified device are displayed. |
| -h                    | Print a usage message.                                                                                                                                                                                                                                                                                                                                               |
| -l                    | List the devices in the system which support performance counters.                                                                                                                                                                                                                                                                                                   |
| -n                    | Do not display a title in the output. The default is to display titles.                                                                                                                                                                                                                                                                                              |

*-r device-inst*

Read and display all pic values for the specified device

Specify *device-inst* as *device* (name) followed by *instance number*, if specifying an instance number of a device whose counters are to be read and displayed. If all instances of this device are to be read, use *device* (name) without an instance number. All pic values will be sampled when using the *-r* option.

*-w device-inst* [,pic0=*event*] [,picn=*event*]

Program (write) the specified devices to count the specified events. Write access to the counters is restricted to root users only. Non-root users can use *-r* option.

Specify *device-inst* as *device* (name) followed by an optional *instance number*. If specifying an instance number of a device to program these events on. If all instances of this device are to be programmed the same, then use *device* without an instance number. Specify an event to be counted for a specified pic by providing a comma separated list of *picn=event* values.

The *-e* option displays all valid event names for each device. Any devices that are programmed will be sampled every interval seconds and repeated count times. It is recommended that the interval specified is small enough to ensure that counter wraparound will be detected. The rate at which counters wraparound varies from device to device. If a user is programming events using the *-w* option and *busstat* detects that another user has changed the events that are being counted, the tool will terminate as the programmed devices are now being controlled by another user. Only one user can be programming a device instance at any one time. Extra devices can be sampled using the *-r* option. Using multiple instances of the *-w* option on the same command line, with the same *device-inst* specifying a different list of events for the pics will give the effect of multiplexing for that device. *busstat* will

switch between the list of events for that device every interval seconds. Event can be a string representing the event name, or even a number representing the bit pattern to be programmed into the Performance Control Register (PCR). This assumes explicit knowledge of the meaning of the control register bits for a device. The number can be specified in hexadecimal, decimal, or octal, using the usual conventions of `strtol(3C)`.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.
- 2 Another user is writing to the same devices.

## Examples

SPARC Only **EXAMPLE 1** Programming and monitoring the Address Controller counters

In this example, `ac0` refers to the Address Controller instance 0. The counters are programmed to count Memory Bank stalls on an Ultra Enterprise system at 10 second intervals with the values displayed in absolute form instead of deltas.

```
busstat -a -w ac0,pic0=mem_bank0_stall,pic1=mem_bank1_stall 10
time dev event0 pic0 event1 pic1
10 ac0 mem_bank0_stall 1234 mem_bank1_stall 5678
20 ac0 mem_bank0_stall 5678 mem_bank1_stall 12345
30 ac0 mem_bank0_stall 12345 mem_bank1_stall 56789
...
```

For a complete list of the supported events for a device, use the `-e` option.

**EXAMPLE 2** Programming and monitoring the counters on all instances of the Address Controller

In this example, `ac` refers to all `ac` instances. This example programs all instances of the Address Controller counters to count `clock_cycles` and `mem_bank0_rds` at 2 second intervals, 100 times, displaying the values as deltas.

```
busstat -w ac,pic0=clock_cycles,pic1=mem_bank0_rds 2 100
time dev event0 pic0 event1 pic1
2 ac0 clock_cycles 167242902 mem_bank0_rds 3144
2 ac1 clock_cycles 167254476 mem_bank0_rds 1392
4 ac0 clock_cycles 168025190 mem_bank0_rds 40302
4 ac1 clock_cycles 168024056 mem_bank0_rds 40580
...
```

**EXAMPLE 3** Monitoring the events being counted

This example monitors the events that are being counted on the sbus1 device, 100 times at 1 second intervals. It suggests that a root user has changed the events that sbus1 was counting to be dvma\_tlb\_misses and interrupts instead of pio\_cycles.

```
% busstat -r sbus0 1 100
```

| time | dev   | event0          | pic0 | event1     | pic1 |

**EXAMPLE 4** Event Multiplexing

This example programs ac0 to alternate between counting (clock cycles, mem\_bank0\_rds) and (addr\_pkts, data\_pkts) at 2 second intervals while also monitoring what ac1 is counting :

It shows the expected output of the above busstat command. Another root user on the machine has changed the events that this user had programmed and busstat has detected this and terminates the command with a message.

```
busstat -w ac0,pic0=clock_cycles,pic1=mem_bank0_rds \
-w ac0,pic0=addr_pkts,pic1=data_pkts \
-r ac1 2
```

| time | dev | event0       | pic0      | event1        | pic1   |
|------|-----|--------------|-----------|---------------|--------|
| 2    | ac0 | addr_pkts    | 12866     | data_pkts     | 17015  |
| 2    | ac1 | rio_pkts     | 385       | rio_pkts      | 385    |
| 4    | ac0 | clock_cycles | 168018914 | mem_bank0_rds | 2865   |
| 4    | ac1 | rio_pkts     | 506       | rio_pkts      | 506    |
| 6    | ac0 | addr_pkts    | 144236    | data_pkts     | 149223 |
| 6    | ac1 | rio_pkts     | 522       | rio_pkts      | 522    |
| 8    | ac0 | clock_cycles | 168021245 | mem_bank0_rds | 2564   |
| 8    | ac1 | rio_pkts     | 387       | rio_pkts      | 387    |
| 10   | ac0 | addr_pkts    | 144292    | data_pkts     | 159645 |
| 10   | ac1 | rio_pkts     | 506       | rio_pkts      | 506    |
| 12   | ac0 | clock_cycles | 168020364 | mem_bank0_rds | 2665   |
| 12   | ac1 | rio_pkts     | 522       | rio_pkts      | 522    |

```
busstat: events changed (possibly by another busstat).
```

```
#
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcs          |

**Name** cachefs – CacheFS daemon

**Synopsis** /usr/lib/fs/cachefs/cachefs

**Description** The cachefs server implements features of the cache filesystem (CacheFS). It is invoked at boot time and run if the / (root) and /usr filesystems are being cached. If /usr is being cached, cachefs is invoked by [inetd\(1M\)](#) from [inetd.conf\(4\)](#). At run time, cachefs is invoked by the inetd mechanism in response to an RPC request from a user command such as [mount\\_cachefs\(1M\)](#).

The cachefs server supports the “disconnected mode” of CacheFS. In this mode, a user can continue to read and, depending on the option selected, write to files in a cached filesystem when the NFS server for the cached files is not available.

The cachefs daemon performs the following functions in support of the CacheFS:

- Implements the connection policy. The daemon determines whether the NFS server backing the cache is connected or disconnected from the cache, or is in transition from the connected or disconnected states.
- Implements “log rolling,” wherein the daemon monitors a disconnected NFS server for reconnection. After such a server returns to a connected state, cachefs rolls any local changes to cached files (kept in a log) back to the server.
- Manages “packing,” wherein cachefs makes a best effort to ensure that files in a user-specified list are available in the cache in disconnected mode.
- Supports user interfaces by supplying statistics, reporting conflicts between the cache and the back filesystem, and supporting a list of files for packing.

The running of cachefs is required for the disconnected mode of CacheFS.

**Options** The following options are supported:

-r Used for invoking cachefs for the / filesystem.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcs          |

*System Administration Guide: Basic Administration*

**Name** cachefslog – Cache File System logging

**Synopsis** `cachefslog [-f logfile | -h] cachefs_mount_point`

**Description** The `cachefslog` command displays where CacheFS statistics are being logged. Optionally, it sets where CacheFS statistics are being logged, or it halts logging for a cache specified by *cachefs\_mount\_point*. The *cachefs\_mount\_point* argument is a mount point of a cache file system. All file systems cached under the same cache as *cachefs\_mount\_point* will be logged.

**Options** The following options are supported. You must be super-user to use the `-f` and `-h` options.

`-f logfile` Specify the log file to be used.

`-h` Halt logging.

**Operands** *cachefs\_mount\_point* A mount point of a cache file system.

**Usage** See [largefile\(5\)](#) for the description of the behavior of `cachefslog` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**Examples** **EXAMPLE 1** Checking the Logging of a directory.

The example below checks if the directory `/home/sam` is being logged:

```
example% cachefslog /home/sam
not logged: /home/sam
```

**EXAMPLE 2** Changing the *logfile*.

The example below changes the *logfile* of `/home/sam` to `/var/tmp/samlog`:

```
example# cachefslog -f /var/tmp/samlog /home/sam
/var/tmp/samlog: /home/sam
```

**EXAMPLE 3** Verifying the change of a *logfile*.

The example below verifies the change of the previous example:

```
example% cachefslog /home/sam
/var/tmp/samlog: /home/sam
```

**EXAMPLE 4** Halting the logging of a directory.

The example below halts logging for the `/home/sam` directory:

```
example# cachefslog -h /home/sam
not logged: /home/sam
```

**Exit Status** The following exit values are returned:

`0` success

non-zero an error has occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcs          |

**See Also** [cachefsstat\(1M\)](#), [cachefswssize\(1M\)](#), [cfsadmin\(1M\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

**Diagnostics** Invalid path    It is illegal to specify a path within a cache file system.

**Name** cachefspack – pack files and file systems in the cache

**Synopsis** cachefspack [-h] [-i | -p | -u] [-f *packing-list*]  
[-U *cache-directory*] [*file*]. . .

**Description** The cachefspack utility is used to set up and maintain files in the cache. This utility affords greater control over the cache, ensuring that the specified files are in the cache whenever possible.

cachefspack does not pack files when the backfilesystem type for the cache's mount is NFSv4. This is because only pass-through support is available for cache's with NFSv4.

**Options** The following options are supported:

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -f <i>packing-list</i>    | Specify a file containing a list of files and directories to be packed. Options within subdirectories and files can also be specified. The format and rules governing <i>packing-list</i> are described on the <a href="#">packingrules(4)</a> manual page. Directories are packed recursively. Symlinks that match a regular expression on a LIST command are followed. Symlinks encountered while recursively processing directories are not followed. |
| -h                        | Help. Print a brief summary of all the options.                                                                                                                                                                                                                                                                                                                                                                                                          |
| -i                        | View information about the packed files.                                                                                                                                                                                                                                                                                                                                                                                                                 |
| -p                        | Pack the file or files specified by <i>file</i> . This is the default behavior.                                                                                                                                                                                                                                                                                                                                                                          |
| -u                        | Unpack the file or files specified by <i>file</i> .                                                                                                                                                                                                                                                                                                                                                                                                      |
| -U <i>cache-directory</i> | Unpack all files in the specified cache directory.                                                                                                                                                                                                                                                                                                                                                                                                       |

**Operands** The following operands are supported:

*file* A path name of a file to be packed or unpacked.

**Usage** See [largefile\(5\)](#) for the description of the behavior of cachefspack when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**Examples** **EXAMPLE 1** Packing a File in the Cache

The following example packs the file `projects` in the cache:

```
% cachefspack -p projects
```

**EXAMPLE 2** Packint Files in the Cache

The following example packs the files `projects`, `updates`, and `master_plan` in the cache:

```
% cachefspack -p projects updates master_plan
```

**EXAMPLE 3** Unpacking a File From the Cache

The following example unpacks the file `projects` from the cache:

```
% cachefspack -u projects
```

**EXAMPLE 4** Unpacking Files From the Cache

The following example unpacks the files `projects`, `updates`, and `master_plan` from the cache:

```
% cachefspack -u projects updates master_plan
```

**EXAMPLE 5** Unpacking All Files From in a Cache Directory

The following example unpacks all files in the cache directory `cache1`:

```
% cachefspack -U /cache/cache1
```

**EXAMPLE 6** Using a Packing List

The following example illustrates the use of a packing list to specify files to be packed in the cache.

The contents of `lists.pkg` are as follows:

```
IGNORE SCCS BASE /src/junk LIST *.c LIST *.h
```

The following command packs all files in the `/src/junk` directory which have `.c` and `.h` extensions, and do contain the string `SCCS` in the file's path name:

```
% cachefspack -f lists.pkg
```

**Exit Status** 0 Successful completion.

>0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcs          |

**See Also** [cfsadmin\(1M\)](#), [mount\\_cachefs\(1M\)](#), [packingrules\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

**Name** cachefsstat – Cache File System statistics

**Synopsis** /usr/bin/cachefsstat [-z] [*path*]...

**Description** The `cachefsstat` command displays statistical information about the cache file system mounted on *path*. The statistical information includes cache hits and misses, consistency checking, and modification operations. If *path* is not specified, all mounted cache file systems are used.

`cachefsstat` can also be used to reinitialize this information (see `-z` option).

The statistical information has the following format:

```
<cache hit rate>
<consistency checks>
<modifies>
```

where:

<i>hit rate</i>	The percentage of cache hits over the total number of attempts, followed by the actual numbers of hits and misses.
<i>consistency checks</i>	The number of consistency checks performed, followed by the number that passed, and the number that failed.
<i>modifies</i>	The number of modify operations, including writes, creates, etc.

**Options** The following option is supported:

`-z` Zero (reinitialize) statistics. Execute `cachefsstat -z` before executing `cachefsstat` again to gather statistics on the cache performance. This option can only be used by the superuser. The statistics printed reflect those just before the statistics are reinitialized.

**Usage** See [largefile\(5\)](#) for the description of the behavior of `cachefsstat` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**Examples** EXAMPLE1 Using `cachefsstat`

The following example shows the `cachefsstat` command run on file system `/test`:

```
example# cachefsstat /test
/test
 cache hit rate: 100% (0 hits, 0 misses)
 consistency checks: 0 (0 pass, 0 fail)
 modifies: 0
garbage collection: 0
```

**Exit Status** The following exit values are returned:

0	Successful completion.
non-zero	An error occurred.

---

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [cachefslog\(1M\)](#), [cachefswssize\(1M\)](#), [cfsadmin\(1M\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

**Name** cachefswsize – determine working set size for cachefs

**Synopsis** cachefswsize *logfile*

**Description** The cachefswsize command displays the workspace size determined from *logfile*. This includes the amount of cache space needed for each filesystem that was mounted under the cache, as well as a total.

**Usage** See [largefile\(5\)](#) for the description of the behavior of cachefswsize when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**Examples** EXAMPLE 1 A sample output of cachefswsize.  
example% cachefswsize /var/tmp/samlog

---

```
/home/sam
 end size: 10688k
 high water size: 10704k

/foo
 end size: 128k
 high water size: 128k

/usr/dist
 end size: 1472k
 high water size: 1472k

total for cache
 initial size: 110960k
 end size: 12288k
 high water size: 12304k
```

---

**Exit Status** The following exit values are returned:

0            success  
non-zero    an error has occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [cachefslog\(1M\)](#), [cachefsstat\(1M\)](#), [cfsadmin\(1M\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

**Diagnostics** problems were encountered writing log file      There were problems encountered when the kernel was writing the logfile. The most common problem is running out of disk space.

invalid log file      The logfile is not a valid logfile or was created with a newer version of Solaris than the one where cachefswsize is running.

**Name** captoinfo – convert a termcap description into a terminfo description

**Synopsis** captoinfo [-l] [-v]... [-V] [-w *width*] *filename*...

**Description** captoinfo looks in *filename* for termcap descriptions. For each one found, an equivalent terminfo description is written to standard output, along with any comments found. A description which is expressed as relative to another description (as specified in the termcap `tc = field`) is reduced to the minimum superset before being displayed.

If no *filename* is given, then the environment variable TERMCAP is used for the filename or entry. If TERMCAP is a full pathname to a file, only the terminal whose name is specified in the environment variable TERM is extracted from that file. If the environment variable TERMCAP is not set, then the file `/usr/share/lib/termcap` is read.

**Options**

- `-l` Display the fields one to a line. Otherwise, the fields are printed several to a line, with a maximum width of 60 characters.
- `-v` Display tracing information on the standard error as the program runs. Specifying additional `-v` options displays more detailed information.
- `-V` Display the version of the program in use on the standard error and then exit.
- `-w width` Change the output to *width* characters.

**Files** `/usr/share/lib/terminfo/??/*` compiled terminal description database  
`/usr/share/lib/termcap`

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [infocmp\(1M\)](#), [curses\(3CURSES\)](#), [terminfo\(4\)](#), [attributes\(5\)](#)

**Notes** captoinfo should be used to convert termcap entries to terminfo entries because the termcap database may not be supplied in future releases.

**Name** catman – create the formatted files for the reference manual

**Synopsis** /usr/bin/catman [-c] [-n] [-p] [-t] [-w] [-M *directory*]  
[-T *macro-package*] [*sections*]

**Description** The catman utility creates the preformatted versions of the on-line manual from the `nroff(1)` or `sgml(5)` input files. This feature allows easy distribution of the preformatted manual pages among a group of associated machines (for example, with `rdist(1)`), since it makes the directories of preformatted manual pages self-contained and independent of the unformatted entries.

catman also creates the `windex` database file in the directories specified by the `MANPATH` or the `-M` option. The `windex` database file is a three column list consisting of a keyword, the reference page that the keyword points to, and a line of text that describes the purpose of the utility or interface documented on the reference page. Each keyword is taken from the comma separated list of words on the `NAME` line before the ‘-’ (dash). The reference page that the keyword points to is the first word on the `NAME` line. The text after the – on the `NAME` line is the descriptive text in the third column. The `NAME` line must be immediately preceded by the page heading line created by the `.TH` macro (see `NOTES` for required format).

Each manual page is examined and those whose preformatted versions are missing or out of date are recreated. If any changes are made, catman recreates the `windex` database.

If a manual page is a *shadow* page, that is, it sources another manual page for its contents, a symbolic link is made in the `catx` or `fmtx` directory to the appropriate preformatted manual page.

Shadow files in an unformatted `nroff` source file are identified by the first line being of the form `.so manx/yyy.x`.

Shadow files in the `SGML` sources are identified by the string `SHADOW_PAGE`. The file entity declared in the shadow file identifies the file to be sourced.

**Options** The following options are supported:

- c  
Create unformatted `nroff` source files in the appropriate `man` subdirectories from the `SGML` sources. This option will overwrite any existing file in the `man` directory of the same name as the `SGML` file.
- n  
Do not create (or recreate) the `windex` database. If the `-n` option is specified, the `windex` database is not created and the `apropos`, `what is`, `man -f`, and `man -k` commands will fail.
- p  
Print what would be done instead of doing it.
- t  
Create `troffed` entries in the appropriate `fmt` subdirectories instead of `nroffing` into the `cat` subdirectories.

-w

Only create the `windex` database that is used by `what is(1)` and the `man(1)` -f and -k options. No manual reformatting is done.

-M *directory*

Update manual pages located in the specified *directory*, (`/usr/share/man` by default). If the -M option is specified, the directory argument must not contain a ',' (comma), since a comma is used to delineate section numbers. See `man(1)`.

-T *macro-package*

Use *macro-package* in place of the standard manual page macros, (`man(5)` by default).

**Operands** The following operand is supported:

*sections*

If there is one parameter not starting with a '-', it is taken to be a space separated list of manual sections to be processed by `catman`. If this operand is specified, only the manual sections in the list will be processed. For example,

```
catman 1 2 3
```

only updates manual sections 1, 2, and 3. If specific sections are not listed, all sections in the `man` directory specified by the environment variable `MANPATH` are processed.

**Environment Variables**

`TROFF`

The name of the formatter to use when the -t flag is given. If not set, `troff(1)` is used.

`MANPATH`

A colon-separated list of directories that are processed by `catman` and `man(1)`. Each directory can be followed by a comma-separated list of sections. If set, its value overrides `/usr/share/man` as the default directory search path, and the `man.cf` file as the default section search path. The -M and -s flags, in turn, override these values.

**Files** `/usr/share/man`  
default manual directory location

`/usr/share/man/man*/*.*`  
raw nroff input files

`/usr/share/man/sman*/*.*`  
raw SGML input files

`/usr/share/man/cat*/*.*`  
preformatted nroffed manual pages

`/usr/share/man/fmt*/*.*`  
preformatted troffed manual pages

`/usr/share/man/windex`  
table of contents and keyword database

`/usr/lib/makewhatis`  
 command script to make windex database

`/usr/share/lib/tmac/an`  
 default macro package

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	text/doctools
CSI	Enabled

**See Also** [apropos\(1\)](#), [man\(1\)](#), [nroff\(1\)](#), [rdist\(1\)](#), [rm\(1\)](#), [troff\(1\)](#), [whatis\(1\)](#), [attributes\(5\)](#), [man\(5\)](#), [sgml\(5\)](#)

**Diagnostics** `man?/xxx.? (.so'ed from man?/yyy.?)`: No such file or directory  
 The file outside the parentheses is missing, and is referred to by the file inside them.

target of `.so` in `man?/xxx.?` must be relative to `/usr/man`  
 catman only allows references to filenames that are relative to the directory `/usr/man`.

`opendir:man?`: No such file or directory  
 A harmless warning message indicating that one of the directories catman normally looks for is missing.

`*.*`: No such file or directory  
 A harmless warning message indicating catman came across an empty directory.

**Warnings** If a user, who has previously run catman to install the `cat*` directories, upgrades the operating system, the entire `cat*` directory structure should be removed prior to running catman. See [rm\(1\)](#).

Do not re-run catman to re-build the `whatis` database unless the complete set of `man*` directories is present. catman builds this `windex` file based on the `man*` directories.

**Notes** To generate a valid `windex` index file, catman has certain requirements. Within the individual man page file, catman requires two macro lines to have a specific format. These are the `.TH` page heading line and the `.SH NAME` line.

The `.TH` macro requires at least the first three arguments, that is, the filename, section number, and the date. The `.TH` line starts off with the `.TH` macro, followed by a space, the man page filename, a single space, the section number, another single space, and the date. The date should appear in double quotes and is specified as “day month year,” with the month always abbreviated to the first three letters (Jan, Feb, Mar, and so forth).

The `.SH NAME` macro, also known as the `NAME` line, must immediately follow the `.TH` line, with nothing in between those lines. No font changes are permitted in the `NAME` line. The `NAME` line

is immediately followed by a line containing the man page filename; then shadow page names, if applicable, separated by commas; a dash; and a brief summary statement. These elements should all be on one line; no carriage returns are permitted.

An example of proper coding of these lines is:

```
.TH nismatch 1M "10 Apr 1998"
.SH NAME
nismatch, nisgrep \- utilities for searching NIS tables
```

**Name** `cfgadm` – configuration administration

**Synopsis** `/usr/sbin/cfgadm [-f] [-y | -n] [-v] [-o hardware_options]`  
`-c function ap_id...`

`/usr/sbin/cfgadm [-f] [-y | -n] [-v] [-o hardware_options]`  
`-x hardware_function ap_id...`

`/usr/sbin/cfgadm [-v] [-a] [-s listing_options]`  
`[-o hardware_options] [-l [ap_id | ap_type]]`

`/usr/sbin/cfgadm [-v] [-o hardware_options] -t ap_id...`

`/usr/sbin/cfgadm [-v] [-o hardware_options] -h`  
`[ap_id | ap_type]`

**Description** The `cfgadm` command provides configuration administration operations on dynamically reconfigurable hardware resources. These operations include displaying status, (`-l`), initiating testing, (`-t`), invoking configuration state changes, (`-c`), invoking hardware specific functions, (`-x`), and obtaining configuration administration help messages (`-h`). Configuration administration is performed at *attachment points*, which are places where system software supports dynamic reconfiguration of hardware resources during continued operation of Solaris.

Configuration administration makes a distinction between hardware resources that are physically present in the machine and hardware resources that are configured and visible to Solaris. The nature of configuration administration functions are hardware specific, and are performed by calling hardware specific libraries.

Configuration administration operates on an *attachment point*. Hardware resources located at attachment points can or can not be physically replaceable during system operation, but are dynamically reconfigurable by way of the configuration administration interfaces.

An attachment point defines two unique elements, which are distinct from the hardware resources that exist beyond the attachment point. The two elements of an attachment point are a *receptacle* and an *occupant*. Physical insertion or removal of hardware resources occurs at attachment points and results in a receptacle gaining or losing an occupant. Configuration administration supports the physical insertion and removal operations as well as other configuration administration functions at an attachment point.

Attachment points have associated state and condition information. The configuration administration interfaces provide control for transitioning attachment point states. A receptacle can exist in one of three states: `empty`, `disconnected` or `connected`, while an occupant can exist in one of two states: `configured` or `unconfigured`.

A receptacle can provide the `empty` state, which is the normal state of a receptacle when the attachment point has no occupants. A receptacle can also provide the `disconnected` state if it has the capability of isolating its occupants from normal system access. Typically this state is used for various hardware specific testing prior to bringing the occupant's resources into full

use by the system, or as a step in preparing an occupant for physical removal or reconfiguration. A receptacle in the disconnected state isolates its occupant from the system as much as its hardware allows, but can provide access for testing and setup. A receptacle must provide the connected state, which allows normal access to hardware resources contained on any occupants. The connected state is the normal state of a receptacle that contains an occupant and that is not currently undergoing configuration administration operations.

The hardware resources contained on an occupant in the unconfigured state are not represented by normal Solaris data structures and are thus not available for use by Solaris. Operations allowed on an unconfigured occupant are limited to configuration administration operations. The hardware resources of an occupant in the configured state are represented by normal Solaris data structures and thus some or all of those hardware resources can be in use by Solaris. All occupants provide both the configured and unconfigured states,

An attachment point can be in one of five conditions: `unknown`, `ok`, `failing`, `failed`, or `unusable`. An attachment point can enter the system in any condition depending upon results of power-on tests and non-volatile record keeping.

An attachment point with an occupant in the configured state is in one of four conditions: `unknown`, `ok`, `failing`, or `failed`. If the condition is not `failing` or `failed` an attachment point can change to `failing` during the course of operation if a hardware dependent recoverable error threshold is exceeded. If the condition is not `failed` an attachment point can change to `failed` during operation as a result of an unrecoverable error.

An attachment point with an occupant in the unconfigured state can be in any of the defined conditions. The condition of an attachment point with an unconfigured occupant can decay from `ok` to `unknown` after a machine dependent time threshold. Initiating a test function changes the attachment point's condition to `ok`, `failing` or `failed` depending on the outcome of the test. An attachment point that does not provide a test function can leave the attachment point in the `unknown` condition. If a test is interrupted, the attachment point's condition can be set to the previous condition, `unknown` or `failed`. An attachment point in the `unknown`, `ok`, `failing`, or `failed` conditions can be re-tested.

An attachment point can exist in the `unusable` condition for a variety of reasons, such as inadequate power or cooling for the receptacle, an occupant that is unidentifiable, unsupported, incorrectly configured, etc. An attachment point in the `unusable` condition can never be used by the system. It typically remains in this condition until the physical cause is remedied.

An attachment point also maintains busy information that indicates when a state change is in progress or the condition is being reevaluated.

Attachment points are referred to using hardware specific identifiers (*ap\_ids*) that are related to the type and location of the attachment points in the system device hierarchy. An *ap\_id* can not be ambiguous, it must identify a single attachment point. Two types of *ap\_id*

specifications are supported: physical and logical. A physical *ap\_id* contains a fully specified pathname, while a logical *ap\_id* contains a shorthand notation that identifies an attachment point in a more user-friendly way.

For example, an attachment point representing a system's backplane slot number 7 could have a physical *ap\_id* of `/devices/central/fhc/sysctrl:slot7` while the logical *ap\_id* could be `system:slot7`. Another example, the third receptacle on the second PCI I/O bus on a system could have a logical *ap\_id* of `pci2:plug3`.

Attachment points may also be created dynamically. A dynamic attachment point is named relative to a base attachment point which is present in the system. *ap\_ids* for dynamic attachment points consist of a base component followed by two colons (`::`) and a dynamic component. The base component is the base attachment point *ap\_id*. The dynamic component is hardware specific and generated by the corresponding hardware specific library.

For example, consider a base attachment point, which represents a SCSI HBA, with the physical *ap\_id* `/devices/sbus@1f,0/SUNW,fas@e,8800000:scsi` and logical *ap\_id* `c0`. A disk attached to this SCSI HBA could be represented by a dynamic attachment point with logical *ap\_id* `c0::dsk/c0t0d0` where `c0` is the base component and `dsk/c0t0d0` is the hardware specific dynamic component. Similarly the physical *ap\_id* for this dynamic attachment point would be: `/devices/sbus@1f,0/SUNW,fas@e,8800000:scsi::dsk/c0t0d0`

An *ap\_type* is a partial form of a logical *ap\_id* that can be ambiguous and not specify a particular attachment point. An *ap\_type* is a substring of the portion of the logical *ap\_id* up to but not including the colon (`:`) separator. For example, an *ap\_type* of `pci` would show all attachment points whose logical *ap\_ids* begin with `pci`.

The use of *ap\_types* is discouraged. The new `select` sub-option to the `-s` option provides a more general and flexible mechanism for selecting attachment points. See `OPTIONS`.

The `cfgadm` command interacts primarily with hardware dependent functions contained in hardware specific libraries and thus its behavior is hardware dependent.

For each configuration administration operation a service interruption can be required. Should the completion of the function requested require a noticeable service interruption to interactive users, a prompt is output on the standard error output for confirmation on the standard input before the function is started. Confirmation can be overridden using the `-y` or `-n` options to always answer yes or no respectively. Hardware specific options, such as `test level`, are supplied as sub-options using the `-o` option.

Operations that change the state of the system configuration are audited by the system log daemon `syslogd(1M)`.

The arguments for this command conform to the `getopt(3C)` and `getsubopt(3C)` syntax convention.

**Options** The following options are supported:

-a Specifies that the -l option must also list dynamic attachment points.

-c*function* Performs the state change *function* on the attachment point specified by *ap\_id*.

Specify *function* as insert, remove, disconnect, connect, configure or unconfigure. These functions cause state transitions at the attachment point by calling hardware specific library routines and are defined in the following list.

**insert** Performs operations that allows the user to manually insert an occupant or to activate a hardware supplied mechanism that performs the physical insertion. **insert** can have hardware specific side effects that temporarily suspend activity in portions of the system. In such cases the hardware specific library generates appropriate warning messages and informs the user of any special considerations or procedures unique to that hardware. Various hardware specific errors can cause this function to fail and set the receptacle condition to unusable.

**remove** Performs operations that allow the user to manually remove an occupant or to activate a hardware supplied mechanism to perform the physical removal. **remove** can have hardware specific side effects that temporarily suspend activity in portions of the system. In such cases the hardware specific library generates appropriate warning messages and informs the user of any special considerations or procedures unique to that hardware. Various hardware specific errors can cause this function to fail and set the receptacle condition to unusable.

**disconnect** Performs hardware specific operations to put a receptacle in the disconnected state, which can prevent an occupant from operating in a normal fashion through the receptacle.

connect	Performs hardware specific operations to put the receptacle in the connected state, which allows an occupant to operate in a normal fashion through the receptacle.
configure	Performs hardware specific operations that allow an occupant's hardware resources to be usable by Solaris. Occupants that are configured are part of the system configuration and are available for manipulation by Solaris device manipulation maintenance commands (eg: <code>psradm(1M)</code> , <code>mount(1M)</code> , <code>ifconfig(1M)</code> ).
unconfigure	Performs hardware specific operations that logically remove an occupant's hardware resources from the system. The occupant must currently be configured and its hardware resources must not be in use by Solaris.

State transition functions can fail due to the condition of the attachment point or other hardware dependent considerations. All state change *functions* in the direction of adding resources, (`insert`, `connect` and `configure`) are passed onto the hardware specific library when the attachment point is in the `ok` or `unknown` condition. All other conditions require the use of the `force` option to allow these *functions* to be passed on to the hardware specific library. Attachment point condition does not prevent a hardware specific library being called for related to the removal (`remove`, `disconnect` and `unconfigure`), of hardware resources from the system. Hardware specific libraries can reject state change *functions* if the attachment point is in the `unknown` condition.

The condition of an attachment point is not necessarily changed by the state change functions, however errors during state change operations can change the attachment point condition. An attempt to override a condition and force a state change that would otherwise fail can be made by specifying the `force` option (`-f`). Hardware specific safety and integrity checks can prevent the `force` option from having any effect.

- f

Forces the specified action to occur. Typically, this is a hardware dependent override of a safety feature. Forcing a state change operation can allow use of the hardware resources of occupant that is not in the `ok` or `unknown` conditions, at the discretion of any hardware dependent safety checks.

- h [*ap\_id* | *ap\_type* . . . ] Prints out the help message text. If *ap\_id* or *ap\_type* is specified, the help routine of the hardware specific library for the attachment point indicated by the argument is called.
- l [*ap\_id* | *ap\_type* . . . ] Lists the state and condition of attachment points specified. Attachment points can be filtered by using the `-s` option and `select` sub-option. Invoking `cfgadm` without one of the action options is equivalent to `-l` without an argument. The format of the list display is controlled by the `-v` and `-s` options. When the `-a` option is specified attachment points are dynamically expanded.
- n Suppress any interactive confirmation and assume that the answer is *no*. If neither `-n` or `-y` is specified, interactive confirmation is obtained through the standard error output and the standard input. If either of these standard channels does not correspond to a terminal (as determined by `isatty(3C)`) then the `-n` option is assumed.
- o*hardware\_options* Supplies hardware specific options to the main command option. The format and content of the hardware option string is completely hardware specific. The option string *hardware\_options* conforms to the `getsubopt(3C)` syntax convention.
- s*listing\_options* Supplies listing options to the list (`-l`) command. *listing\_options* conforms to the `getsubopt(3C)` syntax convention. The sub-options are used to specify the attachment point selection criteria (`select=select_string`), the type of matching desired (`match=match_type`), order of listing (`sort=field_spec`), the data that is displayed (`cols=field_spec` and `cols2=field_spec`), the column delimiter (`delim=string`) and whether to suppress column headings (`noheadings`).

When the `select` sub-option is specified, only attachment points which match the specified criteria will be listed. The `select` sub-option has the following syntax:

```
cfgadm -s select=attr1(value1):attr2(value2)...
```

where an *attr* is one of `ap_id`, `class` or `type`. `ap_id` refers to the logical *ap\_id* field, `class` refers to attachment point class and `type` refers to the type field. *value1*, *value2*, etc. are the corresponding values to be matched. The type of match can be specified by the `match` sub-option as follows:

```
cfgadm -s match=match_type,select=attr1(value1)...
```

where *match\_type* can be either exact or partial. The default value is exact.

Arguments to the select sub-option can be quoted to protect them from the shell.

A *field\_spec* is one or more *data-fields* concatenated using colon (:), as in *data-field:data-field:data-field*. A *data-field* is one of *ap\_id*, *physid*, *r\_state*, *o\_state*, *condition*, *type*, *busy*, *status\_time*, *status\_time\_p*, *class*, and *info*. The *ap\_id* field output is the logical name for the attachment point, while the *physid* field contains the physical name. The *r\_state* field can be empty, disconnected or connected. The *o\_state* field can be configured or unconfigured. The *busy* field can be either *y* if the attachment point is busy, or *n* if it is not. The *type* and *info* fields are hardware specific. The *status\_time* field provides the time at which either the *r\_state*, *o\_state*, or *condition* of the attachment point last changed. The *status\_time\_p* field is a parsable version of the *status\_time* field. If an attachment point has an associated class, the *class* field lists the class name. If an attachment point does not have an associated class, the *class* field lists none.

The order of the fields in *field\_spec* is significant: For the sort sub-option, the first field given is the primary sort key. For the *cols* and *cols2* sub-options, the fields are printed in the order requested. The order of sorting on a *data-field* can be reversed by placing a minus (-) before the *data-field* name within the *field\_spec* for the sort sub-option. The default value for sort is *ap\_id*. The default values for *cols* and *cols2* depend on whether the *-v* option is given: Without it *cols* is *ap\_id:r\_state:o\_state:condition* and *cols2* is not set. With *-v cols* is *ap\_id:r\_state:o\_state:condition:info* and *cols2* is *status\_time:type:busy:physid:.* The default value for *delim* is a single space. The value of *delim* can be a string of arbitrary length. The delimiter cannot include comma (,) character, see [getsubopt\(3C\)](#). These listing options can be used to create parsable output. See NOTES.

-t

Performs a test of one or more attachment points. The test function is used to re-evaluate the condition of the attachment point. Without a test level specifier in *hardware\_options*, the fastest test that identifies hard faults is used.

More comprehensive tests are hardware specific and are selected using the *hardware\_options*.

The results of the test is used to update the condition of the specified occupant to either ok if no faults are found, failing if recoverable faults are found or failed if any unrecoverable faults are found.

If a test is interrupted, the attachment point's condition can be restored to its previous value or set to unknown if no errors were found or failing if only recoverable errors were found or failed if any unrecoverable errors were found. The attachment point should only be set to ok upon normal completion of testing with no errors.

- v Executes in verbose mode. For the -c, -t and -x options outputs a message giving the results of each attempted operation. Outputs detailed help information for the -h option. Outputs verbose information for each attachment point for the -l option.
- x*hardware\_function* Performs hardware specific functions. Private hardware specific functions can change the state of a receptacle or occupant. Attachment point conditions can change as the result of errors encountered during private hardware specific functions. The format and content of the *hardware\_function* string is completely hardware specific. The option string *hardware\_function* conforms to the [getsubopt\(3C\)](#) syntax convention.
- y Suppresses any interactive confirmation and assume that the answer is yes.

**Usage** The required privileges to use this command are hardware dependent. Typically, a default system configuration restricts all but the list option to the superuser.

**Examples** EXAMPLE 1 Listing Attachment Points in the Device Tree

The following example lists all attachment points except dynamic attachment points.

example# cfgadm

Ap_Id	Type	Receptacle	Occupant	Cond
system:slot0	cpu/mem	connected	configured	ok
system:slot1	sbus-upa	connected	configured	ok
system:slot2	cpu/mem	connected	configured	ok
system:slot3	unknown	connected	unconfigured	unknown
system:slot4	dual-sbus	connected	configured	failing
system:slot5	cpu/mem	connected	configured	ok
system:slot6	unknown	disconnected	unconfigured	unusable

**EXAMPLE 1** Listing Attachment Points in the Device Tree (Continued)

system:slot7	unknown	empty	unconfigured	ok
c0	scsi-bus	connected	configured	unknown
c1	scsi-bus	connected	configured	unknown

**EXAMPLE 2** Listing All Configurable Hardware Information

The following example lists all current configurable hardware information, including those represented by dynamic attachment points:

```
example# cfgadm -al
```

Ap_Id	Type	Receptacle	Occupant	Cond
system:slot0	cpu/mem	connected	configured	ok
system:slot1	sbus-upa	connected	configured	ok
system:slot2	cpu/mem	connected	configured	ok
system:slot3	unknown	connected	unconfigured	unknown
system:slot4	dual-sbus	connected	configured	failing
system:slot5	cpu/mem	connected	configured	ok
system:slot6	unknown	disconnected	unconfigured	unusable
system:slot7	unknown	empty	unconfigured	ok
c0	scsi-bus	connected	configured	unknown
c0::dsk/c0t14d0	disk	connected	configured	unknown
c0::dsk/c0t11d0	disk	connected	configured	unknown
c0::dsk/c0t8d0	disk	connected	configured	unknown
c0::rmt/0	tape	connected	configured	unknown
c1	scsi-bus	connected	configured	unknown

**EXAMPLE 3** Listing Selectively, Based on Attachment Point Attributes

The following example lists all attachment points whose class begins with `scsi`, `ap_id` begins with `c` and type field begins with `scsi`. The argument to the `-s` option is quoted to protect it from the shell.

```
example# cfgadm -s "match=partial,select=class(scsi):ap_id(c):type(scsi)"
```

Ap_Id	Type	Receptacle	Occupant	Cond
c0	scsi-bus	connected	configured	unknown
c1	scsi-bus	connected	configured	unknown

**EXAMPLE 4** Listing Current Configurable Hardware Information in Verbose Mode

The following example lists current configurable hardware information for *ap-type* system in verbose mode:

```
example# cfgadm -v -l system
```

Ap_Id	Type	Receptacle	Occupant	Condition	Information
When		Busy	Phys_Id		

**EXAMPLE 4** Listing Current Configurable Hardware Information in Verbose Mode *(Continued)*

```

system:slot1 connected configured ok
Apr 4 23:50 sbus-upa n /devices/central/fhc/sysctrl:slot1
system:slot3 connected configured ok non-detachable
Apr 17 11:20 cpu/mem n /devices/central/fhc/sysctrl:slot3
system:slot5 connected configured ok
Apr 4 23:50 cpu/mem n /devices/central/fhc/sysctrl:slot5
system:slot7 connected configured ok
Apr 4 23:50 dual-sbus n /devices/central/fhc/sysctrl:slot7

```

The When column represents the `status_time` field.

**EXAMPLE 5** Testing Two Occupants Using the Hardware Specific Extended Test

The following example tests two occupants using the hardware specific extended test:

```

example# cfgadm -v -o extended -t system:slot3 system:slot5
Testing attachment point system:slot3 ... ok
Testing attachment point system:slot5 ... ok

```

**EXAMPLE 6** Configuring an Occupant Using the Force Option

The following example configures an occupant in the failing state to the system using the force option:

```

example# cfgadm -f -c configure system:slot3

```

**EXAMPLE 7** Unconfiguring an Occupant From the System

The following example unconfigures an occupant from the system:

```

example# cfgadm -c unconfigure system:slot4

```

**EXAMPLE 8** Configuring an Occupant at an Attachment Point

The following example configures an occupant:

```

example# cfgadm -c configure c0::disk/c0t0d0

```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `cfgadm`: `LC_TIME`, `LC_MESSAGES`, `NLSPATH` and `TZ`.

`LC_MESSAGES` Determines how `cfgadm` displays column headings and error messages. Listing output data is not affected by the setting of this variable.

`LC_TIME` Determines how `cfgadm` displays human readable status changed time (`status_time`).

`TZ` Specifies the timezone used when converting the status changed time. This applies to both the human readable (`status_time`) and parsable

(`status_time_p`) formats.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.
- 2 Configuration administration not supported on specified target.
- 3 Usage error.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [cfgadm\\_fp\(1M\)](#), [cfgadm\\_ib\(1M\)](#), [cfgadm\\_pci\(1M\)](#), [cfgadm\\_sbd\(1M\)](#), [cfgadm\\_scsi\(1M\)](#), [cfgadm\\_usb\(1M\)](#), [ifconfig\(1M\)](#), [mount\(1M\)](#), [prtdiag\(1M\)](#), [psradm\(1M\)](#), [syslogd\(1M\)](#), [config\\_admin\(3CFGADM\)](#), [getopt\(3C\)](#), [getsubopt\(3C\)](#), [isatty\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#)

**Diagnostics** Diagnostic messages appear on the standard error output. Other than options and usage errors, the following are diagnostic messages produced by this utility:

```

cfgadm: Configuration administration not supported on ap_id
cfgadm: No library found for ap_id
cfgadm: ap_idis ambiguous
cfgadm: operation: Insufficient privileges
cfgadm: Attachment point is busy, try again
cfgadm: No attachment points with specified attributes found
cfgadm: System is busy, try again
cfgadm: operation: Operation requires a service interruption
cfgadm: operation: Data error: error_text
cfgadm: operation: Hardware specific failure: error_text

```

See [config\\_admin\(3CFGADM\)](#) for additional details regarding error messages.

**Notes** Hardware resources enter the unconfigured pool in a hardware specific manner. This can occur at various times such as: system initialization or as a result of an unconfigure operation. An occupant that is in the unconfigured state is not available for use by the system until specific intervention occurs. This intervention can be manifested as an operator initiated command or it can be by way of an automatic configuring mechanism.

The listing option of the `cfgadm` command can be used to provide parsable input for another command, for example within a shell script. For parsable output, the `-s` option must be used to select the fields required. The `-s` option can also be used to suppress the column headings. The following fields always produce parsable output: `ap_id`, `physid`, `r_state`, `o_state`, `condition`, `busy`, `status_time_p`, `class`, and `type`. Parsable output never has white-space characters embedded in the field value.

The following shell script fragment finds the first good unconfigured occupant of type CPU.

```
found=
cfgadm -l -s "noheadings,cols=ap_id:r_state:condition:type" | \
while read ap_id r_state cond type
do
 if ["$r_state" = unconfigured -a "$cond" = ok -a "$type" = CPU]
 then
 if [-z "$found"]
 then
 found=$ap_id
 fi
 fi
done
if [-n "$found"]
then
 echo "Found CPU $found"
fi
```

The format of the parsable time field (`status_time_p`) is `YYYYMMDDhhmmss`, giving the year, month, day, hour, minute and second in a form suitable for string comparison.

Reference should be made to the hardware specific documentation for details of System Configuration Administration support.

**Name** `cfgadm_ac` – EXX00 memory system administration

**Synopsis** `/usr/sbin/cfgadm [-c configure] [-f]`  
`[-o disable-at-boot | enable-at-boot ] ac#:bank# ...`  
`/usr/sbin/cfgadm [-c unconfigure]`  
`[-o disable-at-bootp | enable-at-boot ] ac#:bank# ...`  
`/usr/sbin/cfgadm [-v]`  
`[-o quick | normal | extended, [max_errors=#] ] -t ac#:bank#...`  
`/usr/sbin/cfgadm -x relocate-test ac#:bank# ...`  
`/usr/sbin/cfgadm [-l] -o disable-at-boot | enable-at-boot ac#:bank# ...`

**Description** The `ac` hardware specific library `/usr/platform/sun4u/lib/cfgadm/cfgadm_ac.so.1` provides the functionality for configuring and unconfiguring memory banks on E6X00, E5X00, E4X00 and E3X00 systems as part of the Dynamic Reconfiguration of CPU/Memory boards using [cfgadm\\_sysctrl\(1M\)](#).

Memory banks appear as attachment points in the device tree. For each CPU/Memory board, two attachment points are published, one for each bank on the board: `bank0` and `bank1`. If the bank is unpopulated, the receptacle state is empty. If the bank is populated, the receptacle state is connected. The receptacle state of a memory bank can never be disconnected. The occupant state of a connected memory bank can be configured or unconfigured. If the occupant state is configured, the memory is in use by Solaris, if unconfigured it is not.

**Options** Refer to [cfgadm\(1M\)](#) for complete descriptions of the command options.

The following options are supported:

`-c configure | unconfigure`

Change the occupant state. The `configure` argument ensures that the memory is initialized and adds the memory to the Solaris memory pool. The `unconfigure` argument removes the memory from use by Solaris. When a CPU/Memory board is to be removed from a system, both banks of memory must be unconfigured.

`cfgadm` refuses the `configure` operation if the memory on the board is marked `disabled-at-boot` (see `info` field), unless either the `-f` (force) option or the `enable at boot` flag, (`-o enable-at-boot`), is given. The `configure` operation takes a short time proportional to the size of memory that must be initialized.

`cfgadm` refuses the `unconfigure` operation if there is not enough uncommitted memory in the system (VM viability error) or if the bank to be unconfigured has memory that can't be removed (`non-relocatable`

pages error). The presence of non-relocatable pages is indicated by the word *permanent* in the *info* listing field. Removing memory from use by Solaris may take a significant time due to factors such as system load and how much paging to secondary storage is required. The *unconfigure* operation can be cancelled at any time and the memory returned to the fully configured state by interrupting the command invocation with a signal. The *unconfigure* operation self-cancels if no memory can be removed within a timeout period. The default timeout period of 60 seconds can be changed using the *-o timeout=#* option, with a value of 0 disabling the timeout.

**-f** Force option. Use this option to override the block on configuring a memory bank marked as disabled at boot in the *non-volatile disabled-memory-list* variable. See *Platform Notes:Sun Enterprise 6x00/5x00/4x00/3x00 Systems*

**-l** List option. This option is supported as described in *cfgadm(1M)*.

The type field is always *memory*.

The *info* field has the following information for empty banks:

```
slot# empty
```

The *slot#* indicates the system slot into which the CPU/Memory board is inserted. For example, if this were *slot11* the attachment point for use with *cfgadm* to manipulate the associated board would be *sysctrl0:slot11*. The *info* field has the following information for connected banks:

```
slot# sizeMb|sizeGb [(sizeMb|sizeGb used)] base 0x###
 [interleaved #-way] [disabled at boot] [permanent]
```

The size of the bank is given in Mb or Gb as appropriate. If the memory is less than completely used, the used size is reported. The physical base address is given in hexadecimal. If the memory bank is interleaved with some other bank, the interleave factor is reported. If the memory on the board is disabled at boot using the *non-volatile disabled-memory-list*

	variable, this is reported. If the bank has memory that cannot be removed this is reported as permanent.
-o disable-at-boot   enable-at-boot	These options allow the state of the non-volatile disabled-memory-list variable to be modified. These options can be used in conjunction with the issuing of a -c option or with the explicit or implied listing command, -l, if no command is required. Use of -o enable-at-boot with the configure command to override the block on configuring memory on a board in the disabled memory list.
-o extended   normal   quick	Use with the -t option to specify test level.  The normal test level ensures that each memory cell stores both a 0 and a 1, and checks that all cells are separately addressable. The quick test level only does the 0s and 1s test, and typically misses address line problems. The extended test uses patterns to test for adjacent cell interference problems. The default test level is normal. See -t option.
-o max_errors=#	Use with the -t option to specify the maximum number of allowed errors. If not specified, a default of 32 is assumed.
-o timeout=#	Use with the unconfigure command to set the self-cancelling timeout. The default value is 60 and the unit is seconds. A value of 0 means no timeout.
-t	Test an unconfigured bank of memory. Specify the test level using the -o quick   normal   extended option.  cfgadm exits with a 0 (success) if the test was able to run on the memory bank. The result of the test is available in the condition for the attachment point.
-v	Verbose option. Use this option in combination with the -t option to display detailed progress and results of tests.
-x relocate-test	For all pages of memory in use on the specified memory bank, a relocation operation as used in the unconfigure command is attempted. The success of this operation does not guarantee that the bank can be unconfigured. Failure indicates that it probably cannot be unconfigured. This option is for test purposes only.

**Operands** The following operand is supported:

*ac#:bank#* The attachment points for memory banks are published by instances of the address controller (ac) driver (*ac#*). One instance of the ac driver is created for each system board, but only those instances associated with CPU/Memory boards publish the two bank attachment points, bank0 and bank1.

This form conforms to the logical *ap\_id* specification given in *cfgadm(1M)*. The corresponding physical *ap\_ids* are listed in the FILES section.

The ac driver instance numbering has no relation to the slot number for the corresponding board. The full physical attachment point identifier has the slot number incorporated into it as twice the slot number in hexadecimal directly following the *fhc@* part.

**Files** */devices/fhc@\*,f8800000/ac@0,1000000:bank?* attachment points  
*/usr/platform/sun4u/lib/cfgadm/cfgadm\_ac.so.1* hardware specific library file

`[-o hardware_options] [-l [ap_id]]`

`/usr/sbin/cfgadm [-v] [-o hardware_options] -h [ap_id]`

**Description** The `fp` port driver plug-in `/usr/lib/cfgadm/fp.so.1` provides the functionality for Fibre Channel Fabric device node management through `cfgadm(1M)`. `cfgadm` operates on attachment points. Attachment points are locations in the system where hardware resources can be dynamically reconfigured. Refer to `cfgadm(1M)` for additional details on attachment points.

For Fibre Channel Fabric device node management, each `fp` port node is represented by an attachment point in the device tree. In addition, each Fibre Channel device is represented by a dynamic attachment point. Attachment points are named through `ap_ids`. Two types of `ap_ids` are defined: logical and physical. The physical `ap_id` is based on the physical pathname. The logical `ap_id` is a shorter, more user-friendly name. For `fp` port nodes, the logical `ap_id` is the corresponding disk controller number. For example, `c0` is a typical logical `ap_id`.

Fibre Channel devices are named with a port World Wide Name (WWN). If a disk device is connected to controller `c0`, its `ap_id` can be:

```
c0::50020f2300006077
```

where `50020f2300006077` identifies the port WWN of a specific Fibre Channel device.

Each device on the Fibre Channel private loop port, Fabric port or public loop port is probed and made available to Solaris by default. Devices connected to the Fibre Channel Fabric port or public loop port can be made unavailable to Solaris by initiating an application or an end user operation. The operation is similar to the hot unplugging of devices by way of management user interfaces. Applications or users can use the `/usr/lib/cfgadm/fp.so.1` library to enable `libcfgadm` to provide interfaces to accomplish this task.

The list of currently connected Fabric devices is generated in the form of the attachment point.

A simple listing of attachment points in the system includes attachment points at `fp` port nodes but not Fibre Channel devices. The following example uses the `-a` flag to the list option (`-l`) to list Fibre Channel devices:

```
cfgadm -l
Ap_Id Type Receptacle Occupant Condition
c0 fc-fabric connected configured unknown
c1 fc-private connected configured unknown
c2 fc-pt_to_pt connected configured unknown
c3 fc connected unconfigured unknown
```

```

sysctrl0:slot0 cpu/mem connected configured ok
sysctrl0:slot1 sbus-upa connected configured ok

```

The following example lists Fibre Channel devices connected to fp ports.

```

cfgadm -al
Ap_Id Type Receptacle Occupant Condition
c0 fc-fabric connected configured unknown
c0::50020f2300006077 disk connected configured unknown
c0::50020f23000063a9 disk connected configured unknown
c0::50020f2300005f24 disk connected configured unknown
c0::50020f2300006107 disk connected configured unknown
c1 fc-private connected configured unknown
c1::220000203708b69c disk connected configured unknown
c1::220000203708ba7d disk connected configured unknown
c1::220000203708b8d4 disk connected configured unknown
c1::220000203708b9b2 disk connected configured unknown
c2 fc-pt_to_pt connected configured unknown
c2::500104f000937528 tape connected configured unknown
c3 fc connected unconfigured unknown
sysctrl0:slot0 cpu/mem connected configured ok
sysctrl0:slot1 sbus-upa connected configured ok

```

In this example, the `fc-fabric` type of `ap_id c0` indicates that the fp port is connected to Fabric. For an fp port with a Fabric-related type such as `fc-fabric` and `fc-public`, device node creation happens by default at the boot time and can be managed by the `cfgadm` `configure` and `unconfigure` operations. The `fc-private` type of `ap_id c1` indicates that fp port is connected to private-loop and device node creation happens by default as well. The `fc-pt_to_pt` type of `ap_id c2` indicates that the fp port is directly connected to another N\_port and device node creation also happens by default. The `fc` type of `ap_id c3` indicates that nothing is attached to fp port c2. The `Type` field of a Fibre Channel device `ap_id` shows the SCSI device type of LUN 0 in the device.

A Fibre Channel device with multiple FCP SCSI LUNs is configured into Solaris and each FCP SCSI LUN is available as a Solaris device. Suppose that `ap_ids c0::50020f2300006077` and `c0::50020f23000063a9` represent Fibre Channel devices with multiple FCP SCSI LUNs.

The following example shows how to list `ap_ids` with FCP SCSI LUN information:

```

cfgadm -al -o show_SCSI_LUN
Ap_Id Type Receptacle Occupant Condition
c0 fc-fabric connected configured unknown
c0::50020f2300006077,0 disk connected configured unknown
c0::50020f2300006077,1 disk connected configured unknown
c0::50020f2300006077,2 disk connected configured unknown
c0::50020f2300006077,3 disk connected configured unknown
c0::50020f23000063a9,0 disk connected configured unknown
c0::50020f23000063a9,1 disk connected configured unknown
c0::50020f23000063a9,2 disk connected configured unknown

```

```

c0::50020f23000063a9,3 disk connected configured unknown
c0::50020f2300005f24,0 disk connected unconfigured unknown
c0::50020f2300005f24,1 disk connected unconfigured unknown
c0::50020f2300006107,0 disk connected unconfigured unknown
c0::50020f2300006107,1 disk connected unconfigured unknown
c1 fc-private connected configured unknown
c1::220000203708b69c,0 disk connected configured unknown
c1::220000203708ba7d,0 disk connected configured unknown
c1::220000203708b8d4,0 disk connected configured unknown
c1::220000203708b9b2,0 disk connected configured unknown
c2 fc-pt_to_pt connected configured unknown
c2::500104f000937528,0 tape connected configured unknown
c3 fc connected unconfigured unknown

```

In this example, the `ap_id c0::50020f2300006077,0` identifies the FCP SCSI LUN 0 of the Fibre Channel device which is represented by port `WWN 50020f2300006077`. The Fibre Channel device is reported to have 4 FCP SCSI LUNs and they are all configured. 4 FCP SCSI LUN level `ap_ids` associated with port `WWN 50020f2300006077` are listed. The listing also displays FCP SCSI LUNs for unconfigured Fibre Channel devices. The Fibre Channel device represented by `c0::50020f2300005f24` is reported to have two FCP SCSI LUNs. The configure operation on `c0::50020f2300005f24` creates two Solaris devices. The Type field of FCP SCSI LUN level `ap_ids` show the SCSI device type of each LUN. When a Fibre Channel device has different device type LUNs, the Type field reflects that.

The receptacle and occupant state for attachment points at the fp port have the following meanings:

configured

One or more devices configured on the fp port

connected

fp port active

disconnected

fp port quiesced (IO activity is suspended)

empty

Not applicable

unconfigured

No devices configured on the fp port

The state for individual Fibre Channel devices on an fp port:

configured

Device is configured into Solaris and is available for use

connected

fp port to which the device is connected to is active

disconnected

fp port to which the device is attached is quiesced

unconfigured

Device is available to be configured

The `condition` field for attachment points at the `fp` port has the following meanings:

failed

An error condition has prevented the `fp` port from being able to detect the presence or type of a Fibre Channel connection.

The `condition` field for individual Fibre Channel devices on an `fp` port has the following meanings:

failed

An error is encountered while probing a device on Fabric.

failing

A device was configured on a host and its state as seen by Solaris appears to be normal (i.e., online) but it is either not currently present or visible in the fabric or its presence could not be verified due to an error condition on the local port through which the device was configured.

unusable

A device has been configured on the host, but is currently offline or failed.

The `unknown condition` indicates that probing a device on Fabric completed without an error and the device state within Solaris host is normal if the device was configured previously. The internal condition of the device cannot be guaranteed.

**Options** `cfgadm` defines several types of operations in addition to listing (`-l`). These operations include invoking configuration state changes and obtaining configuration administration help messages (`-h`).

The following options are supported:

`-c function`

The following generic commands are defined for the `fp-transport-specific` library:

For Fibre Channel device attachment points on the `fc-fabric` type `fp` port attachment point, the following configuration state change operations are supported:

`configure`

Configure a connected Fibre Channel Fabric device to a host. When a Fibre Channel device is listed as an unknown type in the output of the `list` operation the device might not be configurable. No attempt is made to configure devices with unknown types. The `force` option (`-f`) can be used to force the `fp` port driver plug-in to make an attempt to configure any devices. Any errors in the process are reported. By default, each FCP SCSI

LUN that is discovered on a Fibre channel Fabric device is configured. However, FCP SCSI LUNs that are specified in the “pwwn-lun-blacklist” property in the `fp.conf` file will remain unconfigured. The FCP SCSI LUN level listing reflects the state of such FCP SCSI LUNs. They stay in the “unconfigured” state after reboot or Solaris Dynamic Reconfiguration on the controller that they are connected through. Refer to [fp\(7d\)](#) for additional details on the “pwwn-lun-blacklist” property.

#### unconfigure

Unconfigure a Fibre Channel Fabric device from a host. This device stays unconfigured until the next reboot or Solaris Dynamic Reconfiguration on the controller that the device is connected, at which time all fabric devices are automatically enumerated. The default behavior may be changed through the use of the “manual\_configuration\_only” property in the `fp.conf` file. If the property is set, the device remains unconfigured after reboot. Refer to [fp\(7d\)](#) for additional details on the “manual\_configuration\_only” property.

For Fibre Channel private loop devices and `N_Port` point-to-point devices, the `configure` command returns success without doing any operation. The `unconfigure` command is not supported on the private loop devices and `N_Port` point-to-point devices. The private loop devices and `N_Port` point-to-point devices are configured by Solaris Fibre Channel drivers by default and are not managed through end user- or application-initiated operations. The `pwwn-lun-blacklist` property in the `fp.conf` file is applied to the private loop device and `N_Port` point-to-point device in the same way it is applied to a Fabric device.

-f

Force the `configure` change state operation to occur irrespective of the `condition` or `type`. Refer to the above description of the `configure` change state operation.

-h *ap\_id*

Obtain `fp`—transport-specific help. Specify any `fp` attachment point.

-o *hardware\_options*

The following hardware options are supported.

#### show\_SCSI\_LUN

Lists `ap_ids` associated with each FCP SCSI LUN for discovered Fibre Channel devices when specified with the `list` option `-al`. Refer to the previously mentioned description and example of FCP SCSI LUN level listing. Device node creation is not supported on the FCP SCSI LUN level. See **NOTES**.

All Fibre Channel devices are available to Solaris by default. Enabling only a subset of Fabric devices available to Solaris by default can be accomplished by setting the property “manual\_configuration\_only” in `/kernel/drv/fp.conf` file. When “manual\_configuration\_only” in `fp.conf` is set, all Fabric devices are not available to Solaris unless an application or an end user had previously requested the device be configured into Solaris. The `configure` state-change command makes the device available

to Solaris. After a successful `configure` operation on a Fabric device, the associated links are added to the `/dev` namespace. The `unconfigure` state-change command makes a device unavailable to Solaris.

When a Fibre Channel Fabric device is configured successfully to a host using the `-c configure` operation, its physical `ap_id` is stored in a repository. When a Fibre Channel Fabric device is unconfigured using the `-c unconfigure` operation, its physical `ap_id` is deleted from the same repository. All fabric devices are automatically enumerated by default and the repository is used only if the `fp.conf` “`manual_configuration_only`” property is set. Refer to [fp\(7d\)](#) for additional details on the “`manual_configuration_only`” property.

You can specify the following commands with the `-c` option to control the update behavior of the repository:

`force_update`

For `configure`, the attachment point is unconditionally added to the repository; for `unconfigure`, the attachment point is unconditionally deleted.

`no_update`

No update is made to the repository regardless of the operation.

These options should not be used for normal `configure` and `unconfigure` operations. See **WARNINGS**.

When a Fibre Channel device has multiple FCP SCSI LUNs configured and any Solaris device associated with its FCP SCSI LUN is in the unusable condition, the whole Fibre Channel device is reported as unusable. The following option with the `-c unconfigure` command removes only Solaris devices with the unusable condition for a Fibre Channel device.

`unusable_SCSI_LUN`

For `unconfigure` operation, any offlined device nodes for a target device is removed.

`-s listing_options`

Refer to [cfgadm\(1M\)](#) for usage information.

`-t ap_id`

No test commands are available at present.

`-x hardware_function`

No hardware specific functions are available at present.

All other options have the same meaning as defined in the [cfgadm\(1M\)](#) man page.

### Examples **EXAMPLE 1** Unconfiguring a Disk

The following command unconfigures a disk:

```
cfgadm -c unconfigure c0::210000203708b606
```

**EXAMPLE 2** Unconfigure all the Configured Disks under Single Attachment Point

The following command unconfigures all configured disks under the attachment point `c0`.

```
cfgadm -c unconfigure c0
```

**EXAMPLE 3** Configuring a Disk

The following command configures a disk:

```
cfgadm -c configure c0::210000203708b606
```

**EXAMPLE 4** Configure all the Unconfigured Disks under Single Attachment Point

The following command configures all unconfigured disks under the attachment point `c0`.

```
cfgadm -c configure c0
```

**EXAMPLE 5** Removing the Fibre Channel Fabric Device Attachment Point from Repository

The following command unconditionally removes the fibre channel fabric device attachment point from the Fabric device repository.

```
cfgadm -c unconfigure -o force_update c0::210000203708b606
```

**EXAMPLE 6** Removing Offlined Solaris Device Nodes for a Target Device

The following command removes offlined Solaris device nodes for a target device:

```
cfgadm -c unconfigure -o unusable_SCSI_LUN c0::210000203708b606
```

**Files** `/usr/lib/cfgadm/fp.so.1`

Hardware-specific library for Fibre Channel Fabric device node management.

`/etc/cfg/fp/fabric_wwn_map`

Repository of physical `ap_ids` of Fabric devices currently configured. It is used only to reconfigure those Fabric devices at boot time. This repository is only used when the “`manual_configuration_only`” `/kernel/drv/fp.conf` file is set.

`/etc/rcS.d/fdevattach`

Reconfigures Fabric device(s) of which physical `ap_id` is listed in `/etc/cfg/fp/fabric_wwn_map` on boot time.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/storage/fibre-channel/fc-fabric, service/storage/fibre-channel/fc-fabricx

**See Also** [svcs\(1\)](#), [cfgadm\(1M\)](#), [svcadm\(1M\)](#), [config\\_admin\(3CFGADM\)](#), [libcfgadm\(3LIB\)](#), [attributes\(5\)](#), [smf\(5\)](#), [fp\(7d\)](#)

**Warnings** Do not use hardware-specific options for the repository update under normal `configure/unconfigure` operations. The hardware-specific options are expected to be used when the node creation of a Fabric device fails at boot time and the error condition is considered to be permanent. The `unconfigure` command with `force_update` hardware-specific option unconditionally removes the attachment point of a failing Fabric device from the repository.

**Notes** For devices with unknown or no SCSI device type (for example, a Fibre Channel Host Bus Adapter), the `configure` operation might not be applicable.

The `configure` and `unconfigure` commands operate on the Fibre Channel device level which is represented by port WWN `ap_id`. If a Fibre Channel device has multiple FCP SCSI LUNs configured, the `configure` command on the associated port WWN `ap_id` results in creating a Solaris device for each FCP SCSI LUN unless it is specified in the “`pwwn-lun-blacklist`” property in the `fp.conf` file. The `unconfigure` command removes all Solaris devices associated with the port WWN `ap_id`. The FCP SCSI LUN level `ap_id` is not valid for the `configure` and `unconfigure` commands.

The deprecated `show_FCP_dev` option has been replaced by the new `show_SCSI_LUN` option, and the deprecated `unusable_FCP_dev` option has been replaced by the new `unusable_SCSI_LUN` option.

The `cfgadm_fp` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/device/fc-fabric:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

No administrative actions on this service are required for Fabric device configuration once this service is started on boot time.

**Name** `cfgadm_ib` – InfiniBand hardware specific commands for `cfgadm`

**Synopsis** `/usr/sbin/cfgadm -f [-y | -n] [-v] -c function ap_id...`  
`/usr/sbin/cfgadm [-f] [-y | -n] [-v] [-o hardware_options]`  
`-x hardware_function ap_id...`  
`/usr/sbin/cfgadm -v [-a] [-s listing_option] [-] [ap_id | ap_type...]`  
`/usr/sbin/cfgadm -v -h [ap_id]...`

**Description** The InfiniBand hardware specific library `/usr/lib/cfgadm/ib.so.1` provides the functionality for administering its fabric through the `cfgadm(1M)` utility. `cfgadm` operates on attachment points. See `cfgadm(1M)`.

An InfiniBand (IB) device is enumerated by the IB nexus driver, `ib(7D)`, based on the services from the IB Device Manager (IBDM).

The IB nexus driver creates and initializes five types of child device nodes:

- IB Port devices
- IB HCA service (HCA\_SVC) devices
- IB Virtual Physical Point of Attachment (VPPA) devices
- I/O Controller (IOC)
- IB Pseudo devices

See `ib(7D)` for details on enumeration of IB Port, IB VPPA, and IB HCA\_SVC devices. For additional information on IBDM, see `ibdm(7D)`. See `ib(4)` for details on IB Pseudo devices.

For IB administration, two types of static attachment point are created for the fabric administration as seen by the given host. There is one static attachment point `ib` and all IB devices (either an IOC, Port, VPPA, HCA\_SVC, or a Pseudo device) in the fabric are represented as dynamic attachment points based off of it. There is another static attachment point for each Host Channel Adapter (HCA) in the host based on its node Globally Unique Identifier (GUID) value.

Attachment points are named through `ap_ids`. There are two types of `ap_ids`: logical and physical. The physical `ap_id` is based on the physical path name. For the IB fabric it is `/devices/ib: fabric`. The logical `ap_id` is a shorter, and has a more user friendly name.

The static `ap_id` for the IB fabric is `ib`. The IB devices are dynamic attachment points and have no physical `ap_id`. The logical `ap_id` of an IOC contains its GUID, `ib: :IOC-GUID`. An example of an IOC `ap_id` is `ib: :80020123456789a`. The logical `ap_id` of a Pseudo device, see `ib(4)` for details, is of the format `ib: :driver_name, unit-address`. An example of a pseudo `ap_id` would be `ib: :sdp, 0` where “sdp” is the driver name and “0” is its `unit-address` property. The logical `ap_id` of Port, VPPA and HCA\_SVC device contains its Partition Key (`P_Key`), `Port GUID / Node GUID` and a communication service-name. The format of `ap_id` is as below:

Port device

`ib: :PORT_GUID, 0, service-name`

VPPA device

`ib::PORT_GUID,P_Key,service-name`

HCA\_SVC device

`ib::HCA_GUID,0, servicename`

The Partition Key (*P\_Key*) is 0 for Port and HCA\_SVC devices. The *P\_Key* helps determine the partition to which this port belongs for a VPPA device node. A port might have more than one *P\_Key*. An example of a VPPA device logical *ap\_id* point is `ib::80245678,ffff,ipib`. The *port-GUID* is 80245678, the *P\_Key* is 0xffff, and the service name is ipib. The service-name information is obtained from the file `/kernel/drv/ib.conf` which contains service-name strings. The HCA's logical *ap\_id* contains its node GUID value, `hca:HCA-GUID`. An example is `hca:21346543210a987`.

A listing of the IB attachment points includes information on all IB devices (IOC, VPPA, HCA\_SVC, Pseudo, and Port devices seen by the IBDM and the IB nexus driver) in the fabric even if they are not seen by the host and configured for use.

The following shows a listing of five IB devices (two IOC, one VPPA, one Port, one HCA\_SVC) and one HCA:

```
example# cfgadm -al
Ap_Id Type Receptacle Occupant Condition
hca:21346543210a987 IB-HCA connected configured ok
ib IB-FABRIC connected configured ok
ib::80020123456789a IB-IOC connected configured ok
ib::802abc9876543 IB-IOC connected unconfigured unknown
ib::80245678,ffff,ipib IB-VPPA connected configured ok
ib::12245678,0,nfs IB-PORT connected configured ok
ib::21346543,0,hnfs IB-HCA_SVC connected configured ok
ib::sdp,0 IB-PSEUDO connected configured ok
```

The *ap\_id* `ib::802abc9876543` shows an IOC device that is not yet configured by the host for use or had been previously offlined by an explicit

```
cfgadm -c unconfigure
```

operation. The distinction was made by the information displayed under the *Condition* column. The IB device with a zero *P\_Key* and HCA GUID is a HCA\_SVC device. Refer to [cfgadm\(1M\)](#) for more information regarding listing attachment points.

The receptacle state for attachment points have the following meanings:

**connected**

For an IOC/VPPA/Port/Pseudo/HCA\_SVC device, *connected* implies that it has been seen by the host. The device might not have been configured for use by Solaris.

For a HCA attachment point, *connected* implies that it has been configured and is in use.

All IB *ap\_ids* are always shown as *connected*.

The occupant state for attachment points have the following meanings:

configured

The IB device, and the HCA `ap_id`, are configured and usable by Solaris.

unconfigured

The IB device at the `ap_id` was explicitly offlined using `cfgadm -c unconfigure`, was not successfully configured. This could be because it was not successfully configured for use with Solaris (no driver, or a device problem), or because it was never configured for use by the IB nexus driver.

The `unconfigured` operation is not supported for the HCA attachment point. The IB static `apid, ib`, is shown `unconfigured` if the system has no IB hardware.

The attachment point conditions are:

failed

Not used.

failing

Not used.

ok

Normal state. Ready for use.

unknown

This state is only valid for IB device that have been probed by IBDM but not yet configured for use by Solaris. It is also shown for devices that have been explicitly offlined by a `cfgadm -c unconfigure` operation. This condition does not apply to a HCA attachment point.

unusable

Not used.

**Options** The following options are supported:

`-c function`

The IB hardware specific library supports two generic commands (*functions*). These commands are not supported on the static attachment points (that is, the HCA `ap_ids` and the IB static `ib ap_id`).

The following generic commands are supported:

`configure`

Configure the IB device to be used by Solaris.

`unconfigure`

Unconfigure the IB device. If successful, `cfgadm` reports the condition of this `ap_id` as `unknown`.

`-f`

Not supported.

-h *ap\_id*

Obtain IB specific help for an IB attachment point.

-l

List the state and condition of IB attachment points. The -l option works as described in [cfgadm\(1M\)](#).

When paired with the -a option, displays the dynamic attachment points as well (IOC, VPPA, Port, Pseudo, and HCA\_SVC devices).

When paired with -v option, displays verbose data about the ap\_ids. For an IOC, the Info field in the

```
cfgadm -avl
```

output displays the following information: VendorID, IOCDeviceID, DeviceVersion, SubsystemVendorID, SubsystemID, Class, Subclass, Protocol, ProtocolVersion and IDString from the IOCControllerProfile. If the ID string isn't provided then nothing is displayed in its place. These fields are defined in the InfiniBand Specification Volume 1 (<http://www.infinibandta.org>).

For a VPPA, Port, or HCA\_SVC device the Info field in the `cfgadm -lav` display shows the service name information to which this device is bound. If no such information exists, nothing is displayed.

For a Pseudo device `cfgadm -alv` displays the driver name and its unit-address information. For a HCA the verbose listing displays the VendorID, ProductID of the HCA, number of ports it has, and the PortGUID value of its ports. See EXAMPLES.

-o *hardware\_option*

This option is not currently defined.

-s *listing\_option*

Attachment points of class ib can be listed by using the select sub-option. Refer to the [cfgadm\(1M\)](#) man page for more information.

-x *hardware\_function*

Perform a hardware specific function. Note that the *name* can not be more than 4 characters long.

The following hardware specific functions are supported:

```
add_service -ocomm=[port|vppa|hca_svc],service=name
```

This hardware specific function is supported on the static IB attachment point. It can be used to add a new service to `/kernel/drv/ib.conf` file and to update the [ib\(7D\)](#) driver.

You must use the `service=name` option to indicate the new service to be added. You must use the `comm=[port|vppa|hca_svc]` option to add the name service to either `port-svc-list` or to the `hca-svc-list` in the `/kernel/drv/ib.conf` file. See EXAMPLES.

`delete_service -ocomm=[port|vppa|hca_svc],service=name`

This hardware specific function is supported on the static IB attachment point only. It can be used to delete an existing service from the `/kernel/drv/ib.conf` file and also from the [ib\(7D\)](#) driver's data base. You must use the `service=name` option to indicate which service to delete. You must use the `comm=[port|vppa|hca_svc]` option to delete this service from the `port-svc-list`, `vppa-svc-list`, or `vppa-svc-list` of the `/kernel/drv/ib.conf` file. See [EXAMPLES](#).

`list_clients`

Supported on HCA attachment points. Displays all the kernel IB clients using this HCA. It also displays the respective `ap_ids` of these kernel IB clients and if they have opened an alternate HCA device. See [EXAMPLES](#).

.

If a given kernel IB client does not have a valid `ap_id` then a - is displayed in that column.

`list_services`

This hardware specific function is supported on the static IB attachment point only. It lists all the Port and VPPA services as read from the `/kernel/drv/ib.conf` file. See [EXAMPLES](#).

`unconfig_clients`

This hardware specific function is supported on the static HCA attachment point only. It can be used to unconfigure all IB kernel clients of this given HCA. Only IB kernel clients that do not have an alternate HCA are unconfigured. See [EXAMPLES](#).

`update_ioc_config`

This hardware specific function is supported on static ib attachment point and the IOC attachment points. For the `ib` APID, this function updates properties of all the IOC device nodes. For the IOC APID, this function updates the properties of specified IOC device node. This command updates the `port-list`, `port-entries`, `service-id`, and `service-name` IOC node properties.

See [ib\(7D\)](#).

`update_pkey_tbls`

Supported on the static `ib` attachment point. Updates the PKEY information inside IBTL. IBTL re-reads the `P_Key` tables for all the ports on each HCA present on the host.

See [ibt1\(7D\)](#).

### **Examples** EXAMPLE 1 Listing the State and Condition of IB Devices

The following command lists the state and condition of IB devices on the system. It only shows the static attachment points.

**EXAMPLE 1** Listing the State and Condition of IB Devices (Continued)

```
example# cfgadm
hca:21346543210a987 IB-HCA connected configured ok
ib IB-FABRIC connected configured ok
```

The -a option lists all attachment points. The following example uses the -a option and lists all attachment points:

```
example# cfgadm -a
hca:21346543210a987 IB-HCA connected configured ok
ib IB-FABRIC connected configured ok
ib::80020123456789a IB-IOC connected unconfigured ok
ib::80245678,ffff,ipib IB-VPPA connected configured ok
ib::21346543,0,hnfs IB-HCA_SVC connected configured ok
ib::12245678,0,nfs IB-PORT connected configured ok
ib::sdp,0 IB-PSEUDO connected configured ok
```

**EXAMPLE 2** Listing the Verbose Status of a IB VPPA Device

The following command lists the verbose status of a IB VPPA device:

```
example# cfgadm -alv ib::80245678,ffff,ipib
Ap_Id Receptacle Occupant Condition Information
When Type Busy Phys_Id
ib::80245678,ffff,ipib connected configured ok ipib
unavailable IB-VPPA n /devices/ib:fabric::80245678,ffff,ipib
```

A verbose listing of an IOC shows additional information. The following command shows a verbose listing:

```
example# cfgadm -alv ib::80020123456789a
Ap_Id Receptacle Occupant Condition Information
When Type Busy Phys_Id
ib::80020123456789a connected configured ok VID: 0xeaea
DEVID: 0xeaea VER: 0x5 SUBSYS_VID: 0x0 SUBSYS_ID: 0x0 CLASS: 0xffff
SUBCLASS: 0xff PROTO: 0xff PROTOVER: 0x1 ID_STRING: Sample Host Adapter
unavailable IB-IOC n /devices/ib:fabric::80020123456789a
```

A verbose listing of a Pseudo device shows:

```
example# cfgadm -alv ib::sdp,0
Ap_Id Receptacle Occupant Condition Information
When Type Busy Phys_Id
ib::sdp,0 connected configured ok Driver = "sd
p" Unit-address = "0"
unavailable IB-PSEUDO n /devices/ib:fabric::sdp,0
```

A verbose listing of a HCA shows:

**EXAMPLE 2** Listing the Verbose Status of a IB VPPA Device (Continued)

```
example# cfgadm -alv hca:21346543210a987
Ap_Id Receptacle Occupant Condition Information
When Type Busy Phys_Id
hca:21346543210a987 connected configured ok VID: 0x15b3,
PID: 0x5a44, #ports: 0x2, port1 GUID: 0x80245678, port2 GUID: 0x80245679
unavailable IB-HCA n /devices/ib:21346543210a987
```

You can obtain more user-friendly output if you specify these following `cfgadm` class and field selection options: `-s "select=class(ib),cols=ap_id:info"`

The following command displays only IB `ap_ids`. The output only includes the `ap_id` and Information fields.

```
cfgadm -al -s "cols=ap_id:info" ib::80245678,ffff,ipib
Ap_Id Information
ib::80245678,ffff,ipib ipib
```

**EXAMPLE 3** Unconfiguring an Existing IB IOC

The following command unconfigures the IB IOC attached to `ib::80020123456789a`, then displays the status of the `ap_id`:

```
cfgadm -c unconfigure ib::80020123456789a
Unconfigure the device: /devices/ib:fabric::80020123456789a
This operation will suspend activity on the IB device
Continue (yes/no)?
```

Enter: y

IB device unconfigured successfully.

```
cfgadm -al ib::80020123456789a
Ap_Id Type Receptacle Occupant Condition
ib::80020123456789 IB-IOC connected unconfigured unknown
#
```

The condition unknown implies that the device node doesn't exist anymore and this IB device's existence is known only to the IB Device Manager.

**EXAMPLE 4** Configuring an IB IOC

The following series of commands configures an IB device attached to `ib::80020123456789a`:

```
cfgadm -yc configure ib::80020123456789a
cfgadm -al ib::80020123456789a
Ap_Id Type Receptacle Occupant Condition
ib::80020123456789a IB-IOC connected configured ok
```

**EXAMPLE 5** Listing All Kernel IB Clients of a HCA

The following command lists all kernel IB clients of an HCA attached to hca:21346543210a987:

```
cfgadm -x list_clients hca:21346543210a987
Attachment Point Clients Alternate HCA
ib::80020123456789a iocl Yes
ib::80245678,ffff,ipib ipib No
ib::21346543,0,hnfs hnfs No
- ibdm No
- ibmf No
```

**EXAMPLE 6** Adding a Port Service

The following command adds a new Port service called srp:

```
cfgadm -o comm=port,service=srp -x add_service ib
```

**EXAMPLE 7** Deleting a VPPA Service

The following command deletes the ibd VPPA service ibd:

```
cfgadm -o comm=vppa,service=ipib -x delete_service ib
```

**EXAMPLE 8** Listing Port, VPPA, HCA\_SVC Services

The following command lists all Port, VPPA, and HCA\_SVC services:

```
cfgadm -x list_services ib
Port communication services:
 srp

VPPA communication services:
 ipib
 nfs

HCA_SVC communication services:
 hnfs
```

**EXAMPLE 9** Reprobing IOC Devices

The following command reprobes all IOC device nodes.

```
cfgadm -x update_ioc_config ib
This operation can update properties of IOC devices.
Continue (yes/no)?

Enter: y

#
```

**EXAMPLE 10** Unconfiguring All Kernel Clients of a HCA

The following command unconfigures all kernel clients of a HCA

```
cfgadm -x unconfig_clients hca:21346543
This operation will unconfigure clients of this HCA.
Continue (yes/no)?
```

```
Enter: y
```

**Files** /usr/lib/cfgadm/ib.so.1  
Hardware-specific library for generic InfiniBand device administration

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTETYPE	ATTRIBUTEVALUE
Availability	system/library

**See Also** [cfgadm\(1M\)](#), [config\\_admin\(3CFGADM\)](#), [libcfgadm\(3LIB\)](#), [ib\(4\)](#), [attributes\(5\)](#), [ib\(7D\)](#), [ibdm\(7D\)](#), [ibtl\(7D\)](#)

InfiniBand Specification Volume 1 (<http://www.infinibandta.org>)

**Notes** Apart from the listing (`cfgadm -l` or `cfgadm -x list_clients`), only the superuser can execute any functions on an attachment point.

**Name** `cfgadm_pci` – PCI, CompactPCI, and PCI Express Hotplug hardware specific commands for `cfgadm`

**Synopsis**

```

/usr/sbin/cfgadm [-f] [-y | -n] [-v]
 [-o hardware_options] -c function ap_id [ap_id]

/usr/sbin/cfgadm [-f] [-y | -n] [-v]
 [-o hardware_options] -x hardware_function ap_id
 [ap_id]

/usr/sbin/cfgadm [-v] [-s listing_options]
 [-o hardware_options] [-l [ap_id | ap_type]]

/usr/sbin/cfgadm [-v] [-o hardware_options] -t ap_id [ap_id]

/usr/sbin/cfgadm [-v] [-o hardware_function] -h
 [ap_id] ap_type

```

**Description** The PCI hardware specific library, `/usr/lib/cfgadm/pci.so.1`, provides the support for hotplugging PCI and CompactPCI adapter cards into the respective hotpluggable slots in a system that is hotplug capable, through the `cfgadm` command (see [cfgadm\(1M\)](#)). This library does not include support for PCI Express Hotplug or Standard PCI Hotplug adapter cards, which are provided by a different library (see [cfgadm\\_shp\(1M\)](#)). Hotplug administrative models between PCI, CompactPCI remain the same except where noted in this document.

For PCI Hot Plug, each hotplug slot on a specific PCI bus is represented by an attachment point of that specific PCI bus.

An attachment point consist of two parts: a receptacle and an occupant. The receptacle under PCI Hot Plug is usually referred to as the physical hotpluggable slot; and the occupant is usually referred to as the PCI adapter card that plugs into the slot.

Attachment points are named through `ap_ids`. There are two types of `ap_ids`: logical and physical. The physical `ap_id` is based on the physical pathname, that is, `/devices/pci@1/hpc0_slot3`, whereas the logical `ap_id` is a shorter, and more user-friendly name. For PCI hotpluggable slots, the logical `ap_id` is usually the corresponding hotplug controller driver name plus the logical slot number, that is, `pci0:hpc0slot1`; PCI nexus driver, with hotplug controller driver named `hpc` and slot number 1. The `ap_type` for PCI Hot Plug is `pci`.

Note that the `ap_type` is not the same as the information in the Type field.

See the *System Administration Guide: Basic Administration* for a detailed description of the hotplug procedure.

**Options** The following options are supported:

`-c function`

The following *functions* are supported for PCI hotpluggable slots:

configure

Configure the PCI device in the slot to be used by Solaris.

connect

Connect the slot to PCI bus.

disconnect

Disconnect the slot from the PCI bus.

insert

Not supported.

remove

Not supported.

unconfigure

Logically remove the PCI device's resources from the system.

-f

Not supported.

-h *ap\_id* | *ap\_type*

Print out PCI Hot Plug-specific help message.

-l *list*

List the values of PCI Hot Plug slots.

-o *hardware\_options*

No hardware specific options are currently defined.

-s *listing\_options*

Same as the generic [cfgadm\(1M\)](#).

-t *ap\_id*

This command is only supported on platforms which support testing capability on the slot.

-v

Execute in verbose mode.

When the `-v` option is used with the `-l` option, the `cfgadm` command outputs information about the attachment point. For PCI Hotplug attachment points located in a PCI Express hierarchy, see [cfgadm\\_shp\(1M\)](#) for details. For PCI Hot Plug attachment points not located in a PCI Express hierarchy, the `Information` field will be the slot's system label, if any. This string will be obtained from the `slot-name` property of the slot's bus node. The information in the `Type` field is printed with or without the `v` option. The occupant `Type` field will describe the contents of the slot. There are 2 possible values:

unknown

The slot is empty. If a card is in the slot, the card is not configured or there is no driver for the device on the card.

*subclass/board*

The card in the slot is either a single-function or multi-function device.

*subclass* is a string representing the subclass code of the device, for example, SCSI, ethernet, pci - isa, and so forth. If the card is a multi-functional device, MULT will get printed instead.

*board* is a string representing the board type of the device. For example, hp is the string used for a PCI Hot Plug adapter, hs is used for a Hot Swap Board, nhs for a Non—Hot Swap cPCI Board, bhs for a Basic Hot Swap cPCI Board, and fhs for a Full Hot Swap cPCI Board.

Most PCI cards with more than one device are not multi-function devices, but are implemented as a PCI bridge with arbitrary devices behind them. In those cases, the subclass displayed is that of the PCI bridge. Most commonly, the bridges are pci - pci , a generic PCI to PCI bridge or stpci , a semi-transparent PCI bridge.

*-x hardware\_function*

Perform hardware specific function. These hardware specific functions should not normally change the state of a receptacle or occupant.

The following *hardware\_functions* are supported:

*enable\_slot | disable\_slot*

Change the state of the slot and preserve the state of slot across reboot. Preservation of state across reboot is only supported on select platforms.

*enable\_slot* enables the addition of hardware to this slot for hotplugging and at boot time.

*disable\_slot* disables the addition of hardware to this slot for hotplugging and at boot time. When a slot is disabled its condition is shown as unusable.

*enable\_autoconfig | disable\_autoconfig*

Change the ability to autoconfigure the occupant of the slot. Only platforms that support auto configuration support this feature.

*enable\_autoconfig* enables the ability to autoconfigure the slot.

*diabile\_autoconfig* disables the ability to autoconfigure the slot.

Autoconfiguration is done through the attention button on the PCI Express platforms and through the injector/ejector latch on the CompactPCI platforms. When autoconfiguration is disabled, the attention button or latch mechanism cannot be used to configure the occupant of the slot.

*led=[led\_sub\_arg],mode=[mode\_sub\_arg]*

Without sub-arguments, print a list of the current LED settings. With sub-arguments, set the mode of a specific LED for a slot.

Specify *led\_sub\_arg* as *fault*, *power*, *attn*, or *active*.

Specify *mode\_sub\_arg* as *on*, *off* or *blink*.

Changing the state of the LED does not change the state of the receptacle or occupant. Normally, the LEDs are controlled by the hotplug controller, no user intervention is necessary. Use this command for testing purposes.

*Caution:* Changing the state of the LED can misrepresent the state of occupant or receptacle.

The following command prints the values of LEDs:

```
example# cfgadm -x led pci0:hpc0_slot1
Ap_Id Led
pci0:hpc0_slot1 power=on, fault=off, active=off, attn=off
```

The following command turns on the Fault LED:

```
example# cfgadm -x led=fault,mode=on pci0:hpc0_slot1
```

The following command turns off the Power LED:

```
example# cfgadm -x led=power,mode=off pci0:hpc0_slot0
```

The following command sets the *active* LED to blink to indicate the location of the slot:

```
example# cfgadm -x led=active,mode=on pci0:hpc0_slot3
```

### Examples EXAMPLE 1 Printing out the Value of Each Slot

The following command prints out the values of each slot:

```
example# cfgadm -l
Ap_Id Type Receptacle Occupant Condition
c0 scsi-bus connected configured unknown
c1 scsi-bus connected unconfigured unknown
c2 scsi-bus connected unconfigured unknown
cpci_slot1 stpci/fhs connected configured ok
cpci_slot2 unknown empty unconfigured unknown
cpci_slot4 stpci/fhs connected configured ok
cpci_slot5 stpci/fhs connected configured ok
```

### EXAMPLE 2 Replacing a Card

The following command lists all DR-capable attachment points:

```
example# cfgadm
```

```
Type Receptacle Occupant Condition
c0 scsi-bus connected configured unknown
c1 scsi-bus connected unconfigured unknown
```

**EXAMPLE 2** Replacing a Card *(Continued)*

```

c2 scsi-bus connected unconfigured unknown
cpci_slot1 stpci/fhs connected configured ok
cpci_slot2 unknown empty unconfigured unknown
cpci_slot4 stpci/fhs connected configured ok
cpci_slot5 stpci/fhs connected configured ok

```

The following command unconfigures and electrically disconnects the card:

```
example# cfgadm -c disconnect cpci_slot4
```

The change can be verified by entering the following command:

```
example# cfgadm cpci_slot4
```

```

Ap_Id Type Receptacle Occupant Condition
cpci_slot4 unknown disconnected unconfigured unknown

```

Now the card can be swapped. The following command electrically connects and configures the card:

```
example# cfgadm -c configure cpci_slot4
```

The change can be verified by entering the following command:

```
example# cfgadm cpci_slot4
```

```

Ap_Id Type Receptacle Occupant Condition
cpci_slot4 stpci/fhs connected configured ok

```

**Files** /usr/lib/cfgadm/pci.so.1

Hardware specific library for PCI hotplugging.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

*System Administration Guide: Basic Administration*

**Name** `cfgadm_sata` – SATA hardware-specific commands for `cfgadm`

**Synopsis** `/usr/sbin/cfgadm [-f] [-y | -n] [-v] [-o hardware_options]`  
`-c function ap_id...`

`/usr/sbin/cfgadm [-f] [-y | -n] [-v] [-o hardware_options]`  
`-x hardware_function ap_id...`

`/usr/sbin/cfgadm [-v] [-a] [-s listing_options]`  
`[-o hardware_options] [-l [ap_id | ap_type]...]`

`/usr/sbin/cfgadm [-v] [-o hardware_options] -t ap_id...`

`/usr/sbin/cfgadm [-v] [-o hardware_options] -h [ap_id]...`

**Description** The SATA hardware specific library, `/usr/lib/cfgadm/sata.so.1`, provides the functionality for SATA hot plugging through the `cfgadm` command. `cfgadm` operates on attachment points, which are locations in the system where hardware resources can be dynamically reconfigured. See [cfgadm\(1M\)](#) for information regarding attachment points.

Each SATA controller's and port multiplier's device port is represented by an attachment point in the device tree. SATA devices, connected and configured in the system are shown as the attachment point name extension. The terms “attachment point” and “SATA port” are used interchangeably in the following description.

Attachment points are named through `ap_ids`. All the SATA attachment points `ap_id` consist of a string in the following form:

```
sataX/P[.M][::dsk/cXtYd0]
```

where

X is the SATA controller number

P is the SATA controller's device port number (0 to 31)

M is the port multiplier's device port number (0 to 14) the port multiplier host port number (15). It is used only when the port multiplier is attached to the SATA controller's device port.

`dev/cXtYd0` identifies the attached SATA device

Y is a target number

In general, the device identifier is derived from the corresponding logical link for the device in `/dev`. Because only one LUN (LUN 0) is supported by the SATA device, the “d” component of the device string will always have number 0 (zero).

For example, the logical `ap_id` of the device port 4 of the port multiplier connected to the device port 5 of the SATA controller 2 would be:

```
sata2/5.4
```

If the SATA disk or CD/DVD device is connected to this attachment point, and the device is configured, the *ap\_id* would be:

```
sata2/5.4::dsk/c2t645d0
```

The *cXtYd0* string identifying a device has one-to-one correspondence to the device attachment point.

A simple listing of attachment points in the system will include all SATA device ports and attached devices. For example:

```
#cfgadm -l
Ap_Id Type Receptacle Occupant Condition
sata0/0::dev/c0t0d0 disk connected configured ok
sata0/1::dev/c0t1d0 disk connected configured ok
sata0/2::dev/c0t2d0 cd-dvd connected configured ok
sata0/3 sata-port empty unconfigured ok
sata1/0 sata-port disconnected unconfigured unknown
sata1/1 sata port disconnected unconfigured unknown
sata1/2 sata port empty unconfigured ok
sata1/3.15 sata-pmult connected configured ok
sata1/3.0::dev/c0t512d0 disk connected configured ok
sata1/3.1 sata-port empty unconfigured ok
sata1/3.2 sata-port empty unconfigured ok
sata1/3.3 sata-port empty unconfigured ok
usb0/1 unknown empty unconfigured ok
usb0/2 unknown empty unconfigured ok
```

See [cfgadm\(1M\)](#) for more information regarding listing of attachment points.

The receptacle state for attachment point at the SATA port have the following meanings:

empty	The SATA port is powered-on and enabled. No device presence was detected on this port.
disconnected	The SATA port is not enabled or the SATA device presence was detected but no communication with the device was established, or the port has failed.
connected	The SATA device is detected on the port the communication with the device is established.

The occupant (device attached to the SATA port) state have the following meanings:

configured	The attached SATA device is configured and ready to use by the operating system.
unconfigured	No device is attached, or the SATA device attached to the SATA port was not yet configured. To configure it, run the command “ <code>cfgadm -c configure ap_id</code> ”.

The attachment point (SATA port) condition have the following meanings:

- ok           The SATA port is powered-on and enabled, and is ready for use.
- failed       The SATA port failed. It may be disabled and/or powered-off by the system. It is unusable and its condition is unknown. It may be due to the device plugged-in.
- unknown     The SATA port is disabled and its condition is unknown.

A “state table” is the combination of an attachment point receptacle state, an occupant state, and an attachment point (SATA port) condition. The valid states are:

- empty/unconfigured/ok           The SATA port is enabled and active. No device presence was detected.
- disconnected/unconfigured/ok    The SATA port is enabled and a device presence was detected but no communications with the device was established.
- disconnected/unconfigured/unknown   The SATA Port is disabled and its condition is unknown.
- disconnected/unconfigured/failed    The SATA Port is disabled and unusable. The port was disabled by the system due to a system-detected failure.
- connected/unconfigured/ok         The SATA Port is enabled and active. A device presence was detected and the communication with a device was established. The device is not configured to be used by the OS.
- connected/configured/ok            The device is present and configured, and is ready to use by the OS.

**Options** `cfgadm` defines several types of operations besides listing (`-l`). These operations include testing, (`-t`), invoking configuration state changes, (`-c`), invoking hardware specific functions (`-x`), and obtaining configuration administration help messages (`-h`).

*-c function*

The following generic *functions* are defined for the SATA hardware specific library. For SATA port attachment point, the following configuration state change operations are supported:

`connect`

Enable (activate) the SATA port and establish the communication with an attached device. This operation implies powering-on the port if necessary.

`disconnect`

Unconfigure the attached device, if it is not already unconfigured, and disable (deactivate) the SATA port. A subsequent “connect” command enables SATA port

operation but does not bring a device to the “configured” state.

For a SATA device attached to the SATA port following state change operations are supported:

<code>configure</code>	Configure new device for use by the operating system if it is not already configured. This command also implies connect operation, if necessary.
<code>unconfigure</code>	Unconfigure the device connected to the SATA port if it is not already unconfigured.

The `configure` and `unconfigure` operations cannot be used for an attachment point where the port multiplier is connected. Port multipliers are configured and unconfigured automatically by the system. However, `configure` and `unconfigure` operations apply to all SATA devices connected to the port multiplier's device ports.

- f  
Not supported.
- h *ap\_id*  
SATA specific help can be obtained by using the help option with any SATA attachment point.
- l [-v]  
The -l option works as described in [cfgadm\(1M\)](#). When paired with the -v option, the “Information” field contains the following SATA-specific information:
  - Mfg: manufacturer string
  - Product: product string
  - No: product Serial Number
- o *hardware\_options*  
No hardware specific options are currently defined.
- s *listing\_options*  
Attachment points of class SATA can be listed by using the select suboption. See [cfgadm\(1M\)](#).
- t *ap\_id*  
Perform self-test of the SATA port, if supported by the SATA controller. If a port self-test operation is not supported by the SATA controller, an error message is issued.
- x *hardware\_function*  
Perform hardware specific function.

Some of the following commands used on the SATA ports or the SATA controller may affect any SATA devices that have been attached, as noted. `ap_id` refers to SATA port or the entire SATA controller, as noted. If the operation implies unconfiguring a device, but it cannot be unconfigured (that is, the device contains a mounted filesystem), an error

message is issued and the operation is not performed. An error message will be also issued if the SATA controller does not support specified operation.

`sata_reset_device ap_id`

Reset the SATA device attached to `ap_id` SATA port. The SATA port state does not change.

`sata_reset_port ap_id`

Reset the SATA port specified by `ap_id`. If a SATA device is attached to the port, it is also reset. This operation may be also performed on the port to which a port multiplier is connected. If a port multiplier is connected to the SATA controller port, the SATA devices attached to the port multiplier may not be reset

`sata_reset_all ap_id`

Reset SATA controller specified by the controller number part in `ap_id` and all attached devices and re-enumerate all connected devices, including port multipliers and devices connected to port multipliers' device ports.

This operations implies unconfiguring all attached devices prior to the operation. Any newly enumerated devices will be left unconfigured.

`sata_port_deactivate ap_id`

Force the deactivation of the port when all else fails. This is meant as an emergency step; use with caution.

`sata_port_activate ap_id`

Force the activation of a port. This is meant for emergency situations on a port which was deactivated to recover from errors.

`sata_port_self_test ap_id`

Perform self-test operation on the SATA controller. This operation implies unconfiguring all devices and resetting the SATA controller.

-v

Execute in verbose mode.

The following Transitions table reports the state transitions resulting from the `-c` operations and hotplugging actions:

current state	operation	possible new state
-----	-----	-----
empty/ unconfigured/ok	device plug-in	connected/unconfigured/ok, or disconnected/unconfigured/ok, or disconnected/unconfigured/failed
empty/ unconfigured/ok	<code>-c unconfigure</code>	error message, no state change
empty/		

unconfigured/ok	-c configure	error message, no state change
empty/ unconfigured/ok	-c connect	error message, no state change
empty/ unconfigured/ok	-c disconnect	disconnected/unconfigured/unknown, or disconnected/unconfigured/failed
disconnected/ unconfigured/ok	device unplug	no state change
disconnected/ unconfigured/ok	-c unconfigure	error message, no state change
disconnected/ unconfigured/ok	-c configure	error message, no state change
disconnected/ unconfigured/ok	-c connect	error message, no state change
disconnected/ unconfigured/ok	-c disconnect	error message, no state change
disconnected/ unconfigured/ unknown (no disk plugged)	-c configure	error message, state change to empty/unconfigured/ok, or disconnected/unconfigured/failed
disconnected/ unconfigured/ unknown (disk plugged)	-c configure	state change to connected/configured/ok or, connected/unconfigured/ok, or disconnected/unconfigured/failed and possible error message
disconnected/ unconfigured/ unknown	-c connect	empty/unconfigured/ok, or connected/unconfigured/ok, or disconnected/unconfigured/ok, or disconnected/unconfigured/unknown, or disconnected/unconfigured/failed
disconnected/		

unconfigured/ unknown	-c disconnect	error message, no state change
disconnected/ unconfigured/ failed	any command other than -x commands	error message, no state change
connected/ unconfigured/ok	disk unplug	error message and state: empty/unconfigured/ok, or disconnected/unconfigured/failed
connected/ unconfigured/ok	-c configure	connected/unconfigured/ok, or connected/configured/ok, or disconnected/unconfigured/ok, or disconnected/unconfigured/failed
connected/ unconfigured/ok	-c unconfigure	error message, no state change
connected/ unconfigured/ok	-c connect	error message, no state change
connected/ unconfigured/ok	-c disconnect	disconnected/unconfigured/unknown, or disconnected/unconfigured/failed
connected/ configured/ok	disk unplug	error message and state: empty/unconfigured/ok, or disconnected/unconfigured/failed
connected/ configured/ok	-c configure	error message, no state change
connected/ configured/ok	-c unconfigure	error message, if device cannot be unconfigured, no state change, or connected/unconfigured/ok, or disconnected/unconfigured/ok, or disconnected/unconfigured/failed
connected/ configured/ok	-c connect	error message, no state change

```
connected/
configured/ok -c disconnect error message, if device cannot be
 unconfigured, no state change, or
 disconnected/unconfigured/unknown, or
 disconnected/unconfigured/failed
```

**Examples** EXAMPLE 1 Configuring a Disk

The following command configures a disk attached to SATA controller 0, port 0:

```
example# cfgadm -c configure sata0/0
```

This command should be issued only when there is a device connected to the SATA port.

EXAMPLE 2 Unconfiguring a Disk

The following command unconfigures a disk attached to SATA controller 0, port 3:

```
example# cfgadm -c unconfigure sata0/3::dsk/c0t3d0
```

The device identifying string is shown when the attachment point receptacle state is “connected” and occupant state is “configured”.

EXAMPLE 3 Encountering a Mounted File System While Unconfiguring a Disk

The following command illustrates encountering a mounted file system while unconfiguring a disk:

```
example# cfgadm -c unconfigure sata1/5::dsk/c0t135d0
```

The system responds with the following:

```
cfgadm: Component system is busy, try again: failed to offline:
/devices/pci@0,0/pci8086,244e@1e/pci1095,3124@1/sd@5,0
 Resource Information

/dev/dsk/c1t5d0s0 mounted filesystem "/mnt"
```

**Files** /usr/lib/cfgadm/sata.so.1 Hardware specific library for generic SATA hot plugging.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/library

**See Also** [cfgadm\(1M\)](#), [config\\_admin\(3CFGADM\)](#), [libcfcadm\(3LIB\)](#), [attributes\(5\)](#)

**Notes** The emergency “sata\_port\_deactivate” operation is not supported on ports with attached disks containing critical partitions such as root (/), /usr, swap, or /var. The deactivate operation should not be attempted on such ports. Incorrect usage can result in a system hang and require a reboot.

Hotplugging operations are not supported by all SATA controllers.

If SATA connectors are the hot-pluggable type and the SATA controller supports hotplugging, a SATA device can be hotplugged at any time. The system detects the event and establishes the communication with the device. The device has to be configured by the explicit “`cfgadm -c configure ap_id`” command.

If the SATA connectors are the hot-pluggable type and the SATA controller supports hotplugging, unplugging a device without unconfiguring it may result in system hang or data loss. If a device is unconfigured but receptacle state is not in a disconnected state, unplugging a device from the SATA port will result in error message.

**Warnings** The connectors on some SATA devices do not conform to SATA hotplug specifications. Performing hotplug operations on such devices can cause damage to the SATA controller and/or the SATA device.

**Name** `cfgadm_sbd` – `cfgadm` commands for system board administration

**Synopsis** `cfgadm -l [-a] [-o parsable] ap_id...`  
`cfgadm -c function [-f] [-y | -n]`  
`[-o unassign | nopoweroff] [-v] ap_id...`  
`cfgadm -t [-v] ap_id...`  
`cfgadm -x [-f] [-v] function ap_id...`

**Description** The `cfgadm_sbd` plugin provides dynamic reconfiguration functionality for connecting, configuring, unconfiguring, and disconnecting class sbd system boards. It also enables you to connect or disconnect a system board from a running system without having to reboot the system.

The `cfgadm` command resides in `/usr/sbin`. See [cfgadm\(1M\)](#). The `cfgadm_sbd` plugin resides `/usr/platform/sun4u/lib/cfgadm`.

Each board slot appears as a single attachment point in the device tree. Each component appears as a dynamic attachment point. You can view the type, state, and condition of each component, and the states and condition of each board slot by using the `-a` option.

The `cfgadm` options perform differently depending on the platform. Additionally, the form of the attachment points is different depending on the platform. See the Platform Notes section for more information.

**Component Conditions** The following are the names and descriptions of the component conditions:

`failed`        The component failed testing.  
`ok`            The component is operational.  
`unknown`      The component has not been tested.

**Component States** The following is the name and description of the receptacle state for components:

`connected`    The component is connected to the board slot.

The following are the names and descriptions of the occupant states for components:

`configured`    The component is available for use by the Solaris operating environment.  
`unconfigured` The component is not available for use by the Solaris operating environment.

**Board Conditions** The following are the names and descriptions of the board conditions.

`failed`        The board failed testing.  
`ok`            The board is operational.  
`unknown`      The board has not been tested.

unusable      The board slot is unusable.

**Board States**    Inserting a board changes the receptacle state from empty to disconnected. Removing a board changes the receptacle state from disconnected to empty.

**Caution:** Removing a board that is in the connected state or that is powered on and in the disconnected state crashes the operating system and can result in permanent damage to the system.

The following are the names and descriptions of the receptacle states for boards:

connected      The board is powered on and connected to the system bus. You can view the components on a board only after it is in the connected state.

disconnected    The board is disconnected from the system bus. A board can be in the disconnected state without being powered off. However, a board must be powered off and in the disconnected state before you remove it from the slot.

empty            A board is not present.

The occupant state of a disconnected board is always unconfigured. The following table contains the names and descriptions of the occupant states for boards:

configured      At least one component on the board is configured.

unconfigured    All of the components on the board are unconfigured.

**Dynamic System Domains**    Platforms based on dynamic system domains (DSDs, referred to as domains in this document) divide the slots in the chassis into electrically isolated hardware partitions (that is, DSDs). Platforms that are not based on DSDs assign all slots to the system permanently.

A slot can be empty or populated, and it can be assigned or available to any number of domains. The number of slots available to a given domain is controlled by an available component list (ACL) that is maintained on the system controller. The ACL is not the access control list provided by the Solaris operating environment.

A slot is visible to a domain only if the slot is in the domain's ACL and if it is not assigned to another domain. An unassigned slot is visible to all domains that have the slot in their ACL. After a slot has been assigned to a domain, the slot is no longer visible to any other domain.

A slot that is visible to a domain, but not assigned, must first be assigned to the domain before any other state changing commands are applied. The assign can be done explicitly using `-x assign` or implicitly as part of a connect. A slot must be unassigned from a domain before it can be used by another domain. The unassign is always explicit, either directly using `-x unassign` or as an option to disconnect using `-o unassign`.

**State Change Functions** Functions that change the state of a board slot or a component on the board can be issued concurrently against any attachment point. Only one state changing operation is permitted at a given time. A Y in the Busy field in the state changing information indicates an operation is in progress.

The following list contains the functions that change the state:

- configure
- unconfigure
- connect
- disconnect

**Availability Change Functions** Commands that change the availability of a board can be issued concurrently against any attachment point. Only one availability change operation is permitted at a given time. These functions also change the information string in the `cfgadm -l` output. A Y in the Busy field indicates that an operation is in progress.

The following list contains the functions that change the availability:

- assign
- unassign

**Condition Change Functions** Functions that change the condition of a board slot or a component on the board can be issued concurrently against any attachment point. Only one condition change operation is permitted at a given time. These functions also change the information string in the `cfgadm -l` output. A Y in the Busy field indicates an operation is in progress.

The following list contains the functions that change the condition:

- poweron
- poweroff
- test

**Unconfigure Process** This section contains a description of the unconfigure process, and illustrates the states of source and target boards at different stages during the process of moving permanent memory.

In the following code examples, the permanent memory on board 0 must be moved to another board in the domain. Thus, board 0 is the source, and board 1 is the target.

A status change operation cannot be initiated on a board while it is marked as busy. For brevity, the CPU information has been removed from the code examples.

The process is started with the following command:

```
cfgadm -c unconfigure -y SB0::memory &
```

First, the memory on board 1 in the same address range as the permanent memory on board 0 must be deleted. During this phase, the source board, the target board, and the memory attachment points are marked as busy. You can display the status with the following command:

```
cfgadm -a -s cols=ap_id:type:r_state:o_state:busy SB0 SB1
```

Ap_Id	Type	Receptacle	Occupant	Busy
SB0	CPU	connected	configured	y
SB0::memory	memory	connected	configured	y
SB1	CPU	connected	configured	y
SB1::memory	memory	connected	configured	y

After the memory has been deleted on board 1, it is marked as unconfigured. The memory on board 0 remains configured, but it is still marked as busy, as in the following example.

Ap_Id	Type	Receptacle	Occupant	Busy
SB0	CPU	connected	configured	y
SB0::memory	memory	connected	configured	y
SB1	CPU	connected	configured	y
SB1::memory	memory	connected	unconfigured	n

The memory from board 0 is then copied to board 1. After it has been copied, the occupant state for the memory is switched. The memory on board 0 becomes unconfigured, and the memory on board 1 becomes configured. At this point in the process, only board 0 remains busy, as in the following example.

Ap_Id	Type	Receptacle	Occupant	Busy
SB0	CPU	connected	configured	y
SB0::memory	memory	connected	unconfigured	n
SB1	CPU	connected	configured	n
SB1::memory	memory	connected	configured	n

After the entire process has been completed, the memory on board 0 remains unconfigured, and the attachment points are not busy, as in the following example.

Ap_Id	Type	Receptacle	Occupant	Busy
SB0	CPU	connected	configured	n
SB0::memory	memory	connected	unconfigured	n
SB1	CPU	connected	configured	n
SB1::memory	memory	connected	configured	n

The permanent memory has been moved, and the memory on board 0 has been unconfigured. At this point, you can initiate a new state changing operation on either board.

**Platform-Specific Options** You can specify platform-specific options that follow the options interpreted by the system board plugin. All platform-specific options must be preceded by the `platform` keyword. The following example contains the general format of a command with platform-specific options:

```
command -o sbd_options,platform=platform_options
```

**Options** This man page does not include the `-v`, `-a`, `-s`, or `-h` options for the `cfgadm` command. See `cfgadm(1M)` for descriptions of those options. The following options are supported by the `cfgadm_sbd` plugin:

`-c function` Performs a state change function. You can use the following functions:

`unconfigure` Changes the occupant state to unconfigured. This function applies to system board slots and to all of the components on the system board.

The `unconfigure` function removes the CPUs from the CPU list and deletes the physical memory from the system memory pool. If any device is still in use, the `cfgadm` command fails and reports the failure to the user. You can retry the command as soon as the device is no longer busy. If a CPU is in use, you must ensure that it is off line before you proceed. See [pbind\(1M\)](#), [psradm\(1M\)](#) and [psrinfo\(1M\)](#).

The `unconfigure` function moves the physical memory to another system board before it deletes the memory from the board you want to unconfigure. Depending of the type of memory being moved, the command fails if it cannot find enough memory on another board or if it cannot find an appropriate physical memory range.

For permanent memory, the operating system must be suspended (that is, quiesced) while the memory is moved and the memory controllers are reprogrammed. If the operating system must be suspended, you will be prompted to proceed with the operation. You can use the `-y` or `-n` options to always answer yes or no respectively.

Moving memory can take several minutes to complete, depending on the amount of memory and the system load. You can monitor the progress of the operation by issuing a status command against the memory attachment point. You can also interrupt the memory operation by stopping the `cfgadm` command. The deleted memory is returned to the system memory pool.

disconnect	<p>Changes the receptacle state to disconnected. This function applies only to system board slots.</p> <p>If the occupant state is configured, the <code>disconnect</code> function attempts to unconfigure the occupant. It then powers off the system board. At this point, the board can be removed from the slot.</p> <p>This function leaves the board in the assigned state on platforms that support dynamic system domains.</p> <p>If you specify <code>-o nopoweroff</code>, the <code>disconnect</code> function leaves the board powered on. If you specify <code>-o unassign</code>, the <code>disconnect</code> function unassigns the board from the domain.</p> <p>If you unassign a board from a domain, you can assign it to another domain. However, if it is assigned to another domain, it is not available to the domain from which it was unassigned.</p>
configure	<p>Changes the occupant state to configured. This function applies to system board slots and to any components on the system board.</p> <p>If the receptacle state is disconnected, the <code>configure</code> function attempts to connect the receptacle. It then walks the tree of devices that is created by the <code>connect</code> function, and attaches the devices if necessary. Running this function configures all of the components on the board, except those that have already been configured.</p> <p>For CPUs, the <code>configure</code> function adds the CPUs to the CPU list. For memory, the <code>configure</code> function ensures that the memory is initialized then adds the memory to the system memory pool. The CPUs and the memory are ready for use after the <code>configure</code> function has been completed successfully.</p> <p>For I/O devices, you must use the <code>mount</code> and the <code>ifconfig</code> commands before the devices can be used. See <a href="#">ifconfig(1M)</a> and <a href="#">mount(1M)</a>.</p>
connect	<p>Changes the receptacle state to connected. This function applies only to system board slots.</p>

If the board slot is not assigned to the domain, the connect function attempts to assign the slot to the domain. Next, it powers on and tests the board, then it connects the board electronically to the system bus and probes the components.

After the connect function is completed successfully, you can use the -a option to view the status of the components on the board. The connect function leaves all of the components in the unconfigured state.

The assignment step applies only to platforms that support dynamic system domains.

-f Overrides software state changing constraints.

The -f option never overrides fundamental safety and availability constraints of the hardware and operating system.

-l Lists the state and condition of attachment points specified in the format controlled by the -s, -v, and -a options as specified in [cfgadm\(1M\)](#). The `cfgadm_sbd` plugin provides specific information in the info field as described below. The format of this information might be altered by the -o parsable option.

The parsable info field is composed of the following:

cpu	The cpu type displays the following information:
cpuid=#[ , #...]	Where # is a number, and represents the ID of the CPU. If more than one # is present, this CPU has multiple active virtual processors.
speed=#	Where # is a number and represents the speed of the CPU in MHz.
ecache=#	Where # is a number and represents the size of the ecache in MBytes. If the CPU has multiple active virtual processors, the ecache could either be shared among the virtual processors, or divided between them.
memory	The memory type displays the following information, as appropriate:
address=#	Where # is a number, representing the base physical address.
size=#	Where # is a number, representing the size of the memory in KBytes.

	permanent=#	Where # is a number, representing the size of permanent memory in KBytes.
	unconfigurable	An operating system setting that prevents the memory from being unconfigured.
	inter-board-interleave	The board is participating in interleaving with other boards.
	source= <i>ap_id</i>	Represents the source attachment point.
	target= <i>ap_id</i>	Represents the target attachment point.
	deleted=#	Where # is a number, representing the amount of memory that has already been deleted in KBytes.
	remaining=#	Where # is a number, representing the amount of memory to be deleted in KBytes.
io	The io type displays the following information:	
	device= <i>path</i>	Represents the physical path to the I/O component.
	referenced	The I/O component is referenced.
board	The board type displays the following boolean names. If they are not present, then the opposite applies.	
	assigned	The board is assigned to the domain.
	powered-on	The board is powered on.
	The same items appear in the <code>info</code> field in a more readable format if the <code>-o parsable</code> option is not specified.	
-o parsable	Returns the information in the <code>info</code> field as a boolean <i>name</i> or a set of <code>name=value</code> pairs, separated by a space character.	
	The <code>-o parsable</code> option can be used in conjunction with the <code>-s</code> option. See the <a href="#">cfgadm(1M)</a> man page for more information about the <code>-s</code> option.	
-t	Tests the board.	
	Before a board can be connected, it must pass the appropriate level of testing.	

Use of this option always attempts to test the board, even if it has already passed the appropriate level of testing. Testing is also performed when a -c connect state change function is issued, in which case the test step can be skipped if the board already shows an appropriate level of testing. Thus the -t option can be used to explicitly request that the board be tested.

- x *function* Performs an sbd-class function. You can use the following functions:
- assign Assigns a board to a domain.  
The receptacle state must be disconnected or empty. The board must also be listed in the domain available component list. See Dynamic System Domains.
  - unassign Unassigns a board from a domain.  
The receptacle state must be disconnected or empty. The board must also be listed in the domain available component list. See Dynamic System Domains.
  - poweron Powers the system board on.  
The receptacle state must be disconnected.
  - poweroff Powers the system board off.  
The receptacle state must be disconnected.

**Operands** The following operands are supported:

- Receptacle *ap\_id* For the Sun Fire high-end systems such as the Sun Fire 15K, the receptacle attachment point ID takes the form SBX or IOX, where X equals the slot number.  
  
The exact format depends on the platform and typically corresponds to the physical labelling on the machine. See the platform specific information in the NOTES section.
- Component *ap\_id* The component attachment point ID takes the form *component\_typeX*, where *component\_type* equals one of the component types described in “Component Types” and X equals the component number. The component number is a board-relative unit number.  
  
The above convention does not apply to memory components. Any DR action on a memory attachment point affects all of the memory on the system board.

**Examples** The following examples show user input and system output on a Sun Fire 15K system. User input, specifically references to attachment points and system output might differ on other Sun Fire systems, such as the Sun Fire midrange systems such as the 6800. Refer to the Platform Notes for specific information about using the `cfgadm_sbd` plugin on non-Sun Fire high-end models.

**EXAMPLE 1** Listing All of the System Board

```
cfgadm -a -s "select=class(sbd)"
```

Ap_Id	Type	Receptacle	Occupant	Condition
SB0	CPU	connected	configured	ok
SB0::cpu0	cpu	connected	configured	ok
SB0::memory	memory	connected	configured	ok
I01	HPCI	connected	configured	ok
I01::pci0	io	connected	configured	ok
I01::pci1	io	connected	configured	ok
SB2	CPU	disconnected	unconfigured	failed
SB3	CPU	disconnected	unconfigured	unusable
SB4	unknown	empty	unconfigured	unknown

This example demonstrates the mapping of the following conditions:

- The board in Slot 2 failed testing.
- Slot 3 is unusable; thus, you cannot hot plug a board into that slot.

**EXAMPLE 2** Listing All of the CPUs on the System Board

```
cfgadm -a -s "select=class(sbd):type(cpu)"
```

Ap_Id	Type	Receptacle	Occupant	Condition
SB0::cpu0	cpu	connected	configured	ok
SB0::cpu1	cpu	connected	configured	ok
SB0::cpu2	cpu	connected	configured	ok
SB0::cpu3	cpu	connected	configured	ok

**EXAMPLE 3** Displaying the CPU Information Field

```
cfgadm -l -s noheadings,cols=info SB0::cpu0
```

```
cpuid 16, speed 400 MHz, ecache 8 Mbytes
```

**EXAMPLE 4** Displaying the CPU Information Field in Parsable Format

```
cfgadm -l -s noheadings,cols=info -o parsable SB0::cpu0
```

```
cpuid=16 speed=400 ecache=8
```

**EXAMPLE 5** Displaying the Devices on an I/O Board

```
cfgadm -a -s noheadings,cols=ap_id:info -o parsable IO1

IO1 powered-on assigned
IO1::pci0 device=/devices/saf@0/pci@0,2000 referenced
IO1::pci1 device=/devices/saf@0/pci@1,2000 referenced
```

**EXAMPLE 6** Monitoring an Unconfigure Operation

In the following example, the memory sizes are displayed in Kbytes.

```
cfgadm -c unconfigure -y SB0::memory &
cfgadm -l -s noheadings,cols=info -o parsable SB0::memory SB1::memory

address=0x0 size=2097152 permanent=752592 target=SB1::memory
 deleted=1273680 remaining=823472
address=0x1000000 size=2097152 source=SB0::memory
```

**EXAMPLE 7** Assigning a Slot to a Domain

```
cfgadm -x assign SB2
```

**EXAMPLE 8** Unassigning a Slot from a Domain

```
cfgadm -x unassign SB3
```

**Attributes** See [attributes\(5\)](#) for a description of the following attribute:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWkvm.u
Stability	See below.

The interface stability is evolving. The output stability is unstable.

**See Also** [cfgadm\(1M\)](#), [devfsadm\(1M\)](#), [ifconfig\(1M\)](#), [mount\(1M\)](#), [pbind\(1M\)](#), [psradm\(1M\)](#), [psrinfo\(1M\)](#), [config\\_admin\(3CFGADM\)](#), [attributes\(5\)](#)

**Notes** This section contains information on how to monitor the progress of a memory delete operation. It also contains platform specific information.

**Memory Delete Monitoring** The following shell script can be used to monitor the progress of a memory delete operation.

```
cfgadm -c unconfigure -y SB0::memory &
watch_memdel SB0

#!/bin/sh
This is the watch_memdel script.
```

```

if [-z "$1"]; then
 printf "usage: %s board_id\n" `basename $0`
 exit 1
fi

board_id=$1

cfgadm_info='cfgadm -s noheadings,cols=info -o parsable'

eval `cfgadm_info $board_id::memory`

if [-z "$remaining"]; then
 echo no memory delete in progress involving $board_id
 exit 0
fi

echo deleting target $target

while true
do
 eval `cfgadm_info $board_id::memory`

 if [-n "$remaining" -a "$remaining" -ne 0]
 then
 echo $deleted KBytes deleted, $remaining KBytes remaining
 remaining=
 else
 echo memory delete is done
 exit 0
 fi
 sleep 1
done
exit 0

```

Sun Enterprise 10000 Platform Notes The following syntax is used to refer to Platform Notes attachment points on the Sun Enterprise 10000 system:

*board::component*

where *board* refers to the system board; and *component* refers to the individual component. System boards can range from SB0 (zero) to SB15. A maximum of sixteen system boards are available.

The DR 3.0 model running on a Sun Enterprise 10000 domain supports a limited subset of the functionality provided by the `cfgadm_sbd` plugin. The only supported operation is to view the status of attachment points in the domain. This corresponds to the `-l` option and all of its associated options.

Attempting to perform any other operation from the domain will result in an error that states that the operation is not supported. All operations to add or remove a system board must be initiated from the System Service Processor.

Sun Fire High-End  
System Platform Notes

The following syntax is used to refer to attachment points on the Sun Fire high-end systems:

*board* : : *component*

where *board* refers to the system board or I/O board; and *component* refers to the individual component.

Depending on the system's configuration, system boards can range from SB0 (zero) through SB17, and I/O boards can range from IO0 (IO zero) through IO17. (A maximum of eighteen system and I/O boards are available).

The -t and -x options behave differently on the Sun Fire high-end system platforms. The following list describes their behavior:

- t                      The system controller uses a CPU to test system boards by running LPOST, sequenced by the hpost command. To test I/O boards, the driver starts the testing in response to the -t option, and the test runs automatically without user intervention. The driver unconfigures a CPU and a stretch of contiguous physical memory. Then, it sends a command to the system controller to test the board. The system controller uses the CPU and memory to test the I/O board from inside of a transaction/error cage. You can only use CPUs from system boards (not MCPU boards) to test I/O boards.
- x assign | unassign      In the Sun Fire high-end system administration model, the platform administrator controls the platform hardware through the use of an available component list for each domain. This information is maintained on the system controller. Only the platform administrator can modify the available component list for a domain.  
  
The domain administrator is only allowed to assign or unassign a board if it is in the available component list for that domain. The platform administrator does not have this restriction, and can assign or unassign a board even if it is not in the available component list for a domain.

Sun Fire 15K  
Component Types

The following are the names and descriptions of the component types:

cpu	CPU
io	I/O device
memory	Memory

**Note:** An operation on a memory component affects all of the memory components on the board.

Sun Fire Midrange  
Systems Platform  
Notes

References to attachment points are slightly different on Sun Fire midrange servers such as the 6800, 4810, 4800, and 3800 systems than on the Sun Fire high-end systems. The following syntax is used to refer to attachment points on Sun Fire systems other than the Sun Fire 15K:

*N# .board : :component*

where **N#** refers to the node; *board* refers to the system board or I/O board; and *component* refers to the individual component.

Depending on the system's configuration, system boards can range from SB0 through SB5, and I/O boards can range from IB6 through IB9. (A maximum of six system and four I/O boards are available).

Sun Fire Midrange  
System Component  
Types

The following are the names and descriptions of the component types:

cpu	CPU
pci	I/O device
memory	Memory

**Note:** An operation on a memory component affects all of the memory components on the board.

**Name** `cfgadm_scsi` – SCSI hardware specific commands for `cfgadm`

**Synopsis** `/usr/sbin/cfgadm [-f] [-y | -n] [-v] [-o hardware_option]`  
`-c function ap_id...`

`/usr/sbin/cfgadm [-f] [-y | -n] [-v] [-o hardware_option]`  
`-x hardware_function ap_id...`

`/usr/sbin/cfgadm [-v] [-a] [-s listing_option] [-o hardware_option]`  
`[-l [ap_id | ap_type ... ]]`

`/usr/sbin/cfgadm [-v] [-o hardware_option] -t ap_id...`

`/usr/sbin/cfgadm [-v] [-o hardware_option] -h [ap_id]...`

**Description** The SCSI hardware specific library `/usr/lib/cfgadm/scsi.so.1` provides the functionality for SCSI hot-plugging through the [cfgadm\(1M\)](#) command. `cfgadm` operates on attachment points, which are locations in the system where hardware resources can be dynamically reconfigured. Refer to [cfgadm\(1M\)](#) for information regarding attachment points.

For SCSI hot-plugging, each SCSI controller is represented by an attachment point in the device tree. In addition, each SCSI device is represented by a dynamic attachment point. Attachment points are named through `ap_ids`. Two types of `ap_ids` are defined: logical and physical. The physical `ap_id` is based on the physical pathname, whereas the logical `ap_id` is a shorter more user-friendly name. For SCSI controllers, the logical `ap_id` is usually the corresponding disk controller number. For example, a typical logical `ap_id` would be `c0`.

SCSI devices are named relative to the controller `ap_id`. Thus if a disk device is attached to controller `c0`, its `ap_id` can be:

```
c0::dsk/c0t0d0
```

where `dsk/c0t0d0` identifies the specific device. In general, the device identifier is derived from the corresponding logical link for the device in `/dev`. For example, a SCSI tape drive logical `ap_id` could be `c0::rmt/0`. Here `c0` is the logical `ap_id` for the SCSI controller and `rmt/0` is derived from the logical link for the tape drive in `/dev/rmt`. If an identifier can not be derived from the link in `/dev`, a unique identifier will be assigned to it. For example, if the tape device has no link in `/dev`, it can be assigned an `ap_id` of the form `c0::st3` where `st3` is a unique internally generated identifier.

When a controller is capable of supporting the Solaris I/O multipathing feature (formerly known as MPxIO or the Sun StorEdge Traffic Manager [STMS]) and is enabled, the controller provides a path to a [scsi\\_vhci\(7D\)](#) multipath device. If a device attached to such controller is supported by [scsi\\_vhci\(7D\)](#) its `ap_id` can be:

```
c0::0,0
```

...where 0,0 uniquely identifies the target and logical unit information. The Type field for a path of such ap\_ids indicates if it represent a path to the `scsi_vhci(7D)` multipath devices, along with the type of device that is connected to through the path.

A simple listing of attachment points in the system will include attachment points at SCSI controllers but not SCSI devices. Use the `-a` flag to the list option (`-l`) to list SCSI devices as well. For example:

```
cfgadm -l
Ap_Id Type Receptacle Occupant Condition
c0 scsi-bus connected configured unknown
sysctrl0:slot0 cpu/mem connected configured ok
sysctrl0:slot1 sbus-upa connected configured ok
```

To list SCSI devices in addition to SCSI controllers:

```
cfgadm -al
Ap_Id Type Receptacle Occupant Condition
c0 scsi-bus connected configured unknown
c0::dsk/c0t14d0 disk connected configured unknown
c0::dsk/c0t11d0 disk connected configured unknown
c0::dsk/c0t8d0 disk connected configured unknown
c0::dsk/c0t0d0 disk connected configured unknown
c0::rmt/0 tape connected configured unknown
sysctrl0:slot0 cpu/mem connected configured ok
sysctrl0:slot1 sbus-upa connected configured ok
```

If the controller `c0` was enabled with Solaris I/O multipathing and the connected disk and tape devices are supported by Solaris I/O multipathing the output would be:

```
cfgadm -al
Ap_Id Type Receptacle Occupant Condition
c0 scsi-bus connected configured unknown
c0::11,0 disk-path connected configured unknown
c0::14,0 disk-path connected configured unknown
c0::8,0 disk-path connected configured unknown
c0::0,0 disk-path connected configured unknown
c0::a.0 tape-path connected configured unknown
sysctrl0:slot0 cpu/mem connected configured ok
sysctrl0:slot1 sbus-upa connected configured ok
```

Refer to `cfgadm(1M)` for more information regarding listing attachment points. The receptacle and occupant state for attachment points at the SCSI controller have the following meanings:

- empty
- not applicable

disconnected  
bus quiesced (I/O activity on bus is suspended)

connected  
bus active

configured  
one or more devices on the bus is configured

unconfigured  
no device on the bus is configured

The corresponding states for individual SCSI devices are:

empty  
not applicable

disconnected  
bus to which the device is attached is quiesced

connected  
bus to which device is attached is active

configured  
device or path to a multipath SCSI device is configured

unconfigured  
device or path to a multipath SCSI device is not configured

**Options** `cfgadm` defines several types of operations besides listing (`-l`). These operations include testing, (`-t`), invoking configuration state changes, (`-c`), invoking hardware specific functions (`-x`), and obtaining configuration administration help messages (`-h`).

*-c function*

The following generic commands are defined for the SCSI hardware specific library:

For SCSI controller attachment points, the following configuration state change operations are supported:

`connect`  
Unquiesce the SCSI bus.

`disconnect`  
Quiesce the bus (suspend I/O activity on bus).

Incorrect use of this command can cause the system to hang. See NOTES.

`configure`  
Configure new devices on SCSI bus.

`unconfigure`  
Unconfigure all devices connected to bus.

The following generic commands are defined for SCSI devices and for paths to multipath SCSI devices:

`configure`

Configure a specific device or a specific path to a multipath SCSI device.

`unconfigure`

Unconfigure a specific device or a specific path to a multipath SCSI device.

`-f`

When used with the `disconnect` command, forces a quiesce of the SCSI bus, if supported by hardware.

Incorrect use of this command can cause the system to hang. See NOTES.

`-h ap_id`

SCSI specific help can be obtained by using the `help` option with any SCSI attachment point.

`-o hardware_option`

No hardware specific options are currently defined.

`-s listing_option`

Attachment points of class `scsi` can be listed by using the `select` sub-option. Refer to the [cfgadm\(1M\)](#) man page for additional information.

`-t ap_id`

No test commands are available at present.

`-x hardware_function`

Some of the following commands can only be used with SCSI controllers and some only with SCSI devices.

In the following, *controller\_ap\_id* refers to an `ap_id` for a SCSI controller, for example, `c0`. *device\_ap\_id* refers to an `ap_id` for a SCSI device, for example: `c0::disk/c0dt3d0`.

The following hardware specific functions are defined:

`insert_device controller_ap_id`

Add a new device to the SCSI controller, *controller\_ap\_id*.

This command is intended for interactive use only.

`remove_device device_ap_id`

Remove device *device\_ap\_id*.

This command is intended for interactive use only.

`replace_device device_ap_id`

Remove device *device\_ap\_id* and replace it with another device of the same kind.

This command is intended for interactive use only.

```

reset_device device_ap_id
 Reset device_ap_id.

reset_bus controller_ap_id
 Reset bus controller_ap_id without resetting any devices attached to the bus.

reset_all controller_ap_id
 Reset bus controller_ap_id and all devices on the bus.

locator [=on|off] device_ap_id
 Sets or gets the hard disk locator LED, if it is provided by the platform. If the [on|off]
 suboption is not set, the state of the hard disk locator is printed.

led[=LED,mode=on|off|blink] device_ap_id
 If no sub-arguments are set, this function print a list of the current LED settings. If
 sub-arguments are set, this function sets the mode of a specific LED for a slot.

```

### Examples EXAMPLE 1 Configuring a Disk

The following command configures a disk attached to controller `c0`:

```
cfgadm -c configure c0::dsk/c0t3d0
```

### EXAMPLE 2 Unconfiguring a Disk

The following command unconfigures a disk attached to controller `c0`:

```
cfgadm -c unconfigure c0::dsk/c0t3d0
```

### EXAMPLE 3 Adding a New Device

The following command adds a new device to controller `c0`:

```
cfgadm -x insert_device c0
```

The system responds with the following:

```

Adding device to SCSI HBA: /devices/sbus@1f,0/SUNW,fas@a,88000000
This operation will suspend activity on SCSI bus c0
Continue (yes/no)?

```

Enter:

```
y
```

The system responds with the following:

```

SCSI bus quiesced successfully.
It is now safe to proceed with hotplug operation.
Enter y if operation is complete or n to abort (yes/no)?

```

Enter:

```
y
```

**EXAMPLE 4** Replacing a Device

The following command replaces a device attached to controller `c0`:

```
cfgadm -x replace_device c0::dsk/c0t3d0
```

The system responds with the following:

```
Replacing SCSI device: /devices/sbus@1f,0/SUNW,fas@e,8800000/sd@3,0
This operation will suspend activity on SCSI bus: c0
Continue (yes/no)?
```

Enter:

```
y
```

The system responds with the following:

```
SCSI bus quiesced successfully.
It is now safe to proceed with hotplug operation.
Enter y if operation is complete or n to abort (yes/no)?
```

Enter:

```
y
```

**EXAMPLE 5** Encountering a Mounted File System While Unconfiguring a Disk

The following command illustrates encountering a mounted file system while unconfiguring a disk:

```
cfgadm -c unconfigure c1::dsk/c1t0d0
```

The system responds with the following:

```
cfgadm: Component system is busy, try again: failed to offline:
/devices/pci@1f,4000/scsi@3,1/sd@1,0
 Resource Information

/dev/dsk/c1t0d0s0 mounted filesystem "/mnt"
```

**EXAMPLE 6** Displaying the Value of the Locator for a Disk

The following command displays the value of the locator for a disk. This example is specific to the SPARC Enterprise Server family:

```
cfgadm -x locator c0::dsk/c0t6d0
```

The system responds with the following:

```
Disk Led
c0t6d0 locator=on
```

**EXAMPLE 7** Setting the Value of the Locator for a Disk

The following command sets the value of the locator for a disk. This example is specific to the SPARC Enterprise Server family:

```
cfgadm -x locator=off c0::dsk/c0t6d0
```

The system does not print anything in response.

**EXAMPLE 8** Configuring a Path to a Multipath SCSI Disk

The following command configures a path connected through controller c0:

```
cfgadm -c configure c0::2,0
```

**EXAMPLE 9** Unconfiguring a Path to a Multipath SCSI Disk

The following command unconfigures a path connected through controller c0:

```
cfgadm -c unconfigure c0::2,0
```

**Files** /usr/lib/cfgadm/scsi.so.1  
hardware-specific library for generic SCSI hot-plugging

/usr/platform/SPARC-Enterprise/lib/cfgadm/scsi.so.1  
platform-specific library for generic SCSI hot-plugging

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/library

**See Also** [cfgadm\(1M\)](#), [luxadm\(1M\)](#), [config\\_admin\(3CFGADM\)](#), [libcfgadm\(3LIB\)](#), [attributes\(5\)](#), [scsi\\_vhci\(7D\)](#)

**Notes** The `disconnect` (quiesce) operation is not supported on controllers which control disks containing critical partitions such as `root (/)`, `/usr`, `swap`, or `/var`. The `disconnect` operation should not be attempted on such controllers. Incorrect usage can result in a system hang and require a reboot.

When a controller is in the disconnected (quiesced) state, there is a potential for deadlocks occurring in the system. The `disconnect` operation should be used with caution. A controller should be kept in the disconnected state for the minimum period of time required to accomplish the DR operation. The `disconnect` command is provided only to allow the replacement of the SCSI cables while the system is running. It should not be used for any other purpose. The only fix for a deadlock (if it occurs) is to reboot the system.

Hotplugging operations are not supported by all SCSI controllers.

**Warnings** The connectors on some SCSI devices do not conform to SCSI hotplug specifications. Performing hotplug operations on such devices can cause damage to the hardware on the SCSI bus. Refer to your hardware manual for additional information.

**Name** `cfgadm_sdcard` – SD/MMC hardware-specific commands for `cfgadm`

**Synopsis** `/usr/sbin/cfgadm [-f] [-y | -n] [-o hardware_options]`  
`-c function ap_id...`

`/usr/sbin/cfgadm [-f] [-y | -n] [-o hardware_options]`  
`-c hardware_function ap_id...`

`/usr/sbin/cfgadm [-v] [-a] [-s listing_options]`  
`[-o hardware_options] [-l [ap_id | ap_type...]]]`

`/usr/sbin/cfgadm [-v] [-o hardware_options] -h [ap_id...]`

**Description** The Secure Digital (SD) and MultiMediaCard (MMC) hardware specific library, `/usr/lib/cfgadm/sdcard.so.1`, provides the functionality for SD/MMC hot-plugging through the `cfgadm(1M)` command. The `cfgadm` command operates on attachment points, which are locations in the system where hardware resources can be dynamically reconfigured. See `cfgadm(1M)` for information on attachment points.

Each SD/MMC slot is represented by an attachment point in the device tree. Card devices that are connected and configured in the system are shown as attachment point name extensions. The terms "attachment point" and "SD/MMC slot" are used interchangeably throughout this manpage.

Attachment points are named through `ap_ids`. All SD/MMC attachment points consist of a string in the following form:

```
sdcardX/[S][: : dsk/cXtYd0]
```

Where:

`X` is the SD/MMC controller number.

`S` is the slot number on the controller (0 to 8).

`dev/cXtYd0` identifies the inserted memory card.

`Y` is a target number.

In general, the device identifier is derived from the corresponding logical link for the device in `/dev`. Because only one LUN (LUN 0) is supported by the SD/MMC device, the "d" component of the device string will always have number 0 (zero). For example, the logical `ap_id` of slot 4 of SD/MMC controller 2 would be `sdcard2/4`. If the SD/MMC media card is inserted in this attachment point and the device is configured, the `ap_id` might be `sdcard2/4::dsk/c2t0d0`.

The `cXtYd0` string identifying a device has one-to-one correspondence to the device attachment point.

A simple listing of attachment points in the system includes all SD/MMC device slots and attached devices. For example:

```
#cfgadm -l
Ap_Id Type Receptacle Occupant Condition
sdcards0/0::dev/c2t0d0 sdcards connected configured ok
sata0/1::dev/c0t1d0 disk connected configured ok
sata0/2::dev/c0t2d0 cd-dvd connected configured ok
sata0/3 sata-port empty unconfigured ok
usb0/1 unknown empty unconfigured ok
usb0/2 unknown empty unconfigured ok
```

See [cfgadm\(1M\)](#) for more information regarding listing of attachment points.

The receptacle state for an attachment point at the SD/MMC slot has the following meanings:

empty

The SD/MMC slot is powered-on and enabled. No device presence was detected for this slot.

disconnected

The SD/MMC slot is not enabled, or the SD/MMC device presence was detected but no communication with the device was established, or the slot has failed.

connected

The SD/MMC device is detected in the slot and device communication is established.

The occupant (device inserted in the SD/MMC slot) state has the following meanings:

configured

The attached SD/MMC device is configured and ready to use by the operating system.

unconfigured

No device is attached, or the SD/MMC device inserted in the SD/MMC slot is not yet configured. To configure, run the command **cfgadm -c configure ap\_id**.

The attachment point (SD/MMC slot) condition has the following meanings:

ok

The SD/MMC slot is powered-on, enabled and ready for use.

failed

The SD/MMC slot failed. It may be disabled and/or powered-off by the system. It is unusable and its condition is unknown. The failure may be due to the device inserted in the slot.

unknown

The SD/MMC slot is disabled and its condition is unknown.

**Options** The `cfgadm` command defines several types of operations besides listing (`-l`). These operations include invoking configuration state changes (`-c`), invoking hardware specific functions (`-x`), and obtaining configuration administration help messages (`-h`).

-c: For SD/MMC slot attachment points, the following configuration state change operations are supported:

connect

Enable (activate) the SD/MMC slot and establish the communication with an attached device. This operation implies powering-on the slot if necessary.

disconnect

Unconfigure the inserted device if it is not already unconfigured and disable (deactivate) the SD/MMC slot. A subsequent "connect" command enables SD/MMC slot operation but does not bring a device to the "configured" state.

The following state change operations are supported for an SD/MMC card inserted in to the SD/MMC slot:

configure

Configure new device for use by the operating system if it is not already configured. This command also implies connect operation, if necessary.

unconfigure

Unconfigure the device inserted in the SD/MMC slot if it is not already unconfigured.

-f : Not supported.

-h *ap\_id*: SD/MMC specific help can be obtained by using the help option with any SD/MMC attachment point.

-l [-v]: The -l option works as described in [cfgadm\(1M\)](#). When paired with the -v option, the "Information" field contains the following SD/MMC-specific information:

Mod: product model string

Rev: product revision number (major.minor)

Date: month and year of manufacture

SN: product serial number (hexadecimal)

-o *hardware\_options* — No hardware specific options are currently defined.

-s *listing\_options*: Attachment points of class SD/MMC can be listed by using the select suboption. See [cfgadm\(1M\)](#).

-t *ap\_id*: Self-test functionality. Not supported by SD/MMC slots.

-x *hardware\_function*: Perform hardware specific function. *sdcard\_reset\_slot ap\_id* indicates reset of the SD/MMC slot specified by *ap\_id*. If an SD/MMC device is inserted in the slot, it is also reset.

-v: Execute in verbose mode.

**Examples** Example 1 – Configuring an SD/MMC card:

The following command configures a card attached to SD/MMC controller 0, slot 0. It should be issued only when there is a device inserted in the SD/MMC slot.

```
cfgadm -c configure sdcard0/0
```

Example 2 – Unconfiguring an SD/MMC card:

The following command unconfigures a card inserted in SD/MMC controller 0, slot 3:

```
cfgadm -c unconfigure sdcard0/3
```

Example 3 — Encountering a mounted file system while unconfiguring a disk:

The following command illustrates encountering a mounted file system while unconfiguring a disk:

```
cfgadm -c unconfigure sdcard1/5::disk/c01t35d0
```

The system responds with the following:

```
cfgadm: Component system is busy, try again: failed to offline:
 /devices/pci@0,0/pci8086,244e@1e/pci1095,3124@1/sd@5,0
 Resource Information

 /dev/dsk/c1t5d0s0 mounted filesystem "/mnt"
```

**Files** /usr/lib/cfgadm/sdcard.so.1  
Hardware specific library for generic SD/MMC hot plugging.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/library

**See Also** [cfgadm\(1M\)](#), [config\\_admin\(3CFGADM\)](#), [libcfgadm\(3LIB\)](#), [attributes\(5\)](#), [sda\(7D\)](#), [sdcard\(7D\)](#), [sdhost\(7D\)](#)

**Notes** Under normal operation, SD/MMC media cards are automatically configured when a card is inserted. Most administrators do not find it necessary to use this command under normal use.

Removing an SD/MMC card without first unconfiguring it may result in data loss if the device is being written to when it's being removed. Devices that are mounted read-only can be safely removed at any time.

Devices that have filesystems other than [pcfs\(7FS\)](#) on them should always be explicitly unconfigured before removal.

**Name** `cfgadm_shp` – PCI Express and Standard PCI Hotplug hardware-specific commands for `cfgadm`

**Synopsis** `/usr/sbin/cfgadm [-f] [-y | -n] [-v]`  
`[-o hardware_options] -c function ap_id [ap_id]`  
`/usr/sbin/cfgadm [-f] [-y | -n] [-v]`  
`[-o hardware_options] -x hardware_function ap_id [ap_id]`  
`/usr/sbin/cfgadm [-v] [-s listing_options]`  
`[-o hardware_options] -x hardware_function ap_id [ap_id]`  
`/usr/sbin/cfgadm [-v] [-o hardware_options] -tap_id [ap_id]`  
`/usr/sbin/cfgadm [-v] [-o hardware_function] -h [ap_id | ap_type]`

**Description** The PCI Express and Standard PCI Hotplug hardware-specific library, `/usr/lib/cfgadm/shp.so.1`, provides support for hotplugging PCI Express and Standard PCI Hotplug adapter cards into the respective hotpluggable slots in a system that is hotplug-capable, through the `cfgadm` command (see [`cfgadm\(1M\)`](#)). Support for the rest PCI Hotplug adapter cards (other than PCI Express and Standard PCI Hotplug cards) are provided by `cfgadm_pci` library (see [`cfgadm\_pci\(1M\)`](#)). Hotplug administrative models between PCI Express Hotplug and Standard PCI Hotplug remain the same except where noted in this man page.

For PCI hotplug, each hotplug slot on a specific PCI bus is represented by an attachment point of that PCI bus.

An attachment point consist of two parts: a receptacle and an occupant. The receptacle under PCI hotplug is usually referred to as the physical hot pluggable slot; and the occupant is usually referred to as the PCI adapter card that plugs into the slot.

Attachment points are named through `ap_ids`. There are two types of `ap_ids`: logical and physical. The physical `ap_id` is based on the physical pathname, for example:

```
/devices/pci@7c,0/pci10de,5d@d:pcie2
```

Whereas the logical `ap_id` is a shorter, more user-friendly name, for example, `pcie2`. The `ap_type` for Hotplug PCI is `pci`.

Note that the `ap_type` is not the same as the information in the `Type` field.

**PCI Express `ap_id` Naming** For attachment points located in a PCI Express hierarchy (that is, the parent or an ancestor is a PCI Express device), including attachment points that are not PCI Express devices themselves, the naming scheme shown below is used.

Grammar:

**APID** : *absolute-slot-path*  
 Fundamental term.

*absolute-slot-path* : *slot-path*[:*slot-path*[:*slotpath* ...]]

...where *fru-id* indicates the chassis FRU, if any, containing the *slot-id*.

*fru-id* : *fru-type*[*serialid*#]

...where *fru-type* is “iob” for a PCI Express expansion chassis, followed by its serial number *serialid*#, if available

*slot-id* : *slot-name* | *device-type* *physical-slot*# | \

*nexus-driver-name* *nexus-driver-instance*.\

*device-type* *pci-device-number*

...where *slot-name* is a name assigned by the platform or hardware itself. *device-type* is either *pcie* for PCI Express devices or *pci* for PCI devices. *nexus-driver-name* is the driver name for the device component; *physical-slot*# is the hardware slot number; and *pci-device-number* is the PCI device number in standard PCI nomenclature.

First, an *absolute-slot-path* is constructed that attempts to describe the attachment point's topological location in more physically identifiable terms for the user. This *absolute-slot-path* consists of *slot-path* components each separated by a : (colon). The leaf or leftmost *slot-path* component describes the device of the attachment point itself, while its right-adjacent *slot-path* component up to the rightmost or topmost *slot-path* component describes the parent up to the root devices, respectively.

Each *slot-path* consists of a *slot-id* optionally preceded by a *fru-id*, which identifies an expansion chassis containing the device described by *slot-id* (detailed below). *fru-id* consists of *fru-type* followed by an optional *serialid*#. *fru-type* is “iob” for PCI Express expansion chassis types, while *serialid*# is either a 64-bit hexadecimal number indicating a raw serial number obtained from the expansion chassis hardware, or an upper-case, ASCII four-character sequence for a Sun-branded expansion chassis.

Each *slot-id* consists of one of three possible forms:

*slot-id* form (1)

*slot-names*

*slot-id* form (2)

*device-type* *physical-slot*#

*slot-id* form (3)

*nexus-driver-name* *nexus-driver-instance* *device-type* *pci-device-number*

The precedence of which form to select flows from the lowest form number to the highest form number, or from top to bottom as described above. If a form cannot be successfully constructed, then the next numerically higher form is attempted.

The *slot-names* in *slot-id* form (1) is taken from the `slot-names` property of the corresponding node in the device tree and is a name assigned by hardware or the platform. This format is not predefined or established.

In *slot-id* form (2), *device-type* indicates the device type of the component's slot, and is either *pcie* for PCI Express or *pci* for PCI, while *physical-slot#*, taken from the `physical-slot#` property of its corresponding device node, indicates the hardware slot number of the component.

*slot-id* form (3) is used when all other forms cannot be successfully constructed, and is considered to be the default form. *nexus-driver-name* is the component's driver name; *nexus-driver-instance* is this driver's instance; *device-type* is the same as described in form (2); *pci-device-number* is the PCI device number as described and used for device configuration cycles in standard PCI nomenclature.

In summary of the *slot-path* component, expanding the optional FRU component that might precede it, *slot-path* will consist one of the following forms in order:

- (1) [ *iob[serialid#].* ]  
*slot-names*
- (2) [ *iob[serialid#].* ]  
*device\_type physical\_slot#*
- (2) [ *iob[serialid#].* ]  
*nexus-driver-name nexus-driver-instance.*  
  
*device\_type pci-device-number*

Lastly, the final form of the actual `ap_id` name used in `cfgadm` is decided as follows, specified in order of precedence:

*ap\_id* form (1)

If the *absolute-slot-path* can fit within the fixed length limit of `cfgadm`'s `ap_id` field, then *absolute-slot-path* itself is used

*ap\_id* form (2)

(*absolute-slot-path* exceeds the `ap_id` length limit) If the last *slot\_path* component is contained within an expansion chassis, and it contains a *serialid#*, then the last *slot\_path* component is used. The requirement for a *serialid#* in this form is to ensure a globally unique `ap_id`.

*ap\_id* form (3)

(*absolute-slot-path* exceeds the `ap_id` length limit) The default form, *slot-id* form (3), of the last *slot\_path* component is used.

Whichever final `ap_id` name is used, the *absolute-slot-path* is stored in the Information (`info`) field which can be displayed using the `-s` or `-v` options. This information can be used to physically locate any `ap_ids` named using *ap\_id* form (2) or *ap\_id* form (3). The *absolute-slot-path* is transformed slightly when stored in the information field, by the replacement of a colon (`:`) with forward slashes (`/`) to more closely denote a topological context. The *absolute-slot-path* can include *slot-path* components that are not hotpluggable above the leaf or rightmost *slot-path* component up to the onboard host slot.

See the Examples section for a list of hotpluggable examples.

**Options** The following options are supported:

-c *function*

The following functions are supported for PCI hotpluggable slots:

configure

Configure the PCI device in the slot to be used by Solaris.

connect

Connect the slot to PCI bus.

disconnect

Disconnect the slot from the PCI bus.

insert

Not supported.

remove

Not supported.

unconfigure

Logically remove the PCI device's resources from the system.

-f

Not supported.

-h *ap\_id* | *ap\_type*

Display PCI hotplug-specific help message.

-l *list*

List the values of PCI Hot Plug slots.

-o *hardware\_options*

No hardware specific options are currently defined.

-s *listing\_options*

Same as the generic `cfgadm(1M)`.

-t *ap\_id*

This command is only supported on platforms that support testing capability on the slot.

-v

Execute in verbose mode.

When the -v option is used with the -l option, the `cfgadm` command outputs information about the attachment point. For attachment points located in a PCI Express hierarchy, the Information field will contain the attachment point's absolute slot path location, including any hardware- or platform-specific labeling information for each component in the slot path. Each component in the slot path will be separated by a / (forward slash). See "PCI Express `ap_id` Naming," above. For PCI Hot Plug attachment points not located in a PCI

Express hierarchy, see `cfgadm_pci(1M)`. The information in the Type field is printed with or without the `-v` option. The occupant Type field will describe the contents of the slot. There are two possible values:

*unknown*

The slot is empty. If a card is in the slot, the card is not configured or there is no driver for the device on the card.

*subclass/board*

The card in the slot is either a single-function or multi-function device.

*subclass* is a string representing the subclass code of the device, for example, SCSI, ethernet, pci-isa, and so forth. If the card is a multi-functional device, MULT will get displayed instead.

*board* is a string representing the board type of the device. For example, hp is the string used for a PCI Hot Plug adapter.

`-x hardware_function`

Perform hardware-specific function. These hardware-specific functions should not normally change the state of a receptacle or occupant.

The following *hardware\_function* is supported:

`led=[led_sub_arg],mode=[mode_sub_arg]`

Without subarguments, display a list of the current LED settings. With subarguments, set the mode of a specific LED for a slot.

Specify *led\_sub\_arg* as `fault`, `power`, `attn`, or `active`.

Specify *mode\_sub\_arg* as `on`, `off`, or `blink`.

For PCI Express, only the `power` and `attn` LEDs are valid and only the state of the `attn` LED can be changed.

Changing the state of the LED does not change the state of the receptacle or occupant. Normally, the LEDs are controlled by the hotplug controller, no user intervention is necessary. Use this command for testing purposes.

**Caution** – Changing the state of the LED can misrepresent the state of occupant or receptacle.

The following command displays the values of LEDs:

```
example# cfgadm -x led pcie2
Ap_Id Led
pcie2 power=on, fault=off, active=off, attn=off
```

The following command sets the `attn` LED to blink to indicate the location of the slot:

```
example# cfgadm -x led=attn,mode=blink pcie2
```

**Examples** EXAMPLE 1 Displaying the Value of Each Slot

The following command displays the values of each slot:

```
example# cfgadm -l
Ap_Id Type Receptacle Occupant Condition
c0 scsi-bus connected configured unknown
c1 scsi-bus connected unconfigured unknown
c2 scsi-bus connected unconfigured unknown
pcie7 etherne/hp connected configured ok
pcie8 unknown empty unconfigured unknown
pcie9 fibre/hp connected configured ok
```

## EXAMPLE 2 Replacing a Card

The following command lists all DR-capable attachment points:

```
example# cfgadm
Type Receptacle Occupant Condition
c0 scsi-bus connected configured unknown
c1 scsi-bus connected unconfigured unknown
c2 scsi-bus connected unconfigured unknown
pcie7 etherne/hp connected configured ok
pcie8 unknown empty unconfigured unknown
pcie9 fibre/hp connected configured ok
```

The following command unconfigures and electrically disconnects the card identified by pcie7:

```
example# cfgadm -c disconnect pcie7
```

The change can be verified by entering the following command:

```
example# cfgadm pcie7
Ap_Id Type Receptacle Occupant Condition
pcie7 unknown disconnected unconfigured unknown
```

At this point the card can be swapped. The following command electrically connects and configures the replacement card:

```
example# cfgadm -c configure pcie7
```

The change can be verified by entering the following command:

```
example# cfgadm pcie7
Ap_Id Type Receptacle Occupant Condition
pcie7 etherne/hp connected configured ok
```

## EXAMPLE 3 Interpreting ApIds in a PCI Express Topology

The following command shows a listing for a topology with both PCI Express and PCI attachment points in an I/O expansion chassis connected to hotpluggable slots at the host level:

**EXAMPLE 3** Interpreting ApIds in a PCI Express Topology (Continued)

```

example# cfgadm -s cols=ap_id:info
Ap_Id Information
iou#0-pci#0 Location: iou#0-pci#0
iou#0-pci#1 Location: iou#0-pci#1
iou#0-pci#1:iob.pci3 Location: iou#0-pci#1/iob.pci3
iou#0-pci#1:iob.pci4 Location: iou#0-pci#1/iob.pci4
iou#0-pci#2 Location: iou#0-pci#2
iou#0-pci#2:iob58071.pcie1 Location: iou#0-pci#2/iob58071.pcie1
iou#0-pci#2:iob58071.special Location: iou#0-pci#2/iob58071.special
iou#0-pci#3 Location: iou#0-pci#3
iou#0-pci#3:iobBADF.pcie1 Location: iou#0-pci#3/iobBADF.pcie1
iou#0-pci#3:iobBADF.pcie2 Location: iou#0-pci#3/iobBADF.pcie2
iou#0-pci#3:iobBADF.pcie3 Location: iou#0-pci#3/iobBADF.pcie3
iou#0-pci#3:iobBADF.pci1 Location: iou#0-pci#3/iobBADF.pci1
iou#0-pci#3:iobBADF.pci2 Location: iou#0-pci#3/iobBADF.pci2

```

In this example, the `iou#0-pci#[0-3]` entries represents the topmost hotpluggable slots in the system. Because the `iou#n-pci#n` form does not match any of the forms stated in the grammar specification section described above, we can infer that such a name for the base component in this hotplug topology is derived from the platform through the `slot-names` property.

The slots in the preceding output are described as follows:

**Slot `iou#0-pci#0`**

This slot is empty or its occupant is unconfigured.

**Slot `iou#0-pci#1`**

This slot contains an expansion chassis with two hotpluggable slots, `pci3` and `pci4`. `pci3` and `pci4` represent two PCI slots contained within that expansion chassis with physical slot numbers 3 and 4, respectively. The expansion chassis in this case does not have or export a serial-id.

**Slot `iou#0-pci#2`**

This slot contains a third-party expansion chassis with a hexadecimal serial-id of 58071. Within that expansion chassis are two hotpluggable slots, `pcie1` and `special`. `pcie1` represents a PCI Express slot with physical slot number 1. The slot `special` has a label which is derived from the platform, hardware, or firmware.

**Slot `iou#0-pci#3`**

This slot contains a Sun expansion chassis with an FRU identifier of BADF. This expansion chassis contains three PCI Express slots, `pcie1`, `pcie2`, and `pcie3` with physical slot numbers 1, 2, and 3, respectively; and two PCI slots, `pci1` and `pci2`, with physical slot numbers 1 and 2, respectively.

The following command shows a listing for a topology with both PCI Express and PCI attachment points in an I/O expansion chassis with connected hotpluggable and non-hotpluggable host slots:

**EXAMPLE 3** Interpreting ApIds in a PCI Express Topology (Continued)

```
example# cfgadm -s cols=ap_id:info
Ap_Id Information
Slot1 Location: Slot1
Slot2:iob4ffa56.pcie1 Location: Slot2/iob4ffa56.pcie1
Slot2:iob4ffa56.pcie2 Location: Slot2/iob4ffa56.pcie2
Slot5:iob3901.pci1 Location: Slot2/iob3901.pci1
Slot5:iob3901.pci2 Location: Slot2/iob3901.pci2
```

In this example, the host system only has one hotpluggable slot, Slot1. We can infer that Slot2 and Slot5 are not hotpluggable slots because they do not appear as attachment points themselves in `cfgadm`. However, Slot2 and Slot5 each contains a third party expansion chassis with hotpluggable slots.

The following command shows a listing for a topology with attachment points that are lacking in certain device properties:

```
example# cfgadm -s cols=ap_id:info
Ap_Id Information
px_pci7.pcie0 Location: px_pci7.pcie0
px_pci11.pcie0 Location: px_pci11.pcie0
px_pci11.pcie0:iob.pcie1 Location: px_pci11.pcie0/iob.pcie1
px_pci11.pcie0:iob.pcie2 Location: px_pci11.pcie0/iob.pcie2
px_pci11.pcie0:iob.pcie3 Location: px_pci11.pcie0/iob.pcie3
```

In this example, the host system contains two hotpluggable slots, `px_pci7.pcie0` and `px_pci11.pcie0`. In this case, it uses `slot-id` form (3) (the default form) for the base *slot-path* component in the *absolute-slot-path*, because the framework could not obtain enough information to produce other more descriptive forms of higher precedence.

Interpreting right-to-left, attachment point `px_pci7.pcie0` represents a PCI Express slot with PCI device number 0 (which does not imply a physical slot number of the same number), bound to nexus driver `px_pci`, instance 7. Likewise, attachment point `px_pci11.pcie0` represents a PCI Express slot with PCI device number 0 bound to driver instance 11 of `px_pci`.

Under `px_pci11.pcie0` is a third-party expansion chassis without a serial-id and with three hotpluggable PCI Express slots.

The following command shows a listing for a topology with attachment point paths exceeding the `ApId` field length limit:

```
example# cfgadm -s cols=ap_id:info
Ap_Id Information
pcie4 Location: pcie4
pcie4:iobSUNW.pcie1 Location: pcie4/iobSUNW.pcie1
pcie4:iobSUNW.pcie2 Location: pcie4/iobSUNW.pcie2
```

**EXAMPLE 3** Interpreting ApIds in a PCI Express Topology (Continued)

```

iob8879c3f3.pci1
 Location: pcie4/iobSUNW.pcie2/iob8879c3f3.pci1
iob8879c3f3.pci2
 Location: pcie4/iobSUNW.pcie2/iob8879c3f3.pci2
iob8879c3f3.pci3
 Location: pcie4/iobSUNW.pcie2/iob8879c3f3.pci3

```

In this example, there is only one hotpluggable slot, `pcie4` in the host. Connected under `pcie4` is a Sun expansion chassis with FRU identifier `SUNW`. Nested under PCI Express slot `pcie2` of that expansion chassis (ApId `pcie4:iobSUNW.pcie2`) lies another expansion chassis with three hotpluggable PCI slots.

Because the length of the absolute-slot-path form of:

```
pcie4/iobSUNW.pcie2/iob8879c3f3.pci1...3
```

...exceeds the ApId field length limit, and the leaf slot-path component is globally unique, `ap_id` form (2) is used, where the leaf *slot-path* component in the *absolute-slot-path* is used as the final ApId.

The following command shows a listing for a topology with attachment point paths exceeding the ApId field-length limit and lacking enough information to uniquely identify the leaf *slot-id* on its own (for example, missing the serial-id):

```

example# cfgadm -s cols=ap_id:info
Ap_Id Information
pcie4 Location: pcie4
pcie4:iob4567812345678.pcie3 Location: pcie4/iob4567812345678.pcie3
px_pci20.pcie0
 Location: pcie4/iob4567812345678.pcie3/iob.pcie1
px_pci21.pcie0
 Location: pcie4/iob4567812345678.pcie3/iob.pcie2

```

In this example, there is only one hotpluggable slot, `pcie4` in the host. Connected under `pcie4` is a third-party expansion chassis with hexadecimal serial-id `4567812345678`. Nested under the PCI Express slot `pcie3` of that expansion chassis (ApId `pcie4:iob4567812345678.pcie3`), lies another third-party expansion chassis without a serial- id and with two hotpluggable PCI Express slots.

Because the length of the absolute-slot-path form of:

```
pcie4/iob4567812345678.pcie3/iob.pcie1...2
```

exceeds the ApId field length limit, and the leaf *slot-path* component is not globally unique, `ap_id` form (3) is used. `ap_id` form (2) is where *slot-id* form (3) (the default form) of the leaf *slot-path* component in the *absolute-slot-path* is used as the final ApId.

**EXAMPLE 3** Interpreting ApIds in a PCI Express Topology *(Continued)*

The default form or slot-id form (3) of the leaf component `.../iob.pcie1` represents a PCI Express slot with device number 0, bound to driver instance 20 of `px_pci`. Likewise, the default form of the leaf component `.../iob.pcie2` represents a PCI Express slot with device number 0, bound to driver instance 21 of `px_pci`.

**Files** `/usr/lib/cfgadm/shp.so.1`  
Hardware-specific library for PCI Express and Standard PCI hotplugging.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/library
Interface Stability	Uncommitted

**See Also** [cfgadm\(1M\)](#), [cfgadm\\_pci\(1M\)](#), [hotplugd\(1M\)](#), [config\\_admin\(3CFGADM\)](#), [libcfgadm\(3LIB\)](#), [attributes\(5\)](#), [smf\(5\)](#)

**Notes** The `cfgadm_shp` library is dependent on the `hotplug` service, which is managed by [smf\(5\)](#) under FMRI:

```
svc:/system/hotplug:default
```

The service must be enabled for the `cfgadm_shp` library to function properly. See [hotplugd\(1M\)](#) for details.

**Name** `cfgadm_sysctrl` – EXX00 system board administration

**Synopsis** `/usr/sbin/cfgadm -c function [-f]`  
`[-o disable-at-boot | enable-at-boot] [-n | -y] sysctrl0:slot# ...`  
`/usr/sbin/cfgadm -x quiesce-test sysctrl0:slot#`  
`/usr/sbin/cfgadm -x insert-test | remove-test sysctrl0:slot# ...`  
`/usr/sbin/cfgadm -x set-condition-test=# sysctrl0:slot# ...`  
`/usr/sbin/cfgadm [-l]`  
`-o disable-at-boot | enable-at-boot sysctrl0:slot# ...`

**Description** The `sysctrl` hardware specific library `/usr/platform/sun4u/lib/cfgadm/sysctrl.so.1` provides dynamic reconfiguration functionality for configuring and disconnecting system boards on E6X00, E5X00, E4X00, and E3X00 systems. You can insert both I/O and CPU boards into a slot on a running system that is configured for Solaris without rebooting. You can also disconnect and remove both types of boards from a running system without rebooting.

System slots appear as attachment points in the device tree, one attachment point for each actual slot in the system chassis. If a board is not in a slot, the receptacle state is `empty`. If a board is powered-off and ready to remove, the receptacle state is `disconnected`. If a board is powered-on and is connected to the system bus, the receptacle state is `connected`.

The occupant state is `unconfigured` when the receptacle state is `empty` or `disconnected`. The occupant state is either `unconfigured` or `configured` when the receptacle state is `connected`.

In the `configured` state the devices on a board are available for use by Solaris. In the `unconfigured` state, the devices on the board are not.

Inserting a board changes the receptacle state from `empty` to `disconnected`. Removing a board changes the receptacle state from `disconnected` to `empty`. Removing a board that is in the `connected` state crashes the operating system and can result in permanent damage to the system.

**Options** Refer to [cfgadm\(1M\)](#) for a more complete description options.

The following options are supported:

<code>-c <i>function</i></code>	Perform the state change function. Specify <i>function</i> as <code>connect</code> , <code>disconnect</code> , <code>configure</code> or <code>unconfigure</code> .
<code>configure</code>	Change the occupant state to <code>configure</code> .  If the receptacle state is <code>disconnected</code> , the <code>configure</code> function first attempts to connect the receptacle. The <code>configure</code> function walks the OBP device tree created as

part of the connect function and creates the Solaris device tree nodes, attaching devices as required. For CPU/Memory boards, configure adds CPUs to the CPU list in the powered-off state. These are visible to the [psrinfo\(1M\)](#) and [psradm\(1M\)](#) commands. Two memory attachment points are published for CPU/memory boards. Use [mount\(1M\)](#) and [ifconfig\(1M\)](#) to use I/O devices on the new board. To use CPUs, use `psradm -n` to on-line the new processors. Use [cfgadm\\_ac\(1M\)](#) to test and configure the memory banks.

#### connect

Change the receptacle state to connected.

Changing the receptacle state requires that the system bus be frozen while the bus signals are connected and the board tested. The bus is frozen by running a `quiesce` operation which stops all process activity and suspends all drivers. Because the `quiesce` operation and the subsequent resume can be time consuming, and are not supported by all drivers, the `-x quiesce-test` is provided. While the system bus is frozen, the board being connected is tested by firmware. This operation takes a short time for I/O boards and a significant time for CPU/Memory boards due to CPU external cache testing. This does not provide memory testing. The user is prompted for confirmation before proceeding with the `quiesce`. Use the `-y` or `-n` option to override the prompt. The connect operation is refused if the board is marked as

	disabled-at-boot, unless either the force flag, -f, or the enable at boot flag, -o enable-at-boot, is given. See -l.
disconnect	<p>Change the receptacle state to disconnected.</p> <p>If the occupant state is configure, the disconnect function first attempts to unconfigure the occupant. The disconnect operation does not require a quiesce operation and operates quickly. The board is powered-off ready for removal.</p>
unconfigure	<p>Change the occupant state to unconfigured.</p> <p>Devices on the board are made invisible to Solaris during this process. The I/O devices on an I/O board are removed from the Solaris device tree. Any device that is still in use stops the unconfigure process and be reported as in use. The unconfigure operation must be retried after the device is made non-busy. For CPU/Memory boards, the memory must have been changed to the unconfigured state prior to issuing the board unconfigure operation. The CPUs on the board are off-lined, powered off and removed from the Solaris CPU list. CPUs that have processes bound to them cannot be off-lined. See <a href="#">psradm(1M)</a>, <a href="#">psrinfo(1M)</a>, <a href="#">pbind(1M)</a>, and <a href="#">p_online(2)</a> for more information on off-lining CPUs.</p>
-f	Force a block on connecting a board marked as disabled-at-boot in the non-volatile

- disabled-board-list variable. See *Platform Notes:Sun Enterprise 6x00/5x00/4x00/3x00 Systems*
- l List options. Supported as described in `cfgadm(1M)``cfgadm(1M)`.
- The *type* field can be one of `cpu/mem`, `mem`, `dual-sbus`, `sbus-upa`, `dual-pci`, `soc+sbus`, `soc+upa`, `disk` or `unknown`.
- The hardware-specific info field is set as follows:  
`[disabled at boot] [non-detachable] [100 MHz capable]`
- For `sbus-upa` and `soc+upa` type boards, the following additional information appears first: `[single buffered ffb|double buffered ffb|no ffb installed]` For disk type boards, the following additional information appears first: `{target: # | no disk} {target: # | no disk}`
- o disable-at-boot | enable-at-boot Modify the state of the non—volatile `disabled-board-list` variable. Use this the `-o` option in conjunction with the `-c function` or `-l` option.
- Use `-o enable-at-boot` with the `-c connect` to override a block on connecting a `disabled-at-boot` board.
- x insert-test | remove-test Perform a test.
- Specify `remove-test` to change the driver state for the specified slot from `disconnected` to `empty` without the need for physically removing the board during automated test sequences.
- Specify `insert-test` to change the driver state of a slot made to appear empty using the `remove-test` command to the `disconnected` state as if it had been inserted.
- x quiesce-test sysctrl0:slot1 Perform a test.
- Allows the quiesce operation required for board connect operations to be exercised. The execution of this test confirms that, with the current software and hardware configuration, it is possible to quiesce the

system. If a device or process cannot be quiesced, its name is printed in an error message. Any valid board attachment point can be used with this command, but since all systems have a slot1 the given form is recommended.

-x set-condition-test=#

Perform a test.

Allows the condition of a system board attachment point to be set for testing the policy logic for state change commands. The new setting is given as a number indicating one of the following condition values:

- 0 unknown
- 1 ok
- 2 failing
- 3 failed
- 4 unusable

**Operands** The following operand is supported:

sysctrl0:slot#

The attachment points for boards on EXX00 systems are published by instance 0 of the sysctrl driver (sysctrl0). The names of the attachment points are numbered from slot0 through slot15. Specify # as a number between 0 and 15, indicating the slot number. This form conforms to the logical ap\_id specification given in [cfgadm\(1M\)](#). The corresponding physical ap\_ids are listed in the FILES section.

**Name** `cfgadm_usb` – USB hardware-specific commands for `cfgadm`

**Synopsis** `/usr/sbin/cfgadm [-f] [-y | -n] [-v] -c function ap_id...`  
`/usr/sbin/cfgadm -f [-y | -n] [-v] [-o hardware_options]`  
`-x hardware_function ap_id...`  
`/usr/sbin/cfgadm -v [-a] [-s listing_option]`  
`[-l [ap_id | ap_type...]]`  
`/usr/sbin/cfgadm -v -h [ap_id]...`

**Description** The Universal Serial Bus (USB) hardware-specific library `/usr/lib/cfgadm/usb.so.1` provides the functionality for administering USB devices via the `cfgadm(1M)` command. `cfgadm` operates on attachment points. For details regarding attachment points, refer to [cfgadm\(1M\)](#).

For USB administration, the only attachment points supported are the ports of hubs attached to the USB bus.

Attachment points are named through attachment point IDs (*ap\_ids*). The USB bus is hierarchical, so the *ap\_ids* are as well. USB hubs have ports, numbered from 1 to *n*. All USB *ap\_ids* consist of a string of the following form:

```
usbN/A[.B[.C[...]]]
```

where

*N* is the *N*th USB host controller on the system,  
*A* is port #*A* on the root (top) hub.  
*B* is port #*B* of the hub plugged into port #*A* of the hub above it.  
*C* is port #*C* of the hub plugged into port #*B* of the hub above it, and so forth.

For example, the first port on the root hub of USB controller 0 (the only controller), has a logical *ap\_id*:

```
usb0/1
```

Similarly, the second port on the first external hub plugged into the first port on the root hub of the first USB controller has a logical *ap\_id*:

```
usb0/1.2
```

For example, if the *ap\_id* is `usb0/1.4.3.4`, it represents port 4 of the hub plugged into port 3 of the hub plugged into port 4 of the hub plugged into port 1 of the root hub of the first USB host controller on the system.

```
example# cfgadm -l
```

Ap_Id	Type	Receptacle	Occupant	Condition
usb0/1	USB-hub	connected	configured	ok
usb0/2	unknown	empty	unconfigured	ok

```
usb0/1.1 USB-storage connected configured ok
usb0/1.2 unknown empty unconfigured ok
usb0/1.3 unknown empty unconfigured ok
usb0/1.4 USB-device connected configured ok
```

USB2.0 chips have one EHCI host USB2.0 host controller and a number of companion USB 1.x host controllers (either OHCI or UHCI host controllers).

When a USB2.0 device has been plugged in, it shows up on the EHCI logical ports which might not have a 1 to 1 mapping to external physical port numbers on the system. When a USB1.x device is plugged in, the EHCI host controller reroutes the device to a companion host controller and the device shows up on the companion's logical port number.

The mapping of logical port numbers to physical port numbers can get quite complicated. For example:

```
% cfgadm
Ap_Id Type Receptacle Occupant Condition
c0 scsi-bus connected configured unknown
usb0/1 usb-mouse connected configured ok
usb0/2 usb-kbd connected configured ok
usb0/3 unknown empty unconfigured ok
usb0/4 usb-hub connected configured ok
usb0/4.1 unknown empty unconfigured ok
usb0/4.2 unknown empty unconfigured ok
usb0/4.3 unknown empty unconfigured ok
usb0/4.4 usb-storage connected configured ok
usb1/1 unknown empty unconfigured ok
usb1/2 unknown empty unconfigured ok
usb1/3 unknown empty unconfigured ok
usb2/1 unknown empty unconfigured ok
usb2/2 usb-device connected configured ok
usb3/1 unknown empty unconfigured ok
usb3/2 unknown empty unconfigured ok
usb3/3 unknown empty unconfigured ok
usb3/4 unknown empty unconfigured ok
usb3/5 unknown empty unconfigured ok
```

In this example usb0 is the onboard USB 1.x host controller. usb1 and usb2 are companion OHCI USB1.x host controllers and usb3 is an EHCI USB2.0 host controller.

The following table shows the somewhat confusing routing for this USB2.0 chip:

logical port number	physical port number
-----	-----
usb1/1	internal port 1
usb1/2	external port 1
usb1/3	external port 3

---

usb2/1	internal port 2
usb2/2	external port 2
usb3/1	internal port 1
usb3/2	internal port 2
usb3/3	external port 1
usb3/4	external port 2
usb3/5	external port 3

Unfortunately, the exact routing can often only be determined by experimentation.

The receptacle states for attachment points at the USB port have the following meanings:

**connected**

USB port is powered on and enabled. A USB device is plugged in to the port. The device is logically connected to the USB bus.

**disconnected**

USB port is powered on and enabled. A USB device is plugged into the port. The device has been logically disconnected from the USB bus (using the `cfgadm -c disconnect` command).

**empty**

USB port is powered on, but no device is plugged in to it.

The occupant states for devices at USB port attachment points at the USB port have the following meanings:

**configured**

The USB device at the USB port is configured and usable by Solaris.

**unconfigured**

The USB device at the USB port was explicitly off-lined using `cfgadm -c unconfigure`, or was not successfully configured for use with Solaris, for example, having no driver or a device problem.

The attachment point conditions are:

**ok**

Normal state - ready for use.

**failing**

Not used.

**failed**

Not used.

**unusable**

The user has physically removed a device while an application had the device open (there might be outstanding I/O). Users need to reinsert the same physical device and close the application properly before removing the device again. The port cannot configure other inserted devices until this is done.

If the original device cannot be reinserted into the port, see the *System Administration Guide: Advanced Administration* for instructions for clearing this attachment point condition.

**unknown**

Not used.

A USB device can be hotplugged or hotunplugged at any time, and the system detects the event and takes the appropriate action.

It is not necessary to transition a receptacle to the `disconnected` state before removing its device from the USB. However, it is not recommended to hot-remove devices currently in use (such as removable disks currently opened by a volume manager or some other application).

**Options** `cfgadm` defines several types of operations. These operations include invoking configuration state changes (`-c`), invoking hardware-specific functions (`-x`), and obtaining configuration administration help messages (`-h`).

If any of these operations fail, the device and attachment point might not be in the expected state. Use the `cfgadm -l` command to display the device's current status.

All other options have the same meaning as defined in `cfgadm(1M)`.

The following options are supported:

**-c *function***

The following generic commands are defined for the USB hardware specific library. The following configuration state change operations are supported:

**configure**

If there is a USB device plugged into the port, this command attempts to configure it and set everything up so that it is usable by Solaris. This command does an implied connect (reverse of `disconnect`) if necessary. This command accomplishes nothing, and returns an error message, if the device at that port is already configured. After successful execution of this command, the device is ready for use under Solaris.

**disconnect**

Performs an `unconfigure` on the `ap_id` (if it is not already `unconfigured`), and then transitions the receptacle to the `disconnected` state, even though a device is still plugged into the port. Issuing a `cfgadm -c configure`, or physically hotplugging the device, brings the device back to the `connected` receptacle state, and to the `configured` occupant state, assuming a driver can be found and there are no problems enumerating and configuring the device.

**unconfigure**

Makes the device plugged into the port unusable by Solaris (offline it). If successful, `cfgadm` reports this *ap\_id*'s occupant state as *unconfigured*. Issuing a `configure` to the *ap\_id* (if successful) brings its occupant back to the configured (online) condition, as it physically hotplugging the device on the port.

**-f**

Not supported.

**-h *ap\_id***

USB specific help can be obtained by using the help option with any USB attachment point.

**-l [*v*]**

The `-l` option works as described in `cfgadm(1M)`. When paired with the `-v` option, the Information field contains the following USB-specific information:

- **Mfg:** manufacturer string (`iManufacturer`)
- **Product:** product string (`iProduct`)
- **NConfigs:** total number of configurations the device supports (`bNumConfigurations`).
- **Config:** current configuration setting in decimal (configuration index, not configuration value).
- **The configuration string descriptor for the current configuration** (`iConfiguration`)

See the Universal Serial Bus specification for a description of these fields.

**-o *hardware\_options***

Hardware options are only supported for the hardware-specific command, `-x usb_config`. See the description of that command below for an explanation of the options available.

**-s *listing\_options***

Attachment points of class USB can be listed by using the `select` sub-option. See `cfgadm(1M)`.

**-x *hardware\_function***

The following hardware-specific functions are defined:

**usb\_config -o config=*n***

This command requires the mandatory `config` value to be specified using the `-o` option.

Sets the USB configuration of a multi-configuration USB device at *ap\_id* to configuration index *n*. The device is set to this configuration henceforth and this setting persists across reboots, hot-removes, and `unconfigure/configure` of the device.

Valid values of *n* range from 0 to (`Nconfigs - 1`). The device is reset by a `disconnect` followed by a `configure`. The `configure` causes the device to be configured to the new configuration setting.

If any of these steps fail, the configuration file and the device are restored to their previous state and an error message is issued.

`usb_reset`

Performs a software reset (re-enumeration) of the device. This is the equivalent of removing the device and inserting it back again. The port on the hub is power cycled if the hub supports power cycling of individual ports.

If the connected device is a hub, this function has the effect of resetting that hub and any devices down the tree of which it is the root.

If any of these steps fail, the device is restored to its previous state and an error message is issued.

State table: attachment points state versus commands:

Valid states:

<code>empty/unconfigured</code>	→ no device connected
<code>disconnected/unconfigured</code>	→ logically disconnected, unavailable, devinfo node removed, device physically connected
<code>connected/unconfigured</code>	→ logically connected, unavailable, devinfo node present
<code>connected/configured</code>	→ connected, available

The table below clarifies the state transitions resulting from actions or commands:

current state	operation	new state
-----	-----	-----
<code>empty/ unconfigured:</code>	<code>device plugged in:</code>	<code>connected/configured or connected/unconfigured (if enumeration failed)</code>
	<code>device removed:</code>	<code>n/a</code>
	<code>cfgadm -c unconfigure:</code>	<code>empty/unconfigured</code>
	<code>cfgadm -c configure:</code>	<code>empty/unconfigured</code>
	<code>cfgadm -c disconnect:</code>	<code>empty/unconfigured (no-op and error)</code>
<code>disconnected/ unconfigured:</code>	<code>device plugged in:</code>	<code>n/a</code>
	<code>device removed:</code>	<code>empty/unconfigured</code>
	<code>cfgadm -c unconfigure:</code>	<code>disconnected/unconfigured</code>
	<code>cfgadm -c configure:</code>	<code>connected/configured, or connected/unconfigured</code>

```

 (if reenumeration failed)
 cfgadm -c disconnect: disconnected/unconfigured

connected/unconfigured:
 device plugged in: n/a
 device removed: empty/unconfigured
 cfgadm -c unconfigure: connected/unconfigured
 cfgadm -c configure: connected/configured, or
 connected/unconfigured
 (if reenumeration failed)
 cfgadm -c disconnect: disconnected/unconfigured

connected/configured:
 device plugged in: n/a
 device removed: empty/unconfigured or
 connected/configured,
 but with ap condition
 'unusable' if device
 was open when removed
 cfgadm -c unconfigure: connected/unconfigured
 cfgadm -c configure: connected/configured
 cfgadm -c disconnect: disconnected/unconfigured

```

### Examples EXAMPLE 1 Listing the Status of All USB Devices

The following command lists the status of all USB devices on the system:

```

cfgadm
Ap_Id Type Receptacle Occupant Condition
usb0/1 USB-hub connected configured ok
usb0/2 unknown empty unconfigured ok
usb0/1.1 USB-storage connected configured ok
usb0/1.2 unknown empty unconfigured ok
usb0/1.3 unknown empty unconfigured ok
usb0/1.4 USB-device connected configured ok

```

Notice that `cfgadm` treats the USB-device device at `ap_id` `usb0/1.4` as a single unit, since it cannot currently control individual interfaces.

### EXAMPLE 2 Listing the Status of a Port with No Device Plugged In

The following command lists the status of a port with no device plugged in:

```

example# cfgadm -l usb0/1.3
Ap_Id Type Receptacle Occupant Condition
usb0/1.3 unknown empty unconfigured ok

```

### EXAMPLE 3 Listing the Status of the Same Port with a Device Plugged In

The following command lists the status of the same port after physically plugging in a device that configures without problems:

**EXAMPLE 3** Listing the Status of the Same Port with a Device Plugged In *(Continued)*

```
example# cfgadm -l usb0/1.3
Ap_Id Type Receptacle Occupant Condition
usb0/1.3 USB-hub connected configured ok
```

**EXAMPLE 4** Unconfiguring an Existing USB Device

The following command unconfigures the USB device attached to `usb0/1.3`, then displays the status of the `ap_id`:

```
example# cfgadm -c unconfigure usb0/1.3
Unconfigure the device: /devices/pci@0,0/pci8086,7112@7,2/hub@2:2.3
This operation suspends activity on the USB device
Continue (yes/no)?
```

Enter:

**y**

```
example# cfgadm -l usb0/1.3
Ap_Id Type Receptacle Occupant Condition
usb0/1.3 unknown connected unconfigured ok
```

**EXAMPLE 5** Unconfiguring and Logically Disconnecting an Existing USB Device

The following command unconfigures and logically disconnects a USB device attached to `usb0/1.3`:

```
example# cfgadm -c disconnect usb0/1.3
Disconnect the device: /devices/pci@0,0/pci8086,7112@7,2/hub@2:2.3
This operation suspends activity on the USB device
Continue (yes/no)?
```

Enter:

**y**

```
example# cfgadm -l usb0/1.3
Ap_Id Type Receptacle Occupant Condition
usb0/1.3 unknown disconnected unconfigured ok
```

A `disconnect` implies that `cfgadm` does an `unconfigure` first. The receptacle status now shows `disconnected`, even though the device is still physically connected. In this case, a physical hotplug or using the `cfgadm -c configure` on the `ap_id` brings it back on-line.

**EXAMPLE 6** Configuring a Previously Unconfigured USB Device

The following command configures a USB device that was previously attached to `usb0/1.3`:

**EXAMPLE 6** Configuring a Previously Unconfigured USB Device *(Continued)*

```
example # cfgadm -yc configure usb0/1.3
example# cfgadm -l usb0/1.3
Ap_Id Type Receptacle Occupant Condition
usb0/1.3 unknown connected configured ok
```

**EXAMPLE 7** Resetting a USB Device

The following command resets a USB device:

```
example# cfgadm -x usb_reset usb0/1.3
Reset the device: /devices/pci@0,0/pci8086,7112@7,2/hub@2:2.3
This operation suspends activity on the USB device
Continue (yes/no)?
```

Enter:

**y**

**EXAMPLE 8** Displaying Detailed Information About a USB Device

The following command displays detailed information about a USB device. This device shows the following USB-specific information in the 'Information' field:

- Manufacturer string: Iomega
- Product string: USB Zip 250
- Number of configurations supported: 1
- Configuration currently active: 0
- Configuration string descriptor for configuration 0: Default

```
example# cfgadm -lv usb0/1.5
Ap_Id Receptacle Occupant Condition Information
When Type Busy Phys_Id
usb0/1.5 connected configured ok Mfg:"Io
mega" Product:"USB Zip 250" NConfigs:1 Config:0 : Default
```

```
example# cfgadm -l -s "cols=ap_id:info" usb0/1.5
Ap_Id Information
usb0/1.5 Mfg:"Iomega" Product:"USB Zip 250"
NConfigs:1 Config:0 : Default
```

**EXAMPLE 9** Displaying Detailed Information About All USB Devices

The following command displays detailed information about all USB devices on the system:

```
example# cfgadm -l -s "select=class(usb),cols=ap_id:info"
Ap_Id Information
usb0/1 Mfg:<undefined> Product:<undefined>
NConfigs:1 Config:0 <no cfg str descr>
usb0/2
```

**EXAMPLE 9** Displaying Detailed Information About All USB Devices (Continued)

```

usb0/1.1 Mfg:<undefined> Product:<undefined>
NConfigs:1 Config:0 <no cfg str descr>
usb0/1.2
usb0/1.3
usb0/1.4 Mfg:"Wizard" Product:"Modem/ISDN"
NConfigs:3 Config:1 : V.90 Analog Modem
usb0/1.5 Mfg:"Iomega" Product:"USB Zip 250"
NConfigs:1 Config:0 : Default
usb0/1.6 Mfg:"SOLID YEAR" Product:"SOLID YEAR
USB"NConfigs:1 Config:0 <no cfg str descr>
usb0/1.7

```

Lines containing only an `ap_id` are empty ports. These can be filtered out. This example only lists USB `ap_ids` with connected devices, and information about those devices.

```

example# cfdm -l -s "select=class(usb),cols=ap_id:info" | grep Mfg
usb0/1 Mfg:<undefined> Product:<undefined>
NConfigs:1 Config:0 <no cfg str descr>
usb0/1.1 Mfg:<undefined> Product:<undefined>
NConfigs:1 Config:0 <no cfg str descr>
usb0/1.4 Mfg:"Wizard" Product:"Modem/ISDN"
NConfigs:3 Config:1 : V.90 Analog Modem
usb0/1.5 Mfg:"Iomega" Product:"USB Zip 250"
NConfigs:1 Config:0 : Default
usb0/1.6 Mfg:"SOLID YEAR" Product:"SOLID YEAR USB"
Config:0 <no cfg str descr>

```

**EXAMPLE 10** Listing Information About a Multi-configuration USB Device

The following example lists information about a multi-configuration USB device.

Notice the `NConfigs` field: the configurations available for this device are 0, 1, and 2 (0 to  $(NConfigs-1)$ ).

```

example# cfdm -l -s "cols=ap_id:info" usb0/1.4
Ap_Id Information
usb0/1.4 Mfg:"Wizard" Product:"Modem/ISDN"
NConfigs:3 Config:1 V.90 Analog Modem"

```

**EXAMPLE 11** Setting the Current Configuration of a Multi-configuration USB Device

The following example sets the current configuration of a multi-configuration USB device:

```

example# cfdm -o config=2 -x usb_config usb0/1.4
Setting the device: /devices/pci@1f,2000/usb@1/device@3
to USB configuration 2
This operation suspends activity on the USB device
Continue (yes/no)?

```

**EXAMPLE 11** Setting the Current Configuration of a Multi-configuration USB Device (Continued)

Enter:

**y**

USB configuration changed successfully.

The device path should be checked to ensure that the right instance of a device is being referred to, in the case where multiple devices of the exact same type are on the same bus. This information is available in the 'Information' field.

**Files** /usr/lib/cfgadm/usb.so.1  
Hardware specific library for generic USB device administration

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/library

**See Also** [cfgadm\(1M\)](#), [config\\_admin\(3CFGADM\)](#), [attributes\(5\)](#), [scca2usb\(7D\)](#), [usba\(7D\)](#)

Universal Serial Bus 1.1 Specification ([www.usb.org](http://www.usb.org))

*System Administration Guide: Advanced Administration*

**Notes** [cfgadm\(1M\)](#) can not unconfigure, disconnect, reset, or change the configuration of any USB device currently opened by any application. These operations also fail on a hub if a device in its hierarchy is opened by an application. See [scca2usb\(7D\)](#) for unconfiguring a USB mass-storage device that is currently in use.

Only super-users can execute any functions on an attachment point. However, one need not be a super-user to list the attachment points.

**Name** cfsadmin – administer disk space used for caching file systems with the Cache File-System (CacheFS)

**Synopsis** *cfsadmin -c [-o cacheFS-parameters] cache\_directory*  
*cfsadmin -d {cache\_ID | all} cache\_directory*  
*cfsadmin -l cache\_directory*  
*cfsadmin -s {mntpt1 ....} | all*  
*cfsadmin -u [-o cacheFS-parameters] cache\_directory*

**Description** The `cfsadmin` command provides the following functions:

- cache creation
- deletion of cached file systems
- listing of cache contents and statistics
- resource parameter adjustment when the file system is unmounted.

You must always supply an option for `cfsadmin`. For each form of the command except `-s`, you must specify a cache directory, that is, the directory under which the cache is actually stored. A path name in the front file system identifies the cache directory. For the `-s` form of the command, you must specify a mount point.

You can specify a cache ID when you mount a file system with CacheFS, or you can let the system generate one for you. The `-l` option includes the cache ID in its listing of information. You must know the cache ID to delete a cached file system.

**Options** The following options are supported:

- |                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>-c [-o cacheFS-parameters] cache_directory</i> | Create a cache under the directory specified by <i>cache_directory</i> . This directory must not exist prior to cache creation.                                                                                                                                                                                                                                                                                                                              |
| <i>-d { cache_ID   all } cache_directory</i>      | Remove the file system whose cache ID you specify and release its resources, or remove all file systems in the cache by specifying <code>all</code> . After deleting a file system from the cache, you must run the <a href="#">fscck_cacheofs(1M)</a> command to correct the resource counts for the cache.<br><br>As indicated by the syntax above, you must supply either a <i>cache_ID</i> or <code>all</code> , in addition to <i>cache_directory</i> . |
| <i>-l cache_directory</i>                         | List file systems stored in the specified cache, as well as statistics about them. Each cached                                                                                                                                                                                                                                                                                                                                                               |

<code>-s { <i>mntpt1 ...</i> }   all</code>	file system is listed by cache ID. The statistics document resource utilization and cache resource parameters.
<code>-u [ -o <i>cacheFS-parameters</i> ] <i>cache_directory</i></code>	Request a consistency check on the specified file system (or all cache fs mounted file systems). The <code>-s</code> option only works if the cache file system was mounted with <code>demandconst</code> enabled (see <a href="#">mount_cacheFs(1M)</a> ). Each file in the specified cache file system is checked for consistency with its corresponding file in the back file system. Note that the consistency check is performed file by file as files are accessed. If no files are accessed, no checks are performed. Use of this option does not result in a sudden "storm" of consistency checks.  As indicated by the syntax above, you must supply one or more mount points, or <code>all</code> .
CacheFS Resource Parameters	<p>You can specify the following CacheFS resource parameters as arguments to the <code>-o</code> option. Separate multiple parameters with commas.</p> <p><code>maxblocks=<i>n</i></code>      Maximum amount of storage space that CacheFS can use, expressed as a percentage of the total number of blocks in the front file system. If CacheFS does not have exclusive use of the front file system, there is no guarantee that all the space the <code>maxblocks</code> parameter allows is available. The default is <code>90</code>.</p> <p><code>minblocks=<i>n</i></code>      Minimum amount of storage space, expressed as a percentage of the total number of blocks in the front file system, that CacheFS is always allowed to use without limitation by its internal control mechanisms. If</p>

CacheFS does not have exclusive use of the front file system, there is no guarantee that all the space the `minblocks` parameter attempts to reserve is available. The default is 0.

`threshblocks=n`

A percentage of the total blocks in the front file system beyond which CacheFS cannot claim resources once its block usage has reached the level specified by `minblocks`. The default is 85.

`maxfiles=n`

Maximum number of files that CacheFS can use, expressed as a percentage of the total number of inodes in the front file system. If CacheFS does not have exclusive use of the front file system, there is no guarantee that all the inodes the `maxfiles` parameter allows is available. The default is 90.

`minfiles=n`

Minimum number of files, expressed as a percentage of the total number of inodes in the front file system, that CacheFS is always allowed to use without limitation by its internal control mechanisms. If CacheFS does not have exclusive use of the front file system, there is no guarantee that all the inodes the `minfiles` parameter attempts to reserve is available. The default is 0.

`threshfiles=n`

A percentage of the total inodes in the front file system beyond which CacheFS cannot claim inodes once its usage has reached the level specified by `minfiles`. The default is 85.

`maxfilesize=n`

Largest file size, expressed in megabytes, that CacheFS is allowed to cache. The default is 3. You cannot decrease the block or inode allotment for a cache. To decrease the size of a cache, you must remove it and create it again with different parameters.

Currently `maxfilesize` is ignored by `cacheofs`, therefore, setting it has no effect.

**Operands** `cache_directory`

The directory under which the cache is actually stored.

`mntpt1`

The directory where the CacheFS is mounted.

**Usage** See [largefile\(5\)](#) for the description of the behavior of `cfsadmin` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**Examples** **EXAMPLE 1** Creating a Cache Directory

The following example creates a cache directory named `/cache`:

```
example# cfsadmin -c /cache
```

**EXAMPLE 2** Creating a Cache

The following example creates a cache named `/cache1` that can claim a maximum of 60 percent of the blocks in the front file system, can use 40 percent of the front file system blocks without interference by CacheFS internal control mechanisms, and has a threshold value of 50 percent. The threshold value indicates that after CacheFS reaches its guaranteed minimum, it cannot claim more space if 50 percent of the blocks in the front file system are already used.

```
example# cfsadmin -c -o maxblocks=60,minblocks=40,threshblocks=50 /cache1
```

**EXAMPLE 3** Changing the `maxfilesize` Parameter

The following example changes the `maxfilesize` parameter for the cache directory `/cache2` to 2 megabytes:

```
example# cfsadmin -u -o maxfilesize=2 /cache2
```

**EXAMPLE 4** Listing the Contents of a Cache Directory

The following example lists the contents of a cache directory named `/cache3` and provides statistics about resource utilization:

```
example# cfsadmin -l /cache3
```

**EXAMPLE 5** Removing a Cached File System

The following example removes the cached file system with cache ID 23 from the cache directory `/cache3` and frees its resources (the cache ID is part of the information returned by `cfsadmin -l`):

```
example# cfsadmin -d 23 /cache3
```

**EXAMPLE 6** Removing All Cached File Systems

The following example removes all cached file systems from the cache directory `/cache3`:

```
example# cfsadmin -d all /cache3
```

**EXAMPLE 7** Checking for Consistency in File Systems

The following example checks for consistency all file systems mounted with `demandconst` enabled. No errors are reported if no `demandconst` file systems were found.

```
example# cfsadmin -s all
```

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [cachefslog\(1M\)](#), [cachefsstat\(1M\)](#), [cachefswssize\(1M\)](#), [fsock\\_cachefs\(1M\)](#), [mount\\_cachefs\(1M\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

**Name** chat – automated conversational exchange tool

**Synopsis** chat [*options*] *script*

**Description** The chat program implements a conversational text-based exchange between the computer and any serial device, including (but not limited to) a modem, an ISDN TA, and the remote peer itself, establishing a connection between the Point-To-Point Protocol daemon (pppd) and the remote pppd process.

**Options** The chat command supports the following options:

- f <*chat file*> Read the chat script from the chat file. This option is mutually exclusive with the chat script parameters. You must have read access to use the file. Multiple lines are permitted in the file. Use the space or horizontal tab characters to separate the strings.
- t <*timeout*> Set the timeout for the expected string to be received. If the string is not received within the time limit, the reply string is not sent. If specified, a 'subexpect' (alternate reply) string can be sent. Otherwise, if no alternate reply strings remain, the chat script fails.. A failed script will cause the chat program to terminate with a non-zero error code.
- r <*report file*> Set the file for output of the report strings. If you use the keyword REPORT, the resulting strings are written to this file. If the -r option is not used and you use the REPORT keyword, the stderr file is used for the report strings.
- e Start with the echo option turned on. You turn echo on or off at specific points in the chat script using the ECHO keyword. When echoing is enabled, all output from the modem is echoed to stderr.
- E Enables environment variable substitution within chat scripts using the standard *\$xxx* syntax.
- v Request that the chat script execute in a verbose mode. The chat program logs the execution state of the chat script as well as all text received from the modem and output strings sent to the modem. The default is to log through [syslog\(3C\)](#) with facility `local2`; the logging method is alterable using the -S and -s options.
- V Request that the chat script be executed in a stderr verbose mode. The chat program logs all text received from the modem and output strings sent to the modem to stderr. stderr is usually the local console at the station running the chat or pppd program.
- s Use stderr. Log messages from -v and error messages are sent to stderr.

- S Do not use syslog. By default, error messages are set to syslog. This option prevents log messages from -v and error messages from being sent to syslog.
- T <*phone number*> Pass in an arbitrary string (usually a telephone number) that will be substituted for the \T substitution metacharacter in a send string.
- U <*phone number 2*> Pass in a second string (usually a telephone number) that will be substituted for the \U substitution metacharacter in a send string. This is useful when dialing an ISDN terminal adapter that requires two numbers.
- script If the script is not specified in a file with the -f option, the script is included as parameters to the chat program.

### Extended Description

Chat Script The chat script defines communications. A script consists of one or more "expect-send" pairs of strings separated by spaces, with an optional "subexpect-subsend" string pair, separated by a dash (as in the following example:)

```
ogin:-BREAK-ogin: ppp ssword: hello2u2
```

The example indicates that the chat program should expect the string "ogin:". If it fails to receive a login prompt within the time interval allotted, it sends a break sequence to the remote and then expects the string "ogin:". If the first "ogin:" is received, the break sequence is not generated.

Upon receiving the login prompt, the chat program sends the string "ppp" and then expects the prompt "ssword:". When the password prompt is received, it sends the password hello2u2.

A carriage return is normally sent following the reply string. It is not expected in the "expect" string unless it is specifically requested by using the \r character sequence.

The expect sequence should contain only what is needed to identify the received data. Because it's stored on a disk file, it should not contain variable information. Generally it is not acceptable to look for time strings, network identification strings, or other variable pieces of data as an expect string.

To correct for characters that are corrupted during the initial sequence, look for the string "ogin:" rather than "login:". The leading "l" character may be received in error, creating problems in finding the string. For this reason, scripts look for "ogin:" rather than "login:" and "ssword:" rather than "password:".

An example of a simple script follows:

```
ogin: ppp ssword: hello2u2
```

The example can be interpreted as: expect ogin:, send ppp, expect ...ssword:, send hello2u2.

When login to a remote peer is necessary, simple scripts are rare. At minimum, you should include sub-expect sequences in case the original string is not received. For example, consider the following script:

```
ogin:--ogin: ppp ssword: hello2u2
```

This script is more effective than the simple one used earlier. The string looks for the same login prompt; however, if one is not received, a single return sequence is sent and then the script looks for login: again. If line noise obscures the first login prompt, send the empty line to generate a login prompt again.

**Comments** Comments can be embedded in the chat script. Comment lines are ignored by the chat program. A comment starts with the hash (“#”) character in column one. If a # character is expected as the first character of the expect sequence, quote the expect string. If you want to wait for a prompt that starts with a # character, write something like this:

```
Now wait for the prompt and send logout string
'# ' logout
```

**Sending Data From A File** If the string to send begins with an at sign (“@”), the remainder of the string is interpreted as the name of the file that contains the string. If the last character of the data read is a newline, it is removed. The file can be a named pipe (or fifo) instead of a regular file. This enables chat to communicate with another program, for example, a program to prompt the user and receive a password typed in.

**Abort** Many modems report the status of a call as a string. These status strings are often “CONNECTED” or “NO CARRIER” or “BUSY.” If the modem fails to connect to the remote, you can terminate the script. Abort strings may be specified in the script using the ABORT sequence. For example:

```
ABORT BUSY ABORT 'NO CARRIER' '' ATZ OK ATDT5551212 CONNECT
```

This sequence expects nothing and sends the string ATZ. The expected response is the string OK. When OK is received, the string ATDT5551212 dials the telephone. The expected string is CONNECT. If CONNECT is received, the remainder of the script is executed. When the modem finds a busy telephone, it sends the string BUSY, causing the string to match the abort character sequence. The script fails because it found a match to the abort string. If the NO CARRIER string is received, it aborts for the same reason.

**Clr\_Abort** The CLR\_ABORT sequence clears previously set ABORT strings. ABORT strings are kept in an array of a pre-determined size; CLR\_ABORT reclaims the space for cleared entries, enabling new strings to use that space.

Say The SAY string enables the script to send strings to a user at a terminal via standard error. If chat is being run by pppd and pppd is running as a daemon (detached from its controlling terminal), standard error is normally redirected to the `/etc/ppp/connect-errors` file.

SAY strings must be enclosed in single or double quotes. If carriage return and line feed are required for the output, you must explicitly add them to your string.

The SAY string can provide progress messages to users even with "ECHO OFF." For example, add a line similar to the following to the script:

```
ABORT BUSY
ECHO OFF
SAY "Dialing your ISP...\n"
'' ATDT5551212
TIMEOUT 120
SAY "Waiting up to 2 minutes for connection ..."
CONNECT ''
SAY "Connected, now logging in ...\n"
ogin: account
ssword: pass
$ \c
SAY "Logged in OK ... \n"
```

This sequence hides script detail while presenting the SAY string to the user. In this case, you will see:

```
Dialing your ISP...
Waiting up to 2 minutes for connection...Connected, now logging in...
Logged in OK ...
```

Report REPORT is similar to the ABORT string. With REPORT, however, strings and all characters to the next control character (such as a carriage return), are written to the report file.

REPORT strings can be used to isolate a modem's transmission rate from its CONNECT string and return the value to the chat user. Analysis of the REPORT string logic occurs in conjunction with other string processing, such as looking for the expect string. It's possible to use the same string for a REPORT and ABORT sequence, but probably not useful.

Report strings may be specified in the script using the REPORT sequence. For example:

```
REPORT CONNECT
ABORT BUSY
ATDT5551212 CONNECT
ogin: account
```

The above sequence expects nothing, then sends the string ATDT5551212 to dial the telephone. The expected string is CONNECT. If CONNECT is received, the remainder of the

script is executed. In addition, the program writes the string CONNECT to the report file (specified by -r) in addition to any characters that follow.

**Clr\_Report** CLR\_REPORT clears previously set REPORT strings. REPORT strings are kept in an array of a pre-determined size; CLR\_REPORT reclaims the space for cleared entries so that new strings can use that space.

**Echo** ECHO determines if modem output is echoed to `stderr`. This option may be set with the `-e` option, but can also be controlled by the ECHO keyword. The "expect-send" pair ECHO ON enables echoing, and ECHO OFF disables it. With ECHO, you can select which parts of the conversation should be visible. In the following script:

```
ABORT 'BUSY'
ABORT 'NO CARRIER'
"" AT&F
OK\r\n ATD1234567
\r\n \c
ECHO ON
CONNECT \c
ogin: account
```

All output resulting from modem configuration and dialing is not visible, but output is echoed beginning with the CONNECT (or BUSY) message.

**Hangup** The HANGUP option determines if a modem hangup is considered as an error. HANGUP is useful for dialing systems that hang up and call your system back. HANGUP can be ON or OFF. When HANGUP is set to OFF and the modem hangs up (for example, following the first stage of logging in to a callback system), chat continues running the script (for example, waiting for the incoming call and second stage login prompt). When the incoming call is connected, use the HANGUP ON string to reinstall normal hang up signal behavior. An example of a simple script follows:

```
ABORT 'BUSY'
"" AT&F
OK\r\n ATD1234567
\r\n \c
CONNECT \c
'Callback login:' call_back_ID
HANGUP OFF
ABORT "Bad Login"
'Callback Password:' Call_back_password
TIMEOUT 120
CONNECT \c
HANGUP ON
ABORT "NO CARRIER"
ogin:--BREAK--ogin: real_account
```

**Timeout** The initial timeout value is 45 seconds. Use the `-t` parameter to change the initial timeout value.

To change the timeout value for the next expect string, the following example can be used:

```
''AT&F
OK ATDT5551212
CONNECT \c
TIMEOUT 10
ogin:--ogin: username
TIMEOUT 5
assword: hello2u2
```

The example changes the timeout to ten seconds when it expects the login: prompt. The timeout is changed to five seconds when it looks for the password prompt.

Once changed, the timeout value remains in effect until it is changed again.

**EOT** The EOT special reply string instructs the chat program to send an EOT character to the remote. This is equivalent to using `^D\c` as the reply string. The EOT string normally indicates the end-of-file character sequence. A return character is not sent following the EOT. The EOT sequence can be embedded into the send string using the sequence `^D`.

**BREAK** The BREAK special reply string sends a break condition. The break is a special transmitter signal. Many UNIX systems handle break by cycling through available bit rates, and sending break is often needed when the remote system does not support autobaud. BREAK is equivalent to using `\K\c` as the reply string. You embed the break sequence into the send string using the `\K` sequence.

**Escape Sequences** Expect and reply strings can contain escape sequences. Reply strings accept all escape sequences, while expect strings accept most sequences. A list of escape sequences is presented below. Sequences that are not accepted by expect strings are indicated.

`''` Expects or sends a null string. If you send a null string, chat sends the return character. If you expect a null string, chat proceeds to the reply string without waiting. This sequence can be a pair of apostrophes or quote mark characters.

`\b` Represents a backspace character.

`\c` Suppresses the newline at the end of the reply string. This is the only method to send a string without a trailing return character. This sequence must be at the end of the send string. For example, the sequence `hello\c` will simply send the characters h, e, l, l, o. (Not valid in expect.)

`\d` Delay for one second. The program uses `sleep(1)` which delays to a maximum of one second. (Not valid in expect.)

`\K` Insert a BREAK. (Not valid in expect.)

---

<code>\n</code>	Send a newline or linefeed character.
<code>\N</code>	Send a null character. The same sequence may be represented by <code>\0</code> . (Not valid in expect.)
<code>\p</code>	Pause for 1/10th of a second. (Not valid in expect.)
<code>\q</code>	Suppress writing the string to syslog. The string <code>?????</code> is written to the log in its place. (Not valid in expect.)
<code>\r</code>	Send or expect a carriage return.
<code>\s</code>	Represents a space character in the string. Can be used when it is not desirable to quote the strings which contains spaces. The sequence <code>'HI TIM'</code> and <code>HI\sTIM</code> are the same.
<code>\t</code>	Send or expect a tab character.
<code>\T</code>	Send the phone number string as specified with the <code>-T</code> option. (Not valid in expect.)
<code>\U</code>	Send the phone number 2 string as specified with the <code>-U</code> option. (Not valid in expect.)
<code>\\</code>	Send or expect a backslash character.
<code>\ddd</code>	Collapse the octal digits ( <code>ddd</code> ) into a single ASCII character and send that character. ( <code>\000</code> is not valid in an expect string.)
<code>^C</code>	Substitute the sequence with the control character represented by <code>C</code> . For example, the character <code>DC1 (17)</code> is shown as <code>^Q</code> . (Some characters are not valid in expect.)

**Environment Variables** Environment variables are available within chat scripts if the `-E` option is specified on the command line. The metacharacter `$` introduces the name of the environment variable to substitute. If the substitution fails because the requested environment variable is not set, nothing is replaced for the variable.

**Exit Status** The chat program terminates with the following completion codes:

0	Normal program termination. Indicates that the script was executed without error to normal conclusion.
1	One or more of the parameters are invalid or an expect string was too large for the internal buffers. Indicates that the program was not properly executed.
2	An error occurred during the execution of the program. This may be due to a read or write operation failing or chat receiving a signal such as <code>SIGINT</code> .
3	A timeout event occurred when there was an expect string without having a <code>"-subsend"</code> string. This indicates that you may not have programmed the script correctly for the condition or that an unexpected event occurred and the expected string could not be found.

- 4 The first string marked as an ABORT condition occurred.
- 5 The second string marked as an ABORT condition occurred.
- 6 The third string marked as an ABORT condition occurred.
- 7 The fourth string marked as an ABORT condition occurred.
- ... The other termination codes are also strings marked as an ABORT condition.

To determine which event terminated the script, use the termination code. It is possible to decide if the string "BUSY" was received from the modem versus "NO DIALTONE." While the first event may be retried, the second probably will not succeed during a retry.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Interface Stability	Committed

**See Also** [sleep\(1\)](#), [uucp\(1C\)](#), [pppd\(1M\)](#), [uucico\(1M\)](#), [syslog\(3C\)](#), [attributes\(5\)](#)

Additional information on chat scripts are available with UUCP documentation. The chat script format was taken from scripts used by the `uucico` program.

**Name** check-hostname – check if sendmail can determine the system's fully-qualified host name

**Synopsis** /usr/sbin/check-hostname

**Description** The check-hostname script is a migration aid for [sendmail\(1M\)](#). This script tries to determine the local host's fully-qualified host name (FQHN) in a manner similar to [sendmail\(1M\)](#). If check-hostname is able to determine the FQHN of the local host, it reports success. Otherwise, check-hostname reports how to reconfigure the system so that the FQHN can be properly determined.

**Files**

/etc/hosts	Host name database
/etc/nsswitch.conf	Name service switch configuration file
/etc/resolv.conf	Configuration file for name server routines

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/smtp/sendmail
Interface Stability	Committed

**See Also** [domainname\(1M\)](#), [sendmail\(1M\)](#), [hosts\(4\)](#), [attributes\(5\)](#)

**Name** check-permissions – check permissions on mail rerouting files

**Synopsis** /usr/sbin/check-permissions [*login*]

**Description** The check-permissions script is intended as a migration aid for [sendmail\(1M\)](#). It checks the /etc/mail/sendmail.cf file for all configured alias files, and checks the alias files for :include: files. It also checks for certain .forward files. For each file that check-permissions checks, it verifies that none of the parent directories are group- or world-writable. If any directories are overly permissive, it is reported. Otherwise it reports that no unsafe directories were found.

As to which .forward files are checked, it depends on the arguments included on the command line. If no argument is given, the current user's home directory is checked for the presence of a .forward file. If any arguments are given, they are assumed to be valid logins, and the home directory of each one is checked.

If the special argument ALL is given, the passwd entry in the /etc/nsswitch.conf file is checked, and all password entries that can be obtained through the switch file are checked. In large domains, this can be time-consuming.

**Operands** The following operands are supported:

*login* Where *login* is a valid user name, checks the home directory for *login*.

ALL Checks the home directory of *all* users.

**Files** /etc/mail/sendmail.cf Defines environment for sendmail  
 /etc/mail/aliases Ascii mail aliases file

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/smtp/sendmail
Interface Stability	Committed

**See Also** [getent\(1M\)](#), [sendmail\(1M\)](#), [aliases\(4\)](#), [attributes\(5\)](#)

**Name** chk\_encodings – check the label encodings file syntax

**Synopsis** /usr/sbin/chk\_encodings [-a] [-c *maxclass*] [*pathname*]

**Description** chk\_encodings checks the syntax of the label-encodings file that is specified by *pathname*. With the -a option, chk\_encodings also prints a semantic analysis of the label-encodings file that is specified by *pathname*. If *pathname* is not specified, chk\_encodings checks and analyzes the /etc/security/tsol/label\_encodings file.

If label-encodings file analysis was requested, whatever analysis can be provided is written to the standard output file even if errors were found.

**Options** -a Provide a semantic analysis of the label encodings file.  
 -c *maxclass* Accept a maximum classification value of *maxclass* (default 255) in the label encodings file CLASSIFICATIONS section.

**Exit Status** When successful, chk\_encodings returns an exit status of 0 (true) and writes to the standard output file a confirmation that no errors were found in *pathname*. Otherwise, chk\_encodings returns an exit status of nonzero (false) and writes an error diagnostic to the standard output file.

**Files** /etc/security/tsol/label\_encodings  
 The label encodings file contains the classification names, words, constraints, and values for the defined labels of this system.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/trusted
Interface Stability	See below.
Standard	DDS-2600-6216-93, <i>Compartmented Mode Workstation Labeling: Encodings Format</i> , September 1993

The command output is Not-an-Interface. The command invocation is Committed for systems that implement the DIA MAC policy.

**See Also** [label\\_encodings\(4\)](#), [attributes\(5\)](#), [labels\(5\)](#)

“How to Analyze and Verify the label\_encodings File” in *Oracle Solaris Trusted Extensions Label Administration*

**Notes** The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

This file is part of the Defense Intelligence Agency (DIA) Mandatory Access Control (MAC) policy. This file might not be applicable to other MAC policies that might be developed for future releases of Solaris Trusted Extensions software.

**Name** chroot – change root directory for a command

**Synopsis** /usr/sbin/chroot *newroot* *command*

**Description** The chroot utility causes *command* to be executed relative to *newroot*. The meaning of any initial slashes ( / ) in the path names is changed to *newroot* for *command* and any of its child processes. Upon execution, the initial working directory is *newroot*.

Notice that redirecting the output of *command* to a file,

```
chroot newroot command >x
```

will create the file *x* relative to the original root of *command*, not the new one.

The new root path name is always relative to the current root. Even if a chroot is currently in effect, the *newroot* argument is relative to the current root of the running process.

This command can be run only by the super-user.

**Return Values** The exit status of chroot is the return value of *command*.

**Examples** EXAMPLE 1 Using the chroot Utility

The chroot utility provides an easy way to extract tar files (see [tar\(1\)](#)) written with absolute filenames to a different location. It is necessary to copy the shared libraries used by tar (see [ldd\(1\)](#)) to the *newroot* filesystem.

```
example# mkdir /tmp/lib; cd /lib
example# cp ld.so.1 libc.so.1 libcmd.so.1 libdl.so.1 \
 libsec.so.1 /tmp/lib
example# cp /usr/bin/tar /tmp
example# dd if=/dev/rmt/0 | chroot /tmp tar xvf -
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [cd\(1\)](#), [tar\(1\)](#), [chroot\(2\)](#), [ttyname\(3C\)](#), [attributes\(5\)](#)

**Notes** Exercise extreme caution when referencing device files in the new root file system.

References by routines such as [ttyname\(3C\)](#) to stdin, stdout, and stderr will find that the device associated with the file descriptor is unknown after chroot is run.

**Name** cimworkshop – start the Sun WBEM CIM WorkShop application

**Synopsis** /usr/sadm/bin/cimworkshop

**Description** The `cimworkshop` command starts Sun WBEM CIM WorkShop, a graphical user interface that enables you to create, modify, and view the classes and instances that describe the managed resources on your system.

Managed resources are described using a standard information model called Common Information Model (CIM). A CIM class is a computer representation, or model, of a type of managed resource, such as a printer, disk drive, or CPU. A CIM instance is a particular managed resource that belongs to a particular class. Instances contain actual data. Objects can be shared by any WBEM-enabled system, device, or application. CIM objects are grouped into meaningful collections called schema. One or more schemas can be stored in directory-like structures called namespaces.

The CIM WorkShop application displays a Login dialog box. Context help is displayed on the left side of the CIM WorkShop dialog boxes. When you click on a field, the help content changes to describe the selected field.

By default, CIM WorkShop uses the RMI protocol to connect to the CIM Object Manager on the local host, in the default namespace, `root\cimv2`. You can select HTTP if you want to communicate to a CIM Object Manager using the standard XML/HTTP protocol from the Desktop Management Task Force. When a connection is established, all classes contained in the default namespace are displayed in the left side of the CIM WorkShop window.

The name of the current namespace is listed in the tool bar. All programming operations are performed within a namespace. Four namespaces are created in a root namespace during installation:

<code>cimv2</code>	Contains the default CIM classes that represent managed resources on your system.
<code>security</code>	Contains the security classes used by the CIM Object Manager to represent access rights for users and namespaces.
<code>system</code>	Contains properties for configuring the CIM Object Manager.
<code>snmp</code>	Contains pre-defined SNMP-related classes and all SNMP MOF files that are compiled.

The `cimworkshop` application allows you to perform the following tasks:

Create, view, and change namespaces.

Use the CIM WorkShop application to view all namespaces. A namespace is a directory-like structure that can store CIM classes and instances.

- Create, delete, and view CIM classes. You cannot modify the unique attributes of the classes that make up the CIM and Solaris Schema. You can create a new instance or subclass of the class and modify the desired attributes in that instance or subclass.
- Create, modify, delete, and view CIM instances. You can add instances to a class and modify its inherited properties or create new properties. You can also change the property values of a CIM instance.
- Invoke methods. You can set input values for a parameter of a method and invoke the method.

When CIM WorkShop connects to the CIM Object Manager in a particular namespace, all subsequent operations occur within that namespace. When you connect to a namespace, you can access the classes and instances in that namespace (if they exist) and in any namespaces contained in that namespace.

When you use CIM WorkShop to view CIM data, the WBEM system validates your login information on the current host. By default, a validated WBEM user is granted read access to the CIM Schema. The CIM Schema describes managed objects on your system in a standard format that all WBEM-enabled systems and applications can interpret.

- Read Only** Allows read-only access to CIM Schema objects. Users with this privilege can retrieve instances and classes, but cannot create, delete, or modify CIM objects.
- Read/Write** Allows full read, write, and delete access to all CIM classes and instances.
- Write** Allows write and delete, but not read access to all CIM classes and instances.
- None** Allows no access to CIM classes and instances.

**Usage** The `cimworkshop` command is not a tool for a distributed environment. Rather, this command is used for local administration on the machine on which the CIM Object Manager is running.

**Exit Status** The `cimworkshop` utility terminates with exit status 0.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWwbdev

**See Also** [mofcomp\(1M\)](#), [wbemlogviewer\(1M\)](#), [init.wbem\(1M\)](#), [attributes\(5\)](#)

**Name** clear\_locks – clear locks held on behalf of an NFS client

**Synopsis** /usr/sbin/clear\_locks [-s] *hostname*

**Description** The clear\_locks command removes all file, record, and share locks created by the *hostname* and held on the current host, regardless of which process created or owns the locks.

This command can be run only by the super-user.

This command should only be used to repair the rare case of a client crashing and failing to clear held locks. Clearing locks held by an active client may cause applications to fail in an unexpected manner.

**Options** -s Remove all locks created by the current machine and held by the server *hostname*.

**Operands** The following operands are supported:

*hostname* name of host server

**Exit Status**

- 0 Successful operation.
- 1 If not root.
- 2 Usage error.
- 3 If unable to contact server (RPC).

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [fcntl\(2\)](#), [attributes\(5\)](#)

**Name** clinfo – display cluster information

**Synopsis** clinfo [-nh]

**Description** The `clinfo` command displays cluster configuration information about the node from which the command is executed.

Without arguments, `clinfo` returns an exit status of 0 if the node is configured and booted as part of a cluster. Otherwise, `clinfo` returns an exit status of 1.

**Options** The following options are supported:

-h Displays the highest node number allowed to be configured. This is different from the maximum number of nodes supported in a given cluster. The current highest configured node number can change immediately after the command returns since new nodes can be dynamically added to a running cluster.

For example, `clinfo -h` might return 64, meaning that the highest number you can use to identify a node is 64. See the *Sun Cluster 3.0 System Administration Guide* for a description of utilities you can use to determine the number of nodes in a cluster.

-n Prints the number of the node from which `clinfo` is executed.

**Exit Status** The following exit values are returned:

0 Successful completion.

1 An error occurred.

This is usually because the node is not configured or booted as part of a cluster.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [attributes\(5\)](#)

**Name** `clri`, `dcopy` – clear inode

**Synopsis** `clri [-F FSType] [-V] special i-number`  
`dcopy [-F FSType] [-V] special i-number`

**Description** `clri` writes zeros on the inodes with the decimal *i-number* on the file system stored on *special*. After `clri`, any blocks in the affected file show up as missing in an `fsck(1M)` of *special*.

Read and write permission is required on the specified file system device. The inode becomes allocatable.

The primary purpose of this routine is to remove a file that for some reason appears in no directory. If it is used to zap an inode that does appear in a directory, care should be taken to track down the entry and remove it. Otherwise, when the inode is reallocated to some new file, the old entry will still point to that file. At that point, removing the old entry will destroy the new file. The new entry will again point to an unallocated inode, so the whole cycle is likely to be repeated again and again.

`dcopy` is a symbolic link to `clri`.

**Options** `-F FSType` Specify the *FSType* on which to operate. The *FSType* should either be specified here or be determinable from `/etc/vfstab` by matching *special* with an entry in the table, or by consulting `/etc/default/fs`.

`-V` Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from `/etc/vfstab`. This option should be used to verify and validate the command line.

**Usage** See [largefile\(5\)](#) for the description of the behavior of `clri` and `dcopy` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**Files** `/etc/default/fs` Default local file system type  
`/etc/vfstab` List of default parameters for each file system

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [fsck\(1M\)](#), [vfstab\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

**Notes** This command might not be supported for all *FSTypes*.

**Name** `consadm` – select or display devices used as auxiliary console devices

**Synopsis** `/usr/sbin/consadm`

`/usr/sbin/consadm [-a device. . .] [-p]`

`/usr/sbin/consadm [-d device. . .] [-p]`

`/usr/sbin/consadm [-p]`

**Description** `consadm` selects the hardware *device* or devices to be used as auxiliary console devices, or displays the current device. Only superusers are allowed to make or display auxiliary console device selections.

Auxiliary console devices receive copies of console messages, and can be used as the console during single user mode. In particular, they receive kernel messages and messages directed to `/dev/sysmsg`. On Solaris x86 based systems they can also be used for interaction with the bootstrap.

By default, selecting a display device to be used as an auxiliary console device selects that device for the duration the system remains up. If the administrator needs the selection to persist across reboots the `-p` option can be specified.

`consadm` runs a daemon in the background, monitoring auxiliary console devices. Any devices that are disconnected (hang up, lose carrier) are removed from the auxiliary console device list, though not from the persistent list. While auxiliary console devices may have been removed from the device list receiving copies of console messages, those messages will always continue to be displayed by the default console device.

The daemon will not run if it finds there are not any auxiliary devices configured to monitor. Likewise, after the last auxiliary console is removed, the daemon will shut itself down. Therefore the daemon persists for only as long as auxiliary console devices remain active.

See [eeprom\(1M\)](#) for instructions on assigning an auxiliary console device as the system console.

**Options** The following options are supported:

`-a device` Adds *device* to the list of auxiliary console devices. Specify *device* as the path name to the device or devices to be added to the auxiliary console device list.

`-d device` Removes *device* from the list of auxiliary console devices. Specify *device* as the path name to the device or devices to be removed from the auxiliary console device list.

`-p` Prints the list of auxiliary consoles that will be auxiliary across reboots.

When invoked with the `-a` or `-d` options, tells the application to make the change persist across reboot.

**Examples** EXAMPLE 1 Adding to the list of devices that will receive console messages

The following command adds `/dev/term/a` to the list of devices that will receive console messages.

```
example# consadm -a /dev/term/a
```

EXAMPLE 2 Removing from the list of devices that will receive console messages

The following command removes `/dev/term/a` from the list of devices that will receive console messages. This includes removal from the persistent list.

```
example# consadm -d -p /dev/term/a
```

EXAMPLE 3 Printing the list of devices selected as auxiliary console devices

The following command prints the name or names of the device or devices currently selected as auxiliary console devices.

```
example# consadm
```

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `consadm`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**Exit Status** The following exit values are returned:

0 Successful completion.  
>0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs
Interface Stability	Committed

**See Also** [kmdb\(1\)](#), [svcs\(1\)](#), [eeprom\(1M\)](#), [svcadm\(1M\)](#), [syslogd\(1M\)](#), [environ\(5\)](#), [attributes\(5\)](#), [smf\(5\)](#), [sysmsg\(7D\)](#), [console\(7D\)](#)

**Notes** Auxiliary console devices are not usable for `kmdb` or firmware I/O, do not receive panic messages, and do not receive output directed to `/dev/console`.

The `consadm` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/consadm
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

**Name** conv\_lp – convert LP configuration

**Synopsis** conv\_lp [-d *dir*] [-f *file*]

**Description** conv\_lp reads LP printer configuration information from a directory and converts it to an output file for use with print client software.

**Options** The following options are supported:

-d *dir* The root ( / ) directory from which LP configuration information is read. The default is root ( / ).

-f *file* The output file to which conv\_lp writes the converted LP configuration information. The default is /etc/printers.conf.

**Examples** EXAMPLE 1 Converting LP Configuration Information from the Default Directory and File

The following example converts LP configuration information from directory root ( / ) to file /etc/printers.conf.

```
% conv_lp
```

EXAMPLE 2 Converting LP Configuration Information From a Specified Directory and File

The following example converts LP configuration information from directory /export/root/client to file /export/root/client/etc/printers.conf.

```
% conv_lp -d /export/root/client -f\
/export/root/client/etc/printers.conf
```

**Exit Status** The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

**Files** /etc/printers.conf System printer configuration database.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

**See Also** [lpset\(1M\)](#), [printers.conf\(4\)](#), [attributes\(5\)](#)

- 
- Name** conv\_lpd – convert LPD configuration
- Synopsis** conv\_lpd [-c printers | -c printcap] [-n] *file*
- Description** conv\_lpd converts LPD printer configuration information from *file* to a printers.conf or a printcap file (see printers.conf(4)). *file* specifies the name of the input file, and can be either in printers.conf or printcap format. If *file* is in printers.conf format, it converts it to a printcap file. If *file* is in printcap format, it converts it to a printers.conf file.
- Options** The following options are supported:
- c printers | -c printcap      Specifies the type of output file produced by the conversion. -c printers converts to a printers.conf file. -c printcap converts to a printcap file. -c printers is the default.
  - n                                  Preserves the namelist during the conversion.
- Operands** The following operands are supported:
- file*      The file to be converted.
- Examples**
- EXAMPLE 1** Converting a printcap file to a printers.conf file.  
The following example converts a printcap file to a printers.conf file.
- ```
example% conv_lpd /etc/printcap
```
- EXAMPLE 2** Converting a printcap file to a printers.conf file and preserving the namelist.
The following example converts a printcap file to a printers.conf file and preserves the namelist.
- ```
example% conv_lpd -c printers -n /etc/printcap
```
- EXAMPLE 3** Converting a printers.conf file to a printcap file and preserving the namelist.  
The following example converts a printers.conf file to a printcap file and preserves the namelist.
- ```
example% conv_lpd -c printcap -n /etc/printers.conf
```
- Exit Status** The following exit values are returned:
- 0 Successful completion.
 - non-zero An error occurred.
- Files**
- /etc/printers.conf System printer configuration database.
 - /etc/printcap SunOS 4.x printer capability database.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

See Also [lpset\(1M\)](#), [printers.conf\(4\)](#), [attributes\(5\)](#)

Name coreadm – core file administration

Synopsis coreadm [-g *pattern*] [-G *content*] [-i *pattern*] [-I *content*]
 [-d *option*]... [-e *option*]...
 coreadm [-p *pattern*] [-P *content*] [*pid*]...

Description coreadm specifies the name and location of core files produced by abnormally-terminating processes. See [core\(4\)](#).

Only users and roles that belong to the “Maintenance and Repair” RBAC profile can execute the first form of the SYNOPSIS. This form configures system-wide core file options, including a global core file name pattern and a core file name pattern for the [init\(1M\)](#) process. All settings are saved persistently and will be applied at boot.

Non-privileged users can execute the second form of the SYNOPSIS. This form specifies the file name pattern and core file content that the operating system uses to generate a per-process core file.

A core file name pattern is a normal file system path name with embedded variables, specified with a leading % character. The variables are expanded from values that are effective when a core file is generated by the operating system. The possible embedded variables are as follows:

%d

Executable file directory name, up to a maximum of MAXPATHLEN characters

%f

Executable file name, up to a maximum of MAXCOMLEN characters

%g

Effective group-ID

%m

Machine name (uname -m)

%n

System node name (uname -n)

%p

Process-ID

%t

Decimal value of [time\(2\)](#)

%u

Effective user-ID

%z

Name of the zone in which process executed (zonename)

%%

Literal %

For example, the core file name pattern `/var/cores/core.%f.%p` would result, for command `foo` with process-ID 1234, in the core file name `/var/cores/core.foo.1234`.

A core file content description is specified using a series of tokens to identify parts of a process's binary image:

`anon`

Anonymous private mappings, including thread stacks that are not main thread stacks

`ctf`

CTF type information sections for loaded object files

`data`

Writable private file mappings

`dism`

DISM mappings

`heap`

Process heap

`ism`

ISM mappings

`rodata`

Read-only private file mappings

`shanon`

Anonymous shared mappings

`shfile`

Shared mappings that are backed by files

`shm`

System V shared memory

`stack`

Process stack

`syntab`

Symbol table sections for loaded object files

`text`

Readable and executable private file mappings

In addition, you can use the token `all` to indicate that core files should include all of these parts of the process's binary image. You can use the token `none` to indicate that no mappings are to be included. The default token indicates inclusion of the system default content (`stack+heap+shm+ism+dism+text+data+rodata+anon+shanon+ctf+syntab`). The `/proc` file system data structures are always present in core files regardless of the mapping content.

You can use `+` and `-` to concatenate tokens. For example, the core file content `default-ism` would produce a core file with the default set of mappings without any intimate shared memory mappings.

The `coreadm` command with no arguments reports the current system configuration, for example:

```
$ coreadm
  global core file pattern: /var/cores/core.%f.%p
  global core file content: all
    init core file pattern: core
    init core file content: default
      global core dumps: enabled
    per-process core dumps: enabled
  global setid core dumps: enabled
per-process setid core dumps: disabled
  global core dump logging: disabled
```

The `coreadm` command with only a list of process-IDs reports each process's per-process core file name pattern, for example:

```
$ coreadm 278 5678
  278:  core.%f.%p default
  5678: /home/george/cores/%f.%p.%t all-ism
```

Only the owner of a process or a user with the `proc_owner` privilege can interrogate a process in this manner.

When a process is dumping core, up to three core files can be produced: one in the per-process location, one in the system-wide global location, and, if the process was running in a local (non-global) zone, one in the global location for the zone in which that process was running. Each core file is generated according to the effective options for the corresponding location.

When generated, a global core file is created in mode `600` and owned by the superuser. Nonprivileged users cannot examine such files.

Ordinary per-process core files are created in mode `600` under the credentials of the process. The owner of the process can examine such files.

A process that is or ever has been `setuid` or `setgid` since its last [exec\(2\)](#) presents security issues that relate to dumping core. Similarly, a process that initially had superuser privileges and lost those privileges through [setuid\(2\)](#) also presents security issues that are related to dumping core. A process of either type can contain sensitive information in its address space to which the current nonprivileged owner of the process should not have access. If `setid` core files are enabled, they are created mode `600` and owned by the superuser.

Options The following options are supported:

-d *option*...

Disable the specified core file option. See the **-e *option*** for descriptions of possible options.

Multiple **-e** and **-d** options can be specified on the command line. Only users and roles belonging to the “Maintenance and Repair” RBAC profile can use this option.

-e *option*...

Enable the specified core file option. Specify *option* as one of the following:

global

Allow core dumps that use global core pattern.

global-setid

Allow set-id core dumps that use global core pattern.

log

Generate a `syslog(3C)` message when generation of a global core file is attempted.

process

Allow core dumps that use per-process core pattern.

proc-setid

Allow set-id core dumps that use per-process core pattern.

Multiple **-e** and **-d** options can be specified on the command line. Only users and roles belonging to the “Maintenance and Repair” RBAC profile can use this option.

-g *pattern*

Set the global core file name pattern to *pattern*. The pattern must start with a `/` and can contain any of the special `%` variables that are described in the `DESCRIPTION`.

Only users and roles belonging to the “Maintenance and Repair” RBAC profile can use this option.

-G *content*

Set the global core file content to *content*. You must specify *content* by using the tokens that are described in the `DESCRIPTION`.

Only users and roles belonging to the “Maintenance and Repair” RBAC profile can use this option.

-i *pattern*

Set the default per-process core file name to *pattern*. This changes the per-process pattern for any process whose per-process pattern is still set to the default. Processes that have had their per-process pattern set or are descended from a process that had its per-process pattern set (using the **-p** option) are unaffected. This default persists across reboot.

Only users and roles belonging to the “Maintenance and Repair” RBAC profile can use this option.

-I *content*

Set the default per-process core file content to *content*. This changes the per-process content for any process whose per-process content is still set to the default. Processes that have had their per-process content set or are descended from a process that had its per-process content set (using the **-P** option) are unaffected. This default persists across reboot.

Only users and roles belonging to the “Maintenance and Repair” RBAC profile can use this option.

-p *pattern*

Set the per-process core file name pattern to *pattern* for each of the specified process-IDs. The pattern can contain any of the special % variables described in the DESCRIPTION and need not begin with /. If the pattern does not begin with /, it is evaluated relative to the directory that is current when the process generates a core file.

A nonprivileged user can apply the **-p** option only to processes that are owned by that user. A user with the `proc_owner` privilege can apply the option to any process. The per-process core file name pattern is inherited by future child processes of the affected processes. See [fork\(2\)](#).

If no process-IDs are specified, the **-p** option sets the per-process core file name pattern to *pattern* on the parent process (usually the shell that ran `coreadm`).

-P *content*

Set the per-process core file content to *content* for each of the specified process-IDs. The content must be specified by using the tokens that are described in the DESCRIPTION.

A nonprivileged user can apply the **-p** option only to processes that are owned by that user. A user with the `proc_owner` privilege can apply the option to any process. The per-process core file name pattern is inherited by future child processes of the affected processes. See [fork\(2\)](#).

If no process-IDs are specified, the **-P** option sets the per-process file content to *content* on the parent process (usually the shell that ran `coreadm`).

Operands The following operands are supported:

pid
process-ID

Examples EXAMPLE 1 Setting the Core File Name Pattern

When executed from a user's `$HOME/.profile` or `$HOME/.login`, the following command sets the core file name pattern for all processes that are run during the login session:

```
example$ coreadm -p core.%f.%p
```

Note that since the process-ID is omitted, the per-process core file name pattern will be set in the shell that is currently running and is inherited by all child processes.

EXAMPLE 2 Dumping a User's Files Into a Subdirectory

The following command dumps all of a user's core dumps into the `corefiles` subdirectory of the home directory, discriminated by the system node name. This command is useful for users who use many different machines but have a shared home directory.

```
example$ coreadm -p $HOME/corefiles/%n.%f.%p 1234
```

EXAMPLE 3 Culling the Global Core File Repository

The following commands set up the system to produce core files in the global repository only if the executables were run from `/usr/bin` or `/usr/sbin`.

```
example# mkdir -p /var/cores/usr/bin
example# mkdir -p /var/cores/usr/sbin
example# coreadm -G all -g /var/cores/%d/%f.%p.%n
```

Files `/var/cores`

Directory provided for global core file storage.

Exit Status The following exit values are returned:

0

Successful completion.

1

A fatal error occurred while either obtaining or modifying the system core file configuration.

2

Invalid command-line options were specified.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [gcore\(1\)](#), [pexec\(1\)](#), [svcs\(1\)](#), [init\(1M\)](#), [svcadm\(1M\)](#), [exec\(2\)](#), [fork\(2\)](#), [setuid\(2\)](#), [time\(2\)](#), [syslog\(3C\)](#), [core\(4\)](#), [prof_attr\(4\)](#), [user_attr\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Notes In a local (non-global) zone, the global settings apply to processes running in that zone. In addition, the global zone's apply to processes run in any zone.

The term *global settings* refers to settings which are applied to the system or zone as a whole, and does not necessarily imply that the settings are to take effect in the global zone.

The `coreadm` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/coreadm:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

The `-g`, `-G`, `-i`, `-I`, `-e`, and `-d` options can be also used by a user, role, or profile that has been granted both the `solaris.smf.manage.coreadm` and `solaris.smf.value.coreadm` authorizations.

Name cpustat – monitor system behavior using CPU performance counters

Synopsis cpustat -c *eventspec* [-c *eventspec*]... [-p *period*] [-T u | d]
 [-sntD] [*interval* [*count*]]
 cpustat -h

Description The cpustat utility allows CPU performance counters to be used to monitor the overall behavior of the CPUs in the system.

If *interval* is specified, cpustat samples activity every *interval* seconds, repeating forever. If a *count* is specified, the statistics are repeated *count* times. If neither are specified, an interval of five seconds is used, and there is no limit to the number of samples that are taken.

Options The following options are supported:

-c *eventspec*

Specifies a set of events for the CPU performance counters to monitor. The syntax of these event specifications is:

```
[picn=]eventn[,attr[n][=val]][, [picn=]eventn  

  [,attr[n][=val]],...]
```

You can use the -h option to obtain a list of available events and attributes. This causes generation of the usage message. You can omit an explicit counter assignment, in which case cpustat attempts to choose a capable counter automatically.

Attribute values can be expressed in hexadecimal, octal, or decimal notation, in a format suitable for `strtoll(3C)`. An attribute present in the event specification without an explicit value receives a default value of 1. An attribute without a corresponding counter number is applied to all counters in the specification.

The semantics of these event specifications can be determined by reading the CPU manufacturer's documentation for the events.

Multiple -c options can be specified, in which case the command cycles between the different event settings on each sample.

-D

Enables debug mode.

-h

Prints an extensive help message on how to use the utility and how to program the processor-dependent counters.

-n

Omits all header output (useful if cpustat is the beginning of a pipeline).

-p *period*

Causes cpustat to cycle through the list of *eventspecs* every *period* seconds. The tool sleeps after each cycle until *period* seconds have elapsed since the first *eventspec* was measured.

When this option is present, the optional *count* parameter specifies the number of total cycles to make (instead of the number of total samples to take). If *period* is less than the number of *eventspecs* times *interval*, the tool acts as if period is 0.

-s

Creates an idle soaker thread to spin while system-only *eventspecs* are bound. One idle soaker thread is bound to each CPU in the current processor set. System-only *eventspecs* contain both the nouser and the sys tokens and measure events that occur while the CPU is operating in privileged mode. This option prevents the kernel's idle loop from running and triggering system-mode events.

-T u | d

Display a time stamp.

Specify u for a printed representation of the internal representation of time. See [time\(2\)](#).
Specify d for standard date format. See [date\(1\)](#).

-t

Prints an additional column of processor cycle counts, if available on the current architecture.

Usage A closely related utility, [cpurack\(1\)](#), can be used to monitor the behavior of individual applications with little or no interference from other activities on the system.

The `cpustat` utility must be run by the super-user, as there is an intrinsic conflict between the use of the CPU performance counters system-wide by `cpustat` and the use of the CPU performance counters to monitor an individual process (for example, by `cpurack`.)

Once any instance of this utility has started, no further per-process or per-LWP use of the counters is allowed until the last instance of the utility terminates.

The times printed by the command correspond to the wallclock time when the hardware counters were actually sampled, instead of when the program told the kernel to sample them. The time is derived from the same timebase as [gethrtime\(3C\)](#).

The processor cycle counts enabled by the `-t` option always apply to both user and system modes, regardless of the settings applied to the performance counter registers.

On some hardware platforms running in system mode using the “sys” token, the counters are implemented using 32-bit registers. While the kernel attempts to catch all overflows to synthesize 64-bit counters, because of hardware implementation restrictions, overflows can be lost unless the sampling interval is kept short enough. The events most prone to wrap are those that count processor clock cycles. If such an event is of interest, sampling should occur frequently so that less than 4 billion clock cycles can occur between samples.

The output of `cpustat` is designed to be readily parseable by [nawk\(1\)](#) and [perl\(1\)](#), thereby allowing performance tools to be composed by embedding `cpustat` in scripts. Alternatively, tools can be constructed directly using the same APIs that `cpustat` is built upon using the facilities of [libcpc\(3LIB\)](#). See [cpc\(3CPC\)](#).

The `cpustat` utility only monitors the CPUs that are accessible to it in the current processor set. Thus, several instances of the utility can be running on the CPUs in different processor sets. See `prset(1M)` for more information about processor sets.

Because `cpustat` uses LWPs bound to CPUs, the utility might have to be terminated before the configuration of the relevant processor can be changed.

Examples

SPARC EXAMPLE 1 Measuring External Cache References and Misses

The following example measures misses and references in the external cache. These occur while the processor is operating in user mode on an UltraSPARC machine.

```
example% cpustat -c EC_ref,EC_misses 1 3
```

| time | cpu | event | pic0 | pic1 |
|-------|-----|-------|--------|-------|
| 1.008 | 0 | tick | 69284 | 1647 |
| 1.008 | 1 | tick | 43284 | 1175 |
| 2.008 | 0 | tick | 179576 | 1834 |
| 2.008 | 1 | tick | 202022 | 12046 |
| 3.008 | 0 | tick | 93262 | 384 |
| 3.008 | 1 | tick | 63649 | 1118 |
| 3.008 | 2 | total | 651077 | 18204 |

x86 EXAMPLE 2 Measuring Branch Prediction Success on Pentium 4

The following example measures branch mispredictions and total branch instructions in user and system mode on a Pentium 4 machine.

```
example% cpustat -c \
    pic12=branch_retired,emask12=0x4,pic14=branch_retired,\
    emask14=0xf,sys 1 3
```

| time | cpu | event | pic12 | pic14 |
|-------|-----|-------|-------|-------|
| 1.010 | 1 | tick | 458 | 684 |
| 1.010 | 0 | tick | 305 | 511 |
| 2.010 | 0 | tick | 181 | 269 |
| 2.010 | 1 | tick | 469 | 684 |
| 3.010 | 0 | tick | 182 | 269 |
| 3.010 | 1 | tick | 468 | 684 |
| 3.010 | 2 | total | 2063 | 3101 |

EXAMPLE 3 Counting Memory Accesses on Opteron

The following example determines the number of memory accesses made through each memory controller on an Opteron, broken down by internal memory latency:

```
cpustat -c \
    pic0=NB_mem_ctrlr_page_access,umask0=0x01, \
    pic1=NB_mem_ctrlr_page_access,umask1=0x02, \
```

EXAMPLE 3 Counting Memory Accesses on Opteron (Continued)

```

pic2=NB_mem_ctrlr_page_access,umask2=0x04,sys \
1

time cpu event    pic0    pic1    pic2
1.003 0 tick      41976   53519   7720
1.003 1 tick      5589    19402   731
2.003 1 tick      6011    17005   658
2.003 0 tick      43944   45473   7338
3.003 1 tick      7105    20177   762
3.003 0 tick      47045   48025   7119
4.003 0 tick      43224   46296   6694
4.003 1 tick      5366    19114   652

```

Warnings By running the `cpustat` command, the super-user forcibly invalidates all existing performance counter context. This can in turn cause all invocations of the `cpurack` command, and other users of performance counter context, to exit prematurely with unspecified errors.

If `cpustat` is invoked on a system that has CPU performance counters which are not supported by Solaris, the following message appears:

```
cpustat: cannot access performance counters - Operation not applicable
```

This error message implies that `cpc_open()` has failed and is documented in [cpc_open\(3CPC\)](#). Review this documentation for more information about the problem and possible solutions.

If a short interval is requested, `cpustat` might not be able to keep up with the desired sample rate. In this case, some samples might be dropped.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-------------------------|
| Availability | diagnostic/cpu-counters |
| Interface Stability | Committed |

See Also [cpurack\(1\)](#), [nawk\(1\)](#), [perl\(1\)](#), [iostat\(1M\)](#), [prstat\(1M\)](#), [psrset\(1M\)](#), [vmstat\(1M\)](#), [cpc\(3CPC\)](#), [cpc_open\(3CPC\)](#), [cpc_bind_cpu\(3CPC\)](#), [gethrtime\(3C\)](#), [strtoll\(3C\)](#), [libcpc\(3LIB\)](#), [attributes\(5\)](#)

Notes When `cpustat` is run on a Pentium 4 with HyperThreading enabled, a CPC set is bound to only one logical CPU of each physical CPU. See [cpc_bind_cpu\(3CPC\)](#).

Name cron – clock daemon

Synopsis /usr/sbin/cron

Description cron starts a process that executes commands at specified dates and times.

You can specify regularly scheduled commands to cron according to instructions found in crontab files in the directory /var/spool/cron/crontabs. Users can submit their own crontab file using the [crontab\(1\)](#) command. Commands which are to be executed only once can be submitted using the [at\(1\)](#) command.

cron only examines crontab or at command files during its own process initialization phase and when the crontab or at command is run. This reduces the overhead of checking for new or changed files at regularly scheduled intervals.

As cron never exits, it should be executed only once. This is done routinely by way of the `svc:/system/cron:default` service. The file /etc/cron.d/FIFO file is used as a lock file to prevent the execution of more than one instance of cron.

cron captures the output of the job's stdout and stderr streams, and, if it is not empty, mails the output to the user. If the job does not produce output, no mail is sent to the user. An exception is if the job is an [at\(1\)](#) job and the -m option was specified when the job was submitted.

cron and at jobs are not executed if your account is locked. Jobs and processes execute. The [shadow\(4\)](#) file defines which accounts are not locked and will have their jobs and processes executed.

Setting cron Jobs Across Timezones The timezone of the cron daemon sets the system-wide timezone for cron entries. This, in turn, is by set by default system-wide using /etc/default/init. The timezone for cron entries can be overridden in a user's crontab file; see [crontab\(1\)](#).

If some form of *daylight savings* or *summer/winter time* is in effect, then jobs scheduled during the switchover period could be executed once, twice, or not at all.

Setting cron Defaults To keep a log of all actions taken by cron, you must specify CRONLOG=YES in the /etc/default/cron file. If you specify CRONLOG=NO, no logging is done. Keeping the log is a user configurable option since cron usually creates huge log files.

You can specify the PATH for user cron jobs by using PATH= in /etc/default/cron. You can set the PATH for root cron jobs using SUPATH= in /etc/default/cron. Carefully consider the security implications of setting PATH and SUPATH.

Example /etc/default/cron file:

```
CRONLOG=YES
PATH=/usr/bin:/usr/ucb:
```

This example enables logging and sets the default PATH used by non-root jobs to /usr/bin:/usr/ucb:. Root jobs continue to use /usr/sbin:/usr/bin.

The cron log file is periodically rotated by [logadm\(1M\)](#).

| | | |
|--------------|-----------------------|------------------------------------------------|
| Files | /etc/cron.d | Main cron directory |
| | /etc/cron.d/FIFO | Lock file |
| | /etc/default/cron | cron default settings file |
| | /var/cron/log | cron history information |
| | /var/spool/cron | Spool area |
| | /etc/cron.d/queuedefs | Queue description file for at, batch, and cron |
| | /etc/logadm.conf | Configuration file for logadm |

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------|----------------|
| Availability | SUNWcs |

See Also [svcs\(1\)](#), [at\(1\)](#), [crontab\(1\)](#), [sh\(1\)](#), [logadm\(1M\)](#), [svcadm\(1M\)](#), [queuedefs\(4\)](#), [shadow\(4\)](#), [attributes\(5\)](#), [rbac\(5\)](#), [smf\(5\)](#), [smf_security\(5\)](#)

Notes The cron service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/cron:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command. Most administrative actions may be delegated to users with the `solaris.smf.manage.cron` authorization (see [rbac\(5\)](#) and [smf_security\(5\)](#)).

Diagnostics A history of all actions taken by cron is stored in `/var/cron/log` and possibly in `/var/cron/olog`.

Name cryptoadm – cryptographic framework administration

Synopsis cryptoadm list [-mpv] [provider=*provider-name*]
[mechanism=*mechanism-list*]

cryptoadm disable
provider=*provider-name* mechanism=*mechanism-list* | random | all

cryptoadm enable
provider=*provider-name* mechanism=*mechanism-list* | random | all

cryptoadm install provider=*provider-name*

cryptoadm install provider=*provider-name*
[mechanism=*mechanism-list*]

cryptoadm uninstall provider=*provider-name*

cryptoadm unload provider=*provider-name*

cryptoadm disable fips-140

cryptoadm enable fips-140

cryptoadm list fips-140

cryptoadm refresh

cryptoadm start

cryptoadm stop

cryptoadm --help

Description The `cryptoadm` utility displays cryptographic provider information for a system, configures the mechanism policy for each provider, and installs or uninstalls a cryptographic provider. The cryptographic framework supports three types of providers: a user-level provider (a PKCS11 shared library), a kernel software provider (a loadable kernel software module), and a kernel hardware provider (a cryptographic hardware device).

For kernel software providers, the `cryptoadm` utility provides the `unload` subcommand. This subcommand instructs the kernel to unload a kernel software providers.

For the cryptographic framework's `metaslot`, the `cryptoadm` utility provides subcommands to enable and disable the `metaslot`'s features, list `metaslot`'s configuration, specify alternate persistent object storage, and configure the `metaslot`'s mechanism policy.

The `cryptoadm` utility provides subcommands to enable and disable FIPS-140 mode in the Cryptographic Framework. It also provides a `list` subcommand to display the current status of FIPS-140 mode.

Administrators will find it useful to use `syslog` facilities (see [syslogd\(1M\)](#) and [logadm\(1M\)](#)) to maintain the cryptographic subsystem. Logging can be especially useful under the following circumstances:

- If kernel-level daemon is dead, all applications fail. You can learn this from syslog and use [svcadm\(1M\)](#) to restart the `svc:/system/cryptosvc` service.
- If there are bad providers plugged into the framework, you can learn this from syslog and remove the bad providers from the framework.

With the exception of the subcommands or options listed below, the `cryptoadm` command needs to be run by a privileged user.

- subcommand `list`, any options
- subcommand `--help`

Options The `cryptoadm` utility has the various combinations of subcommands and options shown below.

`cryptoadm list`

Display the list of installed providers.

`cryptoadm list metaslot`

Display the system-wide configuration for metaslot.

`cryptoadm list -m [provider=provider-name | metaslot]`

Display a list of mechanisms that can be used with the installed providers or metaslot. If a provider is specified, display the name of the specified provider and the mechanism list that can be used with that provider. If the metaslot keyword is specified, display the list of mechanisms that can be used with metaslot.

`cryptoadm list -p [provider=provider-name | metaslot]`

Display the mechanism policy (that is, which mechanisms are available and which are not) for the installed providers. Also display the provider feature policy or metaslot. If a provider is specified, display the name of the provider with the mechanism policy enforced on it only. If the metaslot keyword is specified, display the mechanism policy enforced on the metaslot.

`cryptoadm list -v provider=provider-name | metaslot`

Display details about the specified provider if a provider is specified. If the metaslot keyword is specified, display details about the metaslot.

`-v`

For the various `list` subcommands described above (except for `list -p`), the `-v` (verbose) option provides details about providers, mechanisms and slots.

`cryptoadm disable provider=provider-name
[mechanism=mechanism-list | provider-feature ... | all]`

Disable the mechanisms or provider features specified for the provider. See OPERANDS for a description of *mechanism*, *provider-feature*, and the `all` keyword.

`cryptoadm [mechanism=mechanism-list] [auto-key-migrate]`

Disable the metaslot feature in the cryptographic framework or disable some of metaslot's features. If no operand is specified, this command disables the metaslot feature in the

cryptographic framework. If a list of mechanisms is specified, disable mechanisms specified for metaslot. If all mechanisms are disabled for metaslot, the metaslot will be disabled. See OPERANDS for a description of mechanism. If the `auto-key-migrate` keyword is specified, it disables the migration of sensitive token objects to other slots even if it is necessary for performing crypto operations. See OPERANDS for a description of `auto-key-migrate`.

```
cryptoadm enable provider=provider-name
```

```
[ mechanism=mechanism-list | provider-feature . . . | all ]
```

Enable the mechanisms or provider features specified for the provider. See OPERANDS for a description of *mechanism*, *provider-feature*, and the `all` keyword.

```
cryptoadm enable metaslot [ mechanism=mechanism-list ] |
```

```
[ [ token=token-label] [ slot=slot-description] |
```

```
default-keystore ] | [ auto-key-migrate ]
```

If no operand is specified, this command enables the metaslot feature in the cryptographic framework. If a list of mechanisms is specified, it enables only the list of specified mechanisms for metaslot. If *token-label* is specified, the specified token will be used as the persistent object store. If the *slot-description* is specified, the specified slot will be used as the persistent object store. If both the *token-label* and the *slot-description* are specified, the provider with the matching token label and slot description is used as the persistent object store. If the `default-keystore` keyword is specified, metaslot will use the default persistent object store. If the `auto-key-migrate` keyword is specified, sensitive token objects will automatically migrate to other slots as needed to complete certain crypto operations. See OPERANDS for a description of mechanism, token, slot, `default-keystore`, and `auto-key-migrate`.

```
cryptoadm install provider=provider-name
```

Install a user-level provider into the system. The *provider* operand must be an absolute pathname of the corresponding shared library. If there are both 32-bit and 64-bit versions for a library, this command should be run once only with the path name containing `$ISA`. Note that `$ISA` is not a reference to an environment variable. Note also that `$ISA` must be quoted (with single quotes [for example, '`$ISA`']) or the `$` must be escaped to keep it from being incorrectly expanded by the shell. The user-level framework expands `$ISA` to an empty string or an architecture-specific directory, for example, `sparcv9`.

The preferred way of installing a user-level provider is to build a package for the provider. For more information, see the *Solaris Security for Developer's Guide*.

```
cryptoadm install provider=provider-name
```

```
mechanism=mechanism-list
```

Install a kernel software provider into the system. The provider should contain the base name only. The *mechanism-list* operand specifies the complete list of mechanisms to be supported by this provider.

The preferred way of installing a kernel software provider is to build a package for providers. For more information, see the *Solaris Security for Developer's Guide*.

`cryptoadm uninstall provider=provider-name`

Uninstall the specified *provider* and the associated mechanism policy from the system. This subcommand applies only to a user-level provider or a kernel software provider.

`cryptoadm unload provider=provider-name`

Unload the kernel software module specified by *provider*.

`cryptoadm disable fips-140`

Disable FIPS-140 mode in the Cryptographic Framework and for hardware providers.

`cryptoadm enable fips-140`

Enable FIPS-140 mode in the Cryptographic Framework and for hardware providers. This subcommand does not disable the non-FIPS approved algorithms from the user-level `pkcs11_softtoken` library and the kernel software providers. It is the consumers of the framework that are responsible for using only FIPS-approved algorithms.

Upon completion of this subcommand, a message is issued to inform the administrator that any plugins added that are not within the boundary might invalidate FIPS compliance and to check the Security Policies for those plugins.

The system will require a reboot to perform Power-Up Self Tests that include a cryptographic algorithm test and a software integrity test.

`cryptoadm list fips-140`

Display the current setting of FIPS-140 mode in the Cryptographic Framework and for hardware providers. The status of FIPS-140 mode is `enabled` or `disabled`. The default FIPS-140 mode is `disabled`.

`cryptoadm refresh`

`cryptoadm start`

`cryptoadm stop`

Private interfaces for use by `smf(5)`, these must not be used directly.

`cryptoadm -help`

Display the command usage.

Operands `provider=provider-name`

A user-level provider (a PKCS11 shared library), a kernel software provider (a loadable kernel software module), or a kernel hardware provider (a cryptographic hardware device).

A valid value of the *provider* operand is one entry from the output of a command of the form: `cryptoadm list`. A *provider* operand for a user-level provider is an absolute pathname of the corresponding shared library. A *provider* operand for a kernel software provider contains a base name only. A *provider* operand for a kernel hardware provider is in a “*name/number*” form.

mechanism=mechanism-list

A comma separated list of one or more PKCS #11 mechanisms. A process for implementing a cryptographic operation as defined in PKCS #11 specification. You can substitute `all` for *mechanism-list*, to specify all mechanisms on a provider. See the discussion of the `all` keyword, below.

provider-feature

A cryptographic framework feature for the given provider. Currently only `random` is accepted as a feature. For a user-level provider, disabling the random feature makes the PKCS #11 routines `C_GenerateRandom` and `C_SeedRandom` unavailable from the provider. For a kernel provider, disabling the random feature prevents `/dev/random` from gathering random numbers from the provider.

`all`

The keyword `all` can be used with with the `disable` and `enable` subcommands to operate on all provider features.

token=token-label

The label of a token in one of the providers in the cryptographic framework.

A valid value of the token operand is an item displayed under “Token Label” from the output of the command `cryptoadm list -v`.

slot=slot-description

The description of a slot in one of the providers in the cryptographic framework.

A valid value of the slot operand is an item displayed under “Description” from the output of the command `cryptoadm list -v`.

`default-keystore`

The keyword `default-keystore` is valid only for `metaslot`. Specify this keyword to set the persistent object store for `metaslot` back to using the default store.

`auto-key-migrate`

The keyword `auto-key-migrate` is valid only for `metaslot`. Specify this keyword to configure whether `metaslot` is allowed to move sensitive token objects from the token object slot to other slots for performing cryptographic operations.

The keyword `all` can be used in two ways with the `disable` and `enable` subcommands:

- You can substitute `all` for *mechanism=mechanism-list*, as in:

```
# cryptoadm enable provider=dca/0 all
```

This command enables the mechanisms on the provider *and* any other provider-features, such as `random`.

```
# cryptoadm enable provider=des mechanism=all
```

- You can also use `all` as an argument to `mechanism`, as in:

```
# cryptoadm enable provider=des mechanism=all
```

...which enables all mechanisms on the provider, but enables no other provider-features, such as random.

Examples EXAMPLE 1 Display List of Providers Installed in System

The following command displays a list of all installed providers:

```
example% cryptoadm list
user-level providers:
/usr/lib/security/$ISA/pkcs11_kernel.so
/usr/lib/security/$ISA/pkcs11_softtoken.so
/opt/lib/libcryptoki.so.1
/opt/SUNWconn/lib/$ISA/libpkcs11.so.1

kernel software providers:
  des
  aes
  bfish
  sha1
  md5

kernel hardware providers:
  dca/0
```

EXAMPLE 2 Display Mechanism List for md5 Provider

The following command is a variation of the `list` subcommand:

```
example% cryptoadm list -m provider=md5
md5: CKM_MD5,CKM_MD5_HMAC,CKM_MD5_HMAC_GENERAL
```

EXAMPLE 3 Disable Specific Mechanisms for Kernel Software Provider

The following command disables mechanisms `CKM_DES3_ECB` and `CKM_DES3_CBC` for the kernel software provider `des`:

```
example# cryptoadm disable provider=des
```

EXAMPLE 4 Display Mechanism Policy for a Provider

The following command displays the mechanism policy for the `des` provider:

```
example% cryptoadm list -p provider=des
des: All mechanisms are enabled, except CKM_DES3_ECB, CKM_DES3_CBC
```

EXAMPLE 5 Enable Specific Mechanism for a Provider

The following command enables the `CKM_DES3_ECB` mechanism for the kernel software provider `des`:

```
example# cryptoadm enable provider=des mechanism=CKM_DES3_ECB
```

EXAMPLE 6 Install User-Level Provider

The following command installs a user-level provider:

```
example# cryptoadm install provider=/opt/lib/libcryptoki.so.1
```

EXAMPLE 7 Install User-Level Provider That Contains 32- and 64-bit Versions

The following command installs a user-level provider that contains both 32-bit and 64-bit versions:

```
example# cryptoadm install \  
provider=/opt/SUNWconn/lib/'$ISA'/libpkcs11.so.1
```

EXAMPLE 8 Uninstall a Provider

The following command uninstalls the md5 provider:

```
example# cryptoadm uninstall provider=md5
```

EXAMPLE 9 Disable metaslot

The following command disables the metaslot feature in the cryptographic framework.

```
example# cryptoadm disable metaslot
```

EXAMPLE 10 Specify metaslot to Use Specified Token as Persistent Object Store

The following command specifies that metaslot use the Venus token as the persistent object store.

```
example# cryptoadm enable metaslot token="SUNW,venus"
```

Exit Status The following exit values are returned:

0
Successful completion.

>0
An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | See below. |

The start, stop, and refresh options are Private interfaces. All other options and the utility name are Committed.

See Also `logadm(1M)`, `svcadm(1M)`, `syslogd(1M)`, `libpkcs11(3LIB)`, `exec_attr(4)`, `prof_attr(4)`, `attributes(5)`, `smf(5)`, `random(7D)`

System Administration Guide: Security Services

Solaris Security for Developer's Guide

Notes If a hardware provider's policy was made explicitly (that is, some of its mechanisms were disabled) and the hardware provider has been detached, the policy of this hardware provider is still listed.

`cryptoadm` assumes that, minimally, a 32-bit shared object is delivered for each user-level provider. If both a 32-bit and 64-bit shared object are delivered, the two versions must provide the same functionality. The same mechanism policy applies to both.

Name cvcd – virtual console daemon

Synopsis /platform/platform_name/cvcd [-a *auth*] [-e *encr*]
[-u *esp_auth*]

Description The virtual console daemon, cvcd, is a server process that supports the network console provided on some platforms. The cvcd daemon accepts network console connections from a remote host (only one host at any given time). Console input is read from this connection and forwarded to [cvc\(7D\)](#) by way of [cvcredir\(7D\)](#).

Similarly, console output is read from [cvcredir\(7D\)](#) and forwarded across the network console connection. If cvcd dies, console traffic is automatically rerouted through an internal hardware interface.

The cvcd daemon normally starts at system boot time. Each domain supports only one cvcd process at a time.

Caution – On Sun Enterprise 10000 domains, cvcd uses a configuration file (/etc/ssphostname) to determine the name of the host from which network console connections are allowed. If the remote console host is renamed, you must edit the configuration file to reflect that change.

The cvcd daemon supports per-socket IP Security Architecture (IPsec) through the options described below. See [ipsec\(7P\)](#).

Options The cvcd daemon supports the options listed below.

- a *auth* Controls the IPsec Authentication Header (AH) algorithm. *auth* can be one of none, md5, or sha1.
- e *encr* Controls the IPsec Encapsulating Security Payload (ESP) encryption algorithm. *encr* can be one of none, des, or 3des.
- u *esp_auth* Controls the IPsec Encapsulating Security Payload (ESP) authentication algorithm. *esp_auth* can be one of none, md5, or sha1.

Operands The following operands are supported:

platform_name The official Sun platform name used in packaging and code. For example, for Sun Fire 15K servers, the *platform_name* would be SUNW, Sun-Fire-15000.

Examples EXAMPLE 1 Setting an IPsec Option

The command below sets the value of the IPsec Authentication Header algorithm to md5. As a result of this command, cvcd will use the HMAC-MD5 authentication algorithm.

```
# svccfg -s svc:/system/cvc setprop cvc/ah_auth = "md5"  
# svccfg -s svc:/system/cvc setprop cvc/esp_encr = "none"  
# svccfg -s svc:/system/cvc setprop cvc/esp_auth = "none"
```

EXAMPLE 1 Setting an IPsec Option (Continued)

```
# svcadm refresh svc:/system/cvc
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------|---------------------------------------------------------|
| Architecture | Sun Enterprise 10000 servers, Sun Fire High-End Systems |
| Availability | system/network-console |

See Also [svcs\(1\)](#), [svcadm\(1M\)](#), [svccfg\(1M\)](#), [services\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#), [cvc\(7D\)](#), [cvcredir\(7D\)](#), [ipsec\(7P\)](#)

Sun Enterprise 10000 SSP Reference Manual

System Management Services (SMS) Reference Manual

Notes The cvcd service is managed by the service management facility, [smf\(5\)](#), under the fault management resource identifier (FMRI):

```
svc:/system/cvc
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#) or [svccfg\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Name datadm – maintain DAT static registry file

Synopsis /usr/bin/datadm [-v] [-u] [-a service_provider.conf]
[-r service_provider.conf]

Description The datadm utility maintains the DAT static registry file, `dat.conf(4)`.

This administrative configuration program allows uDAPL service providers to add and remove themselves to the `dat.conf` file.

You can add or remove interface adapters that a service provider supports from a system after its installation. You can use `datadm` to update the `dat.conf` file to reflect the current state of the system. A new set of interface adapters for all the service providers currently installed is regenerated.

Options The following options are supported:

`-a service_provider.conf`

Enumerate each device entry in the `service_provider.conf(4)` file into a list of interface adapters, that is, interfaces to external network that are available to uDAPL consumers.

`-r service_provider.conf`

Remove the list of interface adapters that corresponds to the device entry in the `service_provider.conf(4)` file.

`-u`

Update the `dat.conf` to reflect the current state of the system with an up to date set of interface adapters for the service providers that are currently listed in the DAT static registry.

`-v`

Display the DAT static registry file, `dat.conf`.

Examples EXAMPLE 1 Enumerating a Device Entry

The following example enumerates a device entry in the `service_provider.conf(4)` file into interface adapters in the `dat.conf(4)` file.

Assume that SUNW has a service provider library that supports the device `tavor`. It has a `service_provider.conf(4)` file installed in the directory `/usr/share/dat/SUNWudapl.t.conf` with a single entry as follows:

```
driver_name=tavor u1.2 nonthreadsafe default\  
udapl_tavor.so.1 SUNW.1.0 ""
```

`tavor` is an Infiniband Host Channel Adapter with two ports. Both IB ports exist in a single IB partition, `0x8001`. If an IB partition is created and plumbed to each port (with the names `p8001.ibd0` and `p8001.ibd1`), there will be two IB partition instances. See [d1adm\(1M\)](#) for more information on creating IB partition data links.

EXAMPLE 1 Enumerating a Device Entry *(Continued)*

```
# dladm show-part
```

| LINK | PKEY | OVER | STATE | FLAGS |
|------------|------|------|---------|-------|
| p8001.ibd0 | 8001 | ibd0 | unknown | ---- |
| p8001.ibd1 | 8001 | ibd1 | unknown | ---- |

Running the command:

```
# datadm -a /usr/share/dat/SUNWudapl1t.conf
```

...appends two new entries (if they do not already exist) in the `/etc/dat/dat.conf` file:

```
p8001.ibd0 u1.2 nonthreadsafe default udapl_tavor.so.1 SUNW.1.0 ""
"driver_name=tavor"
p8001.ibd1 u1.2 nonthreadsafe default udapl_tavor.so.1 SUNW.1.0 ""
"driver_name=tavor"
```

EXAMPLE 2 Updating the `dat.conf` to Reflect the Current State of the System

A new IB partition, `0x8002`, is added to the above example covering port 1 of the Host Channel Adapter. If a new IB partition is created on the port 1/partition `0x8002` with the partition link name specified as `p8002.ibd0`, there will be a third IB partition instance: `p8002.ibd0`.

```
# dladm show-part
```

| LINK | PKEY | OVER | STATE | FLAGS |
|------------|------|------|---------|-------|
| p8001.ibd0 | 8001 | ibd0 | unknown | ---- |
| p8001.ibd1 | 8001 | ibd1 | unknown | ---- |
| p8002.ibd0 | 8000 | ibd0 | unknown | ---- |

Running `datadm -u` command, updates the `/etc/dat/dat.conf` file with a new entry added reflecting the current state of the system.

`datadm -v` shows that there are now three entries in the `/etc/dat/dat.conf` file:

```
p8001.ibd0 u1.2 nonthreadsafe default udapl_tavor.so.1 SUNW.1.0 ""
"driver_name=tavor"
p8001.ibd1 u1.2 nonthreadsafe default udapl_tavor.so.1 SUNW.1.0 ""
"driver_name=tavor"
p8002.ibd0 u1.2 nonthreadsafe default udapl_tavor.so.1 SUNW.1.0 ""
"driver_name=tavor"
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------|
| Availability | system/network/udapl |
| Interface Stability | Committed |

See Also [dladm\(1M\)](#), [pkgadd\(1M\)](#), [pkgrm\(1M\)](#), [libdat\(3LIB\)](#), [dat.conf\(4\)](#), [service_provider.conf\(4\)](#), [attributes\(5\)](#)

Name dcs – domain configuration server

Synopsis /usr/lib/dcs [-s *sessions*]
 [[-a *auth*] [-e *encr*] [-u *esp_auth*]] [-l]

Description The Domain Configuration Server (DCS) is a daemon process that runs on Sun servers that support remote Dynamic Reconfiguration (DR) clients. It is started by the Service Management Facility (see [smf\(5\)](#)) when the first DR request is received from a client connecting to the network service `sun-dr`. After the DCS accepts a DR request, it uses the [libcfgadm\(3LIB\)](#) interface to execute the DR operation. After the operation is performed, the results are returned to the client.

The DCS listens on the network service labeled `sun-dr`. Its underlying protocol is TCP. It is invoked as a server program by the SMF using the TCP transport. The fault management resource identifier (FMRI) for DCS is:

```
svc:/platform/sun4u/dcs:default
```

If you disable this service, DR operations initiated from a remote host fail. There is no negative impact on the server.

Security for the DCS connection is provided differently based upon the architecture of the system. The SMF specifies the correct options when invoking the DCS daemon, based upon the current architecture. For all architectures, security is provided on a per-connection basis.

The DCS daemon has no security options that are applicable when used on a Sun Enterprise 10000 system. So there are no options applicable to that architecture.

The security options for Sun Fire high-end systems are based on IPsec options defined as SMF properties. These options include the `-a auth`, `-e encr`, and `-u esp_auth` options, and can be set using the [svccfg\(1M\)](#) command. These options must match the IPsec policies defined for DCS on the system controller. Refer to the `kmd(1M)` man page in the *System Management Services (SMS) Reference Manual*. The `kmd(1M)` man page is not part of the SunOS man page collection.

Security on SPARC Enterprise Servers is not configurable. The DCS daemon uses a platform-specific library to configure its security options when running on such systems. The `-l` option is provided by the SMF when invoking the DCS daemon on SPARC Enterprise Servers. No other security options to the DCS daemon should be used on SPARC Enterprise Servers.

Options The following options are supported:

- `-a auth` Controls the IPsec Authentication Header (AH) algorithm. *auth* can be one of none, md5, or sha1.
- `-e encr` Controls the IPsec Encapsulating Security Payload (ESP) encryption algorithm. *encr* can be one of none, des, or 3des.

- l Enables the use of platform-specific security options on SPARC Enterprise Servers.
- s *sessions* Sets the number of active sessions that the DCS allows at any one time. When the limit is reached, the DCS stops accepting connections until active sessions complete the execution of their DR operation. If this option is not specified, a default value of 128 is used.
- u *esp_auth* Controls the IPsec Encapsulating Security Payload (ESP) authentication algorithm. *esp_auth* can be one of none, md5, or sha1.

Examples **EXAMPLE 1** Setting an IPsec Option

The following command sets the Authentication Header algorithm for the DCS daemon to use the HMAC-MD5 authentication algorithm. These settings are only applicable for using the DCS daemon on a Sun Fire high-end system.

```
# svccfg -s svc:/platform/sun4u/dcs setprop dcs/ah_auth = "md5"
# svccfg -s svc:/platform/sun4u/dcs setprop dcs/esp_encr = "none"
# svccfg -s svc:/platform/sun4u/dcs setprop dcs/esp_auth = "none"
# svcadm refresh svc:/platform/sun4u/dcs
```

Errors The DCS uses [syslog\(3C\)](#) to report status and error messages. All of the messages are logged with the LOG_DAEMON facility. Error messages are logged with the LOG_ERR and LOG_NOTICE priorities, and informational messages are logged with the LOG_INFO priority. The default entries in the `/etc/syslog.conf` file log all of the DCS error messages to the `/var/adm/messages` log.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|--------------------------------------------------------|
| Availability | system/domain-configuration/sparc-enterprise, SUNWdcsr |
| Interface Stability | Committed |

See Also [svcs\(1\)](#), [cfgadm_sbd\(1M\)](#), [svcadm\(1M\)](#), [svccfg\(1M\)](#), [syslog\(3C\)](#), [config_admin\(3CFGADM\)](#), [libcfgadm\(3LIB\)](#), [syslog.conf\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#), [dr\(7d\)](#)

Notes The `dcs` service is managed by the service management facility, [smf\(5\)](#), under the fault management resource identifier (FMRI):

```
svc:/platform/sun4u/dcs:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Name dd – convert and copy a file

Synopsis /usr/bin/dd [*operand=value*]. . .

Description The dd utility copies the specified input file to the specified output with possible conversions. The standard input and output are used by default. The input and output block sizes may be specified to take advantage of raw physical I/O. Sizes are specified in bytes; a number may end with k, b, or w to specify multiplication by 1024, 512, or 2, respectively. Numbers may also be separated by x to indicate multiplication.

The dd utility reads the input one block at a time, using the specified input block size. dd then processes the block of data actually returned, which could be smaller than the requested block size. dd applies any conversions that have been specified and writes the resulting data to the output in blocks of the specified output block size.

cbs is used only if `ascii`, `asciib`, `unblock`, `ebcdic`, `ebcdicb`, `ibm`, `ibmb`, or `block` conversion is specified. In the first two cases, cbs characters are copied into the conversion buffer, any specified character mapping is done, trailing blanks are trimmed, and a `NEWLINE` is added before sending the line to output. In the last three cases, characters up to `NEWLINE` are read into the conversion buffer and blanks are added to make up an output record of size cbs. ASCII files are presumed to contain `NEWLINE` characters. If cbs is unspecified or 0, the `ascii`, `asciib`, `ebcdic`, `ebcdicb`, `ibm`, and `ibmb` options convert the character set without changing the input file's block structure. The `unblock` and `block` options become a simple file copy.

After completion, dd reports the number of whole and partial input and output blocks.

Operands The following operands are supported:

| | |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>if=file</code> | Specifies the input path. Standard input is the default. |
| <code>of=file</code> | Specifies the output path. Standard output is the default. If the <code>seek=expr</code> conversion is not also specified, the output file will be truncated before the copy begins, unless <code>conv=notrunc</code> is specified. If <code>seek=expr</code> is specified, but <code>conv=notrunc</code> is not, the effect of the copy will be to preserve the blocks in the output file over which dd seeks, but no other portion of the output file will be preserved. (If the size of the seek plus the size of the input file is less than the previous size of the output file, the output file is shortened by the copy.) |
| <code>ibs=n</code> | Specifies the input block size in <i>n</i> bytes (default is 512). |
| <code>obs=n</code> | Specifies the output block size in <i>n</i> bytes (default is 512). |
| <code>bs=n</code> | Sets both input and output block sizes to <i>n</i> bytes, superseding <code>ibs=</code> and <code>obs=</code> . If no conversion other than <code>sync</code> , <code>noerror</code> , and <code>notrunc</code> is specified, each input block is copied to the output as a single block without aggregating short blocks. |

| | |
|------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cbs=<i>n</i></code> | Specifies the conversion block size for <code>block</code> and <code>unblock</code> in bytes by <i>n</i> (default is 0). If <code>cbs=</code> is omitted or given a value of 0, using <code>block</code> or <code>unblock</code> produces unspecified results. |
| | This option is used only if ASCII or EBCDIC conversion is specified. For the <code>ascii</code> and <code>asciib</code> operands, the input is handled as described for the <code>unblock</code> operand except that characters are converted to ASCII before the trailing SPACE characters are deleted. For the <code>ebcdic</code> , <code>ebcdicb</code> , <code>ibm</code> , and <code>ibmb</code> operands, the input is handled as described for the <code>block</code> operand except that the characters are converted to EBCDIC or IBM EBCDIC after the trailing SPACE characters are added. |
| <code>files=<i>n</i></code> | Copies and concatenates <i>n</i> input files before terminating (makes sense only where input is a magnetic tape or similar device). |
| <code>skip=<i>n</i></code> | Skips <i>n</i> input blocks (using the specified input block size) before starting to copy. On seekable files, the implementation reads the blocks or seeks past them. On non-seekable files, the blocks are read and the data is discarded. |
| <code>iseek=<i>n</i></code> | Seeks <i>n</i> blocks from beginning of input file before copying (appropriate for disk files, where <code>skip</code> can be incredibly slow). |
| <code>oseek=<i>n</i></code> | Seeks <i>n</i> blocks from beginning of output file before copying. |
| <code>seek=<i>n</i></code> | Skips <i>n</i> blocks (using the specified output block size) from beginning of output file before copying. On non-seekable files, existing blocks are read and space from the current end-of-file to the specified offset, if any, is filled with null bytes. On seekable files, the implementation seeks to the specified offset or reads the blocks as described for non-seekable files. |
| <code>count=<i>n</i></code> | Copies only <i>n</i> input blocks. |
| <code>conv=<i>value</i>[, <i>value</i>. . .]</code> | Where <i>values</i> are comma-separated symbols from the following list: |
| | <code>ascii</code> Converts EBCDIC to ASCII. |
| | <code>asciib</code> Converts EBCDIC to ASCII using BSD-compatible character translations. |
| | <code>ebcdic</code> Converts ASCII to EBCDIC. If converting fixed-length ASCII records without NEWLINES, sets up a pipeline with <code>dd conv=unblock</code> beforehand. |
| | <code>ebcdicb</code> Converts ASCII to EBCDIC using BSD-compatible character translations. If converting fixed-length |

- ASCII records without `NEWLINEs`, sets up a pipeline with `dd conv=unblock` beforehand.
- `ibm` Slightly different map of ASCII to EBCDIC. If converting fixed-length ASCII records without `NEWLINEs`, sets up a pipeline with `dd conv=unblock` beforehand.
- `ibmb` Slightly different map of ASCII to EBCDIC using BSD-compatible character translations. If converting fixed-length ASCII records without `NEWLINEs`, sets up a pipeline with `dd conv=unblock` beforehand.

The `ascii` (or `asciib`), `ebcdic` (or `ebcdicb`), and `ibm` (or `ibmb`) values are mutually exclusive.

- `block` Treats the input as a sequence of `NEWLINE`-terminated or EOF-terminated variable-length records independent of the input block boundaries. Each record is converted to a record with a fixed length specified by the conversion block size. Any `NEWLINE` character is removed from the input line. `SPACE` characters are appended to lines that are shorter than their conversion block size to fill the block. Lines that are longer than the conversion block size are truncated to the largest number of characters that will fit into that size. The number of truncated lines is reported.
- `unblock` Converts fixed-length records to variable length. Reads a number of bytes equal to the conversion block size (or the number of bytes remaining in the input, if less than the conversion block size), delete all trailing `SPACE` characters, and append a `NEWLINE` character.

The `block` and `unblock` values are mutually exclusive.

- `lcase` Maps upper-case characters specified by the `LC_CTYPE` keyword `tolower` to the corresponding lower-case character. Characters for which no mapping is specified are not modified by this conversion.
- `ucase` Maps lower-case characters specified by the `LC_CTYPE` keyword `toupper` to the corresponding upper-case character. Characters for which no mapping is specified are not modified by this conversion.

The `lcase` and `ucase` symbols are mutually exclusive.

| | |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>swab</code> | Swaps every pair of input bytes. If the current input record is an odd number of bytes, the last byte in the input record is ignored. |
| <code>noerror</code> | Does not stop processing on an input error. When an input error occurs, a diagnostic message is written on standard error, followed by the current input and output block counts in the same format as used at completion. If the <code>sync</code> conversion is specified, the missing input is replaced with null bytes and processed normally. Otherwise, the input block will be omitted from the output. |
| <code>notrunc</code> | Does not truncate the output file. Preserves blocks in the output file not explicitly written by this invocation of <code>dd</code> . (See also the preceding <code>of=file</code> operand.) |
| <code>sync</code> | Pads every input block to the size of the <code>ibs=</code> buffer, appending null bytes. (If either <code>block</code> or <code>unblock</code> is also specified, appends SPACE characters, rather than null bytes.) |

If operands other than `conv=` are specified more than once, the last specified operand=*value* is used.

For the `bs=`, `cbs=`, `ibs=`, and `obs=` operands, the application must supply an expression specifying a size in bytes. The expression, `expr`, can be:

1. a positive decimal number
2. a positive decimal number followed by `k`, specifying multiplication by 1024
3. a positive decimal number followed by `b`, specifying multiplication by 512
4. two or more positive decimal numbers (with or without `k` or `b`) separated by `x`, specifying the product of the indicated values.

All of the operands will be processed before any input is read.

Usage See [largefile\(5\)](#) for the description of the behavior of `dd` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples **EXAMPLE 1** Copying from one tape drive to another

The following example copies from tape drive `0` to tape drive `1`, using a common historical device naming convention.

EXAMPLE 1 Copying from one tape drive to another (Continued)

```
example% dd if=/dev/rmt/0h of=/dev/rmt/1h
```

EXAMPLE 2 Stripping the first 10 bytes from standard input

The following example strips the first 10 bytes from standard input:

```
example% dd ibs=10 skip=1
```

EXAMPLE 3 Reading a tape into an ASCII file

This example reads an EBCDIC tape blocked ten 80-byte EBCDIC card images per block into the ASCII file x:

```
example% dd if=/dev/tape of=x ibs=800 cbs=80 conv=ascii,lcas
```

EXAMPLE 4 Using conv=sync to write to tape

The following example uses conv=sync when writing to a tape:

```
example% tar cvf - . | compress | dd obs=1024k of=/dev/rmt/0 conv=sync
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of dd: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status The following exit values are returned:

- 0 The input file was copied successfully.
- >0 An error occurred.

If an input error is detected and the `noerror` conversion has not been specified, any partial output block will be written to the output file, a diagnostic message will be written, and the copy operation will be discontinued. If some other error is detected, a diagnostic message will be written and the copy operation will be discontinued.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------------------------|
| Availability | SUNWcs |
| Interface Stability | Committed |
| Standard | See standards(5) . |

See Also [cp\(1\)](#), [sed\(1\)](#), [tr\(1\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

Diagnostics f+p records in(out) numbers of full and partial blocks read(written)

Notes Do not use dd to copy files between file systems having different block sizes.

Using a blocked device to copy a file will result in extra nulls being added to the file to pad the final block to the block boundary.

When dd reads from a pipe, using the `ibs=X` and `obs=Y` operands, the output will always be blocked in chunks of size Y. When `bs=Z` is used, the output blocks will be whatever was available to be read from the pipe at the time.

When using dd to copy files to a tape device, the file size must be a multiple of the device sector size (for example, 512 Kbyte). To copy files of arbitrary size to a tape device, use [tar\(1\)](#) or [cpio\(1\)](#).

For SIGINT, dd writes status information to standard error before exiting. It takes the standard action for all other signals.

Name devattr – display device attributes

Synopsis devattr [-v] *device* [*attribute*]...

Description devattr displays the values for a device's attributes. The display can be presented in two formats. Used without the -v option, only the attribute values are shown. Used with the -v option, the attributes are shown in an *attribute=value* format. When no attributes are given on the command line, all attributes for the specified device are displayed in alphabetical order by attribute name. If attributes are given on the command line, only those attributes are shown, displayed in command line order.

Options The following options are supported:

-v Specifies verbose format. Attribute values are displayed in an *attribute=value* format.

Operands The following operands are supported:

attribute Defines which attribute, or attributes, should be shown. Default is to show all attributes for a device. See the [putdev\(1M\)](#) manual page for a complete listing and description of available attributes.

device Defines the device whose attributes should be displayed. Can be the pathname of the device or the device alias.

Exit Status The following exit values are returned:

- 0 successful completion.
- 1 Command syntax was incorrect, invalid option was used, or an internal error occurred.
- 2 Device table could not be opened for reading.
- 3 Requested device could not be found in the device table.
- 4 Requested attribute was not defined for the specified device.

Files /etc/device.tab

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [getdev\(1M\)](#), [putdev\(1M\)](#), [attributes\(5\)](#)

Name devfree – release devices from exclusive use

Synopsis devfree *key* [*device*]...

Description devfree releases devices from exclusive use. Exclusive use is requested with the command devreserv.

When devfree is invoked with only the *key* argument, it releases all devices that have been reserved for that *key*. When called with *key* and *device* arguments, devfree releases the specified devices that have been reserved with that *key*.

Operands The following operands are supported:

device Defines device that this command will release from exclusive use. *device* can be the pathname of the device or the device alias.

key Designates the unique key on which the device was reserved.

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 Command syntax was incorrect, an invalid option was used, or an internal error occurred.
- 2 Device table or device reservation table could not be opened for reading.
- 3 Reservation release could not be completely fulfilled because one or more of the devices was not reserved or was not reserved on the specified key.

Files /etc/device.tab

/etc/devlckfile

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [devreserv\(1M\)](#), [attributes\(5\)](#)

Notes The commands devreserv and devfree are used to manage the availability of devices on a system. These commands do not place any constraints on the access to the device. They serve only as a centralized bookkeeping point for those who wish to use them. Processes that do not use devreserv may concurrently use a device with a process that has reserved that device.

Name devfsadm, devfsadmd – administration command for /dev

Synopsis /usr/sbin/devfsadm [-C] [-c *device_class*] [-i *driver_name*]
 [-n] [-r *root_dir*] [-s] [-t *table_file*] [-u] [-v]
 /usr/lib/devfsadm/devfsadmd

Description devfsadm maintains the /dev namespace. It replaces the previous suite of devfs administration tools including [drvconfig\(1M\)](#), [disks\(1M\)](#), [tapes\(1M\)](#), [ports\(1M\)](#), [audlinks\(1M\)](#), and [devlinks\(1M\)](#).

The default operation is to attempt to load every driver in the system and attach to all possible device instances. Next, devfsadm creates logical links to device nodes in /dev and /devices and loads the device policy.

[devfsadmd\(1M\)](#) is the daemon version of devfsadm(1M). The daemon is started during system startup and is responsible for handling both reconfiguration boot processing and updating /dev and /devices in response to dynamic reconfiguration event notifications from the kernel.

For compatibility purposes, [drvconfig\(1M\)](#), [disks\(1M\)](#), [tapes\(1M\)](#), [ports\(1M\)](#), [audlinks\(1M\)](#), and [devlinks\(1M\)](#) are implemented as links to devfsadm.

In addition to managing /dev, devfsadm also maintains the [path_to_inst\(4\)](#) database.

Options The following options are supported:

- C
 Cleanup mode. Prompt devfsadm to cleanup dangling /dev links that are not normally removed. If the -c option is also used, devfsadm only cleans up for the listed devices' classes.
- c *device_class*
 Restrict operations to devices of class *device_class*. Solaris defines the following values for *device_class*: disk, tape, port, audio, and pseudo. This option might be specified more than once to specify multiple device classes.
- i *driver_name*
 Configure only the devices for the named driver, *driver_name*.
- n
 Do not attempt to load drivers or add new nodes to the kernel device tree.
- s
 Suppress any changes to /dev. This is useful with the -v option for debugging.
- t *table_file*
 Read an alternate devlink.tab file. devfsadm normally reads /etc/devlink.tab.

- u
Activate and attach devices for drivers added with [add_drv\(1M\)](#) -u. Cannot be used together with -n or -r.
- r *root_dir*
Presume that the /dev directory trees are found under *root_dir*, not directly under root (/). No other use or assumptions are made about *root_dir*.
- v
Print changes to /dev in verbose mode.

Exit Status The following exit values are returned:

- 0
Successful completion.
- 1
An error occurred.

Files

- /devices
device nodes directory
- /dev
logical symbolic links to /devices
- /usr/lib/devfsadm/devfsadmd
devfsadm daemon
- /dev/.devfsadm_dev.lock
update lock file
- /dev/.devfsadm_daemon.lock
daemon lock file
- /etc/security/device_policy
device policy file
- /etc/security/extra_privs
additional device privileges

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [svcs\(1\)](#), [add_drv\(1M\)](#), [modinfo\(1M\)](#), [modload\(1M\)](#), [modunload\(1M\)](#), [rem_drv\(1M\)](#), [svcadm\(1M\)](#), [tapes\(1M\)](#), [path_to_inst\(4\)](#), [attributes\(5\)](#), [privileges\(5\)](#), [smf\(5\)](#), [devfs\(7FS\)](#)

Notes This document does not constitute an API. The `/devices` directory might not exist or might have different contents or interpretations in a future release. The existence of this notice does not imply that any other documentation that lacks this notice constitutes an API.

`devfsadm` no longer manages the `/devices` name space. See [devfs\(7FS\)](#).

The device configuration service is managed by the service management facility, [smf\(5\)](#), under the service identifier, and can be used to start `devfsadm` during reconfiguration boot by:

```
svc:/system/device/local:default
```

Otherwise, `devfsadm` is started by:

```
svc:/system/sysevent:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Name device_allocate – enable and disable device allocation

Synopsis svc:/system/device/allocate:default

Description The device_allocate service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/device/allocate:default
```

An administrator with the Devices Security Rights Profile can enable or disable this service to provide for or remove the device allocation functionality as described in [allocate\(1\)](#).

Examples EXAMPLE 1 Enabling Device Allocation

The following command enables device allocation.

```
# svcadm enable svc:/system/device/allocate:default
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Volatile |

See Also [allocate\(1\)](#), [deallocate\(1\)](#), [list_devices\(1\)](#), [devfsadm\(1M\)](#), [svcadm\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Name device_remap – administer the Solaris I/O remapping feature

Synopsis /usr/platform/sun4v/sbin/device_remap [-v | -R *dir*]

Description Certain multi-node sun4v platforms, such as T5440 and T5240 servers, have an integrated PCI topology that cause the I/O device paths to change in a CPU node failover condition. The device remapping script, `device_remap`, remaps the device paths in `/etc/path_to_inst` file and the symlinks under `/dev` to match the hardware.

Options The following options are supported:

-v

Displays the `/etc/path_to_inst` and `/dev` symlink changes.

-R *dir*

Perform remapping on the `/etc/path_to_inst` and `/etc/path_to_inst` files in the root image at *dir*.

Usage The primary function of `device_remap` is to remap the device paths in the `/etc/path_to_inst` file and the symlinks under `/dev` in a CPU node failover condition to match the hardware.

After adding CPU node(s) or removing CPU node(s), boot the system to the OBP prompt and use the following procedure:

1. Boot either the failsafe miniroot using: `boot -F failsafe`, or an install miniroot using `boot net -s` or similar command.
2. Mount the root disk as `/mnt`.
3. Change directory to the mounted root disk:

```
# cd /mnt
```

4. Run `device_remap` script:

```
# /mnt/usr/platform/sun4v/sbin/device_remap
```

5. Boot the system from disk.

All the error messages are self-explanatory, except for the error message “missing ioaliases node” which means the firmware on the system does not support device remapping.

Examples EXAMPLE 1 Displaying Changes Following Failover

The following command displays the `path_to_inst` and `/dev` changes following a CPU node failover.

```
# device_remap -v
```

EXAMPLE 2 Changing Directory Prior to Any Changes

The following command changes the directory on which the boot image is mounted prior to making any changes.

```
# device_remap -R /newroot
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-------------------------|
| Availability | system/library/platform |
| Interface Stability | Uncommitted |

See Also [boot\(1M\)](#), [attributes\(5\)](#)

Name devinfo – print device specific information

Synopsis /usr/sbin/devinfo -i *device*
 /usr/sbin/devinfo -p *device*

Description The devinfo command is used to print device specific information about disk devices on standard out. The command can only be used by the superuser.

Options

- i Prints the following device information:
 - Device name
 - Software version (not supported and prints as 0)
 - Drive id number (not supported and prints as 0)
 - Device blocks per cylinder
 - Device bytes per block
 - Number of device partitions with a block size greater than zero
- p Prints the following device partition information:
 - Device name
 - Device major and minor numbers (in hexadecimal)
 - Partition start block
 - Number of blocks allocated to the partition
 - Partition flag
 - Partition tag

This command is used by various other commands to obtain device specific information for the making of file systems and determining partition information. If the device cannot be opened, an error message is reported.

Operands *device* Device name.

Exit Status 0 Successful operation.

2 Operation failed.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [prtvtoc\(1M\)](#), [attributes\(5\)](#)

Name devlinks – adds /dev entries for miscellaneous devices and pseudo-devices

Synopsis /usr/sbin/devlinks [-d] [-r *rootdir*] [-t *table-file*]

Description [devfsadm\(1M\)](#) is now the preferred command for /dev and /devices and should be used instead of devlinks.

devlinks creates symbolic links from the /dev directory tree to the actual block- and character-special device nodes under the /devices directory tree. The links are created according to specifications found in the *table-file* (by default /etc/devlink.tab).

devlinks is called each time the system is reconfiguration-booted, and can only be run after [drvconfig\(1M\)](#) is run.

The *table-file* (normally /etc/devlink.tab) is an ASCII file, with one line per record. Comment lines, which must contain a hash character ('#') as their first character, are allowed. Each entry must contain at least two fields, but may contain three fields. Fields are separated by single TAB characters.

The fields are:

devfs-spec Specification of devinfo nodes that will have links created for them. This specification consists of one or more keyword-value pairs, where the keyword is separated from the value by an equal-sign ('='), and keyword-value pairs are separated from one another by semicolons.

The possible keywords are:

| | |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>type</i> | The devinfo device type. Possible values are specified in ddi_create_minor_node(9F) |
| <i>name</i> | The name of the node. This is the portion of the /devices tree entry name that occurs before the first '@' or ':' character. |
| <i>addr[n]</i> | The address portion of a node name. This is the portion of a node name that occurs between the '@' and the ':' characters. It is possible that a node may have a name without an address part, which is the case for many of the pseudo-device nodes. If a number is given after the <i>addr</i> it specifies a match of a particular comma-separated subfield of the address field: <i>addr1</i> matches the first subfield, <i>addr2</i> matches the second, and so on. <i>addr0</i> is the same as <i>addr</i> and matches the whole field. |
| <i>minor[n]</i> | The minor portion of a node name – the portion of the name after the ':'. As with <i>addr</i> above, a number after the <i>minor</i> keyword specifies a subfield to match. |

Of these four specifications, only the *type* specification must always be present.

name Specification of the /dev links that correspond to the devinfo nodes. This field allows devlinks to determine matching /dev names for the /devices nodes it has found. The specification of this field uses escape-sequences to allow portions of the /devices name to be included in the /dev name, or to allow a counter to be used in creating node names. If a counter is used to create a name, the portion of the name before the counter must be specified absolutely, and all names in the /dev/-subdirectory that match (up to and including the counter) are considered to be subdevices of the same device. This means that they should all point to the same directory, name and address under the /devices/-tree

The possible escape-sequences are:

- \D Substitute the device-name (name) portion of the corresponding devinfo node-name.
- \An Substitute the *n*th component of the address component of the corresponding devinfo node name. Sub-components are separated by commas, and sub-component 0 is the whole address component.
- \Mn Substitute the *n*th sub-component of the minor component of the corresponding devinfo node name. Sub-components are separated by commas, and sub-component 0 is the whole minor component.
- \Nn Substitute the value of a 'counter' starting at *n*. There can be only one counter for each dev-spec, and counter-values will be selected so they are as low as possible while not colliding with already-existing link names.

In a dev-spec the counter sequence should not be followed by a digit, either explicitly or as a result of another escape-sequence expansion. If this occurs, it would not be possible to correctly match already-existing links to their counter entries, since it would not be possible to unambiguously parse the already-existing /dev-name.

extra-dev-link Optional specification of an extra /dev link that points to the initial /dev link (specified in field 2). This field may contain a counter escape-sequence (as described for the *dev-spec* field) but may not contain any of the other escape-sequences. It provides a way to specify an alias of a particular /dev name.

Options The following options are supported:

- d Debugging mode – print out all devinfo nodes found, and indicate what links would be created, but do not do anything.
- r *rootdir* Use *rootdir* as the root of the /dev and /devices directories under which the device nodes and links are created. Changing the root directory does not change the location of the /etc/devlink.tab default table, nor is the root directory applied to the filename supplied to the -t option.
- t *table-file* Set the table file used by devlinks to specify the links that must be created. If this option is not given, /etc/devlink.tab is used. This option gives a way to instruct devlinks just to perform a particular piece of work, since just the links-types that devlinks is supposed to create can be specified in a command-file and fed to devlinks.

Errors If devlinks finds an error in a line of the *table-file* it prints a warning message on its standard output and goes on to the next line in the *table-file* without performing any of the actions specified by the erroneous rule.

If it cannot create a link for some filesystem-related reason it prints an error-message and continues with the current rule.

If it cannot read necessary data it prints an error message and continues with the next *table-file* line.

Examples EXAMPLE 1 Using the /etc/devlink.tab Fields

The following are examples of the /etc/devlink.tab fields:

```
type=pseudo;name=win    win\M0
type=ddi_display    framebuffer/\M0    fb\M0
```

The first example states that all devices of type pseudo with a name component of win will be linked to /dev/win*x*, where *x* is the minor-component of the *devinfo-name* (this is always a single-digit number for the win driver).

The second example states that all devinfo nodes of type ddi_display will be linked to entries under the /dev/framebuffer directory, with names identical to the entire minor component of the /devices name. In addition an extra link will be created pointing from /dev/*fb*n** to the entry under /dev/framebuffer. This entry will use a counter to end the name.

Files

| | |
|------------------|-------------------------------------------------------|
| /dev | entries for the miscellaneous devices for general use |
| /devices | device nodes |
| /etc/devlink.tab | the default rule-file |

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [devfsadm\(1M\)](#), [attributes\(5\)](#), [devfs\(7FS\)](#), [ddi_create_minor_node\(9F\)](#)

Bugs It is very easy to construct mutually-contradictory link specifications, or specifications that can never be matched. The program does not check for these conditions.

Name devnm – device name

Synopsis /usr/sbin/devnm *name* [*name*]...

Description The devnm command identifies the special file associated with the mounted file system where the argument *name* resides. One or more *name* can be specified.

Examples EXAMPLE 1 Using the devnm Command

Assuming that /usr is mounted on /dev/dsk/c0t3d0s6, the following command :

```
/usr/sbin/devnm /usr
```

produces:

```
/dev/dsk/c0t3d0s6 /usr
```

Files /dev/dsk/*

/etc/mnttab

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [mnttab\(4\)](#), [attributes\(5\)](#)

-
- Name** devprop – display device properties
- Synopsis** /sbin/devprop [-n *device-path*] [-vq] [-{b|i|l|s}] [*property*[...]]
- Description** The devprop command displays named device properties from the device tree.
- If a device path is specified on the command line, devprop displays device properties for that device node.
- The output formats, while Volatile, are patterned after those of [prtconf\(1M\)](#).
- Options** The following options are supported:
- b
The properties to be output are sequences of bytes (DI_PROP_TYPE_BYTES). -b, -i, -l, and -s are mutually exclusive of one another.
 - i
The properties to be output are integers (DI_PROP_TYPE_INT).
 - l
The properties to be output are 64-bit integers (DI_PROP_TYPE_INT64).
 - s
The properties to be output are strings (DI_PROP_TYPE_STRING) (the default).
 - n *device-path*
The path to a target device node for which properties are displayed. The default path is that of the root node (equivalent to specifying -n /).
 - q
Specifies quoted output mode, in which string properties are output surrounded by double quotation marks (").
 - v
Specifies verbose mode, in which the name of the property is output before its value.
- Operands** The following operand is supported:
- property*...
Name of the property to be displayed.
- Exit Status** 0
No error occurred.
- non-zero
An error occurred.
- Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | See below. |

The command invocation and output are both Volatile. The location of the utility is Committed.

See Also [prtconf\(1M\)](#), [libdevinfo\(3LIB\)](#), [attributes\(5\)](#)

Name devreserv – reserve devices for exclusive use

Synopsis devreserv [*key* [*device-list*]...]

Description devreserv reserves devices for exclusive use. When the device is no longer required, use devfree to release it.

devreserv reserves at most one device per *device-list*. Each list is searched in linear order until the first available device is found. If a device cannot be reserved from each list, the entire reservation fails.

When devreserv is invoked without arguments, it lists the devices that are currently reserved and shows to which key it was reserved. When devreserv is invoked with only the *key* argument, it lists the devices that are currently reserved to that key.

Operands The following operands are supported:

device-list Defines a list of devices that devreserv will search to find an available device. The list must be formatted as a single argument to the shell.

key Designates a unique key on which the device will be reserved. The key must be a positive integer.

Examples EXAMPLE 1 Reserving a Floppy Disk and a Cartridge Tape

The following example reserves a floppy disk and a cartridge tape:

```
$ key=$$
$ echo "The current Process ID is equal to: $key"
  The Current Process ID is equal to: 10658
$ devreserv $key diskette1 ctape1
```

EXAMPLE 2 Listing All Devices Currently Reserved

The following example lists all devices currently reserved:

```
$ devreserv
disk1          2423
diskette1     10658
ctape1        10658
```

EXAMPLE 3 Listing All Devices Currently Reserved to a Particular Key

The following example lists all devices currently reserved to a particular key:

```
$ devreserv $key
diskette1
ctape1
```

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 Command syntax was incorrect, an invalid was option used, or an internal error occurred.
- 2 Device table or device reservation table could not be opened for reading.
- 3 Device reservation request could not be fulfilled.

Files /etc/device.tab
/etc/devlckfile

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [devfree\(1M\)](#), [attributes\(5\)](#)

Notes The commands `devreserv` and `devfree` are used to manage the availability of devices on a system. Their use is on a participatory basis and they do not place any constraints on the actual access to the device. They serve as a centralized bookkeeping point for those who wish to use them. Devices which have been reserved cannot be used by processes which utilize the device reservation functions until the reservation has been canceled. However, processes that do not use device reservation may use a device that has been reserved since such a process would not have checked for its reservation status.

- Name** `df` – displays number of free disk blocks and free files
- Synopsis** `/usr/bin/df [-F FSType] [-abeghklntVvZ]`
`[-o FSType-specific_options]`
`[block_device | directory | file | resource ...]`
- `/usr/xpg4/bin/df [-F FSType] [-abeghklntVZ]`
`[-o FSType-specific_options]`
`[block_device | directory | file | resource ...]`
- Description** The `df` utility displays the amount of disk space occupied by mounted or unmounted file systems, the amount of used and available space, and how much of the file system's total capacity has been used. The file system is specified by device, or by referring to a file or directory on the specified file system.
- Used without operands or options, `df` reports on all mounted file systems.
- `df` may not be supported for all *FSTypes*.
- If `df` is run on a networked mount point that the automounter has not yet mounted, the file system size will be reported as zero. As soon as the automounter mounts the file system, the sizes will be reported correctly.
- Options** The following options are supported for both `/usr/bin/df` and `/usr/xpg4/bin/df`:
- a
Reports on all file systems including ones whose entries in `/etc/mnttab` (see [mnttab\(4\)](#)) have the `ignore` option set.
 - b
Prints the total number of kilobytes free.
 - e
Prints only the number of files free.
 - F *FSType*
Specifies the *FSType* on which to operate. The `-F` option is intended for use with unmounted file systems. The *FSType* should be specified here or be determinable from `/etc/vfstab` (see [vfstab\(4\)](#)) by matching the *directory*, *block_device*, or *resource* with an entry in the table, or by consulting `/etc/default/fs`. See [default_fs\(4\)](#).
 - g
Prints the entire [statvfs\(2\)](#) structure. This option is used only for mounted file systems. It can not be used with the `-o` option. This option overrides the `-b`, `-e`, `-k`, `-n`, `-P`, and `-t` options.
 - h
Like `-k`, except that sizes are in a more human readable format. The output consists of one line of information for each specified file system. This information includes the file system name, the total space allocated in the file system, the amount of space allocated to existing

files, the total amount of space available for the creation of new files by unprivileged users, and the percentage of normally available space that is currently allocated to all files on the file system. All sizes are scaled to a human readable format, for example, 14K, 234M, 2.7G, or 3.0T. Scaling is done by repetitively dividing by 1024.

This option overrides the `-b`, `-e`, `-g`, `-k`, `-n`, `-t`, and `-V` options. This option only works on mounted filesystems and can not be used together with `-o` option.

`-k`

Prints the allocation in kbytes. The output consists of one line of information for each specified file system. This information includes the file system name, the total space allocated in the file system, the amount of space allocated to existing files, the total amount of space available for the creation of new files by unprivileged users, and the percentage of normally available space that is currently allocated to all files on the file system. This option overrides the `-b`, `-e`, `-n`, and `-t` options.

`-l`

Reports on local file systems only. This option is used only for mounted file systems. It can not be used with the `-o` option.

`-n`

Prints only the *FSType* name. Invoked with no operands, this option prints a list of mounted file system types. This option is used only for mounted file systems. It can not be used with the `-o` option.

`-o FSType-specific_options`

Specifies *FSType-specific* options. These options are comma-separated, with no intervening spaces. See the manual page for the *FSType-specific* command for details.

`-t`

Prints full listings with totals. This option overrides the `-b`, `-e`, and `-n` options.

`-V`

Echoes the complete set of file system specific command lines, but does not execute them. The command line is generated by using the options and operands provided by the user and adding to them information derived from `/etc/mnttab`, `/etc/vfstab`, or `/etc/default/fs`. This option may be used to verify and validate the command line.

`-Z`

Displays mounts in all visible zones. By default, `df` only displays mounts located within the current zone. This option has no effect in a non-global zone.

`/usr/bin/df` The following option is supported for `/usr/bin/df` only:

`-v`

Like `-k`, except that sizes are displayed in multiples of the smallest block size supported by each specified file system.

The output consists of one line of information for each file system. This one line of information includes the following:

- the file system's mount point
- the file system's name
- the total number of blocks allocated to the file system
- the number of blocks allocated to existing files
- the number of blocks available for the creation of new files by unprivileged users
- the percentage of blocks in use by files

`/usr/xpg4/bin/df` The following option is supported for `/usr/xpg4/bin/df` only:

`-P`
Same as `-h` except in 512-byte units.

Operands The `df` utility interprets operands according to the following precedence: *block_device*, *directory*, *file*, *resource*. The following operands are supported:

block_device

Represents a block special device (for example, `/dev/dsk/c1d0s7`).

directory

Represents a valid directory name. `df` reports on the file system that contains *directory*.

file

Represents a valid file name. `df` reports on the file system that contains *file*.

resource

Represents an NFS resource name.

Usage See [largefile\(5\)](#) for the description of the behavior of `df` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples EXAMPLE 1 Executing the `df` command

The following example shows the `df` command and its output:

```
example% /usr/bin/df

/                (/dev/dsk/c0t0d0s0 ): 287530 blocks   92028 files
/system/contract (ctfs                ):    0 blocks 2147483572 files
/system/object   (objfs                ):    0 blocks 2147483511 files
/usr             (/dev/dsk/c0t0d0s6 ): 1020214 blocks 268550 files
/proc            (/proc                 ):    0 blocks    878 files
/dev/fd          (fd                   ):    0 blocks     0 files
/etc/mnttab      (mnttab               ):    0 blocks     0 files
/var/run         (swap                 ): 396016 blocks   9375 files
/tmp             (swap                 ): 396016 blocks   9375 files
/opt             (/dev/dsk/c0t0d0s5 ): 381552 blocks  96649 files
```

EXAMPLE 1 Executing the `df` command (Continued)

```
/export/home      (/dev/dsk/c0t0d0s7 ): 434364 blocks  108220 files
```

where the columns represent the mount point, device (or “filesystem”, according to `df -k`), free blocks, and free files, respectively. For contract file systems, `/system/contract` is the mount point, `ctfs` is the contract file system (used by SMF) with 0 free blocks and 2147483582(INTMAX-1) free files. For object file systems, `/system/object` is the mount point, `objfs` is the object file system (see [objfs\(7FS\)](#)) with 0 free blocks and 2147483511 free files.

EXAMPLE 2 Writing Portable Information About the `/usr` File System

The following example writes portable information about the `/usr` file system:

```
example% /usr/xpg4/bin/df -P /usr
```

EXAMPLE 3 Writing Portable Information About the `/usr/src` file System

Assuming that `/usr/src` is part of the `/usr` file system, the following example writes portable information :

```
example% /usr/xpg4/bin/df -P /usr/src
```

EXAMPLE 4 Using `df` to Display Inode Usage

The following example displays inode usage on all `ufs` file systems:

```
example%/usr/bin/df -F ufs -o i
```

Environment Variables When set, any header which normally displays `files` will now display nodes. See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `df`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

Exit Status The following exit values are returned:

```
0
    Successful completion.
```

```
>0
    An error occurred.
```

Files `/dev/dsk/*`
Disk devices

`/etc/default/fs`
Default local file system type. Default values can be set for the following flags in `/etc/default/fs`. For example: `LOCAL=ufs`, where `LOCAL` is the default partition for a command if no `FSType` is specified.

`/etc/mnttab`
Mount table

`/etc/vfstab`
List of default parameters for each file system

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| <code>/usr/bin/df</code> | ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|--------------------------|----------------|-----------------|
| | Availability | SUNWcs |

| <code>/usr/xpg4/bin/df</code> | ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|-------------------------------|---------------------|------------------------------------|
| | Availability | SUNWxcu4 |
| | Interface Stability | Committed |
| | Standard | See standards(5) . |

See Also [find\(1\)](#), [df_ufs\(1M\)](#), [mount\(1M\)](#), [statvfs\(2\)](#), [default_fs\(4\)](#), [mnttab\(4\)](#), [vfstab\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#), [objfs\(7FS\)](#)

Notes If UFS logging is enabled on a file system, the disk space used for the log is reflected in the `df` report. The log is allocated from free blocks on the file system, and it is sized approximately 1 Mbyte per 1 Gbyte of file system, up to 256 Mbytes. The log size may be larger (up to a maximum of 512 Mbytes) depending on the number of cylinder groups present in the file system.

Name dfmounts – display mounted resource information

Synopsis dfmounts [-F *FSType*] [-h] [-o *specific_options*]
[*restriction*]. . .

Description dfmounts shows the local resources shared through a distributed file system *FSType* along with a list of clients that have the resource mounted. If *restriction* is not specified, dfmounts shows file systems that are currently shared on any NFS server. *specific_options* as well as the availability and semantics of *restriction* are specific to particular distributed file system types.

If dfmounts is entered without arguments, remote resources currently mounted on the local system are displayed, regardless of file system type. However, the dfmounts command does not display the names of NFS Version 4 clients.

dfmounts Output The output of dfmounts consists of an optional header line (suppressed with the -h flag) followed by a list of lines containing whitespace-separated fields. For each resource, the fields are:

resource server pathname clients ...

where:

resource Specifies the resource name that must be given to the [mount\(1M\)](#) command.

server Specifies the system from which the resource was mounted.

pathname Specifies the pathname that must be given to the [share\(1M\)](#) command.

clients Is a comma-separated list of systems that have mounted the resource. Clients are listed in the form *domain.*, *domain.system*, or *system*, depending on the file system type.

A field can be null. Each null field is indicated by a hyphen (-) unless the remainder of the fields on the line are also null, in which case the hyphen can be omitted.

Fields with whitespace are enclosed in quotation marks (" ").

Options -F *FSType* Specify filesystem type. Defaults to the first entry in /etc/dfs/fstypes. Note: currently the only valid *FSType* is nfs.

-h Suppress header line in output.

-o *specific_options* Specify options specific to the filesystem provided by the -F option. Note: currently no options are supported.

Files /etc/dfs/fstypes file system types

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTE VALUE |
|---------------|-----------------|
| Availability | SUNWcs |

See Also [dfshares\(1M\)](#), [mount\(1M\)](#), [share\(1M\)](#), [unshare\(1M\)](#), [attributes\(5\)](#)

Name dfmounts_nfs – display mounted NFS resource information

Synopsis dfmounts [-F nfs] [-h] [*server*]...

Description dfmounts shows the local resources shared through NFS, along with the list of clients that have mounted the resource. The -F flag may be omitted if NFS is the only file system type listed in the file /etc/dfs/fstypes.

dfmounts without options, displays all remote resources mounted on the local system, regardless of file system type.

The output of dfmounts consists of an optional header line (suppressed with the -h flag) followed by a list of lines containing whitespace-separated fields. For each resource, the fields are:

resource server pathname clients ...

where

resource Does not apply to NFS. Printed as a hyphen (-).

server Specifies the system from which the resource was mounted.

pathname Specifies the pathname that must be given to the [share\(1M\)](#) command.

clients Is a comma-separated list of systems that have mounted the resource.

Options -F nfs Specifies the nfs-FSType.

-h Suppress header line in output.

server Displays information about the resources mounted from each server, where *server* can be any system on the network. If no server is specified, the *server* is assumed to be the local system.

Files /etc/dfs/fstypes

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|------------------------|
| Availability | system/file-system/nfs |

See Also [mount\(1M\)](#), [share\(1M\)](#), [unshare\(1M\)](#), [attributes\(5\)](#)

Name dfshares – list available resources from remote or local systems

Synopsis dfshares [-F *FSType*] [-h] [-o *specific_options*] [*server*] . . .

Description dfshares provides information about resources available to the host through a distributed file system of type *FSType*. *specific_options* as well as the semantics of *server* are specific to particular distributed file systems.

If dfshares is entered without arguments, all resources currently shared on the local system are displayed, regardless of file system type.

The output of dfshares consists of an optional header line (suppressed with the -h flag) followed by a list of lines containing whitespace-separated fields. For each resource, the fields are:

resource server access transport

where

resource Specifies the resource name that must be given to the [mount\(1M\)](#) command.

server Specifies the name of the system that is making the resource available.

access Specifies the access permissions granted to the client systems, either ro (for read-only) or rw (for read/write). If dfshares cannot determine access permissions, a hyphen (–) is displayed.

transport Specifies the transport provider over which the resource is shared.

A field may be null. Each null field is indicated by a hyphen (–) unless the remainder of the fields on the line are also null; in which case, the hyphen may be omitted.

Options

- F *FSType* Specify filesystem type. Defaults to the first entry in `/etc/dfs/fstypes`.
- h Suppress header line in output.
- o *specific_options* Specify options specific to the filesystem provided by the -F option.

Files `/etc/dfs/fstypes`

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [dfmounts\(1M\)](#), [mount\(1M\)](#), [share\(1M\)](#), [unshare\(1M\)](#), [attributes\(5\)](#)

Name dfshares_nfs – list available NFS resources from remote systems

Synopsis dfshares [-F nfs] [-h] [server]...

Description dfshares provides information about resources available to the host through NFS. The -F flag may be omitted if NFS is the first file system type listed in the file /etc/dfs/fstypes.

The query may be restricted to the output of resources available from one or more servers.

dfshares without arguments displays all resources shared on the local system, regardless of file system type.

Specifying *server* displays information about the resources shared by each server. *Server* can be any system on the network. If no server is specified, then *server* is assumed to be the local system.

The output of dfshares consists of an optional header line (suppressed with the -h flag) followed by a list of lines containing whitespace-separated fields. For each resource, the fields are:

resource server access transport

where

resource Specifies the resource name that must be given to the [mount\(1M\)](#) command.

server Specifies the system that is making the resource available.

access Specifies the access permissions granted to the client systems; however, dfshares cannot determine this information for an NFS resource and populates the field with a hyphen (-).

transport Specifies the transport provider over which the *resource* is shared; however, dfshares cannot determine this information for an NFS resource and populates the field with a hyphen (-).

A field may be null. Each null field is indicated by a hyphen (-) unless the remainder of the fields on the line are also null; in which case, the hyphen may be omitted.

Options -F nfs Specify the NFS file system type

-h Suppress header line in output.

Files /etc/dfs/fstypes

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|------------------------|
| Availability | system/file-system/nfs |

See Also [mount\(1M\)](#), [share\(1M\)](#), [unshare\(1M\)](#), [attributes\(5\)](#)

Name df_ufs – report free disk space on ufs file systems

Synopsis df -F ufs [*generic_options*] [-o *i*] [*directory* | *special*]

Description df displays the amount of disk space occupied by ufs file systems, the amount of used and available space, and how much of the file system's total capacity has been used. The amount of space reported as used and available is less than the amount of space in the file system; this is because the system reserves a fraction of the space in the file system to allow its file system allocation routines to work well. The amount reserved is typically about 10%; this can be adjusted using [tunefs\(1M\)](#). When all the space on the file system except for this reserve is in use, only the superuser can allocate new files and data blocks to existing files. When the file system is overallocated in this way, df might report that the file system is more than 100% utilized. If neither *directory* nor *special* is specified, df displays information for all mounted ufs file systems.

Options The following options are supported:

generic_options Options supported by the generic df command. See [df\(1M\)](#) for a description of these options.

-o Specify ufs file system specific options. The available option is:

i Report the number of used and free inodes. This option can not be used with *generic_options*.

Files /etc/mnttab list of file systems currently mounted

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|---------------------------|
| Availability | SUNWcs, system/xopen/xcu4 |

See Also [df\(1M\)](#), [fsck\(1M\)](#), [fstyp\(1M\)](#), [tunefs\(1M\)](#), [mnttab\(4\)](#), [attributes\(5\)](#), [ufs\(7FS\)](#),

Notes df calculates its results differently for mounted and unmounted file systems. For unmounted systems, the numbers reflect the 10% reservation. This reservation is not reflected in df output for mounted file systems. For this reason, the available space reported by the generic command can differ from the available space reported by this module.

df might report remaining capacity even though syslog warns filesystem full. This issue can occur because df only uses the available fragment count to calculate available space, but the file system requires contiguous sets of fragments for most allocations.

If you suspect that you have exhausted contiguous fragments on your file system, you can use the [fstyp\(1M\)](#) utility with the -v option. In the fstyp output, look at the nb free (number of blocks free) and nf free (number of fragments free) fields. On unmounted filesystems, you can use [fsck\(1M\)](#) and observe the last line of output, which reports, among other items, the number of fragments and the degree of fragmentation. See [fsck\(1M\)](#).

Name dhcpageant – Dynamic Host Configuration Protocol (DHCP) client daemon

Synopsis dhcpageant [-a] [-d *n*] [-f] [-v]

Description dhcpageant implements the client half of the Dynamic Host Configuration Protocol (DHCP) for machines running Solaris software.

The dhcpageant daemon obtains configuration parameters for the client (local) machine's network interfaces from a DHCP server. These parameters may include a lease on an IP address, which gives the client machine use of the address for the period of the lease, which may be infinite. If the client wishes to use the IP address for a period longer than the lease, it must negotiate an extension using DHCP. For this reason, dhcpageant must run as a daemon, terminating only when the client machine powers down.

For IPv4, the dhcpageant daemon is controlled through [ifconfig\(1M\)](#) in much the same way that the [init\(1M\)](#) daemon is controlled by [telinit\(1M\)](#). dhcpageant can be invoked as a user process, albeit one requiring root privileges, but this is not necessary, as [ifconfig\(1M\)](#) will start it automatically.

For IPv6, the dhcpageant daemon is invoked automatically by [in.ndpd\(1M\)](#). It can also be controlled through [ifconfig\(1M\)](#), if necessary.

When invoked, dhcpageant enters a passive state while it awaits instructions from [ifconfig\(1M\)](#) or [in.ndpd\(1M\)](#). When it receives a command to configure an interface, it brings up the interface (if necessary) and starts DHCP. Once DHCP is complete, dhcpageant can be queried for the values of the various network parameters. In addition, if DHCP was used to obtain a lease on an address for an interface, it configures the address for use. When a lease is obtained, it is automatically renewed as necessary. If the lease cannot be renewed, dhcpageant will unconfigure the address, but the interface will be left up and dhcpageant will attempt to acquire a new address lease. dhcpageant monitors system suspend/resume events and will validate any non-permanent leases with the DHCP server upon resume. Similarly, dhcpageant monitors link up/down events and will validate any non-permanent leases with the DHCP server when the downed link is brought back up. The lease validation mechanism will restart DHCP if the server indicates that the existing lease is no longer valid. If the server cannot be contacted, then the existing lease will continue. This behavior can be modified with the VERIFIED_LEASE_ONLY parameter in the `/etc/default/dhcpageant` file. See the description of this parameter below.

For IPv4, if the configured interface is found to be unplumbed, or to have a different IP address, subnet mask, or broadcast address from those obtained from DHCP, the interface is abandoned from DHCP control.

For IPv6, dhcpageant automatically plumbs and unplumbs logical interfaces as necessary for the IPv6 addresses supplied by the server. The IPv6 prefix length (netmask) is not set by the DHCPv6 protocol, but is instead set by [in.ndpd\(1M\)](#) using prefix information obtained by Router Advertisements. If any of the logical interfaces created by dhcpageant is unplumbed, or

configured with a different IP address, it will be abandoned from DHCP control. If the link-local interface is unplumbed, then all addresses configured by DHCP on that physical interface will be removed.

In addition to DHCP, dhcpcagent also supports BOOTP (IPv4 only). See *RFC 951, Bootstrap Protocol*. Configuration parameters obtained from a BOOTP server are treated identically to those received from a DHCP server, except that the IP address received from a BOOTP server always has an infinite lease.

DHCP also acts as a mechanism to configure other information needed by the client, for example, the domain name and addresses of routers. Aside from the IP address, and for IPv4 alone, the netmask, broadcast address, and default router, the agent does not directly configure the workstation, but instead acts as a database which may be interrogated by other programs, and in particular by `dhcpcinfo(1)`.

On clients with a single interface, this is quite straightforward. Clients with multiple interfaces may present difficulties, as it is possible that some information arriving on different interfaces may need to be merged, or may be inconsistent. Furthermore, the configuration of the interfaces is asynchronous, so requests may arrive while some or all of the interfaces are still unconfigured. To handle these cases, one interface may be designated as primary, which makes it the authoritative source for the values of DHCP parameters in the case where no specific interface is requested. See `dhcpcinfo(1)` and `ifconfig(1M)` for details.

For IPv4, the dhcpcagent daemon can be configured to request a particular host name. See the REQUEST_HOSTNAME description in the FILES section. When first configuring a client to request a host name, you must perform the following steps as root to ensure that the full DHCP negotiation takes place:

```
# pkill dhcpcagent
# rm /etc/dhcp/interface.dhc
# reboot
```

All DHCP packets sent by dhcpcagent include a vendor class identifier (RFC 2132, option code 60; RFC 3315, option code 16). This identifier is the same as the platform name returned by the `uname -i` command, except:

- Any commas in the platform name are changed to periods.
- If the name does not start with a stock symbol and a comma, it is automatically prefixed with SUNW.

Messages The dhcpcagent daemon writes information and error messages in five categories:

critical

Critical messages indicate severe conditions that prevent proper operation.

errors

Error messages are important, sometimes unrecoverable events due to resource exhaustion and other unexpected failure of system calls; ignoring errors may lead to degraded functionality.

warnings

Warnings indicate less severe problems, and in most cases, describe unusual or incorrect datagrams received from servers, or requests for service that cannot be provided.

informational

Informational messages provide key pieces of information that can be useful to debugging a DHCP configuration at a site. Informational messages are generally controlled by the `-v` option. However, certain critical pieces of information, such as the IP address obtained, are always provided.

debug

Debugging messages, which may be generated at two different levels of verbosity, are chiefly of benefit to persons having access to source code, but may be useful as well in debugging difficult DHCP configuration problems. Debugging messages are only generated when using the `-d` option.

When `dhcpageant` is run without the `-f` option, all messages are sent to the system logger `syslog(3C)` at the appropriate matching priority and with a facility identifier `LOG_DAEMON`. When `dhcpageant` is run with the `-f` option, all messages are directed to standard error.

DHCP Events and User-Defined Actions

If an executable (binary or script) is placed at `/etc/dhcp/eventhook`, the `dhcpageant` daemon will automatically run that program when any of the following events occur:

BOUND and BOUND6

These events occur during interface configuration. The event program is invoked when `dhcpageant` receives the DHCPv4 ACK or DHCPv6 Reply message from the DHCP server for the lease request of an address, indicating successful initial configuration of the interface. (See also the `INFORM` and `INFORM6` events, which occur when configuration parameters are obtained without address leases.)

EXTEND and EXTEND6

These events occur during lease extension. The event program is invoked just after `dhcpageant` receives the DHCPv4 ACK or DHCPv6 Reply from the DHCP server for the DHCPv4 REQUEST (renew) message or the DHCPv6 Renew or Rebind message.

Note that with DHCPv6, the server might choose to remove some addresses, add new address leases, and ignore (allow to expire) still other addresses in a given Reply message. The `EXTEND6` event occurs when a Reply is received that leaves one or more address leases still valid, even if the Reply message does not extend the lease for any address. The event program is invoked just before any addresses are removed, but just after any new addresses are added. Those to be removed will be marked with the `IFF_DEPRECATED` flag.

EXPIRE and EXPIRE6

These events occur during lease expiration. For DHCPv4, the event program is invoked just before the leased address is removed from an interface. For DHCPv6, the event program is invoked just before the last remaining leased addresses are removed from the interface.

DROP and DROP6

These events occur during the period when an interface is dropped. The event program is invoked just before the interface is removed from DHCP control. If the interface has been abandoned due the user unplumbing the interface, then this event will occur after the user's action has taken place. The interface might not be present.

INFORM and INFORM6

These events occur when an interface acquires new or updated configuration information from a DHCP server by means of the DHCPv4 INFORM or the DHCPv6 Information-Request message. These messages are sent using an `ifconfig(1M) dhcp inform` command or when the DHCPv6 Router Advertisement O (letter O) bit is set and the M bit is not set. Thus, these events occur when the DHCP client does not obtain an IP address lease from the server, and instead obtains only configuration parameters.

LOSS6

This event occurs during lease expiration when one or more valid leases still remain. The event program is invoked just before expired addresses are removed. Those being removed will be marked with the `IFF_DEPRECATED` flag.

Note that this event is not associated with the receipt of the Reply message, which occurs only when one or more valid leases remain, and occurs only with DHCPv6. If all leases have expired, then the `EXPIRE6` event occurs instead.

RELEASE and RELEASE6

This event occurs during the period when a leased address is released. The event program is invoked just before `dhcpage` relinquishes the address on an interface and sends the DHCPv4 RELEASE or DHCPv6 Release packet to the DHCP server.

The system does not provide a default event program. The file `/etc/dhcp/eventhook` is expected to be owned by root and have a mode of 755.

The event program will be passed two arguments, the interface name and the event name, respectively. For DHCPv6, the interface name is the name of the physical interface.

The event program can use the `dhcpage(1)` utility to fetch additional information about the interface. While the event program is invoked on every event defined above, it can ignore those events in which it is not interested. The event program runs with the same privileges and environment as `dhcpage` itself, except that `stdin`, `stdout`, and `stderr` are redirected to `/dev/null`. Note that this means that the event program runs with root privileges.

If an invocation of the event program does not exit after 55 seconds, it is sent a `SIGTERM` signal. If it does not exit within the next three seconds, it is terminated by a `SIGKILL` signal.

See `EXAMPLES` for an example event program.

Options The following options are supported:

-a

Adopt a configured IPv4 interface. This option is for use with diskless DHCP clients. In the case of diskless DHCP, DHCP has already been performed on the network interface providing the operating system image prior to running `dhcpageant`. This option instructs the agent to take over control of the interface. It is intended primarily for use in boot scripts.

The effect of this option depends on whether the interface is being adopted.

If the interface is being adopted, the following conditions apply:

`dhcpageant` uses the client id specified in `/chosen:<client_id>`, as published by the PROM or as specified on a `boot(1M)` command line. If this value is not present, the client id is undefined. The DHCP server then determines what to use as a client id. It is an error condition if the interface is an Infiniband interface and the PROM value is not present.

If the interface is not being adopted:

`dhcpageant` uses the value stored in `/etc/default/dhcpageant`. If this value is not present, the client id is undefined. If the interface is Infiniband and there is no value in `/etc/default/dhcpageant`, a client id is generated as described by the draft document on DHCP over Infiniband, available at:

<http://www.ietf.org>

-d *n*

Set debug level to *n*. Two levels of debugging are currently available, 1 and 2; the latter is more verbose.

-f

Run in the foreground instead of as a daemon process. When this option is used, messages are sent to standard error instead of to `syslog(3C)`.

-v

Provide verbose output useful for debugging site configuration problems.

Examples **EXAMPLE 1** Example Event Program

The following script is stored in the file `/etc/dhcp/eventhook`, owned by root with a mode of 755. It is invoked upon the occurrence of the events listed in the file.

```
#!/bin/sh

(
echo "Interface name: " $1
echo "Event: " $2

case $2 in
```

EXAMPLE 1 Example Event Program (Continued)

```

"BOUND")
    echo "Address acquired from server "\
        '/sbin/dhccpinfo -i $1 ServerID'
    ;;
"BOUND6")
    echo "Addresses acquired from server " \
        '/sbin/dhccpinfo -v6 -i $1 ServerID'
    ;;
"EXTEND")
    echo "Lease extended for " \
        'sbin/dhccpinfo -i $1 LeaseTim" seconds"
    ;;
"EXTEND6")
    echo "New lease information obtained on $i"
    ;;
"EXPIRE" | "DROP" | "RELEASE")
    ;;

esac
) >/var/run/dhccp_eventhook_output 2>&1

```

Note the redirection of stdout and stderr to a file.

Files /etc/dhccp/if.dhc
 /etc/dhccp/if.dh6

Contains the configuration for interface. The mere existence of this file does not imply that the configuration is correct, since the lease might have expired. On start-up, dhcpcagent confirms the validity of the address using REQUEST (for DHCPv4) or Confirm (DHCPv6).

/etc/dhccp/duid
 /etc/dhccp/iaid

Contains persistent storage for DUID (DHCP Unique Identifier) and IAID (Identity Association Identifier) values. The format of these files is undocumented, and applications should not read from or write to them.

/etc/default/dhccpagent

Contains default values for tunable parameters. All values may be qualified with the interface they apply to by prepending the interface name and a period (".") to the interface parameter name. The parameters include: the interface parameter name.

To configure IPv6 parameters, place the string .v6 between the interface name (if any) and the parameter name. For example, to set the global IPv6 parameter request list, use .v6.PARAM_REQUEST_LIST. To set the CLIENT_ID (DUID) on hme0, use hme0.v6.CLIENT_ID.

The parameters include:

VERIFIED_LEASE_ONLY

Indicates that a **RELEASE** rather than a **DROP** should be performed on managed interfaces when the agent terminates. Release causes the client to discard the lease, and the server to make the address available again. Drop causes the client to record the lease in `/etc/dhcp/interface.dhc` or `/etc/dhcp/interface.dh6` for later use. In addition, when the link status changes to up or when the system is resumed after a suspend, the client will verify the lease with the server. If the server is unreachable for verification, then the old lease will be discarded (even if it has time remaining) and a new one obtained.

Enabling this option is often desirable on mobile systems, such as laptops, to allow the system to recover quickly from moves.

OFFER_WAIT

Indicates how long to wait between checking for valid **OFFERS** after sending a **DISCOVER**. For DHCPv6, sets the time to wait between checking for valid Advertisements after sending a Solicit.

CLIENT_ID

Indicates the value that should be used to uniquely identify the client to the server. This value can take one of three basic forms:

decimal, data...
 0xHHHHH...
 "string..."

The first form is an RFC 3315 DUID. This is legal for both IPv4 DHCP and DHCPv6. For IPv4, an RFC 4361 Client ID is constructed from this value. In this first form, the format of *data...* depends on the decimal value. The following formats are defined for this first form:

1, hwtype, time, lla

Type 1, DUID-LLT. The *hwtype* value is an integer in the range 0-65535, and indicates the type of hardware. The *time* value is the number of seconds since midnight, January 1st, 2000 UTC, and can be omitted to use the current system time. The *lla* value is either a colon-separated MAC address or the name of a physical interface. If the name of an interface is used, the *hwtype* value can be omitted. For example: 1, , , hme0

2, enterprise, hex...

Type 2, DUID-EN. The *enterprise* value is an integer in the range 0-4294967295 and represents the SMI Enterprise number for an organization. The *hex* string is an even-length sequence of hexadecimal digits.

3, hwtype, lla

Type 3, DUID-LL. This is the same as DUID-LLT (type 1), except that a time stamp is not used.

**,hex*

Any other type value (0 or 4-65535) can be used with an even-length hexadecimal string.

The second and third forms of `CLIENT_ID` are legal for IPv4 only. These both represent raw Client ID (without RFC 4361), in hex, or NVT ASCII string format. Thus, “Sun” and `0x53756E` are equivalent.

PARAM_REQUEST_LIST

Specifies a list of comma-separated integer values of options for which the client would like values, or symbolic `Site` or `Option` option names. Symbolic option names for IPv4 are resolved through `/etc/dhcp/inittab`. Option names for IPv6 are resolved by means of `/etc/dhcp/inittab6`.

PARAM_IGNORE_LIST

Specifies a list of options (constructed in the same manner as `PARAM_REQUEST_LIST`) that the DHCP client will ignore. Ignored options are treated as though the server did not return the options specified. Ignored options are not visible using `dhcpinfo(1)` or acted on by the client. This parameter can be used, for example, to disable an unwanted client name or default router.

REQUEST_HOSTNAME

Indicates the client requests the DHCP server to map the client's leased IPv4 address to the host name associated with the network interface that performs DHCP on the client. The host name must be specified in the `/etc/hostname.interface` file for the relevant interface on a line of the form

```
inet hostname
```

where *hostname* is the host name requested.

This option works with DHCPv4 only.

```
/etc/dhcp/eventhook
```

Location of a DHCP event program.

Droms, R. *RFC 3315, Dynamic Host Configuration Protocol for IPv6 (DHCPv6)*. Cisco Systems. July 2003.

Notes The `dhcpagent` daemon can be used on IPv4 logical interfaces, just as with physical interfaces. When used on a logical interface, the daemon automatically constructs a Client ID value based on the DUID and IAID values, according to RFC 4361. The `/etc/default/dhcpagent CLIENT_ID` value, if any, overrides this automatic identifier.

As with physical IPv4 interfaces, the `/etc/hostname.hme0:1` and `/etc/dhcp.hme0:1` files must also be created in order for `hme0:1` to be automatically plumbed and configured at boot. In addition, unlike physical IPv4 interfaces, `dhcpagent` does not add or remove default routes associated with logical interfaces.

DHCP can be performed on IPMP IP interfaces to acquire and maintain IPMP data addresses. Because an IPMP IP interface has no hardware address, the daemon automatically constructs a Client ID using the same approach described above for IPv4 logical interfaces. In addition, the lack of a hardware address means the daemon must set the “broadcast” flag in all DISCOVER and REQUEST messages on IPMP IP interfaces. Some DHCP servers may refuse such requests.

DHCP can be performed on IP interfaces that are part of an IPMP group (to acquire and maintain test addresses). The daemon will automatically set the NOFAILOVER and DEPRECATED flags on each test address. Additionally, the daemon will not add or remove default routes in this case. Note that the actual DHCP packet exchange may be performed over any active IP interface in the IPMP group. It is strongly recommended that test addresses have infinite leases. Otherwise, an extended network outage detectable only by probes may cause test address leases to expire, causing `in.mpathd(1M)` to revert to link-based failure detection and trigger an erroneous repair.

With DHCPv6, the link-local interface must be configured using `/etc/hostname6.hme0` in order for DHCPv6 to run on `hme0` at boot time. The logical interfaces for each address are plumbed by `dhcpagent` automatically.

Name dhcpconfig – DHCP service configuration utility

Synopsis dhcpconfig -D -r *resource* -p *path* [-u *uninterpreted*]
 [-l *lease_length*] [-n] [-d *DNS_domain*]
 [-a *DNS_server_addresses*] [-h *hosts_resource*]
 [-y *hosts_domain*]

dhcpconfig -R *server_addresses*

dhcpconfig -U [-f] [-x] [-h]

dhcpconfig -N *network_address* [-m *subnet_mask*] [-b]
 [-t *router_addresses*] [-y *NIS-domain*]
 [-a *NIS_server_addresses*] [-g]

dhcpconfig -C -r *resource* -p *path* [-f] [-k]
 [-u *uninterpreted*]

dhcpconfig -X *filename* [-m *macro_list*] [-o *option_list*]
 [-a *network_addresses*] [-f] [-x] [-g]

dhcpconfig -I *filename* [-f] [-g]

dhcpconfig -P [*parameter*[=*value*]],...

dhcpconfig -S [-f] [-e | -d | -r | -q]

Description The dhcpconfig command is used to configure and manage the Dynamic Host Configuration Protocol (DHCP) service or BOOTP relay services. It is intended for use by experienced Solaris system administrators and is designed for ease of use in scripts. The dhcpmgr utility is recommended for less experienced administrators or those preferring a graphical utility to configure and manage the DHCP service or BOOTP relay service.

The dhcpconfig command can be run by root, or by other users assigned to the DHCP Management profile. See [rbac\(5\)](#) and [user_attr\(4\)](#).

dhcpconfig requires one of the following function flags: -D, -R, -U, -N, -C, -X, -I, -P or -S.

The dhcpconfig menu driven mode is supported in Solaris 8 and previous versions of Solaris.

Where dhcpconfig
Obtains Configuration
Information

dhcpconfig scans various configuration files on your Solaris machine for information it can use to assign values to options contained in macros it adds to the dhcptab configuration table. The following table lists information dhcpconfig needs, the source used, and how the information is used:

| <i>Information</i> | <i>Source</i> | <i>Where Used</i> |
|--------------------|---------------------------------|-------------------|
| Timezone | System date, timezone settings | Locale macro |
| DNS parameters | nsswitch.conf, /etc/resolv.conf | Server macro |

| | | |
|----------------|--------------------------------------------------|----------------|
| NIS parameters | System domainname, nsswitch.conf, NIS | Network macros |
| Subnetmask | Network interface, netmasks table in nameservice | Network macros |

If you have not set these parameters on your server machine, you should do so before configuring the DHCP server with `dhcpcfg`. Note that if you specify options with the `dhcpcfg -D` command line, the values you supply override the values obtained from the system files.

Options The following options are supported:

-C Convert to using a new data store, recreating the DHCP data tables in a format appropriate to the new data store, and setting up the DHCP server to use the new data store.

The following sub-options are required:

-p *path_to_data* The paths for `SUNWfiles` and `SUNWbinfiles` must be absolute UNIX pathnames. See [dhcpcfg\(5\)](#).

-r *data_resource* New data store resource. One of the following must be specified: `SUNWfiles` or `SUNWbinfiles`. See [dhcpcfg\(5\)](#).

The following sub-options are optional:

-f Do not prompt for confirmation. If **-f** is not used, a warning and confirmation prompt are issued before the conversion starts.

-k Keep the old DHCP data tables after successful conversion. If any problem occurs during conversion, tables are not deleted even if **-k** sub-option is not specified.

-u *uninterpreted* Data which is ignored by `dhcpcfg`, but passed on to the datastore for interpretation. The private layer provides for module-specific configuration information through the use of the `RESOURCE_CONFIG` keyword. Uninterpreted data is stored within `RESOURCE_CONFIG` keyword of `dhcpsvc.conf(4)`. The **-u** sub-option is not used with the `SUNWfiles` and `SUNWbinfiles` data stores. See [dhcpcfg\(5\)](#).

-D

Configure the DHCP service.

The following sub-options are required:

- r *data_resource* One of the following must be specified: SUNwfiles or SUNwbinfiles. Other data stores may be available. See [dhcp_modules\(5\)](#).
- p *path* The paths for SUNwfiles and SUNwbinfiles must be absolute UNIX pathnames. See [dhcp_modules\(5\)](#).

The following sub-options are optional:

- a *DNS_servers* IP addresses of DNS servers, separated with commas.
- d *DNS_domain* DNS domain name.
- h *hosts_resource* Resource in which to place hosts data. Usually, the name service in use on the server. Valid values are files or dns.
- l *seconds* Lease length used for addresses not having a specified lease length, in seconds.
- n Non-negotiable leases
- y *hosts_domain* DNS domain name to be used for hosts data. Valid only if dns is specified for -h sub-option.
- u *uninterpreted* Data which is ignored by dhcpconfig, but passed on to the datastore for interpretation. The private layer provides for module-specific configuration information through the use of the RESOURCE_CONFIG keyword. Uninterpreted data is stored within RESOURCE_CONFIG keyword of [dhcpsvc.conf\(4\)](#). The -u sub-option is not used with the SUNwfiles and SUNwbinfiles data stores. See [dhcp_modules\(5\)](#).

-I *filename*

Import data from *filename*, containing data previously exported from a Solaris DHCP server. Note that after importing, you may have to edit macros to specify the correct domain names, and edit network tables to change the owning server of addresses in imported networks. Use dhtadm and pntadm to do this.

The following sub-options are supported:

- f Replace any conflicting data with the data being imported.

- g Signal the daemon to reload the `dhcptab` once the import has been completed.
- N *net_address* Configure an additional network for DHCP service.
- The following sub-options are supported:
- a *NIS_server_addresses* List of IP addresses of NIS servers.
 - b Network is a point-to-point (PPP) network, therefore no broadcast address should be configured. If -b is not used, the network is assumed to be a LAN, and the broadcast address is determined using the network address and subnet mask.
 - g Signal the daemon to reload the `dhcptab`.
 - m *xxx.xxx.xxx.xxx* Subnet mask for the network; if -m is not used, subnet mask is obtained from netmasks.
 - t *router_addresses* List of router IP addresses; if not specified, router discovery flag is set.
 - y *NIS_domain_name* If NIS is used on this network, specify the NIS domain name.
- P Configure the DHCP service parameters. Each parameter and value are specified by the following pattern:
- parameter*[=*value*], . . .
- Where *parameter* and *value* are:
- parameter* One of the DHCP service parameters listed in [dhcpsvc.conf\(4\)](#). If the corresponding *value* is not specified, the current parameter value is displayed. If *parameter* is not specified, all parameters and current values are displayed.
 - value* Optional string to set the servers parameter to if the value is acceptable. If the value is missing or is empty (""), the parameter and its current value are deleted.
- After a parameter has changed the DHCP server requires re-starting before you can use new parameter values.
- R *server_addresses* Configure the BOOTP relay service. BOOTP or DHCP requests are forwarded to the list of servers specified.

- server_addresses* is a comma separated list of hostnames and/or IP addresses.
- S Control the DHCP service.
- The following sub-options are supported:
- d Disable and stop the DHCP service.
 - e Enable and start the DHCP service.
 - q Display the state of the DHCP service. The state is encoded into the exit status.
 - 0 DHCP service disabled and stopped
 - 1 DHCP service enabled and stopped
 - 2 DHCP service disabled and running
 - 3 DHCP service enabled and running
 - r Enable and restart the DHCP service.
- U Unconfigure the DHCP service or BOOTP relay service.
- The following sub-options are supported:
- f Do not prompt for confirmation. If -f is not used, a warning and confirmation prompt is issued.
 - h Delete hosts entries from name service.
 - x Delete the dhcptab and network tables.
- X *filename* Export data from the DHCP data tables, saving to *filename*, to move the data to another Solaris DHCP server.
- The following sub-options are optional:
- a *networks_to_export* List of networks whose addresses should be exported, or the keyword ALL to specify all networks. If -a is not specified, no networks are exported.
 - g Signal the daemon to reload the dhcptab after the export has been completed.
 - m *macros_to_export* List of macros to export, or the keyword ALL to specify all macros. If -m is not specified, no macros are exported.
 - o *options_to_export* List of options to export, or the keyword ALL to specify all options. If -o is not specified, no options are exported.

-x Delete the data from this server after it is exported. If -x is not specified you are in effect copying the data.

Examples EXAMPLE 1 Configuring DHCP Service with Binary Files Data Store

The following command configures DHCP service, using the binary files data store, in the DNS domain `acme.eng`, with a lease time of 28800 seconds (8 hours),

```
example# dhcpconfig -D -r SUNWbinfiles -p /var/dhcp -l 28800\
-d acme.eng -a 120.30.33.4 -h dns -y acme.eng
```

EXAMPLE 2 Configuring BOOTP Relay Agent

The following command configures the DHCP daemon as a BOOTP relay agent, which forwards BOOTP and DHCP requests to the servers having the IP addresses 120.30.33.7 and 120.30.42.132:

```
example# dhcpconfig -R 120.30.33.7,120.30.42.132
```

EXAMPLE 3 Unconfiguring DHCP Service

The following command unconfigures the DHCP service, with confirmation, and deletes the DHCP data tables and host table entries:

```
example# dhcpconfig -U -x -h
```

EXAMPLE 4 Configuring a Network for DHCP Service

The following command configures an additional LAN network for DHCP service, specifying that clients should use router discovery and providing the NIS domain name and NIS server address:

```
example# dhcpconfig -N 120.30.171.0 -y east.acme.eng.com\
-a 120.30.33.4
```

EXAMPLE 5 Exporting a Network, Macros, and Options from a DHCP Server

The following command exports one network (120.30.171.0) and its addresses, the macro 120.30.171.0, and the options `motd` and `PSptr` from a DHCP server, saves the exported data in file `/export/var/120301710_data`, and deletes the exported data from the server.

```
example# dhcpconfig -X /var/dhcp/120301710_export
-a 120.30.171.0 -m 120.30.171.0 -o motd,PSptr
```

EXAMPLE 6 Importing Data on a DHCP Server

The following command imports DHCP data from a file, `/net/go/duck/export/var/120301710_data`, containing data previously exported from a Solaris DHCP server, overwrites any conflicting data on the importing server, and signals the daemon to reload the `dhcptab` once the import is completed:

EXAMPLE 6 Importing Data on a DHCP Server *(Continued)*

```
example# dhcpconfig -I /net/golduck/export/var/120301710_data -f -g
```

EXAMPLE 7 Setting DHCP Server Parameters

The following command sets the number of minutes that the DHCP server waits before timing out when updating DNS information on DHCP clients to five minutes.

```
example# example# dhcpconfig -P UPDATE_TIMEOUT=5
```

EXAMPLE 8 Re-starting the DHCP server

The following command stops and re-starts the DHCP server.

```
example# example# dhcpconfig -S -r
DHCP server stopped
DHCP server started
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------|
| Availability | service/network/dhcp |
| Interface Stability | Committed |

System Administration Guide: IP Services

-
- Name** dhcpgmr – graphical interface for managing DHCP service
- Synopsis** /usr/sadm/admin/bin/dhcpgmr
- Description** dhcpgmr is a graphical user interface which enables you to manage the Dynamic Host Configuration Protocol (DHCP) service on the local system. It performs the functions of the dhcpcfg, dhtadm, and pntadm command line utilities. You must be root to use dhcpgmr. The dhcpgmr Help, available from the Help menu, contains detailed information about using the tool.
- Usage** You can perform the following tasks using dhcpgmr:
- | | |
|------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| Configure DHCP service | Use dhcpgmr to configure the DHCP daemon as a DHCP server, and select the data store to use for storing network configuration tables.. |
| Configure BOOTP relay service | Use dhcpgmr to configure the DHCP daemon as a BOOTP relay. |
| Manage DHCP or BOOTP relay service | Use dhcpgmr to start, stop, enable, disable or unconfigure the DHCP service or BOOTP relay service, or change DHCP server parameters. |
| Manage DHCP addresses | Use dhcpgmr to add, modify, or delete IP addresses leased by the DHCP service. |
| Manage DHCP macros | Use dhcpgmr to add, modify or delete macros used to supply configuration parameters to DHCP clients. |
| Manage DHCP options | Use dhcpgmr to add, modify or delete options used to define parameters deliverable through DHCP. |
| Convert to a new DHCP data store | Use dhcpgmr to configure the DHCP server to use a different data store, and convert the DHCP data to the format used by the new data store. |
| Move DHCP data to another server | Use dhcpgmr to export data from one Solaris DHCP server and import data onto another Solaris DHCP server. |
- Exit Status** The following exit values are returned:
- | | |
|----------|------------------------|
| 0 | Successful completion. |
| non-zero | An error occurred. |

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------|
| Availability | network/dhcp/dhcpgmr |
| Interface Stability | Committed |

Oracle Solaris DHCP Service Developer's Guide

System Administration Guide: IP Services

Name dhtadm – DHCP configuration table management utility

Synopsis dhtadm -C [-r *resource*] [-p *path*] [-u *uninterpreted*] [-g]

dhtadm -A -s *symbol_name* -d *definition* [-r *resource*]
[-p *path*] [-u *uninterpreted*] [-g]

dhtadm -A -m *macro_name* -d *definition* [-r *resource*]
[-p *path*] [-u *uninterpreted*] [-g]

dhtadm -M -s *symbol_name* -d *definition* [-r *resource*]
[-p *path*] [-u *uninterpreted*] [-g]

dhtadm -M -s *symbol_name* -n *new_name* [-r *resource*]
[-p *path*] [-u *uninterpreted*] [-g]

dhtadm -M -m *macro_name* -n *new_name* [-r *resource*] [-p *path*]
[-u *uninterpreted*] [-g]

dhtadm -M -m *macro_name* -d *definition* [-r *resource*]
[-p *path*] [-u *uninterpreted*] [-g]

dhtadm -M -m *macro_name* -e *symbol=value* [-r *resource*]
[-p *path*] [-u *uninterpreted*] [-g]

dhtadm -D -s *symbol_name* [-r *resource*] [-p *path*]
[-u *uninterpreted*] [-g]

dhtadm -D -m *macro_name* [-r *resource*] [-p *path*]
[-u *uninterpreted*] [-g]

dhtadm -P [-r *resource*] [-p *path*] [-u *uninterpreted*] [-g]

dhtadm -R [-r *resource*] [-p *path*] [-u *uninterpreted*] [-g]

dhtadm -B [-v] [*batchfile*] [-g]

Description dhtadm manages the Dynamic Host Configuration Protocol (DHCP) service configuration table, `dhcptab`. You can use it to add, delete, or modify DHCP configuration macros or options or view the table. For a description of the table format, see [dhcptab\(4\)](#).

The `dhtadm` command can be run by root, or by other users assigned to the DHCP Management profile. See [rbac\(5\)](#) and [user_attr\(4\)](#).

After you make changes with `dhtadm`, you should issue a `SIGHUP` to the DHCP server, causing it to read the `dhcptab` and pick up the changes. Do this using the `-g` option.

Options One of the following function flags must be specified with the `dhtadm` command: `-A`, `-B`, `-C`, `-D`, `-M`, `-P` or `-R`.

The following options are supported:

`-A` Add a symbol or macro definition to the `dhcptab` table.

The following sub-options are required:

- d *definition*** Specify a macro or symbol definition.
- definition* must be enclosed in single quotation marks. For macros, use the form `-d ' :symbol=value:symbol=value: '`. Enclose a *value* that contains colons in double quotation marks. For symbols, the definition is a series of fields that define a symbol's characteristics. The fields are separated by commas. Use the form `-d 'context,code,type,granularity,maximum'`. See [dhcptab\(4\)](#) for information about these fields.
- m *macro_name*** Specify the name of the macro to be added.
- The `-d` option must be used with the `-m` option. The `-s` option cannot be used with the `-m` option.
- s *symbol_name*** Specify the name of the symbol to be added.
- The `-d` option must be used with the `-s` option. The `-m` option cannot be used with the `-s` option.
- B** Batch process `dhtadm` commands. `dhtadm` reads from the specified file or from standard input a series of `dhtadm` commands and execute them within the same process. Processing many `dhtadm` commands using this method is much faster than running an executable batchfile itself. Batch mode is recommended for using `dhtadm` in scripts.
- The following sub-option is optional:
- v** Display commands to standard output as they are processed.
- C** Create the DHCP service configuration table, `dhcptab`.
- D** Delete a symbol or macro definition.
- The following sub-options are required:
- m *macro_name*** Delete the specified macro.
- s *symbol_name*** Delete the specified symbol.

-
- g Signal the DHCP daemon to reload the `dhcptab` after successful completion of the operation.
 - M Modify an existing symbol or macro definition.
The following sub-options are required:
 - d *definition* Specify a macro or symbol definition to modify.

The definition must be enclosed in single quotation marks. For macros, use the form `-d ' :symbol=value:symbol=value: '`. Enclose a *value* that contains colons in double quotation marks. For symbols, the definition is a series of fields that define a symbol's characteristics. The fields are separated by commas. Use the form `-d 'context,code,type,granularity,maximum'`. See [dhcptab\(4\)](#) for information about these fields.
 - e This sub-option uses the `symbol=value` argument. Use it to edit a `symbol/value` pair within a macro. To add a symbol which does not have an associate value, enter:

`symbol=_NULL_VALUE_`

To delete a symbol definition from a macro, enter:

`symbol=`
 - m This sub-option uses the `macro_name` argument. The `-n`, `-d`, or `-e` sub-options are legal companions for this sub-option..
 - n This sub-option uses the `new_name` argument and modifies the name of the object specified by the `-m` or `-s` sub-option. It is not limited to macros. . Use it to specify a new macro name or symbol name.
 - s This sub-option uses the `symbol_name` argument. Use it to specify a symbol. The `-d` sub-option is a legal companion.
 - p *path* Override the `dhcpsvc.conf(4)` configuration value for `PATH=` with *path*. See [dhcpsvc.conf\(4\)](#) for more details regarding *path*. See [dhcp_modules\(5\)](#) for information regarding data storage modules for the DHCP service.

- P Print (display) the dhcptab table.
- r *data_store_resource* Override the dhcpsvc.conf(4) configuration value for RESOURCE= with the *data_store_resource* specified. See dhcpsvc.conf(4) for more details on resource type. See *Oracle Solaris DHCP Service Developer's Guide* for more information about adding support for other data stores. See dhcp_modules(5) for information regarding data storage modules for the DHCP service.
- R Remove the dhcptab table.
- u *uninterpreted* Data which is ignored by dhtadm, but passed to currently configured public module, to be interpreted by the data store. The private layer provides for module-specific configuration information through the use of the RESOURCE_CONFIG keyword. Uninterpreted data is stored within RESOURCE_CONFIG keyword of dhcpsvc.conf(4). See dhcp_modules(5) for information regarding data storage modules for the DHCP service.

Examples EXAMPLE 1 Creating the DHCP Service Configuration Table

The following command creates the DHCP service configuration table, dhcptab:

```
# dhtadm -C
```

EXAMPLE 2 Adding a Symbol Definition

The following command adds a Vendor option symbol definition for a new symbol called MySym to the dhcptab table in the SUNWfiles resource in the /var/mydhcp directory:

```
# dhtadm -A -s MySym
  -d 'Vendor=SUNW.PCW.LAN,20,IP,1,0'
  -r SUNWfiles -p /var/mydhcp
```

EXAMPLE 3 Adding a Macro Definition

The following command adds the aruba macro definition to the dhcptab table. Note that symbol/value pairs are bracketed with colons (:).

```
# dhtadm -A -m aruba \
  -d ':Timeserv=10.0.0.10 10.0.0.11:DNSserv=10.0.0.1:'
```

EXAMPLE 4 Modifying a Macro Definition

The following command modifies the Locale macro definition, setting the value of the UTCOffset symbol to 18000 seconds. Note that any macro definition which includes the definition of the Locale macro inherits this change.

```
# dhtadm -M -m Locale -e 'UTCOffset=18000'
```

EXAMPLE 5 Deleting a Symbol

The following command deletes the Timeserv symbol from the aruba macro. Any macro definition which includes the definition of the aruba macro inherits this change.

```
# dhtadm -M -m aruba -e 'Timeserv='
```

EXAMPLE 6 Adding a Symbol to a Macro

The following command adds the Hostname symbol to the aruba macro. Note that the Hostname symbol takes no value, and thus requires the special value `_NULL_VALUE_`. Note also that any macro definition which includes the definition of the aruba macro inherits this change.

```
# dhtadm -M -m aruba -e 'Hostname=_NULL_VALUE_'
```

EXAMPLE 7 Renaming a Macro

The following command renames the Locale macro to MyLocale. Note that any Include statements in macro definitions which include the Locale macro also need to be changed.

```
# dhtadm -M -m Locale -n MyLocale
```

EXAMPLE 8 Deleting a Symbol Definition

The following command deletes the MySym symbol definition. Note that any macro definitions which use MySym needs to be modified.

```
# dhtadm -D -s MySym
```

EXAMPLE 9 Printing a dhcptab

The following command prints to standard output the contents of the dhcptab that is located in the data store and path indicated in the dhcpsvc.conf file.

```
# dhtadm -P
```

EXAMPLE 10 Executing dhtadm in Batch Mode

The following command runs a series of dhtadm commands contained in a batch file and signals the daemon to reload the dhcptab once the commands have been executed:

```
# dhtadm -B addmacros -g
```

| | | |
|--------------------|---|------------------------|
| Exit Status | 0 | Successful completion. |
| | 1 | Object already exists. |
| | 2 | Object does not exist. |
| | 3 | Non-critical error. |
| | 4 | Critical error. |

Files /etc/inet/dhcpsvc.conf

Name dig – DNS lookup utility

Synopsis dig [@server] [-b *address*] [-c *class*] [-f *filename*]
 [-k *filename*] [-m] [-p *port#*] [-q *name*] [-t *type*] [-x *addr*]
 [-y [*hmac:*]*name:key*] [-4] [-6] [*name*] [*type*] [*class*] [*queryopt*]...
 dig [-h]
 dig [*global-queryopt*...] [*query*...]

Description The dig utility (domain information groper) is a flexible tool for interrogating DNS name servers. It performs DNS lookups and displays the answers that are returned from the name server(s) that were queried. Most DNS administrators use dig to troubleshoot DNS problems because of its flexibility, ease of use and clarity of output. Other lookup tools tend to have less functionality than dig.

Although dig is normally used with command-line arguments, it also has a batch mode of operation for reading lookup requests from a file. A brief summary of its command-line arguments and options is printed when the -h option is specified. Unlike earlier versions, the BIND 9 implementation of dig allows multiple lookups to be issued from the command line.

Unless it is told to query a specific name server, dig tries each of the servers listed in /etc/resolv.conf.

When no command line arguments or options are given, dig performs an NS query for "." (the root).

It is possible to set per-user defaults for dig with \${HOME}/.digrc. This file is read and any options in it are applied before the command line arguments.

The IN and CH class names overlap with the IN and CH top level domains names. Either use the -t and -c options to specify the type and class, or use "IN." and "CH." when looking up these top level domains.

Simple Usage The following is a typical invocation of dig:

```
dig @server name type
```

where:

server

The name or IP address of the name server to query. This can be an IPv4 address in dotted-decimal notation or an IPv6 address in colon-delimited notation. When the supplied *server* argument is a hostname, dig resolves that name before querying that name server. If no *server* argument is provided, dig consults /etc/resolv.conf and queries the name servers listed there. The reply from the name server that responds is displayed.

name

The name of the resource record that is to be looked up.

type

Indicates what type of query is required (ANY, A, MX, SIG, among others.) *type* can be any valid query type. If no *type* argument is supplied, dig performs a lookup for an A record.

Options The following options are supported:

-4

Use only IPv4 transport. By default both IPv4 and IPv6 transports can be used. Options -4 and -6 are mutually exclusive.

-6

Use only IPv6 transport. By default both IPv4 and IPv6 transports can be used. Options -4 and -6 are mutually exclusive.

-b *address*

Set the source IP address of the query to *address*. This must be a valid address on one of the host's network interfaces or 0.0.0.0 or ::. An optional port may be specified by appending: #<*port*>

-c *class*

Override the default query class (IN for internet). The *class* argument is any valid class, such as HS for Hesiod records or CH for CHAOSNET records.

-f *filename*

Operate in batch mode by reading a list of lookup requests to process from the file *filename*. The file contains a number of queries, one per line. Each entry in the file should be organized in the same way they would be presented as queries to dig using the command-line interface.

-h

Print a brief summary of command-line arguments and options.

-k *filename*

Specify a transaction signature (TSIG) key file to sign the DNS queries sent by dig and their responses using TSIGs.

-m

Enable memory usage debugging.

-p *port#*

Query a non-standard port number. The *port#* argument is the port number that dig sends its queries instead of the standard DNS port number 53. This option tests a name server that has been configured to listen for queries on a non-standard port number.

-q *name*

Sets the query name to *name*. This can be useful in that the query name can be easily distinguished from other arguments.

-t *type*

Set the query type to *type*, which can be any valid query type supported in BIND9. The default query type “A”, unless the `-x` option is supplied to indicate a reverse lookup. A zone transfer can be requested by specifying a type of AXFR. When an incremental zone transfer (IXFR) is required, *type* is set to `ixfr=N`. The incremental zone transfer will contain the changes made to the zone since the serial number in the zone’s SOA record was *N*.

-x *addr*

Simplify reverse lookups (mapping addresses to names). The *addr* argument is an IPv4 address in dotted-decimal notation, or a colon-delimited IPv6 address. When this option is used, there is no need to provide the *name*, *class* and *type* arguments. The `dig` utility automatically performs a lookup for a name like `11.12.13.10.in-addr.arpa` and sets the query type and class to PTR and IN, respectively. By default, IPv6 addresses are looked up using nibble format under the IP6.ARPA domain. To use the older RFC1886 method using the IP6.INT domain, specify the `-i` option. Bit string labels (RFC 2874) are now experimental and are not attempted.

-y [*hmac*]:*name*:*key*

Specify a transaction signature (TSIG) key on the command line. This is done to sign the DNS queries sent by `dig`, as well as their responses. You can also specify the TSIG key itself on the command line using the `-y` option. The optional *hmac* is the type of TSIG; the default is HMAC-MD5. The *name* argument is the name of the TSIG key and the *key* argument is the actual key. The key is a base-64 encoded string, typically generated by `dnssec-keygen(1M)`.

Caution should be taken when using the `-y` option on multi-user systems, since the key can be visible in the output from `ps(1)` or in the shell’s history file. When using TSIG authentication with `dig`, the name server that is queried needs to know the key and algorithm that is being used. In BIND, this is done by providing appropriate key and server statements in `named.conf`.

Query Options The `dig` utility provides a number of query options which affect the way in which lookups are made and the results displayed. Some of these set or reset flag bits in the query header, some determine which sections of the answer get printed, and others determine the timeout and retry strategies.

Each query option is identified by a keyword preceded by a plus sign (+). Some keywords set or reset an option. These may be preceded by the string `no` to negate the meaning of that keyword. Other keywords assign values to options like the timeout interval. They have the form `+keyword=value`. The query options are:

+*[no]*tcp

Use [do not use] TCP when querying name servers. The default behaviour is to use UDP unless an AXFR or IXFR query is requested, in which case a TCP connection is used.

- `+[no]vc`
Use [do not use] TCP when querying name servers. This alternate syntax to `+[no]tcp` is provided for backwards compatibility. The “vc” stands for “virtual circuit”.
- `+[no]ignore`
Ignore truncation in UDP responses instead of retrying with TCP. By default, TCP retries are performed.
- `+domain=somename`
Set the search list to contain the single domain *somename*, as if specified in a `domain` directive in `/etc/resolv.conf`, and enable search list processing as if the `+search` option were given.
- `+[no]search`
Use [do not use] the search list defined by the `searchlist` or `domain` directive in `resolv.conf` (if any). The search list is not used by default.
- `+[no]showsearch`
Perform [do not perform] a search showing intermediate results.
- `+[no]defname`
Deprecated, treated as a synonym for `+[no]search`.
- `+[no]aaonly`
Sets the `aa` flag in the query.
- `+[no]aaf flag`
A synonym for `+[no]aaonly`.
- `+[no]adflag`
Set [do not set] the AD (authentic data) bit in the query. This requests that the server return, regardless of whether all of the answer and authority sections have all been validated as secure according to the security policy of the server. A setting of `AD=1` indicates that all records have been validated as secure and the answer is not from an `OPT-OUT` range. `AD=0` indicates that some part of the answer is insecure or not validated.
- `+[no]cdf flag`
Set [do not set] the CD (checking disabled) bit in the query. This requests the server to not perform DNSSEC validation of responses.
- `+[no]cl`
Display [do not display] the CLASS when printing the record.
- `+[no]ttlid`
Display [do not display] the TTL when printing the record.
- `+[no]recurse`
Toggle the setting of the RD (recursion desired) bit in the query. This bit is set by default, which means `dig` normally sends recursive queries. Recursion is automatically disabled when the `+nssearch` or `+trace` query options are used.

-
- `+ [no] nssearch`
When this option is set, `dig` attempts to find the authoritative name servers for the zone containing the name being looked up and display the SOA record that each name server has for the zone.
 - `+ [no] trace`
Toggle tracing of the delegation path from the root name servers for the name being looked up. Tracing is disabled by default. When tracing is enabled, `dig` makes iterative queries to resolve the name being looked up. It will follow referrals from the root servers, showing the answer from each server that was used to resolve the lookup.
 - `+ [no] cmd`
Toggle the printing of the initial comment in the output identifying the version of `dig` and the query options that have been applied. This comment is printed by default.
 - `+ [no] short`
Provide a terse answer. The default is to print the answer in a verbose form.
 - `+ [no] identify`
Show [or do not show] the IP address and port number that supplied the answer when the `+short` option is enabled. If short form answers are requested, the default is not to show the source address and port number of the server that provided the answer.
 - `+ [no] comments`
Toggle the display of comment lines in the output. The default is to print comments.
 - `+ [no] stats`
Toggle the printing of statistics: when the query was made, the size of the reply and so on. The default behaviour is to print the query statistics.
 - `+ [no] qr`
Print [do not print] the query as it is sent. By default, the query is not printed.
 - `+ [no] question`
Print [do not print] the question section of a query when an answer is returned. The default is to print the question section as a comment.
 - `+ [no] answer`
Display [do not display] the answer section of a reply. The default is to display it.
 - `+ [no] authority`
Display [do not display] the authority section of a reply. The default is to display it.
 - `+ [no] additional`
Display [do not display] the additional section of a reply. The default is to display it.
 - `+ [no] all`
Set or clear all display flags.

`+time=T`

Sets the timeout for a query to *T* seconds. The default time out is 5 seconds. An attempt to set *T* to less than 1 will result in a query timeout of 1 second being applied.

`+tries=T`

Sets the maximum number of UDP attempts to *T*. The default number is 3 (1 initial attempt followed by 2 retries). If *T* is less than or equal to zero, the number of retries is silently rounded up to 1.

`+retry=T`

Sets the number of UDP retries to *T*. The default is 2.

`+ndots=D`

Set the number of dots that have to appear in *name* to *D* for it to be considered absolute. The default value is that defined using the `ndots` statement in `/etc/resolv.conf`, or 1 if no `ndots` statement is present. Names with fewer dots are interpreted as relative names and will be searched for in the domains listed in the `search` or `domain` directive in `/etc/resolv.conf`.

`+bufsize=B`

Set the UDP message buffer size advertised using EDNS0 to *B* bytes. The maximum and minimum sizes of this buffer are 65535 and 0 respectively. Values outside this range are rounded up or down appropriately.

`+edns=#`

Specify the EDNS version with which to query. Valid values are 0 to 255. Setting the EDNS version causes a EDNS query to be sent. `+noedns` clears the remembered EDNS version.

`+[no]multiline`

Print records like the SOA records in a verbose multi-line format with human-readable comments. The default is to print each record on a single line, to facilitate machine parsing of the dig output.

`+[no]fail`

Do not try the next server if you receive a `SERVFAIL`. The default is to not try the next server which is the reverse of normal stub resolver behavior.

`+[no]besteffort`

Attempt to display the contents of messages which are malformed. The default is to not display malformed answers.

`+[no]dnssec`

Request DNSSEC records be sent by setting the DNSSEC OK bit (DO) in the OPT record in the additional section of the query.

`+[no]sigchase`

Chase DNSSEC signature chains. Requires dig be compiled with `-DDIG_SIGCHASE`.

`+trusted-key=####`

Specifies a file containing trusted keys to be used with `+sigchase`. Each DNSKEY record must be on its own line.

If not specified dig will look for `/etc/trusted-key.key` then `trusted-key.key` in the current directory.

Requires dig be compiled with `-DDIG_SIGCHASE`.

`+ [no] topdown`

When chasing DNSSEC signature chains, perform a top-down validation. Requires dig be compiled with `-DDIG_SIGCHASE`.

`+ [no] nsid`

Include an EDNS name server ID request when sending a query.

Multiple Queries The BIND 9 implementation of dig supports specifying multiple queries on the command line (in addition to supporting the `-f` batch file option). Each of those queries can be supplied with its own set of flags, options and query options.

In this case, each *query* argument represent an individual query in the command-line syntax described above. Each consists of any of the standard options and flags, the name to be looked up, an optional query type, and class and any query options that should be applied to that query.

A global set of query options, which should be applied to all queries, can also be supplied. These global query options must precede the first tuple of name, class, type, options, flags, and query options supplied on the command line. Any global query options (except the `+ [no] cmd` option) can be overridden by a query-specific set of query options. For example:

```
dig +qr www.isc.org any -x 127.0.0.1 isc.org ns +noqr
```

...shows how dig could be used from the command line to make three lookups: an ANY query for `www.isc.org`, a reverse lookup of `127.0.0.1` and a query for the NS records of `isc.org`. A global query option of `+qr` is applied, so that dig shows the initial query it made for each lookup. The final query has a local query option of `+noqr` which means that dig will not print the initial query when it looks up the NS records for `isc.org`.

Files `/etc/resolv.conf`
Resolver configuration file

`${HOME}/.digrc`
User-defined configuration file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|------------------|
| Availability | network/dns/bind |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Volatile |

See Also [dnssec-keygen\(1M\)](#), [host\(1M\)](#), [named\(1M\)](#), [nslookup\(1M\)](#), [attributes\(5\)](#)

RFC 1035

See the BIND 9 *Administrator's Reference Manual*. As of the date of publication of this man page, this document is available at <https://www.isc.org/software/bind/documentation>.

Bugs There are probably too many query options.

Notes [nslookup\(1M\)](#) and `dig` now report “Not Implemented” as NOTIMP rather than NOTIMPL. This will have impact on scripts that are looking for NOTIMPL.

Name directoryserver – front end for the Directory Server (DS)

 /usr/sbin/directoryserver help [*subcommand*]

Description The `directoryserver` command is a comprehensive, front end to the utility programs provided by the Solaris Directory Server (DS).

Options for the `directoryserver` command itself must appear before the subcommand. Arguments for a subcommand must appear after the subcommand. Subcommands have specific arguments. See SUBCOMMANDS.

Subcommands The following subcommands are supported:

| | |
|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------------|
| <code>account-inactivate</code> <i>args</i> | Inactivates and locks an entry or group of entries. |
| | The <code>account-inactivate</code> subcommand supports the following arguments: |
| <code>[-D <i>rootdn</i>]</code> | Directory Server <i>userDN</i> with root permissions, such as Directory Manager. |
| <code>[-h <i>host</i>]</code> | Host name of Directory Server. The default value is the full hostname of the machine where Directory Server is installed. |
| <code>-I <i>DN</i></code> | Entry DN or role DN to activate. |

-j file Password associated with the user DN. This option allows the password to be stored in clear text in the named file for scripting.

This is considered insecure. Use with extreme caution.

[-p port] Directory Server port. The default value is the LDAP port of Directory Server specified at installation time.

-w password Password associated with the user DN. Supplying the password on the command line is visible using the `/bin/ps` command. This is considered insecure. Use with extreme caution.

The value `-` can be used in place the password. The program prompts the user for a password to be entered from the terminal.

`account-activate` *args*

Activates an entry or group of entries.

The `account-activate` subcommand supports the following arguments

-D rootdn Directory Server userDN with root permissions, such as Directory Manager.

-h host Host name of Directory Server. The default value is the full hostname of the machine where Directory Server is installed.

-I DN Entry DN or role DN to activate.

-j file Password associated with the user DN. This option allows the password to be stored in clear text in the named file for scripting.

This is considered insecure. Use with extreme caution.

-p port Directory Server port. The default value is the LDAP port of Directory Server specified at installation time.

-w password Password associated with the user DN. Supplying the password on the command line is visible using the `/bin/ps` command. This is considered insecure. Use with extreme caution.

The value `-` can be used in place the password. The program prompts the user for a password to be entered from the terminal.

`account-status args`

Provides account status information to establish whether an entry or group of entries is inactivated or not.

The `account-status` subcommand supports the following arguments:

-D rootdn

-h host Host name of Directory Server. The default value is the full hostname of the machine where Directory Server is installed.

-I DN Entry DN or role DN whose status is required.

-j file Password associated with the user DN. This option allows the password to be stored in clear text in the named file for scripting.

This is considered insecure. Use with extreme caution.

-p port Directory Server port. The default value is the LDAP port of Directory Server specified at installation time.

-w password Password associated with the rootDN. Supplying the password on the command line is visible using the

/bin/ps command. This is considered insecure. Use with extreme caution.

The value - can be used in place of the password. The program prompts the user for a password to be entered from the terminal.

admin_ip args

Change the IP address of the administrative server in the configuration.

The *admin_ip* subcommand supports the following arguments:

dir_mgr_DN Directory Manager's DN.

dir_mgr_password Directory Manager's password.

old_ip Old IP.

new_ip New IP.

port_# Port number.

bak2db backup_directory

Restore the database from the most recent archived backup.

Specify *backup_directory* as the backup directory.

bak2db-task args

Restore the data to the database.

The *bak2db-task* subcommand supports the following arguments:

[-a *directory*] Directory where the backup files are stored. By default it is under
/var/ds5/slapd-serverID/bak

-D *rootDN* User DN with root permissions, such as Directory Manager. The default is the DN of the directory manager which is read from the *nsslapd-root* attribute under *cn=config*.

| | |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-j file</code> | <p>Password associated with the user DN. This option allows the password to be stored in clear text in the named file for scripting.</p> <p>This is considered insecure. Use with extreme caution.</p> |
| <code>[-t database_type]</code> | <p>Database type. The only possible database type is <code>ldb</code>.</p> |
| <code>[-v]</code> | <p>Verbose mode.</p> |
| <code>-w password</code> | <p>Password associated with the user DN. Supplying the password on the command line is visible using the <code>/bin/ps</code> command. This is considered insecure. Use with extreme caution.</p> <p>The value <code>-</code> can be used in place the password. The program prompts the user for a password to be entered from the terminal.</p> |

db2bak-task args

Back up the contents of the database. It creates an entry in the directory that launches this dynamic task. An entry is generated based upon the values provided for each option.

The `db2bak-task` subcommand supports the following arguments:

| | |
|-----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>[-a directory]</code> | <p>Directory where the backup files are stored. By default it is under <code>/var/ds5/slapd-serverID/bak</code>. The backup file is named according to the year-month-day-hour format (<code>YYYY_MM_DD_hhmmss</code>).</p> |
| <code>-D rootDN</code> | <p>User DN with root permissions, such as Directory</p> |

| | |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | <p>Manager. The default is the DN of the directory manager which is read from the <code>nsslapd-root</code> attribute under <code>cn=config</code>.</p> |
| <code>-j file</code> | <p>Password associated with the user DN. This option allows the password to be stored in clear text in the named file for scripting.</p> <p>This is considered insecure. Use with extreme caution.</p> |
| <code>-t database_type</code> | <p>Database type. The only possible database type is <code>ldbm</code>.</p> |
| <code>[-v]</code> | <p>Verbose mode.</p> |
| <code>-w password</code> | <p>Password associated with the user DN. Supplying the password on the command line is visible using the <code>/bin/ps</code> command. This is considered insecure. Use with extreme caution.</p> <p>The value <code>-</code> can be used in place the password. The program prompts the user for a password to be entered from the terminal.</p> |
| <code>db2bak [backup_directory]</code> | <p>Create a backup of the current database contents. The server must be stopped to run this subcommand.</p> <p>The default is <code>/var/ds5/slapd-serverID/bak</code>. The backup file is named according to the year-month-day-hour format (<code>YYYY_MM_DD_hhmmss</code>).</p> |
| <code>db2index-text args</code> | <p>Create and generate the new set of indexes to be maintained following the modification of indexing entries in the <code>cn=config</code> configuration file.</p> <p>The <code>db2index-text</code> subcommand supports the following arguments:</p> |

| | |
|-----------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-D <i>rootdn</i></code> | User DN with root permissions, such as Directory Manager. |
| <code>-j <i>file</i></code> | Password associated with the user DN. This option allows the password to be stored in clear text in the named file for scripting. This is considered insecure. Use with extreme caution. |
| <code>-n <i>backend_instance</i></code> | Instance to be indexed. |
| <code>[-t <i>attributeName</i>]</code> | Name of the attribute to be indexed. If omitted, all indexes defined for that instance are generated. |
| <code>[-v]</code> | Verbose mode. |
| <code>-w <i>password</i></code> | Password associated with the user DN. Supplying the password on the command line is visible using the <code>/bin/ps</code> command. This is considered insecure. Use with extreme caution. |
| | The value <code>-</code> can be used in place the password. The program prompts the user for a password to be entered from the terminal. |

`db2ldif-task args`

Exports the contents of the database to LDIF. It creates an entry in the directory that launches this dynamic task. The entry is generated based upon the values you provide for each option. To run this subcommand the server must be running and either `-n backend_instance` or `-s include` suffix is required.

The `db2ldif-task` subcommand supports the following arguments:

| | |
|-------------------------------------|------------------------------------|
| <code>[-a <i>outputfile</i>]</code> | File name of the output LDIF file. |
|-------------------------------------|------------------------------------|

| | |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -C | Only the main db file is used. |
| -D <i>rootDN</i> | User DN with root permissions, such as Directory Manager. |
| -j <i>file</i> | Password associated with the user DN. This option allows the password to be stored in clear text in the named file for scripting. This is considered insecure. Use with extreme caution. |
| [-M] | Output LDIF is stored in multiple files. |
| [-m] | Minimal base 64 encoding. |
| {-n <i>backend_instance</i> }* | Instance to be exported. |
| [-N] | Minimal base 64 encoding. |
| [-o] | Output LDIF to be stored in one file by default with each instance stored in <i>instance_file</i> name. |
| [-r] | Export replica. |
| [-s] <i>includesuffix</i> * | Suffix(es) to be included or to specify the subtrees to be included if -n has been used. |
| [-u] | Request that the unique ID is not exported. |
| [-U] | Request that the output LDIF is not folded. |
| -w <i>password</i> | Password associated with the user DN. Supplying the password on the command line is visible |

| | | |
|----------------------|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | | using the <code>/bin/ps</code> command. This is considered insecure. Use with extreme caution. |
| | | The value <code>-</code> can be used in place the password. The program prompts the user for a password to be entered from the terminal. |
| | <code>{-x <i>excludesuffix</i>}*</code> | Suffixes to be excluded. |
| | <code>[-1]</code> | Delete, for reasons of backward compatibility the first line of the LDIF file that gives the version of the LDIF standard. |
| <code>db2ldif</code> | <i>args</i> | Export the contents of the database to LDIF. You must specify either the <code>-n</code> or the <code>-s</code> option or both. |
| | | The <code>db2ldif</code> subcommand supports the following options: |
| | <code>[-a <i>outputfile</i>]</code> | File name of the output LDIF file. |
| | <code>[-C]</code> | Only use the main db file. |
| | <code>[-m]</code> | Minimal base64 encoding. |
| | <code>[-M]</code> | Use of several files for storing the output LDIF with each instance stored in <i>instance_file name</i> (where file name is the file name specified for <code>-a</code> option). |
| | <code>{-n <i>baclcmd_instance</i>}*</code> | Instance to be exported. |
| | <code>[-N]</code> | Specify that the entry IDs are not to be included in the LDIF output. The entry IDs are necessary |

| | | |
|--------------------------------|------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | | only if the <code>db2ldif</code> output is to be used as input to <code>db2index-text</code> . |
| | <code>[-r]</code> | Export replica. |
| | <code>{-s includesuffix}*</code> | Suffixes to be included or to specify the subtrees to be included if <code>-n</code> has been used. |
| | <code>[{-x excludesuffix}]*</code> | Suffixes to be excluded. |
| | <code>[-u]</code> | Request that the unique id is not exported. |
| | <code>[-U]</code> | Request that the output LDIF is not folded. |
| | <code>[-1]</code> | Delete, for reasons of backward compatibility, the first line of the LDIF file which gives the version of the LDIF standard. |
| <code>help [subcommand]</code> | | Display <code>directoryserver</code> usage message or subcommand specific usage message. |
| <code>idsktune args</code> | | Provide an easy and reliable way of checking the patch levels and kernel parameter settings for your system. You must install the Directory Server before you can run <code>idsktune</code> . It gathers information about the operating system, kernel, and TCP stack to make tuning recommendations. |
| | | The <code>idsktune</code> subcommand supports the following arguments: |
| | <code>[-c]</code> | Client-specific tuning: the output only includes tuning recommendations for running a directory client application. |
| | <code>[-D]</code> | Debug mode: the output includes the commands it runs internally, preceded by <code>DEBUG</code> heading. |
| | <code>[-i installdir]</code> | The install directory. |

| | | |
|-------------------|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | [-q] | Quiet mode. Output only includes tuning recommendations. OS version statements are omitted. |
| | [-v] | Version. Gives the build date identifying the version of the toll. |
| keyupg args | | Upgrade the key from Lite to normal (only one way). |
| | | The keyupg subcommand supports the following arguments: |
| | -kkey | The key to be upgraded. |
| | -f key_file_path | The key file path. |
| ldif2db-task args | | Import data to the directory. It create an entry in the directory that launches this dynamic task. The entry is generated based upon the values you provide for each option. The server must be running when you run this subcommand. |
| | | The ldif2sb-task subcommand supports the following arguments: |
| | [-c] | Request that only the core db is created without attribute indexes. |
| | -D rootDN | User DN with root permissions, such as Directory Manager. |
| | [-g string] | Generation of a unique ID. Enter none for no unique ID to be generated and deterministic for the generated unique ID to be name-based. Generates a time based unique ID by default. |
| | | If you use the deterministic generation to have a name-based unique ID, you can also |

`-g deterministic namespace_id`

`00-xxxxxxxx-xxxxxxxx-xxxxxxxx-xxxxxxxx`

specify the namespace you want the server to use as follows:

where `namespace_id` is a string of characters in the following format

Use this option if you want to import the same LDIF file into two different directory servers, and you want the contents of both directories to have the same set of unique IDs. If unique IDs already exist in the LDIF file you are importing, then the existing IDs are imported to the server regardless of the options you have specified.

`[-G namespace_id]`

Generate a namespace ID as a name-based unique ID. This is the same as specifying `-g deterministic`.

`{-i filename}*`

File name of the input LDIF files. When you import multiple files, they are imported in the order in which you specify them on the command line.

`-j file`

Password associated with the user DN. This option allows the password to be stored in clear text in the named file for scripting. This is considered insecure. Use with extreme caution.

`-n backend_instance`

Instance to be imported.

| | | |
|------------------------|-------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | <code>[-O]</code> | Request that only the core db is created without attribute indexes. |
| | <code>{-s includesuffix }*</code> | Suffixes to be included. This argument can also be used to specify the subtrees to be included with <code>-n</code> . |
| | <code>-w password</code> | Password associated with the user DN. Supplying the password on the command line is visible using the <code>/bin/ps</code> command. This is considered insecure. Use with extreme caution.

The value <code>-</code> can be used in place the password. The program prompts the user for a password to be entered from the terminal. |
| | <code>[{-x excludesuffix }*]</code> | |
| | <code>[-v]</code> | Verbose mode. |
| <code>ldif args</code> | | Format LDIF files, and create base 64 encoded attribute values. With Base 64 Encoding you can represent binary data, such as a JPEG image, in LDIF by using base 64 encoding. You identify base 64 encoded data by using the <code>::</code> symbol. The <code>ldifsubcommand</code> takes any input and formats it with the correct line continuation and appropriate attribute information. The subcommand also senses whether the input requires base 64 encoding.

The <code>ldif</code> subcommand supports the following arguments |
| | <code>[-b]</code> | Interpret the entire input as a single binary value. If <code>-b</code> is not present, each line is considered to be a separate input value. |
| | <code>[attrtype]</code> | If <code>-b</code> is specified, the output is <code>attrtype:: <base 64 encoded</code> |

ldif2db *args*

value.

Import the data to the directory. To run this subcommand the server must be stopped. Note that ldif2db supports LDIF version 1 specifications. You can load an attribute using the URL specifier notation, for example:

```
jpegphoto: file:///tmp/myphoto.jpg
```

`[-c]` Merge chunk size.

`[-g string]` Generation of a unique ID. Type none for no unique ID to be generated and deterministic for the generated unique ID to be name-based. By default a time based unique ID is generated.

If you use the deterministic generation to have a name-based unique ID, you can also specify the namespace you want the server to use as follows:

`-g deterministic namespace_id`

where *namespace_id* is a string of characters in the following format:

```
00-xxxxxxxx-xxxxxxxx-xxxxxxxx-xxxxxxxx
```

Use this option if you want to import the same LDIF file into two different directory servers, and you want the contents of both directories to have the same set of unique IDs. If unique IDs already exist in the LDIF file you are importing, then the existing IDs are imported to the server regardless of the options you have specified.

| | | |
|------------------------|----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | <code>[-G <i>naemspace_id</i>]</code> | Generate a namespace ID as a name-based unique ID. This is the same as specifying the <code>-g deterministic</code> option. |
| | <code>{- <i>filename</i>}*</code> | File name of the input LDIF file(s). When you import multiple files, they are imported in the order in which you specify them on the command line. |
| | <code>-n <i>backend_instance</i></code> | Instance to be imported. |
| | <code>[-O]</code> | Request that only the core db is created without attribute indexes. |
| | <code>{-s <i>includesuffix</i>}*</code> | Suffixes to be included or to specify the subtrees to be included if <code>-n</code> has been used. |
| | <code>[{-x <i>excludesuffix</i>}*]</code> | Suffixes to be excluded |
| <code>ldif2ldap</code> | <code><i>rootDN password filename</i></code> | Perform an import operation over LDAP to the Directory Server. To run this subcommand the server must be running. |
| | | The <code>ldif2ldap</code> subcommand supports the following arguments: |
| | <code><i>rootdn</i></code> | User DN with root permissions, such as Directory Manager. |
| | <code><i>password</i></code> | Password associated with the user DN. |
| | <code><i>filename</i></code> | File name of the file to be imported. When you import multiple files, they are imported in the order in which you specify them on the command line. |
| <code>magt</code> | <code>CONFIG INIT</code> | Start SNMP master agent. The Config and INIT files are in <code>/usr/iplanet/ds5/plugins/snmp/magt</code> . For more information, see the iPlanet Directory Server 5.1 Administrator's Guide . |
| | | The <code>magt</code> subcommand supports the following options: |

| | | |
|---------------------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | CONFIG | The CONFIG file defines the community and the manager that master agent works with. Specify the manager value as a valid system name or an IP address. |
| | INIT | The INIT file is a nonvolatile file that contains information from the MIB-II system group, including system location and contact information. If INIT doesn't already exist, starting the master agent for the first time creates it. An invalid manager name in the CONFIG file causes the master agent start-up to fail. |
| monitor | | Retrieves performance monitoring information using the <code>ldapsearch</code> command-line utility. |
| mmldif <i>args</i> | | Combine multiple LDIF files into a single authoritative set of entries. Typically each LDIF file is from a master server cooperating in a multi master replication agreement. [e.g. masters that refuse to sync up for whatever reason]. Optionally, it can generate LDIF change files that could be applied to original to bring it up to date with authoritative. At least two input files must be specified.

The <code>mmldif</code> subcommand supports the following arguments:
<ul style="list-style-type: none"> [-c <i>inputfile</i> ...] Write a change file (.delta) for each input file. Specify <i>inputfile</i> as the input LDIF files. [-D] Print debugging information. [-o <i>out.ldif</i>] Write authoritative data to this file. |
| nativetoascii <i>args</i> | | Convert one language encoding to another. For example, convert a native language to UTF-8 format.

The <code>nativetoascii</code> subcommand supports the following options:
<ul style="list-style-type: none"> -d <i>Encodings Directory</i> Path to the |

| | |
|-------------------------------------------------------------------|---------------------------------------------|
| | directory which contains the conv directory |
| <code>[-i <i>input_filename</i> -o <i>output_filename</i>]</code> | The input file name and output file name. |
| <code>-l</code> | List supported encodings |
| <code>-r</code> | Replace existing files. |
| <code>-s <i>suffix</i></code> | Suffix to be mapped to the backend. |
| <code>-s <i>SourceEncoding</i></code> | Source Encoding of input stream. |
| <code>-t <i>TargetEncoding</i></code> | Target Encoding of output stream. |
| <code>-v</code> | Verbose output. |

pwdhash *args*

Print the encrypted form of a password using one of the server's encryption algorithms. If a user cannot log in, you can use this script to compare the user's password to the password stored in the directory.

The `pwdhash` subcommand supports the following arguments:

| | | |
|----------------|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | <code>-c comparepwd -s scheme</code> | The available schemes are SSHA, SHA, CRYPT and CLEARE. It generates the encrypted passwords according to scheme's algorithm. The <code>-c</code> specifies the encrypted password to be compared with. The result of comparison is either OK or doesn't match. |
| | <code>-D instance-dir</code> | The instance directory. |
| | <code>[-H]</code> | The passwords are hex-encoded. |
| | <code>password ...</code> | The clear passwords to generate encrypted form from or to be compared with. |
| restart | | Restarts the directory server.

When the <code>-s</code> option is not specified, restarts all instances of servers. When the <code>-s</code> option is specified, restarts the server specified by <code>-s</code> . |
| | restart-admin | Restarts the administration server. |
| restoreconfig | | Restores the most recently saved Administration Server configuration information to the NetscapeRoot partition under <code>/var/ds5/slapd-serverID/confbak</code> . |
| sagt -c CONFIG | | Start proxy SNMP agent. For more information, see the iPlanet Directory Server 5.1 Administrator's Guide .

The <code>sagt</code> subcommand supports the following options: |

| | | |
|--------------------------------------------|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | <i>-c configfile</i> | The CONFIG file includes the port that the SNMP daemon listens to. It also needs to include the MIB trees and traps that the proxy SNMP agent forwards. Edit the CONFIG file located in
<code>/usr/iplanet/ds5/plugins/snmp/sagt.</code> |
| <code>saveconfig</code> | | Saves the administration server configuration information to the
<code>/var/ds5/slapd-serverID/confbak</code> directory. |
| <code>setup [-f configuration_file]</code> | | Configures an instance of the directory server or administration server. Creates a basic configuration for the directory server and the administrative server that is used to manage the directory.

The <code>setup</code> subcommand has two modes of operation. You can invoke it with a curses-based interaction to gather input. Alternatively, you can provide input in a configuration file using the <code>-f</code> option.

The <code>setup</code> subcommand supports the following option:

<i>-f configuration_file</i>

Specifies the configuration file for silent installation. |
| <code>start</code> | | Starts the directory server. When the <code>-s</code> option is not specified, starts servers of all instances. When the <code>-s</code> option is specified, starts the server instance specified by <code>-s</code> . |
| <code>start-admin</code> | | Starts the directory server.

When the <code>-s</code> option is not specified, restarts all instances of servers. When the <code>-s</code> option is specified, restarts the server specified by <code>-s</code> . |
| <code>startconsole</code> | | Starts the directory console.. |
| <code>stop</code> | | Stops the directory server.

When the <code>-s</code> option is not specified, restarts all instances of servers. When the <code>-s</code> option is specified, restarts the server specified by <code>-s</code> . |
| <code>stop-admin</code> | | Stop the administration server. |

| | |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| suffix2instance { -s <i>suffix</i> } | Map a suffix to a backend name.

Specify -s <i>suffix</i> as the suffix to be mapped to the backend. |
| uninstall | Uninstalls the directory server and the administration server.

This subcommand stops servers of all instances and removes all the changes created by setup. |
| vlvindex <i>args</i> | Create virtual list view (VLV) indexes, known in the Directory Server Console as Browsing Indexes. The server must be stopped beforehand.

The <code>vlvindex</code> subcommand supports the following arguments: |
| -d <i>debug_level</i> | Specify the debug level to use during index creation. Debug levels are defined in <code>nsslapd-errorlog-level</code> (error Log Level). See the iPlanet Directory Server 5.1 Configuration, Command, and File Reference . |
| -n <i>backend_instance</i> | Name of the database containing the entries to index. |
| -s <i>suffix</i> | Name of the suffix containing the entries to index. |
| -T <i>VLVTag</i> | Name of the database containing the entries to index. |

Options Options for the `directoryserver` command itself must appear before the subcommand argument.

The following options are supported:

| | |
|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -s <i>server-instance</i> | |
| -server <i>server-instance</i> | The server instance name. Specify the directory server instance to process the command against. For some of the listed subcommands the server instance is optional and for other sub |

commands it is a required option.

Examples EXAMPLE 1 Starting All Instances of the Directory Servers

The following command starts all the instances of the directory servers:

```
example% directoryserver start
```

EXAMPLE 2 Starting the Instances of myhost of the Directory Server

The following command starts the instances myhost of the directory server.

```
example% directoryserver -s myhost start
```

EXAMPLE 3 Running the Monitor Tool and Outputting the Current Status

The following command runs the monitor tool and output the current status of the ephesus directory instance.

```
example% directoryserver -s ephesus monitor
```

EXAMPLE 4 Running the idsktune Tool and Outputting Performance Tuning Information

The following command runs the idsktune tool and outputs performance tuning information:

```
example% directoryserver idsktune
```

Exit Status The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

iPlanet Directory Server 5.1 Configuration, Command, and File Reference

Name disks – creates /dev entries for hard disks attached to the system

Synopsis /usr/sbin/disks [-C] [-r *rootdir*]

Description [devfsadm\(1M\)](#) is now the preferred command for /dev and should be used instead of disks.

disks creates symbolic links in the /dev/dsk and /dev/rdisk directories pointing to the actual disk device special files under the /devices directory tree. It performs the following steps:

1. disks searches the kernel device tree to see what hard disks are attached to the system. It notes the /devices pathnames for the slices on the drive and determines the physical component of the corresponding /dev/dsk or /dev/rdisk name.
2. The /dev/dsk and /dev/rdisk directories are checked for disk entries – that is, symbolic links with names of the form `cN[tN]dNsN`, or `cN[tN]dNpN`, where *N* represents a decimal number. *cN* is the logical controller number, an arbitrary number assigned by this program to designate a particular disk controller. The first controller found on the first occasion this program is run on a system, is assigned number 0. *tN* is the bus-address number of a subsidiary controller attached to a peripheral bus such as SCSI or IPI (the target number for SCSI, and the `facility` number for IPI controllers). *dN* is the number of the disk attached to the controller. *sN* is the *slice* number on the disk. *pN* is the FDISK partition number used by [fdisk\(1M\)](#). (x86 Only)
3. If only some of the disk entries are found in /dev/dsk for a disk that has been found under the /devices directory tree, disks creates the missing symbolic links. If none of the entries for a particular disk are found in /dev/dsk, disks checks to see if any entries exist for other disks attached to the same controller, and if so, creates new entries using the same controller number as used for other disks on the same controller. If no other /dev/dsk entries are found for slices of disks belonging to the same physical controller as the current disk, disks assigns the lowest-unused controller number and creates entries for the disk slices using this newly-assigned controller number.

disks is run automatically each time a reconfiguration-boot is performed or when [add_drv\(1M\)](#) is executed. When invoking disks manually, first run [drvconfig\(1M\)](#) to ensure /devices is consistent with the current device configuration.

Notice to Driver Writers disks considers all devices with a node type of DDI_NT_BLOCK, DDI_NT_BLOCK_CHAN, DDI_NT_CD, DDI_NT_BLOCK_WWN or DDI_NT_CD_CHAN to be disk devices. disks requires the minor name of disk devices obey the following format conventions.

The minor name for block interfaces consists of a single lowercase ASCII character, a through u, representing the slices and the primary partitions. The minor name for logical drive block interfaces consists of the strings p5 through p36. The minor name for character (raw) interfaces consists of a single lowercase ASCII character, a through a, followed by the string , raw, representing the slices and the primary partitions. The minor name for logical drive character (raw) interfaces consists of the string p5 through p36 followed by , raw.

disks performs the following translations:

- a through p to s0 through s15
- q through u to p0 through p4
- p5 through p36 to p5 through p36

SPARC drivers should only use the first eight slices: a through h, while x86 drivers can use a through u, with q through u corresponding to `fdisk(1M)` primary partitions. q represents the entire disk, while r, s, t, and u represent up to four additional primary partitions. For logical drives, p5 to p36 correspond to the 32 logical drives that are supported. The device nodes for logical drives change dynamically as and when they are created or deleted.

To prevent disks from attempting to automatically generate links for a device, drivers must specify a private node type and refrain from using a node type: `DDI_NT_BLOCK`, `DDI_NT_BLOCK_CHAN`, `DDI_NT_CD`, or `DDI_NT_CD_CHAN` when calling `ddi_create_minor_node(9F)`.

Options The following options are supported:

- C Causes disks to remove any invalid links after adding any new entries to `/dev/dsk` and `/dev/rdisk`. Invalid links are links which refer to non-existent disk nodes that have been removed, powered off, or are otherwise inaccessible.
- r *rootdir* Causes disks to presume that the `/dev/dsk`, `/dev/rdisk` and `/devices` directory trees are found under *rootdir*, not directly under `/`.

Errors If disks finds entries of a particular logical controller linked to different physical controllers, it prints an error message and exits without making any changes to the `/dev` directory, since it cannot determine which of the two alternative logical-to-physical mappings is correct. The links should be manually corrected or removed before another reconfiguration-boot is performed.

Examples EXAMPLE 1 Creating Block and Character Minor Devices

The following example demonstrates creating the block and character minor devices from within the `xkdisk` driver's `attach(9E)` function.

```
#include <sys/dkio.h>
/*
 * Create the minor number by combining the instance number
 * with the slice number.
 */
#define MINOR_NUM(i, s) ((i) << 4 | (s))

int
xkdiskattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
    int instance, slice;
    char name[8];
```

EXAMPLE 1 Creating Block and Character Minor Devices (Continued)

```

        /* other stuff in attach... */

instance = ddi_get_instance(dip);
for (slice = 0; slice < V_NUMPAR; slice++) {
    /*
     * create block device interface
     */
    sprintf(name, "%c", slice + 'a');
    ddi_create_minor_node(dip, name, S_IFBLK,
        MINOR_NUM(instance, slice), DDI_NT_BLOCK_CHAN, 0);

    /*
     * create the raw (character) device interface
     */
    sprintf(name, "%c,raw", slice + 'a');
    ddi_create_minor_node(dip, name, S_IFCHR,
        MINOR_NUM(instance, slice), DDI_NT_BLOCK_CHAN, 0);
}
}

```

Installing the `xkdisk` disk driver on a Sun Fire 4800, with the driver controlling a SCSI disk (target 3 attached to an `isp(7D)` SCSI HBA) and performing a reconfiguration-boot (causing disks to be run) creates the following special files in `/devices`.

```

# ls -l /devices/ssm@0,0/pci@18,700000/pci@1/SUNW,isp@0,4/
brw-r----- 1 root sys  32, 16 Aug 29 00:02 xkdisk@3,0:a
crw-r----- 1 root sys  32, 16 Aug 29 00:02 xkdisk@3,0:a,raw
brw-r----- 1 root sys  32, 17 Aug 29 00:02 xkdisk@3,0:b
crw-r----- 1 root sys  32, 17 Aug 29 00:02 xkdisk@3,0:b,raw
brw-r----- 1 root sys  32, 18 Aug 29 00:02 xkdisk@3,0:c
crw-r----- 1 root sys  32, 18 Aug 29 00:02 xkdisk@3,0:c,raw
brw-r----- 1 root sys  32, 19 Aug 29 00:02 xkdisk@3,0:d
crw-r----- 1 root sys  32, 19 Aug 29 00:02 xkdisk@3,0:d,raw
brw-r----- 1 root sys  32, 20 Aug 29 00:02 xkdisk@3,0:e
crw-r----- 1 root sys  32, 20 Aug 29 00:02 xkdisk@3,0:e,raw
brw-r----- 1 root sys  32, 21 Aug 29 00:02 xkdisk@3,0:f
crw-r----- 1 root sys  32, 21 Aug 29 00:02 xkdisk@3,0:f,raw
brw-r----- 1 root sys  32, 22 Aug 29 00:02 xkdisk@3,0:g
crw-r----- 1 root sys  32, 22 Aug 29 00:02 xkdisk@3,0:g,raw
brw-r----- 1 root sys  32, 23 Aug 29 00:02 xkdisk@3,0:h
crw-r----- 1 root sys  32, 23 Aug 29 00:02 xkdisk@3,0:h,raw

```

`/dev/dsk` will contain the disk entries to the block device nodes in `/devices`

```

# ls -l /dev/dsk
/dev/dsk/c0t3d0s0 -> ../../devices/[...]/xkdisk@3,0:a

```

EXAMPLE 1 Creating Block and Character Minor Devices *(Continued)*

```

/dev/dsk/c0t3d0s1 -> ../../devices/[...]/xkdisk@3,0:b
/dev/dsk/c0t3d0s2 -> ../../devices/[...]/xkdisk@3,0:c
/dev/dsk/c0t3d0s3 -> ../../devices/[...]/xkdisk@3,0:d
/dev/dsk/c0t3d0s4 -> ../../devices/[...]/xkdisk@3,0:e
/dev/dsk/c0t3d0s5 -> ../../devices/[...]/xkdisk@3,0:f
/dev/dsk/c0t3d0s6 -> ../../devices/[...]/xkdisk@3,0:g
/dev/dsk/c0t3d0s7 -> ../../devices/[...]/xkdisk@3,0:h

```

and `/dev/rdisk` will contain the disk entries for the character device nodes in `/devices`

```

# ls -l /dev/rdisk
/dev/rdisk/c0t3d0s0 -> ../../devices/[...]/xkdisk@3,0:a,raw
/dev/rdisk/c0t3d0s1 -> ../../devices/[...]/xkdisk@3,0:b,raw
/dev/rdisk/c0t3d0s2 -> ../../devices/[...]/xkdisk@3,0:c,raw
/dev/rdisk/c0t3d0s3 -> ../../devices/[...]/xkdisk@3,0:d,raw
/dev/rdisk/c0t3d0s4 -> ../../devices/[...]/xkdisk@3,0:e,raw
/dev/rdisk/c0t3d0s5 -> ../../devices/[...]/xkdisk@3,0:f,raw
/dev/rdisk/c0t3d0s6 -> ../../devices/[...]/xkdisk@3,0:g,raw
/dev/rdisk/c0t3d0s7 -> ../../devices/[...]/xkdisk@3,0:h,raw

```

Files `/dev/dsk/*` Disk entries (block device interface)
`/dev/rdisk/*` Disk entries (character device interface)
`/devices/*` Device special files (minor device nodes)

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| Availability | SUNWcs |

See Also [add_drv\(1M\)](#), [devfsadm\(1M\)](#), [fdisk\(1M\)](#), [attributes\(5\)](#), [isp\(7D\)](#), [devfs\(7FS\)](#), [dkio\(7I\)](#), [attach\(9E\)](#), [ddi_create_minor_node\(9F\)](#)

Writing Device Drivers

Bugs `disks` silently ignores malformed minor device names.

Name diskscan – perform surface analysis

Synopsis diskscan [-W] [-n] [-y] *raw_device*

Description `diskscan` is used by the system administrator to perform surface analysis on a portion of a hard disk. The disk portion may be a raw partition or slice; it is identified using its raw device name. By default, the specified portion of the disk is read (non-destructive) and errors reported on standard error. In addition, a progress report is printed on standard out. The list of bad blocks should be saved in a file and later fed into [addbadsec\(1M\)](#), which will remap them.

Options The following options are supported:

- n Causes `diskscan` to suppress linefeeds when printing progress information on standard out.
- W Causes `diskscan` to perform write and read surface analysis. This type of surface analysis is destructive and should be invoked with caution.
- y Causes `diskscan` to suppress the warning regarding destruction of existing data that is issued when -W is used.

Operands The following operands are supported:

raw_device The address of the disk drive (see FILES).

Files The raw device should be `/dev/rdisk/c?[t?][d?][ps]?`. See [disks\(1M\)](#) for an explanation of SCSI and IDE device naming conventions.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Architecture | x86 |
| Availability | SUNWcs |

See Also [addbadsec\(1M\)](#), [disks\(1M\)](#), [fdisk\(1M\)](#), [fmthard\(1M\)](#), [format\(1M\)](#), [attributes\(5\)](#)

Notes The [format\(1M\)](#) utility is available to format, label, analyze, and repair SCSI disks. This utility is included with the `diskscan`, [addbadsec\(1M\)](#), [fdisk\(1M\)](#), and [fmthard\(1M\)](#) commands available for x86. To format an IDE disk, use the DOS `format` utility; however, to label, analyze, or repair IDE disks on x86 systems, use the Solaris [format\(1M\)](#) utility.

- Name** `dispadmin` – process scheduler administration
- Synopsis** `dispadmin -l`
- ```
dispadmin -c class [-g [-r res] | -s file]
```
- ```
dispadmin -d [class]
```
- Description** The `dispadmin` command displays or changes process scheduler parameters while the system is running.
- `dispadmin` does limited checking on the values supplied in *file* to verify that they are within their required bounds. The checking, however, does not attempt to analyze the effect that the new values have on the performance of the system. Inappropriate values can have a negative effect on system performance. (See *System Administration Guide: Advanced Administration*.)
- Options** The following options are supported:
- c *class***
Specifies the class whose parameters are to be displayed or changed. Valid *class* values are: RT for the real-time class, TS for the time-sharing class, IA for the inter-active class, FSS for the fair-share class, and FX for the fixed-priority class. The time-sharing and inter-active classes share the same scheduler, so changes to the scheduling parameters of one will change those of the other.
 - d [*class*]**
Sets or displays the name of the default scheduling class to be used on reboot when starting `svc:/system/scheduler:default`. If class name is not specified, the name and description of the current default scheduling class is displayed. If class name is specified and is a valid scheduling class name, then it is saved in `dispadmin`'s private configuration file `/etc/dispadmin.conf`. Only super-users can set the default scheduling class.
 - g**
Gets the parameters for the specified class and writes them to the standard output. Parameters for the real-time class are described in [rt_dptbl\(4\)](#). Parameters for the time-sharing and inter-active classes are described in [ts_dptbl\(4\)](#). Parameters for the fair-share class are described in [FSS\(7\)](#). Parameters for the fixed-priority class are described in [fx_dptbl\(4\)](#).

The `-g` and `-s` options are mutually exclusive: you may not retrieve the table at the same time you are overwriting it.
 - l**
Lists the scheduler classes currently configured in the system.
 - r *res***
When using the `-g` option you may also use the `-r` option to specify a resolution to be used for outputting the time quantum values. If no resolution is specified, time quantum values are in milliseconds. If *res* is specified it must be a positive integer between 1 and 1000000000 inclusive, and the resolution used is the reciprocal of *res* in seconds. For

example, a *res* value of 10 yields time quantum values expressed in tenths of a second; a *res* value of 1000000 yields time quantum values expressed in microseconds. If the time quantum cannot be expressed as an integer in the specified resolution, it is rounded up to the next integral multiple of the specified resolution.

-s *file*

Sets scheduler parameters for the specified class using the values in *file*. These values overwrite the current values in memory—they become the parameters that control scheduling of processes in the specified class. The values in *file* must be in the format output by the *-g* option. Moreover, the values must describe a table that is the same size (has same number of priority levels) as the table being overwritten. Super-user privileges are required in order to use the *-s* option.

Specify time quantum values for scheduling classes in system clock ticks, and not in constant-time units. Time quantum values are based on the value of the kernel's *hz* variable. If kernel variable *hires_tick* is set to 1 to get higher resolution clock behavior, the actual time quanta will be reduced by the order of 10.

The *-g* and *-s* options are mutually exclusive: you may not retrieve the table at the same time you are overwriting it.

Examples EXAMPLE 1 Retrieving the Current Scheduler Parameters for the real-time class

The following command retrieves the current scheduler parameters for the real-time class from kernel memory and writes them to the standard output. Time quantum values are in microseconds.

```
dispadmin -c RT -g -r 1000000
```

EXAMPLE 2 Overwriting the Current Scheduler Parameters for the Real-time Class

The following command overwrites the current scheduler parameters for the real-time class with the values specified in *rt.config*.

```
dispadmin -c RT -s rt.config
```

EXAMPLE 3 Retrieving the Current Scheduler Parameters for the Time-sharing Class

The following command retrieves the current scheduler parameters for the time-sharing class from kernel memory and writes them to the standard output. Time quantum values are in nanoseconds.

```
dispadmin -c TS -g -r 1000000000
```

EXAMPLE 4 Overwriting the Current Scheduler Parameters for the Time-sharing Class

The following command overwrites the current scheduler parameters for the time-sharing class with the values specified in *ts.config*.

```
dispadmin -c TS -s ts.config
```

Files /etc/dispadmin.conf
Possible location for argument to -s option.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [prioctl\(1\)](#), [svcs\(1\)](#), [svcadm\(1M\)](#), [prioctl\(2\)](#), [fx_dptbl\(4\)](#), [rt_dptbl\(4\)](#), [ts_dptbl\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#), [FSS\(7\)](#)

System Administration Guide: Basic Administration Programming Interfaces Guide

Diagnostics dispadmin prints an appropriate diagnostic message if it fails to overwrite the current scheduler parameters due to lack of required permissions or a problem with the specified input file.

Notes The default scheduling class setting facility is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/scheduler:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). Note that disabling the service while it is running will not change anything. The service's status can be queried using the [svcs\(1\)](#) command.

dladm show-usage [-a] -f filename [-p plotfile -F format] [-s time]
    [-e time] [link]

```

Description The `dladm` command is used to administer data-links. A data-link is represented in the system as a STREAMS DLPI (v2) interface which can be plumbed under protocol stacks such as TCP/IP. Each data-link relies on either a single network device or an aggregation of devices to send packets to or receive packets from a network.

Each `dladm` subcommand operates on one of the following objects:

link

A datalink, identified by a name. In general, the name can use any alphanumeric characters (or the underscore, `_`), but must start with an alphabetic character and end with a number. A datalink name can be at most 31 characters, and the ending number must be between 0 and 4294967294 (inclusive). The ending number must not begin with a zero. Datalink names between 3 and 8 characters are recommended.

Some subcommands operate only on certain types or classes of datalinks. For those cases, the following object names are used:

aggr-link

An aggregation datalink (or a key; see NOTES).

ether-link

A physical Ethernet datalink.

iptun-link

An IP tunnel link.

part-link

An InfiniBand (IB) partition data link.

phys-link

A physical datalink.

vlan-link

A VLAN datalink.

vnic-link

A virtual network interface created on a link or an etherstub. It is a pseudo device that can be treated as if it were an network interface card on a machine.

wifi-link

A WiFi datalink.

bridge

A bridge instance, identified by an administratively-chosen name. The name may use any alphanumeric characters or the underscore, `_`, but must start and end with an alphabetic character. A bridge name can be at most 31 characters. The name `default` is reserved, as are all names starting with `SUNW`.

Note that appending a zero (0) to a bridge name produces a valid link name, used for observability.

dev

A network device, identified by concatenation of a driver name and an instance number.

etherstub

An Ethernet stub can be used instead of a physical NIC to create VNICs. VNICs created on an etherstub will appear to be connected through a virtual switch, allowing complete virtual networks to be built without physical hardware.

part

An IB partition link created on a IB physical link.

secobj

A secure object, identified by an administratively-chosen name. The name can use any alphanumeric characters, as well as underscore (`_`), period (`.`), and hyphen (`-`). A secure object name can be at most 32 characters.

Options Each `dladm` subcommand has its own set of options. However, many of the subcommands have the following as a common option:

`-R root-dir, --root-dir=root-dir`

Specifies an alternate root directory where the operation—such as creation, deletion, or renaming—should apply.

SUBCOMMANDS The following subcommands are supported:

`dladm show-link [-P] [-s [-i interval]] [[-p] -o field[,...]][link]`

Show link configuration information either for all datalinks or for the specified link. By default, the system is configured with one datalink for each known network device. The option to print link statistics is moved to `dlstat(1M)`.

`-o field[,...], --output=field[,...]`

A case-insensitive, comma-separated list of output fields to display. When not modified by the `-s` option (described below), the field name must be one of the fields listed below, or the special value `all` to display all fields. By default (without `-o`), `show-link` displays all fields.

LINK

The name of the datalink.

CLASS

The class of the datalink. `dladm` distinguishes between the following classes:

aggr

An IEEE 802.3ad link aggregation. The `show-aggr` subcommand displays more detail for this class of datalink.

part

An IP-over-IB interface. The `show-part` subcommand displays more detail for this class of datalink.

phys

A physical datalink. The `show-phys` subcommand displays more detail for this class of datalink.

vlan

A VLAN datalink. The `show-vlan` subcommand displays more detail for this class of datalink.

vnic

A virtual network interface. The `show-vnic` subcommand displays more detail for this class of datalink.

MTU

The maximum transmission unit size for the datalink being displayed.

STATE

The link state of the datalink. The state can be up, down, or unknown.

BRIDGE

The name of the bridge to which this link is assigned, if any.

OVER

The physical datalink(s) over which the datalink is operating. This applies to `aggr`, `bridge`, and `vlan` and `part` partition classes of datalinks. A VLAN or IB partition is

created over a single physical datalink, a bridge has multiple attached links, and an aggregation is comprised of one or more physical datalinks.

When the `-o` option is used in conjunction with the `-s` option, used to display link statistics, the field name must be one of the fields listed below, or the special value `all` to display all fields

LINK

The name of the datalink.

IPACKETS

Number of packets received on this link.

RBYTES

Number of bytes received on this link.

IERRORS

Number of input errors.

OPACKETS

Number of packets sent on this link.

OBYTES

Number of bytes received on this link.

OERRORS

Number of output errors.

-p, --parseable

Display using a stable machine-parseable format. The `-o` option is required with `-p`. See “Parseable Output Format”, below.

-P, --persistent

Display the persistent link configuration.

-s, --statistics

Display link statistics. This option is made obsolete by `dlstat(1M)`.

-i *interval*, --interval=*interval*

Used with the `-s` option to specify an interval, in seconds, at which statistics should be displayed. This option is made obsolete by `dlstat(1M)`.

dladm rename-link [-R *root-dir*] *link new-link*

Rename *link* to *new-link*. This is used to give a link a meaningful name, or to associate existing link configuration such as link properties of a removed device with a new device. See the EXAMPLES section for specific examples of how this subcommand is used.

-R *root-dir*, --root-dir=*root-dir*

See “Options,” above.

dladm delete-phys *phys-link*

This command is used to delete the persistent configuration of a link associated with physical hardware which has been removed from the system. See the EXAMPLES section.

dladm show-phys [-P] [-m] [[-p] -o *field*[,...]] [-H] [*phys-link*]

Show the physical device and attributes of all physical links, or of the named physical link. Without -P, only physical links that are available on the running system are displayed.

-H

Show hardware resource usage, as returned by the NIC driver. Output from -H displays the following elements:

LINK

A physical device corresponding to a NIC driver.

RINGTYPE

The type of the ring, either RX or TX.

RINGS

The ring index. A ring is an hardware resource, which typically maps to a DMA channel, that can be programmed for specific use. For example, an RX ring can be programmed to receive only packets belonging to a specific MAC address.

CLIENTS

MAC clients that are using the rings.

-m

Display the list of factory MAC addresses, their slot identifiers, and their availability.

-o *field*, --output=*field*

A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value `all`, to display all fields. For each link, the following fields can be displayed:

LINK

The name of the datalink.

MEDIA

The media type provided by the physical datalink.

STATE

The state of the link. This can be up, down, or unknown.

SPEED

The current speed of the link, in megabits per second.

DUPLEX

For Ethernet links, the full/half duplex status of the link is displayed if the link state is up. The duplex is displayed as unknown in all other cases.

DEVICE

The name of the physical device under this link.

-p, --parseable

Display using a stable machine-parseable format. The **-o** option is required with **-p**. See “Parseable Output Format”, below.

-P, --persistent

This option displays persistent configuration for all links, including those that have been removed from the system. The output provides a **FLAGS** column in which the **r** flag indicates that the physical device associated with a physical link has been removed. For such links, **delete-phys** can be used to purge the link's configuration from the system.

`dladm create-aggr [-t] [-R root-dir] [-P policy] [-L mode] [-T time] [-u address] -l ether-link1 [-l ether-link2...] aggr-link`

Combine a set of links into a single IEEE 802.3ad link aggregation named *aggr-link*. The use of an integer *key* to generate a link name for the aggregation is also supported for backward compatibility. Many of the ***-aggr** subcommands below also support the use of a *key* to refer to a given aggregation, but use of the aggregation link name is preferred. See the **NOTES** section for more information on keys.

`dladm` supports a number of port selection policies for an aggregation of ports. (See the description of the **-P** option, below.) If you do not specify a policy, `create-aggr` uses the default, the **L4** policy, described under the **-P** option.

-l *ether-link*, --link=*ether-link*

Each Ethernet link (or port) in the aggregation is specified using an **-l** option followed by the name of the link to be included in the aggregation. Multiple links are included in the aggregation by specifying multiple **-l** options. For backward compatibility with previous versions of Solaris, the `dladm` command also supports the using the **-d** option (or **--dev**) with a device name to specify links by their underlying device name. The other ***-aggr** subcommands that take **-l** options also accept **-d**.

-t, --temporary

Specifies that the aggregation is temporary. Temporary aggregations last until the next reboot.

-R *root-dir*, --root-dir=*root-dir*

See “Options,” above.

-P *policy*, --policy=*policy*

Specifies the port selection policy to use for load spreading of outbound traffic. The policy specifies which *dev* object is used to send packets. A policy is a list of one or more layers specifiers separated by commas. A layer specifier is one of the following:

L2

Select outbound device according to source and destination MAC addresses of the packet.

L3

Select outbound device according to source and destination IP addresses of the packet.

L4

Select outbound device according to the upper layer protocol information contained in the packet. For TCP and UDP, this includes source and destination ports. For IPsec, this includes the SPI (Security Parameters Index).

For example, to use upper layer protocol information, the following policy can be used:

```
-P L4
```

Note that policy *L4* is the default.

To use the source and destination MAC addresses as well as the source and destination IP addresses, the following policy can be used:

```
-P L2,L3
```

```
-L mode, --lACP-mode=mode
```

Specifies whether LACP should be used and, if used, the mode in which it should operate. Supported values are *off*, *active* or *passive*.

```
-T time, --lACP-timer=time
```

Specifies the LACP timer value. The supported values are *short* or *long*.

```
-u address, --unicast=address
```

Specifies a fixed unicast hardware address to be used for the aggregation. If this option is not specified, then an address is automatically chosen from the set of addresses of the component devices.

```
dladm modify-aggr [-t] [-R root-dir] [-P policy] [-L mode] [-T time] [-u address] aggr-link
```

Modify the parameters of the specified aggregation.

```
-t, --temporary
```

Specifies that the modification is temporary. Temporary aggregations last until the next reboot.

```
-R root-dir, --root-dir=root-dir
```

See “Options,” above.

```
-P policy, --policy=policy
```

Specifies the port selection policy to use for load spreading of outbound traffic. See `dladm create-aggr` for a description of valid policy values.

```
-L mode, --lACP-mode=mode
```

Specifies whether LACP should be used and, if used, the mode in which it should operate. Supported values are *off*, *active*, or *passive*.

```
-T time, --lACP-timer=time
```

Specifies the LACP timer value. The supported values are *short* or *long*.

```
-u address, --unicast=address
```

Specifies a fixed unicast hardware address to be used for the aggregation. If this option is not specified, then an address is automatically chosen from the set of addresses of the

component devices.

`dladm delete-aggr [-t] [-R root-dir] aggr-link`

Deletes the specified aggregation.

`-t, --temporary`

Specifies that the deletion is temporary. Temporary deletions last until the next reboot.

`-R root-dir, --root-dir=root-dir`

See “Options,” above.

`dladm add-aggr [-t] [-R root-dir] -l ether-link1 [--link=ether-link2...] aggr-link`

Adds links to the specified aggregation.

`-l ether-link, --link=ether-link`

Specifies an Ethernet link to add to the aggregation. Multiple links can be added by supplying multiple `-l` options.

`-t, --temporary`

Specifies that the additions are temporary. Temporary additions last until the next reboot.

`-R root-dir, --root-dir=root-dir`

See “Options,” above.

`dladm remove-aggr [-t] [-R root-dir] -l ether-link1 [--link=ether-link2...] aggr-link`

Removes links from the specified aggregation.

`-l ether-link, --link=ether-link`

Specifies an Ethernet link to remove from the aggregation. Multiple links can be added by supplying multiple `-l` options.

`-t, --temporary`

Specifies that the removals are temporary. Temporary removal last until the next reboot.

`-R root-dir, --root-dir=root-dir`

See “Options,” above.

`dladm show-aggr [-PLx] [-s [-i interval]] [[-p] -o field[,...]] [aggr-link]`

Show aggregation configuration (the default) or LACP information either for all aggregations or for the specified aggregation.

By default (with no options), the following fields can be displayed:

LINK

The name of the aggregation link.

POLICY

The LACP policy of the aggregation. See the `create-aggr -P` option for a description of the possible values.

ADDRPOLICY

Either `auto`, if the aggregation is configured to automatically configure its unicast MAC address (the default if the `-u` option was not used to create or modify the aggregation), or `fixed`, if `-u` was used to set a fixed MAC address.

LACPACTIVITY

The LACP mode of the aggregation. Possible values are `off`, `active`, or `passive`, as set by the `-l` option to `create-aggr` or `modify-aggr`.

LACPTIMER

The LACP timer value of the aggregation as set by the `-T` option of `create-aggr` or `modify-aggr`.

FLAGS

A set of state flags associated with the aggregation. The only possible flag is `f`, which is displayed if the administrator forced the creation the aggregation using the `-f` option to `create-aggr`. Other flags might be defined in the future.

The `show-aggr` command accepts the following options:

-L, --lACP

Displays detailed LACP information for the aggregation link and each underlying port. Most of the state information displayed by this option is defined by IEEE 802.3. With this option, the following fields can be displayed:

LINK

The name of the aggregation link.

PORT

The name of one of the underlying aggregation ports.

AGGREGATABLE

Whether the port can be added to the aggregation.

SYNC

If yes, the system considers the port to be synchronized and part of the aggregation.

COLL

If yes, collection of incoming frames is enabled on the associated port.

DIST

If yes, distribution of outgoing frames is enabled on the associated port.

DEFAULTED

If yes, the port is using defaulted partner information (that is, has not received LACP data from the LACP partner).

EXPIRED

If yes, the receive state of the port is in the EXPIRED state.

-x, --extended

Display additional aggregation information including detailed information on each underlying port. With -x, the following fields can be displayed:

LINK

The name of the aggregation link.

PORT

The name of one of the underlying aggregation ports.

SPEED

The speed of the link or port in megabits per second.

DUPLEX

The full/half duplex status of the link or port is displayed if the link state is up. The duplex status is displayed as unknown in all other cases.

STATE

The link state. This can be up, down, or unknown.

ADDRESS

The MAC address of the link or port.

PORTSTATE

This indicates whether the individual aggregation port is in the standby or attached state.

-o *field*[,...], --output=*field*[,...]

A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed above, or the special value `all`, to display all fields. The fields applicable to the -o option are limited to those listed under each output mode. For example, if using -L, only the fields listed under -L, above, can be used with -o.

-p, --parseable

Display using a stable machine-parseable format. The -o option is required with -p. See “Parseable Output Format”, below.

-P, --persistent

Display the persistent aggregation configuration rather than the state of the running system.

-s, --statistics

Displays aggregation statistics. This option is made obsolete by [dlstat\(1M\)](#).

-i *interval*, --interval=*interval*

Used with the -s option to specify an interval, in seconds, at which statistics should be displayed. This option is made obsolete by [dlstat\(1M\)](#).

```
dladm create-bridge [ -P protect] [ -R root-dir] [ -p priority] [ -m max-age] [ -h hello-time] [
-d forward-delay] [ -f force-protocol] [ -l link...] bridge-name
```

Create an 802.1D bridge instance and optionally assign one or more network links to the new bridge. By default, no bridge instances are present on the system.

In order to bridge between links, you must create at least one bridge instance. Each bridge instance is separate, and there is no forwarding connection between bridges.

-P protect, *--protect=protect*

Specifies a protection method. The defined protection methods are *stp* for the Spanning Tree Protocol and *trill* for TRILL, which is used on Rbridges. The default value is *stp*.

-R root-dir, *--root-dir=root-dir*

See “Options,” above.

-p priority, *--priority=priority*

Specifies the Bridge Priority. This sets the IEEE STP priority value for determining the root bridge node in the network. The default value is 32768. Valid values are 0 (highest priority) to 61440 (lowest priority), in increments of 4096.

If a value not evenly divisible by 4096 is used, the system silently rounds downward to the next lower value that is divisible by 4096.

-m max-age, *--max-age=max-age*

Specifies the maximum age for configuration information in seconds. This sets the STP Bridge Max Age parameter. This value is used for all nodes in the network if this node is the root bridge. Bridge link information older than this time is discarded. It defaults to 20 seconds. Valid values are from 6 to 40 seconds. See the *-d forward-delay* parameter for additional constraints.

-h hello-time, *--hello-time=hello-time*

Specifies the STP Bridge Hello Time parameter. When this node is the root node, it sends Configuration BPDUs at this interval throughout the network. The default value is 2 seconds. Valid values are from 1 to 10 seconds. See the *-d forward-delay* parameter for additional constraints.

-d forward-delay, *--forward-delay=forward-delay*

Specifies the STP Bridge Forward Delay parameter. When this node is the root node, then all bridges in the network use this timer to sequence the link states when a port is enabled. The default value is 15 seconds. Valid values are from 4 to 30 seconds.

Bridges must obey the following two constraints:

$$2 * (\textit{forward-delay} - 1.0) \geq \textit{max-age}$$

$$\textit{max-age} \geq 2 * (\textit{hello-time} + 1.0)$$

Any parameter setting that would violate those constraints is treated as an error and causes the command to fail with a diagnostic message. The message provides valid alternatives to the supplied values.

`-f force-protocol, --force-protocol=force-protocol`

Specifies the MSTP forced maximum supported protocol. The default value is 3. Valid values are non-negative integers. The current implementation does not support RSTP or MSTP, so this currently has no effect. However, to prevent MSTP from being used in the future, the parameter may be set to 0 for STP only or 2 for STP and RSTP.

`-l link, --link=link`

Specifies one or more links to add to the newly-created bridge. This is similar to creating the bridge and then adding one or more links, as with the `add-bridge` subcommand. However, if any of the links cannot be added, the entire command fails, and the new bridge itself is not created. To add multiple links on the same command line, repeat this option for each link. You are permitted to create bridges without links. For more information about link assignments, see the `add-bridge` subcommand.

Bridge creation and link assignment require the `PRIV_SYS_DL_CONFIG` privilege. Bridge creation might fail if the optional bridging feature is not installed on the system.

```
dladm modify-bridge [ -P protect ] [ -R root-dir ] [ -p priority ] [ -m max-age ] [ -h hello-time ] [
-d forward-delay ] [ -f force-protocol ] [ -l link... ] bridge-name
```

Modify the operational parameters of an existing bridge. The options are the same as for the `create-bridge` subcommand, except that the `-l` option is not permitted. To add links to an existing bridge, use the `add-bridge` subcommand.

Bridge parameter modification requires the `PRIV_SYS_DL_CONFIG` privilege.

```
dladm delete-bridge [ -R root-dir ] bridge-name
```

Delete a bridge instance. The bridge being deleted must not have any attached links. Use the `remove-bridge` subcommand to deactivate links before deleting a bridge.

Bridge deletion requires the `PRIV_SYS_DL_CONFIG` privilege.

The `-R (- - root-dir)` option is the same as for the `create-bridge` subcommand.

```
dladm add-bridge [ -R root-dir ] -l link [ -l link... ] bridge-name
```

Add one or more links to an existing bridge. If multiple links are specified, and adding any one of them results in an error, the command fails and no changes are made to the system.

Link addition to a bridge requires the `PRIV_SYS_DL_CONFIG` privilege.

A link may be a member of at most one bridge. An error occurs when you attempt to add a link that already belongs to another bridge. To move a link from one bridge instance to another, remove it from the current bridge before adding it to a new one.

The links assigned to a bridge must not also be VLANs, VNICs, or tunnels. Only physical Ethernet datalinks, aggregation datalinks, and Ethernet stubs are permitted to be assigned to a bridge.

Links assigned to a bridge must all have the same MTU. This is checked when the link is assigned. The link is added to the bridge in a deactivated form if it is not the first link on the bridge and it has a differing MTU.

Note that systems using bridging should not set the `eeprom(1M) local-mac-address?` variable to false.

The options are the same as for the `create-bridge` subcommand.

```
dladm remove-bridge [-R root-dir] -l link [-l link...] bridge-name
```

Remove one or more links from a bridge instance. If multiple links are specified, and removing any one of them would result in an error, the command fails and none are removed.

Link removal from a bridge requires the `PRIV_SYS_DL_CONFIG` privilege.

The options are the same as for the `create-bridge` subcommand.

```
dladm show-bridge [-flt] [-s [-i interval]] [[-p] -o field...] [bridge-name]
```

Show the running status and configuration of bridges, their attached links, learned forwarding entries, and TRILL nickname databases. When showing overall bridge status and configuration, the bridge name can be omitted to show all bridges. The other forms require a specified bridge.

The `show-bridge` subcommand accepts the following options:

`-i interval`, `--interval=interval`

Used with the `-s` option to specify an interval, in seconds, at which statistics should be displayed. If this option is not specified, statistics will be displayed only once.

`-s`, `--statistics`

Display statistics for the specified bridges or for a given bridge's attached links. This option cannot be used with the `-f` and `-t` options.

`-p`, `--parseable`

Display using a stable machine-parsable format. See “Parsable Output Format,” below.

`-o field[,...]`, `--output=field[,...]`

A case-insensitive, comma-separated list of output fields to display. The field names are described below. The special value `all` displays all fields. Each set of fields has its own default set to display when `-o` is not specified.

By default, the `show-bridge` subcommand shows bridge configuration. The following fields can be shown:

BRIDGE

The name of the bridge.

ADDRESS

The Bridge Unique Identifier value (MAC address).

PRIORITY

Configured priority value; set by `-p` with `create-bridge` and `modify-bridge`.

BMAXAGE

Configured bridge maximum age; set by `-m` with `create-bridge` and `modify-bridge`.

BHELLOTIME

Configured bridge hello time; set by `-h` with `create-bridge` and `modify-bridge`.

BFWDDELAY

Configured forwarding delay; set by `-d` with `create-bridge` and `modify-bridge`.

FORCEPROTO

Configured forced maximum protocol; set by `-f` with `create-bridge` and `modify-bridge`.

TCTIME

Time, in seconds, since last topology change.

TCCOUNT

Count of the number of topology changes.

TCHANGE

This indicates that a topology change was detected.

DESROOT

Bridge Identifier of the root node.

ROOTCOST

Cost of the path to the root node.

ROOTPORT

Port number used to reach the root node.

MAXAGE

Maximum age value from the root node.

HELLOTIME

Hello time value from the root node.

FWDDelay

Forward delay value from the root node.

HOLDTIME

Minimum BPDU interval.

By default, when the `-o` option is not specified, only the `BRIDGE`, `ADDRESS`, `PRIORITY`, and `DESROOT` fields are shown.

When the `-s` option is specified, the `show-bridge` subcommand shows bridge statistics. The following fields can be shown:

BRIDGE

Bridge name.

DROPS

Number of packets dropped due to resource problems.

FORWARDS

Number of packets forwarded from one link to another.

MBCAST

Number of multicast and broadcast packets handled by the bridge.

RECV

Number of packets received on all attached links.

SENT

Number of packets sent on all attached links.

UNKNOWN

Number of packets handled that have an unknown destination. Such packets are sent to all links.

By default, when the `-o` option is not specified, only the **BRIDGE**, **DROPS**, and **FORWARDS** fields are shown.

The `show-bridge` subcommand also accepts the following options:

-l, --link

Displays link-related status and statistics information for all links attached to a single bridge instance. By using this option and without the `-s` option, the following fields can be displayed for each link:

LINK

The link name.

INDEX

Port (link) index number on the bridge.

STATE

State of the link. The state can be disabled, discarding, learning, forwarding, non-stp, or bad-mtu.

UPTIME

Number of seconds since the last reset or initialization.

OPERCOST

Actual cost in use (1-65535).

OPERP2P

This indicates whether point-to-point (P2P) mode been detected.

OPEREDGE

This indicates whether edge mode has been detected.

DESRROOT

The Root Bridge Identifier that has been seen on this port.

DESCOST

Path cost to the network root node through the designated port.

DESBRIDGE

Bridge Identifier for this port.

DESPORT

The ID and priority of the port used to transmit configuration messages for this port.

TCACK

This indicates whether Topology Change Acknowledge has been seen.

When the `-l` option is specified without the `-o` option, only the **LINK**, **STATE**, **UPTIME**, and **DESRROOT** fields are shown.

When the `-l` option is specified, the `-s` option can be used to display the following fields for each link:

LINK

Link name.

CFGBPDU

Number of configuration BPDUs received.

TCNBPDU

Number of topology change BPDUs received.

RSTPBPDU

Number of Rapid Spanning Tree BPDUs received.

TXBPDU

Number of BPDUs transmitted.

DROPS

Number of packets dropped due to resource problems.

RECV

Number of packets received by the bridge.

XMIT

Number of packets sent by the bridge.

When the `-o` option is not specified, only the **LINK**, **DROPS**, **RECV**, and **XMIT** fields are shown.

-f, --forwarding

Displays forwarding entries for a single bridge instance. With this option, the following fields can be shown for each forwarding entry:

DEST

Destination MAC address.

AGE

Age of entry in seconds and milliseconds. Omitted for local entries.

FLAGS

The L (local) flag is shown if the MAC address belongs to an attached link or to a VNIC on one of the attached links.

OUTPUT

For local entries, this is the name of the attached link that has the MAC address. Otherwise, for bridges that use Spanning Tree Protocol, this is the output interface name. For R Bridges, this is the output TRILL nickname.

When the **-o** option is not specified, the **DEST**, **AGE**, **FLAGS**, and **OUTPUT** fields are shown.

-t, --trill

Displays TRILL nickname entries for a single bridge instance. With this option, the following fields can be shown for each TRILL nickname entry:

NICK

TRILL nickname for this R Bridge, which is a number from 1 to 65535.

FLAGS

The L flag is shown if the nickname identifies the local system.

LINK

Link name for output when sending messages to this R Bridge.

NEXTHOP

MAC address of the next hop R Bridge that is used to reach the R Bridge with this nickname.

When the **-o** option is not specified, the **NICK**, **FLAGS**, **LINK**, and **NEXTHOP** fields are shown.

```
dladm create-vlan [-ft] [-R root-dir] -l ether-link -v vid [vlan-link]
```

Create a tagged VLAN link with an ID of *vid* over Ethernet link *ether-link*. The name of the VLAN link can be specified as *vlan-link*. If the name is not specified, a name will be automatically generated (assuming that *ether-link* is *namePPA*) as:

```
<name><1000 * vlan-tag + PPA>
```

For example, if *ether-link* is *bge1* and *vid* is 2, the name generated is *bge2001*.

-f, --force

Force the creation of the VLAN link. Some devices do not allow frame sizes large enough to include a VLAN header. When creating a VLAN link over such a device, the -f option is needed, and the MTU of the IP interfaces on the resulting VLAN must be set to 1496 instead of 1500.

-l *ether-link*

Specifies Ethernet link over which VLAN is created.

-t, --temporary

Specifies that the VLAN link is temporary. Temporary VLAN links last until the next reboot.

-R *root-dir*, --root-dir=*root-dir*

See “Options,” above.

`dladm delete-vlan [-t] [-R root-dir] vlan-link`

Delete the VLAN link specified.

The `delete-vlan` subcommand accepts the following options:

-t, --temporary

Specifies that the deletion is temporary. Temporary deletions last until the next reboot.

-R *root-dir*, --root-dir=*root-dir*

See “Options,” above.

`dladm show-vlan [-P] [[-p] -o field[,...]] [vlan-link]`

Display VLAN configuration for all VLAN links or for the specified VLAN link.

The `show-vlan` subcommand accepts the following options:

-o *field*[,...], --output=*field*[,...]

A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value `all`, to display all fields. For each VLAN link, the following fields can be displayed:

LINK

The name of the VLAN link.

VID

The ID associated with the VLAN.

OVER

The name of the physical link over which this VLAN is configured.

FLAGS

A set of flags associated with the VLAN link. Possible flags are:

f

The VLAN was created using the -f option to `create-vlan`.

i

The VLAN was implicitly created when the DLPI link was opened. These VLAN links are automatically deleted on last close of the DLPI link (for example, when the IP interface associated with the VLAN link is unplumbed).

Additional flags might be defined in the future.

-p, --parseable

Display using a stable machine-parseable format. The **-o** option is required with **-p**. See “Parseable Output Format”, below.

-P, --persistent

Display the persistent VLAN configuration rather than the state of the running system.

`dladm scan-wifi [[-p] -o field[,...]] [wifi-link]`

Scans for WiFi networks, either on all WiFi links, or just on the specified *wifi-link*.

By default, currently all fields but BSSTYPE are displayed.

-o field[,...], --output=field[,...]

A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value `all` to display all fields. For each WiFi network found, the following fields can be displayed:

LINK

The name of the link the WiFi network is on.

ESSID

The ESSID (name) of the WiFi network.

BSSID

Either the hardware address of the WiFi network's Access Point (for BSS networks), or the WiFi network's randomly generated unique token (for IBSS networks).

SEC

Either `none` for a WiFi network that uses no security, `wep` for a WiFi network that requires WEP (Wired Equivalent Privacy), or `wpa` for a WiFi network that requires WPA (Wi-Fi Protected Access).

MODE

The supported connection modes: one or more of `a`, `b`, `g`, or `n`.

STRENGTH

The strength of the signal: one of `excellent`, `very good`, `good`, `weak`, or `very weak`.

SPEED

The maximum speed of the WiFi network, in megabits per second.

BSSTYPE

Either `bss` for BSS (infrastructure) networks, or `ibss` for IBSS (ad-hoc) networks.

-p, --parseable

Display using a stable machine-parseable format. The -o option is required with -p. See “Parseable Output Format”, below.

```
dladm connect-wifi [-e ssid] [-i bssid] [-k key,...] [-s none|wep|wpa] [-a open|shared]
[-b bss|ibss] [-c] [-m a|b|g|n] [-T time] [wifi-link]
```

Connects to a WiFi network. This consists of four steps: *discovery*, *filtration*, *prioritization*, and *association*. However, to enable connections to non-broadcast WiFi networks and to improve performance, if a BSSID or ESSID is specified using the -e or -i options, then the first three steps are skipped and connect-wifi immediately attempts to associate with a BSSID or ESSID that matches the rest of the provided parameters. If this association fails, but there is a possibility that other networks matching the specified criteria exist, then the traditional discovery process begins as specified below.

The discovery step finds all available WiFi networks on the specified WiFi link, which must not yet be connected. For administrative convenience, if there is only one WiFi link on the system, *wifi-link* can be omitted.

Once discovery is complete, the list of networks is filtered according to the value of the following options:

-e *ssid*, --ssid=*ssid*

Networks that do not have the same *ssid* are filtered out.

-b *bss|ibss*, --bss=*bss|ibss*

Networks that do not have the same *bss* type are filtered out.

-m *a|b|g*, --mode=*a|b|g|n*

Networks not appropriate for the specified 802.11 mode are filtered out.

-k *key*,..., --key=*key*, ...

Use the specified *secobj* named by the *key* to connect to the network. Networks not appropriate for the specified *keys* are filtered out.

-s none|wep|wpa, --sec=*none|wep|wpa*

Networks not appropriate for the specified security mode are filtered out.

Next, the remaining networks are prioritized, first by signal strength, and then by maximum speed. Finally, an attempt is made to associate with each network in the list, in order, until one succeeds or no networks remain.

In addition to the options described above, the following options also control the behavior of connect-wifi:

-a open|shared, --auth=*open|shared*

Connect using the specified authentication mode. By default, open and shared are tried in order.

`-c, --create-ibss`

Used with `-b ibss` to create a new ad-hoc network if one matching the specified ESSID cannot be found. If no ESSID is specified, then `-c -b ibss` always triggers the creation of a new ad-hoc network.

`-T time, --timeout=time`

Specifies the number of seconds to wait for association to succeed. If *time* is forever, then the associate will wait indefinitely. The current default is ten seconds, but this might change in the future. Timeouts shorter than the default might not succeed reliably.

`-k key,..., --key=key,...`

In addition to the filtering previously described, the specified keys will be used to secure the association. The security mode to use will be based on the key class; if a security mode was explicitly specified, it must be compatible with the key class. All keys must be of the same class.

For security modes that support multiple key slots, the slot to place the key will be specified by a colon followed by an index. Therefore, `-k mykey:3` places *mykey* in slot 3. By default, slot 1 is assumed. For security modes that support multiple keys, a comma-separated list can be specified, with the first key being the active key.

`dladm disconnect-wifi [-a] [wifi-link]`

Disconnect from one or more WiFi networks. If *wifi-link* specifies a connected WiFi link, then it is disconnected. For administrative convenience, if only one WiFi link is connected, *wifi-link* can be omitted.

`-a, --all-links`

Disconnects from all connected links. This is primarily intended for use by scripts.

`dladm show-wifi [[-p] -o field,...] [wifi-link]`

Shows WiFi configuration information either for all WiFi links or for the specified link *wifi-link*.

`-o field,..., --output=field`

A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value `all`, to display all fields. For each WiFi link, the following fields can be displayed:

LINK

The name of the link being displayed.

STATUS

Either `connected` if the link is connected, or `disconnected` if it is not connected. If the link is disconnected, all remaining fields have the value `--`.

ESSID

The ESSID (name) of the connected WiFi network.

BSSID

Either the hardware address of the WiFi network's Access Point (for BSS networks), or the WiFi network's randomly generated unique token (for IBSS networks).

SEC

Either none for a WiFi network that uses no security, `wep` for a WiFi network that requires WEP, or `wpa` for a WiFi network that requires WPA.

MODE

The supported connection modes: one or more of `a`, `b`, `g`, or `n`.

STRENGTH

The connection strength: one of `excellent`, `very good`, `good`, `weak`, or `very weak`.

SPEED

The connection speed, in megabits per second.

AUTH

Either `open` or `shared` (see `connect-wifi`).

BSSTYPE

Either `bss` for BSS (infrastructure) networks, or `ibss` for IBSS (ad-hoc) networks.

By default, currently all fields but `AUTH`, `BSSID`, `BSSTYPE` are displayed.

`-p`, `--parseable`

Displays using a stable machine-parseable format. The `-o` option is required with `-p`. See “Parseable Output Format”, below.

`dladm show-ether [-x] [[-p] -o field,...] [ether-link]`

Shows state information either for all physical Ethernet links or for a specified physical Ethernet link.

The `show-ether` subcommand accepts the following options:

`-o field,...`, `--output=field`

A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value `all` to display all fields. For each link, the following fields can be displayed:

LINK

The name of the link being displayed.

PTYPE

Parameter type, where `current` indicates the negotiated state of the link, `capable` indicates capabilities supported by the device, `advertised` indicates the advertised capabilities, and `peeradvertised` indicates the capabilities advertised by the link-partner.

STATE

The state of the link.

AUTO

A yes/no value indicating whether auto-negotiation is advertised.

SPEED-DUPLEX

Combinations of speed and duplex values available. The units of speed are encoded with a trailing suffix of G (Gigabits/s) or M (Mb/s). Duplex values are encoded as f (full-duplex) or h (half-duplex).

PAUSE

Flow control information. Can be no, indicating no flow control is available; tx, indicating that the end-point can transmit pause frames, but ignores any received pause frames; rx, indicating that the end-point receives and acts upon received pause frames; or bi, indicating bi-directional flow-control.

REM_FAULT

Fault detection information. Valid values are none or fault.

By default, all fields except REM_FAULT are displayed for the “current” PTYPE.

-p, --parseable

Displays using a stable machine-parseable format. The -o option is required with -p. See “Parseable Output Format”, below.

-x, --extended

Extended output is displayed for PTYPE values of current, capable, adv and peeradv.

dladm set-linkprop [-t] [-R root-dir] -p prop=value[,...] link

Sets the values of one or more properties on the link specified. The list of properties and their possible values depend on the link type, the network device driver, and networking hardware. These properties can be retrieved using show-linkprop.

-t, --temporary

Specifies that the changes are temporary. Temporary changes last until the next reboot.

-R root-dir, --root-dir=root-dir

See “Options,” above.

-p prop=value[,...], --prop prop=value[,...]

A comma-separated list of properties to set to the specified values.

Note that when the persistent value is set, the temporary value changes to the same value.

dladm reset-linkprop [-t] [-R root-dir] [-p prop,...] link

Resets one or more properties to their values on the link specified. Properties are reset to the values they had at startup. If no properties are specified, all properties are reset. See show-linkprop for a description of properties.

-t, --temporary

Specifies that the resets are temporary. Values are reset to default values. Temporary resets last until the next reboot.

`-R root-dir, --root-dir=root-dir`

See “Options,” above.

`-p prop, ..., --prop=prop, ...`

A comma-separated list of properties to reset.

Note that when the persistent value is reset, the temporary value changes to the same value.

`dladm show-linkprop [-P] [[-c] -o field[,...]][-p prop[,...]] [link]`

Show the current or persistent values of one or more properties, either for all datalinks or for the specified link. By default, current values are shown. If no properties are specified, all available link properties are displayed. For each property, the following fields are displayed:

`-o field[,...], --output=field`

A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value `all` to display all fields. For each link, the following fields can be displayed:

LINK

The name of the datalink.

PROPERTY

The name of the property.

PERM

The read/write permissions of the property. The value shown is one of `ro` or `rw`.

VALUE

The current (or persistent) property value. If the value is not set, it is shown as `--`. If it is unknown, the value is shown as `?`. Persistent values that are not set or have been reset will be shown as `--` and will use the system `DEFAULT` value (if any).

DEFAULT

The default value of the property. If the property has no default value, `--` is shown.

POSSIBLE

A comma-separated list of the values the property can have. If the values span a numeric range, *min* - *max* might be shown as shorthand. If the possible values are unknown or unbounded, `--` is shown.

The list of properties depends on the link type and network device driver, and the available values for a given property further depends on the underlying network hardware and its state. General link properties are documented in the “General Link Properties” section. However, link properties that begin with “`_`” (underbar) are specific to a given link or its underlying network device and subject to change or removal. See the appropriate network device driver man page for details.

`-c, --parseable`

Display using a stable machine-parseable format. The `-o` option is required with this option. See “Parseable Output Format”, below.

-P, --persistent
 Display persistent link property information

-p *prop*, ..., --prop=*prop*, ...
 A comma-separated list of properties to show. See the sections on link properties following subcommand descriptions.

`dladm create-secobj [-t] [-R root-dir] [-f file] -c class secobj`

Create a secure object named *secobj* in the specified *class* to be later used as a WEP or WPA key in connecting to an encrypted network. The value of the secure object can either be provided interactively or read from a file. The sequence of interactive prompts and the file format depends on the class of the secure object.

Currently, the classes `wep` and `wpa` are supported. The WEP (Wired Equivalent Privacy) key can be either 5 or 13 bytes long. It can be provided either as an ASCII or hexadecimal string -- thus, 12345 and `0x3132333435` are equivalent 5-byte keys (the `0x` prefix can be omitted). A file containing a WEP key must consist of a single line using either WEP key format. The WPA (Wi-Fi Protected Access) key must be provided as an ASCII string with a length between 8 and 63 bytes.

This subcommand is only usable by users or roles that belong to the “Network Link Security” RBAC profile.

-c *class*, --class=*class*
class can be `wep` or `wpa`. See preceding discussion.

-t, --temporary
 Specifies that the creation is temporary. Temporary creation last until the next reboot.

-R *root-dir*, --root-dir=*root-dir*
 See “Options,” above.

-f *file*, --file=*file*
 Specifies a file that should be used to obtain the secure object's value. The format of this file depends on the secure object class. See the EXAMPLES section for an example of using this option to set a WEP key.

`dladm delete-secobj [-t] [-R root-dir] secobj[,...]`

Delete one or more specified secure objects. This subcommand is only usable by users or roles that belong to the “Network Link Security” RBAC profile.

-t, --temporary
 Specifies that the deletions are temporary. Temporary deletions last until the next reboot.

-R *root-dir*, --root-dir=*root-dir*
 See “Options,” above.

`dladm show-secobj [-P] [[-p] -o field[,...]] [secobj,...]`

Show current or persistent secure object information. If one or more secure objects are specified, then information for each is displayed. Otherwise, all current or persistent secure objects are displayed.

By default, current secure objects are displayed, which are all secure objects that have either been persistently created and not temporarily deleted, or temporarily created.

For security reasons, it is not possible to show the value of a secure object.

`-o field[,...], --output=field[,...]`

A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below. For displayed secure object, the following fields can be shown:

OBJECT

The name of the secure object.

CLASS

The class of the secure object.

`-p, --parseable`

Display using a stable machine-parseable format. The `-o` option is required with `-p`. See “Parseable Output Format”, below.

`-P, --persistent`

Display persistent secure object information

`dladm create-vnic [-t] -l link [-R root-dir] [-m value | auto | {factory [-n slot-identifier]} | {vrrp -A {inet | inet6} -V vrid} | {random [-r prefix]}] [-v vlan-id] [-p prop=value[,...]]`
vnic-link

Create a VNIC with name *vnic-link* over the specified link.

`-t, --temporary`

Specifies that the VNIC is temporary. Temporary VNICs last until the next reboot.

`-R root-dir, --root-dir=root-dir`

See “Options,” above.

`-l link, --link=link`

link can be a physical link or an etherstub.

`-m value | keyword, --mac-address=value | keyword`

Sets the VNIC's MAC address based on the specified value or keyword. If *value* is not a keyword, it is interpreted as a unicast MAC address, which must be valid for the underlying NIC. The following special keywords can be used:

`factory [-n slot-identifier],`

`factory [--slot=slot-identifier]`

Assign a factory MAC address to the VNIC. When a factory MAC address is

requested, `-m` can be combined with the `-n` option to specify a MAC address slot to be

used. If `-n` is not specified, the system will choose the next available factory MAC address. The `-m` option of the `show-phys` subcommand can be used to display the list of factory MAC addresses, their slot identifiers, and their availability.

`random [-r prefix]`,

`random [--mac-prefix=prefix]`

Assign a random MAC address to the VNIC. A default prefix consisting of a valid IEEE OUI with the local bit set will be used. That prefix can be overridden with the `-r` option.

`vrp -A {inet | inet6} -V vrid`

Assign a VRRP virtual MAC address to the VNIC base on the specified address family and *vrid*.

`auto`

Try and use a factory MAC address first. If none is available, assign a random MAC address. `auto` is the default action if the `-m` option is not specified.

`-v vlan-id`

Enable VLAN tagging for this VNIC. The VLAN tag will have id *vlan-id*.

`-p prop=value,..., --prop prop=value,...`

A comma-separated list of properties to set to the specified values.

`dladm delete-vnic [-t] [-R root-dir] vnic-link`

Deletes the specified VNIC.

`-t, --temporary`

Specifies that the deletion is temporary. Temporary deletions last until the next reboot.

`-R root-dir, --root-dir=root-dir`

See “Options,” above.

`dladm show-vnic [-pP] [-s [-i interval]] [-o field[,...]] [-l link] [vnic-link]`

Show VNIC configuration information for all VNICs, all VNICs on a link, or only the specified *vnic-link*.

`-o field[,...], --output=field[,...]`

A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value `all` to display all fields. By default (without `-o`), `show-vnic` displays all fields.

LINK

The name of the VNIC.

OVER

The name of the physical link over which this VNIC is configured.

SPEED

The maximum speed of the VNIC, in megabits per second.

- MACADDRESS
MAC address of the VNIC.
- MACADDRTYPE
MAC address type of the VNIC. `dladm` distinguishes among the following MAC address types:
- random
A random address assigned to the VNIC.
 - factory
A factory MAC address used by the VNIC.
- p, --parseable
Display using a stable machine-parseable format. The -o option is required with -p. See “Parseable Output Format”, below.
- P, --persistent
Display the persistent VNIC configuration.
- s, --statistics
Displays VNIC statistics. This option is made obsolete by `dlstat(1M)`.
- i *interval*, --interval=*interval*
Used with the -s option to specify an interval, in seconds, at which statistics should be displayed. This option is made obsolete by `dlstat(1M)`.
- l *link*, --link=*link*
Display information for all VNICs on the named link.
- `dladm create-part [-t] [-f] [-R root-dir] -l ib-link [-p prop=value[,..]] -P pkey part-link`
Create an IP-over-IB link with the name *part-link* over the specified link. This subcommand is supported only on InfiniBand physical links.
- f, --force
Forces the creation of the partition link even if *pkey* is absent on the port, the multicast group is absent, or the port is down.
 - l *ib-link*, --link=*ib-link*
IP-over-IB physical link name.
 - P, --pkey=*pkey*
Partition key to be used for creating the partition link. *pkey* specified is always treated as hexadecimal, whether it has the 0x prefix or not.
 - p *prop=value[,..]*
--prop *prop=value[,..]*
A comma-separated list of properties to set to the specified values. Supported properties are given “General Link Properties” section below.
 - R *root-dir*, --root-dir=*root-dir*
See “Options,” above.

-t, --temporary
 Specifies that the partition link creation is temporary. Temporary partition links last until the next reboot.

dladm delete-part [-R *root-dir*] *part-link*

Delete the specified partition link.

-R *root-dir*, --root-dir=*root-dir*

See “Options,” above.

-t, --temporary

Specifies that the partition link deletion is temporary. Temporary deletion last until the next reboot.

dladm show-part [-pP] [-l *ib-link*] [-o *field*[,...]] [*part-link*]

Displays IB partition link information for all partition links, for all partitions on *ib-link*, or for only the specified *part-link*.

-l *ib-link*, --link=*ib-link*

Display information for all the partitions on the named link.

-o *field*[,...]

A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value `all` to display all fields. By default (without `-o`), `show-part` displays all fields.

LINK

The name of the partition link.

PKEY

Pkey associated with the partition link.

OVER

The name of the physical link over which this partition link is created.

STATE

Current state of the partition link. Possible values are `up`, `down`, or `unknown`.

FLAGS

A set of state flags used for creating the partition link. Possible values are:

f

Partition was created forcibly (without checking whether creating a partition were possible).

t

Partition link is temporary, lasting only until the next reboot.

-P, --persistent

Display the persistent IB partition link configuration.

`-p, --parseable`

Display using a stable machine-parseable format. The `-o` option is required with `-p`. See “Parseable Output Format”, below.

`dladm show-ib [-pP] [-o field[,...]] [ib-link]`

Display IB physical link information on all or the specified IB links.

`-o field[,...]`

A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value `all` to display all fields. By default (without `-o`), `show-ib` displays all fields.

LINK

The name of the physical link.

HCAGUID

Globally unique identifier of the HCA.

PORTGUID

Globally unique identifier of the port.

PORT

Port number.

STATE

Current state of the physical link. Possible values are `up`, `down`, or `unknown`.

PKEYS

Pkeys available on the port associated with the IP-over-IB link specified in the **LINK** field.

`-P, --persistent`

Display the persistent IB physical link configuration.

`-p, --parseable`

Display using a stable machine-parseable format. The `-o` option is required with `-p`. See “Parseable Output Format”, below.

`dladm create-etherstub [-t] [-R root-dir] etherstub`

Create an etherstub with the specified name.

`-t, --temporary`

Specifies that the etherstub is temporary. Temporary etherstubs do not persist across reboots.

`-R root-dir, --root-dir=root-dir`

See “Options,” above.

VNICs can be created on top of etherstubs instead of physical NICs. As with physical NICs, such a creation causes the stack to implicitly create a virtual switch between the VNICs created on top of the same etherstub.

`dladm delete-etherstub [-t] [-R root-dir] etherstub`

Delete the specified etherstub.

`-t, --temporary`

Specifies that the deletion is temporary. Temporary deletions last until the next reboot.

`-R root-dir, --root-dir=root-dir`

See “Options,” above.

`dladm show-etherstub [etherstub]`

Show all configured etherstubs by default, or the specified etherstub if *etherstub* is specified.

`dladm create-iptun [-t] [-R root-dir] -T type [-a {local|remote}=addr,...] iptun-link`

Create an IP tunnel link named *iptun-link*. Such links can additionally be protected with IPsec using [ipsecconf\(1M\)](#).

An IP tunnel is conceptually comprised of two parts: a virtual link between two or more IP nodes, and an IP interface above this link that allows the system to transmit and receive IP packets encapsulated by the underlying link. This subcommand creates a virtual link. The [ifconfig\(1M\)](#) command is used to configure IP interfaces above the link.

`-t, --temporary`

Specifies that the IP tunnel link is temporary. Temporary tunnels last until the next reboot.

`-R root-dir, --root-dir=root-dir`

See “Options,” above.

`-T type, --tunnel-type=type`

Specifies the type of tunnel to be created. The type must be one of the following:

`ipv4`

A point-to-point, IP-over-IP tunnel between two IPv4 nodes. This type of tunnel requires IPv4 source and destination addresses to function. IPv4 and IPv6 interfaces can be plumbed above such a tunnel to create IPv4-over-IPv4 and IPv6-over-IPv4 tunneling configurations.

`ipv6`

A point-to-point, IP-over-IP tunnel between two IPv6 nodes as defined in IETF RFC 2473. This type of tunnel requires IPv6 source and destination addresses to function. IPv4 and IPv6 interfaces can be plumbed above such a tunnel to create IPv4-over-IPv6 and IPv6-over-IPv6 tunneling configurations.

`6to4`

A 6to4, point-to-multipoint tunnel as defined in IETF RFC 3056. This type of tunnel requires an IPv4 source address to function. An IPv6 interface is plumbed on such a tunnel link to configure a 6to4 router.

`-a {local|remote}=addr,...`

`--address {local|remote}=addr,...`

Literal IP addresses or hostnames corresponding to the local or remote tunnel addresses. Either local or remote can be specified individually, or both can be specified separated by a comma (for example, `-a local=laddr,remote=raddr`).

`dladm modify-iptun [-t] [-R root-dir] -a {local|remote}=addr,... iptun-link`
Modify the parameters of the specified IP tunnel.

`-t, --temporary`

Specifies that the modification is temporary. Temporary modifications last until the next reboot.

`-R root-dir, --root-dir=root-dir`

See “Options,” above.

`-a {local|remote}=addr,...`

`--address {local|remote}=addr,...`

Specify new local or remote addresses for the tunnel link. See `create-iptun` for a description.

`dladm delete-iptun [-t] [-R root-dir] iptun-link`

Delete the specified IP tunnel link.

`-t, --temporary`

Specifies that the deletion is temporary. Temporary deletions last until the next reboot.

`-R root-dir, --root-dir=root-dir`

See “Options,” above.

`dladm show-iptun [-P] [[-p] -o field[,...]] [iptun-link]`

Show IP tunnel link configuration for a single IP tunnel or all IP tunnels.

`-P, --persistent`

Display the persistent IP tunnel configuration.

`-p, --parseable`

Display using a stable machine-parseable format. The `-o` option is required with `-p`. See “Parseable Output Format”, below.

`-o field[,...], --output=field[,...]`

A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value `all`, to display all fields. By default (without `-o`), `show-iptun` displays all fields.

LINK

The name of the IP tunnel link.

TYPE

Type of tunnel as specified by the `-T` option of `create-iptun`.

FLAGS

A set of flags associated with the IP tunnel link. Possible flags are:

s

The IP tunnel link is protected by IPsec policy. To display the IPsec policy associated with the tunnel link, enter:

```
# ipsecconf -ln -i tunnel-link
```

See [ipsecconf\(1M\)](#) for more details on how to configure IPsec policy.

i

The IP tunnel link was implicitly created with [ifconfig\(1M\)](#), and will be automatically deleted when it is no longer referenced (that is, when the last IP interface over the tunnel is unplumbed). See [ifconfig\(1M\)](#) for details on implicit tunnel creation.

LOCAL

The local tunnel address.

REMOTE

The remote tunnel address.

```
dladm show-usage [-a] -f filename [-p plotfile -F format] [-s time] [-e time] [link]
```

This subcommand is made obsolete by the [dlstat\(1M\)](#) `show-link -h` command.

Parseable Output
Format

Many `dladm` subcommands have an option that displays output in a machine-parseable format. The output format is one or more lines of colon (:) delimited fields. The fields displayed are specific to the subcommand used and are listed under the entry for the `-o` option for a given subcommand. Output includes only those fields requested by means of the `-o` option, in the order requested.

When you request multiple fields, any literal colon characters are escaped by a backslash (\) before being output. Similarly, literal backslash characters will also be escaped (\\). This escape format is parseable by using shell [read\(1\)](#) functions with the environment variable `IFS=:` (see [EXAMPLES](#), below). Note that escaping is not done when you request only a single field.

General Link Properties

The following general link properties are supported:

autopush

Specifies the set of STREAMS modules to push on the stream associated with a link when its DLPI device is opened. It is a space-delimited list of modules.

The optional special character sequence `[anchor]` indicates that a STREAMS anchor should be placed on the stream at the module previously specified in the list. It is an error to specify more than one anchor or to have an anchor first in the list.

The `autopush` property is preferred over the more general [autopush\(1M\)](#) command.

cpus

Bind the processing of packets for a given data link to a processor or a set of processors. The value can be a comma-separated list of one or more processor ids or a range of ids. If the list

consists of more than one processor, the processing will spread out to all the processors. Connection to processor affinity and packet ordering for any individual connection will be maintained.

The processor or set of processors are not exclusively reserved for the link. Only the kernel threads and interrupts associated with processing of the link are bound to the processor or the set of processors specified. In case it is desired that processors be dedicated to the link, `psrset(1M)` can be used to create a processor set and then specifying the processors from the processor set to bind the link to.

If the link was already bound to processor or set of processors due to a previous operation, the binding will be removed and the new set of processors will be used instead.

The default is no CPU binding, which is to say that the processing of packets is not bound to any specific processor or processor set.

Specification of the `cpus` property is not allowed on links with a `pool` link property.

`cpus-effective`

This read-only property displays the list of CPUs used for packet processing on the named data link.

If the `cpus` property has been set, `cpus-effective` will be the same.

If the `pool` property has been set, the `cpus-effective` will be selected from the `pool` designated by the administrator.

If neither the `pool` nor `cpus` property is set, the system will select the appropriate value for `cpus-effective`.

`learn_limit`

Limits the number of new or changed MAC sources to be learned over a bridge link. When the number exceeds this value, learning on that link is temporarily disabled. Only non-VLAN, non-VNIC type links have this property.

The default value is `1000`. Valid values are greater or equal to 0.

`learn_decay`

Specifies the decay rate for source changes limited by `learn_limit`. This number is subtracted from the counter for a bridge link every 5 seconds. Only non-VLAN, non-VNIC type links have this property.

The default value is `200`. Valid values are greater or equal to 0.

`maxbw`

Sets the full duplex bandwidth for the link. The bandwidth is specified as an integer with one of the scale suffixes (K, M, or G for Kbps, Mbps, and Gbps). If no units are specified, the input value will be read as Mbps. The default is no bandwidth limit.

pool

Bind the processing of packets for a given data link to a pool of processors defined and administered by `poolcfg(1M)` and `pooladm(1M)`. The binding of processes is similar to what occurs with the `cpus` link property, except that the list of CPUs is not explicit and is instead maintained by the pools facility.

If pools are enabled, and no pool is specified for the link, `pool_default` will be used for packet processing.

For zones with `ip-type=exclusive`, if a pool is specified through a pool zone property or `dedicated-cpus` allocation, that pool will also be used for all data links associated with the zone.

Specification of the `pool` property is not allowed on links with a `cpus` link property.

pool-effective

If the pools facility has been enabled, this read-only property displays the pool that is being used for packet processing. If the administrator has not assigned a pool to a data link, the pool will be `pool_default`.

If the pools facility is disabled, there is no effective pool and the value will be empty.

priority

Sets the relative priority for the link. The value can be given as one of the tokens `high`, `medium`, or `low`. The default is `high`.

rxringsavail

A read-only property that specifies the number of rings available on the receive side.

rxrings

Specifies the number of receive rings side for the MAC client. A value of `0` means this MAC client should not be assigned any RX ring. A non-`0` value means reserve that many rings for this MAC client, if available, and fail if not. If this property is not specified, the MAC client can get one RX ring, if available, or will be software-based.

rxhwcntavail

A read-only property that specifies the number of additional RX hardware-based MAC clients that can be created.

txringsavail

A read-only property that specifies the number of rings available on the transmit side.

txrings

Specifies the number of transmit rings for the MAC client. A value of `0` means this MAC client should not be assigned any TX ring. A non-`0` value means reserve that many rings for this MAC client, if available, and fail if not. If this property is not specified the MAC client can get one TX ring, if available, or will be software-based.

txhwclntavail

A read-only property that specifies the number of additional TX hardware-based MAC clients that can be created.

stp

Enables or disables Spanning Tree Protocol on a bridge link. Setting this value to 0 disables Spanning Tree, and puts the link into forwarding mode with BPDU guarding enabled. This mode is appropriate for point-to-point links connected only to end nodes. Only non-VLAN, non-VNIC type links have this property. The default value is 1, to enable STP.

forward

Enables or disables forwarding for a VLAN. Setting this value to 0 disables bridge forwarding for a VLAN link. Disabling bridge forwarding removes that VLAN from the “allowed set” for the bridge. The default value is 1, to enable bridge forwarding for configured VLANs.

default_tag

Sets the default VLAN ID that is assumed for untagged packets sent to and received from this link. Only non-VLAN, non-VNIC type links have this property. Setting this value to 0 disables the bridge forwarding of untagged packets to and from the port. The default value is VLAN ID 1. Valid values are from 0 to 4094. The default VLAN ID is also referred to as the Port VLAN Identifier (PVID).

You cannot create a tagged VLAN or VLAN-tagged VNIC link with a VLAN ID that matches the default VLAN value of the underlying link. All untagged packets on the link are already associated with the default VLAN (PVID). To successfully create a tagged VLAN or VLAN-tagged VNIC link with VLAN ID equal to the default VLAN value, you must first change the `default_tag` property of the underlying link to a different VLAN value.

When `default_tag=0`, all untagged packets on the link are no longer associated with any VLAN. As a result, you can create a VLAN link with any VLAN ID from 1 to 4094. Note that any received packets that are erroneously tagged with the PVID at an end-point might be dropped. This situation occurs if all the end-points on a given link do not agree on the PVID. All end-points on a link must use the same PVID and must not tag traffic with the PVID.

stp_priority

Sets the STP and RSTP Port Priority value, which is used to determine the preferred root port on a bridge. Lower numerical values are higher priority. The default value is 128. Valid values range from 0 to 255.

stp_cost

Sets the STP and RSTP cost for using the link. The default value is `auto`, which sets the cost based on link speed, using 100 for 10Mbps, 19 for 100Mbps, 4 for 1Gbps, and 2 for 10Gbps. Valid values range from 1 to 65535.

stp_edge

Enables or disables bridge edge port detection. If set to 0 (false), the system assumes that the port is connected to other bridges even if no bridge PDUs of any type are seen. The default value is 1, which detects edge ports automatically.

stp_p2p

Sets bridge point-to-point operation mode. Possible values are true, false, and auto. When set to auto, point-to-point connections are automatically discovered. When set to true, the port mode is forced to use point-to-point. When set to false, the port mode is forced to use normal multipoint mode. The default value is auto.

stp_mcheck

Triggers the system to run the RSTP Force BPDUs Migration Check procedure on this link. The procedure is triggered by setting the property value to 1. The property is automatically reset back to 0. This value cannot be set unless the following are true:

- The link is bridged
- The bridge is protected by Spanning Tree
- The bridge force-protocol value is at least 2 (RSTP)

The default value is 0.

protection

Enables one or more types of link protection. Valid values are:

mac-nospoof

MAC address anti-spoof. An outbound packet's source MAC address must match the link's configured MAC address. Non-matching packets will be dropped. If the link belongs to a zone, turning mac-nospoof on will prevent the zone's owner from modifying the link's MAC address.

ip-nospoof

IP address anti-spoof. This protection type works in conjunction with the link property allowed-ips.

allowed-ips is a list containing IP (IPv4 or IPv6) addresses. This list is empty by default. Addresses that are implicitly in this list are: the link local IPv6 address conforming to RFC 2464 (derived from the link's MAC address); IPv4/IPv6 addresses learned from DHCP replies; the unspecified (all-zeros) IPv4/IPv6 address.

An outbound IP packet can pass if its source address is in allowed-ips.

An outbound ARP packet can pass if its sender protocol address is in allowed-ips.

When a datalink has been protected by setting allowed-ips to a set of one or more IP addresses, any attempts to configure IP addresses that are not in this set will fail with an EPERM error being returned to the user. Moreover, the interface may not be used for forwarding IP packets, and attempts to set the `ipadm(1M)` forwarding property on the interface will encounter an EPERM error.

dhcp-nospoof

DHCP client ID (DUID for DHCPv6) and hardware address anti-spoof. This protection type works in conjunction with the link property `allowed-dhcp-cids`.

Items in the `allowed-dhcp-cids` list should be formatted in the same way as the `CLIENT_ID` field in the `/etc/default/dhcppagent` file. The only difference is that `.` (period) should be used in place of `,` (comma) when specifying DUIDs. See [dhcppagent\(1M\)](#) for details.

An outbound DHCP (v4/v6) packet can pass only if these conditions are satisfied:

- If `allowed-dhcp-cids` is not configured and the packet type is:
 - DHCPv4, the client ID field must match the configured MAC address.
 - DHCPv6, the DUID must be of type 1 or 3 and the link layer address part of the DUID must match the configured MAC address.
- If `allowed-dhcp-cids` is configured and the packet type is:
 - DHCPv4, the client ID field must match one of the IDs on this list or the configured MAC address.
 - DHCPv6, the DUID field must match one of the IDs on this list or, the DUID must be of type 1 or 3 and the link layer address part of the DUID matches the configured MAC address.

restricted

This protection restricts outgoing packet types to just IPv4, IPv6, and ARP.

zone

Specifies the zone to which the link belongs. This property can be modified only temporarily through `dladm`, and thus the `-t` option must be specified. To modify the zone assignment such that it persists across reboots, please use [zonecfg\(1M\)](#). Possible values consist of any exclusive-IP zone currently running on the system. By default, the zone binding is as per [zonecfg\(1M\)](#).

Wifi Link Properties The following WiFi link properties are supported. Note that the ability to set a given property to a given value depends on the driver and hardware.

channel

Specifies the channel to use. This property can be modified only by certain WiFi links when in IBSS mode. The default value and allowed range of values varies by regulatory domain.

powermode

Specifies the power management mode of the WiFi link. Possible values are `off` (disable power management), `max` (maximum power savings), and `fast` (performance-sensitive power management). Default is `off`.

radio

Specifies the radio mode of the WiFi link. Possible values are `on` or `off`. Default is `on`.

speed

Specifies a fixed speed for the WiFi link, in megabits per second. The set of possible values depends on the driver and hardware (but is shown by `show-linkprop`); common speeds include 1, 2, 11, and 54. By default, there is no fixed speed.

Ethernet Link Properties

The following MII Properties, as documented in [ieee802.3\(5\)](#), are supported in read-only mode:

- `duplex`
- `state`
- `adv_autoneg_cap`
- `adv_10gfdx_cap`
- `adv_1000fdx_cap`
- `adv_1000hdx_cap`
- `adv_100fdx_cap`
- `adv_100hdx_cap`
- `adv_10fdx_cap`
- `adv_10hdx_cap`

Each `adv_*` property (for example, `adv_10fdx_cap`) also has a read/write counterpart `en_*` property (for example, `en_10fdx_cap`) controlling parameters used at auto-negotiation. In the absence of Power Management, the `adv_*` speed/duplex parameters provide the values that are both negotiated and currently effective in hardware. However, with Power Management enabled, the speed/duplex capabilities currently exposed in hardware might be a subset of the set of bits that were used in initial link parameter negotiation. Thus the MII `adv_*` parameters are marked read-only, with an additional set of `en_*` parameters for configuring speed and duplex properties at initial negotiation.

Note that the `adv_autoneg_cap` does not have an `en_autoneg_cap` counterpart: the `adv_autoneg_cap` is a 0/1 switch that turns off/on autonegotiation itself, and therefore cannot be impacted by Power Management.

In addition, the following Ethernet properties are reported:

flowctrl

Establishes flow-control modes that will be advertised by the device. Valid input is one of:

`no`

No flow control enabled.

`rx`

Receive, and act upon incoming pause frames.

`tx`

Transmit pause frames to the peer when congestion occurs, but ignore received pause frames.

`bi`

Bidirectional flow control.

Note that the actual settings for this value are constrained by the capabilities allowed by the device and the link partner.

`mtu`

The maximum client SDU (Send Data Unit) supported by the device. Valid range is 68-65536.

`speed`

(read-only) The operating speed of the device, in Mbps.

`tagmode`

This link property controls the conditions in which 802.1Q VLAN tags will be inserted in packets being transmitted on the link. Two mode values can be assigned to this property:

`normal` Insert a VLAN tag in outgoing packets under the following conditions:

- The packet belongs to a VLAN.
- The user requested priority tagging.

`vlanonly` Insert a VLAN tag only when the outgoing packet belongs to a VLAN. If a tag is being inserted in this mode and the user has also requested a non-zero priority, the priority is honored and included in the VLAN tag.

The default value is `vlanonly`.

InfiniBand Link Properties The following properties are supported only on IB partition object links.

`linkmode`

Sets the link transport service type on an IB partition datalink. The default value is `cm`. Valid values are:

`cm`

Connected Mode. This mode uses a default MTU of 65520 and supports a maximum MTU of 65535 bytes. If Connected Mode is not available for a remote node, Unreliable Datagram mode will automatically be used instead.

`ud`

Unreliable Datagram Mode. This mode uses a default MTU of 2044 and supports a maximum MTU of 4092 bytes.

IP Tunnel Link Properties The following IP tunnel link properties are supported.

`hoplimit`

Specifies the IPv4 TTL or IPv6 hop limit for the encapsulating outer IP header of a tunnel link. This property exists for all tunnel types. The default value is 64.

`encaplimit`

Specifies the IPv6 encapsulation limit for an IPv6 tunnel as defined in RFC 2473. This value is the tunnel nesting limit for a given tunneled packet. The default value is 4. A value of 0 disables the encapsulation limit.

Examples EXAMPLE 1 Configuring an Aggregation

To configure a data-link over an aggregation of devices `bge0` and `bge1` with key `1`, enter the following command:

```
# dladm create-aggr -d bge0 -d bge1 1
```

EXAMPLE 2 Connecting to a WiFi Link

To connect to the most optimal available unsecured network on a system with a single WiFi link (as per the prioritization rules specified for `connect-wifi`), enter the following command:

```
# dladm connect-wifi
```

EXAMPLE 3 Creating a WiFi Key

To interactively create the WEP key `mykey`, enter the following command:

```
# dladm create-secobj -c wep mykey
```

Alternatively, to non-interactively create the WEP key `mykey` using the contents of a file:

```
# umask 077
# cat >/tmp/mykey.$$ <<EOF
12345
EOF
# dladm create-secobj -c wep -f /tmp/mykey.$$ mykey
# rm /tmp/mykey.$$
```

EXAMPLE 4 Connecting to a Specified Encrypted WiFi Link

To use key `mykey` to connect to ESSID `wlan` on link `ath0`, enter the following command:

```
# dladm connect-wifi -k mykey -e wlan ath0
```

EXAMPLE 5 Changing a Link Property

To set `powermode` to the value `fast` on link `pcwl0`, enter the following command:

```
# dladm set-linkprop -p powermode=fast pcwl0
```

EXAMPLE 6 Connecting to a WPA-Protected WiFi Link

Create a WPA key `psk` and enter the following command:

```
# dladm create-secobj -c wpa psk
```

To then use key `psk` to connect to ESSID `wlan` on link `ath0`, enter the following command:

```
# dladm connect-wifi -k psk -e wlan ath0
```

EXAMPLE 7 Renaming a Link

To rename the `bge0` link to `mgmt0`, enter the following command:

```
# dladm rename-link bge0 mgmt0
```

EXAMPLE 8 Replacing a Network Card

Consider that the `bge0` device, whose link was named `mgmt0` as shown in the previous example, needs to be replaced with a `ce0` device because of a hardware failure. The `bge0` NIC is physically removed, and replaced with a new `ce0` NIC. To associate the newly added `ce0` device with the `mgmt0` configuration previously associated with `bge0`, enter the following command:

```
# dladm rename-link ce0 mgmt0
```

EXAMPLE 9 Removing a Network Card

Suppose that in the previous example, the intent is not to replace the `bge0` NIC with another NIC, but rather to remove and not replace the hardware. In that case, the `mgmt0` datalink configuration is not slated to be associated with a different physical device as shown in the previous example, but needs to be deleted. Enter the following command to delete the datalink configuration associated with the `mgmt0` datalink, whose physical hardware (`bge0` in this case) has been removed:

```
# dladm delete-phys mgmt0
```

EXAMPLE 10 Using Parseable Output to Capture a Single Field

The following assignment saves the MTU of link `net0` to a variable named `mtu`.

```
# mtu='dladm show-link -p -o mtu net0'
```

EXAMPLE 11 Using Parseable Output to Iterate over Links

The following script displays the state of each link on the system.

```
# dladm show-link -p -o link,state | while IFS=: read link state; do
    print "Link $link is in state $state"
done
```

EXAMPLE 12 Configuring VNICs

Create two VNICs with names `hello0` and `test1` over a single physical link `bge0`:

```
# dladm create-vnic -l bge0 hello0
# dladm create-vnic -l bge0 test1
```

EXAMPLE 13 Configuring VNICs and Allocating Bandwidth and Priority

Create two VNICs with names `hello0` and `test1` over a single physical link `bge0` and make `hello0` a high priority VNIC with a factory-assigned MAC address with a maximum bandwidth of 50 Mbps. Make `test1` a low priority VNIC with a random MAC address and a maximum bandwidth of 100Mbps.

```
# dladm create-vmnic -l bge0 -m factory -p maxbw=50,priority=high hello0
# dladm create-vmnic -l bge0 -m random -p maxbw=100M,priority=low test1
```

EXAMPLE 14 Configuring a VNIC with a Factory MAC Address

First, list the available factory MAC addresses and choose one of them:

```
# dladm show-phys -m bge0
LINK          SLOT          ADDRESS                INUSE    CLIENT
bge0          primary      0:e0:81:27:d4:47      yes      bge0
bge0          1            8:0:20:fe:4e:a5       no
bge0          2            8:0:20:fe:4e:a6       no
bge0          3            8:0:20:fe:4e:a7       no
```

Create a VNIC named `hello0` and use slot 1's address:

```
# dladm create-vmnic -l bge0 -m factory -n 1 hello0
# dladm show-phys -m bge0
LINK          SLOT          ADDRESS                INUSE    CLIENT
bge0          primary      0:e0:81:27:d4:47      yes      bge0
bge0          1            8:0:20:fe:4e:a5       yes      hello0
bge0          2            8:0:20:fe:4e:a6       no
bge0          3            8:0:20:fe:4e:a7       no
```

EXAMPLE 15 Creating a VNIC with User-Specified MAC Address, Binding it to Set of Processors

Create a VNIC with name `hello0`, with a user specified MAC address, and a processor binding `0, 2, 4-6`.

```
# dladm create-vmnic -l bge0 -m 8:0:20:fe:4e:b8 -p cpus=0,2,4-6 hello0
```

EXAMPLE 16 Creating a Virtual Network Without a Physical NIC

First, create an etherstub with name `stub1`:

```
# dladm create-etherstub stub1
```

Create two VNICs with names `hello0` and `test1` on the etherstub. This operation implicitly creates a virtual switch connecting `hello0` and `test1`.

```
# dladm create-vmnic -l stub1 hello0
# dladm create-vmnic -l stub1 test1
```

EXAMPLE 17 Displaying Bridge Information

The following commands use the `show-bridge` subcommand with no and various options.

EXAMPLE 17 Displaying Bridge Information *(Continued)*

```

# dladm show-bridge
BRIDGE      PROTECT ADDRESS                PRIORITY DESROOT
foo         stp      32768/8:0:20:bf:f 32768    8192/0:d0:0:76:14:38
bar         stp      32768/8:0:20:e5:8 32768    8192/0:d0:0:76:14:38

# dladm show-bridge -l foo
LINK        STATE      UPTIME   DESROOT
hme0       forwarding 117      8192/0:d0:0:76:14:38
qfe1       forwarding 117      8192/0:d0:0:76:14:38

# dladm show-bridge -s foo
BRIDGE      DROPS      FORWARDS
foo         0           302

# dladm show-bridge -ls foo
LINK        DROPS      RECV      XMIT
hme0       0          360832    31797
qfe1       0          322311    356852

# dladm show-bridge -f foo
DEST        AGE        FLAGS     OUTPUT
8:0:20:bc:a7:dc 10.860    --       hme0
8:0:20:bf:f9:69  --        L        hme0
8:0:20:c0:20:26 17.420    --       hme0
8:0:20:e5:86:11  --        L        qfe1

```

EXAMPLE 18 Creating an IPv4 Tunnel

The following sequence of commands creates and then displays a persistent IPv4 tunnel link named `mytunnel0` between 66.1.2.3 and 192.4.5.6:

```

# dladm create-iptun -T ipv4 -s 66.1.2.3 -d 192.4.5.6 mytunnel0
# dladm show-iptun mytunnel0
LINK        TYPE  FLAGS  SOURCE        DESTINATION
mytunnel0   ipv4  --     66.1.2.3     192.4.5.6

```

A point-to-point IP interface can then be created over this tunnel link:

```
# ifconfig mytunnel0 plumb 10.1.0.1 10.1.0.2 up
```

As with any other IP interface, configuration persistence for this IP interface is achieved by placing the desired `ifconfig` commands (in this case, the command for “`10.1.0.1 10.1.0.2`”) into `/etc/hostname.mytunnel0`.

EXAMPLE 19 Creating a 6to4 Tunnel

The following command creates a 6to4 tunnel link. The IPv4 address of the 6to4 router is 75.10.11.12.

EXAMPLE 19 Creating a 6to4 Tunnel *(Continued)*

```
# dladm create-iptun -T 6to4 -s 75.10.11.12 sitetunnel0
# dladm show-iptun sitetunnel0
LINK           TYPE  FLAGS  SOURCE           DESTINATION
sitetunnel0    6to4  --     75.10.11.12     --
```

The following command plumbs an IPv6 interface on this tunnel:

```
# ifconfig sitetunnel0 inet6 plumb up
# ifconfig sitetunnel0 inet6
sitetunnel0: flags=2200041 <UP,RUNNING,NOUD,IPv6> mtu 65515 index 3
    inet tunnel src 75.10.11.12
    tunnel hop limit 64
    inet6 2002:4b0a:b0c::1/16
```

Note that the system automatically configures the IPv6 address on the 6to4 IP interface. See [ifconfig\(1M\)](#) for a description of how IPv6 addresses are configured on 6to4 tunnel links.

EXAMPLE 20 Using Link Protection

To enable link protection:

```
# dladm set-linkprop \
-p protection=mac-nospoof,restricted,ip-nospoof,dhcp-nospoof vnic0
```

To disable link protection:

```
# dladm reset-linkprop -p protection vnic0
```

To modify the allowed-ips list:

```
# dladm set-linkprop -p allowed-ips=10.0.0.1,10.0.0.2 vnic0
```

To modify the allowed-dhcp-cids list:

```
# dladm set-linkprop -p allowed-dhcp-cids=hello vnic0
```

To display the resulting configuration:

```
# dladm show-linkprop -p protection,allowed-ips vnic0
```

| LINK | PROPERTY | PERM | VALUE | DEFAULT | POSSIBLE |
|-------|-------------------|------|------------------------------------------------------------|---------|------------------------------------------------------------|
| vnic0 | protection | rw | mac-nospoof,
restricted,
ip-nospoof,
dhcp-nospoof | -- | mac-nospoof,
restricted,
ip-nospoof,
dhcp-nospoof |
| vnic0 | allowed-ips | rw | 10.0.0.1,
10.0.0.2 | -- | -- |
| vnic0 | allowed-dhcp-cids | rw | hello | -- | -- |

EXAMPLE 21 Creating an IB Partition

The following command creates a partition `ffff.ibp0` with partition key `0xffff` on the physical link `ibp0`.

```
# dladm create-part -P ffff -l ibp0 ffff.ibp0
```

EXAMPLE 22 Displaying IB Partition Information

The following command displays IB partition information.

```
# dladm show-part
LINK          PKEY OVER          STATE  FLAGS
ffff.ibp0    FFFF ibp0          up     ----
```

EXAMPLE 23 Displaying IB Data Links Information

The following command displays IB data links information.

```
# dladm show-ib
LINK          HCAGUID            PORTGUID           PORT STATE  PKEYS
ibp0          3BA000100CD7C     3BA000100CD7D     1   down  FFFF
ibp1          3BA000100CD7C     3BA000100CD7E     2   down  FFFF
ibp3          5AD0000033634     5AD0000033636     2   up    FFFF,8001
ibp2          5AD0000033634     5AD0000033635     1   up    FFFF,8001
```

EXAMPLE 24 Deleting a Partition

The following command deletes the partition `ffff.ibp0`.

```
# dladm delete-part ffff.ibp0
```

EXAMPLE 25 Using `show-link` to Display Partition Information

The following command uses the `show-link` subcommand to display partition information.

```
# dladm show-link
LINK          CLASS  MTU  STATE  BRIDGE  OVER
e1000g0      phys   1500 up     --      --

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

```
/usr/sbin
```

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | Committed |

/sbin

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcsr |
| Interface Stability | Committed |

Note that, for both /usr/sbin and /sbin, the -s and -i options to the show-aggr, show-link and show-vmnic subcommands are Committed Obsolete.

See Also [acctadm\(1M\)](#), [autopush\(1M\)](#), [dhcagent\(1M\)](#), [dlstat\(1M\)](#), [ifconfig\(1M\)](#), [ipadm\(1M\)](#), [ipseconf\(1M\)](#), [nnd\(1M\)](#), [pooladm\(1M\)](#), [poolcfg\(1M\)](#), [psrset\(1M\)](#), [vrrpadm\(1M\)](#), [wpad\(1M\)](#), [zonecfg\(1M\)](#), [attributes\(5\)](#), [ieee802.3\(5\)](#), [dlpi\(7P\)](#)

Notes The preferred method of referring to an aggregation in the aggregation subcommands is by its link name. Referring to an aggregation by its integer *key* is supported for backward compatibility, but is not necessary. When creating an aggregation, if a *key* is specified instead of a link name, the aggregation's link name will be automatically generated by `dladm` as *aggrkey*.

Name dlmgmtd – datalink management daemon

Synopsis /sbin/dlmgmtd

svc:/network/datalink-management:default

Description dlmgmtd is a system daemon that handles administrative events for network datalink interfaces. It is controlled through the service management facility (SMF) service instance:

svc:/network/datalink-management:default

The daemon should not be invoked directly. It does not constitute an administrative nor a programming interface. The administrative interface for managing datalinks is [dladm\(1M\)](#).

Options The daemon has no options.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | Private |

See Also [dladm\(1M\)](#), [attributes\(5\)](#)

Name dlstat – report data links statistics

Synopsis dlstat [-r | -t] [-i *interval*] [*link*]

dlstat [-a | -A] [-i *interval*] [-p] [-o *field*[,...]]
[-u R|K|M|G|T|P] [*link*]

dlstat show-phys [-r | -t] [-i *interval*] [-a]
[-p] [-o *field*[,...]] [-u R|K|M|G|T|P] [*link*]

dlstat show-link [-r [-F] | -t] [-i *interval*] [-a]
[-p] [-o *field*[,...]] [-u R|K|M|G|T|P] [*link*]

dlstat show-link -h [-a] -f *filename* [-d] [-F *format*] [-s *time*]
[-e *time*] [*link*]

dlstat show-aggr [-r | -t] [-i *interval*] [-p] [-o *field*[,...]]
[-u R|K|M|G|T|P] [*link*]

Description The `dlstat` command reports run time statistics about data links. `dladm(1M)` `show-phys` provides link-name information to `dlstat show-phys`. `dladm(1M)` `show-link` provides link-name information to `dlstat show-link`. `dladm(1M)` `show-aggr` provides link-aggregation information to `dlstat show-aggr`.

`dlstat` has the six forms of commands shown in the SYNOPSIS, above. The first two forms do not have subcommands, while the remain forms do. All six forms are described under “Subcommands,” below.

Options The `dlstat` command has the following options and operands that are common among a number of command forms shown under “Subcommands,” below.

-a

Dump all total statistics fields.

-i *interval*

Specify an interval in seconds at which statistics are refreshed. The default interval is one second.

-o *field*[,...]

Display a case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value `all` to display all supported fields.

List of supported RX fields:

- link
- iusedby
- ibytes
- ipkts
- intrs
- polls
- hdrops: hardware drops
- sdrops: software drops (owing to bandwidth enforcement)

- `ch<10`: number of packet chains of length < 10
- `ch10-50`: number of packet chains of length between 10 and 50
- `ch>50`: number of packet chains of length > 50

List of TX side fields:

- `link`
- `obytes`
- `opackets`
- `oerrors`
- `opktdrop`
- `blkcnt`
- `ublkcnt`

-p

Display output in a stable, machine-parseable format.

-r

Display receive-side statistics only. Includes bytes and packets received, hardware and software drops, and so forth. See “Examples” for complete listing.

-t

Display transmit-side statistics only. Includes bytes and packets sent, hardware and software drops, and so forth. See “Examples” for complete listing.

-u R|K|M|G|T|P

If used, allows choosing the unit in which to display all statistics, for example, R:raw count, K:Kilobits, M:Megabits, T:Terabits, P:Petabits. If not used, then different units, as appropriate, are used to display the statistics, using the format *xy.zU*, where *x*, *y*, and *z* are numbers and *U* is the appropriate unit.

link

If specified, display the statistics only for the named link, physical device (for `show-phys`), or aggregation (for `show-aggr`). Otherwise, display statistics for all links, devices, or aggregations.

Sub-commands `dlstat` supports the following command forms.

`dlstat [-r | -t] [-i interval] [link]`

Iteratively examine all links and report statistics. The output is sorted in descending order of link utilization. If no link is specified, the system displays statistics for all links. The traffic statistics are displayed per link and not per physical device. For example, for a VNIC configured on a physical link, traffic flowing through that VNIC is not reflected in the statistics for the underlying physical link. However, the link statistics will include traffic that matches user-defined flows configured on top of that link.

This command form has one option that is not described under “Options,” above:

-A

Dump all statistics fields for this data-link. Output statistics of this command are inclusive of all the statistics reported by all other `dlstat` commands.

`dlstat [-a | -A] [-i interval] [-p] [-o field[,...]] [-u R|K|M|G|T|P] [link]`

Allows specifying which statistics to display.

The options for this command form are described under “Options,” above.

`dlstat show-phys [-r | -t] [-i interval] [-a] [-p] [-o field[,...]] [-u R|K|M|G|T|P] [link]`

Display statistics for a physical device.

The options for this subcommand are described under “Options,” above.

`dlstat show-link [-r [-F] | -t] [-i interval] [-a] [-p] [-o field[,...]] [-u R|K|M|G|T|P] [link]`

Display statistics for a link.

This subcommand has one option not described under “Options,” above:

-F Display software fanout statistics.

`dlstat show-link -h [-a] -f filename [-d] [-F format] [-s time] [-e time] [link]`

Show the network usage history from a stored extended accounting file. Use of this syntax requires that net accounting has been previously configured and enabled by using [acctadm\(1M\)](#). The default output is the summary of network usage of the existing links for the entire period when extended accounting was enabled.

The *link* argument is as described under “Options,” above.

-a

Display all historical network usage for the specified period when extended accounting is enabled. This includes usage information about links that have already been deleted.

-f *filename*

Specify the file from which extended accounting records of network usage history are read.

-d

Display the dates for which there is logging information. The date is in the format *mm/dd/yyyy*.

-F *format*

Specify the output format of the network usage history information. `gnuplot` is the only supported format.

-s *time*

-e *time*

Specify start and stop times for data display. Time is in the format *MM/DD/YYYY, hh:mm:ss*. *hh* uses 24-hour clock notation.

`dlstat show-aggr [-r | -t] [-i interval] [-p] [-o field[,...]] [-u R|K|M|G|T|P] [link]`

Display per-port statistics for an aggregation.

The options for this subcommand are described under “Options,” above.

Examples EXAMPLE 1 Displaying Statistics

To display statistics for all the links, enter following command. Statistics are displayed as 3-digits followed by decimal and then 2 digits with the appropriate unit.

```
# dlstat
LINK  IPKTS  RBYTES  OPKTS  OBYTES
e1000g0 101.88K 32.86M 40.16K 4.37M
  nxge1  4.50M  6.78G  1.38M 90.90M
  vnic1      8    336      0      0
```

EXAMPLE 2 Displaying RX-side Statistics

The following command displays receive-side statistics every one second.

```
# dlstat -r -i 1
LINK  IPKTS  RBYTES  INTRS  POLLS  CH<10  CH10-50  CH>50
e1000g0 101.91K 32.86M 87.56K 14.35K 3.70K   205      5
  nxge1  9.61M 14.47G  5.79M  3.82M 379.98K 85.66K  1.64K
  vnic1      8    336      0      0      0      0      0
e1000g0      0      0      0      0      0      0      0
  nxge1 82.13K 123.69M 50.00K 32.13K  3.17K   724     24
  vnic1      0      0      0      0      0      0      0
.      .      .      .      .      .      .      .
.      .      .      .      .      .      .      .
.      .      .      .      .      .      .      .
```

EXAMPLE 3 Displaying Statistics per Hardware Ring

The following commands displays statistics on a per receive-side hardware ring basis.

```
# dlstat show-phys -r nxge1
LINK TYPE INDEX  IPKTS  RBYTES
nxge1 rx    0     21   1.79K
nxge1 rx    1      0      0
nxge1 rx    2   1.39M  2.10G
nxge1 rx    3      0      0
nxge1 rx    4   6.81M 10.26G
nxge1 rx    5   4.63M  6.97G
nxge1 rx    6   3.97M  5.98G
nxge1 rx    7      0      0
```

EXAMPLE 4 Displaying Statistics per Lane

The following commands displays statistics on a per receive-side lane basis. First, an interface with dedicated hardware lanes:

```
# dlstat show-link -r nxge1
LINK TYPE  ID INDEX  IPKTS  RBYTES  INTRS  POLLS  CH<10  CH10-50  CH>50
nxge1 rx  local  --      0      0      0      0      0      0      0
```

EXAMPLE 4 Displaying Statistics per Lane *(Continued)*

```

nxge1 rx hw 1 0 0 0 0 0 0 0
nxge1 rx hw 2 1.73M 2.61G 1.33M 400.22K 67.03K 7.49K 38
nxge1 rx hw 3 0 0 0 0 0 0 0
nxge1 rx hw 4 8.44M 12.71G 4.35M 4.09M 383.28K 91.24K 2.09K
nxge1 rx hw 5 5.68M 8.56G 3.72M 1.97M 203.68K 43.94K 854
nxge1 rx hw 6 4.90M 7.38G 3.11M 1.80M 168.59K 42.34K 620
nxge1 rx hw 7 0 0 0 0 0 0 0

```

Then, an interface without dedicated hardware lanes, that is, a software lane only:

```

# dlstat show-link -r ixgbe0
LINK TYPE ID INDEX IPKTS RBYTES INTRS POLLS CH<10 CH10-50 CH>50
ixgbe0 rx local -- 0 0 0 0 0 0 0
ixgbe0 rx sw -- 794.28K 1.19G 794.28K 0 0 0 0

```

EXAMPLE 5 Displaying Receive-Side Fanout Statistics

The following command displays receive-side fanout statistics. Consider a 10 Gb Ethernet card configured to run with only two of the available RX rings.

```

# dlstat show-link -r -F vnic1
LINK ID INDEX FOUT IPKTS
ixgbe0 local -- 0 0
ixgbe0 hw 0 0 382.47K
ixgbe0 hw 0 1 0
ixgbe0 hw 1 0 367.50K
ixgbe0 hw 1 1 433.24K

```

EXAMPLE 6 Displaying Transmit-Side Statistics

The following command displays transmit-side statistics at five-second intervals.

```

# dlstat -t -i 5
LINK OPKTS OBYTES BLKCNT UBLKCNT
e1000g0 40.24K 4.37M 0 0
nxge1 9.76M 644.14M 0 0
vnic1 0 0 0 0
e1000g0 0 0 0 0
nxge1 26.82K 1.77M 0 0
vnic1 0 0 0 0
. . . . .
. . . . .
. . . . .

```

EXAMPLE 7 Displaying Transmit-Side Ring Statistics

The following command displays transmit-side hardware ring statistics.

EXAMPLE 7 Displaying Transmit-Side Ring Statistics *(Continued)*

```
# dlstat show-phys -t nxge1
LINK TYPE INDEX  OPKTS  OBYTES
nxge1 tx    0      44    3.96K
nxge1 tx    1      0      0
nxge1 tx    2    1.48M 121.68M
nxge1 tx    3    2.45M 201.11M
nxge1 tx    4    1.47M 120.82M
nxge1 tx    5      0      0
nxge1 tx    6    1.97M 161.57M
nxge1 tx    7    4.59M 376.21M
nxge1 tx    8    2.43M 199.24M
nxge1 tx    9      0      0
nxge1 tx   10    3.23M 264.69M
nxge1 tx   11    1.88M 153.96M
```

EXAMPLE 8 Displaying Transmit-Side Lane Statistics

The following command displays transmit-side lane statistics.

```
# dlstat show-link -t nxge1
LINK TYPE  ID INDEX  OPKTS  OBYTES  BLKCNT  UBLKCNT
nxge1 tx   hw    0      32    1.44K      0      0
nxge1 tx   hw    1      0      0 0      0
nxge1 tx   hw    2    1.48M  97.95M      0      0
nxge1 tx   hw    3    2.45M 161.87M      0      0
nxge1 tx   hw    4    1.47M  97.25M      0      0
nxge1 tx   hw    5      3     276      0      0
nxge1 tx   hw    6    1.97M 130.05M      0      0
nxge1 tx   hw    7    4.59M 302.80M      0      0
nxge1 tx   hw    8    2.42M 302.80M      0      0
nxge1 tx   hw    9      0      0      0      0
nxge1 tx   hw   10    3.23M 213.05M      0      0
nxge1 tx   hw   11    1.88M 123.93M      0      0
```

EXAMPLE 9 Selecting a Particular Set of Statistics

The following command shows how you can select a set of statistics of particular interest.

```
# dlstat show-link -r -o LINK,TYPE,ID,INDEX,INTRS,POLLS nxge1
LINK TYPE  ID INDEX  INTRS  POLLS
nxge1 rx   local  --      0      0
nxge1 rx   hw    1      0      0
nxge1 rx   hw    2    2.47M 753.90K
nxge1 rx   hw    3      0      0
nxge1 rx   hw    4    8.24M  7.72M
nxge1 rx   hw    5    6.96M  3.68M
nxge1 rx   hw    6    5.82M  3.36M
nxge1 rx   hw    7      0      0
```

EXAMPLE 10 Displaying Historical Network Usage

Network usage history statistics can be stored by using the extended accounting facility, [acctadm\(1M\)](#), with a command such as the following:

```
# acctadm -e basic -f /var/log/net.log net
acctadm net
Network accounting: active
  Network accounting file: /var/log/net.log
  Tracked Network resources: basic
Untracked Network resources: src_ip,dst_ip,src_port,dst_port,protocol,
                             dsfield
```

The saved historical data can then be retrieved in summary form with a command such as the following:

```
# dlstat show-link -h -f /var/log/net.log
LINK      DURATION  IPACKETS  RBYTES    OPACKETS  OBYTES    BANDWIDTH
e1000g0   80        1031     546908    0         0         2.44 Kbps
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

```
/usr/sbin
```

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcsu |
| Interface Stability | See below |

Screen output is Uncommitted. The invocation is Committed.

See Also [acctadm\(1M\)](#), [dladm\(1M\)](#), [ifconfig\(1M\)](#), [kstat\(1M\)](#), [netstat\(1M\)](#), [attributes\(5\)](#)

Name dmesg – collect system diagnostic messages to form error log

Synopsis /usr/bin/dmesg
/usr/sbin/dmesg

Description dmesg is made obsolete by [syslogd\(1M\)](#) for maintenance of the system error log.

dmesg looks in a system buffer for recently printed diagnostic messages and prints them on the standard output.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|----------------------------------|
| Availability | system/extended-system-utilities |

See Also [syslogd\(1M\)](#), [attributes\(5\)](#)

Name dminfo – report information about a device entry in a device maps file

Synopsis dminfo [-v] [-a] [-f *pathname*]
 dminfo [-v] [-a] [-f *pathname*] -n *dev* -name...
 dminfo [-v] [-a] [-f *pathname*] -d *dev* -path...
 dminfo [-v] [-a] [-f *pathname*] -t *dev* -type...
 dminfo [-v] [-f *pathname*] -u *dm* -entry

Description dminfo reports and updates information about the [device_maps\(4\)](#) file.

Options The following options are supported

- a Succeed if any of the requested entries are found. If used with -v, all entries that match the requested case(s) are printed.
- d *dev-path* Search by *dev-path*. Search [device_maps\(4\)](#) for a device special pathname in the *device_list* field matching the *dev-path* argument. This option cannot be used with -n, -t or -u.
- f *pathname* Use a device_maps file with *pathname* instead of /etc/security/device_maps.
- n *dev-name* Search by *dev-name*. Search [device_maps\(4\)](#) for a *device_name* field matching *dev-name*. This option cannot be used with -d, -t or -u.
- t *dev-type* Search by *dev-type*. Search [device_maps\(4\)](#) for a *device_type* field matching the given *dev-type*. This option cannot be used with -d, -n or -u.
- u *dm-entry* Update the [device_maps\(4\)](#) file. This option is provided to add entries to the [device_maps\(4\)](#) file. The *dm-entry* must be a complete [device_maps\(4\)](#) file entry. The *dm-entry* has fields, as in the device_maps file. It uses the colon (:) as a field separator, and white space as the *device_list* subfield separators. The *dm-entry* is not made if any fields are missing, or if the *dm-entry* would be a duplicate. The default device maps file can be updated only by the super user.
- v Verbose. Print the requested entry or entries, one line per entry, on the standard output. If no entries are specified, all are printed.

Exit Status 0 Successful completion.
 1 Request failed.
 2 Incorrect syntax.

Files /etc/security/device_maps

Notes The functionality described in this man page is available only if the Solaris Auditing feature has been enabled.

Name dns-sd – Multicast DNS (mDNS) & DNS Service Discovery (DNS-SD) Test Tool

Synopsis dns-sd -R *name type domain port* [*key=value ...*]

dns-sd -B *type domain*

dns-sd -L *name type domain*

dns-sd -Q *FQDN rrtype rrclass*

dns-sd -C *FQDN rrtype rrclass*

dns-sd -P *name type domain port host IP* [*key=value ...*]

dns-sd -E | -F | -A | -U | -N | -T | -M | -I

Description The `dns-sd` command is a network diagnostic tool, much like [ping\(1M\)](#) or [traceroute\(1M\)](#). However, unlike those tools, most of its functionality is not implemented in the `dns-sd` executable itself, but in library code that is available to any application. The library API that `dns-sd` uses is documented in `/usr/include/dns_sd.h`.

The `dns-sd` command is primarily intended for interactive use. Because its command-line arguments and output format are subject to change, invoking it from a shell script can be unpredictable. Additionally, the asynchronous nature of DNS Service Discovery does not easily lend itself to script-oriented programming. This style of asynchronous interaction works best with applications that are either multi-threaded, or use a main event-handling loop to receive keystrokes, network data, and other asynchronous event notifications as they happen.

Options The following options are supported:

-R *name type domain port* [*key=value ...*]

Register (advertise) a service in the specified domain with the given *name* and *type* as listening (on the current machine) on the specified *port*.

name can be any arbitrary unicode text, containing any legal unicode characters (including dots, spaces, slashes, colons, and so on without any restrictions), up to 63 UTF-8 bytes long.

type must be of the form “_app-proto._tcp” or “_app-proto._udp”, where “app-proto” is an application protocol name registered at <http://www.dns-sd.org/ServiceTypes.html>.

domain is the domain in which to register the service. In current implementations, only the local multicast domain “local” is supported. In the future, registering will be supported in any arbitrary domain that has a working DNS Update server [RFC 2136]. The domain “.” is a synonym for “pick a sensible default”, which currently means “local”.

port is a number from 0 to 65535, and is the TCP or UDP port number upon which the service is listening. Registering a service on port 0 allows an application to explicitly advertise the non-availability of a service.

Additional attributes of the service may optionally be described by *key/value* pairs, which are stored in the advertised service's DNS TXT record. Allowable keys and values are listed with the service registration at <http://www.dns-sd.org/ServiceTypes.html>

-B *type domain*

Browse for instances of service *type* in *domain*.

For valid types, see <http://www.dns-sd.org/ServiceTypes.html>. Omitting the domain name or using "." means "pick a sensible default."

-L *name type domain*

Look up and display the information necessary to contact and use the named service. This information includes the hostname of the machine where that service is available, the port number on which the service is listening, and (if present) TXT record attributes describing properties of the service.

In a typical application, browsing happens rarely, while lookup (or "resolving") happens every time the service is used. For example, a user does not browse the network to pick a default printer that often, but once a default printer has been picked, that named service is resolved to its current IP address and port number every time the user presses Cmd-P to print.

-Q *FQDN rrtype rrclass*

Generic query for any resource record type and class.

-C *FQDN rrtype rrclass*

Generic query for any resource record type and class. This option also reconfirms each result from the query. Reconfirming the record instructs `mdnsd(1M)` to verify the validity of the record. If the record is not valid `mdnsd(1M)` flushes the record from the daemon's cache and also from other `mdnsd(1M)` caches on the network.

-P *name type domain port host IP [key=value ...]*

Register (advertise) a service in the specified domain with the given *name* and *type* listening on the specified port and accessible on another host. This option should be used to advertise by proxy a service accessible on another host. The host name and IPv4 address to access the service must be specified.

-E

Discover recommended registration domains. This option returns the recommended domains to register a service. The recommended registration domains are returned by querying the name servers in `resolv.conf(4)`.

-F

Discover recommended browsing domains. This option returns the recommended domains for browsing services. The recommended browsing domains are returned by querying the name servers in `resolv.conf(4)`.

- A
Test registering service with Multicast DNS and test the add, update and delete operations of DNS records with Multicast DNS.
- U
Test registering service with Multicast DNS and test updating of DNS TXT records for a service registered with Multicast DNS.
- N
Test adding a large NULL record for a service registered with Multicast DNS.
- T
Test adding a large TXT record for a service registered with Multicast DNS.
- M
Test creating a registration with multiple TXT records.
- I
Test registering and then immediately updating a TXT record.

Examples EXAMPLE 1 Advertising a printing service

The following command advertises the existence of LPR printing service on port 515 on this machine, so that it will be available to DNS-SD compatible printing clients:

```
dns-sd -R "My Test" _printer._tcp. . 515 pdl=application/postscript
```

For this registration to be useful, the LPR service should be available on port 515. Advertising a service that does not exist is not very useful.

EXAMPLE 2 Advertising a web page

The following command advertises a web page being served by an HTTP server on port 80 on this machine, so that it will appear on the Bonjour list in Safari and other DNS-SD compatible Web clients:

```
dns-sd -R "My Test" _http._tcp . 80 path=/path-to-page.html
```

EXAMPLE 3 Finding the advertised web pages on the local network

The following command finds the advertised web pages on the local network (the same list that Safari shows):

```
dns-sd -B _http._tcp
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|--------------------------|
| Availability | service/network/dns/mdns |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Volatile |

See Also [mdnsd\(1M\)](#), [ping\(1M\)](#), [ping\(1M\)](#), [resolv.conf\(4\)](#), [attributes\(5\)](#)

Name dnssec-dsfromkey – DNSSEC DS RR generation tool

Synopsis dnssec-dsfromkey [-v *level*] [-1] [-2] [-a *alg*] *keyfile*
 dnssec-dsfromkey -s [-v *level*] [-1] [-2] [-a *alg*] [-c *class*]
 [-d *dir*] *keyfile*

Description dnssec-dsfromkey

Options The following options are supported:

- 1
Use SHA-1 as the digest algorithm. The default is to use both SHA-1 and SHA-256.
- 2
Use SHA-256 as the digest algorithm.
- a *algorithm*
Select the digest algorithm. The value of *algorithm* must be one of SHA-1 (SHA1) or SHA-256 (SHA256). These values are case-insensitive.
- v *level*
Sets the debugging level.
- s
Keyset mode: in place of the keyfile name, the argument is the DNS domain name of a keyset file. The -c and -d options have meaning only in this mode.
- c *class*
Specifies the DNS class (default is IN); useful only in the keyset mode.
- d *directory*
Look for keyset files in *directory* as the directory; ignored when not in the keyset mode.

Examples To build the SHA-256 DS RR from the `Kexample.com.+003+26160` keyfile name, use a command such as the following:

```
# dnssec-dsfromkey -2 Kexample.com.+003+26160
```

This command would produce output similar to the following:

```
example.com. IN DS 26160 5 2
3A1EADA7A74B8D0BA86726B0C227AA85AB8BBD2B2004F41A868A54F0
C5EA0B94
```

Files The keyfile can be designated by the key identification `Knnnn.+aaa+iiii`, or the full file name `Knnnn.+aaa+iiii.key`, as generated by [dnssec-keygen\(1M\)](#).

The keyset file name is built from the directory, the string `keyset-` and the *dnsname*.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|--------------------------|
| Availability | service/network/dns/bind |
| Interface Stability | Volatile |

See Also [dnssec-keygen\(1M\)](#), [dnssec-signzone\(1M\)](#), [attributes\(5\)](#)

RFC 3658, RFC 4509

See the BIND 9 *Administrator's Reference Manual*. As of the date of publication of this man page, this document is available at <https://www.isc.org/software/bind/documentation>.

Caution A keyfile error can produce a “file not found” message, even if the file exists.

- Name** dnssec-keyfromlabel – DNSSEC key generation tool
- Synopsis** dnssec-keyfromlabel -a *algorithm* -l *label* [-c *class*] [-f *flag*] [-k] [-n *nametype*] [-p *protocol*] [-t *type*] [-v *level*] *name*
- Description** dnssec-keyfromlabel retrieves keys with a specified label from a crypto hardware device and builds key files for DNSSEC (Secure DNS), as defined in RFC 2535 and RFC 4034.
- Options** The following options are supported:
- a *algorithm*
Selects the cryptographic algorithm. The value of *algorithm* must be one of RSAMD5 (RSA) or RSASHA1, DSA, NSEC3RSASHA1, NSEC3DSA, or DH (Diffie-Hellman). These values are case-insensitive.

Note that for DNSSEC, RSASHA1 is a mandatory-to-implement algorithm, and DSA is recommended. Note also that DH automatically sets the -k flag.
 - l *label*
Specifies the label of keys in the crypto hardware (PKCS#11) device.
 - n *nametype*
Specifies the owner type of the key. The value of *nametype* must either be ZONE (for a DNSSEC zone key (KEY/DNSKEY)), HOST or ENTITY (for a key associated with a host (KEY)), USER (for a key associated with a user (KEY)), or OTHER (DNSKEY). These values are case-insensitive.
 - c *class*
Indicates that the DNS record containing the key should have the specified class. If not specified, class IN is used.
 - f *flag*
Set the specified flag in the flag field of the KEY/DNSKEY record. The only recognized flag is KSK (Key Signing Key) DNSKEY.
 - h
Displays a short summary of the options and arguments to dnssec-keyfromlabel.
 - k
Generate KEY records rather than DNSKEY records.
 - p *protocol*
Sets the protocol value for the generated key. The protocol is a number between 0 and 255. The default is 3 (DNSSEC). Other possible values for this argument are listed in RFC 2535 and its successors.
 - t *type*
Indicates the use of the key. *type* must be one of AUTHCONF, NOAUTHCONF, NOAUTH, or NOCONF. The default is AUTHCONF. AUTH refers to the ability to authenticate data, and CONF the ability to encrypt data.

-v level

Sets the debugging level.

Generated Key Files When `dnssec-keyfromlabel` completes successfully, it displays a string of the form `Knnnn.+aaa+iiii` to the standard output. This is an identification string for the key files it has generated, which translates as follows.

- *nnnn* is the key name.
- *aaa* is the numeric representation of the algorithm.
- *iiii* is the key identifier (or footprint).

`dnssec-keyfromlabel` creates two files, with names based on the displayed string. `Knnnn.+aaa+iiii.key` contains the public key, and `Knnnn.+aaa+iiii.private` contains the private key.

The first file contains a DNS KEY record that can be inserted into a zone file (directly or with an `$INCLUDE` statement).

The second file contains algorithm-specific fields. For obvious security reasons, this file does not have general read permission.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------------|--------------------------|
| Availability | service/network/dns/bind |
| Interface Stability | Volatile |

See Also [dnssec-keygen\(1M\)](#), [dnssec-signzone\(1M\)](#), [attributes\(5\)](#)

RFC 2539, RFC 2845, RFC 4033

See the BIND 9 *Administrator's Reference Manual*. As of the date of publication of this man page, this document is available at <https://www.isc.org/software/bind/documentation>.

-
- Name** dnssec-keygen – DNSSEC key generation tool
- Synopsis** dnssec-keygen -a *algorithm* -b *keysize* -n *nametype* [-ehk]
 [-c *class*] [-f *flag*] [-g *generator*] [-p *protocol*]
 [-r *randomdev*] [-s *strength*] [-t *type*] [-v *level*] *name*
- Description** The dnssec-keygen utility generates keys for DNSSEC (Secure DNS), as defined in RFC 2535 and RFC 4034. It can also generate keys for use with TSIG (Transaction Signatures), as defined in RFC 2845.
- Options** The following options are supported:
- a *algorithm*
 Select the cryptographic algorithm. The value of algorithm must be one of RSAMD5 (RSA) or RSASHA1, DSA, NSEC3RSASHA1, NSEC3DSA, DH (Diffie-Hellman), or HMAC-MD5. These values are case insensitive.

 For DNSSEC, RSASHA1 is a mandatory-to-implement algorithm and DSA is recommended. For TSIG, HMAC-MD5 is mandatory.

Note – HMAC-MD5 and DH automatically set the -k flag.
 - b *keysize*
 Specify the number of bits in the key. The choice of key size depends on the algorithm used. RSAMD5 and RSASHA1 keys must be between 512 and 2048 bits. Diffie-Hellman keys must be between 128 and 4096 bits. DSA keys must be between 512 and 1024 bits and an exact multiple of 64. HMAC-MD5 keys must be between 1 and 512 bits.
 - c *class*
 Indicate that the DNS record containing the key should have the specified class. If not specified, class IN is used.
 - e
 Use a large exponent if generating an RSAMD5 or RSASHA1 key.
 - f *flag*
 Set the specified flag in the flag field of the KEY/DNSKEY record. The only recognized flag is KSK (Key Signing Key) DNSKEY.
 - g *generator*
 Use this *generator* if generating a Diffie Hellman key. Allowed values are 2 and 5. If no generator is specified, a known prime from RFC 2539 will be used if possible; otherwise the default is 2.
 - h
 Print a short summary of the options and arguments to dnssec-keygen.
 - k
 Generate KEY records rather than DNSKEY records.

-n *nametype*

Specify the owner type of the key. The value of *nametype* must either be ZONE (for a DNSSEC zone key (KEY/DNSKEY)), HOST or ENTITY (for a key associated with a host (KEY)), USER (for a key associated with a user(KEY)), or OTHER (DNSKEY). These values are case insensitive. Defaults to ZONE for DNSKEY generation.

-p *protocol*

Set the protocol value for the generated key. The *protocol* argument is a number between 0 and 255. The default is 3 (DNSSEC) Other possible values for this argument are listed in RFC 2535 and its successors.

-r *randomdev*

Specify the source of randomness. If the operating system does not provide a */dev/random* or equivalent device, the default source of randomness is keyboard input. *randomdev* specifies the name of a character device or file containing random data to be used instead of the default. The special value "keyboard" indicates that keyboard input should be used.

-s *strength*

Specify the strength value of the key. The *strength* argument is a number between 0 and 15, and currently has no defined purpose in DNSSEC.

-t *type*

Indicate the use of the key. *type* must be one of AUTHCONF, NOAUTHCONF, NOAUTH, or NOCONF. The default is AUTHCONF. AUTH refers to the ability to authenticate data, and CONF the ability to encrypt data.

-v *level*

Set the debugging level.

Generated Keys When `dnssec-keygen` completes successfully, it prints a string of the form `Knnnnn.+aaa+iiii` to the standard output. This is an identification string for the key it has generated.

- *nnnn* is the key name.
- *aaa* is the numeric representation of the algorithm.
- *iiii* is the key identifier (or footprint).

The `dnssec-keygen` utility creates two files, with names based on the printed string.

- `Knnnnn.+aaa+iiii.key` contains the public key.
- `Knnnnn.+aaa+iiii.private` contains the private key.

The `.key` file contains a DNS KEY record that can be inserted into a zone file (directly or with a `$INCLUDE` statement).

The `.private` file contains algorithm specific fields. For obvious security reasons, this file does not have general read permission.

Both `.key` and `.private` files are generated for symmetric encryption algorithm such as HMAC-MD5, even though the public and private key are equivalent.

Examples EXAMPLE 1 Generating a 768-bit DSA Key

To generate a 768-bit DSA key for the domain `example.com`, the following command would be issued:

```
dnssec-keygen -a DSA -b 768 -n ZONE example.com
```

The command would print a string of the form:

```
Kexample.com.+003+26160
```

The following files would be created:

```
Kexample.com.+003+26160.key
Kexample.com.+003+26160.private
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------------|--------------------------|
| Availability | service/network/dns/bind |
| Interface Stability | Volatile |

See Also [dnssec-signzone\(1M\)](#), [attributes\(5\)](#)

RFC 2539, RFC 2845, RFC 4033

See the BIND 9 *Administrator's Reference Manual*. As of the date of publication of this man page, this document is available at <https://www.isc.org/software/bind/documentation>.

Name dnssec-makekeyset – DNSSEC zone signing tool

Synopsis dnssec-makekeyset [-ahp] [-s *start-time*] [-e *end-time*]
[-r *randomdev*] [-t *tll*] [-v *level*] *key...*

Description The dnssec-makekeyset utility generates a key set from one or more keys created by [dnssec-keygen\(1M\)](#). It creates a file containing a KEY record for each key, and self-signs the key set with each zone key. The output file is of the form *keyset-nnnn.*, where *nnnn* is the zone name.

Options

- a Verify all generated signatures.
- e *end-time* Specify the date and time when the generated SIG records expire. As with *start-time*, an absolute time is indicated in YYYYMMDDHHMMSS notation. A time relative to the start time is indicated with +N, which is N seconds from the start time. A time relative to the current time is indicated with now+N. If no *end-time* is specified, 30 days from the start time is used as a default.
- h Print a short summary of the options and arguments to dnssec-makekeyset().
- p Use pseudo-random data when signing the zone. This is faster, but less secure, than using real random data. This option may be useful when signing large zones or when the entropy source is limited.
- r *randomdev* Specify the source of randomness. If the operating system does not provide a /dev/random or equivalent device, the default source of randomness is keyboard input. The *randomdev* argument specifies the name of a character device or file containing random data to be used instead of the default. The special value keyboard indicates that keyboard input should be used.
- s *start-time* Specify the date and time when the generated SIG records become valid. This can be either an absolute or relative time. An absolute start time is indicated by a number in YYYYMMDDHHMMSS notation; 20000530144500 denotes 14:45:00 UTC on May 30th, 2000. A relative start time is indicated by +N, which is N seconds from the current time. If no *start-time* is specified, the current time is used.
- t *tll* Specify the TTL (time to live) of the KEY and SIG records. The default is 3600 seconds.
- v *level* Set the debugging level.

Operands The following operands are supported:

key The list of keys to be included in the keyset file. These keys are expressed in the form *Knnnn.+aaa+iivv* as generated by dnssec-keygen.

Examples **EXAMPLE 1** Generates a keyset containing the DSA key for `example.com`.

The following command generates a keyset containing the DSA key for `example.com` generated in the [dnssec-keygen\(1M\)](#) manual page.

```
dnssec-makekeyset -t 86400 -s 20000701120000 -e +2592000 \
Kexample.com.+003+26160
```

In this example, `dnssec-makekeyset()` creates the file `keyset-example.com`. This file contains the specified key and a self-generated signature.

The DNS administrator for `example.com` could send `keyset-example.com` to the DNS administrator for `.com` for signing, if the `.com` zone is DNSSEC-aware and the administrators of the two zones have some mechanism for authenticating each other and exchanging the keys and signatures securely.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWbind9 |
| Interface Stability | Volatile |

See Also [dnssec-keygen\(1M\)](#), [dnssec-signkey\(1M\)](#), [attributes\(5\)](#)

RFC 2535

BIND 9 Administrator Reference Manual

Notes Source for BIND9 is available in the SUNWbind9S package.

Name dnssec-signkey – DNSSEC key set signing tool

Synopsis dnssec-signkey [-ahp] [-c *class*] [-e *end-time*]
[-r *randomdev*] [-s *start-time*] [-v *level*] *keyset* *key*...

Description The `dnssec-signkey` utility signs a keyset. Typically the keyset will be for a child zone and will have been generated by `dnssec-makekeyset(1M)`. The child zone's keyset is signed with the zone keys for its parent zone. The output file is of the form `signedkey-nnnn`., where *nnnn* is the zone name.

Options The following options are supported:

- a Verify all generated signatures.
- c *class* Specify the DNS class of the key sets.
- e *end-time* Specify the date and time when the generated SIG records expire. As with *start-time*, an absolute time is indicated in YYYYMMDDHHMMSS notation. A time relative to the start time is indicated with +*N*, which is *N* seconds from the start time. A time relative to the current time is indicated with now+*N*. If no *end-time* is specified, 30 days from the start time is used as a default.
- h Prints a short summary of the options and arguments to `dnssec-signkey()`.
- p Use pseudo-random data when signing the zone. This is faster, but less secure, than using real random data. This option may be useful when signing large zones or when the entropy source is limited.
- r *randomdev* Specify the source of randomness. If the operating system does not provide a `/dev/random` or equivalent device, the default source of randomness is keyboard input. *randomdev* specifies the name of a character device or file containing random data to be used instead of the default. The special value `keyboard` indicates that keyboard input should be used.
- s *start-time* Specify the date and time when the generated SIG records become valid. This can be either an absolute or relative time. An absolute start time is indicated by a number in YYYYMMDDHHMMSS notation; 20000530144500 denotes 14:45:00 UTC on May 30th, 2000. A relative start time is indicated by +*N*, which is *N* seconds from the current time. If no *start-time* is specified, the current time is used.
- v *level* Set the debugging level.

Operands The following operands are supported:

- key* The keys used to sign the child's keyset.
- keyset* The file containing the child's keyset.

Examples **EXAMPLE 1** Sign the *keyset* file for `example.com`.

The DNS administrator for a DNSSEC-aware `.com` zone would use the following command to sign the *keyset* file for `example.com` created by `dnssec-makekeyset` with a key generated by `dnssec-keygen`:

```
dnssec-signkey keyset-example.com. Kcom.+003+51944
```

In this example, `dnssec-signkey` creates the file `signedkey-example.com`, which contains the `example.com` keys and the signatures by the `.com` keys.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWbind9 |
| Interface Stability | Volatile |

See Also [dnssec-keygen\(1M\)](#), [dnssec-makekeyset\(1M\)](#), [dnssec-signzone\(1M\)](#), [attributes\(5\)](#)

Notes Source for BIND9 is available in the SUNWbind9S package.

Name dnssec-signzone – DNSSEC zone signing tool

Synopsis dnssec-signzone [-Aaghtz] [-c *class*] [-d *directory*]
 [-e *end-time*] [-f *output-file*] [-H *iterations*] [-I *input_format*]
 [-i *interval*] [-k *key*] [-l *domain*] [-N *soa-serial-format*] [-n *ncpus*]
 [-O *output_format*] [-o *origin*] [-r *randomdev*] [-s *start-time*]
 [-v *level*] [-3 *salt*] *zonefile* [*key*]...

Description The dnssec-signzone utility signs a zone. It generates NSEC and RRSIG records and produces a signed version of the zone. The security status of delegations from the signed zone (that is, whether the child zones are secure or not) is determined by the presence or absence of a keyset file for each child zone.

Options The following options are supported:

-A

When generating an NSEC3 chain, set the OPTOUT flag on all NSEC3 records and do not generate NSEC3 records for insecure delegations.

-a

Verify all generated signatures.

-c *class*

Specify the DNS class of the zone.

-d *directory*

Look for keyset files in *directory*.

-e *end-time*

Specify the date and time when the generated RRSIG records expire. As with *start-time*, an absolute time is indicated in YYYYMMDDHHMMSS notation. A time relative to the start time is indicated with +*N*, which is *N* seconds from the start time. A time relative to the current time is indicated with now+*N*. If no *end-time* is specified, 30 days from the start time is used as a default.

-f *output-file*

The name of the output file containing the signed zone. The default is to append .signed to the input file name.

-g

Generate DS records for child zones from keyset files. Existing DS records will be removed.

-H *iterations*

When generating a NSEC3 chain use the number of iterations specified by *iterations*. The default is 100.

-h

Prints a short summary of the options and arguments to dnssec-signzone().

-I *input-format*

The format of the input zone file. Possible formats are `text` (default) and `raw`. This option is primarily intended for dynamic signed zones so that the dumped zone file in a non-text format containing updates can be signed directly. The use of this option serves no purpose for non-dynamic zones.

-i *interval*

Specify the cycle interval as an offset from the current time (in seconds). When a previously signed zone is passed as input, records could be resigned. If an RRSIG record expires after the cycle interval, it is retained. Otherwise, it is considered to be expiring soon and will be replaced.

The default cycle interval is one quarter of the difference between the signature end and start times. If neither *end-time* or *start-time* are specified, `dnssec-signzone` generates signatures that are valid for 30 days, with a cycle interval of 7.5 days. Any existing RRSIG records due to expire in less than 7.5 days would be replaced.

-j *jitter*

When signing a zone with a fixed signature lifetime, all RRSIG records issued at the time of signing expire simultaneously. If the zone is incrementally signed, that is, a previously-signed zone is passed as input to the signer, all expired signatures have to be regenerated at about the same time. The jitter option specifies a jitter window that will be used to randomize the signature-expire time, thus spreading incremental signature regeneration over time.

Signature lifetime jitter also benefits, to some extent, validators and servers by spreading out cache expiration. That is, if large numbers of RRSIGs from all caches do not expire at the same time, there will be less congestion than if all validators needed to refetch at almost the same time.

-k *key*

Treat specified *key* as a key-signing key, ignoring any key flags. This option can be specified multiple times.

-l *domain*

Generate a DLV set in addition to the key (DNSKEY) and DS sets. The domain is appended to the name of the records.

-N *soa-serial-format*

The SOA serial number format of the signed zone. Possible formats are `keep` (default), `increment` and `unixtime`, described as follows.

`keep`

Do not modify the SOA serial number.

`increment`

Increment the SOA serial number using RFC 1982 arithmetic.

-
- `unixtime`
Set the SOA serial number to the number of seconds since epoch.
- `-n nthreads`
Specifies the number of threads to use. By default, one thread is started for each detected CPU.
- `-O output_format`
The format of the output file containing the signed zone. Possible formats are `text` (default) and `raw`.
- `-o origin`
Specify the zone origin. If not specified, the name of the zone file is assumed to be the origin.
- `-p`
Use pseudo-random data when signing the zone. This is faster, but less secure, than using real random data. This option may be useful when signing large zones or when the entropy source is limited.
- `-r randomdev`
Specifies the source of randomness. If the operating system does not provide a `/dev/random` or equivalent device, the default source of randomness is keyboard input. `randomdev` specifies the name of a character device or file containing random data to be used instead of the default `/dev/random`. The special value `keyboard` indicates that keyboard input should be used.
- `-s start-time`
Specify the date and time when the generated RRSIG records become valid. This can be either an absolute or relative time. An absolute start time is indicated by a number in `YYYYMMDDHHMMSS` notation; `20000530144500` denotes 14:45:00 UTC on May 30th, 2000. A relative start time is indicated by `+N`, which is `N` seconds from the current time. If no `start-time` is specified, the current time minus one hour (to allow for clock skew) is used.
- `-t`
Print statistics at completion.
- `-v level`
Set the debugging level.
- `-z`
Ignore KSK flag on key when determining what to sign.
- `-3 salt`
Generate a NSEC3 chain with the specified hex-encoded `salt`. A dash (`-`) can be used to indicate that no salt is to be used when generating the NSEC3 chain.

Operands The following operands are supported:

zonefile

The file containing the zone to be signed.

key

Specify which keys should be used to sign the zone. If no keys are specified, then the zone will be examined for DNSKEY records at the zone apex. If these are found and there are matching private keys in the current directory, these will be used for signing.

Examples **EXAMPLE 1** Signing a Zone with a DSA Key

The following command signs the `example.com` zone with the DSA key generated in the example in the [dnssec-keygen\(1M\)](#) manual page (`Kexample.com.+003+17247`). The zone's keys must be in the master file (`db.example.com`). This invocation looks for keyset files in the current directory, so that DS records can be generated from them (`-g`).

```
% dnssec-signzone -g -o example.com db.example.com \
Kexample.com.+003+17247
db.example.com.signed
%
```

In the above example, `dnssec-signzone` creates the file `db.example.com.signed`. This file should be referenced in a zone statement in a `named.conf` file.

EXAMPLE 2 Re-signing a Previously Signed Zone

The following commands re-sign a previously signed zone with default parameters. The private keys are assumed to be in the current directory.

```
% cp db.example.com.signed db.example.com
% dnssec-signzone -o example.com db.example.com \
db.example.com.signed
%
```

RFC 4033

See the BIND 9 *Administrator's Reference Manual*. As of the date of publication of this man page, this document is available at <https://www.isc.org/software/bind/documentation>.

Name domainname – set or display name of the current domain

Synopsis domainname [*name-of-domain*]

Description Without an argument, domainname displays the name of the current domain name used in RPC exchanges, usually referred to as the NIS domain name. This name typically encompasses a group of hosts or passwd entries under the same administration. The domainname command is used by various components of Solaris to resolve names for entries such as are found in passwd, hosts and aliases. By default, naming services such as NIS use domainname to resolve names.

With appropriate privileges (root or an equivalent role [see [rbac\(5\)](#)]), you can set the name of the domain by specifying the name as an argument to the domainname command.

The domain name for various naming services can also be set by other means. For example, ypinit can be used to specify a different domain for all NIS calls. The domain name of the machine is usually set during boot time through the domainname command by the svc:/system/identity:domain service. If the new domain name is not saved in the /etc/defaultdomain file, the machine reverts to the old domain after it reboots.

The [sendmail\(1M\)](#) daemon, as shipped with Solaris, and the sendmail implementation provided by [sendmail.org](#) (formerly referred to as “Berkeley 8.x sendmail”) both attempt to determine a local host's fully qualified host name at startup and both pursue follow-up actions if the initial search fails. It is in these follow-up actions that the two implementations differ.

Both implementations use a standard Solaris or Unix system call to determine its fully qualified host name at startup, following the name service priorities specified in [nsswitch.conf\(4\)](#). To this point, the Solaris and [sendmail.org](#) versions behave identically.

If the request for a fully qualified host name fails, the [sendmail.org](#) sendmail sleeps for 60 seconds, tries again, and, upon continuing failure, resorts to a short name. The Solaris version of sendmail makes the same initial request, but then, following initial failure, calls domainname. If successful, the sleep is avoided.

On a Solaris machine, if you run the [sendmail.org](#) version of sendmail, you get the startup behavior (omitting the domainname call) described above. If you run the Solaris sendmail, the domainname call is made if needed.

If the Solaris sendmail cannot determine the fully qualified host name, use [check-hostname\(1M\)](#) as a troubleshooting aid. This script can offer guidance as to appropriate corrective action.

Files /etc/defaultdomain
/etc/nsswitch.conf

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [svcs\(1\)](#), [check-hostname\(1M\)](#), [hostconfig\(1M\)](#), [named\(1M\)](#), [sendmail\(1M\)](#), [svcadm\(1M\)](#), [ypinit\(1M\)](#), [sys-unconfig\(1M\)](#), [aliases\(4\)](#), [defaultdomain\(4\)](#), [hosts\(4\)](#), [nsswitch.conf\(4\)](#), [passwd\(4\)](#), [attributes\(5\)](#), [rbac\(5\)](#), [smf\(5\)](#)

Notes The domainname service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/identity:domain
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Name drd – Logical Domain Dynamic Reconfiguration daemon

Synopsis /usr/lib/ldoms/drd

Description The drd daemon is part of the framework that enables the addition and removal of resources from a Logical Domain. This framework is collectively called Dynamic Reconfiguration (DR).

drd is responsible for various aspects of DR on a Logical Domain and must be enabled to ensure proper DR functionality. It is started at boot time and has no configuration options.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWldomu |
| Interface Stability | Uncommitted |

See Also [svcs\(1\)](#), [svcadm\(1M\)](#), [syslog\(3C\)](#), [syslog.conf\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Errors drd uses [syslog\(3C\)](#) to report status and error messages. All of the messages are logged with the LOG_DAEMON facility. Error messages are logged with the LOG_ERR and LOG_NOTICE priorities, and informational messages are logged with the LOG_INFO priority. The default entries in the /etc/syslog.conf file log all the drd error messages to the /var/adm/messages log.

Notes The drd service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/platform/sun4v/drd:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Name drvconfig – apply permission and ownership changes to devices

Synopsis `drvconfig [-bn] [-a alias_name] [-c class_name]
[-i drivername] [-m major_num] [-r root_dir]`

Description `devfsadm(1M)` is now the preferred command and should be used instead of `drvconfig`.

The default operation of `drvconfig` is to apply permission and ownership changes to devices. Normally, this command is run automatically after a new driver has been installed (with `add_drv(1M)`) and the system has been rebooted.

Options The following options are supported:

- `-a alias_name` Add the name *alias_name* to the list of aliases that this driver is known by. This option, if used, must be used with the `-m major_num`, the `-b` and the `-i drivername` options.
- `-b` Add a new major number to name binding into the kernel's internal `name_to_major` tables. This option is not normally used directly, but is used by other utilities such as `add_drv(1M)`. Use of the `-b` option requires that `-i` and `-m` be used also. No `/devices` entries are created.
- `-c class_name` The driver being added to the system exports the class *class_name*. This option is not normally used directly, but is used by other utilities. It is only effective when used with the `-b` option.
- `-i drivername` Only configure the devices for the named driver. The following options are used by the implementation of `add_drv(1M)` and `rem_drv(1M)`, and may not be supported in future versions of Solaris:
- `-m major_num` Specify the major number *major_num* for this driver to add to the kernel's `name_to_major` binding tables.
- `-n` Do not try to load and attach any drivers, or if the `-i` option is given, do not try to attach the driver named *drivername*.
- `-r root_dir` Perform operations under *root_dir*, rather than directly under root.

Exit Status 0 Successful completion.

non-zero An error occurred.

- Name** dsbitmap – size Availability Suite bitmap volumes
- Synopsis** dsbitmap -h
 dsbitmap -p *data_volume* [*bitmap_volume*]
 dsbitmap -r *data_volume* [*bitmap_volume*]
- Description** The dsbitmap command calculates the size of the Availability Suite bitmap volume required for use with the specified data volume.
- Options** The following options are supported:
- h
 Prints the usage message for the dsbitmap command
 - p *data_volume* [*bitmap_volume*]
 For the given *data_volume*, dsbitmap calculates and display the required size for the associated Availability Suite Point in Time bitmap volume. The bitmap volume sizes for all possible Availability Suite Point in Time set configurations are displayed. These configurations include Independent shadow, Full size dependent shadow, and Compact dependent shadow. If the optional *bitmap_volume* argument is supplied, dsbitmap determines if this volume is large enough to be used as the bitmap volume for *data_volume*.
 - r *data_volume* [*bitmap_volume*]
 For the given *data_volume*, dsbitmap calculates and displays the required size for the associated Availability Suite Remote Mirror bitmap volume. The bitmap volume sizes for all possible Availability Suite Remote Mirror set configurations are displayed. These configurations include Sync replication, Async replication with memory queue, disk queue and 32 bit refcount. If the optional *bitmap_volume* argument is supplied, dsbitmap determines if this volume is large enough to be used as the bitmap volume for *data_volume*.
- Usage** dsbitmap is typically used by the system administrator during the initial stages of configuring Sun StorageTek Availability Suite software in order to determine the required bitmap volume sizes, and then to check if the bitmap volumes that have been created are suitable.
- Exit Status** The following exit values are returned:
- 0 Successful completion. If the name of a bitmap volume was specified, that volume is sufficiently large for all potential uses.
 - 1 An error occurred.
 - 2 An invalid option was supplied on the command line.
 - 3 The specified bitmap volume is not large enough to be used as an Availability Suite Remote Mirror bitmap for an asynchronous set with a disk queue, but is large enough to be used for all other Remote Mirror set configurations.
 - 4 The specified bitmap volume is not large enough to be used as an Availability Suite Remote Mirror bitmap for any Remote Mirror set configuration.

- 5 The specified bitmap volume is not large enough to be used as an Availability Suite Remote Mirror bitmap for any Remote Mirror set configuration.
- 6 The specified bitmap volume is not large enough to be used as an Availability Suite Point in Time bitmap for a compact dependent shadow, but is large enough to be used for all other Point in Time set configurations.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-------------------------------------------------------------------------------|
| Availability | service/storage/avs/cache-management,
service/storage/avs/cache-management |
| Interface Stability | Committed |

See Also [iiadm\(1M\)](#), [sndradm\(1M\)](#), [attributes\(5\)](#)

Name dscfg – configuration tool for Sun StorageTek Availability Suite software

Synopsis dscfg

```
dscfg -L
dscfg -h
dscfg [-C group]
dscfg [-C group] -i [-p parser_config_file]
dscfg [-C group] -a config_file
dscfg [-C group] [-l]
dscfg [-C group] [-l] -s config_location
dscfg -D dgname
```

Description The `dscfg` command controls the Availability Suite configuration by providing facilities to initialize, list, format, restore the configuration database.

Options If no options are specified, `dscfg` displays the current local configuration location. The `dscfg` command supports the following options:

-L

Displays the status of the lock controlling access to the configuration database. If the configuration database is locked, the type of lock (read or write) is displayed along with the process id of the process that holds the lock.

-h

Displays the usage message for the `dscfg` command.

-i

Initializes the configuration database. As it deletes previous or current configuration information, this option prompts you to confirm the deletion before proceeding.

-p *parser_config_file*

When used with the `-i` option, `dscfg` loads the parser configuration file into the persistent configuration, it reformats the configuration database.

-a *config_file*

Restore the specified *config_file* into the configuration. This option does not do any error checking of the file. Use of this option invalidates the configuration file.

-l

Lists the contents of current configuration database in a format that is suitable for the `-a` option. When used in combination with the `-s` option, it displays the contents stored in the location passed to the `-s` option, but does not set the configuration location.

The options below are for Sun Cluster-configured systems only. *group* can be either Sun Cluster device group or as '-' as local devices.

| | |
|-----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-C group</code> | Display the location of cluster configuration database. |
| <code>-C group -i</code> | Initializes the configuration database entries that only associated with group specified. As it deletes previous or current configuration information, this options prompts you to confirm the deletion before proceeding. |
| <code>-C group -p parser_config_file</code> | When used with the <code>-i</code> option, <code>dscfg</code> loads the parser configuration file into the persistent configuration, it reformats the configuration database entries that only associated with group specified. |
| <code>-C group -a config_file</code> | Restore the specified <code>config_file</code> into the configuration database entries that only associated with group specified. This option does not do any error checking of the file. Use of this option invalidates the configuration file. |
| <code>-C group -l</code> | Lists the contents of current configuration database that is associated with resource group specified. |
| <code>-C group -s config_file_location</code> | Specifies where the Sun Cluster configuration database resides, the location has to be DID device. |
| <code>-D device_group</code> | Checks whether the specified <code>device_group</code> is known by Sun Cluster and whether it is available on this node. It displays a information that indicates the device group's status and return values are as follows,

(use <code>echo \$?</code> to retrieve the return value): |
| | 1 Device group is in Sun Cluster and is active on this node; |
| | 0 Device group is in Sun Cluster but active on another node; |
| | -1 Device group is not in Sun Cluster. |

Usage The `dscfg` command is typically run from other scripts, such as package installation scripts, and from `dscfgadm(1M)`. It is not intended for general use. For uses of `dscfg` not covered by `dscfgadm`, please refer to the *Availability Suite Troubleshooting Guide*.

Files `/etc/dscfg_format`
 parser configuration file

`/etc/dscfg_local`
 configuration location for all entries with no cluster tags

`/etc/dscfg_cluster`
 reference file specifying the location of the Sun Cluster configuration database.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-------------------------------------------------------------------------------|
| Availability | service/storage/avs/cache-management,
service/storage/avs/cache-management |
| Interface Stability | Committed |

See Also [dscfgadm\(1M\)](#), [iiadm\(1M\)](#), [scmadm\(1M\)](#), [sndradm\(1M\)](#), [svadm\(1M\)](#), [ds.log\(4\)](#), [attributes\(5\)](#)

Name dscfgadm – administration command for the Availability Suite configuration location and services

Synopsis dscfgadm -i
dscfgadm -e [-r] [-p]
dscfgadm -d [-r]
dscfgadm -s

Description The dscfgadm command controls the Availability Suite configuration location and services by providing facilities to set the configuration location, and to enable and disable the Availability Suite services.

Options If you do not specify any arguments to a dscfgadm command, the utility interactively steps you through setting the configuration location and starting the services. The configuration location is validated to ensure it meets criteria such as size and file type before it is initialized for use.

The dscfgadm command supports the following options.

-d [-r]

Disables the Availability Suite SMF services. This includes stopping daemons and suspending any Point-in-Time Copy or Remote Mirror sets that are currently enabled under the Availability Suite software. When executed with no additional options, the -d option disables all Availability Suite services. This setting is persistent across system boots.

-r

When passed to the -d or -e option, acts only on the Remote Mirror services.

-e [-r] [-p]

Enables the Availability Suite SMF services. This includes starting daemons and resuming any Point-in-Time Copy or Remote Mirror sets that have been previously configured under the Availability Suite software. When executed with no additional options, the -e option enables all Availability Suite services. This setting is persistent across system boots.

-r

When passed to the -d or -e option, acts only on the Remote Mirror services.

-p

When passed to the -e option, enables only the Point-in-Time Copy service.

-i

Displays information on the Availability Suite SMF services.

-s

Allows you to set the location of the configuration database containing information specific to Sun Cluster configurations.

-x

Displays verbose debugging information as the program is executing.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-------------------------------------------------------------------------------|
| Availability | service/storage/avs/cache-management,
service/storage/avs/cache-management |
| Interface Stability | Committed |

Name dscfglockd – Availability Suite Services lock daemon

Synopsis /usr/lib/dscfglockd [-e *program* | -f *file*]

Description The dscfglockd daemon coordinates StorageTek configuration database lock requests between nodes within a cluster.

Options The dscfglockd supports the following options:

-e *program*

Executes the script and arguments in *program*. The executable and any arguments it needs must be supplied with suitable quoting as a single argument to this option. This argument is processed by [sh\(1\)](#).

-f *file*

Reads the list of names for peer hosts from *file*.

If no arguments are specified, dscfglockd acts as a local lock daemon, but coordinates lock requests with any other daemons that might contact the local host as part of their own configuration process.

Exit Status 0 Daemon started successfully.

>0 Daemon failed to start.

Files /lib/svc/method/svc-scm

Shell script for starting and stopping dscfglockd.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-------------------------------------------------------------------------------|
| Availability | service/storage/avs/cache-management,
service/storage/avs/cache-management |
| Interface Stability | Committed |

Name dsstat – report Sun StorageTek Availability Suite I/O statistics

Synopsis dsstat -m *mode* [-r *report-options*] [-d *display-options*]
[-s *volume-sets*] [-f | -F] [-z] [*interval* [*count*]]

Description The dsstat command collects and reports I/O statistics for the Sun StorageTek Availability Suite products.

Options The dsstat supports the following options:

-m *mode*

Specifies the mode(s) of operation. Valid modes are:

cache

Cache statistics

ii

Point-in-Time Copy statistics

sndr

Remote Mirror statistics

To display statistics for multiple services simultaneously, use the -m switch to specify each of the modes required. For example:

```
% dsstat -m ii -m sndr
```

```
% dsstat -m ii -m sndr -m cache
```

To determine which statistics are being reported from which service, use the *role* field, described below. When cache statistics are requested as one of the multiple services, the rkps and wkps statistics is further divided into crkps, drkps, cwkps, and dwkps. If no -m switch is specified, then dsstat displays default statistics for all of the valid modes as described above. See “Field Descriptions,” below for descriptions of these fields.

-r *report-options*

Specifies the volume components to be displayed. Each item is represented by a single character, and multiple items can be selected. The *report-options* vary based on the mode(s) specified above. This option is not used for cache mode.

Valid *report-options* for ii mode are:

m Master volume statistics.

- For the “report-options for ii mode”: m, s, b, o
- For the “report-options for sndr mode”: b, n
- For the “display-options for cache mode”: r, w, d, c, s, f
- For the “display-options for ii mode”: r, w, t, s, p, f

s Shadow volume statistics.

b Bitmap volume statistics.

o Overflow volume statistics, if attached.

Valid *report-options* for *sndr* mode are:

b Bitmap volume statistics.

n Network volume statistics.

-d *display-options*

Specifies the statistics to be displayed. The types of statistics are represented by a single character; multiple types can be specified.

For cache mode, the valid *display-options* are:

r Detailed read statistics.

w Detailed write statistics.

s Summary statistics.

f Cache behavior flags.

The following *display-options* are available only for cache mode, they need to be combined with the mode options (-m)

d Destaged data statistics.

c Write cancellation statistics.

The default *display-options* for cache are *sf*.

For *ii* mode, the valid *display-options* are:

r Detailed read statistics.

w Detailed write statistics.

t Timing statistics.

s Summary statistics.

p Percentage of volume requiring sync.

f Volume type/status flags.

The default *display-options* for *ii* are *spf*. For *sndr* mode, the valid *display-options* are:

r Detailed read statistics.

| | |
|---|--------------------------------------|
| w | Detailed write statistics. |
| t | Timing statistics. |
| s | Summary statistics. |
| p | Percentage of volume requiring sync. |
| f | Volume type/status flags. |
| q | Asynchronous queue statistics. |

The following *display-option* is only available for `sndr` mode, and needs to be combined with the mode options (`-m`).

| | |
|---|--------------------------------|
| q | Asynchronous queue statistics. |
|---|--------------------------------|

The default *display-options* for `sndr` are `spf`.

Specifying the summary *display-option* causes `rwt` *display-options* to be ignored.

| | |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -s <i>volume-sets</i> | Filters the output to include only the specified <i>volume-sets</i> , where <i>volume-sets</i> is a comma-delimited list of volume names. When displaying Remote Mirror statistics, the name specified is compared to the Remote Mirror primary volume to determine if they match. Additionally, an Remote Mirror volume should be specified as <code><host>:<volume></code> where <code><host></code> is the primary or secondary host and <code><volume></code> is the volume name by which that host recognizes the volume set. When specifying multiple Remote Mirror volumes sets, be aware that each volume set specified is evaluated individually, using the rules above. When displaying Point-in-Time Copy statistics, the volume name specified is compared to the Point-in-Time Copy shadow volume to determine if they match. |
| -f | Output field headers at every reporting cycle. |
| -F | Output field headers once, when reporting begins. |
| -z | Suppress report lines that have zero values or no activity. |

Operands The `dsstat` command line supports the following operands:

interval

Specifies the *interval* for each report, in seconds. If no *interval* is specified, a single report with a one second *interval* is output.

Due to the varying number of entries in a given set and the varying number of sets, header information might appear in the middle of a set being reported. To avoid this, use the `-f` or `-F` options to display the header information at the desired time.

count

Specifies the number of reports to generate. If no *count* is specified, output continues until interrupted.

Field Descriptions Unless otherwise specified, all fields are per-second averages based on the data collected during the specified *interval*.

| | |
|-------|-----------------------------------------|
| name | Name of the entity being reported |
| t | Volume type |
| s | Volume status |
| r | Cache read behavior |
| w | Cache write behavior |
| pct | Percentage of volume requiring sync |
| role | Role of the item being reported |
| tps | Total number of reads + writes |
| rtps | Number of reads |
| wtps | Number of writes |
| kps | Total kilobytes read + written |
| rkps | Kilobytes read |
| wkps | Kilobytes written |
| crkps | Kilobytes read from cache |
| drkps | Kilobytes read from disk |
| cwkps | Kilobytes written to cache |
| dwkps | Kilobytes written to disk |
| ckps | Kilobytes transferred to or from cache |
| dkps | Kilobytes transferred to or from disk |
| svt | Service time per operation |
| hit | Read hits during <i>interval</i> |
| ds/s | Kilobytes destaged from cache |
| cn/s | Number of write cancellations |
| q | Type of asynchronous queuing being used |
| qi | Number of items currently queued |

qk Kilobytes currently queued
qhwi High water mark of queued items
qhwk High water mark of queued kilobytes

The name field displays only the last 16 characters of the name.

Valid cache behaviors for cache are:

C Cache reads/writes
D Disk reads/writes

Valid volume types for i i are:

I Independent shadow volume
D Dependent shadow volume

Valid volume status for i i is:

C Copy in progress
- No copy in progress

Valid volume types for snd r are:

P This is the primary host of this volume set
S This is the secondary host of this volume set

Valid volume status for snd r is:

L Changes to this volume are being logged
Q Volume are in queuing mode
R Replicating changes to secondary
SY Synchronization in progress. Sending data.
RS Reverse synchronization in progress. Receiving data.
SN Synchronization needed
RN Reverse synchronization needed
VF Volume failed
BF Bitmap failed
QF Queue failed

Valid queue types for snd r are:

D Disk-based queuing enabled
 M Memory-based queuing enabled

Volume roles for `sndr` are:

net Network volume statistics
 bmp Bitmap volume statistics

Volume roles for `ii` are:

mst Master volume statistics
 shd Shadow volume statistics
 bmp Bitmap volume statistics
 ovr Overflow volume statistics

Examples EXAMPLE 1 Report Cache Statistics

The following example shows the display of Report Cache statistics, with detailed breakdowns of read and writes to cache/disk. Reports are generated at five second intervals. Reporting is limited to the set `/dev/rdisk/c1t1d0s0`.

```
# dsstat -m cache -d rw -s /dev/rdisk/c1t1d0s0 5
- read -           - write -
name              ckps  dkps  hit  ckps  dkps  hit
dev/rdisk/c1t1d0s0  0     0  0.00  0     0  0.00
dev/rdisk/c1t1d0s0  3   2396  0.13  983   763 100.00
dev/rdisk/c1t1d0s0 2399   799 75.00 2815  2686 100.00
dev/rdisk/c1t1d0s0 3200   800 80.00 2755  2908 100.00
dev/rdisk/c1t1d0s0 3999   799 83.33 2809  2868 100.00
dev/rdisk/c1t1d0s0 4800   800 85.71 2867  2931 100.00
```

EXAMPLE 2 Report Master, Shadow and Bitmap Statistics

Report master, shadow and bitmap statistics for Point-in-Time Copy, using default output. Generate reports at two second intervals.

```
# dsstat -m ii -r msb 2
name              t  s  pct role  kps  tps  svt
dev/rdisk/c0t1d0s5 I  C  96.15 mst 19921  38  22
dev/rdisk/c0t1d0s6              shd  9960  19  20
dev/rdisk/c0t1d0s7              bmp   39   77   2
dev/rdisk/c0t1d0s5 I  C  94.24 mst 19623  38  22
dev/rdisk/c0t1d0s6              shd  9939  19  20
dev/rdisk/c0t1d0s7              bmp   39   77   2
dev/rdisk/c0t1d0s5 I  C  92.34 mst 19969  39  22
dev/rdisk/c0t1d0s6              shd  9984  19  20
```

EXAMPLE 2 Report Master, Shadow and Bitmap Statistics (Continued)

```
dev/rdisk/c0t1d0s7          bmp      39   78   2
```

EXAMPLE 3 Report Network Statistics for Remote Mirror

Report network statistics for Remote Mirror, using detailed read, write statistics. Report includes volume type/status flags and percentages. Generate reports at two second intervals. Limit reporting to the set /dev/rdsk/c0t1d0s0.

```
# dsstat -m sndr -r n -d rwpf -s /dev/rdsk/c0t1d0s0 2
name           t s   pct role  rkps  rtps  wkps  wtps
dev/rdsk/c0t1d0s0 P L 100.00 sec    0    0    0    0
dev/rdsk/c0t1d0s0 P SY 99.90 sec    0    0   288    9
dev/rdsk/c0t1d0s0 P SY 97.90 sec    0    0  5296  165
dev/rdsk/c0t1d0s0 P SY 95.81 sec    0    0  5184  161
dev/rdsk/c0t1d0s0 P SY 93.81 sec    0    0  5280  164
dev/rdsk/c0t1d0s0 P SY 91.71 sec    0    0  5198  162
```

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 Successful completion, no statistics to report.
- 2 An invalid argument has been encountered.
- 3 No memory is available to create ksstat statistics.
- 4 An unknown error has occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

Name dsvclockd – DHCP service lock daemon

Synopsis /usr/lib/inet/dsvclockd [-d 1 | 2] [-f] [-v]

Description The dsvclockd daemon is a lock manager that works in conjunction with the Dynamic Host Configuration Protocol (DHCP) Data Service Library (libdhcpsvc). It provides shared or exclusive access to the [dhcp_network\(4\)](#) and [dhcptab\(4\)](#) tables. This service is used by the SUNWbinfiles and SUNWfiles DHCP data store modules. See [dhcp_modules\(5\)](#).

dsvclockd is started on demand by libdhcpsvc. The dsvclockd daemon should be started manually only if command line options need to be specified.

Options The following options are supported:

- d 1 | 2 Set debug level. Two levels of debugging are currently available, 1 and 2. Level 2 is more verbose.
- f Run in the foreground instead of as a daemon process. When this option is used, messages are sent to standard error instead of to [syslog\(3C\)](#).
- v Provide verbose output.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------|
| Availability | service/network/dhcp |
| Interface Stability | Uncommitted |

Name dtrace – DTrace dynamic tracing compiler and tracing utility

Synopsis dtrace [-32 | -64] [-aACeFGHh\lqSvVwZ] [-b *bufsz*] [-c *cmd*]
 [-D *name* [=value]] [-I *path*] [-L *path*] [-o *output*]
 [-s *script*] [-U *name*] [-x *arg* [=val]]
 [-X a | c | s | t] [-p *pid*]
 [-P *provider* [[*predicate*] *action*]]
 [-m [*provider:*] *module* [[*predicate*] *action*]]
 [-f [[*provider:*] *module:*] *function* [[*predicate*] *action*]]
 [-n [[*provider:*] *module:*] *function:*] *name* [[*predicate*] *action*]]
 [-i *probe-id* [[*predicate*] *action*]]

Description DTrace is a comprehensive dynamic tracing framework for the Solaris Operating System. DTrace provides a powerful infrastructure that permits administrators, developers, and service personnel to concisely answer arbitrary questions about the behavior of the operating system and user programs.

The *Solaris Dynamic Tracing Guide* describes how to use DTrace to observe, debug, and tune system behavior. Refer to this book for a detailed description of DTrace features, including the bundled DTrace observability tools, instrumentation providers, and the D programming language.

The `dt race` command provides a generic interface to the essential services provided by the DTrace facility, including:

- Options that list the set of probes and providers currently published by DTrace
- Options that enable probes directly using any of the probe description specifiers (provider, module, function, name)
- Options that run the D compiler and compile one or more D program files or programs written directly on the command line
- Options that generate anonymous tracing programs
- Options that generate program stability reports
- Options that modify DTrace tracing and buffering behavior and enable additional D compiler features

You can use `dt race` to create D scripts by using it in a `#!` declaration to create an interpreter file. You can also use `dt race` to attempt to compile D programs and determine their properties without actually enabling tracing using the `-e` option. See **OPTIONS**. See the *Solaris Dynamic Tracing Guide* for detailed examples of how to use the `dt race` utility to perform these tasks.

Options The arguments accepted by the `-P`, `-m`, `-f`, `-n`, and `-i` options can include an optional D language *predicate* enclosed in slashes `//` and optional D language *action* statement list enclosed in braces `{}`. D program code specified on the command line must be appropriately quoted to avoid interpretation of meta-characters by the shell.

The following options are supported:

-32 | -64

The D compiler produces programs using the native data model of the operating system kernel. You can use the `isainfo -b` command to determine the current operating system data model. If the `-32` option is specified, `dt race` forces the D compiler to compile a D program using the 32-bit data model. If the `-64` option is specified, `dt race` forces the D compiler to compile a D program using the 64-bit data model. These options are typically not required as `dt race` selects the native data model as the default. The data model affects the sizes of integer types and other language properties. D programs compiled for either data model can be executed on both 32-bit and 64-bit kernels. The `-32` and `-64` options also determine the ELF file format (ELF32 or ELF64) produced by the `-G` option.

-a

Claim anonymous tracing state and display the traced data. You can combine the `-a` option with the `-e` option to force `dt race` to exit immediately after consuming the anonymous tracing state rather than continuing to wait for new data. See the [Solaris Dynamic Tracing Guide](#) for more information about anonymous tracing.

-A

Generate `driver.conf(4)` directives for anonymous tracing. This option constructs a set of `dtrace(7D)` configuration file directives to enable the specified probes for anonymous tracing and then exits. By default, `dt race` attempts to store the directives to the file `/kernel/drv/dtrace.conf`. You can modify this behavior if you use the `-o` option to specify an alternate output file.

-b *bufsz*

Set principal trace buffer size (*bufsz*). The trace buffer size can include any of the size suffixes `k`, `m`, `g`, or `t`. If the buffer space cannot be allocated, `dt race` attempts to reduce the buffer size or exit depending on the setting of the `bufresize` property.

-c *cmd*

Run the specified command *cmd* and exit upon its completion. If more than one `-c` option is present on the command line, `dt race` exits when all commands have exited, reporting the exit status for each child process as it terminates. The process-ID of the first command is made available to any D programs specified on the command line or using the `-s` option through the `$target` macro variable. Refer to the [Solaris Dynamic Tracing Guide](#) for more information on macro variables.

-C

Run the C preprocessor `cpp(1)` over D programs before compiling them. You can pass options to the C preprocessor using the `-D`, `-U`, `-I`, and `-H` options. You can select the degree of C standard conformance if you use the `-X` option. For a description of the set of tokens defined by the D compiler when invoking the C preprocessor, see `-X`.

-D *name* [=value]

Define *name* when invoking `cpp(1)` (enabled using the `-C` option). If you specify the equals sign (=) and additional *value*, the name is assigned the corresponding value. This option passes the `-D` option to each `cpp` invocation.

- e
Exit after compiling any requests and consuming anonymous tracing state (-a option) but prior to enabling any probes. You can combine this option with the -a option to print anonymous tracing data and exit. You can also combine this option with D compiler options. This combination verifies that the programs compile without actually executing them and enabling the corresponding instrumentation.
- f [*provider*:]*module*:]*function*[[*predicate*]*action*]
Specify function name to trace or list (-l option). The corresponding argument can include any of the probe description forms *provider:module:function*, *module:function*, or *function*. Unspecified probe description fields are left blank and match any probes regardless of the values in those fields. If no qualifiers other than *function* are specified in the description, all probes with the corresponding *function* are matched. The -f argument can be suffixed with an optional D probe clause. You can specify more than one -f option on the command line at a time.
- F
Coalesce trace output by identifying function entry and return. Function entry probe reports are indented and their output is prefixed with ->. Function return probe reports are unindented and their output is prefixed with <-. System call entry probe reports are indented and their output is prefixed with =>. System call return probe reports are unindented and their output is prefixed with <=.
- G
Generate an ELF file containing an embedded DTrace program. The DTrace probes specified in the program are saved inside of a relocatable ELF object which can be linked into another program. If the -o option is present, the ELF file is saved using the pathname specified as the argument for this operand. If the -o option is not present and the DTrace program is contained with a file whose name is *filename.d*, then the ELF file is saved using the name *filename.o*. Otherwise the ELF file is saved using the name *d.out*.
- H
Print the pathnames of included files when invoking `cpp(1)` (enabled using the -C option). This option passes the -H option to each `cpp` invocation, causing it to display the list of pathnames, one for each line, to `stderr`.
- h
Generate a header file containing macros that correspond to probes in the specified provider definitions. This option should be used to generate a header file that is included by other source files for later use with the -G option. If the -o option is present, the header file is saved using the pathname specified as the argument for that option. If the -o option is not present and the DTrace program is contained with a file whose name is *filename.d*, then the header file is saved using the name *filename.h*.
- i *probe-id*[[*predicate*]*action*]
Specify probe identifier (*probe-id*) to trace or list (-l option). You can specify probe IDs using decimal integers as shown by `dtrace -l`. The -i argument can be suffixed with an optional D probe clause. You can specify more than one -i option at a time.

- I *path*
Add the specified directory *path* to the search path for `#include` files when invoking `cpp(1)` (enabled using the `-C` option). This option passes the `-I` option to each `cpp` invocation. The specified *path* is inserted into the search path ahead of the default directory list.
- L *path*
Add the specified directory *path* to the search path for DTrace libraries. DTrace libraries are used to contain common definitions that can be used when writing D programs. The specified *path* is added after the default library search path.
- l
List probes instead of enabling them. If the `-l` option is specified, `dtrace` produces a report of the probes matching the descriptions given using the `-P`, `-m`, `-f`, `-n`, `-i`, and `-s` options. If none of these options are specified, this option lists all probes.
- m `[[provider:] module: [[predicate] action]]`
Specify module name to trace or list (`-l` option). The corresponding argument can include any of the probe description forms *provider:module* or *module*. Unspecified probe description fields are left blank and match any probes regardless of the values in those fields. If no qualifiers other than *module* are specified in the description, all probes with a corresponding *module* are matched. The `-m` argument can be suffixed with an optional D probe clause. More than one `-m` option can be specified on the command line at a time.
- n `[[provider:] module:] function:] name [[predicate] action]`
Specify probe name to trace or list (`-l` option). The corresponding argument can include any of the probe description forms *provider:module:function:name*, *module:function:name*, *function:name*, or *name*. Unspecified probe description fields are left blank and match any probes regardless of the values in those fields. If no qualifiers other than *name* are specified in the description, all probes with a corresponding *name* are matched. The `-n` argument can be suffixed with an optional D probe clause. More than one `-n` option can be specified on the command line at a time.
- o *output*
Specify the *output* file for the `-A`, `-G`, `-h`, and `-l` options, or for the traced data itself. If the `-A` option is present and `-o` is not present, the default output file is `/kernel/drv/dtrace.conf`. If the `-G` option is present and the `-s` option's argument is of the form *filename.d* and `-o` is not present, the default output file is *filename.o*. Otherwise the default output file is `d.out`.
- p *pid*
Grab the specified process-ID *pid*, cache its symbol tables, and exit upon its completion. If more than one `-p` option is present on the command line, `dtrace` exits when all commands have exited, reporting the exit status for each process as it terminates. The first process-ID is made available to any D programs specified on the command line or using the `-s` option through the `$target` macro variable. Refer to the [Solaris Dynamic Tracing Guide](#) for more information on macro variables.

-
- P *provider* [*[predicate] action*]
Specify provider name to trace or list (-l option). The remaining probe description fields module, function, and name are left blank and match any probes regardless of the values in those fields. The -P argument can be suffixed with an optional D probe clause. You can specify more than one -P option on the command line at a time.
 - q
Set quiet mode. dtrace suppresses messages such as the number of probes matched by the specified options and D programs and does not print column headers, the CPU ID, the probe ID, or insert newlines into the output. Only data traced and formatted by D program statements such as `trace()` and `printf()` is displayed to `stdout`.
 - s
Compile the specified D program source file. If the -e option is present, the program is compiled but instrumentation is not enabled. If the -l option is present, the program is compiled and the set of probes matched by it is listed, but instrumentation is not enabled. If none of -e, -l, -G, or -A are present, the instrumentation specified by the D program is enabled and tracing begins.
 - S
Show D compiler intermediate code. The D compiler produces a report of the intermediate code generated for each D program to `stderr`.
 - U *name*
Undefine the specified *name* when invoking `cpp(1)` (enabled using the -C option). This option passes the -U option to each `cpp` invocation.
 - v
Set verbose mode. If the -v option is specified, dtrace produces a program stability report showing the minimum interface stability and dependency level for the specified D programs. DTrace stability levels are explained in further detail in the *Solaris Dynamic Tracing Guide*.
 - V
Report the highest D programming interface version supported by dtrace. The version information is printed to `stdout` and the dtrace command exits. Refer to the *Solaris Dynamic Tracing Guide* for more information about DTrace versioning features.
 - w
Permit destructive actions in D programs specified using the -s, -P, -m, -f, -n, or -i options. If the -w option is not specified, dtrace does not permit the compilation or enabling of a D program that contains destructive actions.
 - x *arg* [=*val*]
Enable or modify a DTrace runtime option or D compiler option. The list of options is found in the *Solaris Dynamic Tracing Guide*. Boolean options are enabled by specifying their name. Options with values are set by separating the option name and value with an equals sign (=).

-X a | c | s | t

Specify the degree of conformance to the ISO C standard that should be selected when invoking `cpp(1)` (enabled using the `-C` option). The `-X` option argument affects the value and presence of the `__STDC__` macro depending upon the value of the argument letter.

The `-X` option supports the following arguments:

- a Default. ISO C plus K&R compatibility extensions, with semantic changes required by ISO C. This is the default mode if `-X` is not specified. The predefined macro `__STDC__` has a value of 0 when `cpp` is invoked in conjunction with the `-Xa` option.
- c Conformance. Strictly conformant ISO C, without K&R C compatibility extensions. The predefined macro `__STDC__` has a value of 1 when `cpp` is invoked in conjunction with the `-Xc` option.
- s K&R C only. The macro `__STDC__` is not defined when `cpp` is invoked in conjunction with the `-Xs` option.
- t Transition. ISO C plus K&R C compatibility extensions, without semantic changes required by ISO C. The predefined macro `__STDC__` has a value of 0 when `cpp` is invoked in conjunction with the `-Xt` option.

As the `-X` option only affects how the D compiler invokes the C preprocessor, the `-Xa` and `-Xt` options are equivalent from the perspective of D and both are provided only to ease re-use of settings from a C build environment.

Regardless of the `-X` mode, the following additional C preprocessor definitions are always specified and valid in all modes:

- `__sun`
- `__unix`
- `__SVR4`
- `__sparc` (on SPARC systems only)
- `__sparcv9` (on SPARC systems only when 64-bit programs are compiled)
- `__i386` (on x86 systems only when 32-bit programs are compiled)
- `__amd64` (on x86 systems only when 64-bit programs are compiled)
- `__'uname -s' 'uname -r'` (for example, `__SunOS_5_10`)
- `__SUNW_D=1`
- `__SUNW_D_VERSION=0xMMmmmmuuu`

Where *MM* is the major release value in hexadecimal, *mmm* is the minor release value in hexadecimal, and *uuu* is the micro release value in hexadecimal. Refer to the [Solaris Dynamic Tracing Guide](#) for more information about DTrace versioning.

-Z

Permit probe descriptions that match zero probes. If the -Z option is not specified, dt race reports an error and exits if any probe descriptions specified in D program files (-s option) or on the command line (-P, -m, -f, -n, or -i options) contain descriptions that do not match any known probes.

Operands You can specify zero or more additional arguments on the dt race command line to define a set of macro variables (\$1, \$2, and so forth). The additional arguments can be used in D programs specified using the -s option or on the command line. The use of macro variables is described further in the *Solaris Dynamic Tracing Guide*.

Exit Status The following exit values are returned:

0 Successful completion.

For D program requests, an exit status of 0 indicates that programs were successfully compiled, probes were successfully enabled, or anonymous state was successfully retrieved. dt race returns 0 even if the specified tracing requests encountered errors or drops.

1 An error occurred.

For D program requests, an exit status of 1 indicates that program compilation failed or that the specified request could not be satisfied.

2 Invalid command line options or arguments were specified.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------|
| Availability | developer/dtrace |
| Interface Stability | See below. |

The command-line syntax is Committed. The human-readable output is Uncommitted.

See Also [cpp\(1\)](#), [isainfo\(1\)](#), [ssh\(1\)](#), [libdtrace\(3LIB\)](#), [driver.conf\(4\)](#), [attributes\(5\)](#), [dtrace\(7D\)](#)

Solaris Dynamic Tracing Guide

Usage When using the -p flag, dt race stops the target processes while it is inspecting them and reporting results. A process can do nothing while it is stopped. This means that, if, for example, the X server is inspected by dt race running in a window under the X server's control, the whole window system can become deadlocked, because the proc tool would be attempting to display its results to a window that cannot be refreshed. In such a case, logging in from another system using [ssh\(1\)](#) and killing the offending proc tool clears the deadlock.

Name dumpadm – configure operating system crash dump

Synopsis /usr/sbin/dumpadm [-nuy] [-c *content-type*] [-d *dump-device*]
 [-m *mink* | *minm* | *min%*] [-s *savecore-dir*]
 [-r *root-dir*] [-z on | off]

Description The dumpadm program is an administrative command that manages the configuration of the operating system crash dump facility. A crash dump is a disk copy of the physical memory of the computer at the time of a fatal system error. When a fatal operating system error occurs, a message describing the error is printed to the console. The operating system then generates a crash dump by writing the contents of physical memory to a predetermined dump device, which is typically a local disk partition. The dump device can be configured by way of dumpadm. Once the crash dump has been written to the dump device, the system will reboot.

Fatal operating system errors can be caused by bugs in the operating system, its associated device drivers and loadable modules, or by faulty hardware. Whatever the cause, the crash dump itself provides invaluable information to your support engineer to aid in diagnosing the problem. As such, it is vital that the crash dump be retrieved and given to your support provider. Following an operating system crash, the [savecore\(1M\)](#) utility is executed automatically during boot to retrieve the crash dump from the dump device and write it to your file system in compressed form, to a file name `vmdump.X`, where `X` is an integer identifying the dump. Afterwards, [savecore\(1M\)](#) can be invoked on the same or another system to expand the compressed crash dump to a pair of files named `unix.X` and `vmcore.X`. The directory in which the crash dump is saved on reboot can be configured using dumpadm.

For systems with a UFS root file system, the default dump device is configured to be an appropriate swap partition. Swap partitions are disk partitions reserved as virtual memory backing store for the operating system. Thus, no permanent information resides in swap to be overwritten by the dump. See [swap\(1M\)](#). For systems with a ZFS root file system, dedicated ZFS volumes are used for swap and dump areas. For further information about setting up a dump area with ZFS, see the *ZFS Administration Guide*. To view the current dump configuration, use the dumpadm command with no arguments:

```
example# dumpadm

Dump content: kernel pages
Dump device: /dev/dsk/c0t0d0s1 (swap)
Savecore directory: /var/crash/saturn
Savecore enabled: yes
Save compressed: yes
```

When no options are specified, dumpadm displays the current crash dump configuration. The example above shows the set of default values: the dump content is set to kernel memory pages only, the dump device is a swap disk partition, the directory for savecore files is set to `/var/crash/hostname`. savecore is set to run automatically on reboot and save the crash dump in a compressed format.

When one or more options are specified, `dumpadm` verifies that your changes are valid, and if so, reconfigures the crash dump parameters and displays the resulting configuration. You must be root to view or change dump parameters.

Options The following options are supported:

-c *content-type*

Modify the dump configuration so that the crash dump consists of the specified dump content. The content should be one of the following:

kernel

Kernel memory pages only.

all

All memory pages.

curproc

Kernel memory pages, and the memory pages of the process whose thread was currently executing on the CPU on which the crash dump was initiated. If the thread executing on that CPU is a kernel thread not associated with any user process, only kernel pages will be dumped.

-d *dump-device*

Modify the dump configuration to use the specified dump device. The dump device may be one of the following:

dump-device

A specific dump device specified as an absolute pathname, such as `/dev/dsk/cNtNdNsN` when the system is running a UFS root file system. Or, specify a ZFS volume, such as `/dev/zvol/dsk/rpool/dump`, when the system is running a ZFS root file system.

swap

If the special token `swap` is specified as the dump device, `dumpadm` examines the active swap entries and selects the most appropriate entry to configure as the dump device. See [swap\(1M\)](#). Refer to the NOTES below for details of the algorithm used to select an appropriate swap entry. When the system is first installed with a UFS root file system, `dumpadm` uses the value for `swap` to determine the initial dump device setting. A given ZFS volume cannot be configured for both the swap area and the dump device.

-m *mink* | *minm* | *min%*

Create a `minfree` file in the current `savecore` directory indicating that `savecore` should maintain at least the specified amount of free space in the file system where the `savecore` directory is located. The `min` argument can be one of the following:

k

A positive integer suffixed with the unit `k` specifying kilobytes.

m

A positive integer suffixed with the unit `m` specifying megabytes.

%

A % symbol, indicating that the `minfree` value should be computed as the specified percentage of the total current size of the file system containing the `savecore` directory.

The `savecore` command will consult the `minfree` file, if present, prior to writing the dump files. If the size of these files would decrease the amount of free disk space below the `minfree` threshold, no dump files are written and an error message is logged. The administrator should immediately clean up the `savecore` directory to provide adequate free space, and re-execute the `savecore` command manually. The administrator can also specify an alternate directory on the `savecore` command-line.

-n

Modify the dump configuration to not run `savecore` automatically on reboot. This is not the recommended system configuration; if the dump device is a swap partition, the dump data will be overwritten as the system begins to swap. If `savecore` is not executed shortly after boot, crash dump retrieval may not be possible.

-r *root-dir*

Specify an alternate root directory relative to which `dumpadm` should create files. If no -r argument is specified, the default root directory / is used.

-s *savecore-dir*

Modify the dump configuration to use the specified directory to save files written by `savecore`. The directory should be an absolute path and exist on the system. If upon reboot the directory does not exist, it will be created prior to the execution of `savecore`. See the NOTES section below for a discussion of security issues relating to access to the `savecore` directory. The default `savecore` directory is `/var/crash/hostname` where *hostname* is the output of the -n option to the `uname(1)` command.

-u

Forcibly update the kernel dump configuration based on the contents of `/etc/dumpadm.conf`. Normally this option is used only on reboot when starting `svc:/system/dumpadm:default`, when the `dumpadm` settings from the previous boot must be restored. Your dump configuration is saved in the configuration file for this purpose. If the configuration file is missing or contains invalid values for any dump properties, the default values are substituted. Following the update, the configuration file is resynchronized with the kernel dump configuration.

-y

Modify the dump configuration to automatically run `savecore` on reboot. This is the default for this dump setting. See NOTES.

-z on | off

Modify the dump configuration to control the operation of `savecore` on reboot. The options are `on`, to enable saving core files in a compressed format, and `off`, to automatically uncompress the crash dump file. The default is `on`, because crash dump files can be very large and require less file system space if saved in a compressed format.

Examples EXAMPLE 1 Reconfiguring The Dump Device To A Dedicated Dump Device:

The following command reconfigures the dump device to a dedicated dump device:

```
example# dumpadm -d /dev/dsk/c0t2d0s2
```

```

Dump content: kernel pages
Dump device: /dev/dsk/c0t2d0s2 (dedicated)
Savecore directory: /var/crash/saturn
Savecore enabled: yes
Save compressed: yes

```

Exit Status The following exit values are returned:

- 0
Dump configuration is valid and the specified modifications, if any, were made successfully.
- 1
A fatal error occurred in either obtaining or modifying the dump configuration.
- 2
Invalid command line options were specified.

Files /dev/dump
Dump device.

/etc/dumpadm.conf
Contains configuration parameters for dumpadm. Modifiable only through that command.

savecore-directory/minfree
Contains minimum amount of free space for *savecore-directory*. See [savecore\(1M\)](#).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [svcs\(1\)](#), [uname\(1\)](#), [savecore\(1M\)](#), [svcadm\(1M\)](#), [swap\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Notes The system crash dump service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/dumpadm:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

- Dump Device Selection** When the special swap token is specified as the argument to `dumpadm -d` the utility will attempt to configure the most appropriate swap device as the dump device. `dumpadm` configures the largest swap block device as the dump device; if no block devices are available for swap, the largest swap entry is configured as the dump device. If no swap entries are present, or none can be configured as the dump device, a warning message will be displayed. While local and remote swap files can be configured as the dump device, this is not recommended.
- Dump Device/Swap Device Interaction (UFS File Systems Only)** In the event that the dump device is also a swap device, and the swap device is deleted by the administrator using the `swap -d` command, the `swap` command will automatically invoke `dumpadm -d swap` in order to attempt to configure another appropriate swap device as the dump device. If no swap devices remain or none can be configured as the dump device, the crash dump will be disabled and a warning message will be displayed. Similarly, if the crash dump is disabled and the administrator adds a new swap device using the `swap -a` command, `dumpadm -d swap` will be invoked to re-enable the crash dump using the new swap device.
- Once `dumpadm -d swap` has been issued, the new dump device is stored in the configuration file for subsequent reboots. If a larger or more appropriate swap device is added by the administrator, the dump device is not changed; the administrator must re-execute `dumpadm -d swap` to reselect the most appropriate device from the new list of swap devices.
- Minimum Free Space** If the `dumpadm -m` option is used to create a `minfree` file based on a percentage of the total size of the file system containing the `savecore` directory, this value is not automatically recomputed if the file system subsequently changes size. In this case, the administrator must re-execute `dumpadm -m` to recompute the `minfree` value. If no such file exists in the `savecore` directory, `savecore` will default to a free space threshold of one megabyte. If no free space threshold is desired, a `minfree` file containing size 0 can be created.
- Security Issues** If, upon reboot, the specified `savecore` directory is not present, it will be created prior to the execution of `savecore` with permissions 0700 (read, write, execute by owner only) and owner root. It is recommended that alternate `savecore` directories also be created with similar permissions, as the operating system crash dump files themselves may contain secure information.
- Default for savecore** System installation software might reserve a dedicated dump device (for example, a disk slice or a ZFS volume). In such a case, the `dumpadm` default can be set to `-n`, meaning that `savecore` does not run automatically when the system reboots. A crash image will be preserved on the dump device. Run `/usr/sbin/savecore` manually as root to retrieve the crash image and copy it to a file under `/var/crash`. The crash image will remain on the dump device until overwritten by a later one.

Name editmap – query and edit single records in database maps for sendmail

Synopsis editmap -C *file* [-N] [-f] [-q | -u | -x] *maptype mapname key*
["*value*"]...

Description The editmap command queries or edits one record in a database maps used by the keyed map lookups in [sendmail\(1M\)](#). Arguments are passed on the command line and output (for queries) is directed to standard output.

Depending on how it is compiled, editmap handles up to three different database formats, selected using the *maptype* parameter. See OPERANDS.

If the TrustedUser option is set in the sendmail configuration file and editmap is invoked as root, the generated files are owned by the specified TrustedUser.

Options The following options are supported:

- C *file* Use the specified sendmail configuration file (*file*) to look up the TrustedUser option.
- f Disable the folding of all upper case letters in the key to lower case. Normally, all upper case letters in the key are folded to upper case. This is intended to mesh with the -f flag in the K line in sendmail.cf. The value is never case folded.
- N Include the null byte that terminates strings in the map (for alias maps).
- q Query the map for the specified key. If found, print value to standard output and exit with 0. If not found then print an error message to stdout and exit with EX_UNAVAILABLE.
- u Update the record for key with value or inserts a new record if one doesn't exist. Exits with 0 on success or EX_IOERR on failure.
- x Delete the specific key from the map. Exit with 0 on success or EX_IOERR on failure.

Operands The following operands are supported:

key The left hand side of a record.

Each record is of the form:

key value

key and *value* are separated by white space.

mapname File name of the database map being created.

maptype Specifies the database format. The following *maptype* parameters are available:

dbm Specifies DBM format maps.

btree Specifies B-Tree format maps.

hash Specifies hash format maps.
value The right hand side of a record.

Each record is of the form:

key value

key and *value* are separated by white space.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------------|
| Availability | service/network/smtp/sendmail |

See Also [makemap\(1M\)](#), [sendmail\(1M\)](#), [attributes\(5\)](#)

Name edquota – edit user quotas for ufs file system

Synopsis edquota [-p *proto_user*] *username* . . .
edquota -t

Description edquota is a quota editor. One or more users may be specified on the command line. For each user a temporary file is created with an ASCII representation of the current disk quotas for that user for each mounted ufs file system that has a quotas file, and an editor is then invoked on the file. The quotas may then be modified, new quotas added, etc. Upon leaving the editor, edquota reads the temporary file and modifies the binary quota files to reflect the changes made.

The editor invoked is `vi(1)` unless the EDITOR environment variable specifies otherwise.

Only the super-user may edit quotas. In order for quotas to be established on a file system, the root directory of the file system must contain a file, owned by root, called quotas. (See `quotaon(1M)`.)

proto_user and *username* can be numeric, corresponding to the UID of a user. Unassigned UIDs may be specified; unassigned names may not. In this way, default quotas can be established for users who are later assigned a UID.

If no options are specified, the temporary file created will have one or more lines of the format, where a block is considered to be a 1024 byte (1K) block:

```
fs mount_point blocks (soft =number, \
    hard =number ) inodes (soft =number, \
    hard =number)
```

The *number* fields may be modified to reflect desired values.

Options The following options are supported:

- p Duplicate the quotas of the *proto_user* specified for each *username* specified. This is the normal mechanism used to initialize quotas for groups of users.
- t Edit the soft time limits for each file system. If the time limits are zero, the default time limits in `/usr/include/sys/fs/ufs_quota.h` are used. The temporary file created will have one or more lines of the form

```
fs mount_point blocks time limit = number tmunit, files time limit = number tmunit
```

tmunit may be one of “month”, “week”, “day”, “hour”, “min” or “sec”; characters appended to these keywords are ignored, so you may write “months” or “minutes” if you prefer. The *number* and *tmunit* fields may be modified to set desired values. Time limits are printed in the greatest possible time unit such that the value is greater than or equal to one. If “default” is printed after the *tmunit*, this indicates that the value shown is zero (the default).

Usage See [largefile\(5\)](#) for the description of the behavior of edquota when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files `quotas` quota file at the file system root
`/etc/mnttab` table of mounted file systems

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [vi\(1\)](#), [quota\(1M\)](#), [quotacheck\(1M\)](#), [quotaon\(1M\)](#), [repquota\(1M\)](#), [attributes\(5\)](#), [largefile\(5\)](#), [quotactl\(7I\)](#)

Notes All UIDs can be assigned quotas.

Name eeprom – EEPROM display and load utility

Synopsis /usr/sbin/eeprom [-] [-f *device*] [*parameter*[=*value*]]

Description eeprom displays or changes the values of parameters in the EEPROM. It processes parameters in the order given. When processing a *parameter* accompanied by a *value*, eeprom makes the indicated alteration to the EEPROM; otherwise, it displays the *parameter*'s value. When given no parameter specifiers, eeprom displays the values of all EEPROM parameters. A ‘-’ (hyphen) flag specifies that parameters and values are to be read from the standard input (one *parameter* or *parameter=value* per line).

Only the super-user may alter the EEPROM contents.

eeprom verifies the EEPROM checksums and complains if they are incorrect.

platform-name is the name of the platform implementation and can be found using the -i option of [uname\(1\)](#).

SPARC SPARC based systems implement firmware password protection with eeprom, using the `security-mode`, `security-password` and `security-#badlogins` properties.

x86 EEPROM storage is simulated using a file residing in the platform-specific boot area. The `/boot/solaris/bootenv.rc` file simulates EEPROM storage.

Because x86 based systems typically implement password protection in the system BIOS, there is no support for password protection in the eeprom program. While it is possible to set the `security-mode`, `security-password` and `security-#badlogins` properties on x86 based systems, these properties have no special meaning or behavior on x86 based systems.

Options -f *device*
Use *device* as the EEPROM device.

Operands

x86 Only *acpi-user-options*

A configuration variable that controls the use of Advanced Configuration and Power Interface (ACPI), a power management specification. The acceptable values for this variable depend on the release of the Solaris operating system you are using.

For all releases of Solaris 10 and Solaris 11, a value of `0x0` means that there will be an attempt to use ACPI if it is available on the system. A value of `0x2` disables the use of ACPI.

For the Solaris 10 1/06 release, a value of `0x8` means that there will be an attempt to use ACPI in a mode compatible with previous releases of Solaris 10 if it is available on the system. The default for Solaris 10 1/06 is `0x8`.

For releases of Solaris 10 after the 1/06 release and for Solaris 11, the default is `0x0`.

Most users can safely accept the default value, which enables ACPI if available. If issues related to the use of ACPI are suspected on releases of Solaris after Solaris 1/06, it is suggested to first try a value of `0x8` and then, if you do not obtain satisfactory results, `0x02`.

console

Specifies the console device. Possible values are `ttya`, `ttyb`, and `text`. In text mode, console output goes to the frame buffer and input comes from the keyboard. When this property is not present, the console device falls back to the device specified by `input-device` and `output-device`. When neither the console property or the `input-device` and `output-device` property pair are present, the console defaults to the frame buffer and keyboard.

**Nvram
Configuration
Parameters**

Not all OpenBoot systems support all parameters. Defaults vary depending on the system and the PROM revision. See the output in the “Default Value” column of the `printenv` command, as entered at the `ok` (OpenBoot) prompt, to determine the default for your system.

auto-boot?

If `true`, boots automatically after power-on or reset. Defaults to `true`. On x86, this parameter is controlled by the `grub` menu file. See [installgrub\(1M\)](#).

ansi-terminal?

Configuration variable used to control the behavior of the terminal emulator. The value `false` makes the terminal emulator stop interpreting ANSI escape sequences; instead, echoes them to the output device. Defaults to `true`.

boot-args

Holds a string of arguments that are passed to the boot subsystem. For example, you can use `boot-args=' - install dhcp'` to request a customer jumpstart installation. See [boot\(1M\)](#), [kmdb\(1\)](#), and [kernel\(1M\)](#).

boot-command

Command executed if `auto-boot?` is `true`. Defaults to `boot`.

boot-device

Device from which to boot. *boot-device* may contain 0 or more device specifiers separated by spaces. Each device specifier may be either a prom device alias or a prom device path. The boot prom will attempt to open each successive device specifier in the list beginning with the first device specifier. The first device specifier that opens successfully will be used as the device to boot from. Defaults to `disk net`.

boot-file

File to boot (an empty string lets the secondary booter choose default). Defaults to empty string.

boot-from

Boot device and file (OpenBoot PROM version 1.x only). Defaults to `vmunix`.

boot-from-dia

Diagnostic boot device and file (OpenBoot PROM version 1.x only). Defaults to `le()unix`.

boot-ncpus

Configuration variable that controls the number of processors with which the system should boot. By default, the system boots with maximum supported number of processors.

comX-noprobe

Where *X* is the number of the serial port, prevents device probe on serial port *X*.

diag-device

Diagnostic boot source device. Defaults to net.

diag-file

File from which to boot in diagnostic mode. Defaults to empty string.

diag-level

Diagnostics level. Values include `off`, `min`, `max` and `menus`. There may be additional platform-specific values. When set to `off`, POST is not called. If POST is called, the value is made available as an argument to, and is interpreted by POST. Defaults to platform-dependent.

diag-switch?

If `true`, run in diagnostic mode. Defaults to `false` on most desktop systems, `true` on most servers.

error-reset-recovery

Recover after an error reset trap. Defaults to platform-specific setting.

On platforms supporting this variable, it replaces the `watchdog-reboot?`, `watchdog-sync?`, `redmode-reboot?`, `redmode-sync?`, `sir-sync?`, and `xir-sync?` parameters.

The options are:

none

Print a message describing the reset trap and go to OpenBoot PROM's user interface, *aka* OK prompt.

sync

Invoke OpenBoot PROM's sync word after the reset trap. Some platforms may treat this as none after an externally initiated reset (XIR) trap.

boot

Reboot after the reset trap. Some platforms may treat this as none after an XIR trap.

fcode-debug?

If `true`, include name parameter for plug-in device FCodes. Defaults to `false`.

hardware-revision

System version information.

input-device

Input device used at power-on (usually keyboard, `ttya`, or `ttyb`). Defaults to keyboard.

keyboard-click?

If `true`, enable keyboard click. Defaults to `false`.

keyboard-layout

A string that specifies the layout name for non-self-identifying keyboards (type 7c). Invoke `kbd -s` to obtain a list of acceptable layout names. See `kbd(1)`.

keymap

Keymap for custom keyboard.

last-hardware-update

System update information.

load-base

Default load address for client programs. Default value is 16384.

local-mac-address?

If true, network drivers use their own MAC address, not the system's. Defaults to `false`.

mfg-mode

Manufacturing mode argument for POST. Possible values include `off` or `chamber`. The value is passed as an argument to POST. Defaults to `off`.

mfg-switch?

If true, repeat system self-tests until interrupted with STOP-A. Defaults to `false`.

nvrामrc

Contents of NVRAMRC. Defaults to empty.

network-boot-arguments

Arguments to be used by the PROM for network booting. Defaults to an empty string. `network-boot-arguments` can be used to specify the boot protocol (RARP/DHCP) to be used and a range of system knowledge to be used in the process.

The syntax for arguments supported for network booting is:

```
[protocol,] [key=value,]*
```

All arguments are optional and can appear in any order. Commas are required unless the argument is at the end of the list. If specified, an argument takes precedence over any default values, or, if booting using DHCP, over configuration information provided by a DHCP server for those parameters.

protocol, above, specifies the address discovery protocol to be used.

Configuration parameters, listed below, are specified as *key=value* attribute pairs.

tftp-server

IP address of the TFTP server

file

file to download using TFTP or URL for WAN boot

`host-ip`
IP address of the client (in dotted-decimal notation)

`router-ip`
IP address of the default router (in dotted-decimal notation)

`subnet-mask`
subnet mask (in dotted-decimal notation)

`client-id`
DHCP client identifier

`hostname`
hostname to use in DHCP transactions

`http-proxy`
HTTP proxy server specification (IPADDR[:PORT])

`tftp-retries`
maximum number of TFTP retries

`dhcp-retries`
maximum number of DHCP retries

If no parameters are specified (that is, `network-boot-arguments` is an empty string), the PROM will use the platform-specific default address discovery protocol.

Absence of the protocol parameter when other configuration parameters are specified implies manual configuration.

Manual configuration requires that the client be provided with all the information necessary for boot. If using manual configuration, information required by the PROM to load the second-stage boot program must be provided in `network-boot-arguments` while information required for the second-stage boot program can be specified either as arguments to the boot program or by means of the boot program's interactive command interpreter.

Information required by the PROM when using manual configuration includes the booting client's IP address, name of the boot file, and the address of the server providing the boot file image. Depending on network configuration, it might be required that the subnet mask and address of the default router to use also be specified.

`oem-banner`
Custom OEM banner (enabled by setting `oem-banner?` to `true`). Defaults to empty string.

`oem-banner?`
If `true`, use custom OEM banner. Defaults to `false`.

`oem-logo`
Byte array custom OEM logo (enabled by setting `oem-logo?` to `true`). Displayed in hexadecimal.

oem-logo?

If `true`, use custom OEM logo (else, use Sun logo). Defaults to `false`.

pci-mem64?

If true, the OpenBoot PROM allocates 64-bit PCI memory addresses to a PCI device that can support 64-bit addresses.

This variable is available on SPARC platforms only and is optional. Some versions of SunOS do not support PCI MEM64 addresses and will fail in unexpected ways if the OpenBoot PROM allocates PCI MEM64 addresses.

The default value is system-dependent. If the variable exists, the default value is appropriate to the lowest version of the SunOS that shipped with a specific platform.

output-device

Output device used at power-on (usually `screen`, `ttya`, or `ttyb`). Defaults to `screen`.

redmode-reboot?

Specify `true` to reboot after a redmode reset trap. Defaults to `true`. (Sun Enterprise 10000 only.)

redmode-sync?

Specify `true` to invoke OpenBoot PROM's sync word after a redmode reset trap. Defaults to `false`. (Sun Enterprise 10000 only.)

rootpath

Specifies the root device of the operating system.

sbus-probe-list

Designate which SBus slots are probed and in what order. Defaults to `0123`.

screen-#columns

Number of on-screen columns (characters/line). Defaults to `80`.

screen-#rows

Number of on-screen rows (lines). Defaults to `34`.

scsi-initiator-id

SCSI bus address of host adapter, range 0-7. Defaults to `7`.

sd-targets

Map SCSI disk units (OpenBoot PROM version 1.x only). Defaults to `31204567`, which means that unit 0 maps to target 3, unit 1 maps to target 1, and so on.

security-#badlogins

Number of incorrect security password attempts. This property has no special meaning or behavior on x86 based systems.

security-mode

Firmware security level (options: none, command, or full). If set to command or full, system will prompt for PROM security password. Defaults to none. This property has no special meaning or behavior on x86 based systems.

security-password

Firmware security password (never displayed). Can be set only when security-mode is set to command or full. This property has no special meaning or behavior on x86 based systems.

```
example# eeprom security-password=
Changing PROM password:
New password:
Retype new password:
```

selftest-#megs

Megabytes of RAM to test. Ignored if diag-switch? is true. Defaults to 1.

sir-sync?

Specify true to invoke OpenBoot PROM's sync word after a software-initiated reset (SIR) trap. Defaults to false. (Sun Enterprise 10000 only.)

skip-vme-loopback?

If true, POST does not do VMEbus loopback tests. Defaults to false.

st-targets

Map SCSI tape units (OpenBoot PROM version 1.x only). Defaults to 45670123, which means that unit 0 maps to target 4, unit 1 maps to target 5, and so on.

sunmon-compat?

If true, display Restricted Monitor prompt (>). Defaults to false.

testarea

One-byte scratch field, available for read/write test. Defaults to 0.

tpe-link-test?

Enable 10baseT link test for built-in twisted pair Ethernet. Defaults to true.

ttya-mode

TTYA (baud rate, #bits, parity, #stop, handshake). Defaults to 9600, 8, n, 1, -.

Fields, in left-to-right order, are:

Baud rate:

110, 300, 1200, 4800, 9600 . . .

Data bits:

5, 6, 7, 8

Parity:

n(none), e(even), o(odd), m(mark), s(space)

Stop bits:

1, 1.5, 2

Handshake:

-(none), h(hardware:rts/cts), s(software:xon/xoff)

ttyb-mode

TTYB (baud rate, #bits, parity, #stop, handshake). Defaults to 9600, 8, n, 1, -.

Fields, in left-to-right order, are:

Baud rate:

110, 300, 1200, 4800, 9600 . . .

Data bits:

5, 6, 7, 8

Stop bits:

1, 1.5, 2

Parity:

n(none), e(even), o(odd), m(mark), s(space)

Handshake:

-(none), h(hardware:rts/cts), s(software:xon/xoff)

ttya-ignore-cd

If true, operating system ignores carrier-detect on TTYA. Defaults to true.

ttyb-ignore-cd

If true, operating system ignores carrier-detect on TTYB. Defaults to true.

ttya-rts-dtr-off

If true, operating system does not assert DTR and RTS on TTYA. Defaults to false.

ttyb-rts-dtr-off

If true, operating system does not assert DTR and RTS on TTYB. Defaults to false.

use-nvramrc?

If true, execute commands in NVRAMRC during system start-up. Defaults to false.

verbosity

Controls the level of verbosity of PROM messages. Can be one of debug, max, normal, min, or none. Defaults to normal.

version2?

If true, hybrid (1.x/2.x) PROM comes up in version 2.x. Defaults to true.

watchdog-reboot?

If true, reboot after watchdog reset. Defaults to false.

watchdog-sync?

Specify `true` to invoke OpenBoot PROM's sync word after a watchdog reset trap. Defaults to `false`. (Sun Enterprise 10000 only.)

xir-sync?

Specify `true` to invoke OpenBoot PROM's sync word after an XIR trap. Defaults to `false`. (Sun Enterprise 10000 only.)

Examples EXAMPLE 1 Changing the Number of Megabytes of RAM.

The following example demonstrates the method for changing from one to two the number of megabytes of RAM that the system will test.

```
example# eeprom selftest-#megs
selftest-#megs=1
```

```
example# eeprom selftest-#megs=2
```

```
example# eeprom selftest-#megs
selftest-#megs=2
```

EXAMPLE 2 Setting the auto-boot? Parameter to `true`.

The following example demonstrates the method for setting the auto-boot? parameter to `true`.

```
example# eeprom auto-boot?=true
```

When the `eeprom` command is executed in user mode, the parameters with a trailing question mark (?) need to be enclosed in double quotation marks (“”) to prevent the shell from interpreting the question mark. Preceding the question mark with an escape character (\) will also prevent the shell from interpreting the question mark.

```
example% eeprom "auto-boot?"=true
```

EXAMPLE 3 Using network-boot-arguments

To use DHCP as the boot protocol and a hostname of `abcd.example.com` for network booting, set these values in `network-boot-arguments` as:

```
example# eeprom network-boot-arguments="dhcp,hostname=abcd.example.com"
```

...then boot using the command:

```
ok boot net
```

Note that network boot arguments specified from the PROM command line cause the contents of `network-boot-arguments` to be ignored. For example, with `network-boot-arguments` set as shown above, the boot command:

```
ok boot net:dhcp
```

EXAMPLE 3 Using network-boot-arguments (Continued)

...causes DHCP to be used, but the hostname specified in network-boot-arguments will not be used during network boot.

EXAMPLE 4 Setting System Console to Auxiliary Device

The command below assigns the device `/dev/term/a` as the system console device. You would make such an assignment prior to using [tip\(1\)](#) to establish a tip connection to a host.

On a SPARC machine:

```
# eeprom output-device=/dev/term/a
```

On an x86 machine:

```
# eeprom console=ttya
```

On a SPARC machine, the preceding command would be sufficient for assigning the console to an auxiliary device. For an x86 machine, you might, in addition, need to set the characteristics of the serial line, for which you would have to consult the BIOS documentation for that machine. Also, on some x86 machines, you might use a device other than device `a`, as shown above. For example, you could set console to `ttyb` if the second serial port is present.

EXAMPLE 5 Specifying that SPARC System Boots into kmdb

To specify that a SPARC machine boots into [kmdb\(1\)](#), enter the following command:

```
# eeprom boot-command="boot -k"
```

Files `/boot/solaris/bootenv.rc`
File storing eeprom values on x86 machines.

`/dev/openprom`
Device file

`/usr/platform/platform-name/sbin/eeprom`
Platform-specific version of eeprom. Use `uname -i` to obtain *platform-name*.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [kmdb\(1\)](#), [passwd\(1\)](#), [sh\(1\)](#), [svcs\(1\)](#), [tip\(1\)](#), [uname\(1\)](#), [boot\(1M\)](#), [kernel\(1M\)](#), [init\(1M\)](#), [svcadm\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#)

OpenBoot 3.x Command Reference Manual

ONC+ Developer's Guide

Name efdaemon – embedded FCode interpreter daemon

Synopsis /usr/lib/efcode/sparcv9/efdaemon [-d]

Description efdaemon, the embedded FCode interpreter daemon, invokes the embedded FCode interpreter when the daemon receives an interpretation request. A new session of the interpreter is started for each unique request by invoking the script /usr/lib/efcode/efcode.

efdaemon is used on selected platforms as part of the processing of some dynamic reconfiguration events.

Options The following option is supported:

-d Set debug output. Log debug messages as LOG_DEBUG level messages by using `syslog()`. See [syslog\(3C\)](#).

| | |
|-------------------------------------|-------------------------------------------------------------------------------------------------|
| Files /dev/fcode | FCode interpreter pseudo device, which is a portal for receipt of FCode interpretation requests |
| /usr/lib/efcode/efcode | Shell script that invokes the embedded FCode interpreter |
| /usr/lib/efcode/interpreter | Embedded FCode interpreter |
| /usr/lib/efcode/sparcv9/interpreter | Embedded FCode interpreter |

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|----------------------------------------------------------------------|
| Availability | SUNWefcx, SUNWefcux,
system/embedded-fcode-interpreter, SUNWefclx |

See Also [svcs\(1\)](#), [prtconf\(1M\)](#), [svcadm\(1M\)](#), [syslog\(3C\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Notes The efdaemon service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/platform/sun4u/efdaemon:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Name embedded_su – allow an application to prompt for credentials and execute commands as the super user or another user

Synopsis /usr/lib/embedded_su [-] [*username* [arg...]]

Description The embedded_su command allows an application to prompt the user for security credentials and then use those credentials to execute a program as another user or role (see [rbac\(5\)](#) for information on role-based access control). The default *username* is root (super user).

embedded_su is identical to [su\(1M\)](#), except that the user interaction is packaged in a form suitable for another program to interpret and display. Typically, embedded_su would be used to allow a graphical program to prompt for the super user password and execute a command as the super user, without requiring that the requesting program be run as the super user.

PROTOCOL embedded_su implements a simple protocol over standard input, standard output, and standard error. This protocol consists of three phases, roughly corresponding to PAM initialization, the PAM dialog, and PAM completion.

Phase 1: Initialization

After starting embedded_su, the application must send an initialization block on embedded_su's standard input. This block is a text block, as described under “Text Blocks”. There are currently no initialization parameters defined; the application should send an empty block by sending a line consisting solely of a period (.).

Phase 2: Conversation

embedded_su then emits zero or more conversation blocks on its standard output. Each conversation block may require zero or more responses.

A conversation block starts with a line consisting of the word CONV, followed by whitespace, followed by the number of messages in the conversation block as a decimal integer. The number of messages may be followed by whitespace and additional data. This data, if present, must be ignored.

Each message consists of a line containing a header followed by a text block, as described under “Text Blocks”. A single newline is appended to each message, allowing the message to end with a line that does not end with a newline.

A message header line consists of a PAM message style name, as described in [pam_start\(3PAM\)](#). The message header values are:

| | |
|---------------------|------------------------------------------------------------------------------------------|
| PAM_PROMPT_ECHO_OFF | The application is to prompt the user for a value, with echoing disabled. |
| PAM_PROMPT_ECHO_ON | The application is to prompt the user for a value, with echoing enabled. |
| PAM_ERROR_MSG | The application is to display the message in a form appropriate for displaying an error. |

`PAM_TEXT_INFO` The application is to display the message in a form appropriate for general information.

The PAM message style may be followed by whitespace and additional data. This data, if present, must be ignored.

After writing all of the messages in the conversation block, if any of them were `PAM_PROMPT_ECHO_OFF` or `PAM_PROMPT_ECHO_ON`, `embedded_su` waits for the response values. It expects the response values one per line, in the order the messages were given.

Phase 3: Completion

After zero or more conversation blocks, `embedded_su` emits a result block instead of a conversation block.

Upon success, `embedded_su` emits a single line containing the word “SUCCESS”. The word SUCCESS may be followed by whitespace and additional data. This data, if present, must be ignored.

Upon failure, `embedded_su` emits a single line containing the word “ERROR”, followed by a text block as described under “Text Blocks”. The text block gives an error message. The word ERROR may be followed by whitespace and additional data. This data, if present, must be ignored.

Text Blocks

Initialization blocks, message blocks, and error blocks are all text blocks. These are blocks of text that are terminated by a line containing a single period (.). Lines in the block that begin with a “.” have an extra “.” prepended to them.

Internationalization All messages are localized to the current locale; no further localization is required.

SECURITY `embedded_su` uses [pam\(3PAM\)](#) for authentication, account management, and session management. Its primary function is to export the PAM conversation mechanism to an unprivileged program. Like [su\(1M\)](#), the PAM configuration policy can be used to control `embedded_su`. The PAM service name used is “`embedded_su`”.

`embedded_su` is almost exactly equivalent to [su\(1M\)](#) for security purposes. The only exception is that it is slightly easier to use `embedded_su` in writing a malicious program that might trick a user into providing secret data. For those sites needing maximum security, potentially at the expense of application functionality, the **EXAMPLES** section shows how to disable `embedded_su`.

Examples In the following examples, left angle brackets (<<<) indicate a line written by `embedded_su` and read by the invoking application. Right angle brackets (>>>) indicate a line written by the application and read by `embedded_su`.

EXAMPLE 1 Executing a command with the Correct Password

The following example shows an attempt to execute “somecommand” as “someuser”, with the correct password supplied:

```
/usr/lib/embedded_su someuser -c somecommand
>>>.
<<<CONV 1
<<<PAM_PROMPT_ECHO_OFF
<<<Password:
<<<.
>>>[ correct password ]
<<<SUCCESS
[ somecommand executes ]
```

EXAMPLE 2 Executing a command with the Incorrect Password

The following example shows an attempt to execute “somecommand” as “someuser”, with the incorrect password supplied:

```
/usr/lib/embedded_su someuser -c somecommand
>>>.
<<<CONV 1
<<<PAM_PROMPT_ECHO_OFF
<<<Password:
<<<.
>>>[ incorrect password ]
[ delay ]
<<<ERROR
<<<embedded_su:Sorry
<<<.
[ exit ]
```

EXAMPLE 3 Message Examples

A `pam_message` structure with `msg_style` equal to `PAM_TEXT_INFO` and `msg` equal to “foo” produces:

```
PAM_TEXT_INFO
foo
.
```

A `pam_message` structure with `msg_style` equal to `PAM_ERROR_MESSAGE` and `msg` equal to “bar\n” produces:

```
PAM_ERROR_MESSAGE
bar
[ blank line ]
.
```

EXAMPLE 3 Message Examples (Continued)

A `pam_message` structure with `msg_style` equal to `PAM_ERROR_MESSAGE` and `msg` equal to “`aaa\nbbb`” produces:

```
PAM_ERROR_MESSAGE
aaa
bbb
.
```

A `pam_message` structure with `msg_style` equal to `PAM_TEXT_INFO` and `msg` equal to "" produces:

```
PAM_TEXT_INFO
[ blank line ]
.
```

A `pam_message` structure with `msg_style` equal to `PAM_TEXT_INFO` and `msg` equal to `NULL` produces:

```
PAM_TEXT_INFO
.
```

EXAMPLE 4 Disabling `embedded_su`

To disable `embedded_su`, add a line to the `/etc/pam.conf` file similar to:

```
embedded_su auth requisite pam_deny.so.1
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

Name etrn – start mail queue run

Synopsis `etrn [-b] [-v] server-host [client-hosts]`

Description SMTP's ETRN command allows an SMTP client and server to interact, giving the server an opportunity to start the processing of its queues for messages to go to a given host. This is meant to be used in start-up conditions, as well as for mail nodes that have transient connections to their service providers.

The `etrn` utility initiates an SMTP session with the host *server-host* and sends one or more ETRN commands as follows: If no *client-hosts* are specified, `etrn` looks up every host name for which `sendmail(1M)` accepts email and, for each name, sends an ETRN command with that name as the argument. If any *client-hosts* are specified, `etrn` uses each of these as arguments for successive ETRN commands.

Options The following options are supported:

-b System boot special case. Make sure localhost is accepting SMTP connections before initiating the SMTP session with *server-host*.

This option is useful because it prevents race conditions between `sendmail(1M)` accepting connections and *server-host* attempting to deliver queued mail. This check is performed automatically if no *client-hosts* are specified.

-v The normal mode of operation for `etrn` is to do all of its work silently. The `-v` option makes it verbose, which causes `etrn` to display its conversations with the remote SMTP server.

Environment Variables No environment variables are used. However, at system start-up, `svc:/network/smtp:sendmail` reads `/etc/default/sendmail`. In this file, if the variable `ETRN_HOSTS` is set, `svc:/network/smtp:sendmail` parses this variable and invokes `etrn` appropriately. `ETRN_HOSTS` should be of the form:

```
"s1:c1.1,c1.2      s2:c2.1 s3:c3.1,c3.2,c3.3"
```

That is, white-space separated groups of *server:client* where *client* can be one or more comma-separated names. The *:client* part is optional. *server* is the name of the server to prod; a mail queue run is requested for each *client* name. This is comparable to running:

```
/usr/lib/sendmail -qR client
```

on the host *server*.

Examples EXAMPLE 1 Using `etrn`

Inserting the line:

```
ETRN_HOSTS="s1.domain.com:clnt.domain.com s2.domain.com:clnt.domain.com"
```

EXAMPLE 1 Using etrn (Continued)

in `/etc/default/sendmail` results in `svc:/network/smtp:sendmail` invoking `etrn` such that ETRN commands are sent to both `s1.domain.com` and `s2.domain.com`, with both having `clnt.domain.com` as the ETRN argument.

The line:

```
ETRN_HOSTS="server.domain.com:client1.domain.com,client2.domain.com"
```

results in two ETRN commands being sent to `server.domain.com`, one with the argument `client1.domain.com`, the other with the argument `client2.domain.com`.

The line:

```
ETRN_HOSTS="server1.domain.com server2.domain.com"
```

results in set of a ETRN commands being sent to both `server1.domain.com` and `server2.domain.com`; each set contains one ETRN command for each host name for which [sendmail\(1M\)](#) accepts email, with that host name as the argument.

Files `/etc/mail/sendmail.cf` sendmail configuration file
`/etc/default/sendmail` Variables used by `svc:/network/smtp:sendmail`

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

RFC 1985

Notes Not all SMTP servers support ETRN.

Name fbconfig – frame buffer configuration utility

Synopsis fbconfig [-dev *device_file*] [-help]
fbconfig -list
fbconfig -gui
fbconfig -res \?
fbconfig [-dev *device_file*] [-file machine | system]
[*device_specific_options*] [-res *video-mode*] [*defaults*]
[-prconf] [-prdid[raw] [parsed]] [-propt]

Description fbconfig is the generic command line interface to query and/or to configure a frame buffer device. Depending on the command line options, fbconfig can invoke a GUI program, or it can invoke a device-specific configuration program. The choice of device configuration program depends both on the device (specified with -dev) and on the currently configured X server.

The options recognized by fbconfig are shown in the first three command forms in the SYNOPSIS section. The remaining forms illustrate options that may be passed to a device-specific configuration program that performs the actual operations. The interpretation of these options will depend upon the specific configuration program that is invoked. The options shown are supported by most device configuration programs.

If the -dev option is omitted, the default frame buffer (/dev/fb or /dev/fb0) is assumed.

Options The following options are supported by fbconfig:

-dev *device_file*

Specify the frame buffer device by its full pathname or simple filename. Pathnames of installed devices can be displayed using the -list option. If the -dev option is omitted, the default device is /dev/fb.

-gui

Invoke the Graphical User Interface (GUI). The GUI is available if the SUNWdcm package is installed. All other options are ignored.

The GUI can configure devices (as an alternative to the fbconfig command line) and can update the Xservers file without directly editing the file. The GUI allows the user that is logged in on the graphics device or devices to configure which graphics displays the window system should use, their screen layout (where they appear on the user's desktop), and screen properties (X attributes).

In addition, the GUI allows advanced users to create a new video format (resolution) that some graphics devices can select from fbconfig command line or from the device-dependent portion of the GUI. The GUI's online help explains all options and features.

-help

Displays the supported fbconfig command line options, along with a brief explanation of each. Also displays the -help text of the device-specific configuration program, if any. The frame buffer device can be specified using the -dev option, otherwise the default is used. Other fbconfig options are ignored. This is the default fbconfig option.

-list

Displays the pathnames of the installed frame buffer devices, the device model of each, and the configuration program that would be invoked for each device with the currently configured X server. Other fbconfig options are ignored.

| Device File Name | Device Model | Config Program |
|---------------------|--------------|----------------|
| ----- | ----- | ----- |
| /dev/fbs/kfb0 | XVR-2500 | SUNWkfb_config |
| /dev/fbs/kfb1 | XVR-2500 | SUNWkfb_config |
| /dev/fbs/nfb0 [a b] | XVR-300 | SUNWnfb_config |
| /dev/fbs/pfb0 [a b] | XVR-100 | SUNWpfb_config |

The following options are commonly supported by the device-specific configuration programs:

-defaults

Sets configuration options to their default values.

-file machine | system

Specifies which xorg.conf configuration file to use.

-prconf

Display the current configuration for the frame buffer and display device(s).

-predid [raw] [parsed]

Display the E-EDID (Enhanced Extended Display Identification Data) information obtained from the display device(s), which must be online, connected to the frame buffer. The output will be raw hexadecimal and/or human-readable text. The default is parsed.

-propt

Display the current software configuration.

-res \?

Display the video modes (resolutions) that can be used with the -res *video-mode* option.

Other supported options are determined by the device-specific configuration program:

device-specific-options

The syntax and descriptions of additional device-specific options are displayed in the -help output of fbconfig or the device-specific program. They are also contained in the man page for the device-specific program.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|--------------------------|
| Availability | system/graphics/fbconfig |

See Also [SUNWgfb_config\(1M\)](#), [SUNWifb_config\(1M\)](#), [SUNWjfb_config\(1M\)](#), [SUNWkfb_config\(1M\)](#), [SUNWnfb_config\(1M\)](#), [SUNWpfb_config\(1M\)](#), [SUNWzulu_config\(1M\)](#), [afbconfig\(1M\)](#), [fbconf_xorg\(1M\)](#), [ffbconfig\(1M\)](#), [m64config\(1M\)](#), [pgxconfig\(1M\)](#), [attributes\(5\)](#)

Xserver(1), *Xorg(1)*, *Xsun(1)*, which are part of the OpenWindow, not the SunOS, man page collection.

Limitations Because of limitations in the m64 kernel driver and related software, fbconfig (with the -prconf option) is unable to distinguish between a current depth of 24 or 8+24. The -propt option returns the depth specified in the OWconfig file, which will be in effect following the next restart of the window system. The xwininfo utility, usually shipped in the package containing frame buffer software (such as SUNWxwplt), reports current depth of a specified window.

Name fbconf_xorg – configure frame buffer devices for Xorg

Synopsis /usr/lib/fbconfig/fbconf_xorg [-dev *device-file*]
 [-file *machine* | *system* | *config-path*]
 [-res *video-mode* [nocheck | noconfirm]]
 [*device-specific-options*]
 [-defaults] [-prconf] [-predid [raw] [parsed]] [-propt]
 /usr/lib/fbconfig/fbconf_xorg [-dev *device-file*] [-prconf] [-propt]
 /usr/lib/fbconfig/fbconf_xorg [-dev *device-file*] [-help] [-res ?]

For kfb devices:

```
/usr/lib/fbconfig/fbconf_xorg [-dev device-file]
[-file machine | system | config-path]
[-res video-mode [nocheck | noconfirm]]
[-deflinear true | false] [-defoverlay true | false]
[-deftransparent true | false]
[-doublehigh enable | disable]
[-g gamma-correction-value]
[-multisample available | disable | forceon]
[-offset x-val y-val] [-samples 1 | 2 | 4 | 8 | 16 ]
[-slave disable | multiview] [-stereo true | false]
[-defaults] [-prconf] [-predid [raw] [parsed]] [-propt]
```

Description The fbconf_xorg utility configures Frame Buffer devices and some of the X11 window system defaults for Xorg by updating the xorg.conf configuration file.

The first fbconf_xorg command form shown in the SYNOPSIS section stores the specified option values in the xorg.conf configuration file. These settings are used to initialize the frame buffer device the next time the window system is run on that device. The persistence of these settings across window system sessions and system reboots is determined by the xorg.conf file.

The second and third command forms display information, and do not alter the xorg.conf file. The presence of the -help and/or -res ? options will cause any other option (not shown in the third form) to be ignored.

You can configure only one frame buffer device at a time. To configure multiple devices, invoke the fbconf_xorg utility separately for each device.

Only frame buffer device options can be specified with fbconf_xorg. Use the normal window system options to specify default depth (see [svccfg\(1M\)](#)), default visual class, and so forth. Specify these as device modifiers on the command line. See *Xserver(1)*, part of the OpenWindows, not the SunOS, man page collection.

You can specify which xorg.conf file to open. By default, fbconf_xorg opens the machine-specific file, /etc/X11/xorg.conf. Use the -file option to specify an alternate file. For example, the system-global file, /usr/X11/xorg.conf, can be opened instead.

These standard `xorg.conf` files can be written only by the superuser or someone with the Primary Administrator role. Consequently, the `fbconf_xorg` program is run with `setuid root` permission.

Options The following options are supported for all frame buffer devices:

`-defaults`

Sets configuration options for the specified device to their default values. This does not affect the `-res` video mode setting. See the device-specific portions of the `DEFAULTS` section below.

`-dev device-file`

Specifies the frame buffer device by either its full pathname or simple filename (for example, `/dev/fbs/kfb0` or `kfb0`). Pathnames of installed devices can be displayed using the `-list` option to `fbconfig(1M)`. If the `-dev` option is omitted, the default device, `/dev/fb`, is used.

`-file machine | system | config-path`

Specifies which `xorg.conf` file to open. If `machine` is specified, the machine-specific `/etc/X11/xorg.conf` file is opened. If `system` is specified, the global `/usr/X11/xorg.conf` file is opened. The absolute pathname of a configuration file can be used instead. If the specified file does not exist and is to be updated, it will be created. The file system that will contain the `xorg.conf` file must be writable by someone with superuser-like privileges. This option has no effect unless other options are specified. The default is `machine`.

`-help`

Display the `fbconf_xorg` command line options that are supported in conjunction with the frame buffer device, along with a brief explanation of each option. The frame buffer device can be specified using the `-dev` option.

`-prconf`

Display the current configuration for the frame buffer device and attached display device(s). The frame buffer device can be specified using the `-dev` option.

The `-prconf` output might resemble:

Monitor/Resolution Information:

```
Monitor manufacturer: SUN
Product Code: 4
Serial Number: 12212555
Manufacture date: 2000, week 9
EDID Version: 1.1
Monitor dimensions: 36x29 cm
Default Gamma: 2.62
Monitor preferred resolution: SUNW_STD_1280x1024x60
Monitor supported resolutions from EDID: SUNW_STD_1280x1024x60,
SUNW_STD_1280x1024x76, 1152x900x66, VESA_STD_1280x1024x75,
VESA_STD_1280x1024x60, SUNW_STD_1152x900x66,
VESA_STD_720x400x70, VESA_STD_640x480x60,
```

```

VESA_STD_640x480x67, VESA_STD_640x480x72,
VESA_STD_640x480x75, VESA_STD_800x600x56,
VESA_STD_800x600x60, VESA_STD_800x600x72,
VESA_STD_800x600x75, VESA_STD_832x624x75,
VESA_STD_1024x768x60, VESA_STD_1024x768x70, 1024x768x75
Current resolution setting: FALLBACK_1152x900x66

```

```

FrameLock Configuration:
  Slave Mode: Disabled

```

-predid [raw] [parsed]

Display the E-EDID (Enhanced Extended Display Identification Data) information obtained from the display device(s), which must be online, connected to the frame buffer. The frame buffer device can be specified using the `-dev` option. The output will be raw hexadecimal and/or human-readable (parsed) text. The default is parsed.

The `-predid raw` output might resemble:

```

--- EDID Data for /dev/fbs/kfb0 ---

Block 0: EDID Base Block
0x00:  00 FF FF FF FF FF FF 00 04 43 06 F2 01 00 00 00
0x10:  01 11 01 04 0F 2B 20 78 2B 9C 68 A0 57 4A 9B 26
0x20:  12 48 4C FF FF 80 A9 59 A9 4F A9 4A A9 45 81 99
0x30:  81 80 61 59 45 59 48 3F 40 30 62 B0 32 40 40 C0
0x40:  13 00 AB 40 11 00 00 1E 00 00 00 FD 00 32 5A 1E
0x50:  6E 17 04 11 00 C8 90 00 50 3C 00 00 00 F7 00 0A
0x60:  F7 0F 03 87 C0 00 00 00 00 00 00 00 00 00 00 FC
0x70:  00 41 42 43 20 4C 43 44 32 31 0A 20 20 20 00 0B

```

-propt

Display all option settings for the frame buffer device, either as they currently are or as they will be represented in the `xorg.conf` configuration file when `fbconf_xorg` completes. The device can be specified using the `-dev` option, and the file using the `-file` option.

The `-propt` output might resemble:

```

--- Graphics Configuration for /dev/fbs/kfb0 ---

xorg.conf: machine -- /etc/X11/xorg.conf
  Screen section: "kfb0"
  Device section: "kfb0"
  Monitor section: "kfb0"

Video Mode: SUNW_STD_1280x1024x76
  StereoEnable: False

Multisample Information:
  Multisample Mode: Disable
  Samples Per Pixel: 4

```

Screen Information:

```

DoubleWide: Disabled
DoubleHigh: Disabled
Offset/Overlap: [0, 0]

```

Visual Information:

```

Default Visual: Non-Linear Normal Visual
Gamma Correction Value: Using gamma value 2.22

```

-res ?

Display a list of video modes that can be used with the `-res video-mode` option.

The `?` argument may need to be escaped or placed in quotes (`\?`, `"?"`, or `'?'`), to protect it from misinterpretation by the shell.

The `-res ?` output might resemble:

Video modes accepted by the `-res` option:

```

AUTO [1][2]
NONE [1][2]
SUNW_STD_1920x1200x75
SUNW_STD_1920x1200x70
SUNW_DIG_1920x1200x60
SUNW_STD_1920x1080x72
SUNW_DIG_1920x1080x60
...
...
VESA_STD_640x480x75 [1]
VESA_STD_640x480x72 [1]
VESA_STD_640x480x60 [1]

```

[1] Resolution is supported by monitor

[2] Preferred resolution for monitor

Abbreviations such as “1280x1024x75” might also be used.

-res *video-mode* [nocheck | noconfirm]

Set the video mode for the display device that is connected to the frame buffer device.

A list of video modes can be displayed using the `-res ?` option.

The basic format of a video-mode is *widthxheightxrate*, where:

- *width* is the screen width in pixels.
- *height* is the screen height in pixels.
- *rate* is the vertical frequency of the screen refresh.

A video-mode argument may have an @ (at sign) instead of x preceding the refresh rate. For instance, 1280x1024x76 and 1280x1024@76 are equivalent.

A video-mode name may carry additional information, as with `SUNW_STD_1280x1024x76`.

The `-res` argument, `auto`, represents the video mode that is currently programmed into the device. The argument, `none`, is a synonym for `auto`.

Note that some video modes might be inappropriate for certain frame buffer devices and/or display devices.

The `-res` option accepts suboption keywords following the video-mode specification.

`nocheck`

The `nocheck` suboption causes the video-mode argument to be accepted, regardless of whether it is supported by the currently attached monitor, whether it is known within the current configuration, and so forth. Note that using an unchecked, inappropriate video mode can leave the system without usable video output. This suboption is useful if a different monitor is to be connected to the frame buffer device. This suboption also implies `noconfirm`.

`noconfirm`

If the video-mode argument is unable to be validated, the default action is to display a warning message and ask the user whether to continue. The `noconfirm` suboption suppresses this confirmation request. This suboption is useful when `fbconf_xorg` is being run from a shell script.

The following device-specific options are supported for certain frame buffer devices. Unless specified otherwise, these options do not take effect until the user logs out and back in.

`-deflinear true | false`

This option selects the default X visual. Two types of visuals are supported, linear and nonlinear. Linear visuals are gamma corrected. Nonlinear visuals are not.

If the value of this option is `true`, the default visual is set to default depth 24 and the default class is `TrueColor` with gamma correction enabled. If `false`, a nonlinear visual that satisfies the other default visual selection options, such as the default depth and default class, is chosen as the default visual.

The `-deflinear`, `-defoverlay`, and `-deftransparent` options each select the default X visual. Only one of these may be enabled at a time. Enabling one causes the others to be disabled.

`-defoverlay true | false`

This option selects the default X visual. The `kfb` device provides an 8-bit `PseudoColor` visual whose pixels are disjoint from the rest of the visuals. This is called the overlay visual. Windows created in this visual will not damage windows created in other visuals. The converse, however, is not true: Windows created in other visuals will damage overlay windows.

If the value of this option is `true`, the overlay visual is the default visual. The default depth is 8-bit and the default class is `PseudoColor`. If `false`, the non-overlay visual that satisfies the other default visual selection options, such as the default depth and the default class, is chosen as the default visual.

The `-deflinear`, `-defoverlay`, and `-deftransparent` options each select the default X visual. Only one of these may be enabled at a time. Enabling one causes the others to be disabled.

`-deftransparent true | false`

This option selects the default X visual. The `kfb` device provides an 8-bit `PseudoColor` visual whose pixels are disjoint from the rest of the visuals. This is called the overlay visual. Windows created in this visual will not damage windows created in other visuals.

If the value of this option is `true`, the overlay visual used as the default is a transparent overlay visual. A visual with transparency supports a colormap with 255 colors and one transparent pixel. The default depth is 8-bit and the default class is `PseudoColor`. If `false`, the nonoverlay visual that satisfies the other default visual selection options, such as the default depth and the default class, is chosen as the default visual.

The `-deflinear`, `-defoverlay`, and `-deftransparent` options each select the default X visual. Only one of these may be enabled at a time. Enabling one causes the others to be disabled.

`-doublehigh enable | disable`

Configures the two outputs of the frame buffer device into one vertical virtual display. The default is `disable`. The `-doublewide` and `-doublehigh` options are mutually exclusive. Enabling one causes the other to be disabled.

`-doublewide enable | disable`

Configures the two outputs of the frame buffer device into one horizontal virtual display. The default is `disable`. The `-doublewide` and `-doublehigh` options are mutually exclusive. Enabling one causes the other to be disabled.

`-g gamma-correction-value`

Sets the gamma correction value. All linear visuals provide gamma correction. The gamma correction value should be in the range, `0.1` to `10.0`. The default is `2.22`. This option can be used while the window system is running. Changing the gamma correction value affects all of the windows displayed by linear visuals.

`-g file gamma-correction-file`

Loads the gamma correction table from the file specified by `gamma-correction-file`. This text file specifies the gamma correction values for the R, G, and B channels. Three consecutive values form an RGB triplet. For a `kfb` device, there must be exactly 256 RGB triplets. A value may be represented in hexadecimal, decimal, or octal format (for example, `0x3FF`, `1023`, or `01777`, respectively). Values are separated by one or more whitespace or new line characters. Comments begin with a hash sign character (`#`) and end at the end of the line.

You can load the gamma correction table with this option while the window system is running. The new gamma correction affects all the windows being displayed using the linear visuals. When gamma correction is done using a user-specified table, the gamma correction value (`-g`) is undefined. By default, the window system assumes a gamma correction value of 2.22 and loads the gamma table it creates corresponding to this value.

The following is an example of a *gamma-correction-file* file:

```
# Gamma Correction Table
0x00 0x00 0x00
0x01 0x01 0x01
0x02 0x02 0x02
... ..
... ..
0xFF 0xFF 0xFF
```

`-multisample available | disable | forceon`

If set to `disable`, no multisample is possible. If set to `available`, multisample is possible but is selected on a per-window basis using a library interface. If set to `forceon`, all Sun OpenGL windows are rendered using multisampling. To query the number of samples used, specify the `-propt` option or run the `xglnfo` utility. The `xglnfo` utility can return the number of multisamples if `-multisample` is set to `available`. The default is `disable`. `xglnfo` is described in the `xglnfo(1)` man page, in the Sun OpenGL man page collection.

`-offset x-val y-val`

Adjusts the position of the specified stream by the value specified. This option is only implemented in `-doublewide` and `-doublehigh` modes. For `-doublewide`, use the `x-val` to position the rightmost stream. Negative is left (overlaps with the left stream). For `-doublehigh`, use the `y-val` to position the bottom stream. Negative is up (overlaps with top stream). The default is `[0, 0]`.

`-samples 1 | 2 | 4 | 8 | 16`

Requests the number of samples to compute per display pixel. The requested number of samples per pixel is used if `-multisample` is not disabled and resources exist for the request. To query the number of samples used, specify the `-propt` option or run the `xglnfo` utility. The `xglnfo` utility can return the number of multisamples after you specify the option `-multisample available`. The default is 4.

`-slave disable | multiview`

If you set the `multiview` argument for the `-slave` option, the device synchronizes video with a master through the multiview genlock ribbon cable. The system should be powered off whenever connecting or disconnecting this cable. Both devices should be running the same resolution and the option should be issued when the window system is running. The default is `disable`.

Defaults Certain options have implied default arguments. The default argument is used when the option is not present on the `fbconf_xorg` command line. For instance, a default argument for `-dev` is `/dev/fb`.

Options that set configuration state do not have implied defaults. The `-res` option is one example. If a configuration option is omitted from the `fbconf_xorg` command line, the corresponding `xorg.conf` configuration setting will remain unchanged. The exception is that if configuration options are mutually exclusive, setting one will automatically unset each of the others. An example is `-deflinear`, `-defoverlay`, and `-deftransparent`.

If a configuration setting is not present in the configuration file when the window system is run, a default value will be used. For instance, the default state associated with `-res` is `auto`. A setting might not be present in the file, or the file itself might not exist, until `fbconf_xorg` has been invoked with the corresponding command line option.

The `-defaults` option sets the default values for most configuration settings.

Options and their defaults are shown below.

Device-independent defaults:

| Option | Default Argument |
|--------------------|----------------------|
| <code>-dev</code> | <code>/dev/fb</code> |
| <code>-file</code> | <code>machine</code> |

| Option | Default State |
|-------------------|-------------------|
| <code>-res</code> | <code>auto</code> |

kfb-specific defaults:

| Option | Default State or <code>-defaults</code> Value |
|------------------------------|-----------------------------------------------|
| <code>-deflinear</code> | <code>false</code> |
| <code>-defoverlay</code> | <code>false</code> |
| <code>-deftransparent</code> | <code>false</code> |
| <code>-doublehigh</code> | <code>disable</code> |
| <code>-doublewide</code> | <code>disable</code> |
| <code>-g</code> | <code>2.22</code> |
| <code>-multisample</code> | <code>disable</code> |
| <code>-offset</code> | <code>0 0</code> |
| <code>-samples</code> | <code>4</code> |
| <code>-slave</code> | <code>disable</code> |
| <code>-stereo</code> | <code>false</code> |

Examples **EXAMPLE 1** Switching the Resolution of the Monitor Type

The following example sets the video mode for the monitor on the `/dev/fbs/kfb0` device to 1280 x 1024 at 76 Hz:

```
example% fbconf_xorg -dev kfb0 -res 1280x1024x76
```

Exit Status The following exit values are returned:

- 0
Execution completed successfully.
- 1
Invalid command line usage.
- 2
An error occurred.

Files /dev/fb Symbolic link to the default frame buffer device.

 /dev/fbs/kfbn Device special file for a kfb frame buffer

 /usr/lib/fbconfig/SunModes_xorg.conf Video mode definitions included in new configuration files.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|---------------------------------------|
| Availability | system/graphics/fbconfig/fbconfig-kfb |
| Interface Stability | Uncommitted |

 fcadm list-fcoe-ports *MAC_Interface*
 fcadm force-lip *Port_WWN*
 fcinfo [-V]
 fcadm [-V]
 fcinfo [-?]
 fcadm [-?]

Description fcinfo and fcadm are command line interfaces that collect administrative information on fibre channel host bus adapter (HBA) ports on a host. They also collect data on any fibre channel targets that might be connected to those ports in a Storage Area Network (SAN).

A port can be either in initiator mode or target mode. The same FC attribute information and remote port information are applied to both the initiator and the target modes port except that SCSI-related operations described below do not apply for the target mode port.

SUBCOMMANDS The following subcommands are supported by both fcinfo and fcadm:

| | |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| hba-port | Lists information for the HBA port referenced by the specified <i>HBA_port_WWN</i> . If <i>HBA_port_WWN</i> is not specified, all initiator mode and target mode fibre channel HBA ports on the host will be listed. |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| | |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>remote-port</code> | Lists the <i>remote-port</i> information for those remote ports that are specified. If no <i>REMOTE_port_WWN</i> is specified, all remote ports that are visible through <i>HBA_port_WWN</i> are listed. |
| <code>logical-unit lu</code> | Lists the logical unit referenced by the specified <i>device_path</i> . If <i>device_path</i> is not specified, all fibre channel logical units will be listed. This subcommand applies only to the initiator mode. |

The following subcommands, which administer N_Port ID Virtualization (NPIV) HBA ports, are supported only by `fcadm`:

`create-npiv-port`
Create an NPIV virtual port on the specified adapter.

`delete-npiv-port`
Delete an NPIV virtual port. This delete only ports create by `fcadm`.

The following subcommands, which administer Fibre Channel over Ethernet (FCoE) ports, are supported only by `fcadm`:

`create-fcoe-port`
Creates a FCoE port associated with the given MAC interface and the given *Port_WWN/Node_WWN*. If `-p` or `-n` is not specified, the Port WWN or Node WWN will be generated automatically. If the specified MAC interface does not support multiple unicast address, no FCoE port will be created and you receive a message indicating that you can add an `-f` option to force enabling promiscuous mode on the specified MAC interface to enable FCoE.

`delete-fcoe-port`
Deletes the FCoE port associated with the specified MAC interface.

`list-fcoe-ports`
List information of FCoE ports.

`force-lip`
Force the link to reinitialize. When issuing this subcommand on the target port side, causes a reset of the target port. When issuing it from the host port side, resets the host port. When an FC switch is connected, other FC ports in the SAN will get a RSCN (Remote State Change Notification). Furthermore, other initiators will always rediscover the port after this, and the FC login session will be established or reused. Also, I/Os will be continued. This command is disruptive to I/Os, but it is not destructive, as it does not cause any data loss.

Options The following options are supported:

`-e, --fcoe`
Lists the information for all FCoE ports.

-f, --fcoe-promiscuous

Used with `create-fcoe-port` to create an FCoE port on a MAC interface associated with a NIC that does not support multiple unicast address. Promiscuous mode will be enabled for the specified MAC interface.

-l, --linkstat

Lists the link error statistics information for the port referenced by the specified *HBA_port_WWN* or *REMOTE_port_WWN*.

-n *HBA_node_WWN*, --node *HBA_node_WWN*

When used with NPIV options, specify a virtual node WWN. If used with `create-npiv-port`, it can be omitted, and a random based WWN will be used. It is mandatory for `delete-npiv-port`.

When used with `create-fcoe-port` subcommand, specify the node WWN for the FCoE port. It can be omitted, in which case a WWN will be generated based on the MAC address of the specified MAC interface.

-p *HBA_port_WWN*, --port *HBA_port_WWN*

Retrieve remote port information from the *HBA_port_WWN* of the local HBA port on the host. When used with the `remote-port` subcommand, the `-p` option is mandatory.

When used with NPIV options, specify a virtual port WWN. If used with `create-npiv-port`, it can be omitted, and a random based WWN will be used. It is mandatory for `delete-npiv-port`.

When used with `create-fcoe-port` subcommand, specify the port WWN for the FCoE port. It can be omitted, in which case a WWN will be generated based on the MAC address of the specified MAC interface.

-s, --scsi-target

Lists the SCSI target information for all remote ports the user has asked for. The `-p, --port` option must always be specified and must be a valid HBA port on the host. This HBA port will be used as the initiator for which to retrieve the SCSI level target information. Note that this will only function on remote port fibre channel World-Wide Names that support an FC4 type of SCSI. This option applies only to an initiator mode port.

-t [*HBA_node_WWN*], --target [*HBA_node_WWN*]

Lists the information for the port with the target mode referenced by the specified *HBA_node_WWN* or all target mode ports discovered in the host.

When used with `create-fcoe-port`, create a FCoE target mode port.

-v, --verbose

When used with the `logical-unit` subcommand, the `-v` displays additional information for the logical unit, including SCSI vendor and product information and device type as well as the FC World-Wide names for the local and remote fibre channel ports to which this device is attached.

- V, --version
Displays the version information.
- ?, --help
Displays the usage information.

Examples EXAMPLE 1 Listing All HBA Ports

The following command lists all initiator mode fibre channel HBA ports on the host:

```
# fcinfo hba-port

HBA Port WWN: 210000e08b074cb5
  Port Mode: Initiator
  OS Device Name: /dev/cfg/c1
  Manufacturer: QLogic Corp.
  Model: 375-3108-xx
  Firmware Version: 3.3.116
  FCode/BIOS Version: 1.13.08
  Serial Number: not available
  Driver Name: qlc
  Driver Version: 20070212-2.19
  Type: N-port
  State: online
  Supported Speeds: 1Gb 2Gb
  Current Speed: 2Gb
  Node WWN: 200000e08b074cb5
NPIV Port List:
  Virtual Port 1:
    Port WWN: 200000e08b074cb1
    Node WWN: 200000e08b074cb3
HBA Port WWN: 210100e08b274cb5
  Port Mode: Initiator
  OS Device Name: /dev/cfg/c2
  Manufacturer: QLogic Corp.
  Model: 375-3108-xx
  Firmware Version: 3.3.116
  FCode/BIOS Version: 1.13.08
  Serial Number: not available
  Driver Name: qlc
  Driver Version: 20070212-2.19
  Type: N-port
  State: online
  Supported Speeds: 1Gb 2Gb
  Current Speed: 2Gb
  Node WWN: 200100e08b274cb5
HBA Port WWN: 210000e08b072ab5
  Port Mode: Initiator
  OS Device Name: /dev/cfg/c3
```

EXAMPLE 1 Listing All HBA Ports *(Continued)*

```

Manufacturer: QLogic Corp.
Firmware Version: 3.3.116
FCode/BIOS Version: 1.13.08
Model: 375-3108-xx
Serial Number: not available
Driver Name: qlc
Driver Version: 20070212-2.19
Type: L-port
State: online
Supported Speeds: 1Gb 2Gb
Current Speed: 2Gb
Node WWN: 200000e08b072ab5
HBA Port WWN: 210100e08b272ab5
Port Mode: Initiator
OS Device Name: /dev/cfg/c4
Manufacturer: QLogic Corp.
Model: 375-3108-xx
Firmware Version: 3.3.116
FCode/BIOS Version: 1.13.08
Serial Number: 0402F00-0549112808
Driver Name: qlc
Driver Version: 20070212-2.19
Type: N-port
State: online
Supported Speeds: 1Gb 2Gb
Current Speed: 2Gb
Node WWN: 200100e08b272ab5

```

EXAMPLE 2 Listing Target Mode HBA Ports

The following command lists all target mode fibre channel HBA ports on the host:

```

# fcinfo hba-port -t
HBA Port WWN: 210100e08bb09221
Port Mode: Target
Port ID: 10700
OS Device Name: Not Applicable
Manufacturer: QLogic Corp.
Model: d30ac7e0
Firmware Version: 4.0.109
FCode/BIOS Version: N/A
Type: F-port
State: online
Supported Speeds: not established
Current Speed: 2Gb
Node WWN: 200100e08bb09221
HBA Port WWN: 210000e08b909221

```

EXAMPLE 2 Listing Target Mode HBA Ports (Continued)

```
Port Mode: Target
Port ID: 10900
OS Device Name: Not Applicable
Manufacturer: QLogic Corp.
Model: d37ad1e0
Firmware Version: 4.0.109
FCode/BIOS Version: N/A
Type: F-port
State: online
Supported Speeds: not established
Current Speed: 2Gb
Node WWN: 200000e08b909221
HBA Port WWN: 200000144fc2d508
Port Mode: Target
Port ID: 9a0025
OS Device Name: Not Applicable
Manufacturer: Sun Microsystems, Inc.
Model: FCoE Virtual FC HBA
Firmware Version: N/A
FCode/BIOS Version: N/A
Serial Number: N/A
Driver Name: COMSTAR FCOET
Driver Version: 1.0
Type: F-port
State: online
Supported Speeds: 1Gb 10Gb
Current Speed: 10Gb
Node WWN: 100000144fc2d508
HBA Port WWN: 200000144fc2d509
Port Mode: Target
Port ID: 9a0023
OS Device Name: Not Applicable
Manufacturer: Sun Microsystems, Inc.
Model: FCoE Virtual FC HBA
Firmware Version: N/A
FCode/BIOS Version: N/A
Serial Number: N/A
Driver Name: COMSTAR FCOET
Driver Version: 1.0
Type: F-port
State: online
Supported Speeds: 1Gb 10Gb
Current Speed: 10Gb
Node WWN: 100000144fc2d509
```

EXAMPLE 3 Listing HBA Ports and Link Statistics

The following command lists information for the HBA ports and the link statistics for those ports:

```
# fcinfo hba-port -l 210000e08b074cb5 210100e08b274cb5
```

```
HBA Port WWN: 210000e08b074cb5
  Port Mode: Initiator
  OS Device Name: /dev/cfg/c1
  Manufacturer: QLogic Corp.
  Model: 375-3108-xx
  Firmware Version: 3.3.116
  FCode/BIOS Version: 1.13.08
  Serial Number: 0402F00-0549112808
  Driver Name: qlc
  Driver Version: 20070212-2.19
  Type: N-port
  State: online
  Supported Speeds: 1Gb 2Gb
  Current Speed: 2Gb
  Node WWN: 200000e08b074cb5
  Link Error Statistics:
    Link Failure Count: 0
    Loss of Sync Count: 0
    Loss of Signal Count: 0
    Primitive Seq Protocol Error Count: 0
    Invalid Tx Word Count: 0
    Invalid CRC Count: 0
HBA Port WWN: 210100e08b274cb5
  Port Mode: Initiator
  OS Device Name: /dev/cfg/c2
  Manufacturer: QLogic Corp.
  Model: 375-3108-xx
  Firmware Version: 3.3.116
  FCode/BIOS Version: 1.13.08
  Serial Number: 0402F00-0549112808
  Driver Name: qlc
  Driver Version: 20070212-2.19
  Type: N-port
  State: online
  Supported Speeds: 1Gb 2Gb
  Current Speed: 2Gb
  Node WWN: 200100e08b274cb5
  Link Error Statistics:
    Link Failure Count: 0
    Loss of Sync Count: 0
    Loss of Signal Count: 0
    Primitive Seq Protocol Error Count: 0
```

EXAMPLE 3 Listing HBA Ports and Link Statistics *(Continued)*

```
Invalid Tx Word Count: 0
Invalid CRC Count: 0
```

EXAMPLE 4 Listing All Remote Ports

The following command lists all remote ports that are visible through the given HBA port:

```
# fcinfo remote-port -p 210100e08b274cb5
```

```
Remote Port WWN: 50020f230000b4af
  Active FC4 Types: SCSI
  SCSI Target: yes
  Port Symbolic Name: unknown
  Node WWN: 50020f200000b4af
Remote Port WWN: 210000e08b07daa6
  Active FC4 Types: SCSI
  SCSI Target: no
  Port Symbolic Name: unknown
  Node WWN: 200000e08b07daa6
Remote Port WWN: 20030003ba27c788
  Active FC4 Types: SCSI
  SCSI Target: yes
  Port Symbolic Name: unknown
  Node WWN: 10000003ba27c788
Remote Port WWN: 210000e08b096a60
  Active FC4 Types: SCSI,IP
  SCSI Target: no
  Port Symbolic Name: unknown
  Node WWN: 200000e08b096a60
```

EXAMPLE 5 Listing Remote Ports and Link Statistics

The following command lists information for the remote ports and the link statistics for those ports:

```
# fcinfo remote-port -l -p 210100e08b272ab5
```

```
Remote Port WWN: 210100e08b296a60
  Active FC4 Types: SCSI,IP
  SCSI Target: no
  Port Symbolic Name: unknown
  Node WWN: 200100e08b296a60
  Link Error Statistics:
    Link Failure Count: 0
    Loss of Sync Count: 0
    Loss of Signal Count: 0
    Primitive Seq Protocol Error Count: 0
    Invalid Tx Word Count: 0
```

EXAMPLE 5 Listing Remote Ports and Link Statistics (Continued)

```

        Invalid CRC Count: 0
Remote Port WWN: 20030003ba27d56d
  Active FC4 Types: SCSI
  SCSI Target: yes
  Port Symbolic Name: unknown
  Node WWN: 10000003ba27d56d
  Link Error Statistics:
    Link Failure Count: 0
    Loss of Sync Count: 4765165
    Loss of Signal Count: 4765165
    Primitive Seq Protocol Error Count: 0
    Invalid Tx Word Count: 0
    Invalid CRC Count: 0
Remote Port WWN: 210100e08b27f7a6
  Active FC4 Types: SCSI
  SCSI Target: no

    Loss of Sync Count: 0
    Loss of Signal Count: 0
```

EXAMPLE 5 Listing Remote Ports and Link Statistics (Continued)

```

        Primitive Seq Protocol Error Count: 0
        Invalid Tx Word Count: 0
        Invalid CRC Count: 0
Remote Port WWN: 210000e08b074cb5
  Active FC4 Types: SCSI,IP
  SCSI Target: no
  Port Symbolic Name: unknown
  Node WWN: 200000e08b074cb5
  Link Error Statistics:
    Link Failure Count: 0
    Loss of Sync Count: 0
    Loss of Signal Count: 0
    Primitive Seq Protocol Error Count: 0
    Invalid Tx Word Count: 0
    Invalid CRC Count: 0
Remote Port WWN: 210100e08b296060
  Active FC4 Types: SCSI
  SCSI Target: no
  Port Symbolic Name: unknown
  Node WWN: 200100e08b296060
  Link Error Statistics:
    Link Failure Count: 0
    Loss of Sync Count: 0
    Loss of Signal Count: 0
    Primitive Seq Protocol Error Count: 0
    Invalid Tx Word Count: 0
    Invalid CRC Count: 0

```

EXAMPLE 6 Listing All SCSI Targets and Link Statistics

The following command lists all remote ports as well as the link statistics and *scsi-target* information:

```
# fcinfo remote-port -sl -p 210100e08b272ab5
```

```

Remote Port WWN: 210100e08b296a60
  Active FC4 Types: SCSI,IP
  SCSI Target: no
  Port Symbolic Name: unknown
  Node WWN: 200100e08b296a60
  Link Error Statistics:
    Link Failure Count: 0
    Loss of Sync Count: 0
    Loss of Signal Count: 0
    Primitive Seq Protocol Error Count: 0
    Invalid Tx Word Count: 0
    Invalid CRC Count: 0

```

EXAMPLE 8 Listing the Logical Unit

The following command lists the logical unit:

```
# fcinfo logical-unit
```

```

/dev/rdisk/c0t600C0FF000000000036223AE73EB705d0s2
/dev/rdisk/c0t600C0FF0000000000362272539E5B03d0s2
/dev/rmt/0n

```

EXAMPLE 9 Displaying Additional Information for the Logical Unit

The following command displays additional information about the logical unit using the `-v` option for device `/dev/rmt/0n`:

```
# fcinfo lu -v /dev/rmt/0n
```

```

OS Device Name: /dev/rmt/0n
  HBA Port WWN: 210000e07c030b91
  Remote Port WWN: 21010003b7830a6

```

EXAMPLE 9 Displaying Additional Information for the Logical Unit *(Continued)*

```

                LUN: 0
Vendor: STK
Product: 9940A
Device Type: Tape device

```

The following command displays additional information about the logical unit using the `-v` option for device `/dev/rdisk/c0t600C0FF000000000036223AE73EB705d0s2`

```

# fcinfo logical-unit -v \
  /dev/rdisk/c0t600C0FF000000000036223AE73EB705d0s2

OS Device Name: /dev/rdisk/c0t600C0FF000000000036223AE73EB705d0s2
  HBA Port WWN: 210100e08b27a8a1
    Remote Port WWN: 256000c0ffc03622
      LUN: 0
    Remote Port WWN: 216000c0ff803622
      LUN: 0
  HBA Port WWN: 210000e08b07a8a1
    Remote Port WWN: 256000c0ffc03622
      LUN: 0
    Remote Port WWN: 216000c0ff803622
      LUN: 0

Vendor: SUN
Product: StorEdge 3510
Device Type: Disk device

```

EXAMPLE 10 Adding an NIPV Port

The following command adds an NPIV port to the HBA with a port name:

```
210000e08b170f1c
```

The NPIV port has a port name of `2000000000000001` and a node name of `2100000000000001`.

```
# fcadm create-npiv-port -p 2000000000000001 -n 2100000000000001 \
210000e08b170f1c
```

```
Created NPIV Port:
  HBA Port WWN: 2000000000000001
  Node WWN: 2100000000000001
  Physical HBA Port WWN: 210000e08b170f1c
```

EXAMPLE 11 Adding an NIPV Port with Random WWN

The following command adds an NPIV port to the HBA with a randomly assigned port name of `210000e08b170f1c`.

EXAMPLE 11 Adding an NIPV Port with Random WWN (Continued)

```
# fcadm create-npiv-port 210000e08b170f1c
```

Created NPIV Port:

HBA Port WWN: 2038295824942801

Node WWN: 2100392849248001

Physical HBA Port WWN: 210000e08b170f1c

EXAMPLE 12 Deleting an NIPV Port

The following command deletes an NPIV port.

```
# fcadm delete-npiv-port -p 2000000000000001 -w 2100000000000001 \
210000e08b170f1c
```

EXAMPLE 13 Creating an FCoE Target Port

The following command creates an FCoE port associated with the MAC interface nxge0.

```
# fcadm create-fcoe-port -t nxge0
```

EXAMPLE 14 Deleting an FCoE Port

The following command deletes the FCoE port associated with the MAC interface nxge0.

```
# fcadm delete-fcoe-port -t nxge0
```

EXAMPLE 15 Listing Information for an FCoE Port

The following command lists information for FCoE ports.

```
# fcadm list-fcoe-ports
HBA Port WWN: 200000144fc2d508
  Port Type: Target
  MAC Name: nxge0
  MTU Size: 9194
  MAC Factory Address: 00144fc2d508
  MAC Current Address: 00144fc2d508
HBA Port WWN: 200000144fc2d509
  Port Type: Target
  MAC Name: nxge1
  MTU Size: 9194
  MAC Factory Address: 00144fc2d509
  MAC Current Address: 00144fc2d509
```

EXAMPLE 16 Reinitializing the Link of an FC Port

The following command forces the link connected with the port 200000144fc2d508 to reinitialize.

```
# fcadm force-lip 200000144fc2d508
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

Error Messages Errors that can occur in addition to the errors normally associated with system administration commands:

- *HBA_port_WWN*: not found
- *Remote_port_WWN*: not found
- *HBA_port_WWN*: NPIV not supported on this HBA

Name fdetach – detach a name from a STREAMS-based file descriptor

Synopsis fdetach *path*

Description The fdetach command detaches a STREAMS-based file descriptor from a name in the file system. Use the *path* operand to specify the path name of the object in the file system name space, which was previously attached. See [fattach\(3C\)](#).

The user must be the owner of the file or a user with the appropriate privileges. All subsequent operations on *path* will operate on the underlying file system entry and not on the STREAMS file. The permissions and status of the entry are restored to the state they were in before the STREAMS file was attached to the entry.

Operands The following operands are supported:

path Specifies the path name of the object in the file system name space, which was previously attached.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [fattach\(3C\)](#), [fdetach\(3C\)](#), [attributes\(5\)](#), [streamio\(7I\)](#)

STREAMS Programming Guide

Name fdisk – create or modify fixed disk partition table

Synopsis fdisk [-o *offset*] [-s *size*] [-P *fill_patt*] [-S *geom_file*]
 [-w | -r | -d | -n | -I | -B | -t | -T | -g | -G | -R | -E]
 [--F *fdisk_file*] [[-v] -W {*fdisk_file* | -}]
 [-h] [-b *masterboot*]
 [-A *id* : *act* : *bhead* : *bsect* : *bcyl* : *ehhead* : *esect* :
 ecyl : *rsect* : *numsect*]
 [-D *id* : *act* : *bhead* : *bsect* : *bcyl* : *ehhead* : *esect* :
 ecyl : *rsect* : *numsect*] *rdevice*

Description This command is used to do the following:

- Create and modify an fdisk partition table on x86 systems
- Create and modify an fdisk partition table on removable media on SPARC or x86 systems
- Install the master boot record that is put in the first sector of the fixed disk on x86 systems only

This table is used by the first-stage bootstrap (or firmware) to identify parts of the disk reserved for different operating systems, and to identify the partition containing the second-stage bootstrap (the *active* Solaris partition). The *rdevice* argument must be used to specify the raw device associated with the fixed disk, for example, /dev/rdisk/c0t0d0p0.

The program can operate in three different modes. The first is interactive mode. In interactive mode, the program displays the partition table as it exists on the disk, and then presents a menu allowing the user to modify the table. The menu, questions, warnings, and error messages are intended to be self-explanatory.

In interactive mode, if there is no partition table on the disk, the user is given the options of creating a default partitioning or specifying the initial table values. The default partitioning allocates the entire disk for the Solaris system and makes the Solaris system partition active. In either case, when the initial table is created, fdisk also writes out the first-stage bootstrap (x86 only) code along with the partition table. In this mode, (x86 only) when creating an entry for a non-EFI partition on a disk that is larger than 2 TB (terabytes), fdisk warns that the maximum size of the partition is 2 TB. Under these conditions percentages displayed by fdisk are based on 2 TB.

The second mode of operation is used for automated entry addition, entry deletion, or replacement of the entire fdisk table. This mode can add or delete an entry described on the command line. In this mode the entire fdisk table can be read in from a file replacing the original table. fdisk can also be used to create this file. There is a command line option that will cause fdisk to replace any fdisk table with the default of the whole disk for the Solaris system.

The third mode of operation is used for disk diagnostics. In this mode, a section of the disk can be filled with a user-specified pattern and mode sections of the disk can also be read or written.

Note – The third mode of operation is not currently supported for extended partitions

When `fdisk` creates a partition, the space is allocated in the `fdisk` partition table, but the allocated disk space is not initialized. `newfs(1M)` is required to create and write file system metadata to the new partition, and `format(1M)` is required to write the VTOC or EFI/GPT metadata.

Menu Options The menu options for interactive mode given by the `fdisk` program are:

Create a partition

This option allows the user to create a new partition. The maximum number of partitions is 4. The program will ask for the type of the partition (SOLARIS, MS-DOS, UNIX, or other). It will then ask for the size of the partition as a percentage of the disk. The user may also enter the letter `c` at this point, in which case the program will ask for the starting cylinder number and size of the partition in cylinders. If a `c` is not entered, the program will determine the starting cylinder number where the partition will fit. In either case, if the partition would overlap an existing partition or will not fit, a message is displayed and the program returns to the original menu.

Change Active (Boot from) partition

This option allows the user to specify the partition where the first-stage bootstrap will look for the second-stage bootstrap, otherwise known as the *active* partition.

Delete a partition

This option allows the user to delete a previously created partition. Note that this will destroy all data in that partition.

Change between Solaris and Solaris2 Partition IDs

This option allows the user to switch between the current `fdisk` operating system partition identifier and the previous one. This does not affect any data in the disk partition and is provided for compatibility with older software.

Edit/View extended partitions

This option provides the extended partition menu to the user. Use the extended partition menu to add and delete logical drives, change the `sysid` of the logical drives, and display logical drive information. To commit the changes made in the extended partition, you must return to the main menu using the extended partition submenu option `r`. There is also an option to display the list of options that the extended partition submenu supports. Given below is the list:

a Add a logical drive.

Use this submenu option to add a logical drive. There are three pieces of information that are required: The beginning cylinder, the size (in cylinders or in human readable form - KB, MB, or GB), and the partition ID. While specifying the partition ID, there is an option (`I`) that you can use to list the supported partitions.

d Delete a logical drive.

Use this submenu option to delete a logical drive. The only input required is the number of the logical drive that is to be deleted.

h Display the help menu.

This submenu option displays the supported operations in the extended partition submenu.

i Change the id of the logical drive.

Use this submenu option to change the system ID of the existing logical drives. A list of supported system IDs is displayed when you use the I option when in this submenu.

p Display the logical drive layout.

Displays the logical drive information to stdout. This output reflects any changes made during the current run of the `fdisk` program. The changes are not committed to the disk until return to the main menu (using the submenu `r`) and choose the option to commit the changes to the disk.

r Return to the main `fdisk` menu.

Exit the extended partition submenu and return to the main menu.

Note the dynamic nature of the numbering of extended partitions. For example, consider a Solaris system with the partitions `p1`, `p2`, `p3`, and `p4`. Following creation of an extended partition, the same system has a logical device node, `p5`, and successive nodes numbered consecutively up to a maximum of `p36`. If one logical drive is deleted, say, `p8`, then all nodes following `p8` (`p9` up to `p36`) move up one in the list of partitions, so that `p9` becomes `p8`, `p10` becomes `p9`, and so forth.

Use the following options to include your modifications to the partition table at this time or to cancel the session without modifying the table:

`Exit` This option writes the new version of the table created during this session with `fdisk` out to the fixed disk, and exits the program.

`Cancel` This option exits without modifying the partition table.

Options The following options apply to `fdisk`:

`-A id:act:bhead:bsect:bcyl:ehhead:esect:ecyl:rsect:numsect`

Add a partition as described by the argument (see the `-F` option below for the format). Use of this option will zero out the VTOC on the Solaris partition if the `fdisk` table changes.

`-b master_boot`

Specify the file `master_boot` as the master boot program. The default master boot program is `/usr/lib/fs/ufs/mboot`.

- B
Default to one Solaris partition that uses the whole disk. On an x86 machine, if the disk is larger than 2 TB (terabytes), the default size of the Solaris partition will be limited to 2 TB.
- d
Turn on verbose *debug* mode. This will cause `fdisk` to print its state on `stderr` as it is used. The output from this option should not be used with `-F`.
- D *id:act:bhead:bsect:bcyl:ehhead:esect:ecyl:rsect:numsect*
Delete a partition as described by the argument (see the `-F` option below for the format). Note that the argument must be an exact match or the entry will not be deleted! Use of this option will zero out the VTOC on the Solaris partition if the `fdisk` table changes.
- E
Create an EFI partition that uses the entire disk.
- F *fdisk_file*
Use `fdisk` file *fdisk_file* to initialize table. Use of this option will zero out the VTOC on the Solaris partition if the `fdisk` table changes.

The *fdisk_file* contains four specification lines for the primary partitions followed by specification lines for the logical drives. You must have four lines for the primary partitions if there is at least one logical drive. In this case, if the number of primary partitions to be configured is less than four, the remaining lines should be filled with zeros.

Each line is composed of entries that are position-dependent, are separated by whitespace or colons, and have the following format:

```
id act bhead bsect bcyl ehhead esect ecyl rsect numsect
```

...where the entries have the following values:

| | |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>id</i> | This is the type of partition and the correct numeric values may be found in <code>fdisk.h</code> . |
| <i>act</i> | This is the active partition flag; <code>0</code> means not active and <code>128</code> means active. For logical drives, this flag will always be set to <code>0</code> even if specified as <code>128</code> by the user. |
| <i>bhead</i> | This is the head where the partition starts. If this is set to <code>0</code> , <code>fdisk</code> will correctly fill this in from other information. |
| <i>bsect</i> | This is the sector where the partition starts. If this is set to <code>0</code> , <code>fdisk</code> will correctly fill this in from other information. |
| <i>bcyl</i> | This is the cylinder where the partition starts. If this is set to <code>0</code> , <code>fdisk</code> will correctly fill this in from other information. |
| <i>ehhead</i> | This is the head where the partition ends. If this is set to <code>0</code> , <code>fdisk</code> will correctly fill this in from other information. |

- esect* This is the sector where the partition ends. If this is set to 0, `fdisk` will correctly fill this in from other information.
- ecyl* This is the cylinder where the partition ends. If this is set to 0, `fdisk` will correctly fill this in from other information.
- rssect* The relative sector from the beginning of the disk where the partition starts. This must be specified and can be used by `fdisk` to fill in other fields. For logical drives, you must make sure that there are at least 63 free sectors before the *rssect* specified for a logical drive.
- numsect* The size in sectors of this disk partition. This must be specified and can be used by `fdisk` to fill in other fields.
- g** Get the label geometry for disk and display on stdout (see the **-S** option for the format).
- G** Get the physical geometry for disk and display on stdout (see the **-S** option for the format).
- h** Issue verbose message; message will list all options and supply an explanation for each.
- I** Forgo device checks. This is used to generate a file image of what would go on a disk without using the device. Note that you must use **-S** with this option (see above).
- n** Don't update `fdisk` table unless explicitly specified by another option. If no other options are used, **-n** will only write the master boot record to the disk. In addition, note that `fdisk` will not come up in interactive mode if the **-n** option is specified.
- o *offset*** Block offset from start of disk. This option is used for **-P**, **-r**, and **-w**. Zero is assumed when this option is not used.
- P *fill_patt*** Fill disk with pattern *fill_patt*. *fill_patt* can be decimal or hex and is used as number for constant long word pattern. If *fill_patt* is #, then pattern is block # for each block. Pattern is put in each block as long words and fills each block (see **-o** and **-s**).
- r** Read from disk and write to stdout. See **-o** and **-s**, which specify the starting point and size of the operation.
- R** Treat disk as read-only. This is for testing purposes.
- s *size*** Number of blocks to perform operation on (see **-o**).

-S *geom_file*

Set the label geometry to the content of the *geom_file*. The *geom_file* contains one specification line. Each line is delimited by a new-line character (`\n`). If the first character of a line is an asterisk (*), the line is treated as a comment. Each line is composed of entries that are position-dependent, are separated by white space, and have the following format:

```
pcyl n cyl acyl bcyl nheads nsectors sectsiz
```

where the entries have the following values:

pcyl This is the number of physical cylinders for the drive.
ncyl This is the number of usable cylinders for the drive.
acyl This is the number of alt cylinders for the drive.
bcyl This is the number of offset cylinders for the drive (should be zero).
nheads The number of heads for this drive.
nsectors The number of sectors per track.
sectsiz The size in bytes of a sector.

-t

Adjust incorrect slice table entries so that they will not cross partition table boundaries.

-T

Remove incorrect slice table entries that span partition table boundaries.

-v

Output the HBA (virtual) geometry dimensions. This option must be used in conjunction with the `-w` flag. This option will work for platforms which support virtual geometry. (x86 only)

-w

Write to disk and read from stdin. See `-o` and `-s`, which specify the starting point and size of the operation.

-W-

Output the disk table to stdout.

-W *fdisk_file*

Create an `fdisk` file *fdisk_file* from disk table. This can be used with the `-F` option below.

Files `/dev/rdisk/c0t0d0p0` Raw device associated with the fixed disk.
 `/usr/lib/fs/ufs/mboot` Default master boot program.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Architecture | x86 and SPARC |
| Availability | SUNWcs |

Diagnostics Most messages will be self-explanatory. The following may appear immediately after starting the program:

Fdisk: cannot open <device>

This indicates that the device name argument is not valid.

Fdisk: unable to get device parameters for device <device>

This indicates a problem with the configuration of the fixed disk, or an error in the fixed disk driver.

Fdisk: error reading partition table

This indicates that some error occurred when trying initially to read the fixed disk. This could be a problem with the fixed disk controller or driver, or with the configuration of the fixed disk.

Fdisk: error writing boot record

This indicates that some error occurred when trying to write the new partition table out to the fixed disk. This could be a problem with the fixed disk controller, the disk itself, the driver, or the configuration of the fixed disk.

Name ff – list file names and statistics for a file system

Synopsis ff [-F *FSType*] [-V] [*generic_options*] [-o *specific_options*] *special...*

Description ff prints the pathnames and inode numbers of files in the file system which resides on the special device *special*. Other information about the files may be printed using options described below. Selection criteria may be used to instruct ff to only print information for certain files. If no selection criteria are specified, information for all files considered will be printed (the default); the -i option may be used to limit files to those whose inodes are specified.

Output is sorted in ascending inode number order. The default line produced by ff is:

path-name i-number

The maximum information the command will provide is:

path-name i-number size uid

- Options**
- F Specify the *FSType* on which to operate. The *FSType* should either be specified here or be determinable from /etc/vfstab by matching the *special* with an entry in the table, or by consulting /etc/default/fs.
 - V Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from /etc/vfstab. This option may be used to verify and validate the command line.
 - generic_options* Options that are supported by most *FSType*-specific modules of the command. The following options are available:
 - I Do not print the i-node number after each path name.
 - l Generate a supplementary list of all path names for multiply-linked files.
 - p *prefix* The specified *prefix* will be added to each generated path name. The default is '.' (dot).
 - s Print the file size, in bytes, after each path name.
 - u Print the owner's login name after each path name.
 - a -n Select if the file has been accessed in *n* days.
 - m -n Select if the file has been written or created in *n* days.
 - c -n Select if file's status has been changed in *n* days.
 - n *file* Select if the file has been modified more recently than the argument *file*.

-i *i-node-list* Generate names for only those *i*-nodes specified in *i-node-list*. *i-node-list* is a list of numbers separated by commas (with no intervening spaces).

-o Specify *FSType*-specific options in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the *FSType*-specific module of the command.

Operands *special* A special device.

Usage See [largefile\(5\)](#) for the description of the behavior of `ff` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files `/etc/default/fs` default local file system type. Default values can be set for the following flags in `/etc/default/fs`. For example: `LOCAL=ufs`

`LOCAL` The default partition for a command if no *FSType* is specified.

`/etc/vfstab` list of default parameters for each file system

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [find\(1\)](#), [ncheck\(1M\)](#), [stat\(2\)](#), [vfstab\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#) Manual pages for the *FSType*-specific modules of `ff`.

Notes This command may not be supported for all *FSTypes*.

The `-a`, `-m`, and `-c` flags examine the `st_atime`, `st_mtime`, and `st_ctime` fields of the `stat` structure respectively. (See [stat\(2\)](#).)

Name ffbconfig, SUNWffb_config – configure the FFB Graphics Accelerator

Synopsis /usr/sbin/ffbconfig [-dev *device-filename*]
 [-res *video-mode* [now | try] [noconfirm | nocheck]]
 [-file | machine | system]
 [-deflinear | true | false]
 [-defoverlay | true | false]
 [-linearorder | first | last]
 [-overlayorder | first | last]
 [-expvis | enable | disable]
 [-sov | enable | disable] [-maxwids *n*]
 [-extovl | enable | disable]
 [-g *gamma-correction-value*]
 [-gfile *gamma-correction-file*] [-propt] [-prconf]
 [-defaults]

 /usr/sbin/ffbconfig [-propt] [-prconf]
 /usr/sbin/ffbconfig [-help] [-res ?]

Description ffbconfig configures the FFB Graphics Accelerator and some of the X11 window system defaults for FFB.

The first form of ffbconfig stores the specified options in the OWconfig file. These options will be used to initialize the FFB device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots.

The second and third forms of ffbconfig, which invoke only the -prconf, -propt, -help, and -res ? options do not update the OWconfig file. Additionally, for the third form all other options are ignored.

Options may be specified for only one FFB device at a time. Specifying options for multiple FFB devices requires multiple invocations of ffbconfig.

Only FFB-specific options can be specified through ffbconfig. The normal window system options for specifying default depth, default visual class and so forth are still specified as device modifiers on the openwin command line. See the *Open Windows Desktop Reference Manual* for details.

The user can also specify the OWconfig file that is to be updated. By default, the machine-specific file in the /etc/openwin directory tree is updated. The -file option can be used to specify an alternate file to use. For example, the system-global OWconfig file in the /usr/openwin directory tree can be updated instead.

Both of these standard OWconfig files can only be written by root. Consequently, the ffbconfig program, which is owned by the root user, always runs with setuid root permission.

Options -dev *device-filename*

Specifies the FFB special file. The default is `/dev/fbs/ffb0`.

-file *machine|system*

Specifies which `OWconfig` file to update. If *machine* is specified, the machine-specific `OWconfig` file in the `/etc/openwin` directory tree is updated. If *system* is specified, the global `OWconfig` file in the `/usr/openwin` directory tree is updated. If the specified file does not exist, it is created. This option has no effect unless other options are specified. The default is *machine*.

-res *video-mode* [*now* | *try* [*noconfirm* | *nocheck*]]

Specifies the video mode used to drive the monitor connected to the specified FFB device.

video-mode has the format of *widthxheightxrate* where *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh.

The *s* suffix, as in `960x680x112s` and `960x680x108s`, indicates stereo video modes. The *i* suffix, as in `640x480x60i` and `768x575x50i`, indicates interlaced video timing. If absent, non-interlaced timing will be used.

-res (the third form in the SYNOPSIS) also accepts formats with @ (at sign) in front of the refresh rate instead of x. `1280x1024@76` is an example of this format.

Some video-modes are supported only on certain revisions of FFB. Also, some video-modes, supported by FFB, may not be supported by the monitor. The list of video-modes supported by the FFB device and the monitor can be obtained by running `ffbconfig` with the `-res ?` option.

The following table lists all possible video modes supported on FFB:

| Name | Description |
|--------------|-------------|
| 1024x768x60 | |
| 1024x768x70 | |
| 1024x768x75 | |
| 1024x768x77 | |
| 1024x800x84 | |
| 1152x900x66 | |
| 1152x900x76 | |
| 1280x800x76 | |
| 1280x1024x60 | |
| 1280x1024x67 | |

| Name | Description |
|---------------|--------------|
| 1280x1024x76 | |
| 960x680x112s | (stereo) |
| 960x680x108s | (stereo) |
| 640x480x60 | |
| 640x480x60i | (interlaced) |
| 768x575x50i | (interlaced) |
| 1440x900x76 | (hi-res) |
| 1600x1000x66 | (hi-res) |
| 1600x1000x76i | (hi-res) |
| 1600x1280x76 | (hi-res) |
| 1920x1080x72 | (hi-res) |
| 1920x1200x70 | (hi-res) |

Symbolic names

For convenience, some video modes have symbolic names defined for them. Instead of the form *widthxheightxrate*, one of these names may be supplied as the argument to `-res`. The meaning of the symbolic name `none` is that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.

| Name | Corresponding Video Mode |
|---------------------|---------------------------------------------|
| <code>svga</code> | 1024x768x60 |
| <code>1152</code> | 1152x900x76 |
| <code>1280</code> | 1280x1024x76 |
| <code>stereo</code> | 960x680x112s |
| <code>ntsc</code> | 640x480x60i |
| <code>pal</code> | 768x575x50i |
| <code>none</code> | (video mode currently programmed in device) |

The `-res` option also accepts additional, optional arguments immediately following the video mode specification. Any or all of these may be present.

now

Specifies that the FFB device will be immediately programmed to display this video mode, in addition to updating the video mode in the OWconfig file. This option is useful for changing the video mode before starting the window system.

It is inadvisable to use this suboption with `ffbconfig` while the configured device is being used (for example, while running the window system); unpredictable results may occur. To run `ffbconfig` with the `now` suboption, first bring the window system down. If the `now` suboption is used within a window system session, the video mode will be changed immediately, but the width and height of the affected screen won't change until the window system is exited and re-entered. In addition, the system may not recognize changes in stereo mode. Consequently, this usage is strongly discouraged.

noconfirm

Instructs `ffbconfig` to bypass confirmation and warning messages and to program the requested video mode anyway.

Using the `-res` option, the user could potentially put the system into an unusable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this, the default behavior of `ffbconfig` is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. This option is useful when `ffbconfig` is being run from a shell script.

nocheck

Suspends normal error checking based on the monitor sense code. The video mode specified by the user will be accepted regardless of whether it is appropriate for the currently attached monitor. This option is useful if a different monitor is to be connected to the FFB device. Note: Use of this option implies `noconfirm` as well.

try

Programs the specified video mode on a trial basis. The user will be asked to confirm the video mode by typing `y` within 10 seconds. The user may also terminate the trial before 10 seconds are up by typing any character. Any character other than `y` or RETURN is considered a `no` and the previous video mode will be restored and `ffbconfig` will not change the video mode in the OWconfig file and other options specified will still take effect. If a RETURN is pressed, the user is prompted for a yes or no answer on whether to keep the new video mode.

This sub-option should not be used with `ffbconfig` while the configured device is being used (for example, while running the window system) as unpredictable results may occur. To run `fbconfig` with the `try` sub-option, the window system should be brought down first.

`-deflinear true | false`

FFB possesses two types of visuals: linear and nonlinear. Linear visuals are gamma corrected and nonlinear visuals are not. There are two visuals that have both linear and nonlinear versions: 24-bit TrueColor and 8-bit StaticGray.

`-deflinear true` sets the default visual to the linear visual that satisfies other specified default visual selection options. Specifically, the default visual selection options are those set by the Xsun (1) `defdepth` and `defclass` options. See [OpenWindows Desktop Reference Manual](#) for details.

`-deflinear false` (or if there is no linear visual that satisfies the other default visual selection options) sets the default visual to the non-linear visual as the default.

This option cannot be used when the `-defoverlay` option is present, because FFB does not possess a linear overlay visual.

`-defoverlay true | false`

FFB provides an 8-bit PseudoColor visual whose pixels are disjoint from the rest of the FFB visuals. This is called the overlay visual. Windows created in this visual will not damage windows created in other visuals. The converse, however, is not true. Windows created in other visuals will damage overlay windows. This visual has 256 `maxwids` of opaque color values. See `-maxwids` in `OPTIONS`.

If `-defoverlay` is `true`, the overlay visual will be made the default visual. If `-defoverlay` is `false`, the nonoverlay visual that satisfies the other default visual selection options, such as `defdepth` and `defclass`, will be chosen as the default visual. See the [OpenWindows Desktop Reference Manual](#) for details.

Whenever `-defoverlay true` is used, the default depth and class chosen on the `openwin` command line must be 8-bit PseudoColor. If not, a warning message will be printed and the `-defoverlay` option will be treated as `false`. This option cannot be used when the `-deflinear` option is present, because FFB doesn't possess a linear overlay visual.

`-linearorder first | last`

If `first`, linear visuals will come before their non-linear counterparts on the X11 screen visual list for the FFB screen. If `last`, the nonlinear visuals will come before the linear ones.

`-overlayorder first | last`

If `true`, the depth 8 PseudoColor Overlay visual will come before the non-overlay visual on the X11 screen visual list for the FFB screen. If `false`, the non-overlay visual will come before the overlay one.

`-expvis enable | disable`

If enabled, OpenGL Visual Expansion will be activated. Multiple instances of selected visual groups (8-bit PseudoColor, 24-bit TrueColor and so forth) can be found in the screen visual list.

-sov enable | disable

Advertises the root window's `SERVER_OVERLAY_VISUALS` property. SOV visuals will be exported and their transparent types, values and layers can be retrieved through this property. If `-sov disable` is specified, the `SERVER_OVERLAY_VISUALS` property will not be defined. SOV visuals will not be exported.

-maxwids *n*

Specifies the maximum number of FFB X channel pixel values that are reserved for use as window sIDs (WIDs). The remainder of the pixel values in overlay colormaps are used for normal X11 opaque color pixels. The reserved WIDs are allocated on a first-come first-serve basis by 3D graphics windows (such as XGL), MBX windows, and windows that have a non-default visual. The X channel codes 0 to (255-*n*) will be opaque color pixels. The X channel codes (255-*n*+1) to 255 will be reserved for use as WIDs. Legal values on FFB, FFB2 are: 1, 2, 4, 8, 16, and 32. Legal values on FFB2+ are: 1, 2, 4, 8, 16, 32, and 64.

-extovl enable | disable

This option is available only on FFB2+. If enabled, extended overlay is available. The overlay visuals will have 256 opaque colors. The SOV visuals will have 255 opaque colors and 1 transparent color. This option enables hardware supported transparency which provides better performance for windows using the SOV visuals.

-g *gamma-correction value*

This option is available only on FFB2+. This option allows changing the gamma correction value. All linear visuals provide gamma correction. By default the gamma correction value is 2.22. Any value less than zero is illegal. The gamma correction value is applied to the linear visual, which then has an effective gamma value of 1.0, which is the value returned by `XSolarisGetVisualGamma(3)`. See `XSolarisGetVisualGamma(3)` for a description of that function.

This option can be used while the window system is running. Changing the gamma correction value will affect all the windows being displayed using the linear visuals.

-g file *gamma-correction file*

This option is available only on FFB2+. This option loads gamma correction table from the specified file. This file should be formatted to provide the gamma correction values for R, G and B channels on each line. This file should provide 256 triplet values, each in hexadecimal format and separated by at least 1 space. Following is an example of this file:

```
0x00 0x00 0x00
0x01 0x01 0x01
0x02 0x02 0x02
...
...
0xff 0xff 0xff
```

Using this option, the gamma correction table can be loaded while the window system is running. The new gamma correction will affect all the windows being displayed using the linear visuals. Note, when gamma correction is being done using user specified table, the

gamma correction value is undefined. By default, the window system assumes a gamma correction value of 2.22 and loads the gamma table it creates corresponding to this value.

-defaults

Resets all option values to their default values.

-propt

Prints the current values of all FFB options in the OWconfig file specified by the `-file` option for the device specified by the `-dev` option. Prints the values of options as they will be in the OWconfig file after the call to `ffbcfg` completes. The following is a typical display using the `-propt` option:

```
--- OpenWindows Configuration for /dev/fbs/ffb0 ---
OWconfig: machine
Video Mode: NONE
Default Visual: Non-Linear Normal Visual
Visual Ordering: Linear Visuals are last
                  Overlay Visuals are last
OpenGL Visuals: disabled
SOV: disabled
Allocated WIDs: 32
```

-prconf

Prints the FFB hardware configuration. The following is a typical display using the `-prconf` option:

```
--- Hardware Configuration for /dev/fbs/ffb0 ---
Type: double-buffered FFB2 with Z-buffer
Board: rev x
PROM Information: @(#)ffb2.fth x.x xx/xx/xx
FBC: version x
DAC: Brooktree 9068, version x
3DRAM: Mitsubishi 1309, version x
EDID Data: Available - EDID version 1 revision x
Monitor Sense ID: 4 (Sun 37x29cm RGB color monitor)
Monitor possible resolutions: 1024x768x60, 1024x768x70,
                              1024x768x75, 1152x900x66, 1152x900x76,
                              1280x1024x67, 1280x1024x76,
                              960x680x112s, 640x480x60
Current resolution setting: 1280x1024x76
```

-help

Prints a list of the `ffbcfg` command line options, along with a brief explanation of each.

Defaults For a given invocation of `ffbcfg` command line if an option does not appear on the command line, the corresponding OWconfig option is not updated; it retains its previous value.

When the window system is run, if an FFB option has never been specified via `ffbcfg`, a default value is used. The option defaults are listed in the following table:

| Option | Default |
|---------------|---------------|
| -dev | /dev/fbs/ffb0 |
| -file | machine |
| -res | none |
| -deflinear | false |
| -defoverlay | false |
| -linearorder | last |
| -overlayorder | last |
| -expvis | enabled |
| -sov | enabled |
| -maxwids | 32 |

The default for the `-res` option of `none` means that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.

This provides compatibility for users who are used to specifying the device resolution through the PROM. On some devices (for example, GX) this is the only way of specifying the video mode. This means that the PROM ultimately determines the default FFB video mode.

Examples EXAMPLE 1 Changing The Monitor Type

The following example switches the monitor type to the resolution of 1280 × 1024 at 76 Hz:

```
example% /usr/sbin/ffbconfig -res 1280x1024x76
```

Files /dev/fbs/ffb0 device special file

Open Windows Desktop Reference Manual

Name ff_ufs – list file names and statistics for a ufs file system

Synopsis ff -F ufs [*generic_options*] [-o a,m,s] *special*...

Description ff prints the pathnames and inode numbers of files in the file system which resides on the special device *special*.

See [ff\(1M\)](#) for information regarding the ff command. See OPTIONS for information regarding the ufs-specific options.

Options The following options are supported:

- o Specify ufs file system specific options. The following options available are:
 - a Print the '.' and '..' directory entries.
 - m Print mode information. This option must be specified in conjunction with the -i *i-node-list* option (see [ff\(1M\)](#)).
 - s Print only special files and files with set-user-ID mode.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [find\(1\)](#), [ff\(1M\)](#), [ncheck\(1M\)](#), [attributes\(5\)](#)

Name fiocompress – file compression utility

Synopsis /sbin/fiocompress -c [-m] [-b *block_size*] *input_file output_file*
 /sbin/fiocompress -d *input_file output_file*

Description The `fiocompress` utility is a file compression tool that works together with the `dcfs(7FS)` file system to perform per-file compression. You can use `fiocompress` to decompress a compressed file or mark a compressed file as compressed, causing automatic decompression on read. The primary use of `fiocompress` is to compress files in the boot archive.

Note that this utility is not a Committed interface. See [attributes\(5\)](#).

Options The following options are supported:

-b *block_size*

Specify a block size for compression. The default block size is 8192.

-c

Compress the specified file.

-d

Decompress the specified file.

-m

Mark the compressed file for automatic decompression on read. Can be used only in conjunction with -c.

Exit Status 0

The command completed successfully.

-1

The command exited due to an error.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | Private |

See Also [boot\(1M\)](#), [bootadm\(1M\)](#), [dcfs\(7FS\)](#), [ufs\(7FS\)](#), [attributes\(5\)](#)

Notes This compression/decompression utility works only with files stored in a UFS file system.

There is no obvious way to determine whether a given file is compressed, other than copying the file and comparing the number of disk blocks of the copy against the original.

Name flar – administer flash archives

Synopsis flar create -n *name* [-R *root*] [-A *system_image*] [-H] [-I] [-M] [-S] [-c] [-t [-p *posn*] [-b *blocksize*]] [-i *date*] [-u *section*]... [-m *master*] [-f [*filelist* | -] [-F]] [-a *author*] [-e *descr* | -E *descr_file*] [-L *archiver*] [-T *type*] [-U *key=value*]... [-x *exclude*]... [-y *include*]... [-z *filelist*]... [-X *filelist*]... *archive*

flar combine [-d *dir*] [-u *section*]... [-t [-p *posn*] [-b *blocksize*]] *archive*

flar split [-d *dir*] [-u *section*]... [-f] [-S *section*] [-t [-p *posn*] [-b *blocksize*]] *archive*

flar info [-l] [-k *keyword*] [-t [-p *posn*] [-b *blocksize*]] *archive*

Description The flar command is used to administer flash archives. A flash archive is an easily transportable version of a reference configuration of the Solaris operating environment, plus optional other software. Such an archive is used for the rapid installation of Solaris on large numbers of machines. You can create a flash archive using either flar with the create subcommand or the flarcreate(1M) command. See flash_archive(4).

In flash terminology, a system on which an archive is created is called a *master*. The system image stored in the archive is deployed to systems that are called *clones*.

There are two types of flash archives: full and differential. Both are created with the create subcommand. A full archive contains all the files that are in a system image. A differential archive contains only differences between two system images. Installation of a differential archive is faster and consumes fewer resources than installation of a full archive.

In creating a differential archive, you compare two system images. A system image can be any of:

- a Live Upgrade boot environment, mounted on some directory using lumount(1M) (see live_upgrade(5))
- a clone system mounted over NFS with root permissions
- a full flash archive expanded into some local directory

To explain the creation of a differential flash archive, the following terminology is used:

old The image prior to upgrade or other modification. This is likely the image as it was installed on clone systems.

new The old image, plus possible additions or changes and minus possible deletions. This is likely the image you want to duplicate on clone systems.

The flar command compares *old* and *new*, creating a differential archive as follows:

- files on *new* that are not in *old* are added to the archive;

- files of the same name that are different between *old* and *new* are taken from *new* and added to the archive;
- files that are in *old* and not in *new* are put in list of files to be deleted when the differential archive is installed on clone systems.

When creating a differential flash archive, the currently running image is, by default, the new image and a second image, specified with the `-A` option, is the old image. You can use the `-R` option to designate an image other than the currently running system as the new image. These options are described below.

You can run `flarcreate` in multi- or single-user mode. You can also use the command when the master system is booted from the first Solaris software CD or from a Solaris net image. Archive creation should be performed when the master system is in as stable a state as possible.

Following creation of a flash archive, you can use JumpStart to clone the archive on multiple systems.

Subcommands The `flar` command includes subcommands for creating, combining, splitting, and providing information about archives. A subcommand is the first argument in a `flar` command line. These subcommands are as follows:

`create` Create a new flash archive, of a name you specify with the `-n` argument, based on the currently running system. Use the `-A` option (described below) to create a differential flash archive.

`combine` Combine the individual sections that make up an archive into the archive. If *dir* is specified (see `-d` option below), the sections will be gathered from *dir*; otherwise, they will be gathered from the current directory. Each section is assumed to be in a separate file, the names of which are the section names. At a minimum, the archive cookie (`cookie`), archive identification (`identification`), and archive files (`archive`) sections must be present. If *archive* is a directory, its contents are archived using `files_archived_method` (`cpio` and `pax`) prior to inclusion in the archive. If so specified in the `identification` section, the contents are compressed.

Note that no validation is performed on any of the sections. In particular, no fields in the `identification` section are validated or updated. See [flash_archive\(4\)](#) for a description of the archive sections.

`info` Extract information on an archive. This subcommand is analogous to `pkginfo`.

`split` Split an archive into one file for each section of the archive. Each section is copied into a separate file in *dir*, if *dir* is specified (see `-d` option below), or the current directory if it is not. The files resulting from the split are named after the sections. The archive cookie is stored in a file named `cookie`. If *section* is specified (see `-u`

option below), only the named section is copied.

The `create` subcommand requires root privileges.

The options for each subcommand are described below.

Options The options for the `create` subcommand are below. Many of these options supply values for keywords in the identification section of a file containing a flash archive. See [flash_archive\(4\)](#) for a description of these keywords.

- a *author* *author* is used to provide an author name for the archive identification section of the new flash archive. If you do not specify -a, no author name is included in the identification section.
- A *system_image* Create a differential flash archive by comparing a new system image (see DESCRIPTION) with the image specified by the *system_image* argument. By default, the new system image is the currently running system. You can change the default with the -R option, described below. *system_image* is a directory containing an image. It can be accessible through UFS, NFS, or [lumount\(1M\)](#).

The rules for inclusion and exclusion of files in a differential archive are described in DESCRIPTION. You can modify the effect of these rules with the use of the -x, -X, -y, and -z options, described below.
- c Compress the archive using [compress\(1\)](#)
- f *filelist* Use the contents of *filelist* as a list of files to include in the archive. The files are included in addition to the normal file list, unless -F is specified (see below). If *filelist* is -, the list is taken from standard input. *filelist* can include directories. If a directory is listed, all files and subdirectories under that directory are included.
- e *descr* The description to be included in the archive as the value of the `content_description` archive identification key. This option is incompatible with -E.
- E *descr_file* The description to be used as the value of the archive identification `content_description` key is retrieved from the file *descr_file*. This option is incompatible with -e.
- F Include only files in the list specified by -f. This option makes -f *filelist* an absolute list, rather than a list that is appended to the normal file list.
- H Do not generate hash identifier.
- I Ignore integrity check. To prevent you from excluding important system files from an archive, `flar` runs an integrity check. This check examines

all files registered in a system package database and stops archive creation if any of them are excluded. Use this option to override this integrity check.

-i *date* By default, the value for the `creation_date` field in the identification section is generated automatically, based on the current system time and date. If you specify the **-i** option, *date* is used instead. *date* is in the format `YYYYMMDDhhmmss`, so that, for example:

20060905031000

...stands for 3:10 AM on September 5, 2006.

-L *archiver* By default, the value for the `files_archived_method` field in the identification section is `pax(1)`. If you specify **-L**, the archiver (`cpio(1)` and `pax`) is used instead.

-m *master* By default, the value for the `creation_master` field in the identification section is the name of the system on which you run `flar create`, as reported by `uname -n`. If you specify **-m**, *master* is used instead.

-M Used only when you are creating a differential flash archive. When creating a differential archive, `flar` creates a long list of the files in the system that remain the same, are changed, and are to be deleted on clone systems. This list is stored in the manifest section of the archive (see [flash_archive\(4\)](#)). When the differential archive is deployed, the flash software uses this list to perform a file-by-file check, ensuring the integrity of the clone system. Use of this option to avoids such a check and saves the space used by the manifest section in a differential archive. However, you must weigh the savings in time and disk space against the loss of an integrity check upon deployment. Because of this loss, use of this option is not recommended.

-n *name* *name* is supplied as the value of the `content_name` keyword. See [flash_archive\(4\)](#).

The **-n *name*** option, with *name* argument, is required for the `create` subcommand.

-R *root* Create the archive from the file system tree rooted at *root*. If you do not specify this option, `flar` creates an archive from a file system rooted at `/`. When creating a differential flash archive, the system image specified by **-R** replaces the currently running system as the *new* image. See [DESCRIPTION](#).

Note – The root file system of any non-global zones must not be referenced with the **-R** option. Doing so might damage the global zone's

- file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).
- S Skip the disk space check and do not write archive size data to the archive. Without -S, flar builds a compressed archive in memory before writing the archive to disk, to ensure you have sufficient disk space. Use -S to skip this step. The result of the use of -S is a significant decrease in the time it takes to create an archive.
 - T *type* Content type included in the archive as the value of the `content_type` archive identification key. If you do not specify -T, the `content_type` keyword is not included.
 - U *key=value...* Include the user-defined keyword(s) and values in the archive identification section. See [flash_archive\(4\)](#).
 - u *section...* Include the user-defined section located in the file *section* in the archive. *section* must be a blank-separated list of section names as described in [flash_archive\(4\)](#).
 - x *exclude ...* Exclude the file or directory *exclude* from the archive. Note that the *exclude* file or directory is assumed to be relative to the alternate root specified using -R. If the parent directory of the file *exclude* is included with the -y option (see -y *include*), then only the specific file or directory specified by *exclude* is excluded. Conversely, if the parent directory of an included file is specified for exclusion, then only the file *include* is included. For example, if you specify:

```
-x /a -y /a/b
```

 all of /a except for /a/b is excluded. If you specify:

```
-y /a -x /a/b
```

 all of /a except for /a/b is included.
 - y *include ...* Include the file or directory *include* in the archive. Note that the *exclude* file or directory is assumed to be relative to the alternate root specified using -R. See the description of the -x option, above, for a description of the interaction of the -x and -y options.
 - X *filelist ...* Use the contents of *filelist* as a list of files to exclude from the archive. If *filelist* is -, the list is taken from standard input.
 - z *filelist ...* *filelist* is a list of files prefixed with a plus (+) or minus (-). A plus indicates that a file should be included in the archive; the minus indicates exclusion. If *filelist* is -, the list is taken from standard input.

The options for flar info subcommand are as follows:

- k *keyword* Only the value of the keyword *keyword* is returned.
- l List all files in the archive. Does not process content from any sections other than the archive section.

The following are flar info options used with tape archives:

- b *blocksize* The block size to be used when creating the archive. If not specified, a default block size of 64K is used.
- p *posn* Specifies the position on the tape device where the archive should be created. If not specified, the current position of the tape device is examined.
- t The archive to be analyzed is located on a tape device. The path to the device is specified by *archive* (see OPERANDS).

The options for flar split and combine (split and combine archives) subcommands are as follows:

- d *dir* Retrieve sections from *dir*, rather than from the current directory.
- f (Used with split only.) Extract the archive section into directory called *archive*, rather than placing it in a file of the same name as the section.
- S *section* (Used with split only.) Extract only the section named *section* from the archive.
- u *section...* Appends *section* to the list of sections to be included. The default list includes the cookie, identification, and archive sections. *section* can be a single section name or a space-separated list of section names.

The following options are used with tape archives (with both split and combine):

- b *blocksize* The block size to be used when creating the archive. If not specified, a default block size of 64K is used.
- p *posn* Used only with -t. Specifies the position on the tape device where the archive should be created. If not specified, the current position of the tape device is used.
- t Create an archive on or read an archive from a tape device. The *archive* operand (see OPERANDS) is assumed to be the name of the tape device.

Operands The following operand is supported:

- archive* Path to tape device if the -t option was used. Otherwise, the complete path name of a flash archive. By convention, a file containing a flash archive has a file extension of .flar.

Examples EXAMPLE 1 Creating a Flash Archive

The command below creates a flash archive named `pogoS9` and stores it in `/export/home/archives/s9fcs.flar`. The currently running system is the basis for the new archive.

```
# flar create -n pogoS9 /export/home/archives/s9fcs.flar
```

EXAMPLE 2 Creating Differential Flash Archives

The command below creates a differential flash archive.

```
# flar create -n diff_pogoS9 -A /images \
/export/home/archives/diff_s9fcs.flar
```

In the following example the *old* system image is accessed through `lumount`.

```
# lumount s9BE /test
# flar create -n diff_pogoS9 -A /test \
/export/home/archives/diff_s9fcs.flar
```

The following example shows the use of the `-R` option to specify a new system image other than the currently running system.

```
# flar create -n diff_pogoS9 -R /test \
-A /images /export/home/archives/diff_s9fcs.flar
```

Note the caveat on the use of the `-R` option in the description of that option, above.

Exit Status The following exit values are returned for the `create`, `split`, and `combine` subcommands:

- 0 Successful completion.
- >0 An error occurred.

The following exit values are returned for the `info` subcommand:

- 0 Successful completion.
- 1 Command failed. If the `-k` option is used and the requested keyword is not found, `flar` returns 2.

Name flarcreate – create a flash archive from a master system

Synopsis flarcreate -n *name* [-R *root*] [-A *system_image*] [-H] [-I] [-M] [-S] [-c] [-t [-p *posn*] [-b *blocksize*]] [-i *date*] [-u *section*]. . . [-m *master*] [-f [*filelist* | -] [-F]] [-a *author*] [-e *descr* | -E *descr_file*] [-L *archiver*] [-T *type*] [-U *key=value*]. . . [-x *exclude*]. . . [-y *include*]. . . [-z *filelist*]. . . [-X *filelist*]. . . *archive*

Description The `flarcreate` command creates a flash archive from a master system. A master system is one that contains a reference configuration, which is a particular configuration of the Solaris operating environment, plus optional other software. A flash archive is an easily transportable version of the reference configuration.

In flash terminology, a system on which an archive is created is called a *master*. The system image stored in the archive is deployed to systems that are called *clones*.

There are two types of flash archives: full and differential. A full archive contains all the files that are in a system image. A differential archive contains only differences between two system images. Installation of a differential archive is faster and consumes fewer resources than installation of a full archive.

In creating a differential archive, you compare two system images. A system image can be any of:

- a Live Upgrade boot environment, mounted on some directory using `lumount(1M)` (see `live_upgrade(5)`)
- a clone system mounted over NFS with root permissions
- a full flash archive expanded into some local directory

To explain the creation of a differential flash archive, the following terminology is used:

old The image prior to upgrade or other modification. This is likely the image as it was installed on clone systems.

new The old image, plus possible additions or changes and minus possible deletions. This is likely the image you want to duplicate on clone systems.

The `flarcreate` command compares *old* and *new*, creating a differential archive as follows:

- files on *new* that are not in *old* are added to the archive;
- files of the same name that are different between *old* and *new* are taken from *new* and added to the archive;
- files that are in *old* and not in *new* are put in list of files to be deleted when the differential archive is installed on clone systems.

When creating a differential flash archive, the currently running image is, by default, the new image and a second image, specified with the `-A` option, is the old image. You can use the `-R` option to designate an image other than the currently running system as the new image. These options are described below.

Following creation of a flash archive, you can use JumpStart to clone the archive on multiple systems.

You can run `flarcreate` in multi- or single-user mode. You can also use the command when the master system is booted from the first Solaris software CD or from a Solaris net image.

Archive creation should be performed when the master system is in as stable a state as possible. Following archive creation, use the `flar(1M)` command to administer a flash archive.

See `flash_archive(4)` for a description of the flash archive.

The `flarcreate` command requires root privileges.

Options The `flarcreate` command has one required argument:

`-n name` Specifies the name of the flash archive. *name* is supplied as the value of the `content_name` keyword. See `flash_archive(4)`.

The `flarcreate` command has the following general options:

`-A system_image` Create a differential flash archive by comparing a new system image (see DESCRIPTION) with the image specified by the *system_image* argument. By default, the new system image is the currently running system. You can change the default with the `-R` option, described below. *system_image* is a directory containing an image. It can be accessible through UFS, NFS, or `lumount(1M)`.

The rules for inclusion and exclusion of files in a differential archive are described in DESCRIPTION. You can modify the effect of these rules with the use of the `-x`, `-X`, `-y`, and `-z` options, described below.

`-c` Compress the archive using `compress(1)`

`-f filelist` Use the contents of *filelist* as a list of files to include in the archive. The files are included in addition to the normal file list, unless `-F` is specified (see below). If *filelist* is `-`, the list is taken from standard input. *filelist* can include directories. If a directory is listed, all files and subdirectories under that directory are included.

`-F` Include only files in the list specified by `-f`. This option makes `-f filelist` an absolute list, rather than a list that is appended to the normal file list.

-
- H Do not generate hash identifier.
- I Ignore integrity check. To prevent you from excluding important system files from an archive, `flarcreate` runs an integrity check. This check examines all files registered in a system package database and stops archive creation if any of them are excluded. Use this option to override this integrity check.
- L *archiver* By default, the value for the `files_archived_method` field in the identification section is `pax(1)`. If you specify `-L`, the archiver (`cpio(1)` and `pax`) is used instead.
- M Used only when you are creating a differential flash archive. When creating a differential archive, `flarcreate` creates a long list of the files in the system that remain the same, are changed, and are to be deleted on clone systems. This list is stored in the manifest section of the archive (see `flash_archive(4)`). When the differential archive is deployed, the flash software uses this list to perform a file-by-file check, ensuring the integrity of the clone system. Use of this option to avoid such a check and saves the space used by the manifest section in a differential archive. However, you must weigh the savings in time and disk space against the loss of an integrity check upon deployment. Because of this loss, use of this option is not recommended.
- R *root* Create the archive from the file system tree rooted at *root*. If you do not specify this option, `flarcreate` creates an archive from a file system rooted at `/`.
- Note** – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See `zones(5)`.
- S Skip the disk space check and do not write archive size data to the archive. Without `-S`, `flarcreate` builds a compressed archive in memory before writing the archive to disk, to determine the size of the archive. This size information is written to the header of the archive in the `files_archived_size` field and is used during archive deployment on the client to ensure enough disk space is available on the client. Use `-S` to skip this step. The result of the use of `-S` is a significant decrease in the time it takes to create an archive.
- U *key=value...* Include the user-defined keyword(s) and values in the archive identification section.
- x *exclude...* Exclude the file or directory *exclude* from the archive. Note that the *exclude* file or directory is assumed to be relative to the alternate root

specified using `-R`. If the parent directory of the file *exclude* is included with the `-y` option (see `-y include`), then only the specific file or directory specified by *exclude* is excluded. Conversely, if the parent directory of an included file is specified for exclusion, then only the file *include* is included. For example, if you specify:

```
-x /a -y /a/b
```

all of `/a` except for `/a/b` is excluded. If you specify:

```
-y /a -x /a/b
```

all of `/a` except for `/a/b` is included.

- `-y include...` Include the file or directory *include* in the archive. Note that the *include* file or directory is assumed to be relative to the alternate root specified using `-R`. See the description of the `-x` option, above, for a description of the interaction of the `-x` and `-y` options.
- `-X filelist...` Use the contents of *filelist* as a list of files to exclude from the archive. If *filelist* is `-`, the list is taken from standard input.
- `-z filelist...` *filelist* is a list of files prefixed with a plus (+) or minus (-). A plus indicates that a file should be included in the archive; the minus indicates exclusion. If *filelist* is `-`, the list is taken from standard input.

Use the following option with user-defined sections.

- `-u section...` Include the user-defined section located in the file *section* in the archive. *section* must be a blank-separated list of section names as described in [flash_archive\(4\)](#).

Use the following options with tape archives.

- `-b blocksize` The block size to be used when creating the archive. If not specified, a default block size of 64K is used.
- `-p posn` Used only with `-t`. Specifies the position on the tape device where the archive should be created. If not specified, the current position of the tape device is used.
- `-t` Create an archive on a tape device. The *archive* operand (see OPERANDS) is assumed to be the name of the tape device.

The following options are used for archive identification.

- `-a author` *author* is used to provide an author name for the archive identification section. If you do not specify `-a`, no author name is included in the identification section.

- e *descr*** The description to be included in the archive as the value of the `content_description` archive identification key. This option is incompatible with `-E`.
- E *descr_file*** The description to be used as the value of the archive identification `content_description` key is retrieved from the file *descr_file*. This option is incompatible with `-e`.
- i *date*** By default, the value for the `creation_date` field in the identification section is generated automatically, based on the current system time and date. If you specify the `-i` option, *date* is used instead. *date* is in the format `YYYYMMDDhhmmss`, so that, for example:
- 20060905031000
- ...stands for 3:10 AM on September 5, 2006.
- m *master*** By default, the value for the `creation_master` field in the identification section is the name of the system on which you run `flarcreate`, as reported by `uname -n`. If you specify `-m`, *master* is used instead.
- T *type*** Content type included in the archive as the value of the `content_type` archive identification key. If you do not specify `-T`, the `content_type` keyword is not included.

Operands The following operand is supported:

- archive*** Path to tape device if the `-t` option was used. Otherwise, the complete path name of a flash archive. By convention, a file containing a flash archive has a file extension of `.flar`.

Exit Status The following exit values are returned:

- `0` Successful completion.
- `>0` An error occurred.

Name flowadm – administer bandwidth resource control and priority for protocols, services, containers, and virtual machines

Synopsis flowadm show-flow [-pP] [-l *link*] [-o *field*[,...]] [*flow*]
 flowadm add-flow [-t] [-R *root-dir*] -l *link* -a *attr=value*[,...]
 -p *prop=value*[,...] *flow*
 flowadm remove-flow [-t] [-R *root-dir*] {-l *link* | *flow*}
 flowadm set-flowprop [-t] [-R *root-dir*] -p *prop=value*[,...] *flow*
 flowadm reset-flowprop [-t] [-R *root-dir*] [-p *prop*[,...]] *flow*
 flowadm show-flowprop [-cP] [-l *link*] [-o *field*[,...]]
 [-p *prop*[,...]] [*flow*]

Description The flowadm command is used to create, modify, remove, and show networking bandwidth and associated resources for a type of traffic on a particular link.

The flowadm command allows users to manage networking bandwidth resources for a transport, service, or a subnet. The service is specified as a combination of transport and local port. The subnet is specified by its IP address and subnet mask. The command can be used on any type of data link, including physical links, virtual NICs, and link aggregations.

A flow is defined as a set of attributes based on Layer 3 and Layer 4 headers, which can be used to identify a protocol, service, or a virtual machine. When a flow is identified based on flow attributes, separate kernel resources including layer 2, 3, and 4 queues, their processing threads, and other resources are uniquely created for it, such that other traffic has minimal or zero impact on it.

Inbound and outbound packet are matched to flows in a very fast and scalable way, so that limits can be enforced with minimal performance impact.

The flowadm command can be used to identify a flow without imposing any bandwidth resource control. This would result in the traffic type getting its own resources and queues so that it is isolated from rest of the networking traffic for more observable and deterministic behavior.

flowadm is implemented as a set of subcommands with corresponding options. Options are described in the context of each subcommand.

Sub-commands The following subcommands are supported:

flowadm show-flow [-pP] [-o *field*[,...]] [-l *link*] [*flow*]
 Show flow configuration information (the default) or statistics, either for all flows, all flows on a link, or for the specified *flow*.
 -o *field*[,...]
 A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or a special value all, to display all fields. For each flow found, the following fields can be displayed:

`flow`

The name of the flow.

`link`

The name of the link the flow is on.

`ipaddr`

IP address of the flow. This can be either local or remote depending on how the flow was defined.

`transport`

The name of the layer for protocol to be used.

`port`

Local port of service for flow.

`dsfield`

Differentiated services value for flow and mask used with DSFIELD value to state the bits of interest in the differentiated services field of the IP header.

`-p, --parseable`

Display using a stable machine-parseable format.

`-P, --persistent`

Display persistent flow property information.

`-l link, --link=link | flow`

Display information for all flows on the named link or information for the named flow.

`flowadm add -flow [-t] [-R root-dir] -l link -a attr=value[,...] -p prop=value[,...] flow`
 Adds a flow to the system. The flow is identified by its flow attributes and properties.

As part of identifying a particular flow, its bandwidth resource can be limited and its relative priority to other traffic can be specified. If no bandwidth limit or priority is specified, the traffic still gets its unique layer 2, 3, and 4 queues and processing threads, including NIC hardware resources (when supported), so that the selected traffic can be separated from others and can flow with minimal impact from other traffic.

`-t, --temporary`

The changes are temporary and will not persist across reboots. Persistence is the default.

`-R root-dir, --root-dir=root-dir`

Specifies an alternate root directory where `flowadm` should apply persistent creation.

`-l link, --link=link`

Specify the link to which the flow will be added.

`-a attr=value[,...], --attr=value`

A comma-separated list of attributes to be set to the specified values.

`-p prop=value[,...], --prop=value[,...]`

A comma-separated list of properties to be set to the specified values.

`flowadm remove-flow [-t] [-R root-dir] -l {link | flow}`

Remove an existing flow identified by its link or name.

`-t, --temporary`

The changes are temporary and will not persist across reboots. Persistence is the default.

`-R root-dir, --root-dir=root-dir`

Specifies an alternate root directory where `flowadm` should apply persistent removal.

`-l link | flow, --link=link | flow`

If a link is specified, remove all flows from that link. If a single flow is specified, remove only that flow.

`flowadm set-flowprop [-t] [-R root-dir] -p prop=value[,...] flow`

Set values of one or more properties on the flow specified by name. The complete list of properties can be retrieved using the `show-flow` subcommand.

`-t, --temporary`

The changes are temporary and will not persist across reboots. Persistence is the default.

`-R root-dir, --root-dir=root-dir`

Specifies an alternate root directory where `flowadm` should apply persistent setting of properties.

`-p prop=value[,...], --prop=value[,...]`

A comma-separated list of properties to be set to the specified values.

`flowadm reset-flowprop [-t] [-R root-dir] -p [prop=value[,...]] flow`

Resets one or more properties to their default values on the specified flow. If no properties are specified, all properties are reset. See the `show-flowprop` subcommand for a description of properties, which includes their default values.

`-t, --temporary`

Specifies that the resets are temporary. Temporary resets last until the next reboot.

`-R root-dir, --root-dir=root-dir`

Specifies an alternate root directory where `flowadm` should apply persistent setting of properties.

`-p prop=value[,...], --prop=value[,...]`

A comma-separated list of properties to be reset.

`flowadm show-flowprop [-cP] [-l link] [-p prop[,...]] [flow]`

Show the current or persistent values of one or more properties, either for all flows, flows on a specified link, or for the specified flow.

By default, current values are shown. If no properties are specified, all available flow properties are displayed. For each property, the following fields are displayed:

FLOW

The name of the flow.

PROPERTY

The name of the property.

VALUE

The current (or persistent) property value. The value is shown as -- (double hyphen), if it is not set, and ? (question mark), if the value is unknown. Persistent values that are not set or have been reset will be shown as -- and will use the system DEFAULT value (if any).

DEFAULT

The default value of the property. If the property has no default value, -- (double hyphen), is shown.

POSSIBLE

A comma-separated list of the values the property can have. If the values span a numeric range, the minimum and maximum values might be shown as shorthand. If the possible values are unknown or unbounded, -- (double hyphen), is shown.

Flow properties are documented in the “Flow Properties” section, below.

-c, --parseable

Display using a stable machine-parseable format.

-P, --persistent

Display persistent flow property information.

-p prop[,...], --prop=prop[,...]

A comma-separated list of properties to show.

Flow Attributes The flow operand that identify a flow in a `flowadm` command is a comma-separated list of one or more keyword, value pairs from the list below.

`local_ip[/prefix_len]`

Identifies a network flow by the local IP address. *value* must be a IPv4 address in dotted-decimal notation or an IPv6 address in colon-separated notation. *prefix_len* is optional.

If *prefix_len* is specified, it describes the netmask for a subnet address, following the same notation convention of `ifconfig(1M)` and `route(1M)` addresses. If unspecified, the given IP address will be considered as a host address for which the default prefix length for a IPv4 address is /32 and for IPv6 is /128.

`remote_ip[/prefix_len]`

Identifies a network flow by the remote IP address. The syntax is the same as `local_ip` attributes

`transport={tcp|udp|sctp|icmp|icmpv6}`

Identifies a layer 4 protocol to be used. It is typically used in combination with `local_port` or `remote_port` to identify the local or remote service that needs special attention.

`local_port`

Identifies a service specified by the local port.

`remote_port`

Identifies a service specified by the remote port.

`dsfield[:dsfield_mask]`

Identifies the 8-bit differentiated services field (as defined in RFC 2474).

The optional `dsfield_mask` is used to state the bits of interest in the differentiated services field when comparing with the `dsfield` value. A 0 in a bit position indicates that the bit value needs to be ignored and a 1 indicates otherwise. The mask can range from 0x01 to 0xff. If `dsfield_mask` is not specified, the default mask 0xff is used. Both the `dsfield` value and mask must be in hexadecimal.

The following types of combinations of attributes are supported:

```
local_ip[/prefixlen]=address
remote_ip[/prefixlen]=address
transport={tcp|udp|sctp|icmp|icmpv6}
transport={tcp|udp|sctp},local_port=port
transport={tcp|udp|sctp},remote_port=port
dsfield=val[:dsfield_mask]
```

On a given link, the combinations above are mutually exclusive. An attempt to create flows of different combinations will fail.

Restrictions There are individual flow restrictions and flow restrictions per zone.

Individual Flow Restrictions

Restrictions on individual flows do not require knowledge of other flows that have been added to the link.

An attribute can be listed only once for each flow. For example, the following command is not valid:

```
# flowadm add-flow -l vnic1 -a local_port=80,local_port=8080 httpflow
```

transport and local_port or transport and remote_port:

TCP, UDP, or SCTP flows can be specified with a local port or with a remote port. An ICMP or ICMPv6 flow that specifies a port is not allowed.

If either local_port or remote_port is specified, the transport must be either TCP, UDP or SCTP.

The following commands are valid:

```
# flowadm add-flow -l e1000g0 -a transport=udp udpflow
# flowadm add-flow -l e1000g0 -a transport=tcp,local_port=80 \
udp80flow
```

The following commands are not valid:

```
# flowadm add-flow -l e1000g0 -a remote_port=25 flow25
# flowadm add-flow -l e1000g0 -a transport=icmpv6,remote_port=16 \
flow16
```

Flow Restrictions Per Zone

Within a zone, no two flows can have the same name. After adding a flow with the link specified, the link will not be required for display, modification, or deletion of the flow.

Flow Properties The following flow properties are supported. Note that the ability to set a given property to a given value depends on the driver and hardware.

maxbw

Sets the full duplex bandwidth for the flow. The bandwidth is specified as an integer with one of the scale suffixes (K, M, or G for Kbps, Mbps, and Gbps). If no units are specified, the input value will be read as Mbps. The default is no bandwidth limit.

priority

Sets the relative priority for the flow. The value can be given as one of the tokens high, medium, or low. The default is medium.

Examples

EXAMPLE 1 Creating a Policy Around a Mission-Critical Port

The command below creates a policy around inbound HTTPS traffic on an HTTPS server so that HTTPS obtains dedicated NIC hardware and kernel TCP/IP resources. The name specified, `https-1`, can be used later to modify or delete the policy.

```
# flowadm add-flow -l bge0 -a transport=TCP,local_port=443 https-1
# flowadm show-flow -l bge0
```

| FLOW | LINK | IP ADDR | PROTO | PORT | RPORT | DSFLD |
|--------|------|---------|-------|------|-------|-------|
| https1 | bge0 | -- | tcp | 443 | -- | -- |

EXAMPLE 2 Modifying an Existing Policy to Add Bandwidth Resource Control

The following command modifies the `https-1` policy from the preceding example. The command adds bandwidth control and give the policy a high priority.

```
# flowadm set-flowprop -p maxbw=500M,priority=high https-1
# flowadm show-flow https-1
```

| FLOW | LINK | IP ADDR | PROTO | PORT | RPORT | DSFLD |
|--------|------|---------|-------|------|-------|-------|
| https1 | bge0 | -- | tcp | 443 | -- | -- |

```
# flowadm show-flowprop https-1
```

| FLOW | PROPERTY | VALUE | DEFAULT | POSSIBLE |
|---------|----------|-------|---------|-----------------|
| https-1 | maxbw | 500 | -- | -- |
| https-1 | priority | HIGH | -- | LOW,NORMAL,HIGH |

EXAMPLE 3 Limiting the UDP Bandwidth Usage

The following command creates a policy for UDP protocol so that it cannot consume more than 100Mbps of available bandwidth. The flow is named `limit-udp-1`.

```
# flowadm add-flow -l bge0 -a transport=UDP -p maxbw=100M, \
priority=low limit-udp-1
```

EXAMPLE 4 Setting Policy, Making Use of `dsfield` Attribute

The following command sets a policy for EF PHB (DSCP value of 101110 from RFC 2598) with a bandwidth of 500 Mbps and a high priority. The `dsfield` value for this flow will be `0x2e` (101110) with the `dsfield_mask` being `0xfc` (because we want to ignore the 2 least significant bits).

```
# flowadm add-flow -l bge0 -a dsfield=0x2e:0xfc \
-p maxbw=500M,priority=high efphb-flow
```

Exit Status `0`
All actions were performed successfully.

`>0`
An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | system/network |
| Interface Stability | Committed |

See Also [acctadm\(1M\)](#), [dladm\(1M\)](#), [flowstat\(1M\)](#), [ifconfig\(1M\)](#), [prstat\(1M\)](#), [route\(1M\)](#), [attributes\(5\)](#), [ifconfig\(1M\)](#)

Notes The `show-usage` subcommand, present in previous releases of `flowadm`, has been replaced by the [flowstat\(1M\) -h](#) command.

Name flowstat – report flow statistics

Synopsis flowstat [-r | -t] [-i *interval*] [-l *link*] [*flow*]

flowstat [-S] [-A] [-i *interval*] [-p] [-o *field[,...]*]
[-u R|K|M|G|T|P] [*link*] [-l *link*] [*flow*]

flowstat -h [-a] -f *filename* [-d] [-F *format*] [-s *time*]
[-e *time*] [*flow*]

Description The flowstat command reports run time statistics about user defined flows. flowadm show-flow provides the flow name information for this command.

Options The flowstat command has the following options and operands that are common among a number of command forms shown under “Subcommands,” below.

Sub-commands flowstat supports the following command forms.

flowstat [-r | -t] [-i *interval*] [-l *link*] [*flow*]

This form of the command iteratively examines all flows and reports statistics. The output is sorted in descending order of flow utilization. If no flow is specified, the system displays statistics for all flows.

-r

Display receive-side statistics only. Includes bytes and packets received, drops, and so forth. See examples for complete listing.

-t

Display transmit-side statistics only. Includes bytes and packets sent, drops, and so forth. See examples below.

-i *interval*

Specify an interval in seconds at which statistics are refreshed. The default interval is one second.

-l *link* | *flow*

Display statistics for all flows on the specified link or statistics for the specified flow.

flowstat [-S] [-A] [-i *interval*] [-p] [-o *field[,...]*] [-u R|K|M|G|T|P] [-l *link*] [*flow*]

This form of the command allows you to specify which statistics to display.

-A

Dump all statistics fields for this flow. Output statistics of this command are inclusive of all the statistics reported by all other flowstat commands.

-i *interval*

Specify an interval in seconds at which statistics are refreshed. The default interval is one second.

{-l *link*} | *flow*

Display statistics for all flows on the specified link or for the specified flow.

-o *field*[,...]

Display a case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value `all` to display all supported fields.

List of supported RX fields:

- `flow`
- `link`
- `ibytes`
- `ipkts`
- `intrs`
- `polls`

List of TX fields:

- `flow`
- `link`
- `obytes`
- `opackets`
- `oerrors`

-p

Display output in a stable, machine-parseable format.

-S

Continuously display network utilization by flow in a manner similar to the way that [prstat\(1M\)](#) displays CPU utilization by process.

-u R|K|M|G|T|P

If used, allows choosing the unit in which to display all statistics, for example, R: Raw Numbers, K:Kilobits, M:Megabits, T:Terabits, P:Petabits. If not used, then different units, as appropriate, are used to display the statistics.

`flowstat -h [-a] -f filename [-d] [-F format] [-s time] [-e time] [flow]`

Show the network usage history from a stored extended accounting file. Use of this syntax requires that net accounting has been previously configured and enabled by using [acctadm\(1M\)](#). The default output is the summary of network usage of the existing links for the entire period when extended accounting was enabled.

-a

Display all historical network usage for the specified period when extended accounting is enabled. This includes usage information for the flows that have already been deleted.

-f *filename*

Specify the file from which extended accounting records of network flow usage history are read.

- d**
Display the dates for which there is logging information. The date is in the format *mm/dd/yyyy*.
- F format**
Specify the output format of the network flow usage history information. *gnuplot* is the only supported format.
- s time**
-e time
Specify start and stop times for data display. Time is in the format *MM/DD/YYYY, hh:mm:ss*. *hh* uses 24-hour clock notation.
- flow**
If specified, display the historical network usage only for the named flow. Otherwise, display historical network usage for all flows.

Examples EXAMPLE 1 Displaying Statistics

To display statistics for all the flows, enter following command. Statistics are displayed as 3-digit numbers with the appropriate unit. Default interval is one second.

```
# flowstat -i 1
FLOW  IPKTS  RBYTES  IERRS  OPKTS  OBYTES  OERRS
flow1 528.54K 787.39M      0 179.39K 11.85M      0
flow2 742.81K  1.10G      0      0      0      0
flow3      0      0      0      0      0      0
flow1  67.73K 101.02M      0 21.04K  1.39M      0
flow2      0      0      0      0      0      0
flow3      0      0      0      0      0      0
      .      .      .      .      .      .
      .      .      .      .      .      .
      .      .      .      .      .      .
```

EXAMPLE 2 Displaying RX-Side Statistics

The following command displays receive-side statistics

```
# flowstat -r
FLOW  IPKTS  RBYTES  IERRS
flow1 4.01M  5.98G      0
flow2 742.81K 1.10G      0
flow3      0      0      0
```

EXAMPLE 3 Displaying TX-Side Statistics

The following command displays transmit-side statistics at a five-second interval.

```
# flowstat -t
FLOW  OPKTS  OBYTES  OERRS
flow1 24.37M 1.61G      0
```

EXAMPLE 3 Displaying TX-Side Statistics (Continued)

```
flow2      0      0      0
flow3      4     216     0
```

EXAMPLE 4 Displaying Particular Set of Statistics

The following command displays a specified set of statistics fields.

```
# flowstat -o FLOW,IPKTS
FLOW IPKTS
flow1 68.58M
flow2 742.81K
flow3      4
```

EXAMPLE 5 Show Historical Network Usage

Flow usage statistics can be stored by using the extended accounting facility, [acctadm\(1M\)](#).

```
# acctadm -e extended -f /var/log/net.log net
# acctadm net
Network accounting: active
Network accounting file: /var/log/net.log
Tracked Network resources: extended
Untracked Network resources: none
```

The saved historical data can be retrieved as follows:

```
# flowstat -h -f /var/log/net.log
LINK      DURATION  IPACKETS  RBYTES      OPACKETS  OBYTES      BANDWIDTH
flowtcp   100       1031      546908      0          0           43.76Kbps
flowudp   0         0         0           0          0           0.00Mbps
```

Display logging information for `flowtcp` starting at February 19, 2008 at 10:38:46 and ending on the same day at 10:40:06:

```
# flowstat -h -s 02/19/2008,10:39:06 -e 02/19/2008,10:40:06 \
-f /var/log/net.log flowtcp
FLOW      START      END          RBYTES  OBYTES      BANDWIDTH
flowtcp   10:39:06  10:39:26    1546    6539        3.23 Kbps
flowtcp   10:39:26  10:39:46    3586    9922        5.40 Kbps
flowtcp   10:39:46  10:40:06    240     216         182.40 bps
flowtcp   10:40:06  10:40:26    0        0           0.00 bps
```

Generate the same output information as above as a plotfile:

```
# flowstat -h -s 02/19/2008,10:39:06 -e 02/19/2008,10:40:06 \
-F gnuplot -f /var/log/net.log flowtcp
# Time tcp-flow
10:39:06 3.23
10:39:26 5.40
```

EXAMPLE 5 Show Historical Network Usage *(Continued)*

10:39:46 0.18

10:40:06 0.00

Exit Status 0

All actions were performed successfully.

>0

An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

/usr/sbin

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | See below |

Screen output is Uncommitted. The invocation is Committed.

See Also [acctadm\(1M\)](#), [dladm\(1M\)](#), [dlstat\(1M\)](#), [flowadm\(1M\)](#), [ifconfig\(1M\)](#), [prstat\(1M\)](#), [route\(1M\)](#), [attributes\(5\)](#), [dmpi\(7P\)](#)

Name fmadm – fault management configuration tool

Synopsis fmadm [-q] [*subcommand* [*arguments*]]

Description The fmadm utility can be used by administrators and service personnel to view and modify system configuration parameters maintained by the Solaris Fault Manager, [fmd\(1M\)](#). fmd receives telemetry information relating to problems detected by the system software, diagnoses these problems, and initiates proactive self-healing activities such as disabling faulty components.

fmadm can be used to:

- view the set of diagnosis engines and agents that are currently participating in fault management,
- view the list of system components that have been diagnosed as faulty, and
- perform administrative tasks related to these entities.

The Fault Manager attempts to automate as many activities as possible, so use of fmadm is typically not required. When the Fault Manager needs help from a human administrator, service repair technician, or Sun, it produces a message indicating its needs. It also refers you to a knowledge article on Sun's web site, <http://www.oracle.com/us/sun/msg/>. The web site might ask you to use fmadm or one of the other fault management utilities to gather more information or perform additional tasks. The documentation for [fmd\(1M\)](#), [fmdump\(1M\)](#), and [fmstat\(1M\)](#) describe more about tools to observe fault management activities.

The fmadm utility requires the user to possess the SYS_CONFIG privilege. Refer to the [System Administration Guide: Security Services](#) for more information about how to configure Solaris privileges. The fmadm load subcommand requires that the user possess all privileges.

SUBCOMMANDS fmadm accepts the following subcommands. Some of the subcommands accept or require additional options and operands. The load, unload, reset, and rotate subcommands are intended for trained technical personnel. We recommend against use of these subcommands without the specific guidance of, for example, a Knowledge Base article.

fmadm acquit *fmri* | *label* [*uuid*]

Notify the Fault Manager that the specified resource is not to be considered to be a suspect in the fault event identified by *uuid*, or if no UUID is specified, then in any fault or faults that have been detected. The fmadm acquit subcommand should be used only at the direction of a documented Sun repair procedure. Administrators might need to apply additional commands to re-enable a previously faulted resource.

fmadm acquit *uuid*

Notify the Fault Manager that the fault event identified by *uuid* can be safely ignored. The fmadm acquit subcommand should be used only at the direction of a documented Sun repair procedure. Administrators might need to apply additional commands to re-enable any previously faulted resources.

fmadm config

Display the configuration of the Fault Manager itself, including the module name, version, and description of each component module. Fault Manager modules provide services such as automated diagnosis, self-healing, and messaging for hardware and software present on the system.

fmadm faulty [-afgiprsv] [-n *max*] [-u *uid*]

Display status information for resources that the Fault Manager currently believes to be faulty.

The following options are supported:

- a Display all faults. By default, the `fmadm faulty` command only lists output for resources that are currently present and faulty. If you specify the `-a` option, all resource information cached by the Fault Manager is listed, including faults which have been automatically corrected or where no recovery action is needed. The listing includes information for resources that might no longer be present in the system.
- f Display faulty `fru`'s (Field replaceable units).
- g Group together faults which have the same `fru`, class and fault message.
- i Display persistent cache identifier for each resource in the Fault Manager.
- n *max* If faults or resources are grouped together with the `-a` or `-g` options, limit the output to *max* entries.
- p Pipe output through pager with form feed between each fault.
- r Display Fault Management Resource with their Identifier (FMRI) and their fault management state.
- s Display 1 line fault summary for each fault event.
- u *uid* Only display fault with given *uid*.
- v Display full output.

The percentage certainty is displayed if a fault has multiple suspects, either of different classes or on different `fru`'s. If more than one resource is on the same `fru` and it is not 100% certain that the fault is associated with the `fru`, the maximum percentage certainty of the possible suspects on the `fru` is displayed.

The Fault Manager associates the following states with every resource for which telemetry information has been received:

ok

The resource is present and in use and has no known problems so far as the Fault Manager is concerned.

unknown

The resource is not present or not usable but has no known problems. This might indicate the resource has been disabled or deconfigured by an administrator. Consult appropriate management tools for more information.

faulted

The resource is present but is not usable because one or more problems have been diagnosed by the Fault Manager. The resource has been disabled to prevent further damage to the system.

degraded

The resource is present and usable, but one or more problems have been diagnosed in the resource by the Fault Manager.

If all affected resources are in the same state, this is reflected in the message at the end of the list. Otherwise the state is given after each affected resource.

fmadm flush *fmri*

Flush the information cached by the Fault Manager for the specified resource, named by its FMRI. This subcommand should only be used when indicated by a documented Sun repair procedure. Typically, the use of this command is not necessary as the Fault Manager keeps its cache up-to-date automatically. If a faulty resource is flushed from the cache, administrators might need to apply additional commands to enable the specified resource.

fmadm load *path*

Load the specified Fault Manager module. *path* must be an absolute path and must refer to a module present in one of the defined directories for modules. Typically, the use of this command is not necessary as the Fault Manager loads modules automatically when Solaris initially boots or as needed.

fmadm unload *module*

Unload the specified Fault Manager module. Specify *module* using the basename listed in the `fmadm config` output. Typically, the use of this command is not necessary as the Fault Manager loads and unloads modules automatically based on the system configuration

fmadm repaired *fmri* | *label*

Notify the Fault Manager that a repair procedure has been carried out on the specified resource. The `fmadm repaired` subcommand should be used only at the direction of a documented Sun repair procedure. Administrators might need to apply additional commands to re-enable a previously faulted resource.

fmadm replaced *fmri* | *label*

Notify the Fault Manager that the specified resource has been replaced. This command should be used in those cases where the Fault Manager is unable to automatically detect the replacement. The `fmadm replaced` subcommand should be used only at the direction of a documented Sun repair procedure. Administrators might need to apply additional commands to re-enable a previously faulted resource.

```
fmadm reset [-s serd] module
```

Reset the specified Fault Manager module or module subcomponent. If the `-s` option is present, the specified Soft Error Rate Discrimination (SERD) engine is reset within the module. If the `-s` option is not present, the entire module is reset and all persistent state associated with the module is deleted. The `fmadm reset` subcommand should only be used at the direction of a documented Sun repair procedure. The use of this command is typically not necessary as the Fault Manager manages its modules automatically.

```
fmadm rotate errlog | fltlog | infolog | infolog_hival
```

The rotate subcommand is a helper command for [logadm\(1M\)](#), so that `logadm` can rotate live log files correctly. It is not intended to be invoked directly (and invoking it directly is likely to lose log history). Use one of the following commands to cause the appropriate logfile to be rotated, if the current one is not zero in size:

```
# logadm -p now -s 1b /var/fm/fmd/errlog
# logadm -p now -s 1b /var/fm/fmd/fltlog
# logadm -p now -s 1b /var/fm/fmd/infolog
# logadm -p now -s 1b /var/fm/fmd/infolog_hival
```

Options The following options are supported:

`-q` Set quiet mode. `fmadm` does not produce messages indicating the result of successful operations to standard output.

Operands The following operands are supported:

cmd The name of a subcommand listed in SUBCOMMANDS.

args One or more options or arguments appropriate for the selected *subcommand*, as described in SUBCOMMANDS. Among these arguments are `fmri`, `uuid`, and `label`. These identify resources that are the objects of `fmadm` subcommands. Use `fmadm faulty` to obtain the `fmri`, `uuid`, and `label` for a targeted resource. See EXAMPLES. In general, `label` is the most user-friendly of these operands.

Examples EXAMPLE 1 Invoking `faulty` Subcommand

The following command invokes the `faulty` subcommand, which displays the `uuid`, `label`, and `fmri` for a component.

```
# fmadm faulty
-----
TIME          EVENT-ID                                     MSG-ID      SEVERITY
-----
Sep 09 16:15 96609fae-113c-e48c-b1cf-ebf4b0902d72  DISK-8000-3E Critical
                                                injected

Host          : x4170-brm-02
Platform      : SUN-FIRE-X4170-SERVER    Chassis_id  : 0920XF508B
Product_sn:
```

EXAMPLE 1 Invoking faulty Subcommand *(Continued)*

```
Fault class: fault.io.scsi.cmd.disk.dev.rqs.derr
Affects : dev:///devid=id1,sd@n5000c5000940edbb//scsi_vhci/disk@g5000c\
5000940edbb out of service, but associated components no longer faulty
FRU      : "DISK 11"
(hc://:product-id=SUN-Storage-J4410:server-id=:chassis-id=:serial=000930\

Location: DISK 11
```

Note that `label` is the easiest-to-use identifier.

EXAMPLE 2 Obtaining Module Name

The following command displays the module name for each component. The module name is specified as input to the `fmadm unload` command.

EXAMPLE 2 Obtaining Module Name (Continued)

```
# fmadm config
MODULE                VERSION STATUS DESCRIPTION
cpumem-retire         1.1    active CPU/Memory Retire Agent
disk-transport        1.0    active Disk Transport Agent
eft                   1.16   active eft diagnosis engine
..
```

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred. Errors include a failure to communicate with `fmd` or insufficient privileges to perform the requested operation.
- 2 Invalid command-line options were specified.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|--------------------------|
| Availability | service/fault-management |
| Interface Stability | See below. |

The command-line options are Committed. The human-readable output is not-an-interface.

System Administration Guide: Advanced Administration

Name fmd – fault manager daemon

Synopsis /usr/lib/fm/fmd/fmd [-V] [-f *file*] [-o *opt=val*] [-R *dir*]

Description fmd is a daemon that runs in the background on each Solaris system. fmd receives telemetry information relating to problems detected by the system software, diagnoses these problems, and initiates proactive self-healing activities such as disabling faulty components. When appropriate, the fault manager also sends a message to the [syslogd\(1M\)](#) service to notify an administrator that a problem has been detected. The message directs administrators to a knowledge article on Sun's web site, <http://www.sun.com/msg/>, which explains more about the problem impact and appropriate responses.

Each problem diagnosed by the fault manager is assigned a Universal Unique Identifier (UUID). The UUID uniquely identifies this particular problem across any set of systems. The [fmdump\(1M\)](#) utility can be used to view the list of problems diagnosed by the fault manager, along with their UUIDs and knowledge article message identifiers. The [fmadm\(1M\)](#) utility can be used to view the resources on the system believed to be faulty. The [fmstat\(1M\)](#) utility can be used to report statistics kept by the fault manager. The fault manager is started automatically when Solaris boots, so it is not necessary to use the fmd command directly. Sun's web site explains more about what capabilities are currently available for the fault manager on Solaris.

Notification Services syslog (package service/fault-management)

The standard notification mechanism for new diagnoses is by means of syslog, using the syslog-msgs fmd module delivered in the same package as fmd itself.

By default, only new problem diagnoses are messaged by means of syslog-msgs, using the syslog facility and severity as listed in the table below. An administrator can use [svccfg\(1M\)](#) to request that other events in the problem resolution lifecycle are messaged through syslog-msgs:

```
# svccfg setnotify event syslog:{active|inactive}
```

See [svccfg\(1M\)](#) for additional detail.

| Event | Disposition | Facility | Severity |
|-------------------|-------------|------------|------------|
| problem-diagnosed | active | LOG_DAEMON | LOG_ERR |
| problem-updated | inactive | LOG_DAEMON | LOG_NOTICE |
| problem-repaired | inactive | LOG_DAEMON | LOG_NOTICE |
| problem-resolved | inactive | LOG_DAEMON | LOG_NOTICE |

Email (package service/fault-management/smtp-notify)

Notification by means of email is an option for which an additional package must be installed. The SMF service, svc:/system/fm/smtp-notify:default, is delivered by means of the package service/fault-management/smtp-notify and notification preferences configured by means of [svccfg\(1M\)](#). See [smtp-notify\(1M\)](#) for additional detail. Note that in addition to configuring notification preferences for the problem lifecycle events listed

above (problem-diagnosed, and so forth) this mechanism can also be configured through [svccfg\(1M\)](#) to provide notification of SMF instance state transition and other events.

SNMP (package `service/fault-management/snmp-notify`)

Notification of new events using SNMP traps is an option delivered by the package `service/fault-management/snmp-notify`. The service

`svc:/system/fm/snmp-notify:default` is responsible for raising SNMP traps for problem lifecycle and other designated events (including SMF instance state transition events, if so configured). See [snmp-notify\(1M\)](#) for additional detail.

Global and Non-Global Solaris Zones The fault manager service `svc:/system/fmd:default` service is configured in both global and non-global Solaris zones. In non-global zones, various hardware-oriented fault manager modules are not delivered, so it is a cut-down fault manager that runs there. In a non-global zone, the fault manager is focussed on software events.

Options The following options are supported

`-f file`

Read the specified configuration *file* prior to searching for any of the default fault manager configuration files.

`-o opt=value`

Set the specified fault manager option to the specified value. Fault manager options are currently a Private interface; see [attributes\(5\)](#) for information about Private interfaces.

`-R dir`

Use the specified root directory for all pathnames evaluated by the fault manager, instead of the default root (`/`).

`-V`

Print the fault manager's version to stdout and exit.

Exit Status The following exit values are returned:

- 0 Successful completion
- 1 An error occurred which prevented the fault manager from initializing, such as failure to open the telemetry transport.
- 2 Invalid command-line options were specified.

Files

| | |
|------------------------------|---------------------------------------|
| <code>/etc/fm/fmd</code> | Fault manager configuration directory |
| <code>/usr/lib/fm/fmd</code> | Fault manager library directory |
| <code>/var/fm/fmd</code> | Fault manager log directory |

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|--------------------------|
| Availability | service/fault-management |
| Interface Stability | Committed |

See Also [svcs\(1\)](#), [fmadm\(1M\)](#), [fmdump\(1M\)](#), [fmstat\(1M\)](#), [smtp-notify\(1M\)](#), [snmp-notify\(1M\)](#), [svccfg\(1M\)](#), [syslogd\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#)

<http://www.sun.com/msg/>

Notes The Fault Manager is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/fmd:default
```

The service's status can be queried using the [svcs\(1\)](#) command. Administrators should not disable the Fault Manager service.

Name fmdump – fault management log viewer

Synopsis fmdump [[-e | -i | -I] | -A] [-f] [-mvVp] [-c *class*] [-R *root*]
 [-t *time*] [-T *time*] [-u *uid*] [-n *name*[.*name*]*[=*value*]] [*file*] ...

Description The fmdump utility can be used to display the contents of any of the log files associated with the Solaris Fault Manager, [fmd\(1M\)](#). The Fault Manager runs in the background on each Solaris system. It receives telemetry information relating to problems detected by the system software, diagnoses these problems, and initiates proactive self-healing activities such as disabling faulty components.

The fmdump utility is not intended as the primary administrative interface to the Fault Manager. For that purpose, use [fmadm](#) (and see [fmadm\(1M\)](#)). The fmdump utility simply dumps Fault Manager historical logs with little further interpretation, and can include implementation detail without explanation. See the ATTRIBUTES section below.

The Fault Manager maintains several sets of log files for use by service personnel and, to a lesser extent, administrators:

- error log A log that records error telemetry, the symptoms of problems detected by the system.
- info log A log that records informational events. This is realized as two sets of log files: high-value informational events, and other informational events.
- fault log A log that records fault diagnosis information, the problems believed to explain the symptoms recorded in the error and info logs.

A log file set consists of the current active log file together with a possible number of older rotated log files in that set. All logs are managed with [logadm\(1M\)](#) and have entries in `/etc/logadm.conf`.

Note that the fmdump utility dumps the current log file and all rotated log files for the target set. It therefore displays the entire log history. For the fault log, in particular, it is important to recognize that fmdump will show all problems *ever* diagnosed and is not limited to still-current problems. (Use [fmadm](#) `faulty` for that information.)

By default, fmdump displays the contents of the fault log, which records the result of each diagnosis made by the fault manager or one of its component modules. The error log can be selected using `-e`, the info log with `-i`, and the high-value info log with `-I`; or a specific log file path may be specified as `[file]` on the command line (which will dump just that file and not look for rotated versions of the log). One can also use option `-A` to aggregate all logs, or a set of log file paths listed on the command line.

An example of a default fmdump display follows:

```
# fmdump
TIME                UUID                SUNW-MSG-ID EVENT
Mar 23 14:06:35.2682 0a11a1a7-a8ce-c941-8527-8d7a9d320071 ZFS-8000-CS Diagnosed
```

```

Mar 25 14:51:41.2261 0a11a1a7-a8ce-c941-8527-8d7a9d320071 FMD-8000-4M Repaired
Mar 25 14:51:41.2523 0a11a1a7-a8ce-c941-8527-8d7a9d320071 FMD-8000-6U Resolved
May 31 23:35:39.9146 c63ac52e-506b-c1cc-e965-ff3b8544490d SMF-8000-YX Diagnosed
...

```

(Output wraps on displays of 80 or fewer characters.)

This dumps the fault log, because no command line options or arguments selected any other log. The fault log records the lifecycle of problems diagnosed by the Fault Manager or its component modules, from initial problem diagnosis to problem resolution.

Each problem recorded in the fault log is identified by:

- The timestamp of the event describing the problem lifecycle state change.
- A Universal Unique Identifier (UUID) that can be used to uniquely identify this particular problem across any set of systems. All events describing problem lifecycle state changes for a given problem will use the same UUID (as above: we see initial diagnosis and, later, repair and resolution all quoting the same problem UUID).
- A message identifier that can be used to access a corresponding knowledge article located at Sun's web site, <http://www.oracle.com/us/sun/msg/>

If a problem requires action by a human administrator or service technician or affects system behavior, the Fault Manager also issues a human-readable message to `syslogd(1M)`. This message provides a summary of the problem and a reference to the knowledge article on the Sun web site, <http://www.oracle.com/us/sun/msg/>. The `fmdump` utility can dump `fltlog` entries in a similar format to that rendered to `syslog` through use of the `-m` option.

You can use the `-v` and `-V` options to expand the display from a single-line summary to increased levels of detail for each event recorded in the log. The `-p` option can be used with `-V` to request “prettier” output.

The `-c`, `-t`, `-T`, `-n` and `-u` options can be used to filter the output by selecting only those events that match the specified class, range of times, or `uuid`. If more than one filter option is present on the command-line, the options combine to display only those events that are selected by the logical AND of the options. If more than one instance of the same filter option is present on the command-line, the like options combine to display any events selected by the logical OR of the options. For example, the command:

```
# fmdump -u uuid1 -u uuid2 -t 02Dec09
```

...selects events whose attributes are (`uuid1` OR `uuid2`) AND (time on or after `02Dec09`).

Options The following options are supported:

`-A`

Perform log aggregation. If one or more log file paths are listed on the command line, then aggregate those files; otherwise aggregate all known log types, including all `logadm`-rotated

files. Logs are merged in time order but with the characteristic that any two records from the same log file are ordered in the aggregation exactly as they were in the original log file (which is in the order they were received and processed by the Fault Manager, which will be an approximate time order).

You cannot use other log set selection options with `-A`: `-e`, `-i`, or `-I`. Filter options such as `-c`, `-t`, `-T`, and `-n` can be used, but `-u` cannot. Output options `-v`, `-V`, and `-p` are available, but `-m` is not. Option `-f` will follow all the selected logs.

`-c class`

Select events that match the specified class. The class argument can use the glob pattern matching syntax described in [sh\(1\)](#). The class represents a hierarchical classification string indicating the type of telemetry event. More information about Sun's telemetry protocol is available at Sun's web site, <http://www.oracle.com/us/sun/msg/>.

`-e`

Display events from the fault management error log instead of the fault log.

The error log contains Private telemetry information used by Sun's automated diagnosis software. This information is recorded to facilitate post-mortem analysis of problems and event replay, and should not be parsed or relied upon for the development of scripts and other tools. See [attributes\(5\)](#) for information about Sun's rules for Private interfaces.

`-f`

Follow the growth of the log file (or files if using `-A`) by waiting for additional data. `fmdump` enters an infinite loop where it will sleep for a second, attempt to read and format new data from the log file, and then go back to sleep. This loop can be terminated at any time by sending an interrupt (`Control-C`).

`-m`

Print the localized diagnosis message associated with each entry in the fault log.

`-n name[.name]*[=value]`

Select log events (from the log(s) selected on the command line) that have properties with a matching name (and optionally a matching value). For string properties the value can be a regular expression match. Regular expression syntax is described in the EXTENDED REGULAR EXPRESSIONS section of the [regex\(5\)](#) manual page. Be careful when using the characters:

```
$ * { ^ | ( ) \
```

...or a regular expression, because these are meaningful to the shell. It is safest to enclose any of these in single quotes. For numeric properties, the value can be octal, hex, or decimal.

`-p`

Combined with `-V` (very verbose) option, requests that the pretty-printing options that are available are, in fact, performed.

-R *dir*

Use the specified root directory for the log files accessed by `fmdump`, instead of the default root (`/`).

-t *time*

Select events that occurred at or after the specified time. The time can be specified using any of the following forms:

mm/dd/yy hh:mm:ss

Month, day, year, hour in 24-hour format, minute, and second. Any amount of whitespace can separate the date and time. The argument should be quoted so that the shell interprets the two strings as a single argument.

mm/dd/yy hh:mm

Month, day, year, hour in 24-hour format, and minute. Any amount of whitespace can separate the date and time. The argument should be quoted so that the shell interprets the two strings as a single argument.

mm/dd/yy

12:00:00AM on the specified month, day, and year.

ddMonyy hh:mm:ss

Day, month name, year, hour in 24-hour format, minute, and second. Any amount of whitespace can separate the date and time. The argument should be quoted so that the shell interprets the two strings as a single argument.

ddMonyy hh:mm

Day, month name, year, hour in 24-hour format, and minute. Any amount of whitespace can separate the date and time. The argument should be quoted so that the shell interprets the two strings as a single argument.

Mon dd hh:mm:ss

Month, day, hour in 24-hour format, minute, and second of the current year.

yyyy-mm-dd [T hh:mm[:ss]]

Year, month, day, and optional hour in 24-hour format, minute, and second. The second, or hour, minute, and second, can be optionally omitted.

ddMonyy

12:00:00AM on the specified day, month name, and year.

hh:mm:ss

Hour in 24-hour format, minute, and second of the current day.

hh:mm

Hour in 24-hour format and minute of the current day.

Tns | Tnsec

T nanoseconds ago where *T* is an integer value specified in base 10.

*T*us | *T*usec

T microseconds ago where *T* is an integer value specified in base 10.

*T*ms | *T*msec

T milliseconds ago where *T* is an integer value specified in base 10.

*T*s | *T*sec

T seconds ago where *T* is an integer value specified in base 10.

*T*m | *T*min

T minutes ago where *T* is an integer value specified in base 10.

*T*h | *T*hour

T hours ago where *T* is an integer value specified in base 10.

*T*d | *T*day

T days ago where *T* is an integer value specified in base 10.

You can append a decimal fraction of the form *.n* to any *-t* option argument to indicate a fractional number of seconds beyond the specified time.

-T time

Select events that occurred at or before the specified time. *time* can be specified using any of the time formats described for the *-t* option.

-u uuid

Select problem diagnosis events in the fault log that exactly match the specified *uuid*. Each diagnosis is associated with a Universal Unique Identifier (UUID) for identification purposes. The *-u* option can be combined with other options, such as *-v*, to show all of the details associated with a particular diagnosis. Note that multiple fault log events can be associated with the same problem diagnosis UUID—all events describing the lifecycle of a single problem (from initial diagnosis to final resolution) quote the same problem UUID.

If the *-e* option and *-u* option are both present, the error events that are cross-referenced by the specified diagnosis are displayed.

-v

Display verbose event detail. The event display is enlarged to show additional common members of the selected events.

-V

Display very verbose event detail. The event display is enlarged to show every member of the name-value pair list associated with each event. In addition, for fault logs, the event display includes a list of cross-references to the corresponding errors that were associated with the diagnosis.

Use *-p* with *-V* to request pretty-printing.

Operands The following operands are supported:

file Specifies an alternate log file (or files if using -A) to display instead of the system fault log. The fmdump utility determines the type of the specified log automatically and produces appropriate output for the selected log.

Examples EXAMPLE 1 Retrieving Given Class from fmd Log

Use any of the following commands to retrieve information about a specified class from the fmd log. The complete class name is `ereport.io.ddi.context`.

```
# fmdump -Ve -c 'ereport.io.ddi.context'
# fmdump -Ve -c 'ereport.*.context'
# fmdump -Ve -n 'class=ereport.io.ddi.context'
# fmdump -Ve -n 'class=ereport.*.context'
```

Any of the preceding commands produces the following output:

```
Oct 06 2007 11:53:20.975021712 ereport.io.ddi.context
  nvlist version: 0
    class = ereport.io.ddi.context
    ena = 0x1b03a15ecf00001
    detector = (embedded nvlist)
      nvlist version: 0
        version = 0x0
        scheme = dev
        device-path = /
      (end detector)

  __ttl = 0x1
  __tod = 0x470706b0 0x3a1da690
```

EXAMPLE 2 Retrieving Specific Detector Device Path from fmd Log

The following command retrieves a detector device path from the fmd log.

```
# fmdump -Ve -n 'detector.device-path=.*disk@1,0$'
Oct 06 2007 12:04:28.065660760 ereport.io.scsi.disk.rqs
  nvlist version: 0
    class = ereport.io.scsi.disk.rqs
    ena = 0x453ff3732400401
    detector = (embedded nvlist)
      nvlist version: 0
        version = 0x0
        scheme = dev
        device-path = /pci@0,0/pci1000,3060@3/disk@1,0
      (end detector)

  __ttl = 0x1
  __tod = 0x4707094c 0x3e9e758
```

Exit Status The following exit values are returned:

- 0 Successful completion. All records in the log file were examined successfully.
- 1 A fatal error occurred. This prevented any log file data from being examined, such as failure to open the specified file.
- 2 Invalid command-line options were specified.
- 3 The log file was opened successfully, but one or more log file records were not displayed, either due to an I/O error or because the records themselves were malformed. `fmdump` issues a warning message for each record that could not be displayed, and then continues on and attempts to display other records.

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|--------------------------|
| Availability | service/fault-management |
| Interface Stability | See below. |

The command-line options are Uncommitted. The human-readable error log and informational log output is Private. The human-readable fault log output is Uncommitted.

See Also [sh\(1\)](#), [fmadm\(1M\)](#), [fmd\(1M\)](#), [fmstat\(1M\)](#), [logadm\(1M\)](#), [syslogd\(1M\)](#), [libexacct\(3LIB\)](#), [attributes\(5\)](#), [regex\(5\)](#)

System Administration Guide: Security Services

<http://www.oracle.com/us/sun/msg/>

Notes Fault logs contain references to records stored in error logs that can be displayed using `fmdump -V` to understand the errors that were used in the diagnosis of a particular fault. These links are preserved if an error log is renamed as part of log rotation. They can be broken by removing an error log file, or by moving it to another filesystem directory. `fmdump` can not display error information for such broken links. It continues to display any and all information present in the fault log.

Name fmstat – report fault management module statistics

Synopsis fmstat [-astTz] [-d u | d] [-m *module*] [*interval* [*count*]]

Description The `fmstat` utility can be used by administrators and service personnel to report statistics associated with the Solaris Fault Manager, [fmd\(1M\)](#) and its associated set of modules. The Fault Manager runs in the background on each Solaris system. It receives telemetry information relating to problems detected by the system software, diagnoses these problems, and initiates proactive self-healing activities such as disabling faulty components.

You can use `fmstat` to view statistics for diagnosis engines and agents that are currently participating in fault management. The documentation for [fmd\(1M\)](#), [fmadm\(1M\)](#), and [fmdump\(1M\)](#) describes more about tools to observe fault management activities.

If the `-m` option is present or the `-t` option is present, `fmstat` reports any statistics kept by the specified fault management module. The module list can be obtained using `fmadm config`.

If the `-m` option is not present, `fmstat` reports the following statistics for each of its client modules:

| | |
|----------------------|-----------------------------------------------------------------------------------------------|
| <code>module</code> | The name of the fault management module, as reported by <code>fmadm config</code> . |
| <code>ev_recv</code> | The number of telemetry events received by the module. |
| <code>ev_acpt</code> | The number of events accepted by the module as relevant to a diagnosis. |
| <code>wait</code> | The average number of telemetry events waiting to be examined by the module. |
| <code>svc_t</code> | The average service time for telemetry events received by the module, in milliseconds. |
| <code>%w</code> | The percentage of time that there were telemetry events waiting to be examined by the module. |
| <code>%b</code> | The percentage of time that the module was busy processing telemetry events. |
| <code>open</code> | The number of active cases (open problem investigations) owned by the module. |
| <code>solve</code> | The total number of cases solved by this module since it was loaded. |
| <code>memsz</code> | The amount of dynamic memory currently allocated by this module. |
| <code>bufsz</code> | The amount of persistent buffer space currently allocated by this module. |

The `fmstat` utility requires the user to possess the `SYS_ADMIN` privilege. Refer to the [System Administration Guide: Security Services](#) for more information about how to configure Solaris privileges.

Options The following options are supported:

- a Print all statistics for a module, including those kept on its behalf by `fmd`. If the `-a` option is not present, only those statistics kept by the module are reported. If the `-a` option is used without the `-m module`, a set of global statistics associated with `fmd` are displayed.
- d u | d Display a time stamp.

Specify `u` for a printed representation of the internal representation of time. See [time\(2\)](#). Specify `d` for standard date format. See [date\(1\)](#).
- m *module* Print a report on the statistics associated with the specified fault management module, instead of the default statistics report. Modules can publish an arbitrary set of statistics to help Sun service the fault management software itself. The module statistics constitute a Private interface. See [attributes\(5\)](#) for information on Sun's rules for Private interfaces. Scripts should not be written that depend upon the values of fault management module statistics as they can change without notice.
- s Print a report on Soft Error Rate Discrimination (SERD) engines associated with the module instead of the default module statistics report. A SERD engine is a construct used by fault management software to determine if a statistical threshold measured as N events in some time T has been exceeded. The `-s` option can only be used in combination with the `-m` option.
- t Print a report on the statistics associated with each fault management event transport. Each fault management module can provide the implementation of one or more event transports.
- T Print a table of the authority information associated with each fault management event transport. If the `-m` option is present, only transports associated with the specified module are displayed.
- z Omit statistics with a zero value from the report associated with the specified fault management module. The `-z` option can only be used in combination with the `-m` option.

Operands The following operands are supported:

- count* Print only count reports, and then exit.
- interval* Print a new report every *interval* seconds.

If no *interval* and no *count* are specified, a single report is printed and `fmstat` exits. If an *interval* is specified but no *count* is specified, `fmstat` prints reports every *interval* seconds indefinitely until the command is interrupted.

Exit Status The following exit values are returned:

- 0 Successful completion.

- 1 A fatal error occurred. A fatal error could be the failure to communicate with [fmd\(1M\)](#). It could also be that insufficient privileges were available to perform the requested operation.
- 2 Invalid command-line options were specified.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------------|--------------------------|
| Availability | service/fault-management |
| Interface Stability | See below. |

The command-line options are Committed. The human-readable default report is Uncommitted. The human-readable module report is Private.

See Also [fmadm\(1M\)](#), [fmd\(1M\)](#), [fmdump\(1M\)](#), [attributes\(5\)](#)

System Administration Guide: Security Services

Name fmthard – populate label on hard disks

Synopsis

```
SPARC fmthard -d data | -n volume_name | -s datafile [-i] /dev/rdisk/c?
      [t?] d?s2

x86   fmthard -d data | -n volume_name | -s datafile [-i] /dev/rdisk/c?
      [t?] d?s2
```

Description The fmthard command updates the VTOC (Volume Table of Contents) on hard disks and, on x86 systems, adds boot information to the Solaris fdisk partition. One or more of the options -s *datafile*, -d *data*, or -n *volume_name* must be used to request modifications to the disk label. To print disk label contents, see prtvtoc(1M). The /dev/rdisk/c?[t?]d?s2 file must be the character special file of the device where the new label is to be installed. On x86 systems, fdisk(1M) must be run on the drive before fmthard.

If you are using an x86 system, note that the term “partition” in this page refers to *slices* within the x86 fdisk partition on x86 machines. Do not confuse the partitions created by fmthard with the partitions created by fdisk.

Options The following options are supported:

-d *data*

The *data* argument of this option is a string representing the information for a particular partition in the current VTOC. The string must be of the format *part:tag:flag:start:size* where *part* is the partition number, *tag* is the ID TAG of the partition, *flag* is the set of permission flags, *start* is the starting sector number of the partition, and *size* is the number of sectors in the partition. See the description of the *datafile* below for more information on these fields.

-i

This option allows the command to create the desired VTOC table, but prints the information to standard output instead of modifying the VTOC on the disk.

-n *volume_name*

This option is used to give the disk a *volume_name* up to 8 characters long.

-s *datafile*

This option is used to populate the VTOC according to a *datafile* created by the user. If the *datafile* is – (a hyphen), fmthard reads from standard input. The *datafile* format is described below. This option causes all of the disk partition timestamp fields to be set to zero.

Every VTOC generated by fmthard will also have partition 2, by convention, that corresponds to the whole disk. If the input in *datafile* does not specify an entry for partition 2, a default partition 2 entry will be created automatically in VTOC with the tag V_BACKUP and size equal to the full size of the disk.

The *datafile* contains one specification line for each partition, starting with partition 0. Each line is delimited by a new-line character (\n). If the first character of a line is an asterisk (*), the line is treated as a comment. Each line is composed of entries that are position-dependent, separated by white space and having the following format:

```
partition tag flag starting_sector size_in_sectors
```

where the entries have the following values:

partition

The partition number. Currently, for Solaris SPARC, a disk can have up to 8 partitions, 0–7. Even though the *partition* field has 4 bits, only 3 bits are currently used. For x86, all 4 bits are used to allow slices 0–15. Each Solaris *fdisk* partition can have up to 16 slices.

tag

The partition tag: a decimal number. The following are reserved codes: 0 (V_UNASSIGNED), 1 (V_BOOT), 2 (V_ROOT), 3 (V_SWAP), 4 (V_USR), 5 (V_BACKUP), 6 (V_STAND), 7 (V_VAR), and 8 (V_HOME).

flag

The flag allows a partition to be flagged as unmountable or read only, the masks being: V_UNMNT 0x01, and V_RDONLY 0x10. For mountable partitions use 0x00.

starting_sector

The sector number (decimal) on which the partition starts.

size_in_sectors

The number (decimal) of sectors occupied by the partition.

You can save the output of a *prtvtoc* command to a file, edit the file, and use it as the *datafile* argument to the *-s* option.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [uname\(1\)](#), [format\(1M\)](#), [prtvtoc\(1M\)](#), [attributes\(5\)](#)

x86 Only [fdisk\(1M\)](#), [installgrub\(1M\)](#)

Notes Special care should be exercised when overwriting an existing VTOC, as incorrect entries could result in current data being inaccessible. As a precaution, save the old VTOC.

For disks under two terabytes, *fmthard* cannot write a VTOC on an unlabeled disk. Use [format\(1M\)](#) for this purpose.

Name format – disk partitioning and maintenance utility

Synopsis format [-f *command-file*] [-l *log-file*] [-x *data-file*]
 [-d *disk-name*] [-t *disk-type*] [-p *partition-name*]
 [-s] [-m] [-M] [-e] [*disk-list*]

Description format enables you to format, label, repair, and analyze disks on your system. Unlike previous disk maintenance programs, format runs under SunOS. Because there are limitations to what can be done to the system disk while the system is running, format is also supported within the memory-resident system environment. For most applications, however, running format under SunOS is the more convenient approach.

format first uses the disk list defined in *data-file* if the -x option is used. format then checks for the FORMAT_PATH environment variable, a colon-separated list of filenames and/or directories. In the case of a directory, format searches for a file named format.dat in that directory; a filename should be an absolute pathname, and is used without change. format adds all disk and partition definitions in each specified file to the working set. Multiple identical definitions are silently ignored. If FORMAT_PATH is not set, the path defaults to /etc/format.dat.

disk-list is a list of disks in the form c?t?d? or /dev/rdisk/c?t?d?s?. With the latter form, shell wildcard specifications are supported. For example, specifying /dev/rdisk/c2* causes format to work on all drives connected to controller c2 only. If no *disk-list* is specified, format lists all the disks present in the system that can be administered by format.

Removable media devices are listed only when users execute format in expert mode (option -e). This feature is provided for backward compatibility. Use [rmformat\(1\)](#) for rewritable removable media devices.

Options The following options are supported:

- d *disk-name* Specify which disk should be made current upon entry into the program. The disk is specified by its logical name (for instance, -d c0t1d0). This can also be accomplished by specifying a single disk in the disk list.
- e Enable SCSI expert menu. Note this option is not recommended for casual use.
- f *command-file* Take command input from *command-file* rather than the standard input. The file must contain commands that appear just as they would if they had been entered from the keyboard. With this option, format does not issue continue? prompts; there is no need to specify y(es) or n(o) answers in the *command-file*. In non-interactive mode, format does not initially expect the input of a disk selection number. The user must specify the current working disk with the -d *disk-name* option when format is invoked, or specify disk and the disk selection number in the *command-file*.

| | |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -l <i>log-file</i> | Log a transcript of the <code>format</code> session to the indicated <i>log-file</i> , including the standard input, the standard output and the standard error. |
| -m | Enable extended messages. Provides more detailed information in the event of an error. |
| -M | Enable extended and diagnostic messages. Provides extensive information on the state of a SCSI device's mode pages, during formatting. |
| -p <i>partition-name</i> | Specify the partition table for the disk which is current upon entry into the program. The table is specified by its name as defined in the data file. This option can be used only if a disk is being made current, and its type is either specified or available from the disk label. |
| -s | Silent. Suppress all of the standard output. Error messages are still displayed. This is generally used in conjunction with the <code>-f</code> option. |
| -t <i>disk-type</i> | Specify the type of disk which is current upon entry into the program. A disk's type is specified by name in the data file. This option can only be used if a disk is being made current as described above. |
| -x <i>data-file</i> | Use the list of disks contained in <i>data-file</i> . |

Usage When you invoke `format` with no options or with the `-e`, `-l`, `-m`, `-M`, or `-s` options, the program displays a numbered list of available disks and prompts you to specify a disk by list number. If the machine has more than 10 disks, press SPACE to see the next screenful of disks.

You can specify a disk by list number even if the disk is not displayed in the current screenful. For example, if the current screen shows disks 11-20, you can enter 25 to specify the twenty-fifth disk on the list. If you enter a number for a disk that is not currently displayed, `format` prompts you to verify your selection. If you enter a number from the displayed list, `format` silently accepts your selection.

After you specify a disk, `format` displays its main menu. This menu enables you to perform the following tasks:

| | |
|---------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| analyze | Run read, write, compare tests, and data purge. The data purge function implements the National Computer Security Center Guide to Understanding Data Remnance (NCSC-TG-025 version 2) Overwriting Algorithm. See NOTES. |
| backup | Search for backup labels. |
| cache | Enable, disable, and query the state of the write cache and read cache. This menu item only appears when <code>format</code> is invoked with the <code>-e</code> option, and is only supported on SCSI devices.. |
| current | Display the device name, the disk geometry, and the pathname to the disk device. |

| | |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| defect | Retrieve and print defect lists. This option is supported only on SCSI devices. IDE disks perform automatic defect management. Upon using the defect option on an IDE disk, you receive the message:

Controller does not support defect management
or disk supports automatic defect management. |
| disk | Choose the disk that will be used in subsequent operations (known as the current disk.) |
| fdisk | Run the <code>fdisk(1M)</code> program to create a <code>fdisk</code> partition for Solaris software (x86 based systems only). |
| format | Format and verify the current disk. This option is supported only on SCSI devices. IDE disks are pre-formatted by the manufacturer. Upon using the format option on an IDE disk, you receive the message:

Cannot format this drive. Please use your
manufacturer-supplied formatting utility. |
| inquiry | Display the vendor, product name, and revision level of the current drive. |
| label | Write a new label to the current disk. |
| partition | Create and modify slices. |
| quit | Exit the format menu. |
| repair | Repair a specific block on the disk. |
| save | Save new disk and slice information. |
| type | Select (define) a disk type. |
| verify | Read and display labels. Print information such as the number of cylinders, alternate cylinders, heads, sectors, and the partition table. |
| volname | Label the disk with a new eight character volume name. |

Environment Variables `FORMAT_PATH` a colon-separated list of filenames and/or directories of disk and partition definitions. If a directory is specified, `format` searches for the file `format.dat` in that directory.

Files `/etc/format.dat` default data file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [fmthard\(1M\)](#), [prtvtoc\(1M\)](#), [rmformat\(1\)](#), [format.dat\(4\)](#), [attributes\(5\)](#), [sd\(7D\)](#)

System Administration Guide: Basic Administration

x86 Only [fdisk\(1M\)](#)

Warnings When the format function is selected to format the Maxtor 207MB disk, the following message displays:

```
Mode sense page(4) reports rpm value as 0, adjusting it to 3600
```

This is a drive bug that may also occur with older third party drives. The above message is not an error; the drive will still function correctly.

Cylinder 0 contains the partition table (disk label), which can be overwritten if used in a raw disk partition by third party software.

format supports writing EFI-compliant disk labels in order to support disks or LUNs with capacities greater than one terabyte. However, care should be exercised since many software components, such as filesystems and volume managers, are still restricted to capacities of one terabyte or less. See the *System Administration Guide: Basic Administration* for additional information.

By default, on an unlabeled disk, EFI labels will be written on disks larger than 2 TB. When format is invoked with the `-e` option, on writing the label, the label type can be chosen. Booting is not currently supported on a disk with an EFI label.

Notes format provides a help facility you can use whenever format is expecting input. You can request help about what information is expected by simply entering a question mark (?) and format prints a brief description of what type of input is needed. If you enter a ? at the menu prompt, a list of available commands is displayed.

For SCSI disks, formatting is done with both Primary and Grown defects list by default. However, if only Primary list is extracted in defect menu before formatting, formatting will be done with Primary list only.

Changing the state of the caches is only supported on SCSI devices, and not all SCSI devices support changing or saving the state of the caches.

The NCSC-TG-025 algorithm for overwriting meets the DoD 5200.28-M (ADP Security Manual) Eraser Procedures specification. The NIST Guidelines for Media Sanitization (NIST SP 800-88) also reference this algorithm.

Name fpsd – Fp-scrubber daemon

Synopsis /usr/lib/fps/fpsd

Description fpsd is a user-level daemon that periodically runs non-intrusive tests to validate proper functioning of FPU (Floating Point Unit) hardware in the system. A fault management action is initiated by means of [fmd\(1M\)](#), in case an error is detected by the test.

fpsd is not supported on all Sun systems. On a system on which it is not supported, fpsd is automatically disabled.

Exit Status The following exit values are returned:

0
Successful completion.

non-zero
An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|--------------------------------|
| Availability | system/floating-point-scrubber |
| Interface Stability | Uncommitted |

See Also [svcs\(1\)](#), [fmd\(1M\)](#), [svcadm\(1M\)](#), [svccfg\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Notes The fpsd service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/fpsd:default
```

You can use [svccfg\(1M\)](#) to change the default fpsd behavior:

| Property Name | Type | Description |
|---------------------|---------|------------------------------------------------------------------------|
| ----- | ---- | ----- |
| config/exclude_cpus | astring | comma delimited list of CPU IDs to be excluded from proactive testing. |

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Disabling the service can increase system's vulnerability to silent data corruption, if a fault were to develop in an FPU within the system.

Name fruadm – prints and updates customer data associated with FRUs

Synopsis /usr/platform/sun4u/sbin/fruadm
/usr/platform/sun4u/sbin/fruadm -l
/usr/platform/sun4u/sbin/fruadm [-r] *path* [*text*]

Description fruadm prints or sets the customer data for Field-Replaceable Units (FRUs).

Without arguments, fruadm prints the paths of all FRU ID-capable FRUs (containers) in the system, along with the contents of the customer data record, if present, for each such FRU; for FRUs without customer data, fruadm prints only the container's path.

Only a privileged user can create or update data in containers. The privileges required to perform these write operations are hardware dependent. Typically, a default system configuration restricts write operations to the superuser or to the platform-administrator user.

Options The following options are supported:

- l List the system's frutree paths.
- r Recursively display or update the data for all containers rooted at the argument *path*.

Operands The following operands are supported:

path A full or partial system frutree path for or under which to print or set the customer data. The first field of each line of output of fruadm -l gives the valid full frutree paths for the system.

Paths can include shell meta-characters; such paths should be quoted appropriately for the user's shell. For partial paths, the first matching full path is selected for display or update. Without the -r option, the path must be that of a container; with the -r option, all containers (if any) under *path* will be selected.

text Up to 80 characters of text set as the customer data. If the text contains white space or shell metacharacters, it should be quoted appropriately for the user's shell.

Examples EXAMPLE 1 Displaying All Customer Data

The following example prints all customer data available from FRUs on the system. For containers with no customer data, only the containers' paths will be listed.

```
example% fruadm
```

EXAMPLE 2 Displaying Customer Data For a Single FRU

The following command prints the customer data, if present, for the specified FRU:

```
example% fruadm /frutree/chassis/system-board
```

EXAMPLE 3 Displaying Customer Data For a Single FRU

The following command prints the customer data, if present, for the first mem-module found:

```
example% fruadm mem-module
```

EXAMPLE 4 Setting Customer Data

The following example sets the customer data for a FRU:

```
example# fruadm system-board 'Asset Tag 123456'
```

EXAMPLE 5 Setting Customer Data

The following command sets the customer data for all FRUs under chassis:

```
example# fruadm -r /frutree/chassis "Property of XYZ, Inc."
```

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------------|------------------------|
| Availability | system/fru-id/platform |
| Interface Stability | Uncommitted |

See Also [prtfru\(1M\)](#), [attributes\(5\)](#)

Name fsck – check and repair file systems

Synopsis fsck [-F *FSType*] [-m] [-V] [-v] [*special*] . . .

fsck [-F *FSType*] [-n | N | y | Y] [-V] [-v]
[-o *FSType-specific-options*] [*special*] . . .

Description fsck audits and interactively repairs inconsistent file system conditions. If the file system is inconsistent the default action for each correction is to wait for the user to respond yes or no. If the user does not have write permission fsck defaults to a no action. Some corrective actions will result in loss of data. The amount and severity of data loss can be determined from the diagnostic output.

FSType-specific-options are options specified in a comma-separated (with no intervening spaces) list of options or keyword-attribute pairs for interpretation by the *FSType*-specific module of the command.

special represents the character special device on which the file system resides, for example, /dev/rdisk/c1t0d0s7. Note: the character special device, not the block special device, should be used. fsck will not work if the block device is mounted.

If no *special* device is specified fsck checks the file systems listed in /etc/vfstab. Those entries in /etc/vfstab which have a character special device entry in the fsckdev field and have a non-zero numeric entry in the fsckpass field will be checked. Specifying -F *FSType* limits the file systems to be checked to those of the type indicated.

If *special* is specified, but -F is not, the file system type will be determined by looking for a matching entry in /etc/vfstab. If no entry is found, the default local file system type specified in /etc/default/fs will be used.

If a file system type supports parallel checking, for example, ufs, some file systems eligible for checking may be checked in parallel. Consult the file system-specific man page (for example, fsck_ufs(1M)) for more information.

Options The following generic options are supported:

-F *FSType*

Specify the file system type on which to operate.

-m

Check but do not repair. This option checks that the file system is suitable for mounting, returning the appropriate exit status. If the file system is ready for mounting, fsck displays a message such as:

```
ufs fsck: sanity check: /dev/rdisk/c0t3d0s1 okay
```

-n | -N

Assume a no response to all questions asked by fsck; do not open the file system for writing.

- V
Echo the expanded command line but do not execute the command. This option may be used to verify and to validate the command line.
- v
Enables verbose output. Might not be supported by all filesystem-specific `fsock` implementations.
- y | Y
Assume a yes response to all questions asked by `fsock`.
- o *specific-options*
These *specific-options* can be any combination of the following separated by commas (with no intervening spaces).
 - b=*n*
Use block *n* as the super block for the file system. Block 32 is always one of the alternate super blocks. Determine the location of other super blocks by running `newfs(1M)` with the `-Nv` options specified.
 - c
If the file system is in the old (static table) format, convert it to the new (dynamic table) format. If the file system is in the new format, convert it to the old format provided the old format can support the file system configuration. In interactive mode, `fsock` will list the direction the conversion is to be made and ask whether the conversion should be done. If a negative answer is given, no further operations are done on the file system. In preen mode, the direction of the conversion is listed and done if possible without user interaction. Conversion in preen mode is best used when all the file systems are being converted at once. The format of a file system can be determined from the first line of output from `fstyp(1M)`. Note: the `c` option is seldom used and is included only for compatibility with pre-4.1 releases. There is no guarantee that this option will be included in future releases.
 - f
Force checking of file systems regardless of the state of their super block clean flag.
 - p
Check and fix the file system non-interactively (“preen”). Exit immediately if there is a problem requiring intervention. This option is required to enable parallel file system checking.
 - w
Check writable file systems only.

Exit Status 0
file system is unmounted and OK

1
erroneous parameters are specified

- 32
file system is unmounted and needs checking (`fsck -m` only)
- 33
file system is already mounted
- 34
cannot stat device
- 35
a filesystem that is mounted read/write was modified – reboot
- 36
uncorrectable errors detected - terminate normally
- 37
a signal was caught during processing
- 39
uncorrectable errors detected - terminate immediately
- 40
file system is mounted read-only and is OK

Usage The `fsck` command is *large file aware* for UFS file systems, per the [largefile\(5\)](#) man page.

Files `/etc/default/fs`
default local file system type. Default values can be set for the following flags in `/etc/default/fs`. For example: `LOCAL=ufs`.

`LOCAL`

The default partition for a command if no `FSType` is specified.

`/etc/vfstab`

list of default parameters for each file system

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | Committed |

See Also [clri\(1M\)](#), [fsck_cacheufs\(1M\)](#), [fsck_ufs\(1M\)](#), [fsdb_ufs\(1M\)](#), [fsirand\(1M\)](#), [fstyp\(1M\)](#), [mkfs\(1M\)](#), [mkfs_ufs\(1M\)](#), [mountall\(1M\)](#), [newfs\(1M\)](#), [reboot\(1M\)](#), [vfstab\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#), [ufs\(7FS\)](#)

Warnings The operating system buffers file system data. Running `fsck` on a mounted file system can cause the operating system's buffers to become out of date with respect to the disk. For this reason, the file system should be *unmounted* when `fsck` is used. If this is not possible, care should be taken that the system is quiescent and that it is rebooted immediately after `fsck` is run. Quite often, however, this will not be sufficient. A panic will probably occur if running `fsck` on a file system modifies the file system.

Notes This command may not be supported for all *FSTypes*.

Starting with Solaris 9, `fsck` manages extended attribute data on the disk. (See [fsattr\(5\)](#) for a description of extended file attributes.) A file system with extended attributes can be mounted on versions of Solaris that are not attribute-aware (versions prior to Solaris 9), but the attributes will not be accessible and `fsck` will strip them from the files and place them in `lost+found`. Once the attributes have been stripped, the file system is completely stable on versions of Solaris that are not attribute-aware, but would be considered corrupted on attribute-aware versions. In the latter circumstance, run the attribute-aware `fsck` to stabilize the file system before using it in an attribute-aware environment.

Name fsck_cacheofs – check integrity of data cached with CacheFS

Synopsis fsck -F cacheofs [-m] [-o noclean] *cache_directory*

Description The CacheFS version of the fsck command checks the integrity of a cache directory. This utility corrects any CacheFS problems it finds by default. There is no interactive mode. The most likely invocation of fsck for CacheFS file systems is at boot time from an entry in the /etc/vfstab file. See [vfstab\(4\)](#).

Options The following options are supported:

-m Check, but do not repair.

-o noclean Force a check on the cache even if there is no reason to suspect there is a problem.

Examples **EXAMPLE 1** Using fsck_cacheofs to Force a Check on the Cache Directory

The following example forces a check on the cache directory /cache3:

```
example% fsck -F cacheofs -o noclean /cache3
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [cfsadmin\(1M\)](#), [fsck\(1M\)](#), [mount_cacheofs\(1M\)](#), [vfstab\(4\)](#), [attributes\(5\)](#)

Name fsck_pcfs – file system consistency check and interactive repair

Synopsis fsck -F pcfs [*generic_options*] *special*
 fsck -F pcfs [*generic_options*] [-o *specific_options*] *special*

Description The fsck utility audits and interactively repairs inconsistent conditions on file systems. *special* represents the character special device on which the file system resides, for example /dev/rdiskette. The character special device, not the block special device, should be used.

In the case of correcting serious inconsistencies, by default, fsck asks for confirmation before making a repair and waits for the operator to respond either yes or no. If the operator does not have write permission on the file system, fsck defaults to a -n (no corrections) action. See [fsck\(1M\)](#).

Repairing some file system inconsistencies may result in loss of data. The amount and severity of data loss may be determined from the diagnostic output.

When executed with the verify option (-o v), fsck_pcfs automatically scans the entire file system to verify that all of its allocation units are accessible. If it finds any units inaccessible, it updates the file allocation table (FAT) appropriately. It also updates any effected directory entries to reflect the problem. This directory update includes truncating the file at the point in its allocation chain where the file data is no longer accessible. Any remaining accessible allocation units become orphaned.

Orphaned chains of accessible allocation units are, with the operator's concurrence, linked back into the file system as files in the root directory. These files are assigned names of the form fileNNNN.chk, where the *Ns* are digits in the integral range from 0 through 9.

After successfully scanning and correcting any errors in the file system, fsck displays a summary of information about the file system. This summary includes the size of the file system in bytes, the number of bytes used in directories and individual files, and the number of available allocation units remaining in the file system.

Options *generic_options* The following generic options are supported:

| | |
|---------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -m | Check but do not repair. This option checks that the file system is suitable for mounting, returning the appropriate exit status. If the file system is ready for mounting, fsck displays a message such as: |
| | pcfs fsck: sanity check:
/dev/rdiskette okay |
| -n -N | Assume a no response to all questions asked by fsck; do not open the file system for writing. |
| -V | Echo the expanded command line, but do not execute the command. This option may be used to verify and to validate the command line. |

- y | -Y Assume a yes response to all questions asked by fsck.
- o *specific_options* Specify pcfs file system specific options in a comma-separated list, in any combination, with no intervening spaces.
- v Verify all allocation units are accessible prior to correcting inconsistencies in the metadata.
 - p Check and fix the file system non-interactively (preen). Exit immediately if there is a problem requiring intervention.
 - w Check writable file systems only.

Files *special* The device which contains the pcfs. The device name for a diskette is specified as /dev/rdiskette0 for the first diskette drive, or /dev/rdiskette1 for a second diskette drive. A hard disk device or high-capacity removable device name must be qualified with a suffix to indicate the proper FDISK partition.

For example, in the names: /dev/rdisk/c0t0d0p0:c and /dev/rdisk/c0t4d0s2:c, the :c suffix indicates the first partition on the disk contains the pcfs.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------------------|
| Availability | system/extended-system-utilities |
| Interface Stability | Committed |

See Also [fsck\(1M\)](#), [fstyp\(1M\)](#), [fdisk\(1M\)](#), [mkfs\(1M\)](#), [mkfs_pcfs\(1M\)](#), [mountall\(1M\)](#), [attributes\(5\)](#), [pcfs\(7FS\)](#),

Warnings The operating system buffers file system data. Running fsck on a mounted file system can cause the operating system's buffers to become out of date with respect to the disk. For this reason, the file system should be unmounted when fsck is used. If this is not possible, care should be taken that the system is quiescent and that it is rebooted immediately after fsck is run. Quite often, however, this is not sufficient. A panic will probably occur if running fsck on a file system modifies the file system.

Name fscck_udfs – file system consistency check and interactive repair

Synopsis fscck -F udfs [*generic_options*] [*special* ...]

fscck -F udfs [*generic_options*] [-o *specific_options*]
[*special* ...]

Description fscck audits and interactively repairs inconsistent conditions on file systems. A file system to be checked can be specified by giving the name of the block or character special device or by giving the name of its mount point if a matching entry exists in `/etc/vfstab`.

special represents the character special device, for example, `/dev/rdisk/c0t2d0s0`, on which the file system resides. The character special device, not the block special device should be used. fscck does not work on a mounted block device.

If no special device is specified, all udfs file systems specified in the `vfstab` file with a `fscckdev` entry are checked. If the `-p` (preen) option is specified, udfs file systems with an `fscckpass` number greater than 1 are checked in parallel. See [fscck\(1M\)](#).

In the case of correcting serious inconsistencies, by default, fscck asks for confirmation before making a repair and waits for the operator to respond with either `yes` or `no`. If the operator does not have write permission on the file system, fscck defaults to the `-n` (no corrections) option. See [fscck\(1M\)](#).

Repairing some file system inconsistencies can result in loss of data. The amount and severity of data loss can be determined from the diagnostic output.

fscck automatically corrects innocuous inconsistencies. It displays a message for each corrected inconsistency that identifies the nature of the correction which took place on the file system. After successfully correcting a file system, fscck prints the number of files on that file system and the number of used and free blocks.

Inconsistencies checked are as follows:

- Blocks claimed by more than one file or the free list
- Blocks claimed by a file or the free list outside the range of the file system
- Incorrect link counts in file entries
- Incorrect directory sizes
- Bad file entry format
- Blocks not accounted for anywhere
- Directory checks, file pointing to unallocated file entry and absence of a parent directory entry
- Descriptor checks, more blocks for files than there are in the file system
- Bad free block list format
- Total free block count incorrect

Options The following options are supported:

- generic_options* The following *generic_options* are supported:
- m Check but do not repair. This option checks to be sure that the file system is suitable for mounting, and returns the appropriate exit status. If the file system is ready for mounting, `fsck` displays a message such as:

```
udfs fsck: sanity check: /dev/rdisk/c0t2d0s0 okay
```
 - n | -N Assume a no response to all questions asked by `fsck`; do not open the file system for writing.
 - V Echo the expanded command line, but do not execute the command. This option can be used to verify and to validate the command line.
 - y | -Y Assume a yes response to all questions asked by `fsck`.
- o specific_options* Specify `udfs` file system specific options in a comma-separated list with no intervening spaces. The following *specific_options* are available:
- f Force checking of file systems regardless of the state of their logical volume integrity state.
 - p Check and fix the file system non-interactively (`preen`). Exit immediately if there is a problem that requires intervention. This option is required to enable parallel file system checking.
 - w Check writable file systems only.

Files `/etc/vfstab` List of default parameters for each file system.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------|
| Availability | system/file-system/udfs |

See Also [fsock\(1M\)](#), [fsdb_udfs\(1M\)](#), [fstyp\(1M\)](#), [mkfs\(1M\)](#), [mkfs_udfs\(1M\)](#), [mountall\(1M\)](#), [reboot\(1M\)](#), [vfstab\(4\)](#), [attributes\(5\)](#)

Warnings The operating system buffers file system data. Running `fsck` on a mounted file system can cause the operating system's buffers to become out of date with respect to the disk. For this reason, use `fsck` only when the file system is unmounted. If this is not possible, take care that the system is quiescent and that it is rebooted immediately after running `fsck`. A panic will probably occur if running `fsck` on a file system that modifies the file system while it is mounted.

If an unmount of the file system is not done before the system is shut down, the file system might become corrupted. In this case, a file system check needs to be completed before the next mount operation.

Diagnostics not writable

You cannot write to the device.

Currently Mounted on

The device is already mounted and cannot run `fscck`.

FILE SYSTEM WAS MODIFIED

File system has been modified to bring it to a consistent state.

Can't read allocation extent

Cannot read the block containing allocation extent.

Bad tag on alloc extent

Invalid tag detected when expecting an allocation extent.

Volume sequence tag error

Invalid tag detected in the volume sequence.

Space bitmap tag error

Invalid tag detected in the space bitmap.

UNEXPECTED INCONSISTENCY; RUN `fscck` MANUALLY

Use `fscck` in interactive mode.

Name fsck_ufs – file system consistency check and interactive repair

Synopsis fsck -F ufs [*generic-options*] [*special*] . . .

fsck -F ufs [*generic-options*] [-o *specific-options*]
[*special*] . . .

Description The fsck utility audits and interactively repairs inconsistent conditions on file systems. A file system to be checked may be specified by giving the name of the block or character *special* device or by giving the name of its mount point if a matching entry exists in `/etc/vfstab`.

The *special* parameter represents the character special device, for example, `/dev/rdsk/c1t0d0s7`, on which the file system resides. The character special device, not the block special device should be used. The fsck utility will not work if the block device is mounted, unless the file system is error-locked.

If no *special* device is specified, all ufs file systems specified in the `vfstab` with a `fsckdev` entry will be checked. If the `-p` (“preen”) option is specified, ufs file systems with an `fsckpass` number greater than 1 are checked in parallel. See [fsck\(1M\)](#).

In the case of correcting serious inconsistencies, by default, fsck asks for confirmation before making a repair and waits for the operator to respond either yes or no. If the operator does not have write permission on the file system, fsck will default to a `-n` (no corrections) action. See [fsck\(1M\)](#).

Repairing some file system inconsistencies can result in loss of data. The amount and severity of data loss can be determined from the diagnostic output.

The fsck utility automatically corrects innocuous inconsistencies such as unreferenced inodes, too-large link counts in inodes, missing blocks in the free list, blocks appearing in the free list and also in files, or incorrect counts in the super block. It displays a message for each inconsistency corrected that identifies the nature of the correction on the file system which took place. After successfully correcting a file system, fsck prints the number of files on that file system, the number of used and free blocks, and the percentage of fragmentation.

Inconsistencies checked include:

- Blocks claimed by more than one inode or the free list.
- Blocks claimed by an inode or the free list outside the range of the file system.
- Incorrect link counts.
- Incorrect directory sizes.
- Bad inode format.
- Blocks not accounted for anywhere.
- Directory checks, file pointing to unallocated inode, inode number out of range, and absence of `‘.`’ and `‘..`’ as the first two entries in each directory.
- Super Block checks: more blocks for inodes than there are in the file system.

- Bad free block list format.
- Total free block and/or free inode count incorrect.

Orphaned files and directories (allocated but unreferenced) are, with the operator's concurrence, reconnected by placing them in the `lost+found` directory. The name assigned is the inode number. If the `lost+found` directory does not exist, it is created. If there is insufficient space in the `lost+found` directory, its size is increased.

An attempt to mount a `ufs` file system with the `-o nolargefiles` option will fail if the file system has ever contained a large file (a file whose size is greater than or equal to 2 Gbyte). Invoking `fsck` resets the file system state if no large files are present in the file system. A successful mount of the file system after invoking `fsck` indicates the absence of large files in the file system. An unsuccessful mount attempt indicates the presence of at least one large file. See [mount_ufs\(1M\)](#).

Options The *generic-options* consist of the following options:

- m Check but do not repair. This option checks that the file system is suitable for mounting, returning the appropriate exit status. If the file system is ready for mounting, `fsck` displays a message such as:

```
ufs fsck: sanity check: /dev/rdisk/c0t3d0s1 okay
```
- n | N Assume a no response to all questions asked by `fsck`; do not open the file system for writing.
- V Echo the expanded command line, but do not execute the command. This option may be used to verify and to validate the command line.
- v Enables verbose output. Might not be supported by all filesystem-specific `fsck` implementations.
- y | Y Assume a yes response to all questions asked by `fsck`.

See generic [fsck\(1M\)](#) for the details for specifying *special*.

- o *specific-options* Specify `ufs` file system specific options. These options can be any combination of the following separated by commas (with no intervening spaces).
 - b=*n* Use block *n* as the super block for the file system. Block 32 is always one of the alternate super blocks. Determine the location of other super blocks by running [newfs\(1M\)](#) with the `-Nv` options specified.
 - f Force checking of file systems regardless of the state of their super block clean flag.

- p Check and fix the file system non-interactively (“preen”). Exit immediately if there is a problem requiring intervention. This option is required to enable parallel file system checking.
- w Check writable file systems only.

Files /etc/vfstab list of default parameters for each file system

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [clri\(1M\)](#), [fsck\(1M\)](#), [fsdb_ufs\(1M\)](#), [fsirand\(1M\)](#), [fstyp\(1M\)](#), [mkfs\(1M\)](#), [mkfs_ufs\(1M\)](#), [mount_ufs\(1M\)](#), [mountall\(1M\)](#), [newfs\(1M\)](#), [reboot\(1M\)](#), [vfstab\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#), [ufs\(7FS\)](#)

Warnings The operating system buffers file system data. Running `fsck` on a mounted file system can cause the operating system's buffers to become out of date with respect to the disk. For this reason, the file system should be *unmounted* when `fsck` is used. If this is not possible, care should be taken that the system is quiescent and that it is rebooted immediately after `fsck` is run. Quite often, however, this will not be sufficient. A panic will probably occur if running `fsck` on a file system modifies the file system.

Notes It is usually faster to check the character special device than the block special device.

Running `fsck` on file systems larger than 2 Gb fails if the user chooses to use the block interface to the device:

```
fsck /dev/dsk/c?t?d?s?
```

rather than the raw (character special) device:

```
fsck /dev/rdisk/c?t?d?s?
```

Name fsdb – file system debugger

Synopsis fsdb [-F *FSType*] [-V] [-o *FSType-specific_options*] *special*

Description fsdb is a file system debugger that allows for the manual repair of a file system after a crash. *special* is a special device used to indicate the file system to be debugged. fsdb is intended for experienced users only. *FSType* is the file system type to be debugged. Since different *FSTypes* have different structures and hence different debugging capabilities, the manual pages for the *FSType*-specific fsdb should be consulted for a more detailed description of the debugging capabilities.

Options

- F Specify the *FSType* on which to operate. The *FSType* should either be specified here or be determinable from `/etc/vfstab` by matching the *special* with an entry in the table, or by consulting `/etc/default/fs`.
- V Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from `/etc/vfstab`. This option may be used to verify and validate the command line.
- o Specify *FSType*-specific options.

Usage See [largefile\(5\)](#) for the description of the behavior of fsdb when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files `/etc/default/fs` default local file system type. Default values can be set for the following flags in `/etc/default/fs`. For example: LOCAL=ufs

LOCAL: The default partition for a command if no *FSType* is specified.

`/etc/vfstab` list of default parameters for each file system

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [vfstab\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#) Manual pages for the *FSType*-specific modules of fsdb.

Notes This command may not be supported for all *FSTypes*.

Name fsdb_udfs – udfs file system debugger

Synopsis fsdb [-F] udfs [*generic_option*] [-o *specific_option*] *special*

Description The `fsdb_udfs` command is an interactive tool that can be used to patch up a damaged udfs file system. `fsdb_udfs` has conversions to translate block and i-numbers into their corresponding disk addresses. Mnemonic offsets to access different parts of an inode are also included. Mnemonic offsets greatly simplify the process of correcting control block entries or descending the file system tree.

`fsdb` contains several error-checking routines to verify inode and block addresses. These can be disabled if necessary by invoking `fsdb` with the `-o` option or by using the `o` command.

`fsdb` reads one block at a time, and therefore works with raw as well as block I/O devices. A buffer management routine is used to retain commonly used blocks of data in order to reduce the number of read system calls. All assignment operations result in an immediate write-through of the corresponding block. In order to modify any portion of the disk, `fsdb` must be invoked with the `-w` option.

Wherever possible, adb-like syntax has been adopted to promote the use of `fsdb` through familiarity.

Options The following options are supported:

| | |
|----------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-o <i>specific_option</i></code> | Specify udfs file system specific options in a comma-separated list with no intervening spaces. The following specific options are supported: |
| <code>o</code> | Override some error conditions. |
| <code>p=<i>string</i></code> | Set prompt to <i>string</i> . |
| <code>w</code> | Open for write. |
| <code>?</code> | Display usage. |

Usage Numbers are considered hexadecimal by default. The user has control over how data is to be displayed or accepted. The base command displays or sets the input and output base. Once set, all input defaults to this base and all output displays in this base. The base can be overridden temporarily for input by preceding hexadecimal numbers by `0x`, preceding decimal numbers with a `0t`, or octal numbers with a `0`. Hexadecimal numbers beginning with `a-f` or `A-F` must be preceded with a `0x` to distinguish them from commands.

Disk addressing by `fsdb` is at the byte level. However, `fsdb` offers many commands to convert a desired inode, directory entry, block, and so forth, to a byte address. After the address has been calculated, `fsdb` records the result in the current address (`dot`).

Several global values are maintained by `fsdb`:

- Current base (referred to as `base`)
- Current address (referred to as `dot`)

- Current inode (referred to as `inode`)
- Current count (referred to as `count`)
- Current type (referred to as `type`)

Most commands use the preset value of `dot` in their execution. For example,

```
> 2:inode
```

first sets the value of `dot` (`.`) to 2, colon (`:`), signifies the start of a command, and the `inode` command sets `inode` to 2. A count is specified after a comma (`,`). Once set, count remains at this value until a new command is encountered that resets the value back to 1 (the default).

So, if

```
> 2000,400/X
```

is entered, 400 hex longs are listed from 2000, and when completed, the value of `dot` is $2000 + 400 * \text{sizeof}(\text{long})$. If a RETURN is then entered, the output routine uses the current values of `dot`, `count`, and `type` and displays 400 more hex longs. An asterisk (`*`) causes the entire block to be displayed. An example showing several commands and the use of RETURN would be:

```
> 2:ino; 0:dir?d
```

or

```
> 2:ino; 0:db:block?d
```

The two examples are synonymous for getting to the first directory entry of the root of the file system. Once there, subsequently entering a RETURN, plus (`+`), or minus (`-`) advances to subsequent entries. Notice that

```
> 2:inode; :ls
```

or

```
> :ls /
```

is again synonymous.

Expressions The following symbols are recognized by `fsdb`:

RETURN Update the value of `dot` by the current value of `type` and `display` using the current value of `count`.

Update the value of `dot` by specifying a numeric expression. Specify numeric expressions using addition, subtraction, multiplication, and division operators (`+`, `-`, `*`, and `%`). Numeric expressions are evaluated from left to right and can use parentheses. After evaluation, the value of `dot` is updated.

| | |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>,count</i> | Update the count indicator. The global value of <i>count</i> is updated to <i>count</i> . The value of <i>count</i> remains until a new command is run. A <i>count</i> specifier of * attempts to show a block's worth of information. The default for <i>count</i> is 1. |
| <i>?f</i> | Display in structured style with format specifier <i>f</i> . See Formatted Output. |
| <i>/f</i> | Display in unstructured style with format specifier <i>f</i> . See Formatted Output. |
| <i>.</i> | Display the value of dot. |
| <i>+e</i> | Increment the value of dot by the expression <i>e</i> . The amount actually incremented is dependent on the size of type: $\text{dot} = \text{dot} + e * \text{sizeof}(\text{type})$ The default for <i>e</i> is 1. |
| <i>-e</i> | Decrement the value of dot by the expression <i>e</i> . See +. |
| <i>*e</i> | Multiply the value of dot by the expression <i>e</i> . Multiplication and division don't use <i>type</i> . In the above calculation of dot, consider the <i>sizeof (type)</i> to be 1. |
| <i>%e</i> | Divide the value of dot by the expression <i>e</i> . See *. |
| <i>< name</i> | Restore an address saved in register <i>name</i> . <i>name</i> must be a single letter or digit. |
| <i>> name</i> | Save an address in register <i>name</i> . <i>name</i> must be a single letter or digit. |
| <i>=f</i> | Display indicator. If <i>f</i> is a legitimate format specifier (see Formatted Output), then the value of dot is displayed using format specifier <i>f</i> . Otherwise, assignment is assumed. See = [s] [e]. |
| <i>= [s] [e]</i> | Change the value of dot using an assignment indicator. The address pointed to by dot has its contents changed to the value of the expression <i>e</i> or to the ASCII representation of the quoted (") string <i>s</i> . This can be useful for changing directory names or ASCII file information. |
| <i>+= e</i> | Change the value of dot using an incremental assignment. The address pointed to by dot has its contents incremented by expression <i>e</i> . |
| <i>-= e</i> | Change the value of dot using a decremental assignment. Decrement the contents of the address pointed to by dot by expression <i>e</i> . |
| Commands | A command must be prefixed by a colon (:). Only enough letters of the command to uniquely distinguish it are needed. Multiple commands can be entered on one line by separating them by a SPACE, TAB, or semicolon (;). |

To view a potentially unmounted disk in a reasonable manner, fsdb supports the `cd`, `pwd`, `ls`, and `find` commands. The functionality of each of these commands basically matches that of its UNIX counterpart. See `cd(1)`, `pwd(1)`, `ls(1)`, and `find(1)` for details. The *, ,, ?, and - wildcard characters are also supported.

The following commands are supported:

| | |
|-------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| base[= <i>b</i>] | Display or set the base. All input and output is governed by the current base. Without the = <i>b</i> , displays the current base. Otherwise, sets the current base to <i>b</i> . Base is interpreted using the old value of base, so to ensure correctness use the 0, 0t, or 0x prefix when changing the base. The default for base is hexadecimal. |
| block | Convert the value of dot to a block address. |
| cd [<i>dir</i>] | Change the current directory to directory <i>dir</i> . The current values of inode and dot are also updated. If <i>dir</i> is not specified, changes directories to inode 2, root (/). |
| directory | If the current inode is a directory, converts the value of dot to a directory slot offset in that directory, and dot now points to this entry. |
| file | Set the value of dot as a relative block count from the beginning of the file. The value of dot is updated to the first byte of this block. |
| find <i>dir</i> [-name <i>n</i>] [-inum <i>i</i>] | Find files by name or i-number. Recursively searches directory <i>dir</i> and below for file names whose i-number matches <i>i</i> or whose name matches pattern <i>n</i> . Only one of the two options (-name or -inum) can be used at one time. The find -print is not necessary or accepted. |
| fill= <i>p</i> | Fill an area of disk with pattern <i>p</i> . The area of disk is delimited by dot and count. |
| inode | Convert the value of dot to an inode address. If successful, the current value of inode is updated as well as the value of dot. As a convenient shorthand, if :inode appears at the beginning of the line, the value of dot is set to the current inode and that inode is displayed in inode format. |
| ls [-R] [-l] <i>pat1 pat2...</i> | List directories or files. If no file is specified, the current directory is assumed. Either or both of the options can be used (but, if used, must be specified before the filename specifiers). Wild card characters are available and multiple arguments are acceptable. The long listing shows only the i-number and the name; use the inode command with ?i to get more information. |
| override | Toggle the value of override. Some error conditions might be overridden if override is toggled to on. |
| prompt " <i>p</i> " | Change the fsdb prompt to <i>p</i> . <i>p</i> must be enclosed in quotes. |

| | |
|------|-------------------------------------------------------------------------------------------------------|
| pwd | Display the current working directory. |
| quit | Quit fsdb. |
| tag | Convert the value of dot and if this is a valid tag, print the volume structure according to the tag. |
| ! | Escape to the shell. |

Inode Commands In addition to the above commands, several other commands deal with inode fields and operate directly on the current inode (they still require the colon (:)). They can be used to more easily display or change the particular fields. The value of dot is only used by the :db and :ib commands. Upon completion of the command, the value of dot is changed so that it points to that particular field. For example,

```
> :ln+=1
```

increments the link count of the current inode and sets the value of dot to the address of the link count field.

The following inode commands are supported:

| | |
|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| at | Access time |
| bs | Block size |
| ct | Creation time |
| gid | Group id |
| ln | Link number |
| mt | Modification time |
| md | Mode |
| maj | Major device number |
| min | Minor device number |
| nm | This command actually operates on the directory name field. Once poised at the desired directory entry (using the directory command), this command allows you to change or display the directory name. For example,
<pre>> 7:dir:nm="foo"</pre> gets the 7th directory entry of the current inode and changes its name to foo. Directory names cannot be made larger than the field allows. If an attempt is made to make a directory name larger than the field allows,, the string is truncated to fit and a warning message is displayed. |
| sz | File size |

uid User ID
 uniq Unique ID

Formatted Output Formatted output comes in two styles and many format types. The two styles of formatted output are: structured and unstructured. Structured output is used to display inodes, directories, and so forth. Unstructured output displays raw data.

Format specifiers are preceded by the slash (/) or question mark (?) character. *type* is updated as necessary upon completion.

The following format specifiers are preceded by the ? character:

i Display as inodes in the current base.
 d Display as directories in the current base.

The following format specifiers are preceded by the / character:

b Display as bytes in the current base.
 c Display as characters.
 o | O Display as octal shorts or longs.
 d | D Display as decimal shorts or longs.
 x | X Display as hexadecimal shorts or longs.

Examples **EXAMPLE 1** Using fsdb as a calculator for complex arithmetic

The following command displays 2010 in decimal format, and is an example of using fsdb as a calculator for complex arithmetic.

```
> 2000+400%(20+20)=D
```

EXAMPLE 2 Using fsdb to display an i-number in inode format

The following command displays the i-number 386 in inode format. 386 becomes the current inode.

```
> 386:ino?i
```

EXAMPLE 3 Using fsdb to change the link count

The following command changes the link count for the current inode to 4.

```
> :ln=4
```

EXAMPLE 4 Using fsdb to increment the link count

The following command increments the link count by 1.

```
> :ln=+1
```

EXAMPLE 5 Using fsdb to display the creation time as a hexadecimal long

The following command displays the creation time as a hexadecimal long.

```
> :ct=X
```

EXAMPLE 6 Using fsdb to display the modification time in time format

The following command displays the modification time in time format.

```
> :mt=t
```

EXAMPLE 7 Using fsdb to display in ASCII

The following command displays, in ASCII, block 0 of the file associated with the current inode.

```
> 0:file/c
```

EXAMPLE 8 Using fsdb to display the directory entries for the root inode

The following command displays the first block's directory entries for the root inode of this file system. This command stops prematurely if the EOF is reached.

```
> 2:ino,*?d
```

EXAMPLE 9 Using fsdb to change the current inode

The following command changes the current inode to that associated with the 5th directory entry (numbered from 0) of the current inode. The first logical block of the file is then displayed in ASCII.

```
> 5:dir:inode; 0:file,*/c
```

EXAMPLE 10 Using fsdb to change the i-number

The following command changes the i-number for the 7th directory slot in the root directory to 3.

```
> 2:inode; 7:dir=3
```

EXAMPLE 11 Using fsdb to change the name field

The following command changes the *name* field in the directory slot to name.

```
> 7:dir:nm="name"
```

EXAMPLE 12 Using fsdb to display the a block

The following command displays the 3rd block of the current inode as directory entries.

EXAMPLE 13 Using fsdb to set the contents of address

The following command sets the contents of address 2050 to 0xffffffff. 0xffffffff can be truncated, depending on the current type.

```
> 2050=0xffff
```

EXAMPLE 14 Using fsdb to place an ASCII string at an address

The following command places the ASCII string this is some text at address 1c92434.

```
> 1c92434="this is some text"
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------|
| Availability | system/file-system/udfs |

See Also [clri\(1M\)](#), [fsck_udfs\(1M\)](#), [dir\(4\)](#), [attributes\(5\)](#)

Name fsdb_ufs – ufs file system debugger

Synopsis fsdb -F ufs [*generic_options*] [*specific_options*] *special*

Description The fsdb_ufs command is an interactive tool that can be used to patch up a damaged UFS file system. It has conversions to translate block and i-numbers into their corresponding disk addresses. Also included are mnemonic offsets to access different parts of an inode. These greatly simplify the process of correcting control block entries or descending the file system tree.

fsdb contains several error-checking routines to verify inode and block addresses. These can be disabled if necessary by invoking fsdb with the -o option or by the use of the o command.

fsdb reads a block at a time and will therefore work with raw as well as block I/O devices. A buffer management routine is used to retain commonly used blocks of data in order to reduce the number of read system calls. All assignment operations result in an immediate write-through of the corresponding block. Note that in order to modify any portion of the disk, fsdb must be invoked with the w option.

Wherever possible, adb-like syntax was adopted to promote the use of fsdb through familiarity.

Options The following option is supported:

- o Specify UFS file system specific options. These options can be any combination of the following separated by commas (with no intervening spaces). The options available are:
 - ? Display usage
 - o Override some error conditions
 - p='string' set prompt to string
 - w open for write

Usage Numbers are considered hexadecimal by default. However, the user has control over how data is to be displayed or accepted. The base command will display or set the input/output base. Once set, all input will default to this base and all output will be shown in this base. The base can be overridden temporarily for input by preceding hexadecimal numbers with '0x', preceding decimal numbers with '0t', or octal numbers with '0'. Hexadecimal numbers beginning with a-f or A-F must be preceded with '0x' to distinguish them from commands.

Disk addressing by fsdb is at the byte level. However, fsdb offers many commands to convert a desired inode, directory entry, block, superblock and so forth to a byte address. Once the address has been calculated, fsdb will record the result in dot (.).

Several global values are maintained by fsdb:

- the current base (referred to as base),

- the current address (referred to as dot),
- the current inode (referred to as inode),
- the current count (referred to as count),
- and the current type (referred to as type).

Most commands use the preset value of dot in their execution. For example,

```
> 2:inode
```

will first set the value of dot to 2, ':', will alert the start of a command, and the inode command will set inode to 2. A count is specified after a ':'. Once set, count will remain at this value until a new command is encountered which will then reset the value back to 1 (the default). So, if

```
> 2000,400/X
```

is typed, 400 hex longs are listed from 2000, and when completed, the value of dot will be $2000 + 400 * \text{sizeof}(\text{long})$. If a RETURN is then typed, the output routine will use the current values of dot, count, and type and display 400 more hex longs. A '*' will cause the entire block to be displayed.

End of fragment, block and file are maintained by fsdb. When displaying data as fragments or blocks, an error message will be displayed when the end of fragment or block is reached. When displaying data using the db, ib, directory, or file commands an error message is displayed if the end of file is reached. This is mainly needed to avoid passing the end of a directory or file and getting unknown and unwanted results.

An example showing several commands and the use of RETURN would be:

```
> 2:ino; 0:dir?d
    or
> 2:ino; 0:db:block?d
```

The two examples are synonymous for getting to the first directory entry of the root of the file system. Once there, any subsequent RETURN (or +, -) will advance to subsequent entries.

Note that

```
> 2:inode; :ls
    or
> :ls /
```

is again synonymous.

Expressions The symbols recognized by fsdb are:

RETURN update the value of dot by the current value of type and display using the current value of count.

| | |
|-----------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| # | numeric expressions may be composed of +, -, *, and % operators (evaluated left to right) and may use parentheses. Once evaluated, the value of dot is updated. |
| , <i>count</i> | count indicator. The global value of count will be updated to count. The value of count will remain until a new command is run. A count specifier of '*' will attempt to show a <i>blocks's</i> worth of information. The default for count is 1. |
| ? <i>f</i> | display in structured style with format specifier <i>f</i> . See FormattedOutput. |
| / <i>f</i> | display in unstructured style with format specifier <i>f</i> . See FormattedOutput. |
| . | the value of dot. |
| + <i>e</i> | increment the value of dot by the expression <i>e</i> . The amount actually incremented is dependent on the size of type:

$\text{dot} = \text{dot} + e * \text{sizeof}(\text{type})$ <p>The default for <i>e</i> is 1.</p> |
| - <i>e</i> | decrement the value of dot by the expression <i>e</i> . See +. |
| * <i>e</i> | multiply the value of dot by the expression <i>e</i> . Multiplication and division don't use type. In the above calculation of dot, consider the sizeof (type) to be 1. |
| % <i>e</i> | divide the value of dot by the expression <i>e</i> . See *. |
| < <i>name</i> | restore an address saved in register <i>name</i> . <i>name</i> must be a single letter or digit. |
| > <i>name</i> | save an address in register <i>name</i> . <i>name</i> must be a single letter or digit. |
| = <i>f</i> | display indicator. If <i>f</i> is a legitimate format specifier, then the value of dot is displayed using the format specifier <i>f</i> . See FormattedOutput. Otherwise, assignment is assumed. See =. |
| = [<i>s</i>] [<i>e</i>] | assignment indicator. The address pointed to by dot has its contents changed to the value of the expression <i>e</i> or to the ASCII representation of the quoted (") string <i>s</i> . This may be useful for changing directory names or ASCII file information. |
| += <i>e</i> | incremental assignment. The address pointed to by dot has its contents incremented by expression <i>e</i> . |
| -= <i>e</i> | decremental assignment. The address pointed to by dot has its contents decremented by expression <i>e</i> . |

Commands A command must be prefixed by a ':' character. Only enough letters of the command to uniquely distinguish it are needed. Multiple commands may be entered on one line by separating them by a SPACE, TAB or ';'.

In order to view a potentially unmounted disk in a reasonable manner, `fsdb` offers the `cd`, `pwd`, `ls` and `find` commands. The functionality of these commands substantially matches those of its UNIX counterparts. See individual commands for details. The '*', '?', and '[' wild card characters are available.

| | |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>base=b</code> | display or set base. As stated above, all input and output is governed by the current base. If the <code>=b</code> is omitted, the current base is displayed. Otherwise, the current base is set to <i>b</i> . Note that this is interpreted using the old value of base, so to ensure correctness use the '0', '0t', or '0x' prefix when changing the base. The default for base is hexadecimal. |
| <code>block</code> | convert the value of <code>dot</code> to a block address. |
| <code>cd dir</code> | change the current directory to directory <i>dir</i> . The current values of <code>inode</code> and <code>dot</code> are also updated. If no <i>dir</i> is specified, then change directories to inode 2 ("/"). |
| <code>cg</code> | convert the value of <code>dot</code> to a cylinder group. |
| <code>directory</code> | If the current <code>inode</code> is a directory, then the value of <code>dot</code> is converted to a directory slot offset in that directory and <code>dot</code> now points to this entry. |
| <code>file</code> | the value of <code>dot</code> is taken as a relative block count from the beginning of the file. The value of <code>dot</code> is updated to the first byte of this block. |
| <code>find dir [-name n] [-inum i]</code> | find files by name or <i>i</i> -number. <code>find</code> recursively searches directory <i>dir</i> and below for filenames whose <i>i</i> -number matches <i>i</i> or whose name matches pattern <i>n</i> . Note that only one of the two options (<code>-name</code> or <code>-inum</code>) may be used at one time. Also, the <code>-print</code> is not needed or accepted. |
| <code>fill=p</code> | fill an area of disk with pattern <i>p</i> . The area of disk is delimited by <code>dot</code> and <code>count</code> . |
| <code>fragment</code> | convert the value of <i>dot</i> to a fragment address. The only difference between the <code>fragment</code> command and the <code>block</code> command is the amount that is able to be displayed. |
| <code>inode</code> | convert the value of <i>dot</i> to an inode address. If successful, the current value of <code>inode</code> will be updated as well as the value of <i>dot</i> . As a convenient shorthand, if <code>:inode</code> appears at the beginning of the line, the value of <i>dot</i> is set to the current <code>inode</code> and that <code>inode</code> is displayed in inode format. |
| <code>log_chk</code> | run through the valid log entries without printing any information and verify the layout. |

| | |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>log_delta</code> | count the number of deltas into the log, using the value of <code>dot</code> as an offset into the log. No checking is done to make sure that offset is within the head/tail offsets. |
| <code>log_head</code> | display the header information about the file system logging. This shows the block allocation for the log and the data structures on the disk. |
| <code>log_otodb</code> | return the physical disk block number, using the value of <code>dot</code> as an offset into the log. |
| <code>log_show</code> | display all deltas between the beginning of the log (BOL) and the end of the log (EOL). |
| <code>ls</code> | [-R] [-l] <i>pat1 pat2</i> . . . list directories or files. If no file is specified, the current directory is assumed. Either or both of the options may be used (but, if used, <i>must</i> be specified before the filename specifiers). Also, as stated above, wild card characters are available and multiple arguments may be given. The long listing shows only the i-number and the name; use the <code>inode</code> command with <code>'i'</code> to get more information. |
| <code>override</code> | toggle the value of <code>override</code> . Some error conditions may be overridden if <code>override</code> is toggled on. |
| <code>prompt p</code> | change the <code>fsdb</code> prompt to <i>p</i> . <i>p</i> must be surrounded by ("")s. |
| <code>pwd</code> | display the current working directory. |
| <code>quit</code> | quit <code>fsdb</code> . |
| <code>sb</code> | the value of <code>dot</code> is taken as a cylinder group number and then converted to the address of the superblock in that cylinder group. As a shorthand, <code>:sb</code> at the beginning of a line will set the value of <code>dot</code> to <i>the</i> superblock and display it in superblock format. |
| <code>shadow</code> | if the current inode is a shadow inode, then the value of <code>dot</code> is set to the beginning of the shadow inode data. |
| <code>!</code> | escape to shell |

Inode Commands In addition to the above commands, there are several commands that deal with inode fields and operate directly on the current `inode` (they still require the `'`). They may be used to more easily display or change the particular fields. The value of `dot` is only used by the `':db'` and `':ib'` commands. Upon completion of the command, the value of `dot` is changed to point to that particular field. For example,

```
> :ln=+1
```

would increment the link count of the current `inode` and set the value of `dot` to the address of the link count field.

`at` access time.

`bs` block size.

`ct` creation time.

`db` use the current value of `dot` as a direct block index, where direct blocks number from 0 - 11. In order to display the block itself, you need to 'pipe' this result into the `block` or `fragment` command. For example,

```
> 1:db:block,20/X
```

would get the contents of data block field 1 from the `inode` and convert it to a block address. 20 longs are then displayed in hexadecimal. See `FormattedOutput`.

`gid` group id.

`ib` use the current value of `dot` as an indirect block index where indirect blocks number from 0 - 2. This will only get the indirect block itself (the block containing the pointers to the actual blocks). Use the `file` command and start at block 12 to get to the actual blocks.

`ln` link count.

`mt` modification time.

`md` mode.

`maj` major device number.

`min` minor device number.

`nm` although listed here, this command actually operates on the directory name field. Once poised at the desired directory entry (using the `directory` command), this command will allow you to change or display the directory name. For example,

```
> 7:dir:nm="foo"
```

will get the 7th directory entry of the current `inode` and change its name to `foo`. Note that names cannot be made larger than the field is set up for. If an attempt is made, the string is truncated to fit and a warning message to this effect is displayed.

`si` shadow inode.

`sz` file size.

`uid` user id.

Formatted Output There are two styles and many format types. The two styles are structured and unstructured. Structured output is used to display inodes, directories, superblocks and the like. Unstructured displays raw data. The following shows the different ways of displaying:

```
?
    c    display as cylinder groups
    i    display as inodes
    d    display as directories
    s    display as superblocks
    S    display as shadow inode data

/
    b    display as bytes
    c    display as characters
    o O  display as octal shorts or longs
    d D  display as decimal shorts or longs
    x X  display as hexadecimal shorts or longs
```

The format specifier immediately follows the '/' or '?' character. The values displayed by '/b' and all '?' formats are displayed in the current base. Also, type is appropriately updated upon completion.

Examples EXAMPLE 1 Displaying in Decimal

The following command displays 2010 in decimal (use of fsdb as a calculator for complex arithmetic):

```
> 2000+400%(20+20)=D
```

EXAMPLE 2 Displaying an i-number in Inode Format

The following command displays i-number 386 in an inode format. This now becomes the current inode:

```
> 386:ino?i
```

EXAMPLE 3 Changing the Link Count

The following command changes the link count for the current inode to 4:

```
> :ln=4
```

EXAMPLE 4 Incrementing the Link Count

The following command increments the link count by 1:

```
> :ln+=1
```

EXAMPLE 5 Displaying the Creation Time

The following command displays the creation time as a hexadecimal long:

```
> :ct=X
```

EXAMPLE 6 Displaying the Modification Time

The following command displays the modification time in time format:

```
> :mt=t
```

EXAMPLE 7 Displaying in ASCII

The following command displays in ASCII, block zero of the file associated with the current inode:

```
> 0:file/c
```

EXAMPLE 8 Displaying the First Block's Worth of Directory Entries

The following command displays the first block's worth of directory entries for the root inode of this file system. It will stop prematurely if the EOF is reached:

```
> 2:ino,*?d
```

EXAMPLE 9 Displaying Changes to the Current Inode

The following command displays changes to the current inode to that associated with the 5th directory entry (numbered from zero) of the current inode. The first logical block of the file is then displayed in ASCII:

```
> 5:dir:inode; 0:file,*/c
```

EXAMPLE 10 Displaying the Superblock

The following command displays the superblock of this file system:

```
> :sb
```

EXAMPLE 11 Displaying the Cylinder Group

The following command displays cylinder group information and summary for cylinder group 1:

```
> 1:cg?c
```

EXAMPLE 12 Changing the i-number

The following command changes the i-number for the seventh directory slot in the root directory to 3:

```
> 2:inode; 7:dir=3
```

EXAMPLE 13 Displaying as Directory Entries

The following command displays the third block of the current inode as directory entries:

```
> 2:db:block,*?d
```

EXAMPLE 14 Changing the Name Field

The following command changes the name field in the directory slot to *name*:

```
> 7:dir:nm="name"
```

EXAMPLE 15 Getting and Filling Elements

The following command gets fragment 3c3 and fill 20 type elements with 0x20:

```
> 3c3:fragment,20:fill=0x20
```

EXAMPLE 16 Setting the Contents of an Address

The following command sets the contents of address 2050 to 0xffffffff. 0xffffffff may be truncated depending on the current type:

```
> 2050=0xfffff
```

EXAMPLE 17 Placing ASCII

The following command places the ASCII for the string at 1c92434:

```
> 1c92434="this is some text"
```

EXAMPLE 18 Displaying Shadow Inode Data

The following command displays all of the shadow inode data in the shadow inode associated with the root inode of this file system:

```
> 2:ino:si:ino;0:shadow,*?S
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [clri\(1M\)](#), [fsck_ufs\(1M\)](#), [dir_ufs\(4\)](#), [attributes\(5\)](#), [ufs\(7FS\)](#)

Warnings Since fsdb reads the disk raw, extreme caution is advised in determining its availability of fsdb on the system. Suggested permissions are 600 and owned by bin.

Notes The old command line syntax for clearing i-nodes using the ufs-specific ' - z i - number ' option is still supported by the new debugger, though it is obsolete and will be removed in a future release. Use of this flag will result in correct operation, but an error message will be printed warning of the impending obsolescence of this option to the command. The equivalent functionality is available using the more flexible [clri\(1M\)](#) command.

Name fsirand – install random inode generation numbers

Synopsis fsirand [-p] *special*

Description `fsirand` installs random inode generation numbers on all the inodes on device *special*, and also installs a file system ID in the superblock. This helps increase the security of file systems exported by NFS.

`fsirand` must be used only on an unmounted file system that has been checked with [fsck\(1M\)](#). The only exception is that it can be used on the root file system in single-user mode, if the system is immediately re-booted afterwards.

Options -p Print out the generation numbers for all the inodes, but do not change the generation numbers.

Usage See [largefile\(5\)](#) for the description of the behavior of `fsirand` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [fsck\(1M\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

Name fssnap – create temporary snapshots of a file system

Synopsis fssnap [-F *FSType*] [-V] -o *special_options* /mount/point
 fssnap -d [-F *FSType*] [-V] /mount/point | *dev*
 fssnap -i [-F *FSType*] [-V] [-o *special_options*]
 [/mount/point | *dev*]

Description The `fssnap` command creates a stable, read-only snapshot of a file system when given either an active mount point or a special device containing a mounted file system, as in the first form of the synopsis. A snapshot is a temporary image of a file system intended for backup operations.

While the snapshot file system is stable and consistent, an application updating files when the snapshot is created might leave these files in an internally inconsistent, truncated, or otherwise unusable state. In such a case, the snapshot will contain these partially written or corrupted files. It is a good idea to ensure active applications are suspended or checkpointed and their associated files are also consistent during snapshot creation.

File access times are not updated while the snapshot is being created.

A path to the virtual device that contains this snapshot is printed to standard output when a snapshot is created.

Options The following options are supported:

- d Deletes the snapshot associated with the given file system.
- F *FSType* Specifies the file system type to be used. The *FSType* should either be specified here or be determined by matching the block special device with an entry in the `/etc/vfstab` table, or by consulting `/etc/default/fs`.
- i Displays the state of any given *FSType* snapshot. If a mount-point or device is not given, a list of all snapshots on the system is displayed. When a mount-point or device is specified, detailed information is provided for the specified file system snapshot by default. The format and meaning of this information is file-system dependent. See the *FSType*-specific `fssnap` man page for details.
- o *special_options* See the *FSType*-specific man page for `fssnap`.
- V Echoes the complete command line, but does not execute the command.

Operands The following operands are supported:

/mount/point The directory where the file system resides.

Examples See FSType-specific man pages for examples.

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Files /etc/vfstab Specifies file system type.

/etc/default/fs Specifies the default local file system type.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [fssnap_ufs\(1M\)](#), [attributes\(5\)](#)

Notes This command might not be supported for all FSTypes.

Name fssnap_ufs – create a temporary snapshot of a UFS file system

Synopsis fssnap [-F ufs] [-V] -o *backing-store=path*,
 [*specific-options*] /mount/point

fssnap -d [-F ufs] [-V] /mount/point | dev

fssnap -i [-F ufs] [-V] [-o *specific-options*] /mount/point | dev

Description The fssnap command queries, creates, or deletes a temporary snapshot of a UFS file system. A snapshot is a point-in-time image of a file system that provides a stable and unchanging device interface for backups.

When creating a file system snapshot, you must specify the file system to be captured and the backing-store file. The backing-store file(s) are where the snapshot subsystem saves old file system data before it is overwritten. Beyond the first backing-store file, fssnap automatically creates additional backing-store files on an as-needed basis.

The number and size of the backing store files varies with the amount of activity in the file system. The destination path must have enough free space to hold the backing-store file(s). This location must be different from the file system that is being captured in a snapshot. The backing-store file(s) can reside on any type of file system, including another UFS file system or an NFS-mounted file system.

Options The following options are supported:

-d

Deletes the snapshot associated with the given file system.

-i

Displays the state of one or all UFS snapshots. If a mount-point or device is not specified, a list of all snapshots on the system is displayed. When a mount-point or device is specified, detailed information is provided for the specified file system snapshot by default.

Use the -o options with the -i option to specify what snapshot information is displayed. Since this feature is provided primarily for use in scripts and on the command line, no labels are displayed for the data. Sizes are all in bytes, and the output is not internationalized or localized. The information is displayed on one line per option. Unrecognized options display a single ? on the line. One line per option guarantees that there are the same number of lines as options specified and there is a one-to-one correspondence between an output line and an option.

The following -o options display specific information for a given snapshot. See the EXAMPLES section for examples of how to use these options.

snapnumber

Display the snapshot number.

blockdevname

Display the block device path.

rawdevname

Display the raw device path.

mountpoint

Display the mount point of the master file system.

state

Display the state of the snapshot device.

backing-store

Display the location of the first backing-store file for this snapshot. If there are multiple backing-store files, subsequent files have the same name as the first file, with the suffixes .2, .3, and so forth.

backing-store-len

Display the sum of the sizes of the backing-store files.

maxsize

Display the maxsize value specified for the backing-store file(s).

createtime

Display the time that the snapshot was created.

chunksiz

Display the copy-on-write granularity.

-o *specific-options*

Without -d or -i, the default action is to create a snapshot. Specify the following options when creating a snapshot. All of these options are discretionary, except for the backing-store file, which is required.

backing-store=*path*

Uses *path* in the creation of the backing-store file(s). *path* must not reside on the file system that is being captured in a snapshot and must not be the name of an existing file. If *path* is a directory, then a backing-store file is created within it using a name that is generated automatically. If *path* is not a directory and does not already exist, then a backing-store file with that name is created. If more than one backing-store file is required, fssnap creates subsequent files automatically. The second and subsequent files have the same name as the first file, with suffixes of .2, .3, and so forth.

This option can be abbreviated as *bf=path* or *bs=path*.

unlink

Unlinks the backing-store file after the snapshot is created. This option specifies that the backing-store file does not need to be removed manually when the snapshot is deleted. This might make administration more difficult since the file is not visible in the file system. If this option is not specified, the backing-store files should be removed manually after the snapshot is deleted.

`chunksize=n [k,m,g]`

Uses *n* for the chunk size. Chunk size is the granularity of the data that is sent to the backing store.

Specify `chunksize` in the following units: k for kilobytes, m for megabytes, or g for gigabytes. By default, chunk size is four times the block size of the file system (typically 32k).

`maxsize=n[k,m,g]`

Does not allow the sum of the sizes of the backing-store file(s) to exceed *n*, where *n* is the unit specified. The snapshot is deleted automatically when the sum of the sizes of the backing-store file(s) exceeds `maxsize`.

Specify `maxsize` in the following units: k for kilobytes, m for megabytes, or g for gigabytes.

`raw`

Displays to standard output the name of the raw device instead of the block device when a snapshot is created. The block device is printed by default (when `raw` is not specified). This option makes it easier to embed `fssnap` commands in the command line for commands that require the raw device instead. Both devices are always created. This option affects only the output.

Operands The following operands are supported:

mount-point

The directory where the file system resides.

special

The physical device for the file system, such as `/dev/dsk/c0t0d0s7`.

Examples **EXAMPLE 1** Creating a Snapshot of a File System

The following example creates a snapshot of a file system. The block special device created for the snapshot is `/dev/fssnap/0`.

```
# fssnap -F ufs -o backing-store=/var/tmp /export/home
/dev/fssnap/0
```

EXAMPLE 2 Backing Up a File System Snapshot Without Having To Unmount the File System

The following example backs up a file system snapshot without having to unmount the file system. Since `ufsdump` requires the path to a raw device, the `raw` option is used. The `/export/home` file system snapshot is removed in the second command.

```
# ufsdump 0uf /dev/rmt/0 'fssnap -F ufs
-o raw,bs=/export/snap /export/home'
<output from ufsdump>
# fssnap -F ufs -d /export/home
```

EXAMPLE 3 Backing Up a File System

When backing up a file system, do not let the backing-store file(s) exceed 400 Mbytes. The second command removes the /export/home file system snapshot.

```
# ufsdump 0uf /dev/rmt/0 'fssnap -F ufs
    -o maxsize=400m,backing-store=/export/snap,raw
    /export/home'
# fssnap -F ufs -d /export/home
```

EXAMPLE 4 Performing an Incremental Dump of a Snapshot

The following example uses `ufsdump` to back up a snapshot of /var. Note the use of the `N` option to `ufsdump`, which writes the name of the device being dumped, rather than the name of the snapshot device, to /etc/dumpdates file. See [ufsdump\(1M\)](#) for details on the `N` flag.

```
# ufsdump lfNu /dev/rmt/0 /dev/rdisk/c0t3d0s2 'fssnap -F ufs
-o raw,bs=/export/scratch,unlink /var'
```

EXAMPLE 5 Finding Out What Snapshots Currently Exist

The following command displays the currently existing snapshots.

```
# fssnap -i
0 /src
1 /export/home
<output continues>
```

EXAMPLE 6 Mounting a File System Snapshot

The following example creates a file system snapshot. After you create a file system snapshot, mount it on /tmp/mount for temporary read-only access.

```
# fssnap -F ufs -o backing-store=/nfs/server/scratch /export/home
/dev/fssnap/1
# mkdir /tmp/mount
# mount -F ufs -o ro /dev/fssnap/1 /tmp/mount
```

EXAMPLE 7 Creating a File System Snapshot and Unlinking the Backing-store File

The following example creates a file system snapshot and unlinks the backing-store file. After creating a file system snapshot and unlinking the backing-store file, check the state of the snapshot.

```
# fssnap -o bs=/scratch,unlink /src
/dev/fssnap/0
# fssnap -i /src
Snapshot number          : 0
Block Device             : /dev/fssnap/0
Raw Device                : /dev/rfssnap/0
Mount point              : /src
Device state              : active
```

EXAMPLE 7 Creating a File System Snapshot and Unlinking the Backing-store File (Continued)

```
Backing store path      : /scratch/snapshot2 <UNLINKED>
Backing store size     : 192 KB
Maximum backing store size : Unlimited
Snapshot create time   : Sat May 06 10:55:11 2000
Copy-on-write granularity : 32 KB
```

EXAMPLE 8 Displaying the Size and Location of the Backing-store File(s) and the Creation Time for the Snapshot

The following example displays the size of the backing-store file(s) in bytes, the location of the backing store, and the creation time for the snapshot of the /test file system.

```
# fssnap -i -o backing-store-len,backing-store,createtime /test
196608
/snapshot2
Sat May 6 10:55:11 2000
```

Note that if there are multiple backing-store files stored in /snapshot2, they will have names of the form *file* (for the first file), *file.1*, *file.2*, and so forth.

Exit Status The following exit values are returned:

```
0
    Successful completion.
>0
    An error occurred.
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

The script-readable output mode is a stable interface that can be added to, but will not change. All other interfaces are subject to change.

See Also [mlock\(3C\)](#), [attributes\(5\)](#)

See the `ntpd` man page, delivered in the SUNWntpu package (not a SunOS man page).

Notes The `fssnap` device files should be treated like a regular disk block or character device.

The association between a file system and the snapshot is lost when the snapshot is deleted or the system reboots. Snapshot persistence across reboots is not currently supported.

To avoid unnecessary performance impacts, perform the snapshot and system backup when the system is least active.

It is not possible to perform a snapshot of a file system if any of the following conditions are true:

- The file system is in use by system accounting
- The file system contains a local swap file
- The file system is used as backing store by an application that uses `mlock(3C)` to lock its pages. Typically, these are real time applications, such as `ntpd` (delivered in the `SUNWntpu` package).

These conditions result in `fssnap` being unable to write lock the file system prior to performing the snapshot.

Name fsstat – report file system statistics

Synopsis fsstat [-a|f|i|n|v] [-T | u|d] {-F | {fstype|path}...}
[interval [count]]

Description fsstat reports kernel file operation activity by the file system type (*fstype*) or by the path name, which is converted to a mount point. The first set of lines of output reports all activity since:

- The file system module was loaded (in the case of *fstype*)
- The file system was mounted (in the case of mount point)

Statistics are gathered at the file system independent layer at both the *fstype* and the mount point levels. However, not all file system types are represented in the gathering of statistics. (See the NOTES section of this man page.)

The output of fsstat is dependent on the mode (option) requested. All statistic fields are displayed using “smart numbers” which automatically scale the units in a human readable form that fits in a maximum of 5 characters. For example:

```
100          is displayed as 100
2048         is displayed as 2K
3000000      is displayed as 2.86M
```

The unit modifiers are: K (Kbyte), M (Mbyte), G (Gbyte), T (terabyte), P (petabyte), and E (exabyte).

During the execution of fsstat, the state of the system can change. If relevant, a state change message is included in the fsstat output in one of the following forms:

```
<<mount point no longer available: {path}>>
<<file system module no longer loaded: {fstype}>>
```

After the state change messages are displayed, fsstat continues to display the statistics as directed. If all of the *fstypes* and mount points that fsstat was reporting on are no longer available, then fsstat exits.

The user is required to specify the -F option (all available file system types) or a list of one or more *fstypes* and/or mount points.

The default report shows general file system activity. This display combines similar operations into general categories as follows:

```
new file      Number of creation operations for file system objects (for example, files,
              directories, symlinks, etc.)
name remov    Number of name removal operations
name chng     Number of name change operations
```

| | |
|-------------|-------------------------------------------------|
| attr get | Number of object attribute retrieval operations |
| attr set | Number of object attribute change operations |
| lookup ops | Number of object lookup operations |
| rddir ops | Number of read directory operations |
| read ops | Number of data read operations |
| read bytes | Bytes transferred by data read operations |
| write ops | Number of data write operations |
| write bytes | Bytes transferred by data write operations |

The entity being reported on (*fstype* or mount point) is displayed in the last column.

Options The following options are supported:

- a Report the activity for kernel attribute operations. The following statistics are reported:

| | |
|---------|------------------------------------------------------|
| getattr | Number of file attribute retrieval calls |
| setattr | Number of file attribute modification calls |
| getsec | Number of file security attribute retrieval calls |
| setsec | Number of file security attribute modification calls |

The entity being reported on (*fstype* or mount point) is displayed in the last column.

- f Report the full activity for all kernel file operations. Each file operation is listed in the left column. The following statistics are reported for each operation:

| | |
|-------|-----------------------------------------------------------------------|
| #ops | Number of calls for this operation |
| bytes | Average transfer size in bytes (only applies to read, write, readdir) |

The entity being reported on (*fstype* or mount point) is displayed in the first row.

- i Reports the activity for kernel I/O operations. The following statistics are reported:

| | |
|-------------|--------------------------------|
| read ops | Number of data read calls |
| read bytes | Number of bytes read |
| write ops | Number of data write calls |
| write bytes | Number of bytes written |
| rddir ops | Number of read directory calls |

rddir bytes Number of bytes read by reading directories
 rwlock ops Number of internal file system lock operations
 rwunlock ops Number of internal file system unlock operations

The entity being reported on (*fstype* or mount point) is displayed in the last column.

-n Reports the activity for kernel naming operations. The following statistics are reported:

lookup Number of file name retrieval calls
 creat Number of file creation calls
 remov Number of file remove calls
 link Number of link calls
 renam Number of file renaming calls
 mkdir Number of directory creation calls
 rmdir Number of directory removal calls
 rddir Number of directory read calls
 symlink Number of symlink creation calls
 rdlink Number of symlink read calls

The entity being reported on (*fstype* or mount point) is displayed in the last column.

-v Reports the activity for calls to the virtual memory operations. The following statistics are reported.

map Number of calls mapping a file
 addmap Number of calls setting additional mapping to a mapped file
 delmap Number of calls deleting mapping to a file
 getpag Number of calls retrieving a page of data from a file
 putpag Number of calls writing a page of data to a file
 pagio Number of calls to transfer pages in file system swap files

The entity being reported on (*fstype* or mount point) is displayed in the last column.

-F Report on all available file system types.

`-T u|d` Display a time stamp.

Specify *u* for a printed representation of the internal representation of time (see [time\(2\)](#)) Specify *d* for the standard date format. (See [date\(1\)](#)). The time stamp is only used when an interval is set.

Operands The following operands are supported:

count Display only *count* reports.

fstype Explicitly specify the file system type(s) to be reported. The file system module must be loaded.

interval Report once each *interval* seconds.

path Specify the path(s) of the mount point(s) to be reported. If path is not a mount point, the mount point containing path will be determined and displayed in the output.

If no *interval* and no *count* are specified, a single report is printed and `fsstat` exits. If an *interval* is specified but no *count* is specified, `fsstat` prints reports every *interval* seconds indefinitely until the command is interrupted.

Examples EXAMPLE 1 Displaying General Activity

The following example shows general activity for all file system types.

```
$ fsstat -F
new name name attr attr lookup rddir read read write write
file remov chng get set ops ops ops bytes ops bytes
313K 214K 38.5K 2.16M 56.2K 8.36M 52.8K 19.7M 39.9G 18.8M 39.1G ufs
0 0 0 2.95K 0 3.81K 282 2.52K 466K 0 0 proc
0 0 0 0 0 0 0 0 0 0 0 nfs
10 8 2 86 9 98 15 413 103M 8.43K 1.05G zfs
13 14 4 98 16 125 10 1.01K 258M 15.9K 127M lofs
8.73K 3.29K 5.25K 55.3K 37 1.20M 44 37.9K 38.3M 47.2K 35.9M tmpfs
0 0 0 4.93K 0 0 0 1.08K 913K 0 0 mntfs
3 2 1 503 3 897 13 122 25.8K 128 272K nfs3
10 8 0 615 10 10.1K 18 61 45.6K 292 2.26M nfs4
```

EXAMPLE 2 Displaying Naming Activity

The following example shows the naming activity for `ufs`, `nfs`, `nfs3`, `nfs4`, and `tmpfs`:

```
$ fsstat -n ufs nfs nfs3 nfs4 tmpfs
lookup creat remov link renam mkdir rmdir rddir symlnk rdlnk
3.57M 3.10K 586 6 24 115 100 30.2K 5 330K ufs
0 0 0 0 0 0 0 0 0 0 nfs
18.3K 3 5 0 0 0 0 1.03K 2 346 nfs3
535 0 0 0 0 0 0 46 0 4 nfs4
```

EXAMPLE 2 Displaying Naming Activity (Continued)

```
146    24    15    0    0    4    0    4    0    0 tmpfs
```

EXAMPLE 3 Displaying Attribute Activity

The following example shows the attribute activity for the FS type ufs and the mounted file systems “/” and “/export/home” every three seconds for every third iteration:

```
# fsstat -a ufs / /export/home 3 3
getattr setattr getsec setsec
 378K   91.9K 11.8K    0 ufs
 367K   82.3K 11.6K    0 /
11.3K    9.6K  198    0 /export/home
4.97K   2.27K 163    0 ufs
3.94K   1.36K 162    0 /
1.03K    927    1    0 /export/home
2.30K   1.06K  73    0 ufs
1.95K    766    71    0 /
   361    317    2    0 /export/home
2.33K   1.06K  78    0 ufs
1.64K    451    77    0 /
   711    631    1    0 /export/home
```

EXAMPLE 4 Displaying File Operation Statistics

The following example shows the statistics for each file operation for “/” (using the -f option):

```
$ fsstat -f /
Mountpoint: /
operation #ops bytes
  open 8.54K
  close 9.8K
  read 43.6K 65.9M
  write 1.57K 2.99M
  ioctl 2.06K
  setfl 4
  getattr 40.3K
  setattr 38
  access 9.19K
  lookup 203K
  create 595
  remove 56
  link 0
  rename 9
  mkdir 19
  rmdir 0
  readdir 2.02K 2.27M
  symlink 4
```

EXAMPLE 4 Displaying File Operation Statistics (Continued)

```

readlink 8.31K
fsync    199
inactive 2.96K
fid      0
rwlock  47.2K
rwunlock 47.2K
seek    29.1K
cmp     42.9K
frlock  4.45K
space   8

getpage 104K
putpage 2.69K
map     13.2K
addmap  34.4K
delmap  33.4K
poll    287
dump    0
pathconf 54
pageio  0
dumpctl 0
dispose 23.8K
getsecattr 697
setsecattr 0
shrlock 0
vnevent 0

```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `fsstat`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, and `NLSPATH`.

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 A fatal error occurred. A fatal error could be a failed system call or another internal error.
- 2 Invalid command-line options were specified.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |
| CSI | Enabled |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | See below. |

The command-line options are Uncommitted. The human-readable output is not considered an interface.

See Also [date\(1\)](#), [time\(2\)](#), [attributes\(5\)](#)

Notes All display options (`-a`, `-f`, `-i`, `-n`, `-v`) are mutually exclusive. Entering more than one of these options will result in an error.

The *fstype* and *path* operands must appear after the option, but before the *interval* or *count* on the command line. For example, “`fsstat -a fstype interval`”. Preference is given to *fstype* so that if a user wishes to see the statistics for a directory that has the same name as an *fstype* (for example, `ufs`), then the path must be specified unambiguously (for example, `./ufs`). Similarly, in order to define a file with a numeric name (for example, “10”) from an interval or count operand, the name should be prefixed accordingly (for example, `./10`).

When an interval is used, headers repeat after more than 12 lines of statistics have been displayed and the set of lines to be displayed in the current interval have completed.

Statistics are not displayed for all pseudo-file systems. The output displayed with the `-F` option shows which of the loaded filesystem types are supported.

Unbundled file systems may not be recognized by `fsstat`.

The command-line options are classified as Uncommitted and could change. The output is not considered to be an interface. The construction of higher level software tools depend on either the command-line options or the output of `fsstat` is not recommended.

Name fstyp – determine file system type

Synopsis fstyp [-a | -v] *special* [:*logical-drive*]

Description fstyp allows the user to determine the file system type of unmounted file systems using heuristic programs.

An fstyp module for each file system type to be checked is executed; each of these modules applies an appropriate heuristic to determine whether the supplied *special* file is of the type for which it checks. If it is, the program prints on standard output the usual file system identifier for that type (for example, “ufs”) and exits with a return code of 0; if none of the modules succeed, the error message `unknown_fstyp (no matches)` is returned and the exit status is 1. If more than one module succeeds, the error message `unknown_fstyp (multiple matches)` is returned and the exit status is 2. Other errors are printed in the same format.

This command is unreliable and its results should not be used to make any decisions about subsequent use of a storage device or disk partition.

Options -a Output all available file system attributes. If a file system has been successfully identified, and this option is specified, the *FSType* identifier is followed by one or more “name-value” pairs, one per line, in the format:

```
name: value
```

The following conventions are recognized for the file system attributes:

- String values are put in single quotes.
- Nested “name-value” list increases the indentation of its values by four whitespaces.
- For an array of “name-value” pairs, one array entry is printed per line, with the index following the name in square brackets.

For instance, in the following example, “*top_list*” is a “name-value” list, consisting of a string array “*string_array*” and a “name-value” list array “*list_array*”. The second “*list_array*” element is an integer array “*int_array*” containing three elements.

```
top_string: 'String'
top_list:
  string_array[0]: 'S0'
  string_array[1]: 'S1'
  list_array[0]:
    int_one: 1
    string_two: 'S2'
  list_array[1]:
    int_array[0]: 1
    int_array[1]: 2
    int_array[2]: 3
```

In addition to the *FSType*-specific attributes, the following generic attributes may be present:

- gen_clean* Allowable values are “true” or “false”. If the value is “false”, the file system is damaged or was not unmounted cleanly and the [fsck\(1M\)](#) command must be run before this file system can be mounted.
- gen_guid* Globally unique identifier. This string uniquely identifies the file system.
- gen_version* A string describing the file system version.
- gen_volume_label* Volume label, a human-readable string used to either describe or identify the file system.
- v Produce verbose output. This is usually information about the file systems superblock and varies across different *FSTypes*. See [ufs\(7FS\)](#), [mkfs_ufs\(1M\)](#), and [tunefs\(1M\)](#) for details.

Usage See [largefile\(5\)](#) for the description of the behavior of `fstyp` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [fsck\(1M\)](#), [mkfs_ufs\(1M\)](#), [tunefs\(1M\)](#), [attributes\(5\)](#), [libfstyp\(3LIB\)](#), [largefile\(5\)](#), [hsfs\(7FS\)](#), [ufs\(7FS\)](#), [pcfs\(7FS\)](#)

Notes The use of heuristics implies that the result of `fstyp` is not guaranteed to be accurate.

This command is unreliable and its results should not be used to make any decisions about subsequent use of a storage device or disk partition.

Name ftppaddhost – set up a virtual FTP host

Synopsis `ftppaddhost -c | -l [-b] [-x xferlog] hostname root_dir`

Description The `ftppaddhost` script is executed by the super user to set up virtual FTP hosts. The `ftppaddhost` command configures the virtual host *hostname* under directory *root_dir*. The value of *hostname* can be an IP address or the name of a host.

Options The `ftppaddhost` script supports the following options:

- b Create a banner for the virtual host. This option is useful to confirm that the virtual host is working.
- c Configure complete virtual hosting. This option allows each virtual host to have its own version of the `ftppaccess`, `ftppconversions`, `ftppgroups`, `ftpphosts`, and `ftppusers` files. The master version of each of these configuration files is copied from the `/etc/ftpd` directory and placed in the `/etc/ftpd/virtual-ftpd/hostname` directory. If the `/etc/ftppusers` file exists it is appended to the virtual `ftppusers` file. If a virtual host lacks its own version of a configuration file, the master version is used.
- l Configure limited virtual hosting. This option allows a small number of parameters to be configured differently for a virtual host. See the `virtual` keyword on the `ftppaccess(4)` manual page.
- x *xferlog* Create a logfile entry such that the transfer logs for the virtual host are written to the specified file. An absolute path must be specified for the *xferlog* file.

Operands The following operands are supported:

hostname The host name or IP address of the virtual server.

root_dir The absolute pathname of the directory under which the virtual server is set up.

Exit Status The following exit values are returned:

- 0 Successful completion
- 1 Improper usage of the command
- 2 Command failed

Files `/etc/ftpd/virtual-ftpd/hostname` The configuration files directory for the virtual host *hostname*.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|---------------------|
| Availability | service/network/ftp |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Committed |

See Also [ftpconfig\(1M\)](#), [in.ftpd\(1M\)](#), [ftpaccess\(4\)](#), [ftpconversions\(4\)](#), [ftpgroups\(4\)](#), [ftphosts\(4\)](#), [ftpusers\(4\)](#), [xferlog\(4\)](#), [attributes\(5\)](#)

Name ftpconfig – set up anonymous FTP

Synopsis ftpconfig [*ftpd*dir]
ftpconfig -d *ftpd*dir

Description The ftpconfig script is executed by the super user to set up anonymous FTP. Anonymous FTP allows users to remotely log on to the FTP server by specifying the user name ftp or anonymous and the user's email address as password. The anonymous users are logged on to the FTP Server and given access to a restricted file area with its own file system root. See [chroot\(2\)](#). The FTP area has its own minimal system files.

This command will copy and set up all the components needed to operate an anonymous FTP server, including creating the *ftp* user account, creating device nodes, copying */usr/lib* files, and copying timezone data. The *passwd* and *group* files set up have been stripped down to prevent malicious users from finding login names on the server. The anonymous file area will be placed under *ftpd*dir. If the *ftp* user account already exists, then the current FTP area is used, and the system files in it are updated. All other files are left untouched. This command should be run to update the anonymous FTP area's configuration whenever a system patch is installed, or the system is upgraded.

Options -d Create a new or update an existing *ftpd*dir without creating or updating the *ftp* user account. Use this option when creating guest FTP user accounts.

Operands The following operands are supported:

*ftpd*dir The absolute pathname of the directory under which the anonymous FTP area is set up.

Exit Status The following exit values are returned:

- 0 Successful completion
- 1 Improper usage of the command
- 2 Command failed

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|---------------------|
| Availability | service/network/ftp |
| Interface Stability | Committed |

See Also [ftpaddhost\(1M\)](#), [in.ftpd\(1M\)](#), [useradd\(1M\)](#), [chroot\(2\)](#), [attributes\(5\)](#)

Name ftprestart – restart previously shutdown FTP Servers

Synopsis ftprestart [-V]

Description Use the ftprestart command to restart an FTP Server previously shut down by means of [ftpshut\(1M\)](#). The ftprestart command reads the shutdown capability from the [ftpaccess\(4\)](#) file to determine the path of the shutdown message files. It then reenables the FTP Server by removing any shutdown message files in the anonymous and virtual FTP Server area, as well as the system wide shutdown message file.

Options The ftprestart command supports the following options:

-V Display program copyright and version information, then terminate.

Examples EXAMPLE 1 Sample Output from ftprestart

The following example shows sample output from the ftprestart command:

```
example% ftprestart
ftprestart: /export/home/ftp/etc/ftpd/shutdown.msg removed.
ftprestart: /export/home/virtual1/etc/ftpd/shutdown.msg removed.
ftprestart: /etc/ftpd/shutdown.msg removed.
```

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Files /etc/ftpd/ftpaccess

/etc/ftpd/ftpservers

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|---------------------|
| Availability | service/network/ftp |
| Interface Stability | Volatile |

See Also [ftpshut\(1M\)](#), [in.ftpd\(1M\)](#), [ftpaccess\(4\)](#), [ftpservers\(4\)](#), [attributes\(5\)](#)

Name ftpshut – close down the FTP Servers at a given time

Synopsis ftpshut [-V] [-v] [-l *min*] [-d *min*] *time*
[*warning-message*] . . .

Description The ftpshut command provides an automated shutdown procedure that the superuser can use to notify FTP users when the FTP Server is shutting down.

Ten minutes before shutdown, or immediately if the value of *time* is less than ten minutes, any new FTP Server connections will be disabled. You may adjust the shutdown of new FTP Server connections by means of the -l option.

Five minutes before shutdown, or immediately if the value of *time* is less than five minutes, all current FTP connections will be disconnected. You may adjust the shutdown of current FTP connections by means of the -d option.

The ftpshut command creates shutdown message files that the FTP Server uses to determine when to shutdown. Separate shutdown message files are created in the anonymous and virtual host FTP Server areas, in addition to the system wide shutdown message file. Once the shutdown occurs, the server continues to refuse connections until the appropriate shutdown message file is removed. This normally is done by using the [ftprestart\(1M\)](#) command. The location of the shutdown message file is specified by the shutdown capability in the ftpaccess file.

The following magic cookies are available:

- %s The time system is going to shut down.
- %r The time new connections will be denied.
- %d The time current connections will be dropped.
- %C The current working directory.
- %E The maintainer's email address as defined in the ftpaccess file.
- %F The free space in the partition of CWD, in kilobytes.
- %L The local host name.
- %M The maximum allowed number of users in this class.
- %N The current number of users in this class.
- %R The remote host name.
- %T The local time (form Thu Nov 15 17:12:42 1990).
- %U The username given at login time.

Options The ftpshut command supports the following options:

- V Display program copyright and version information, then terminate.
- d *min* The time ahead of shutdown, in minutes, that existing connections will be disconnected upon completion of their current or next (if idle) FTP request.
- l *min* The time ahead of shutdown, in minutes, that new connections will be refused.
- v Verbose. Output the pathname of the shutdown message files created.

Operands The ftpshut command supports the following operands:

- time* The *time* at which ftpshut will bring the FTP Servers down. *time* can have a value of *now*, which indicates an immediate shutdown. Alternatively, *time* can specify a future time in one of two formats: *+number* or *HHMM*. The first form brings the FTP Server down in *number* minutes. The second brings the FTP Server down at the time of day indicated, using a 24-hour clock format. When using the absolute time format, you can only specify times between now and 23:59.
- warning-message* The message to display that warns of the imminent shutdown. The *warning-message* will be formatted at 70 characters wide. ftpshut knows the actual string length of the magic cookies. If no warning-message is supplied, the default message “System shutdown at %s” is used.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Files /etc/ftpd/ftpaccess
/etc/ftpd/ftpservers

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|---------------------|
| Availability | service/network/ftp |
| Interface Stability | Volatile |

See Also [in.ftpd\(1M\)](#), [ftprestart\(1M\)](#), [shutdown\(1M\)](#), [ftpaccess\(4\)](#), [ftpservers\(4\)](#), [attributes\(5\)](#)

Name fuser – identify users of files and devices

Synopsis /usr/sbin/fuser [-c | -d | -f] [-nu] [-k | -s *sig*] *files*
[[-] [-c | -d | -f] [-nu] [-k | -s *sig*] *files* ...

Description The fuser utility displays the process IDs of the processes that are using the *files* specified as arguments.

Each process ID is followed by a letter code. These letter codes are interpreted as follows. If the process is using the file as

- c Indicates that the process is using the file as its current directory.
- m Indicates that the process is using a file mapped with `mmap(2)`. See `mmap(2)` for details.
- n Indicates that the process is holding a non-blocking mandatory lock on the file.
- o Indicates that the process is using the file as an open file.
- r Indicates that the process is using the file as its root directory.
- t Indicates that the process is using the file as its text file.
- y Indicates that the process is using the file as its controlling terminal.

For block special devices with mounted file systems, all processes using any file on that device are listed. For all types of files (text files, executables, directories, devices, and so forth), only the processes using that file are reported.

For all types of devices, fuser also displays any known kernel consumers that have the device open. Kernel consumers are displayed in one of the following formats:

```
[module_name]  
[module_name, dev_path=path]  
[module_name, dev=(major, minor) ]  
[module_name, dev=(major, minor) , dev_path=path]
```

If more than one group of files are specified, the options may be respecified for each additional group of files. A lone dash cancels the options currently in force.

The process IDs are printed as a single line on the standard output, separated by spaces. All other output, including the single terminating newline, is written on standard error.

Any user can run fuser, but only the superuser can terminate another user's process.

Options The following options are supported:

- c Reports on files that are mount points for file systems, and any files within that mounted file system.

- d Report device usage information for all minor nodes bound to the same device node as the specified minor node. This option does not report file usage for files within a mounted file system.
- f Prints a report for the named file, not for files within a mounted file system.
- k Sends the SIGKILL signal to each process. Since this option spawns kills for each process, the kill messages may not show up immediately (see [kill\(2\)](#)). No signals will be sent to kernel file consumers.
- n Lists only processes with non-blocking mandatory locks on a file.
- s *sig* Sends a signal to each process. The *sig* option argument specifies one of the symbolic names defined in the `<signal.h>` header, or a decimal integer signal number. If *sig* is a symbolic name, it is recognized in a case-independent fashion, without the SIG prefix. The -k option is equivalent to -s KILL or -s 9. No signals will be sent to kernel file consumers.
- u Displays the user login name in parentheses following the process ID.

Examples EXAMPLE 1 Reporting on the Mount Point and Files

The following example reports on the mount point and files within the mounted file system.

```
example% fuser -c /export/foo
```

EXAMPLE 2 Restricting Output when Reporting on the Mount Point and Files

The following example reports on the mount point and files within the mounted file system, but the output is restricted to processes that hold non-blocking mandatory locks.

```
example% fuser -cn /export/foo
```

EXAMPLE 3 Sending SIGTERM to Processes Holding a Non-blocking Mandatory Lock

The following command sends SIGTERM to any processes that hold a non-blocking mandatory lock on file `/export/foo/my_file`.

```
example% fuser -fn -s term /export/foo/my_file
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `fuser`: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | Committed |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|------------------------------------|
| Standard | See standards(5) . |

See Also [ps\(1\)](#), [mount\(1M\)](#), [kill\(2\)](#), [mmap\(2\)](#), [signal\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Notes Because fuser works with a snapshot of the system image, it may miss processes that begin using a file while fuser is running. Also, processes reported as using a file may have stopped using it while fuser was running. These factors should discourage the use of the `-k` option.

Name fwflash – firmware query and update utility

Synopsis /usr/sbin/fwflash [-l [-c *device_class* | ALL]]
 | [-v] | [-h]
 fwflash [-f *file1,file2,file3,...* | -r *file*]
 [-y] [-d *device_path*]

Description The `fwflash` command writes a binary image file to supported flashable devices attached to a Solaris host. It also provides the ability to read firmware to a file if supported by the device. Because changing the firmware in a device can have significant impact on the stability of a system, only users with the privilege `ALL` are allowed to execute this command. Users authorized to run `fwflash` can be granted the “Firmware Flash Update” Rights Profile.

The first form of the command, above, provides information about devices. It lists all devices currently available on the system that are supported by `fwflash` for firmware upgrade. You can filter the list operation, to display only specified classes of devices. The second form of the command provides the operations to read or write the firmware images to specific devices.

Options The following options are supported:

-c *device_class*

An optional parameter, valid only when used with the `-l` option. This option causes the command to list only devices of a specific class type. Currently supported classes are `IB`, `ses`, `sesgen`, or `ALL`. If `-c` is not specified for the `-l` option, the class defaults to `ALL`.

-d *dev_path*

The *dev_path* is absolute path name of the device that the user wants to modify with the `-f` or `-r` operation. If the device cannot be found, the command fails. If the `-d` option is specified, then either `-f` or `-r` must also be specified.

-f *file1,file2,file3,...*

Specify the path to one or more binary firmware image files you want to write to the device. `fwflash` will verify that each file is a valid firmware image for the specified device. If it is not, the command fails with an appropriate error message.

If multiple firmware image files are specified, each image is verified and flashed to the device in the order given on the command line. If any of the specified files cannot be successfully flashed, then an appropriate message is displayed.

After a new firmware image is flashed to a device, a reboot is required to correctly activate the new firmware.

-h

Display the command line usage message for `fwflash`.

-l

List the devices on a system available for firmware upgrade and display information specific to each device or device class.

For InfiniBand (IB) devices, the list operation displays the `guids` (Globally Unique Identifier) currently set for the HCA, as well as the current firmware revision installed. There are four separate `guids` on the HCA; two of them can be set with the same value.

For SCSI Enclosure Services (`ses` or `sgen`) devices, an identifying target-port worldwide name is displayed, if available.

-r *file*

Specify the path to a file to create when reading the firmware from the device. The `-f` and `-r` options are mutually exclusive.

Not all flashable devices support reading firmware images back from the device. At present, only InfiniBand (IB) devices are supported for this operation. A message will be displayed if the selected device does not support this operation.

-v

Display `fwflash` version information and exit.

-y

Valid only when a flash read (`-r`) or write (`-f`) operation is specified. This option causes `fwflash` not to prompt for confirmation during operation and operate non-interactively. Note that there is no option that allows you to forcibly flash an incompatible firmware image onto a device.

Examples EXAMPLE 1 Entering Command Without Arguments

The following command shows `fwflash` when the command is entered without arguments.

```
example# fwflash
```

```
Usage:
```

```
Usage:
```

```
fwflash [-l [-c device_class | ALL]] | [-v] | [-h]
fwflash [-f file1,file2,file3,... | -r file] [-y] -d device_path
```

```
-l          list flashable devices in this system
-c device_class limit search to a specific class
             eg IB for InfiniBand, ses for SCSI Enclosures
-v          print version number of fwflash utility
-h          print this usage message
```

```
-f file1,file2,file3,...
             firmware image file list to flash
-r file     file to dump device firmware to
-y          answer Yes/Y/y to prompts
-d device_path pathname of device to be flashed
```

```
If -d device_path is specified, then one of -f <files>
or -r <file> must also be specified
```

EXAMPLE 1 Entering Command Without Arguments *(Continued)*

If multiple firmware images are required to be flashed they must be listed together, separated by commas. The images will be flashed in the order specified.

EXAMPLE 2 Listing Devices Available to Flash

The following command lists the devices available to be flashed.

```
example# fwflash -l
List of available devices:
Device[0], /devices/pci@0,0/pci8086,3595@2/pci8086,32a@0,2/\
pci15b3,5a46@c/pci15b3,5a44@0:devctl
Class [IB]
  GUID: System Image - 0002c901081e33b3
  Node      - 0000000000003446
  Port 1    - 0002c901081e33b1
  Port 2    - 0002c901081e33b2
  Firmware revision: 3.3.0002
  No hardware information available for this device

Device[1], /devices/pci@0,0/pci8086,3597@4/pci15b3,6278@0:devctl
Class [IB]
  GUID: System Image - 0002c9010a99e3b3
  Node      - 0002c9010a99e3b0
  Port 1    - 0002c9010a99e3b1
  Port 2    - 0002c9010a99e3b2
  Firmware revision: 4.8.00c8
  Product   : MTLP25208-CF256T (Lion cub)
  PSID     : MT_00B0000001
```

Alternatively, for a SAS Expander presented as a SCSI Enclosure Services device, we might see output such as this:

```
example# fwflash -l
List of available devices:
Device[0] /devices/pci@0/pci@0/pci@2/scsi@0/ses@3,0:ses
Class [sgen]
  Target port WWN : 500605b00002453d
  Vendor          : SUN
  Product         : 16Disk Backplane
  Firmware revision: 5021
```

EXAMPLE 3 Flash Upgrading an IB HCA Device

The following command flash upgrades an IB HCA device.

```
example# fwflash -f ./version.3.2.0000 \
-d /devices/pci@0,0/pci8086,3597@4/pci15b3,6278@0:devctl
About to update firmware on:
```

EXAMPLE 3 Flash Upgrading an IB HCA Device *(Continued)*

```
/devices/pci@0,0/pci8086,3597@4/pci15b3,6278@0:devctl
Continue (Y/N): Y
```

```
Updating . . . . .
Done. New image will be active after the system is rebooted.
```

Note that you are prompted before the upgrading proceeds and that it is mandatory that you reboot your host to activate the new firmware image.

The following command adds the `-y` option to the command.

```
example# fwflash -y -f ./version.3.2.0000 \
-d /devices/pci@0,0/pci8086,3597@4/pci15b3,6278@0:devctl
About to update firmware on:
/devices/pci@0,0/pci8086,3597@4/pci15b3,6278@0:devctl
```

```
Updating . . . . .
Done. New image will be active after the system is rebooted.
```

EXAMPLE 4 Reading Device Firmware to File

The command shown below reads the device firmware to a file. The command uses the `-y` option so that read occurs without prompting.

```
example# fwflash -y -r /firmware.bin \
-d /devices/pci@1d,700000/pci@1/pci15b3,5a44@0:devctl
About to read firmware on:
/devices/pci@1d,700000/pci@1/pci15b3,5a44@0:devctl
to filename: /firmware.bin
```

```
Reading . . .
Done.
```

EXAMPLE 5 When No Flashable Devices Are Found

The command output shown below informs the user that there are no supported flashable devices found in the system:

```
example# fwflash -l
fwflash: No flashable devices attached with the ses driver in this system
fwflash: No flashable devices attached with the sgen driver in this system
fwflash: No flashable devices attached with the tavor driver in this system
fwflash: No flashable devices in this system
```

Each plugin found in `/usr/lib/fwflash/identify` is loaded in turn, and walks the system device tree, determining whether any currently-attached devices can be flashed. For the list of device types and drivers that are currently supported, please see the NOTES section below.

Return Values The `fwflash` command returns the following values:

- 0
Success
- 1
Failure

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------|
| Availability | system/flash/fwflash |
| Interface Stability | Committed |

See Also [attributes\(5\)](#), [hermon\(7D\)](#), [ses\(7D\)](#), [tavor\(7D\)](#)

The InfiniBand Trade Association website, <http://www.infinibandta.org>

The SCSI Storage Interfaces committee website, <http://www.t10.org>

SCSI Primary Commands-4, SPC4

SCSI Enclosure Services-2, SES2

Serial Attached SCSI-2, SAS2

Notes The `fwflash` command supports:

- InfiniBand Host Channel Adapters (IB HCAs) containing either the AMD or the Intel parallel flash parts.
- SCSI Enclosure Services devices such as SAS Expanders, attached with [ses\(7D\)](#) drivers.

Name fwtmp, wtmpfix – manipulate connect accounting records

Synopsis /usr/lib/acct/fwtmp [-ic]
 /usr/lib/acct/wtmpfix [*file*]...

Description fwtmp reads from the standard input and writes to the standard output, converting binary records of the type found in /var/adm/wtmpx to formatted ASCII records. The ASCII version is useful when it is necessary to edit bad records.

wtmpfix examines the standard input or named files in utmpx format, corrects the time/date stamps to make the entries consistent, and writes to the standard output. A hyphen (-) can be used in place of *file* to indicate the standard input. If time/date corrections are not performed, [acctcon\(1M\)](#) will fault when it encounters certain date-change records.

Each time the date is set, a pair of date change records are written to /var/adm/wtmpx. The first record is the old date denoted by the string "old time" placed in the `line` field and the flag `OLD_TIME` placed in the `type` field of the utmpx structure. The second record specifies the new date and is denoted by the string `new time` placed in the `line` field and the flag `NEW_TIME` placed in the `type` field. wtmpfix uses these records to synchronize all time stamps in the file.

In addition to correcting time/date stamps, wtmpfix will check the validity of the `name` field to ensure that it consists solely of alphanumeric characters or spaces. If it encounters a name that is considered invalid, it will change the login name to `INVALID` and write a diagnostic to the standard error. In this way, wtmpfix reduces the chance that acctcon will fail when processing connect accounting records.

Options -ic Denotes that input is in ASCII form, and output is to be written in binary form.

Files /var/adm/wtmpx history of user access and administration information

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

System Administration Guide: Basic Administration

Name getdev – lists devices based on criteria

Synopsis getdev [-ae] [*criteria*]\... [*device*]\...

Description getdev generates a list of devices that match certain criteria. The criteria includes a list of attributes (given in expressions) and a list of devices. If no criteria are given, all devices are included in the list.

Devices must satisfy at least one of the criteria in the list unless the -a option is used. Then, only those devices which match all of the criteria in a list will be included.

Devices which are defined on the command line and which match the criteria are included in the generated list. However, if the -e option is used, the list becomes a set of devices to be *excluded* from the list. See OPTIONS and OPERANDS.

Options The following options are supported:

- a Specifies that a device must match all criteria to be included in the list generated by this command. The option has no effect if no criteria are defined.
- e Specifies that the list of devices which follows on the command line should be *excluded* from the list generated by this command. Without the -e the named devices are *included* in the generated list. The flag has no effect if no devices are defined.

Operands The following operands are supported:

criteria Defines the criteria that a device must match to be included in the generated list. *criteria* is specified by expressions.

There are four possible expression types which the criteria specified in the *criteria* argument may follow:

- attribute=value* Selects all devices whose attribute *attribute* is defined and is equal to *value*.
- attribute!=value* Selects all devices whose attribute *attribute* is defined and does not equal *value*.
- attribute:** Selects all devices which have the attribute *attribute* defined.
- attribute! :** Selects all devices which do not have the attribute *attribute* defined.

See the [putdev\(1M\)](#) manual page for a complete listing and description of available attributes.

device Defines the devices which should be included in the generated list. This can be the pathname of the device or the device alias.

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 Command syntax was incorrect, invalid option was used, or an internal error occurred.
- 2 Device table could not be opened for reading.

Files /etc/device.tab

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [devattr\(1M\)](#), [getdgrp\(1M\)](#), [putdev\(1M\)](#), [putdgrp\(1M\)](#), [attributes\(5\)](#)

Name getdevpolicy – inspect the system's device policy

Synopsis /usr/sbin/getdevpolicy [*device...*]

Description Without arguments, `getdevpolicy` outputs the device policy in effect to standard output.

With arguments, each argument is treated as a pathname to a device and the device policy in effect for that specific device is printed preceeded by the supplied pathname.

Usage The device policy adds access restrictions over and above the file permissions.

Exit Status The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | See below |

The invocation is evolving. The output is unstable.

See Also [add_drv\(1M\)](#), [rem_drv\(1M\)](#), [update_drv\(1M\)](#), [attributes\(5\)](#), [privileges\(5\)](#), [devfs\(7FS\)](#)

Name getdgrp – lists device groups which contain devices that match criteria

Synopsis /usr/sbin/getdgrp [-a ϵ l] [*criteria*]... [*dgroup*]...

Description getdgrp generates a list of device groups that contain devices matching the given criteria. The criteria is given in the form of expressions.

Options The following options are supported:

- a Specifies that a device must match all criteria to be included in the list generated by this command. The option has no effect if no criteria are defined.
- e Specifies that the list of device groups on the command line should be *excluded* from the list generated by this command. Without the -e option the named device groups are *included* in the generated list. The flag has no effect if no devices are defined.
- l Specifies that all device groups (subject to the -e option and the *dgroup* list) should be listed even if they contain no valid device members. This option has no affect if *criteria* is specified on the command line.

Operands The following operands are supported:

criteria Defines criteria that a device must match before a device group to which it belongs can be included in the generated list. Specify *criteria* as an expression or a list of expressions which a device must meet for its group to be included in the list generated by getdgrp. If no criteria are given, all device groups are included in the list.

Devices must satisfy at least one of the criteria in the list. However, the -a option can be used to define that a "logical and" operation should be performed. Then, only those groups containing devices which match all of the criteria in a list will be included.

There are four possible expressions types which the criteria specified in the *criteria* argument may follow:

attribute=value Selects all device groups with a member whose attribute *attribute* is defined and is equal to *value*.

attribute!=value Selects all device groups with a member whose attribute *attribute* is defined and does not equal *value*.

*attribute:** Selects all device groups with a member which has the attribute *attribute* defined.

*attribute! :** Selects all device groups with a member which does not have the attribute *attribute* defined.

See [putdev\(1M\)](#) for a complete listing and description of available attributes.

dgroup Defines a set of device groups which should be included in or excluded from the generated list. Device groups that are defined and which contain devices matching the criteria are included.

If the `-e` option is used, this list defines a set of device groups to be excluded. When the `-e` option is used and *criteria* is also defined, the generated list will include device groups containing devices which match the criteria and are not in the command line list.

Exit Status The following exit values are returned:

- 0 Successful completion of the task.
- 1 Command syntax was incorrect, invalid option was used, or an internal error occurred.
- 2 Device table or device group table could not be opened for reading.

Files `/etc/device.tab`

`/etc/dgroup.tab`

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [devattr\(1M\)](#), [getdev\(1M\)](#), [putdev\(1M\)](#), [putdgrp\(1M\)](#), [attributes\(5\)](#)

Name getent – get entries from administrative database

Synopsis getent *database* [*key*]. . .

Description getent gets a list of entries from the administrative database specified by *database*. The information generally comes from one or more of the sources that are specified for the *database* in `/etc/nsswitch.conf`.

database is the name of the database to be examined. This can be `passwd`, `group`, `hosts`, `ipnodes`, `services`, `protocols`, `ethers`, `project`, `networks`, or `netmasks`. For each of these databases, getent uses the appropriate library routines described in [getpwnam\(3C\)](#), [getgrnam\(3C\)](#), [gethostbyaddr\(3NSL\)](#), [gethostbyname\(3NSL\)](#), [getipnodebyaddr\(3SOCKET\)](#), [getipnodebyname\(3SOCKET\)](#), [getservbyname\(3SOCKET\)](#), [getprotobyname\(3SOCKET\)](#), [ethers\(3SOCKET\)](#), [getprojbyname\(3PROJECT\)](#) and [getnetbyname\(3SOCKET\)](#), respectively.

Each *key* must be in a format appropriate for searching on the respective database. For example, it can be a *username* or *numeric-uid* for `passwd`; *hostname* or *IP address* for `hosts`; or *service*, *service/protocol*, *port*, or *port/proto* for `services`.

getent prints out the database entries that match each of the supplied keys, one per line, in the format of the matching administrative file: [passwd\(4\)](#), [group\(4\)](#), [project\(4\)](#), [hosts\(4\)](#), [services\(4\)](#), [protocols\(4\)](#), [ethers\(4\)](#), [networks\(4\)](#), or [netmasks\(4\)](#). If no key is given, all entries returned by the corresponding enumeration library routine, for example, `getpwent()` or `gethostent()`, are printed. Enumeration is not supported on `ipnodes`, `ethers`, and `netmasks`.

Key Interpretation for `passwd` and `group` Databases When getent is invoked with `database` set to `passwd`, each key value is processed as follows:

- If the key value consists only of numeric characters, getent assumes that the key value is a numeric user ID and searches the user database for a matching user ID.
- If the user ID is not found in the user database or if the key value contains any non-numeric characters, getent assumes the key value is a user name and searches the user database for a matching user name.

Similarly, when getent is invoked with `database` set to `group`, each key value is processed as follows:

- If the key value consists only of numeric characters, getent assumes that the key value is a numeric group ID and searches the group database for a matching group ID.
- If the group ID is not found in the group database or if the key value contains any non-numeric characters, getent assumes the key value is a group name and searches the group database for a matching group name.

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 Command syntax was incorrect, an invalid option was used, or an internal error occurred.
- 2 At least one of the specified entry names was not found in the database.
- 3 There is no support for enumeration on this database.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [ethers\(3SOCKET\)](#), [getgrnam\(3C\)](#), [gethostbyaddr\(3NSL\)](#), [gethostbyname\(3NSL\)](#), [gethostent\(3NSL\)](#), [getipnodebyaddr\(3SOCKET\)](#), [getipnodebyname\(3SOCKET\)](#), [getnetbyname\(3SOCKET\)](#), [getprojbyname\(3PROJECT\)](#), [getprotobyname\(3SOCKET\)](#), [getpwnam\(3C\)](#), [getservbyname\(3SOCKET\)](#), [ethers\(4\)](#), [group\(4\)](#), [hosts\(4\)](#), [netmasks\(4\)](#), [networks\(4\)](#), [nsswitch.conf\(4\)](#), [passwd\(4\)](#), [project\(4\)](#), [protocols\(4\)](#), [services\(4\)](#), [attributes\(5\)](#)

Name gettable – get DoD Internet format host table from a host

Synopsis /usr/sbin/gettable *host*

Description gettable is a simple program used to obtain the DoD Internet host table from a “hostname” server. The specified *host* is queried for the table. The table is placed in the file `hosts.txt`.

gettable operates by opening a TCP connection to the port indicated in the service specification for “hostname”. A request is then made for all names and the resultant information is placed in the output file.

gettable is best used in conjunction with the [htable\(1M\)](#) program which converts the DoD Internet host table format to that used by the network library lookup routines.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|--------------------|
| Availability | system/network/nis |

See Also [htable\(1M\)](#), [attributes\(5\)](#) Harrenstien, Ken, Mary Stahl, and Elizabeth Feinler, *HOSTNAME Server*, RFC 953, Network Information Center, SRI International, Menlo Park, California, October 1985.

Notes Should allow requests for only part of the database.

Name getty – set terminal type, modes, speed, and line discipline

Synopsis /usr/lib/saf/ttymon [-h] [-t *timeout*] *line*
 [*speed* [*type* [*linedisc*]]]
 /usr/lib/saf/ttymon -c *file*

Description getty sets terminal type, modes, speed, and line discipline. getty is a symbolic link to /usr/lib/saf/ttymon. It is included for compatibility with previous releases for the few applications that still call getty directly.

getty can only be executed by the super-user, (a process with the user ID root). Initially getty prints the login prompt, waits for the user's login name, and then invokes the login command. getty attempts to adapt the system to the terminal speed by using the options and arguments specified on the command line.

Without optional arguments, getty specifies the following: The *speed* of the interface is set to 300 baud, either parity is allowed, NEWLINE characters are converted to carriage return-line feed, and tab expansion is performed on the standard output. getty types the login prompt before reading the user's name a character at a time. If a null character (or framing error) is received, it is assumed to be the result of the user pressing the BREAK key. This will cause getty to attempt the next *speed* in the series. The series that getty tries is determined by what it finds in /etc/ttydefs .

Options The following options are supported:

- h If the -h flag is not set, a hangup will be forced by setting the speed to zero before setting the speed to the default or a specified speed.
- t *timeout* Specifies that getty should exit if the open on the line succeeds and no one types anything in *timeout* seconds.
- c *file* The -c option is no longer supported. Instead use /usr/sbin/sttydefs -l to list the contents of the /etc/ttydefs file and perform a validity check on the file.

Operands The following operands are supported:

- line* The name of a TTY line in /dev to which getty is to attach itself. getty uses this string as the name of a file in the /dev directory to open for reading and writing.
- speed* The *speed* argument is a label to a speed and TTY definition in the file /etc/ttydefs. This definition tells getty at what speed to run initially, what the initial TTY settings are, and what speed to try next, (should the user press the BREAK key to indicate that the speed is inappropriate). The default *speed* is 300 baud.
- type* and *linedisc* These options are obsolete and will be ignored.

Files /etc/ttydefs

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [ct\(1C\)](#), [login\(1\)](#), [sttydefs\(1M\)](#), [ttypmon\(1M\)](#), [ioctl\(2\)](#), [attributes\(5\)](#), [tty\(7D\)](#)

Name getvol – verifies device accessibility

Synopsis /usr/bin/getvol -n [-l *label*] *device*
/usr/bin/getvol [-f | -F] [-ow] [-l *label* | -x *label*] *device*

Description getvol verifies that the specified device is accessible and that a volume of the appropriate medium has been inserted. The command is interactive and displays instructional prompts, describes errors, and shows required label information.

Options The following options are supported:

- n Runs the command in non-interactive mode. The volume is assumed to be inserted upon command invocation.
- l *label* Specifies that the label *label* must exist on the inserted volume (can be overridden by the -o option).
- f Formats the volume after insertion, using the format command defined for this device in the device table.
- F Formats the volume after insertion and places a file system on the device. Also uses the format command defined for this device in the device table.
- o Allows the administrator to override a label check.
- w Allows administrator to write a new label on the device. User is prompted to supply the label text. This option is ineffective if the -n option is enabled.
- x *label* Specifies that the label *label* must exist on the device. This option should be used in place of the -l option when the label can only be verified by visual means. Use of the option causes a message to be displayed asking the administrator to visually verify that the label is indeed *label*.

Operands The following operands are supported:

device Specifies the device to be verified for accessibility.

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 Command syntax was incorrect, invalid option was used, or an internal error occurred.
- 3 Device table could not be opened for reading.

Files /etc/device.tab

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [attributes\(5\)](#)

Notes This command uses the device table to determine the characteristics of the device when performing the volume label checking.

Name gkadmin – Kerberos principals and policies administration GUI

Synopsis /usr/sbin/gkadmin

Description gkadmin is an interactive graphical user interface (GUI) that enables you to maintain Kerberos principals and policies. gkadmin provides much the same functionality as the [kadmin\(1M\)](#) command.

gkadmin does not support the management of keytabs. You must use [kadmin](#) for keytabs management. gkadmin uses Kerberos authentication and an encrypted RPC to operate securely from anywhere on the network.

When gkadmin is invoked, the login window is populated with default values. For the principal name, gkadmin determines your user name from the `USER` environment variable. It appends `/admin` to the name (`username/admin`) to create a default user instance in the same manner as [kadmin](#). It also selects appropriate defaults for realm and master KDC (`admin_server`) from the `/etc/krb5/krb5.conf` file.

You can change these defaults on the login window. When you enter your password, a session is started with `kadmin`. Operations performed are subject to permissions that are granted or denied to the chosen user instance by the Kerberos ACL file. See [kadm5.acl\(4\)](#).

After the session is started, a tabbed folder is displayed that contains a principal list and a policy list. The functionality is mainly the same as [kadmin](#), with addition, deletion, and modification of principal and policy data available.

gkadmin also includes an interface to specify principal key encryption types when modifying or creating principal records. The default set of encryption types is used if they are not selected through this interface. The default set of encryption types can be found in [krb5.conf\(4\)](#) under the `default_tkt_enctypes` section.

In addition, gkadmin provides the following features:

- New principal or policy records can be added either from default values or from the settings of an existing principal.
- A comment field is available for principals.
- Default values are saved in `$HOME/.gkadmin`.
- A logout option permits you to log back in as another user instance without exiting the tool.
- Principal and policy lists and attributes can be printed or saved to a file.
- Online context-sensitive help and general help is available in the `Help` menu.

Files /etc/krb5/krb5.conf Kerberos configuration information on a Kerberos client. Used to search for default realm and master KDC (`admin_server`), including a port number for the master KDC.

`$HOME/.gkadmin` Default parameters used to initialize new principals created during the session.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------------|
| Availability | system/security/kerberos-5 |
| Interface Stability | Committed |

See Also [kpasswd\(1\)](#), [kadmin\(1M\)](#), [kadmind\(1M\)](#), [kadmin.local\(1M\)](#), [kdb5_util\(1M\)](#), [kadm5.acl\(4\)](#), [kdc.conf\(4\)](#), [krb5.conf\(4\)](#), [attributes\(5\)](#), [kerberos\(5\)](#)

Diagnostics The `gkadmin` interface is currently incompatible with the MIT `kadmind` daemon interface, so you cannot use this interface to administer an MIT-based Kerberos database. However, clients running the Solaris implementation of Kerberos can still use an MIT-based KDC.

Name groupadd – add (create) a new group definition on the system

Synopsis /usr/sbin/groupadd [-g *gid* [-o]] *group*

Description The groupadd command creates a new group definition on the system by adding the appropriate entry to the /etc/group file.

Options The following options are supported:

- g *gid* Assigns the group id *gid* for the new group. This group id must be a non-negative decimal integer below MAXUID as defined in /usr/include/sys/param.h. The group ID defaults to the next available (unique) number above the highest number currently assigned. For example, if groups 100, 105, and 200 are assigned as groups, the next default group number is 201. (Group IDs from 0–99 are reserved by SunOS for future applications.)
- o Allows the *gid* to be duplicated (non-unique).

Operands The following operands are supported:

- group* A string consisting of characters from the set of lower case alphabetic characters and numeric characters. A warning message is written if the string exceeds MAXGLEN - 1, which is usually eight characters. The *group* field must contain at least one character; it accepts lower case or numeric characters or a combination of both, and must not contain a colon (:) or NEWLINE.

Exit Status The following exit values are returned:

- 0 Successful completion.
- 2 Invalid command syntax. A usage message for the groupadd command is displayed.
- 3 An invalid argument was provided to an option.
- 4 The *gid* is not unique (when -o option is not used).
- 9 The *group* is not unique.
- 10 The /etc/group file cannot be updated.

- Files**
- /etc/group
 - /usr/include/userdefs.h

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [users\(1B\)](#), [groupdel\(1M\)](#), [groupmod\(1M\)](#), [grpck\(1M\)](#), [logins\(1M\)](#), [pwck\(1M\)](#), [useradd\(1M\)](#), [userdel\(1M\)](#), [usermod\(1M\)](#), [group\(4\)](#), [attributes\(5\)](#)

Notes `groupadd` only adds a group definition to the local system. If a network name service such as NIS is being used to supplement the local `/etc/group` file with additional entries, `groupadd` cannot change information supplied by the network name service. However, `groupadd` verifies the uniqueness of group name and group ID against the external name service.

If the number of characters in a group entry exceeds 2047, group maintenance commands, such as [groupdel\(1M\)](#) and [groupmod\(1M\)](#), fail.

- Name** groupdel – delete a group definition from the system
- Synopsis** /usr/sbin/groupdel *group*
- Description** The groupdel utility deletes a group definition from the system. It deletes the appropriate entry from the /etc/group file.
- Operands** *group* An existing group name to be deleted.
- Exit Status** The following exit values are returned:
- 0 Success.
 - 2 Invalid command syntax. A usage message for the groupdel command is displayed.
 - 6 *group* does not exist.
 - 10 Cannot update the /etc/group file.
- Files** /etc/group system file containing group definitions
- Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [users\(1B\)](#), [groupadd\(1M\)](#), [groupmod\(1M\)](#), [logins\(1M\)](#), [useradd\(1M\)](#), [userdel\(1M\)](#), [usermod\(1M\)](#), [attributes\(5\)](#)

Notes The groupdel utility only deletes a group definition that is in the local /etc/group file. If a network nameservice such as NIS or NIS+ is being used to supplement the local /etc/group file with additional entries, groupdel cannot change information supplied by the network nameservice.

groupdel fails if a group entry (a single line in /etc/group) exceeds 2047 characters.

Name groupmod – modify a group definition on the system

Synopsis /usr/sbin/groupmod [-g *gid* [-o]] [-n *name*] *group*

Description The groupmod command modifies the definition of the specified group by modifying the appropriate entry in the /etc/group file.

Options The following options are supported:

- g *gid* Specify the new group ID for the group. This group ID must be a non-negative decimal integer less than MAXUID, as defined in <param.h>. The group ID defaults to the next available (unique) number above 99. (Group IDs from 0-99 are reserved by SunOS for future applications.)
- n *name* Specify the new name for the group. The *name* argument is a string of no more than eight bytes consisting of characters from the set of lower case alphabetic characters and numeric characters. A warning message will be written if these restrictions are not met. A future Solaris release may refuse to accept group fields that do not meet these requirements. The *name* argument must contain at least one character and must not include a colon (:) or NEWLINE (\n).
- o Allow the *gid* to be duplicated (non-unique).

Operands The following operands are supported:

group An existing group name to be modified.

Exit Status The groupmod utility exits with one of the following values:

- 0 Success.
- 2 Invalid command syntax. A usage message for the groupmod command is displayed.
- 3 An invalid argument was provided to an option.
- 4 *gid* is not unique (when the -o option is not used).
- 6 *group* does not exist.
- 9 *name* already exists as a group name.
- 10 Cannot update the /etc/group file.

Files /etc/group *group* file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also `users(1B)`, `groupadd(1M)`, `groupdel(1M)`, `logins(1M)`, `useradd(1M)`, `userdel(1M)`, `usermod(1M)`, `group(4)`, `attributes(5)`

Notes The `groupmod` utility only modifies group definitions in the `/etc/group` file. If a network name service such as NIS is being used to supplement the local `/etc/group` file with additional entries, `groupmod` cannot change information supplied by the network name service. The `groupmod` utility will, however, verify the uniqueness of group name and group ID against the external name service.

`groupmod` fails if a group entry (a single line in `/etc/group`) exceeds 2047 characters.

Name growfs – non-destructively expand a UFS file system

Synopsis /usr/sbin/growfs [-M *mount-point*] [*newfs-options*]
[*raw-device*]

Description growfs non-destructively expands a mounted or unmounted UNIX file system (UFS) to the size of the file system's slice(s).

Typically, disk space is expanded by first adding a slice to a metadvice, then running the growfs command. When adding space to a mirror, you expand each submirror before expanding the file system.

growfs will “write-lock” (see [lockfs\(1M\)](#)) a mounted file system when expanding. The length of time the file system is write-locked can be shortened by expanding the file system in stages. For instance, to expand a 1 Gbyte file system to 2 Gbytes, the file system can be grown in 16 Mbyte stages using the -s option to specify the total size of the new file system at each stage. The argument for -s is the number of sectors, and must be a multiple of the cylinder size. Note: The file system cannot be grown if a cylinder size of less than 2 is specified. Refer to the [newfs\(1M\)](#) man page for information on the options available when growing a file system.

growfs displays the same information as mkfs during the expansion of the file system.

If growfs is aborted, recover any lost free space by unmounting the file system and running the fsck command, or run the growfs command again.

Note: If growfs is aborted and the file system is used before fsck is run on it, UFS metadata might be left in an incomplete state, with the result that the file system would be corrupted. In such a circumstance, you would have to restore the file system from backups.

Options Root privileges are required for all of the following options.

-M mount-point The file system to be expanded is mounted on *mount-point*. File system locking (lockfs) will be used.

newfs-options The options are documented in the newfs man page.

raw-device Specifies the name of a raw metadvice or raw special device, residing in /dev/md/rdisk, or /dev/rdisk, respectively, including the disk slice, where you want the file system to be grown.

Examples EXAMPLE 1 Expanding nonmetadvice slice for /export file system

The following example expands a nonmetadvice slice for the /export file system. In this example, the existing slice, /dev/dsk/clt0d0s3, is converted to a metadvice so additional slices can be concatenated.

```
# metainit -f d8 2 1 clt0d0s3 1 c2t0d0s3
# umount /export
```

EXAMPLE 2 Associate /export with new metadvice

Edit the `/etc/vfstab` file to change the entry for `/export` to the newly defined metadvice, `d8`.

```
# mount /export
# growfs -M /export /dev/md/rdisk/d8
```

The first example starts by running the `metainit` command with the `-f` option to force the creation of a new concatenated metadvice `d8`, which consists of the existing slice `/dev/dsk/c1t0d0s3` and a new slice `/dev/dsk/c2t0d0s3`. Next, the file system on `/export` must be unmounted. The `/etc/vfstab` file is edited to change the entry for `/export` to the newly defined metadvice name, rather than the slice name. After the file system is remounted, the `growfs` command is run to expand the file system. The file system will span the entire metadvice when `growfs` completes. The `-M` option enables the `growfs` command to expand a mounted file system. During the expansion, write access for `/export` is suspended until `growfs` unlocks the file system. Read access is not affected, though access times are not kept when the lock is in effect.

EXAMPLE 3 Dynamic Expansion of /export file system

The following example picks up from the previous one. Here, the `/export` file system mounted on metadvice `d8` is dynamically expanded.

```
# metattach d8 c0t1d0s2
# growfs -M /export /dev/md/rdisk/d8
```

This example begins by using the `metattach` command to dynamically concatenate a new slice, `/dev/dsk/c0t1d0s2`, to the end of an existing metadvice, `d8`. Next, the `growfs` command specifies that the mount-point is `/export` and that it is to be expanded onto the raw metadvice `/dev/md/rdisk/d8`. The file system will span the entire metadvice when `growfs` completes. During the expansion, write access for `/export` is suspended until `growfs` unlocks the file system. Read access is not affected, though access times are not kept when the lock is in effect.

EXAMPLE 4 Expanding mounted file system to existing mirror

The following example expands a mounted file system `/files`, to an existing mirror, `d80`, which contains two submirrors, `d9` and `d10`.

```
# metattach d9 c0t2d0s5
# metattach d10 c0t3d0s5
# growfs -M /files /dev/md/rdisk/d80
```

In this example, the `metattach` command dynamically concatenates the new slices to each submirror. The `metattach` command must be run for each submirror. The mirror will automatically grow when the last submirror is dynamically concatenated. The mirror will grow to the size of the smallest submirror. The `growfs` command then expands the file system. The `growfs` command specifies that the mount-point is `/files` and that it is to be expanded

EXAMPLE 4 Expanding mounted file system to existing mirror (Continued)

onto the raw metadvice `/dev/md/rdisk/d80`. The file system will span the entire mirror when the `growfs` command completes. During the expansion, write access for the file system is suspended until `growfs` unlocks the file system. Read access is not affected, though access times are not kept when the lock is in effect.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | storage/svm |

Solaris Volume Manager Administration Guide

Limitations Only UFS file systems (either mounted or unmounted) can be expanded using the `growfs` command. Once a file system is expanded, it cannot be decreased in size. The following conditions prevent you from expanding file systems: When `acct` is activated and the accounting file is on the target device. When C2 security is activated and the logging file is on the target file system. When there is a local swap file in the target file system. When the file system is `root (/)`, `/usr`, or `swap`.

Name gsscred – add, remove, and list gsscred table entries

Synopsis gsscred [-n *user* [-o *oid*] [-u *uid*]] [-c *comment*] -m *mech* -a
 gsscred [-n *user* [-o *oid*]] [-u *uid*] [-m *mech*] -r
 gsscred [-n *user* [-o *oid*]] [-u *uid*] [-m *mech*] -l

Description The `gsscred` utility is used to create and maintain a mapping between a security principal name and a local UNIX *uid*. The format of the user name is assumed to be `GSS_C_NT_USER_NAME`. You can use the `-o` option to specify the object identifier of the *name* type. The OID must be specified in dot-separated notation, for example: 1.2.3.45464.3.1

The `gsscred` table is used on server machines to lookup the *uid* of incoming clients connected using `RPCSEC_GSS`.

When adding users, if no *user* name is specified, an entry is created in the table for each user from the `passwd` table. If no *comment* is specified, the `gsscred` utility inserts a comment that specifies the user name as an ASCII string and the GSS-API security mechanism that applies to it. The security mechanism will be in string representation as defined in the `/etc/gss/mech` file.

The parameters are interpreted the same way by the `gsscred` utility to delete users as they are to create users. At least one of the following options must be specified: `-n`, `-u`, or `-m`. If no security mechanism is specified, then all entries will be deleted for the user identified by either the *uid* or *user* name. If only the security mechanism is specified, then all *user* entries for that security mechanism will be deleted.

Again, the parameters are interpreted the same way by the `gsscred` utility to search for users as they are to create users. If no options are specified, then the entire table is returned. If the *user* name or *uid* is specified, then all entries for that *user* are returned. If a security mechanism is specified, then all *user* entries for that security mechanism are returned.

Options

- a Add a table entry.
- c *comment* Insert comment about this table entry.
- l Search table for entry.
- m *mech* Specify the mechanism for which this name is to be translated.
- n *user* Specify the optional principal name.
- o *oid* Specify the OID indicating the name type of the user.
- r Remove the entry from the table.
- u *uid* Specify the *uid* for the *user* if the *user* is not local.

Examples EXAMPLE 1 Creating a gsscred Table for the Kerberos v5 Security Mechanism

The following shows how to create a gsscred table for the kerberos v5 security mechanism. gsscred obtains *user* names and *uid*'s from the passwd table to populate the table.

```
example% gsscred -m kerberos_v5 -a
```

EXAMPLE 2 Adding an Entry for root/host1 for the Kerberos v5 Security Mechanism

The following shows how to add an entry for root/host1 with a specified *uid* of 0 for the kerberos v5 security mechanism.

```
example% gsscred -m kerberos_v5 -n root/host1 -u 0 -a
```

EXAMPLE 3 Listing All User Mappings for the Kerberos v5 Security Mechanism

The following lists all user mappings for the kerberos v5 security mechanism.

```
example% gsscred -m kerberos_v5 -l
```

EXAMPLE 4 Listing All Mappings for All Security Mechanism for a Specified User

The following lists all mappings for all security mechanisms for the user bsimpson.

```
example% gsscred -n bsimpson -l
```

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------------------|
| Availability | system/library/security/gss |
| Interface Stability | Committed |

See Also [gssd\(1M\)](#), [gsscred.conf\(4\)](#), [attributes\(5\)](#)

Notes Some GSS mechanisms, such as kerberos_v5, provide their own authenticated-name-to-local-name (uid) mapping and thus do not usually have to be mapped using gsscred. See [gsscred.conf\(4\)](#) for more information.

Name gssd – generates and validates GSS-API tokens for kernel RPC

Synopsis /usr/lib/gss/gssd

Description gssd is the user mode daemon that operates between the kernel rpc and the Generic Security Service Application Program Interface (GSS-API) to generate and validate GSS-API security tokens. In addition, gssd maps the GSS-API principal names to the local user and group ids. By default, all groups that the requested user belongs to will be included in the grouplist credential. gssd is invoked by the Internet daemon [inetd\(1M\)](#) the first time that the kernel RPC requests GSS-API services.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------------|
| Availability | system/kernel/security/gss |
| Interface Stability | Committed |

See Also [kill\(1\)](#), [pkill\(1\)](#), [svcs\(1\)](#), [inetadm\(1M\)](#), [inetd\(1M\)](#), [gsscred\(1M\)](#), [svcadm\(1M\)](#), [gsscred.conf\(4\)](#), [resolv.conf\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

RFC 2078

Notes The following signal has the specified effect when sent to the server process using the [kill\(1\)](#) command:

SIGHUP gssd rereads the [gsscred.conf\(4\)](#) options.

When one of the mechanisms being used is Kerberos, then the gssd process must be restarted after adding or changing the [resolv.conf\(4\)](#) file.

The gssd service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/rpc/gss:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). Responsibility for initiating and restarting this service is delegated to [inetd\(1M\)](#). Use [inetadm\(1M\)](#) to make configuration changes and to view configuration information for this service. The service's status can be queried using the [svcs\(1\)](#) command.

Name hald – daemon that supports hardware abstraction layer

Synopsis /usr/lib/hal/hald [--daemon={yes | no}] [--help] [--use-syslog] [--verbose={yes | no}] [--version]

Description The hald daemon supports the recognition of hardware changes for devices that conform to the Hardware Abstraction Layer (HAL) specification.

The enabling and disabling of hald can be performed through the service management facility (SMF) (see [smf\(5\)](#)). hald is managed using the fault management resource identifier (FMRI) svc:/system/hal. Options can be specified as SMF properties. See EXAMPLES.

Options The following options are supported:

- daemon Run as a daemon.
- help Display usage information and exit.
- use-syslog Display debug messages to syslog instead of stderr. Use this option to record debug messages if HAL runs as daemon.
- verbose Display debug information.
- version Display version information and exit.

Examples EXAMPLE 1 Specifying a Property

The following [svccfg\(1M\)](#) command specifies the --verbose option.

```
example# svccfg
svc:> select hal
svc:/system/hal> listprop hal/*
hal/verbose          boolean false
hal/use_syslog       boolean false
svc:/system/hal> setprop hal/verbose=true
svc:/system/hal> exit
```

Files /usr/lib/hal HAL-related files
 /etc/hal/fdi Device information files

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | service/hal |
| Interface Stability | Volatile |

See Also [svccfg\(1M\)](#), [attributes\(5\)](#), [hal\(5\)](#)

Name hal-device – manage HAL devices

Synopsis hal-device [-h] [--a *udi* | --r *udi*]

Description The Hardware Abstraction Layer (HAL) provides a view of the various hardware attached to a system. The `hal-device` command enables you to manage devices that conform to the HAL standard. Specifically, `hal-device` lets you add or remove a device to or from the HAL global device list. Device properties are read from stdin in `lshal(1M)` syntax.

Options The following options are supported:

- a, --add *udi* Add device specified by Universal Device Identifier *udi* to HAL's global device list.
- h Display usage information.
- r, --remove *udi* Remove device specified by Universal Device Identifier *udi* from HAL's global device list.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | service/hal |
| Interface Stability | Volatile |

See Also [hald\(1M\)](#), [attributes\(5\)](#), [hal\(5\)](#)

Name hal-fdi-validate – validate HAL device information files

Synopsis hal-fdi-validate [-f *dtd*] *file* [*file*]...

Description The hal-fdi-validate command validates one or more device information files. See [fdi\(4\)](#). The standard DTD file will be used unless the -f option is used to specify a different file.

Options The following option is supported:

-f *dtd* Specify path to a DTD file.

Operands The hal-fdi-validate command accepts the following operand(s):

file [*file*...] One or more DTD files to be validated.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | service/hal |
| Interface Stability | Volatile |

See Also [hal\(1M\)](#), [fdi\(4\)](#), [attributes\(5\)](#), [hal\(5\)](#)

Name hal-find, hal-find-by-capability, hal-find-by-property – search HAL global device list

Synopsis hal-find-by-capability --capability *capability* [--help]
 [--verbose] [--version]
 hal-find-by-property --key *key* --string *value* [--help]
 [--verbose] [--version]

Description The hal-find commands, hal-find-by-capability and hal-find-by-property, search the Hardware Abstraction Layer (HAL) device list by specified criteria and displays results on the standard output. hal-find-by-capability searches by capability, such as volume or block. hal-find-by-property searches by property, such as block.is_volume or volume.disc.has_audio.

Options The following options are supported:

--capability *capability* HAL device capability to search for.
 --help Display list of options.
 --key *key* The *key* to the property that is the basis of the search.
 --string *value* The string *value* associated with the property that is the basis of the search.
 --verbose Verbose mode.
 --version Display version and exit.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | service/hal |
| Interface Stability | Volatile |

See Also [hald\(1M\)](#), [attributes\(5\)](#), [hal\(5\)](#)

-
- Name** hal-get-property, hal-set-property – get and set HAL device properties
- Synopsis** hal-get-property --udi *udi* --key *key* [--help] [--verbose] [--version]
- hal-set-property --udi *udi* --key *key* {--int *value* | --uint64 *value* | --string *value* | --bool *value* | --strlist-pre *value* | --strlist-post *value* | --strlist-rem *value* | --double *value* | --remove *value*} [--help] [--version]
- Description** The Hardware Abstraction Layer (HAL) provides a view of the various hardware attached to a system. This view is updated dynamically as hardware configuration changes by means of hotplug or other mechanisms. HAL represents a piece of hardware as a device object. A device object is identified by a unique identifier and carries a set of key/value pairs, referred to as device properties. Some properties are derived from the actual hardware, some are merged from device information files (.fdi files), and some are related to the actual device configuration.
- The hal-get-property and hal-set-property commands allow you to get and set properties of hardware that conforms to HAL specifications.
- Options** The following options are supported:
- udi *udi*
Unique device ID.
 - key *key*
Key of the property to set.
 - int
Set value to an integer. Accepts decimal or hexadecimal value prefixed with 0x or x.
 - uint64
Set value to an integer. Accepts decimal or hexadecimal value prefixed with 0x or x.
 - string *value*
Set value to a string.
 - double *value*
Set value to a floating point number.
 - boolean *value*
Set value to a boolean, that is, true or false
 - strlist-pre *value*
Prepend a string to a list.
 - strlist-post *value*
Append a string to a list.
 - strlist-rem *value*
Remove a string from a list.

- remove *value*
Indicates that the property should be removed.
- version
Display version and exit.
- help
Display list of options and exit

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------------|----------------|
| Availability | service/hal |
| Interface Stability | Volatile |

See Also [hald\(1M\)](#), [attributes\(5\)](#), [hal\(5\)](#)

Name halt, poweroff – stop the processor

Synopsis /usr/sbin/halt [-dlnqy]
/usr/sbin/poweroff [-dlnqy]

Description The `halt` and `poweroff` utilities write any pending information to the disks and then stop the processor. The `poweroff` utility has the machine remove power, if possible.

The `halt` and `poweroff` utilities normally log the system shutdown to the system log daemon, [syslogd\(1M\)](#), and place a shutdown record in the login accounting file `/var/adm/wtmpx`. These actions are inhibited if the `-n` or `-q` options are present.

Options The following options are supported:

- d Force a system crash dump before rebooting. See [dumpadm\(1M\)](#) for information on configuring system crash dumps.
- l Suppress sending a message to the system log daemon, [syslogd\(1M\)](#), about who executed `halt`.
- n Prevent the [sync\(1M\)](#) before stopping.
- q Quick halt. No graceful shutdown is attempted.
- y Halt the system, even from a dialup terminal.

Files `/var/adm/wtmpx` History of user access and administration information.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [dumpadm\(1M\)](#), [init\(1M\)](#), [reboot\(1M\)](#), [shutdown\(1M\)](#), [sync\(1M\)](#), [syslogd\(1M\)](#), [inittab\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Notes The `halt` and `poweroff` utilities do not cleanly shutdown [smf\(5\)](#) services. Execute the scripts in `/etc/rcnum.d` or execute shutdown actions in [inittab\(4\)](#). To ensure a complete shutdown of system services, use [shutdown\(1M\)](#) or [init\(1M\)](#) to reboot a Solaris system.

Name hextoalabel – convert an internal text label to its human readable equivalent

Synopsis /usr/sbin/hextoalabel [*internal-text-sensitivity-label*]
/usr/sbin/hextoalabel -c [*internal-text-clearance*]

Description hextoalabel converts an internal text label into its human readable equivalent and writes the result to the standard output file. This internal form is often hexadecimal. If no option is supplied, the label is assumed to be a sensitivity label.

If no internal text label is specified, the label is read from the standard input file. The expected use of this command is emergency repair of labels that are stored in internal databases.

Options -c Identifies the internal text label as a clearance.

Exit Status The following exit values are returned:

- 0 On success.
- 1 On failure, and writes diagnostics to the standard error file.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | system/trusted |
| Interface Stability | See below. |

The command output is Committed for systems with the same `label_encodings` file. The command invocation is Committed for systems that implement the DIA MAC policy.

Files /etc/security/tsol/label_encodings
The label encodings file contains the classification names, words, constraints, and values for the defined labels of this system.

See Also [atohexlabel\(1M\)](#), [label_to_str\(3TSOL\)](#), [str_to_label\(3TSOL\)](#), [label_encodings\(4\)](#), [attributes\(5\)](#)

“How to Obtain a Readable Label From Its Hexadecimal Form” in *Oracle Solaris Trusted Extensions Configuration and Administration*

Notes The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

This file is part of the Defense Intelligence Agency (DIA) Mandatory Access Control (MAC) policy. This file might not be applicable to other MAC policies that might be developed for future releases of Solaris Trusted Extensions software.

Name host – DNS lookup utility

Synopsis host [-aCdilMrsTvw] [-c *class*] [-N *ndots*] [-R *number*]
[-t *type*] [-W *wait*] [-4 | -6] *name* [*server*]

Description The `host` utility performs simple DNS lookups. It is normally used to convert names to IP addresses and IP addresses to names. When no arguments or options are given, `host` prints a short summary of its command line arguments and options.

The *name* argument is the domain name that is to be looked up. It can also be a dotted-decimal IPv4 address or a colon-delimited IPv6 address, in which case `host` by default performs a reverse lookup for that address. The optional *server* argument is either the name or IP address of the name server that `host` should query instead of the server or servers listed in `/etc/resolv.conf`.

Options The following options are supported:

-4

Use only IPv4 transport. By default, both IPv4 and IPv6 transports can be used. Options -4 and -6 are mutually exclusive.

-6

Use only IPv6 transport. By default, both IPv4 and IPv6 transports can be used. Options -4 and -6 are mutually exclusive.

-a

Equivalent to setting the -v option and asking `host` to make a query of type ANY.

-c *class*

Make a DNS query of class *class*. This can be used to lookup Hesiod or Chaosnet class resource records. The default class is IN (Internet).

-C

Attempt to display the SOA records for zone *name* from all the listed authoritative name servers for that zone. The list of name servers is defined by the NS records that are found for the zone.

-d

Generate verbose output. This option is equivalent to -v. These two options are provided for backward compatibility. In previous versions, the -d option switched on debugging traces and -v enabled verbose output.

-i

Specifies that reverse lookups of IPv6 addresses should use the IP6.INT domain as defined in RFC 1886. The default is to use RFC 3152 domain IP6.ARPA.

- l
List mode. This option makes `host` perform a zone transfer for zone *name*, displaying the NS, PTR and address records (A/AAAA). If combined with `-a`, all records will be displayed. The argument is provided for compatibility with previous implementations. Options `-la` is equivalent to making a query of type AXFR.
- m
Sets the memory usage debugging flags: record, usage, and trace.
- N *ndots*
Set the number of dots that have to be in *name* for it to be considered absolute. The default value is that defined using the `ndots` statement in `/etc/resolv.conf`, or 1 if no `ndots` statement is present. Names with fewer dots are interpreted as relative names and will be searched for in the domains listed in the `search` or `domain` directive in `/etc/resolv.conf`.
- r
Make a non-recursive query. Setting this option clears the RD (recursion desired) bit in the query made by `host`. The name server receiving the query does not attempt to resolve *name*. The `-r` option enables `host` to mimic the behaviour of a name server by making non-recursive queries and expecting to receive answers to those queries that are usually referrals to other name servers.
- R *number*
Change the number of UDP retries for a lookup. The *number* argument indicates how many times `host` will repeat a query that does not get answered. The default number of retries is 1. If *number* is negative or zero, the number of retries will default to 1.
- s
Specifies that the host not send the query to the next name server if any server responds with a SERVFAIL response, which is the reverse of normal stub resolver behavior.
- t *type*
Select the query type. The *type* argument can be any recognised query type: CNAME, NS, SOA, SIG, KEY, and AXFR, among others. When no query type is specified, `host` automatically selects an appropriate query type. By default it looks for A, AAAA, and MX records, but if the `-C` option is specified, queries are made for SOA records. If *name* is a dotted-decimal IPv4 address or colon-delimited IPv6 address, `host` queries for PTR records.

If a query type of IXFR is chosen the starting serial number can be specified by appending an equal followed by the starting serial number (for example: `-t IXFR=12345678`).
- T
Use a TCP connection when querying the name server. TCP is automatically selected for queries that require it, such as zone transfer (AXFR) requests. By default `host` uses UDP when making queries.
- v
Generate verbose output. This option is equivalent to `-d`.

-w

Wait forever for a reply. The time to wait for a response will be set to the number of seconds given by the hardware's maximum value for an integer quantity.

-W *wait*

Wait for *wait* seconds for a reply. If *wait* is less than one, the wait interval is set to one second.

Files /etc/resolv.conf

Name hostconfig – configure a system's host parameters

Synopsis /usr/sbin/hostconfig -p *protocol* [-d] [-h] [-n] [-v]
[-i *interface*] [-f *hostname*]

Description The hostconfig program uses a network protocol to acquire a machine's *host parameters* and set these parameters on the system.

The program selects which protocol to use based on the argument to the required -p flag. Different protocols may set different host parameters. Currently, only one protocol (bootparams) is defined.

Options The following options are supported:

- d Enable debug output.
- f *hostname* Run the protocol as if this machine were named *hostname*.
- h Echo the received *hostname* to stdout, rather than setting *hostname* using the system name directly.
- i *interface* Use only the named network interface to run the protocol.
- n Run the network protocol, but do not set the acquired parameters into the system.
- p *protocol* Run hostconfig using *protocol*. Currently, only one protocol (bootparams) is available. This option is required.

Specifying the -p bootparams option uses the whoami call of the RPC bootparams protocol. This sets the system's *hostname*, *domainname*, and default IP router parameters.
- v Enable verbose output.

Examples EXAMPLE 1 Configuring Host Parameters with Verbose Output

The following command configures a machine's host parameters using the whoami call of the RPC bootparams protocol with a verbose output.

```
example# hostconfig -p bootparams -v
```

EXAMPLE 2 Displaying Host Parameters

The following command displays the parameters that would be set using the whoami call of the RPC bootparams protocol.

```
example# hostconfig -p bootparams -n -v
```

EXAMPLE 3 Configuring Host Parameters Less the System Name

The following command configures a machine's host parameters, less the system name, using the `whoami` call of the RPC `bootparams` protocol.

```
example# hostconfig='hostconfig -p bootparams -h'
```

Name hotplug – configure hotplug connectors and ports

Synopsis hotplug list [-l] [-v] [*path* [*connection*]]

hotplug online *path port*

hotplug offline [-f] [-q] *path port*

hotplug enable *path connector*

hotplug disable [-f] [-q] *path connector*

hotplug poweron *path connector*

hotplug poweroff [-f] [-q] *path connector*

hotplug set -o *options path connector*

hotplug get -o *options path connector*

hotplug -?

Description The hotplug command is used to manage hotplug connections. A connection can be a connector or port. A hotplug connector is a representation of a physical point in the system where components can be inserted or removed. A hotplug port is a representation of a logical point in the system device tree where the connection of a device to the system is managed.

The hotplug command only supports hotplug operations on hotplug connectors for PCI Express buses and PCI buses that implement the Standard PCI Hotplug feature. Hotplug ports on PCI Express and PCI buses in systems with PCI Express fabrics are also supported. Additional buses may be supported in the future.

The hotplug command operates on the following kinds of objects:

path

Hotplug connectors and ports are integrated into the Solaris device tree. The names of connectors and ports are unique relative only to their bus controller. A device path is required to uniquely reference a connector or port.

connector

If a hardware component supports being physically inserted or removed, then a hotplug connector represents the location where this action may occur. When a connector exists, it has a hierarchy of ports and device nodes that depend upon it.

port

All device nodes can be virtually hotplugged, even if their hardware does not support physical hotplugging. A hotplug port exists between a device node and its parent node in the system device tree. It represents the location where the device node and its dependents can be managed.

connection

A hotplug connection is a generic term to refer to either a hotplug connector or a hotplug port.

Hotplug connectors and ports are managed according to a state model. The `hotplug` command can list information about the hotplug connections in a system, or it can initiate change of state operations on specific hotplug connections.

Hotplug connectors can be in the following states:

`empty`

A component is not physically inserted in the connector.

`present`

A component is physically inserted in the connector, but the component is powered off. The component is not in use.

`powered`

A component is physically inserted in the connector, and the component is powered on. The component is disabled and is not in use.

`enabled`

A component is physically inserted in the connector. The component is powered on and has been probed and tested. The component is enabled and devices that represent its functions can be used.

Hotplug ports can be in the following states:

`port-empty`

No device exists for the hotplug port.

`port-present`

A device exists for the hotplug port, but the device has not been probed and it has no attached device driver. The device is not in use.

`offline`

A device exists for the hotplug port, and the device has been probed. A device driver is not attached, and the device is not in use.

`online`

A device exists for the hotplug port, and its device driver is fully attached. The device is in use.

`maintenance`

A device exists for the hotplug port, and its device driver is fully attached. The device is in use, but not fully operational. A maintenance or fault management operation is affecting the device.

The `hotplug` command can also access bus private properties for each hotplug connector. The current values of bus private properties can be displayed. New values for each bus private property can be set directly.

Sub-commands The following subcommands are supported:

list

Show information for hotplug connectors, ports, and their associated devices. Hotplug connectors and hotplug ports are integrated into the Solaris device tree hierarchy. The `list` subcommand therefore displays the hierarchy of device nodes with additional information included to show the locations of hotplug connectors and hotplug ports. The names of hotplug connectors are enclosed in square brackets, and the names of hotplug ports are enclosed in angled brackets. The current state of each hotplug connection is displayed next to its name.

online

Change the state of a hotplug port to the `online` state.

offline

Change the state of a hotplug port to the `offline` state.

enable

Change the state of a hotplug connector to the `enabled` state. All of the hotplug connector's dependent ports will be automatically probed and initialized into the `online` state.

disable

Change the state of a hotplug connector from the `enabled` state to the `powered` state. All dependent ports that are in the `online` state will first be transitioned to the `port-present` state.

poweron

Change the state of a hotplug connector from the `present` state to the `powered` state.

poweroff

Change the state of a hotplug connector from the `powered` or `enabled` state to the `present` state. All dependent ports that are in the `online` state will first be transitioned to the `port-present` state, and will then be removed.

set

Set bus-specific properties for a hotplug connector. The specified option string is a bus specific string of name and value pairs, as could be parsed by `getsubopt(3C)`. The names and values will be passed directly to the bus controller that manages the specified hotplug connector to perform a bus-specific function.

get

Display the current values of bus specific properties for a hotplug connector. The specified option string is a bus specific string of named properties, as could be parsed by `getsubopt(3C)`. The names will be passed directly to the bus controller to specify which properties should be returned. The current values of each named property will then be displayed.

Options The following options are supported:

`-l, --list-path`

Show full paths to connections and device nodes. By default, the `list` subcommand shows hotplug connectors, ports, and devices in the format of a tree. This option enables the display of full paths to each connection and device node.

`-v, --verbose`

Show verbose usage details. By default, the `list` subcommand shows only hotplug connectors, ports, and devices. This option enables the display of more detailed information about how the devices are currently consumed. Examples include mounted filesystems or plumbed network interfaces associated with individual devices.

Note that the `-v` option does not display information for disks under ZFS control.

`-f, --force`

Force the operation. Some change state operations that impact resources currently in use will fail with a warning. A forced operation will attempt to ignore these warnings and proceed.

This option should be used with extreme caution.

`-q, --query`

Query the operation. Instead of actually performing a change state operation, perform a test to predict if the operation would succeed or fail. If it would fail, show the error messages that would be expected if the operation had really been attempted.

It is not possible to predict every failure. An operation that succeeds during a query could still fail for another reason when actually attempted.

This option will not actually change the state of the system.

`-o options, --=options`

Specify bus-specific properties for a `set` or `get` command. The options string conforms to the [getsubopt\(3C\)](#) syntax convention.

For the `get` subcommand, there are two special options that can be used. The special options value of `help` will display all supported properties and their possible values. The special options value of `all` will display the current value of all supported properties.

For the `set` subcommand, there is one special option that can be used. The special options value of `help` will display all supported properties which can be set and their possible values.

See “Notes” section for the properties supported by bus controllers.

`-, --help`

Display a brief help message on proper use of the command.

Examples EXAMPLE 1 Showing All Hotplug Connections

The following command shows all hotplug connections:

```
# hotplug list -v
pci@0,0
  <pci.2,1> (ONLINE)
    pci108e,534a@2,1
      [pci30] (EMPTY)
  <pci.e,0> (ONLINE)
    pci10de,5d@e
      <pci.b,0> (ONLINE)
        display@b
          [NEM0] (ENABLED)
      <pci.a,0> (ONLINE)
        pci108e,534a@a,0
          { Network interface nge0 }
          { nge0: hosts IP addresses: 10.0.0.1 }
      <pci.a,1> (MAINTENANCE)
        pci108e,534a@a,1
          [NEM1] (EMPTY)
  <pci.c,0> (OFFLINE)
    pci108e,534a@4
```

To show the full paths of hotplug connections and devices, enter the following command:

```
# hotplug list -l
/pci@0,0 <pci.2,1> (ONLINE)
/pci@0,0/pci108e,534a@2,1 [pci30] (EMPTY)
/pci@0,0 pci.e,0> (ONLINE)
/pci@0,0/pci10de,5d@e <pci.b,0> (ONLINE)
/pci@0,0/pci10de,5d@e/display@b
/pci@0,0/pci10de,5d@e [NEM0] (ENABLED)
/pci@0,0/pci10de,5d@e <pci.a,0> (ONLINE)
/pci@0,0/pci10de,5d@e/pci108e,534a@a,0
/pci@0,0/pci10de,5d@e <pci.a,1> (MAINTENANCE)
/pci@0,0/pci10de,5d@e/pci108e,534a@a,0
/pci@0,0/pci10de,5d@e [NEM1] (EMPTY)
/pci@0,0 pci.c,0> (OFFLINE)
/pci@0,0/pci108e,534a@4
```

EXAMPLE 2 Reporting Failure During State Change Operation

If a change of state operation fails, an explanation is displayed to describe the failure. An attempt to offline a hotplug port with dependent devices that are currently in use by the system might fail as follows:

```
# hotplug offline /pci@0,0/pci10de,5d@e pci.a,0
ERROR: devices or resources are busy.
pci108e,534a@a,0:
```

EXAMPLE 2 Reporting Failure During State Change Operation *(Continued)*

```
{ Network interface nge0 }
{ nge0: hosts IP addresses: 10.0.0.1 }
{ Plumbed IP Address }
```

EXAMPLE 3 Displaying Bus-Specific Properties and Values

The following command displays all supported bus-specific properties and their possible values:

```
# hotplug get -o help /pci@0,0 pci.2,1
power_led=<on|off|blink>
fault_led=<on|off|blink>
active_led=<on|off|blink>
attn_led=<on|off|blink>
card_type=<type description>
board_type=<type description>
```

EXAMPLE 4 Displaying Bus-Specific Options

The following command displays the card type and the current state of the Power LED of a PCI hotplug connector:

```
# hotplug get -o card_type,power_led /pci@0,0 pci.2,1
card_type=fibre
power_led=on
```

EXAMPLE 5 Setting a Bus-Specific Property

The following command turns on the attention LED of a PCI hotplug connector:

```
# hotplug set -o attn_led=on /pci@0,0 pci.2,1
```

- Exit Status**
- 0 Successful completion.
 - 1 Invalid command line options were specified.
 - 2 The specified path or connection does not exist.
 - 3 A fatal error occurred. One or more error messages are displayed on standard error.
 - 4 The hotplug service is not available.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | Committed |

See Also [cfgadm\(1M\)](#), [hotplugd\(1M\)](#), [getsubopt\(3C\)](#), [attributes\(5\)](#)

Diagnostics The following error message is displayed on systems that do not have any supported I/O buses:

```
ERROR: there are no connections to display.
(See hotplug(1m) for more information.)
```

If this error message is seen, note that the system might still have other I/O devices that support hotplugging, through the [cfgadm\(1M\)](#) command instead of `hotplug`.

Notes The `hotplug` service (FMRI `svc:/system/hotplug`) must be enabled as a prerequisite for using the `hotplug` command. The service is disabled by default. See [hotplugd\(1M\)](#).

The authorization `solaris.hotplug.modify` must be granted in order to perform change-of-state operations. Alternatively, the rights profile “Hotplug Management” can be granted, which includes that authorization.

Verbose usage information is gathered from the RCM framework. Its format and content is subject to change.

The following bus specific properties are supported in PCI bus controllers:

`power_led` | `fault_led` | `attn_led` | `active_led`

States of a specific LED of a slot. The value could be `on`, `off`, or `blink`.

They can all be used with `get` subcommand, but only property `attn_led` can be used with `set` subcommand.

`card_type` | `board_type`

Type of a card or board of a slot.

They can all be used with `get` subcommand, but neither can be used with `set` subcommand.

-
- Name** hotplugd – hotplug daemon
- Synopsis** /usr/lib/hotplugd [-d]
- Description** The hotplug daemon, hotplugd, provides user-level services for the management of hotplug connections. It is a system daemon started by the Service Management Facility (see [smf\(5\)](#)). Its fault management resource identifier (FMRI) is:
- ```
svc:/system/hotplug:default
```
- Note that hotplugd is a Consolidation Private interface. See [attributes\(5\)](#).
- The [hotplug\(1M\)](#) command and any other client program that uses the private libhotplug library to query information about hotplug connections or initiate hotplug commands depends upon this daemon. The hotplug daemon is a door server which services requests from all libhotplug clients. The door interface is private.
- Client applications use the private libhotplug interface to administer hotplug connections. libhotplug uses the door interface to administer hotplug connections through the hotplug daemon service. The hotplug daemon acts as a central location to serialize all hotplug operations and coordinate activities with all other parts of the system.
- Options** The following option is supported:
- d, --debug  
Run the daemon in standalone debug mode. Messages will be displayed on the controlling terminal instead of to syslog. And increased verbosity will be enabled to display more details about the internal operations of the daemon.
- Examples**
- EXAMPLE 1** Enabling the Hotplug Service
- The following command enables the hotplug service:
- ```
# svcadm enable svc:/system/hotplug:default
```
- EXAMPLE 2** Disabling the Hotplug Service
- The following command disables the hotplug service:
- ```
svcadm disable svc:/system/hotplug:default
```
- Errors** The hotplug daemon uses [syslog\(3C\)](#) to report status and error messages. All of the messages are logged with the LOG\_DAEMON facility. Error messages are logged with the LOG\_ERR and LOG\_NOTICE priorities, and informational messages are logged with the LOG\_INFO priority. The default entries in the /etc/syslog.conf file log all of the hotplug daemon error messages to the /var/adm/messages log.
- Files**
- /var/run/hotplugd\_door  
Hotplug daemon door
  - /var/run/hotplugd\_pid  
Hotplug daemon lock file

`/usr/lib/hotplugd`  
Hotplug daemon binary

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs, SUNWcs
Interface Stability	Consolidation Private

**See Also** [svcs\(1\)](#), [hotplug\(1M\)](#), [svcadm\(1M\)](#), [syslog\(3C\)](#), [syslog.conf\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

**Notes** The `hotplugd` service is managed by the service management facility, [smf\(5\)](#), under the fault management resource identifier (FMRI):

```
svc:/system/hotplug:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command. To administer the service, the authorization `solaris.smf.manage.hotplug` must be granted. Alternatively, the rights profile “Hotplug Management” can be granted.

The `hotplug` service must be enabled for the [hotplug\(1M\)](#) command and any other `libhotplug` client applications to function properly.

**Name** htable – convert DoD Internet format host table

**Synopsis** /usr/sbin/htable *filename*

**Description** htable converts a host table in the format specified by RFC 952 to the format used by the network library routines. Three files are created as a result of running htable: hosts, networks, and gateways. The hosts file is used by the [gethostbyname\(3NSL\)](#) routines in mapping host names to addresses. The networks file is used by the [getnetbyname\(3SOCKET\)](#) routines in mapping network names to numbers. The gateways file is used by the routing daemon to identify “passive” Internet gateways.

If any of the files localhosts, localnetworks, or localgateways are present in the current directory, the file's contents is prepended to the output file without interpretation. This allows sites to maintain local aliases and entries which are not normally present in the master database.

htable is best used in conjunction with the [gettable\(1M\)](#) program which retrieves the DoD Internet host table from a host.

**Files** localhosts

localnetworks

localgateways

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/nis

**See Also** [gettable\(1M\)](#), [gethostbyname\(3NSL\)](#), [getnetbyname\(3SOCKET\)](#), [attributes\(5\)](#)  
Harrenstien, Ken, Mary Stahl, and Elizabeth Feinler, *DoD Internet Host Table Specification*, RFC 952, Network Information Center, SRI International, Menlo Park, California, October 1985.

**Notes** htable does not properly calculate the gateways file.

**Name** ickey – install a client key for WAN boot

**Synopsis** /usr/lib/inet/wanboot/ickey [-d] [-o type=3des]  
 /usr/lib/inet/wanboot/ickey [-d] [-o type=aes]  
 /usr/lib/inet/wanboot/ickey [-d] [-o type=sha1]

**Description** The `ickey` command is used to install WAN boot keys on a running UNIX system so that they can be used the next time the system is installed. You can store three different types of keys: 3DES and AES for encryption and an HMAC SHA-1 key for hashed verification.

`ickey` reads the key from standard input using [getpass\(3C\)](#) so that it does not appear on the command line. When installing keys on a remote system, you must take proper precautions to ensure that any keying materials are kept confidential. At a minimum, use [ssh\(1\)](#) to prevent interception of data in transit.

Keys are expected to be presented as strings of hexadecimal digits; they can (but need not) be preceded by a `0x` or `0X`.

The `ickey` command has a single option, described below. An argument of the type `-o type=keytype` is required.

**Options** The `ickey` command the following option.

`-d` Delete the key specified by the *keytype* argument.

**Exit Status** On success, `ickey` exits with status 0; if a problem occurs, a diagnostic message is printed and `ickey` exits with non-zero status.

**Files** /dev/openprom WAN boot key storage driver

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/boot/wanboot
Interface Stability	Uncommitted

**Name** id – return user identity

**Synopsis** /usr/bin/id [-p] [*user*]  
 /usr/bin/id -a [-p] [*user*]  
 /usr/bin/id -G [-n] [*user*]  
 /usr/bin/id -g [-nr] [*user*]  
 /usr/bin/id -u [-nr] [*user*]  
 /usr/xpg4/bin/id [-p] [*user*]  
 /usr/xpg4/bin/id -a [-p] [*user*]  
 /usr/xpg4/bin/id -G [-n] [*user*]  
 /usr/xpg4/bin/id -g [-nr] [*user*]  
 /usr/xpg4/bin/id -u [-nr] [*user*]

**Description** If no *user* operand is provided, the *id* utility writes the user and group IDs and the corresponding user and group names of the invoking process to standard output. If the effective and real IDs do not match, both are written. If multiple groups are supported by the underlying system, /usr/xpg4/bin/*id* also writes the supplementary group affiliations of the invoking process.

If a *user* operand is provided and the process has the appropriate privileges, the user and group IDs of the selected user are written. In this case, effective IDs are assumed to be identical to real IDs. If the selected user has more than one allowable group membership listed in the group database, /usr/xpg4/bin/*id* writes them in the same manner as the supplementary groups described in the preceding paragraph.

**Formats** The following formats are used when the LC\_MESSAGES locale category specifies the "C" locale. In other locales, the strings *uid*, *gid*, *eid*, *egid*, and *groups* may be replaced with more appropriate strings corresponding to the locale.

```
"uid=%u(%s) gid=%u(%s)\n" <real user ID>, <user-name>,
 <real group ID>, <group-name>
```

If the effective and real user IDs do not match, the following are inserted immediately before the \n character in the previous format:

```
" eid=%u(%s)"
```

with the following arguments added at the end of the argument list:

```
<effective user ID>, <effective user-name>
```

If the effective and real group IDs do not match, the following is inserted directly before the \n character in the format string (and after any addition resulting from the effective and real user IDs not matching):

```
" egid=%u(%s)"
```

with the following arguments added at the end of the argument list:

*<effectivegroup-ID>*, *<effectivegroupname>*

If the process has supplementary group affiliations or the selected user is allowed to belong to multiple groups, the first is added directly before the NEWLINE character in the format string:

" groups=%u(%s) "

with the following arguments added at the end of the argument list:

*<supplementary group ID>*, *<supplementary group name>*

and the necessary number of the following added after that for any remaining supplementary group IDs:

",%u(%s) "

and the necessary number of the following arguments added at the end of the argument list:

*<supplementary group ID>*, *<supplementary group name>*

If any of the user ID, group ID, effective user ID, effective group ID or supplementary/multiple group IDs cannot be mapped by the system into printable user or group names, the corresponding (%s) and name argument is omitted from the corresponding format string.

When any of the options are specified, the output format is as described under OPTIONS.

**Options** The following options are supported by both `/usr/bin/id` and `/usr/xpg4/bin/id`. The `-p` and `-a` options are invalid if specified with any of the `-G`, `-g`, or `-u` options.

`-p` Reports additionally the current project membership of the invoking process. The project is reported using the format:

"projid=%u(%s) "

which is inserted prior to the `\n` character of the default format described in the `Formats` section. The arguments

*<project ID>*, *<project name>*

are appended to the end of the argument list. If the project ID cannot be mapped by the system into a printable project name, the corresponding (%s) and name argument is omitted from the corresponding format string.

`-a` Reports user name, user ID and all the groups to which the user belongs.

`-G` Outputs all different group IDs (effective, real and supplementary) only, using the format "%u\n". If there is more than one distinct group affiliation, output each such affiliation, using the format "%u", before the NEWLINE character is output.

`-g` Outputs only the effective group ID, using the format "%u\n".

`-n` Outputs the name in the format "%s" instead of the numeric ID using the format "%u".

- r Outputs the real ID instead of the effective ID.
- u Outputs only the effective user ID, using the format "%u\n".

**Operands** The following operand is supported:

*user* The user (login) name for which information is to be written.

**Environment Variables** See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `id`: LANG, LC\_ALL, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

/usr/bin/id	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	SUNWcs, system/library/processor
	Interface Stability	Committed

/usr/xpg4/bin/id	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	SUNWxcu4
	Interface Stability	Standard

**See Also** [fold\(1\)](#), [logname\(1\)](#), [who\(1\)](#), [getgid\(2\)](#), [getgroups\(2\)](#), [getprojid\(2\)](#), [getuid\(2\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

**Notes** Output produced by the `-G` option and by the default case could potentially produce very long lines on systems that support large numbers of supplementary groups.

**Name** idmap – configure and manage the Native Identity Mapping service

**Synopsis** idmap

```
idmap -f command-file
idmap add [-d] name1 name2
idmap dump [-n] [-v]
idmap export [-f file] format
idmap flush [-a]
idmap get-namemap name
idmap help
idmap import [-F] [-f file] format
idmap list
idmap remove [-t|-f] name
idmap remove -a
idmap remove [-d] name1 name2
idmap set-namemap [-a authenticationMethod] [-D bindDN]
 [-j passwdfile] name1 name2
idmap show [-c] [-v] [-V] identity [target-type]
idmap unset-namemap [-a authenticationMethod] [-D bindDN]
 [-j passwdfile] name [target-type]
```

**Description** The idmap utility is used to configure and manage the Native Identity Mapping service.

The Native Identity Mapping service supports the following types of mappings between Windows security identities (SIDs) and POSIX user IDs and group IDs (UIDs and GIDs):

- **Name-based mapping.** An administrator maps Windows and UNIX users and groups by name.
- **Ephemeral ID mapping.** A UID or GID is dynamically allocated for every SID that is not already mapped by name.
- **Local-SID mapping.** A non-ephemeral UID or GID is mapped to an algorithmically generated local SID.

The idmap utility can be used to create and manage the name-based mappings and to monitor the mappings in effect.

If the idmap utility is invoked without a subcommand or option, it reads the subcommands from standard input. When standard input is a TTY, the idmap command prints the usage message and exits.

Mapping Mechanisms The `idmapd(1M)` daemon maps Windows user and group SIDs to UNIX UIDs and GIDs as follows:

1. SIDs are mapped by name.

This mapping uses the name-based mappings that are manually set up by the system administrator.

2. If no name-based mapping is found, the SID is mapped to a dynamically allocated ephemeral ID.

This allocation uses the next available UID or GID from  $2^{31}$  to  $2^{32} - 2$ .

Local SID mappings are used to map from UNIX to Windows.

To prevent aliasing problems, all file systems, archive and backup formats, and protocols must store SIDs or map all UIDs and GIDs in the  $2^{31}$  to  $2^{32} - 2$  range to the nobody user and group.

It is possible to create also diagonal mappings. They are the mappings between Windows groups and Solaris users and between Solaris groups and Windows users. They are needed when Windows uses a group identity as a file owner or vice versa.

Name-based Mappings Name-based mappings establish name equivalence between Windows users and groups and their counterparts in the UNIX name service. These mappings persist across reboots. For example, the following command maps Windows users to UNIX users with the same name:

```
idmap add "winuser:*@mywindomain.com" "unixuser:*"
```

If configured to use a directory service, `idmapd(1M)` will first try to use the mapping information that is stored in user or group objects in the Active Directory (AD) and/or the native LDAP directory service. For example, an AD object for a given Windows user or group can be augmented to include the corresponding Solaris user or group name or numeric id. Similarly, the native LDAP object for a given Solaris user or group can be augmented to include the corresponding Windows user or group name.

`idmapd(1M)` can be configured to use AD and/or native LDAP directory-based name mappings by setting the appropriate service management facility (SMF) properties of the `idmap` service. See “Service Properties,” below, for more details.

If directory-based name mapping is not configured or if configured but not found, then `idmapd(1M)` will process locally stored name-based mapping rules.

`idmap` supports the mapping of Windows well-known names. A few of these are listed below:

```
Administrator
Guest
KRBTGT
Domain Admins
Domain Users
Domain Guest
Domain Computers
Domain Controllers
```

When `idmap` rules are added, these well-known names will be expanded to canonical form. That is, either the default domain name will be added (for names that are not well-known) or an appropriate built-in domain name will be added. Depending on the particular well-known name, this domain name might be null, `BUILTIN`, or the local host name.

The following sequence of `idmap` commands illustrate the treatment of the non-well-known name `fred` and the well-known names `administrator` and `guest`.

```
idmap add winname:fred unixuser:fredf
add winname:fred unixuser:fredf

idmap add winname:administrator unixuser:root
add winname:administrator unixuser:root

idmap add winname:guest unixuser:nobody
add winname:guest unixuser:nobody

idmap add wingroup:administrators sysadmin
add wingroup:administrators unixgroup:sysadmin

idmap list
add winname:Administrator@examplehost unixuser:root
add winname:Guest@examplehost unixuser:nobody
add wingroup:Administrators@BUILTIN unixgroup:sysadmin
add winname:fred@example.com unixuser:fredf
```

**Ephemeral Mappings** The `idmapd` daemon attempts to preserve ephemeral ID mappings across daemon restarts. However, when IDs cannot be preserved, the daemon maps each previously mapped SID to a new ephemeral UID or GID value. The daemon will never re-use ephemeral UIDs or GIDs. If the `idmapd` daemon runs out of ephemeral UIDs and GIDs, it returns an error as well as a default UID or GID for SIDs that cannot be mapped by name.

The dynamic ID mappings are not retained across reboots. So, any SIDs that are dynamically mapped to UNIX UIDs or GIDs are most likely mapped to different IDs after rebooting the system.

**Local SID Mappings** If no name-based mapping is found, a non-ephemeral UID or GID is mapped to an algorithmically generated local SID. The mapping is generated as follows:

```
local SID for UID = <machine SID> - <1000 + UID>
local SID for GID = <machine SID> - <2^31 + GID>
```

<machine SID> is a unique SID generated by the `idmap` service for the host on which it runs.

**Rule Lookup Order** When mapping a Windows name to a UNIX name, lookup for name-based mapping rules is performed in the following order:

1. `windows-name@domain` to ""
2. `windows-name@domain` to `unix-name`

3. *windows-name*@\* to ""
4. *windows-name*@\* to *unix-name*
5. \*@*domain* to \*
6. \*@*domain* to ""
7. \*@*domain* to *unix-name*
8. \*@\* to \*
9. \*@\* to ""
10. \*@\* to *unix-name*

When mapping a UNIX name to a Windows name, lookup for name-based mapping rules is performed in the following order:

1. *unix-name* to ""
2. *unix-name* to *windows-name*@*domain*
3. \* to \*@*domain*
4. \* to ""
5. \* to *windows-name*@*domain*

**Service Properties** The service properties determine the behavior of the `idmapd(1M)` daemon. These properties are stored in the SMF repository (see [smf\(5\)](#)) under property group `config`. They can be accessed and modified using `svccfg(1M)`, which requires `solaris.smf.value.idmap` authorization. The service properties for the `idmap` service are:

`config/ad_unixuser_attr`

Specify the name of the AD attribute that contains the UNIX user name. There is no default.

`config/ad_unixgroup_attr`

Specify the name of the AD attribute that contains the UNIX group name. There is no default.

`config/nldap_winname_attr`

Specify the name of the Native LDAP attribute that contains the Windows user/group name. There is no default.

`config/directory_based_mapping`

Controls support for identity mapping using data stored in a directory service.

`none` disables directory-based mapping.

`name` enables name-based mapping using the properties described above.

`idmu` enables mapping using Microsoft's Identity Management for UNIX (IDMU). This Windows component allows the administrator to specify a UNIX user ID for each Windows user, mapping the Windows identity to the corresponding UNIX identity. Only IDMU data from the domain the Solaris system is a member of is used.

Changes to service properties do not affect a running `idmap` service. The service must be refreshed (with `svcadm(1M)`) for the changes to take effect.

**Operands** The `idmap` command uses the following operands:

*format*

Specifies the format in which user name mappings are described for the `export` and `import` subcommands. The Netapp `usermap.cfg` and Samba `smbusers` external formats are supported. These external formats are *only* for users, not groups.

- The `usermap.cfg` rule-mapping format is as follows:

```
windows-username [direction] unix-username
```

*windows-username* is a Windows user name in either the `domain\username` or `username@domain` format.

*unix-username* is a UNIX user name.

*direction* is one of the following:

- `==` means a bidirectional mapping, which is the default.
- `=>` or `<=` means a unidirectional mapping.

The IP qualifier is not supported.

- The `smbusers` rule-mapping format is as follows:

```
unixname = winname1 winname2 ...
```

If *winname* includes whitespace, escape the whitespace by enclosing the value in double quotes. For example, the following file shows how to specify whitespace in a valid format for the `idmap` command:

```
$ cat myusermap
terry="Terry Maddox"
pat="Pat Flynn"
cal=cbrown
```

The mappings are imported as unidirectional mappings from Windows names to UNIX names.

The format is based on the “username map” entry of the `smb.conf` man page, which is available on the `samba.org` web site. The use of an asterisk (\*) for *windows-name* is supported. However, the `@group` directive and the chaining of mappings are not supported.

By default, if no mapping entries are in the `smbusers` file, Samba maps a *windows-name* to the equivalent *unix-name*, if any. If you want to set up the same mapping as Samba does, use the following `idmap` command:

```
idmap add -d "winuser:*@*" "unixuser:*"
```

*identity*

Specifies a user name, user ID, group name, or group ID. *identity* is specified as `type:value`. *type* is one of the following:

---

<code>usid</code>	Windows user SID in text format
<code>gsid</code>	Windows group SID in text format
<code>sid</code>	Windows group SID in text format that can belong either to a user or to a group
<code>uid</code>	Numeric POSIX UID
<code>gid</code>	Numeric POSIX GID
<code>unixuser</code>	UNIX user name
<code>unixgroup</code>	UNIX group name
<code>winuser</code>	Windows user name
<code>wingroup</code>	Windows group name
<code>winname</code>	Windows user or group name

*value* is a number or string that is appropriate to the specified *type*. For instance, `unixgroup:staff` specifies the UNIX group name, `staff`. The identity `gid:10` represents GID 10, which corresponds to the UNIX group `staff`.

#### *name*

Specifies a UNIX name (`unixuser`, `unixgroup`) or a Windows name (`winuser`, `wingroup`) that can be used for name-based mapping rules.

A Windows security entity name can be specified in one of these ways:

- `domain\name`
- `name@domain`
- `name`, which uses the default mapping domain

If *name* is the empty string (`""`), mapping is inhibited. Note that a name of `""` should not be used to preclude logins by unmapped Windows users.

If *name* uses the wildcard (`*`), it matches all names that are not matched by other mappings. Similarly, if *name* is the wildcard Windows name (`*@*`), it matches all names in all domains that are not matched by other mappings.

If *name* uses the wildcard on both sides of the mapping rule, the name is the same for both Windows and Solaris users. For example, if the rule is `"*@domain"=="*"`, the `jp@domain` Windows user name matches this rule and maps to the `jp` Solaris user name.

Specifying the type of *name* is optional if the type can be deduced from other arguments or types specified on the command line.

#### *target-type*

Used with the `show` and `unset -namemap` subcommands. For `show`, specifies the mapping type that should be shown. For example, if *target-type* is `sid`, `idmap show` returns the SID

mapped to the identity specified on the command line. For `unset -namemap`, identifies an attribute within the object specified by the *name* operand.

**Options** The `idmap` command supports one option and a set of subcommands. The subcommands also have options.

**Command-Line Option** `-f command-file`  
Reads and executes `idmap` subcommands from *command-file*. The `idmap -f -` command reads from standard input. This option is not used by any subcommands.

**Subcommands** The following subcommands are supported:

`add [-d] name1 name2`

Adds a name-based mapping rule. By default, the name mapping is bidirectional. If the `-d` option is used, a unidirectional mapping is created from *name1* to *name2*.

Either *name1* or *name2* must be a Windows name, and the other must be a UNIX name. For the Windows name, the `winname` identity type must not be used. Instead, specify one of the `winuser` or `wingroup` types. See “Operands” for information about the *name* operand.

Note that two unidirectional mappings between the same two names in two opposite directions are equivalent to one bidirectional mapping.

This subcommand requires the `solaris.admin.idmap.rules` authorization.

`dump [-n] [-v]`

Dumps all the mappings cached since the last system boot. The `-n` option shows the names, as well. By default, only `sids`, `uids`, and `gids` are shown. The `-v` option shows how the mappings were generated.

`export [-f file] format`

Exports name-based mapping rules to standard output in the specified *format*. The `-f file` option writes the rules to the specified output file.

`flush [-a]`

Flushes the identity mapping cache so that future mapping requests will be fully processed based on the current rules and directory information. This is a non-disruptive operation. A rule change automatically flushes the cache; this manual operation can be used to force newly changed directory information to take effect.

With `-a`, the cache is wiped clean. This operation can potentially disrupt operations that are in process and so should be used only on a quiet system. It should not normally be necessary, but might be appropriate to use `-a` to set up “clean slate” test cases.

`get -namemap name`

Get the directory-based name mapping information from the AD or native LDAP user or group object represented by the specified name.

`help`

Displays the usage message.

`import [-F] [-f file] format`

Imports name-based mapping rules from standard input by using the specified *format*. The `-f file` option reads the rules from the specified file. The `-F` option flushes existing name-based mapping rules before adding new ones.

Regardless of the external format used, the imported rules are processed by using the semantics and order described in the section “Rule Lookup Order,” above.

This subcommand requires the `solaris.admin.idmap.rules` authorization.

`list`

Lists all name-based mapping rules. Each rule appears in its `idmap add` form.

`remove [-t|-f] name`

Removes any name-based mapping rule that involves the specified *name*. *name* can be either a UNIX or Windows user name or group name.

The `-f` option removes rules that use *name* as the source. The `-t` option removes rules that use *name* as the destination. These options are mutually exclusive.

This subcommand requires the `solaris.admin.idmap.rules` authorization.

`remove -a`

Removes all name-based mapping rules.

This subcommand requires the `solaris.admin.idmap.rules` authorization.

`remove [-d] name1 name2`

Removes name-based mapping rules between *name1* and *name2*. If the `-d` option is specified, rules from *name1* to *name2* are removed.

Either *name1* or *name2* must be a Windows name, and the other must be a UNIX name.

This subcommand requires the `solaris.admin.idmap.rules` authorization.

`set-namemap [-a authenticationMethod] [-D bindDN] [-j passwdfile] name1 name2`

Sets name mapping information in the AD or native LDAP user or group object. Either *name1* or *name2* must be a Windows name, and the other must be a UNIX name.

If *name1* is a Windows name, then the UNIX name *name2* is added to the AD object represented by *name1*. Similarly, if *name1* is a UNIX name then the Windows name *name2* is added to the native LDAP entry represented by *name1*.

The following options are supported:

`-a authenticationMethod`

Specify authentication method when modifying native LDAP entry. See [ldapaddent\(1M\)](#) for details. Default value is `sasl/GSSAPI`.

`-D bindDN`

Uses the distinguished name *bindDN* to bind to the directory.

-j *passwdfile*

Specify a file containing the password for authentication to the directory.

show [-c] [-v] [-V] *name* [*target-type*]

Shows the identity of type, *target-type*, that the specified *name* maps to. If the optional *target-type* is omitted, the non-diagonal mapping is shown.

By default, this subcommand shows only mappings that have been established already. The -c option forces the evaluation of name-based mapping configurations or the dynamic allocation of IDs.

The -v option shows how the mapping was generated and also whether the mapping was just generated or was retrieved from the cache. The -V option details the exact steps taken to determine the mapping, including interim steps and approaches that were rejected.

unset -namemap [-a *authenticationMethod*] [-D *bindDN*] [-j *passwdfile*] *name* [*target-type*]

Unsets directory-based name mapping information from the AD or native LDAP user or group object represented by the specified name and optional target type.

See the set -namemap subcommand for options.

### Examples EXAMPLE 1 Using a Wildcard on Both Sides of a Name-Based Mapping Rule

The following command maps all Windows user names in the xyz.com domain to the UNIX users with the same names provided that one exists and is not otherwise mapped. If such a rule is matched but the UNIX user name does not exist, an ephemeral ID mapping is used.

```
idmap add "winuser:*@xyz.com" "unixuser:*"
```

### EXAMPLE 2 Using a Wildcard on One Side of a Name-Based Mapping Rule

The following command maps all unmapped Windows users in the xyz.com domain to the guest UNIX user. The -d option specifies a unidirectional mapping from \*@xyz.com users to the guest user.

```
idmap add -d "winuser:*@xyz.com" unixuser:guest
```

### EXAMPLE 3 Adding a Bidirectional Name-Based Mapping Rule

The following command maps Windows user, foobar@example.com, to UNIX user, foo, and conversely:

```
idmap add winuser:foobar@example.com unixuser:foo
```

This command shows how to remove the mapping added by the previous command:

```
idmap remove winuser:foobar@example.com unixuser:foo
```

### EXAMPLE 4 Showing a UID-to-SID Mapping

- The following command shows the SID that the specified UID, uid:50000, maps to:

**EXAMPLE 4** Showing a UID-to-SID Mapping *(Continued)*

```
idmap show uid:50000 sid
uid:50000 -> usid:S-1-5-21-3223191800-2000
```

- The following command shows the UNIX user name that the specified Windows user name, joe@example.com, maps to:

```
idmap show joe@example.com unixuser
winuser:joe@example.com -> unixuser:joes
```

**EXAMPLE 5** Listing the Cached SID-to-UID Mappings

The following command shows all of the SID-to-UID mappings that are in the cache:

```
idmap dump | grep "uid:"
usid:S-1-5-21-3223191800-2000 == uid:50000
usid:S-1-5-21-3223191800-2001 == uid:50001
usid:S-1-5-21-3223191800-2006 == uid:50010
usid:S-1-5-21-3223191900-3000 == uid:2147491840
usid:S-1-5-21-3223191700-4000 => uid:60001
```

**EXAMPLE 6** Batching idmap Requests

The following commands show how to batch idmap requests. This particular command sequence does the following:

- Removes any previous rules for foobar@example.com.
- Maps Windows user foobar@example.com to UNIX user bar and vice-versa.
- Maps Windows group members to UNIX group staff and vice-versa.

```
idmap <<EOF
 remove winuser:foobar@example.com
 add winuser:foobar@example.com unixuser:bar
 add wingroup:members unixgroup:staff
EOF
```

**EXAMPLE 7** Listing Name-Based Mapping Rules

The following command shows how to list the name-based mapping rules:

```
idmap list
add winuser:foobar@example.com unixuser:bar
add wingroup:members unixgroup:staff
```

**EXAMPLE 8** Importing Name-Based Mapping Rules From the usermap.cfg File

The usermap.cfg file can be used to configure name-based mapping rules. The following usermap.cfg file shows mapping rules that map Windows user foo@example.com to UNIX user foo, and that map foobar@example.com to the UNIX user foo.

**EXAMPLE 8** Importing Name-Based Mapping Rules From the `usermap.cfg` File *(Continued)*

```
cat usermap.cfg
foo@example.com == foo
foobar@example.com => foo
```

The following `idmap` command imports `usermap.cfg` information to the `idmapd` database:

```
cat usermap.cfg | idmap import usermap.cfg
```

This command does the same as the previous command:

```
idmap import -f usermap.cfg usermap.cfg
```

The following commands are equivalent to the previous `idmap import` commands:

```
idmap <<EOF
 add winuser:foo@example.com unixuser:foo
 add -d winuser:foobar@example.com unixuser:foo
EOF
```

**EXAMPLE 9** Using Name-Based and Ephemeral ID Mapping With Identity Function Mapping and Exceptions

The following commands map all users in the `example.com` Windows domain to UNIX user accounts of the same name. The command also specifies mappings for the following Windows users: `joe@example.com`, `jane.doe@example.com`, `administrator@example.com`. The `administrator` from all domains is mapped to `nobody`. Any Windows users without corresponding UNIX accounts are mapped dynamically to available ephemeral UIDs.

```
idmap import usermap.cfg <<EOF
 joe@example.com == joes
 jane.doe@example.com == janed
 administrator@* => nobody
 *@example.com == *
 *@example.com => nobody
EOF
```

**EXAMPLE 10** Adding Directory-based Name Mapping to AD User Object

The following command maps Windows user `joe@example.com` to UNIX user `joe` by adding the UNIX name to AD object for `joe@example.com`.

```
idmap set-namemap winuser:joe@example.com joes
```

**EXAMPLE 11** Adding Directory-based Name Mapping to Native LDAP User Object

The following command maps UNIX user `foo` to Windows user `foobar@example.com` by adding the Windows name to native LDAP object for `foo`.

```
idmap set-namemap unixuser:foo foobar@example.com
```

**EXAMPLE 12** Removing Directory-based Name Mapping from AD User Object

The following command removes the UNIX username `unixuser` from the AD object representing `joe@example.com`.

```
idmap unset-namemap winuser:joe@example.com unixuser
```

**Exit Status** 0 Successful completion.

>0 An error occurred. A diagnostic message is written to standard error.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
Interface Stability	Uncommitted

**See Also** [svcs\(1\)](#), [idmapd\(1M\)](#), [ldapaddent\(1M\)](#), [svcadm\(1M\)](#), [svccfg\(1M\)](#), [ad\(5\)](#), [attributes\(5\)](#), [smf\(5\)](#)

**Notes** The `idmapd` service is managed by the service management facility, [smf\(5\)](#). The service identifier for the `idmapd` service is `svc:/system/idmap`.

Use the `svcadm` command to perform administrative actions on this service, such as enabling, disabling, or restarting the service. These actions require the `solaris.smf.manage.idmap` authorization. Use the `svcs` command to query the service's status.

Windows user names are case-insensitive, while UNIX user names are case-sensitive. The case of Windows names as they appear in `idmap` name-rules and `idmap show` command lines is irrelevant.

Because common practice in UNIX environments is to use all-lowercase user names, wildcard name-rules map Windows names to UNIX user/group names as follows: first, the canonical Windows name (that is, in the case as it appears in the directory) is used as a UNIX user or group name. If there is no such UNIX entity, then the Windows name's case is folded to lowercase and the result is used as the UNIX user or group name.

As a result of this differing treatment of case, user names that appear to be alike might not be recognized as matches. You must create rules to handle such pairings of strings that differ only in case. For example, to map the Windows user `sam@example` to the Solaris user `Sam`, you must create the following rules:

```
idmap add "winuser:*@example" "unixuser:*"
idmap add winuser:sam@example unixuser:Sam
```

For guidance on modifying an Active Directory schema, consult the Microsoft document, *Step-by-Step Guide to Using Active Directory Schema and Display Specifiers*, which you can find at their technet web site, <http://technet.microsoft.com/>.

**Name** idmapd – Native Identity Mapping service daemon

**Synopsis** /usr/lib/idmapd

**Description** The `idmapd` daemon maps Windows Security Identifiers (SIDs) to POSIX Identifiers (UIDs/GIDs) and conversely.

The `idmap(1M)` utility provides a front end to the `idmapd` daemon.

**Files** /var/idmap/idmap.db

Database in which to store local name-based ID mapping rules. The contents of the database are private. The database should not be accessed or modified directly.

/var/run/idmap/idmap.db

Database in which to cache ID mappings that are generated by ephemeral ID mapping and by name-based mapping. The contents of the database are private. The database should not be accessed or modified directly.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs
Interface Stability	See below.

Interface stability for these components is as follows:

`svc:/system/idmap`  
Committed

/var/idmap/idmap.db  
Project Private

/var/run/idmap/idmap.db  
Project Private

**See Also** [svcs\(1\)](#), [idmap\(1M\)](#), [svcadm\(1M\)](#), [svccfg\(1M\)](#), [defaultdomain\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

**Notes** The `idmapd` service is managed by the service management facility (SMF). The service identifier for the `idmapd` service is `svc:/system/idmap`.

Use the `svcadm` command to perform administrative actions on this service, such as enabling, disabling, or restarting the service. These actions require the `solaris.smf.manage.idmap` authorization. Use the `svcs` command to query the service's status.

The functionality of this daemon might change in a future release of the Solaris operating system.

**Name** `idsconfig` – prepare a Directory Server Enterprise Edition (DSEE) to be populated with data and serve LDAP clients

**Synopsis** `/usr/lib/ldap/idsconfig [-v] [-i input_configfile]  
[-o output_configfile]`

**Description** Use the `idsconfig` tool to set up a Directory Server Enterprise Edition (DSEE). You can specify the input configuration file with the `-i` option on the command line. Alternatively, the tool will prompt the user for configuration information. The input configuration file is created by `idsconfig` with the `-o` option on a previous run.

The first time a server is set up, the user is prompted for all the required information. Future installations on that machine can use the configuration file previously generated by `idsconfig` using the `-o` option.

The output configuration file contains the directory administrator's password in clear text. Thus, if you are creating an output configuration file, take appropriate security precautions.

You should back up the directory server's configuration and data prior to running this command.

**Options** The following options are supported:

`-i input_configfile`

Specify the file name for `idsconfig` to use as a configuration file. This file will be read by `idsconfig`, and the values in the file will be used to configure the server. Do not manually edit *input\_configfile*. The *input\_configfile* is only partially validated, as `idsconfig` assumes that the file was created by a previous invocation of the command.

`-o output_configfile`

Create a configuration file.

`-v`

Verbose output.

**Operands** The following operands are supported:

*input\_configfile*

Name of configuration file for `idsconfig` to use.

*output\_configfile*

Configuration file created by `idsconfig`.

**Examples** **EXAMPLE 1** Prompting the User for Input

In the following example, the user is prompted for information to set up DSEE.

```
example# idsconfig
```

**EXAMPLE 2** Creating an Output Configuration File

In the following example, the user is prompted for information to set up DSEE, and an output configuration file, `config.1`, is created when completed.

```
example# idsconfig -o config.1
```

**EXAMPLE 3** Setting up DSEE Using the Specified Configuration File

In the following example, DSEE is set up by using the values specified in the configuration file, `config.1`. The verbose mode is specified, so detailed information will print to the screen.

```
example# idsconfig -v -i config.1
```

**Exit Status** The following exit values are returned:

```
0
 Successful completion.
>0
 An error occurred.
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/nis
Interface Stability	Committed

**See Also** [ldap\(1\)](#), [ldapadd\(1\)](#), [ldapdelete\(1\)](#), [ldaplist\(1\)](#), [ldapmodify\(1\)](#), [ldapmodrdn\(1\)](#), [ldapsearch\(1\)](#), [ldap\\_cachemgr\(1M\)](#), [ldapaddent\(1M\)](#), [ldapclient\(1M\)](#), [suninstall\(1M\)](#), [resolv.conf\(4\)](#), [attributes\(5\)](#)

**Name** ifconfig – configure network interface parameters

**Synopsis** `ifconfig interface [address_family] [address [/prefix_length] [dest_address]] [addif address [/prefix_length]] [removeif address [/prefix_length]] [arp | -arp] [auth_algs authentication_algorithm] [encr_algs encryption_algorithm] [encr_auth_algs authentication_algorithm] [auto-revarp] [broadcast address] [deprecated | -deprecated] [preferred | -preferred] [destination dest_address] [ether [address]] [failover | -failover] [group [name | ""]] [index if_index] [ipmp] [metric n] [modlist] [modinsert mod_name@pos] [modremove mod_name@pos] [mtu n] [netmask mask] [plumb] [unplumb] [private | -private] [nud | -nud] [set [address] [/netmask]] [standby | -standby] [subnet subnet_address] [tdst tunnel_dest_address] [token address/prefix_length] [tsrc tunnel_src_address] [trailers | -trailers] [up] [down] [usesrc [name | none]] [xmit | -xmit] [encaplimit n | -encaplimit] [thoplimit n] [router | -router] [zone zonename | -zone | -all-zones]`

`ifconfig [address_family] interface {auto-dhcp | dhcp} [primary] [wait seconds] drop | extend | inform | ping | release | start | status`

**Description** The command `ifconfig` is used to assign an address to a network interface and to configure network interface parameters. The `ifconfig` command must be used at boot time to define the network address of each interface present on a machine; it may also be used at a later time to redefine an interface's address or other operating parameters. If no option is specified, `ifconfig` displays the current configuration for a network interface. If an address family is specified, `ifconfig` reports only the details specific to that address family. Only privileged users may modify the configuration of a network interface. Options appearing within braces (`{ }`) indicate that one of the options must be specified.

**DHCP Configuration** The forms of `ifconfig` that use the `auto-dhcp` or `dhcp` arguments are used to control the Dynamic Host Configuration Protocol (“DHCP”) configuration of the interface. In this mode, `ifconfig` is used to control operation of `dhcpcagent(1M)`, the DHCP client daemon. Once an interface is placed under DHCP control by using the `start` operand, `ifconfig` should not, in normal operation, be used to modify the address or characteristics of the interface. If the address of an interface under DHCP is changed, `dhcpcagent` will remove the interface from its control.

**Options** The following options are supported:

`addif address`

Create the next unused logical interface on the specified physical interface.

**all-zones**

Make the interface available to every shared-IP zone on the system. The appropriate zone to which to deliver data is determined using the `tnzonecfg` database. This option is available only if the system is configured with the Solaris Trusted Extensions feature.

The `tnzonecfg` database is described in the `tnzonecfg(4)` man page, which is part of the *Solaris Trusted Extensions Reference Manual*.

**anycast**

Marks the logical interface as an anycast address by setting the ANYCAST flag. See “INTERFACE FLAGS,” below, for more information on anycast.

**-anycast**

Marks the logical interface as not an anycast address by clearing the ANYCAST flag.

**arp**

Enable the use of the Address Resolution Protocol (“ARP”) in mapping between network level addresses and link level addresses (default). This is currently implemented for mapping between IPv4 addresses and MAC addresses.

**-arp**

Disable the use of the ARP on a physical interface. ARP cannot be disabled on an IPMP IP interface.

**auth\_algs *authentication algorithm***

For a tunnel, enable IPsec AH with the authentication algorithm specified. The algorithm can be either a number or an algorithm name, including *any* to express no preference in algorithm. All IPsec tunnel properties must be specified on the same command line. To disable tunnel security, specify an `auth_alg` of `none`.

It is now preferable to use the `ipseconf(1M)` command when configuring a tunnel's security properties. If `ipseconf` was used to set a tunnel's security properties, this keyword will not affect the tunnel.

**auto-dhcp**

Use DHCP to automatically acquire an address for this interface. This option has a completely equivalent alias called `dhcp`.

For IPv6, the interface specified must be the zeroth logical interface (the physical interface name), which has the link-local address.

**primary**

Defines the interface as the `primary`. The interface is defined as the preferred one for the delivery of client-wide configuration data. Only one interface can be the primary at any given time. If another interface is subsequently selected as the primary, it replaces the previous one. Nominating an interface as the primary one will not have much significance once the client work station has booted, as many applications will already have started and been configured with data read from the previous primary interface.

*wait seconds*

The `ifconfig` command will wait until the operation either completes or for the interval specified, whichever is the sooner. If no wait interval is given, and the operation is one that cannot complete immediately, `ifconfig` will wait 30 seconds for the requested operation to complete. The symbolic value `forever` may be used as well, with obvious meaning.

*drop*

Remove the specified interface from DHCP control without notifying the DHCP server, and record the current lease for later use. Additionally, for IPv4, set the IP address to zero. For IPv6, unplumb all logical interfaces plumbed by `dhcpgent`.

*extend*

Attempt to extend the lease on the interface's IP address. This is not required, as the agent will automatically extend the lease well before it expires.

*inform*

Obtain network configuration parameters from DHCP without obtaining a lease on IP addresses. This is useful in situations where an IP address is obtained through mechanisms other than DHCP.

*ping*

Check whether the interface given is under DHCP control, which means that the interface is managed by the DHCP agent and is working properly. An exit status of 0 means success.

*release*

Relinquish the IP addresses on the interface by notifying the server and discard the current lease. For IPv4, set the IP address to zero. For IPv6, all logical interfaces plumbed by `dhcpgent` are unplumbed.

*start*

Start DHCP on the interface.

*status*

Display the DHCP configuration status of the interface.

*auto-revarp*

Use the Reverse Address Resolution Protocol (RARP) to automatically acquire an address for this interface. This will fail if the interface does not support RARP; for example, IPoIB (IP over InfiniBand), and on IPv6 interfaces.

*broadcast address*

For IPv4 only. Specify the address to use to represent broadcasts to the network. The default broadcast address is the address with a host part of all 1's. A "+" (plus sign) given for the broadcast value causes the broadcast address to be reset to a default appropriate for the (possibly new) address and netmask. The arguments of `ifconfig` are interpreted left to right. Therefore

```
example% ifconfig -a netmask + broadcast +
```

and

example% `ifconfig -a broadcast + netmask +`

may result in different values being assigned for the broadcast addresses of the interfaces.

deprecated

Marks the logical interface as deprecated. An address associated with a deprecated interface will not be used as source address for outbound packets unless either there are no other addresses available on the interface or the application has bound to this address explicitly. The status display shows DEPRECATED as part of flags. See [INTERFACE FLAGS](#) for information on the flags supported by `ifconfig`.

-deprecated

Marks a logical interface as not deprecated. An address associated with such an interface could be used as a source address for outbound packets.

preferred

Marks the logical interface as preferred. This option is only valid for IPv6 addresses. Addresses assigned to preferred logical interfaces are preferred as source addresses over all other addresses configured on the system, unless the address is of an inappropriate scope relative to the destination address. Preferred addresses are used as source addresses regardless of which physical interface they are assigned to. For example, you can configure a preferred source address on the loopback interface and advertise reachability of this address by using a routing protocol.

-preferred

Marks the logical interface as not preferred.

destination *dest\_address*

Set the destination address for a point-to point interface.

dhcp

This option is an alias for option `auto-dhcp`

down

Mark a logical interface as “down”. (That is, turn off the `IFF_UP` bit.) When a logical interface is marked “down,” the system does not attempt to use the address assigned to that interface as a source address for outbound packets and will not recognize inbound packets destined to that address as being addressed to this host. Additionally, when all logical interfaces on a given physical interface are “down,” the physical interface itself is disabled.

When a logical interface is down, all routes that specify that interface as the output (using the `-ifp` option in the [route\(1M\)](#) command or `RTA_IFP` in a [route\(7P\)](#) socket) are removed from the forwarding table. Routes marked with `RTF_STATIC` are returned to the table if the interface is brought back up, while routes not marked with `RTF_STATIC` are simply deleted.

When all logical interfaces that could possibly be used to reach a particular gateway address are brought down (specified without the interface option as in the previous paragraph), the

affected gateway routes are treated as though they had the `RTF_BLACKHOLE` flag set. All matching packets are discarded because the gateway is unreachable.

#### `encaplimit n`

Set the tunnel encapsulation limit for the interface to `n`. This option applies to IPv4-in-IPv6 and IPv6-in-IPv6 tunnels only, and it simply modifies the `encaplimit` link property of the underlying IPv6 tunnel link (see [dladm\(1M\)](#)). The tunnel encapsulation limit controls how many more tunnels a packet can enter before it leaves any tunnel, that is, the tunnel nesting level.

This option is obsolete, superseded by the [dladm\(1M\)](#) `encaplimit` link property.

#### `-encaplimit`

Disable generation of the tunnel encapsulation limit. This option applies only to IPv4-in-IPv6 and IPv6-in-IPv6 tunnels. This simply sets the `encaplimit` link property of the underlying IPv6 tunnel link to 0 (see [dladm\(1M\)](#) `encaplimit`).

This option is obsolete, superseded by the [dladm\(1M\)](#) `encaplimit` link property.

#### `encr_auth_algs authentication algorithm`

For a tunnel, enable IPsec ESP with the authentication algorithm specified. It can be either a number or an algorithm name, including any or none, to indicate no algorithm preference. If an ESP encryption algorithm is specified but the authentication algorithm is not, the default value for the ESP authentication algorithm will be any.

It is now preferable to use the [ipseccnf\(1M\)](#) command when configuring a tunnel's security properties. If `ipseccnf` was used to set a tunnel's security properties, this keyword will not affect the tunnel.

#### `encr_algs encryption algorithm`

For a tunnel, enable IPsec ESP with the encryption algorithm specified. It can be either a number or an algorithm name. Note that all IPsec tunnel properties must be specified on the same command line. To disable tunnel security, specify the value of `encr_alg` as `none`. If an ESP authentication algorithm is specified, but the encryption algorithm is not, the default value for the ESP encryption will be `null`.

It is now preferable to use the [ipseccnf\(1M\)](#) command when configuring a tunnel's security properties. If `ipseccnf` was used to set a tunnel's security properties, this keyword will not affect the tunnel.

#### `ether [ address ]`

If no address is given and the user is root or has sufficient privileges to open the underlying datalink, then display the current Ethernet address information.

Otherwise, if the user is root or has sufficient privileges, set the Ethernet address of the interfaces to `address`. The address is an Ethernet address represented as `x:x:x:x:x:x` where `x` is a hexadecimal number between 0 and FF. Similarly, for the IPoIB (IP over InfiniBand) interfaces, the address will be 20 bytes of colon-separated hex numbers between 0 and FF.

Some, though not all, Ethernet interface cards have their own addresses. To use cards that do not have their own addresses, refer to section 3.2.3(4) of the IEEE 802.3 specification for a definition of the locally administered address space. Note that all IP interfaces in an IPMP group must have unique hardware addresses; see [in.mpathd\(1M\)](#).

**-failover**

Set NOFAILOVER on the logical interface. This makes the associated address available for use by `in.mpathd` to perform probe-based failure detection for the associated physical IP interface. As a side effect, DEPRECATED will also be set on the logical interface. This operation is not permitted on an IPMP IP interface.

**failover**

Clear NOFAILOVER on the logical interface. This is the default. These logical interfaces are subject to migration when brought up (see IP MULTIPATHING GROUPS).

**group [ *name* | "" ]**

When applied to a physical interface, it places the interface into the named group. If the group does not exist, it will be created, along with one or more IPMP IP interfaces (for IPv4, IPv6, or both). Any UP addresses that are not also marked NOFAILOVER are subject to migration to the IPMP IP interface (see IP MULTIPATHING GROUPS). Specifying a group name of "" removes the physical IP interface from the group.

When applied to a physical IPMP IP interface, it renames the IPMP group to have the new name. If the name already exists, or a name of "" is specified, it fails. Renaming IPMP groups is discouraged. Instead, the IPMP IP interface should be given a meaningful name when it is created by means of the `ipmp` subcommand, which the system will also use as the IPMP group name.

**index *n***

Change the interface index for the interface. The value of *n* must be an interface index (*if\_index*) that is not used on another interface. *if\_index* will be a non-zero positive number that uniquely identifies the network interface on the system.

**ipmp**

Create an IPMP IP interface with the specified name. An interface must be separately created for use by IPv4 and IPv6. The *address\_family* parameter controls whether the command applies to IPv4 or IPv6 (IPv4 if unspecified). All IPMP IP interfaces have the IPMP flag set.

**metric *n***

Set the routing metric of the interface to *n*; if no value is specified, the default is 0. The routing metric is used by the routing protocol. Higher metrics have the effect of making a route less favorable. Metrics are counted as addition hops to the destination network or host.

**modinsert *mod\_name@pos***

Insert a module with name *mod\_name* to the stream of the device at position *pos*. The position is relative to the stream head. Position 0 means directly under stream head.

Based upon the example in the `modlist` option, use the following command to insert a module with name `ipqos` under the `ip` module and above the `firewall` module:

```
example% ifconfig eri0 modinsert ipqos@2
```

A subsequent listing of all the modules in the stream of the device follows:

```
example% ifconfig eri0 modlist
0 arp
1 ip
2 ipqos
3 firewall
4 eri
```

#### `modlist`

List all the modules in the stream of the device.

The following example lists all the modules in the stream of the device:

```
example% ifconfig eri0 modlist
0 arp
1 ip
2 firewall
4 eri
```

#### `modremove mod_name@pos`

Remove a module with name `mod_name` from the stream of the device at position `pos`. The position is relative to the stream head.

Based upon the example in the `modinsert` option, use the following command to remove the `firewall` module from the stream after inserting the `ipqos` module:

```
example% ifconfig eri0 modremove firewall@3
```

A subsequent listing of all the modules in the stream of the device follows:

```
example% ifconfig eri0 modlist
0 arp
1 ip
2 ipqos
3 eri
```

Note that the core IP stack modules, for example, `ip` and `tun` modules, cannot be removed.

#### `mtu n`

Set the maximum transmission unit of the interface to `n`. For many types of networks, the `mtu` has an upper limit, for example, 1500 for Ethernet. This option sets the `FIXEDMTU` flag on the affected interface.

#### `netmask mask`

For IPv4 only. Specify how much of the address to reserve for subdividing networks into subnetworks. The mask includes the network part of the local address and the subnet part, which is taken from the host field of the address. The mask contains 1's for the bit positions

in the 32-bit address which are to be used for the network and subnet parts, and 0's for the host part. The mask should contain at least the standard network portion, and the subnet field should be contiguous with the network portion. The mask can be specified in one of four ways:

1. with a single hexadecimal number with a leading 0x,
2. with a dot-notation address,
3. with a "+" (plus sign) address, or
4. with a pseudo host name/pseudo network name found in the network database [networks\(4\)](#).

If a "+" (plus sign) is given for the netmask value, the mask is looked up in the [netmasks\(4\)](#) database. This lookup finds the longest matching netmask in the database by starting with the interface's IPv4 address as the key and iteratively masking off more and more low order bits of the address. This iterative lookup ensures that the [netmasks\(4\)](#) database can be used to specify the netmasks when variable length subnetmasks are used within a network number.

If a pseudo host name/pseudo network name is supplied as the netmask value, netmask data may be located in the `hosts` or `networks` database. Names are looked up by first using [gethostbyname\(3NSL\)](#). If not found there, the names are looked up in [getnetbyname\(3SOCKET\)](#). These interfaces may in turn use [nsswitch.conf\(4\)](#) to determine what data store(s) to use to fetch the actual value.

For both `inet` and `inet6`, the same information conveyed by *mask* can be specified as a *prefix\_length* attached to the *address* parameter.

#### nud

Enables the neighbor unreachability detection mechanism on a point-to-point physical interface.

#### -nud

Disables the neighbor unreachability detection mechanism on a point-to-point physical interface.

#### plumb

For a physical IP interface, open the datalink associated with the physical interface name and set up the plumbing needed for IP to use the datalink. When used with a logical interface name, this command is used to create a specific named logical interface on an existing physical IP interface.

An interface must be separately plumbed for IPv4 and IPv6 according to the *address\_family* parameter (IPv4 if unspecified). Before an interface has been plumbed, it will not be shown by `ifconfig -a`.

Note that IPMP IP interfaces are not tied to a specific datalink and are instead created with the `ipmp` subcommand.

**private**  
Tells the `in.routed` routing daemon that a specified logical interface should not be advertised.

**-private**  
Specify unadvertised interfaces.

**removeif *address***  
Remove the logical interface on the physical interface specified that matches the *address* specified.

**router**  
Enable IP forwarding on the interface. When enabled, the interface is marked `ROUTER`, and IP packets can be forwarded to and from the interface. Enabling `ROUTER` on any IP interface in an IPMP group enables it on all IP interfaces in that IPMP group.

**-router**  
Disable IP forwarding on the interface. IP packets are not forwarded to and from the interface. Disabling `ROUTER` on any IP interface in an IPMP group disables it on all IP interfaces in that IPMP group.

**set**  
Set the *address*, *prefix\_length* or both, for a logical interface.

**standby**  
Mark the physical IP interface as a `STANDBY` interface. If an interface is marked `STANDBY` and is part of an IPMP group, the interface will not be used for data traffic unless another interface in the IPMP group becomes unusable. When a `STANDBY` interface is functional but not being used for data traffic, it will also be marked `INACTIVE`. This operation is not permitted on an IPMP IP interface.

**-standby**  
Clear `STANDBY` on the interface. This is the default.

**subnet**  
Set the subnet *address* for an interface.

**tdst *tunnel\_dest\_address***  
Set the destination address of a tunnel. The address should not be the same as the *dest\_address* of the tunnel, because no packets leave the system over such a tunnel.

This option is obsolete, superseded by the `dladm(1M)` `create-iptun` and `modify-iptun` subcommands.

**thoplimit *n***  
Set the hop limit for a tunnel interface. The hop limit value is used as the TTL in the IPv4 header for the IPv6-in-IPv4 and IPv4-in-IPv4 tunnels. For IPv6-in-IPv6 and IPv4-in-IPv6 tunnels, the hop limit value is used as the hop limit in the IPv6 header. This option simply modifies the `hoplimit` link property of the underlying IP tunnel link (see `dladm(1M)`).

This option is obsolete, superseded by the `dladm(1M)` `hoplimit` link property.

`token address/prefix_length`

Set the IPv6 token of an interface to be used for address autoconfiguration.

```
example% ifconfig eri0 inet6 token ::1/64
```

`trailers`

This flag previously caused a nonstandard encapsulation of IPv4 packets on certain link levels. Drivers supplied with this release no longer use this flag. It is provided for compatibility, but is ignored.

`-trailers`

Disable the use of a “trailer” link level encapsulation.

`tsrc tunnel_src_address`

Set the source address of a tunnel. This is the source address on an outer encapsulating IP header. It must be an address of another interface already configured using `ifconfig`.

This option is obsolete, superseded by the `dladm(1M)` `create-iptun` and `modify-iptun` subcommands.

`unplumb`

For a physical or IPMP interface, remove all associated logical IP interfaces and tear down any plumbing needed for IP to use the interface. For an IPMP IP interface, this command will fail if the group is not empty. For a logical interface, the logical interface is removed.

An interface must be separately unplumbed for IPv4 and IPv6 according to the `address_family` parameter (IPv4 if unspecified). Upon success, the interface name will no longer appear in the output of `ifconfig -a`.

`up`

Mark a logical interface UP. As a result, the IP module will accept packets destined to the associated address (unless the address is zero), along with any associated multicast and broadcast IP addresses. Similarly, the IP module will allow packets to be sent with the associated address as a source address. At least one logical interface must be UP for the associated physical interface to send or receive packets

`usesrc [ name | none ]`

Specify a physical interface to be used for source address selection. If the keyword `none` is used, then any previous selection is cleared.

When an application does not choose a non-zero source address using `bind(3SOCKET)`, the system will select an appropriate source address based on the outbound interface and the address selection rules (see `ipaddrsel(1M)`).

When `usesrc` is specified and the specified interface is selected in the forwarding table for output, the system looks first to the specified physical interface and its associated logical interfaces when selecting a source address. If no usable address is listed in the forwarding table, the ordinary selection rules apply. For example, if you enter:

**# ifconfig eri0 usesrc vni0**

...and `vni0` has address 10.0.0.1 assigned to it, the system will prefer 10.0.0.1 as the source address for any packets originated by local connections that are sent through `eri0`. Further examples are provided in the EXAMPLES section.

While you can specify any physical interface (or even loopback), be aware that you can also specify the virtual IP interface (see [vni\(7d\)](#)). The virtual IP interface is not associated with any physical hardware and is thus immune to hardware failures. You can specify any number of physical interfaces to use the source address hosted on a single virtual interface. This simplifies the configuration of routing-based multipathing. If one of the physical interfaces were to fail, communication would continue through one of the remaining, functioning physical interfaces. This scenario assumes that the reachability of the address hosted on the virtual interface is advertised in some manner, for example, through a routing protocol.

Because the `ifconfig preferred` option is applied to all interfaces, it is coarser-grained than the `usesrc` option. It will be overridden by `usesrc` and `setsrc` (route subcommand), in that order.

**xmit**

Enable a logical interface to transmit packets. This is the default behavior when the logical interface is up.

**-xmit**

Disable transmission of packets on an interface. The interface will continue to receive packets.

**zone *zonename***

Place the logical interface in `zone zonename`. The named zone must be active in the kernel in the ready or running state. The interface is unplumbed when the zone is halted or rebooted. The zone must be configured to be an shared-IP zone. [zonecfg\(1M\)](#) is used to assign network interface names to exclusive-IP zones.

**-zone**

Place IP interface in the global zone. This is the default.

**Operands** The *interface* operand, as well as address parameters that affect it, are described below.

***interface***

A string of one of the following forms:

- *name physical-unit*, for example, `eri0` or `ce1`
- *name physical-unit:logical-unit*, for example, `eri0:1`
- `ip.tunN`, `ip6.tunN`, or `ip6to4.tunN` for implicit IP tunnel links

If the interface name starts with a dash (-), it is interpreted as a set of options which specify a set of interfaces. In such a case, -a must be part of the options and any of the additional options below can be added in any order. If one of these interface names is given, the commands following it are applied to all of the interfaces that match.

- a Apply the command to all interfaces of the specified address family. If no address family is supplied, either on the command line or by means of `/etc/default/inet_type`, then all address families will be selected.
- d Apply the commands to all “down” interfaces in the system.
- D Apply the commands to all interfaces not under DHCP (Dynamic Host Configuration Protocol) control.
- u Apply the commands to all “up” interfaces in the system.
- Z Apply the commands to all interfaces in the user's zone.
- 4 Apply the commands to all IPv4 interfaces.
- 6 Apply the commands to all IPv6 interfaces.

#### *address\_family*

The address family is specified by the *address\_family* parameter. The `ifconfig` command currently supports the following families: `inet` and `inet6`. If no address family is specified, the default is `inet`.

`ifconfig` honors the `DEFAULT_IP` setting in the `/etc/default/inet_type` file when it displays interface information. If `DEFAULT_IP` is set to `IP_VERSION4`, then `ifconfig` will omit information that relates to IPv6 interfaces. However, when you explicitly specify an address family (`inet` or `inet6`) on the `ifconfig` command line, the command line overrides the `DEFAULT_IP` settings.

#### *address*

For the IPv4 family (`inet`), the *address* is either a host name present in the host name data base (see [hosts\(4\)](#)) or in the Network Information Service (NIS) map `hosts`, or an IPv4 address expressed in the Internet standard “dot notation”.

For the IPv6 family (`inet6`), the *address* is either a host name present in the host name data base (see [hosts\(4\)](#)) or in the Network Information Service (NIS) map `ipnode`, or an IPv6 address expressed in the Internet standard colon-separated hexadecimal format represented as `x:x:x:x:x:x:x` where *x* is a hexadecimal number between 0 and FFFF.

#### *prefix\_length*

For the IPv4 and IPv6 families (`inet` and `inet6`), the *prefix\_length* is a number between 0 and the number of bits in the address. For `inet`, the number of bits in the address is 32; for `inet6`, the number of bits in the address is 128. The *prefix\_length* denotes the number of leading set bits in the netmask.

*dest\_address*

If the *dest\_address* parameter is supplied in addition to the *address* parameter, it specifies the address of the correspondent on the other end of a point-to-point link.

*tunnel\_dest\_address*

An address that is or will be reachable through an interface other than the tunnel being configured. This tells the tunnel where to send the tunneled packets. This address must not be the same as the interface destination address being configured.

*tunnel\_src\_address*

An address that is attached to an already configured interface that has been configured “up” with *ifconfig*.

**Interface Flags** The *ifconfig* command supports the following interface flags. The term “address” in this context refers to a logical interface, for example, *eri0:0*, while “interface” refers to the physical interface, for example, *eri0*.

## ADDRCONF

The address is from stateless *addrconf*. The stateless mechanism allows a host to generate its own address using a combination of information advertised by routers and locally available information. Routers advertise prefixes that identify the subnet associated with the link, while the host generates an “interface identifier” that uniquely identifies an interface in a subnet. In the absence of information from routers, a host can generate link-local addresses. This flag is specific to IPv6.

## ANYCAST

Indicates an anycast address. An anycast address identifies the nearest member of a group of systems that provides a particular type of service. An anycast address is assigned to a group of systems. Packets are delivered to the nearest group member identified by the anycast address instead of being delivered to all members of the group.

## BROADCAST

This broadcast address is valid. This flag and *POINTTOPOINT* are mutually exclusive

## CoS

This interface supports some form of Class of Service (CoS) marking. An example is the 802.1D user priority marking supported on VLAN interfaces. For IPMP IP interfaces, this will only be set if all interfaces in the group have CoS set.

Note that this flag is only set on interfaces over VLAN links and over Ethernet links that have their *dLadm(1M)* *tagmode* link property set to *normal*.

## DEPRECATED

This address is deprecated. This address will not be used as a source address for outbound packets unless there are no other addresses on this interface or an application has explicitly bound to this address. An IPv6 deprecated address is part of the standard mechanism for renumbering in IPv6 and will eventually be deleted when not used. For both IPv4 and IPv6, *DEPRECATED* is also set on all *NOFAILOVER* addresses, though this may change in a future release.

**DHCPRUNNING**

The logical interface's address is managed by `dhcpageant(1M)`. For IPv6, this will also be set on the zeroth logical interface if DHCPv6 has been started on the interface; see `in.ndpd(1M)`.

**DUPLICATE**

The logical interface has been disabled because the IP address configured on the interface is a duplicate. Some other node on the network is using this address. If the address was configured by DHCP or is temporary, the system will choose another automatically, if possible. Otherwise, the system will attempt to recover this address periodically and the interface will recover when the conflict has been removed from the network. Changing the address or netmask, or setting the logical interface to up will restart duplicate detection. Setting the interface to down terminates recovery and removes the DUPLICATE flag.

**FAILED**

The `in.mpathd` daemon has determined that the interface has failed. FAILED interfaces will not be used to send or receive IP data traffic. If this is set on a physical IP interface in an IPMP group, IP data traffic will continue to flow over other usable IP interfaces in the IPMP group. If this is set on an IPMP IP interface, the entire group has failed and no data traffic can be sent or received over any interfaces in that group.

**FIXEDMTU**

The MTU has been set using the `-mtu` option. This flag is read-only. Interfaces that have this flag set have a fixed MTU value that is unaffected by dynamic MTU changes that can occur when drivers notify IP of link MTU changes.

**INACTIVE**

The physical interface is functioning but is not used to send or receive data traffic according to administrative policy. This flag is initially set by the `standby` subcommand and is subsequently controlled by `in.mpathd`. It also set when `FAILBACK=no` mode is enabled (see `in.mpathd(1M)`) to indicate that the IP interface has repaired but is not being used.

**IPMP**

Indicates that this is an IPMP IP interface.

**LOOPBACK**

Indicates that this is the loopback interface.

**MULTI\_BCAST**

Indicates that the broadcast address is used for multicast on this interface.

**MULTICAST**

The interface supports multicast. IP assumes that any interface that supports hardware broadcast, or that is a point-to-point link, will support multicast.

**NOARP**

There is no address resolution protocol (ARP) for this interface that corresponds to all interfaces for a device without a broadcast address. This flag is specific to IPv4.

**NOFAILOVER**

The address associated with this logical interface is available to `in.mpathd` for probe-based failure detection of the associated physical IP interface.

**NOLOCAL**

The interface has no address, just an on-link subnet.

**NONUD**

NUD is disabled on this interface. NUD (neighbor unreachability detection) is used by a node to track the reachability state of its neighbors, to which the node actively sends packets, and to perform any recovery if a neighbor is detected to be unreachable. This flag is specific to IPv6.

**NORTEXCH**

The interface does not exchange routing information. For RIP-2, routing packets are not sent over this interface. Additionally, messages that appear to come over this interface receive no response. The subnet or address of this interface is not included in advertisements over other interfaces to other routers.

**NOXMIT**

Indicates that the address does not transmit packets. RIP-2 also does not advertise this address.

**OFFLINE**

The interface is offline and thus cannot send or receive IP data traffic. This is only set on IP interfaces in an IPMP group. See `if_mpadm(1M)` and `cfgadm(1M)`.

**POINTOPOINT**

Indicates that the address is a point-to-point link. This flag and **BROADCAST** are mutually exclusive

**PREFERRED**

This address is a preferred IPv6 source address. This address will be used as a source address for IPv6 communication with all IPv6 destinations, unless another address on the system is of more appropriate scope. The **DEPRECATED** flag takes precedence over the **PREFERRED** flag.

**PRIVATE**

Indicates that this address is not advertised. For RIP-2, this interface is used to send advertisements. However, neither the subnet nor this address are included in advertisements to other routers.

**PROMISC**

A read-only flag indicating that an interface is in promiscuous mode. All addresses associated with an interface in promiscuous mode will display (in response to `ifconfig -a`, for example) the **PROMISC** flag.

**ROUTER**

Indicates that IP packets can be forwarded to and from the interface.

**RUNNING**

Indicates that the required resources for an interface are allocated. For some interfaces this also indicates that the link is up. For IPMP IP interfaces, RUNNING is set as long as one IP interface in the group is active.

**STANDBY**

Indicates that this physical interface will not be used for data traffic unless another interface in the IPMP group becomes unusable. The INACTIVE and FAILED flags indicate whether it is actively being used.

**TEMPORARY**

Indicates that this is a temporary IPv6 address as defined in RFC 3041.

**UNNUMBERED**

This flag is set when the local IP address on the link matches the local address of some other link in the system

**UP**

Indicates that the logical interface (and the associated physical interface) is up. The IP module will accept packets destined to UP addresses (unless the address is zero), along with any associated multicast and broadcast IP addresses. Similarly, the IP module will allow packets to be sent with an UP address as a source address.

**VIRTUAL**

Indicates that the physical interface has no underlying hardware. It is not possible to transmit or receive packets through a virtual interface. These interfaces are useful for configuring local addresses that can be used on multiple interfaces. (See also the `uses rc` option.)

**L3PROTECT**

Indicates that Layer-3 protection has been enforced on the physical interface using the `allowed-ips` link property in `dladm(1M)`.

**Logical Interfaces** Solaris TCP/IP allows multiple logical interfaces to be associated with a physical network interface. This allows a single machine to be assigned multiple IP addresses, even though it may have only one network interface. Physical network interfaces have names of the form *driver-name physical-unit-number*, while logical interfaces have names of the form *driver-name physical-unit-number:logical-unit-number*. A physical interface is configured into the system using the `plumb` command. For example:

```
example% ifconfig eri0 plumb
```

Once a physical interface has been “plumbed”, logical interfaces associated with the physical interface can be configured by separate `-plumb` or `-addif` options to the `ifconfig` command.

```
example% ifconfig eri0:1 plumb
```

allocates a specific logical interface associated with the physical interface `eri0`. The command

```
example% ifconfig eri0 addif 192.168.200.1/24 up
```

allocates the next available logical unit number on the `eri0` physical interface and assigns an *address* and *prefix\_length*.

A logical interface can be configured with parameters (*address*, *prefix\_length*, and so on) different from the physical interface with which it is associated. Logical interfaces that are associated with the same physical interface can be given different parameters as well. Each logical interface must be associated with an existing and “up” physical interface. So, for example, the logical interface `eri0:1` can only be configured after the physical interface `eri0` has been plumbed.

To delete a logical interface, use the `unplumb` or `removeif` options. For example,

```
example% ifconfig eri0:1 down unplumb
```

will delete the logical interface `eri0:1`.

## Ip Multipathing Groups

Physical interfaces that share the same link-layer broadcast domain *must* be collected into a single IP Multipathing (IPMP) group using the `group` subcommand. Each IPMP group has an associated IPMP IP interface, which can either be explicitly created (the preferred method) by using the `ipmp` subcommand or implicitly created by `ifconfig` in response to placing an IP interface into a new IPMP group. Implicitly-created IPMP interfaces will be named `ipmpN` where *N* is the lowest integer that does not conflict with an existing IP interface name or IPMP group name.

Each IPMP IP interface is created with a matching IPMP group name, though it can be changed using the `group` subcommand. Each IPMP IP interface hosts a set of highly-available IP addresses. These addresses will remain reachable so long as at least one interface in the group is active, where “active” is defined as having at least one UP address and having INACTIVE, FAILED, and OFFLINE clear. IP addresses hosted on the IPMP IP interface may either be configured statically or configured through DHCP by means of the `dhcp` subcommand.

Interfaces assigned to the same IPMP group are treated as equivalent and monitored for failure by `in.mpathd`. Provided that active interfaces in the group remain, IP interface failures (and any subsequent repairs) are handled transparently to sockets-based applications. IPMP is also integrated with the Dynamic Reconfiguration framework (see [cfgadm\(1M\)](#)), which enables network adapters to be replaced in a way that is invisible to sockets-based applications.

The IP module automatically load-spreads all outbound traffic across all active interfaces in an IPMP group. Similarly, all UP addresses hosted on the IPMP IP interface will be distributed across the active interfaces to promote inbound load-spreading. The `ipmpstat(1M)` utility allows many aspects of the IPMP subsystem to be observed, including the current binding of IP data addresses to IP interfaces.

When an interface is placed into an IPMP group, any UP logical interfaces are “migrated” to the IPMP IP interface for use by the group, unless:

- the logical interface is marked NOFAILLOVER;
- the logical interface hosts an IPv6 link-local address;
- the logical interface hosts an IPv4 0.0.0.0 address.

Likewise, once an interface is in a group, if changes are made to a logical interface such that it is UP and not exempted by one of the conditions above, it will also migrate to the associated IPMP IP interface. Logical interfaces never migrate back, even if the physical interface that contributed the address is removed from the group.

Each interface placed into an IPMP group may be optionally configured with a “test” address that `in.mpathd` will use for probe-based failure detection; see `in.mpathd(1M)`. These addresses must be marked NOFAILLOVER (using the `-failover` subcommand) prior to being marked UP. Test addresses may also be acquired through DHCP by means of the `dhcp` subcommand.

For more background on IPMP, please see the IPMP–related chapters of the *System Administration Guide: Network Interfaces and Network Virtualization*.

### Configuring IPv6 Interfaces

When an IPv6 physical interface is plumbed and configured “up” with `ifconfig`, it is automatically assigned an IPv6 link-local address for which the last 64 bits are calculated from the MAC address of the interface.

```
example% ifconfig eri0 inet6 plumb up
```

The following example shows that the link-local address has a prefix of `fe80::/10`.

```
example% ifconfig eri0 inet6
ce0: flags=2000841<UP,RUNNING,MULTICAST,IPv6>
 mtu 1500 index 2
 inet6 fe80::a00:20ff:fe8e:f3ad/10
```

Link-local addresses are only used for communication on the local subnet and are not visible to other subnets.

If an advertising IPv6 router exists on the link advertising prefixes, then the newly plumbed IPv6 interface will autoconfigure logical interface(s) depending on the prefix advertisements. For example, for the prefix advertisement `2001:0db8:3c4d:0:55::/64`, the autoconfigured interface will look like:

```
eri0:2: flags=2080841<UP,RUNNING,MULTICAST,ADDRCONF,IPv6>
 mtu 1500 index 2
 inet6 2001:0db8:3c4d:55:a00:20ff:fe8e:f3ad/64
```

Even if there are no prefix advertisements on the link, you can still assign global addresses manually, for example:

```
example% ifconfig eri0 inet6 addif \
2001:0db8:3c4d:55:a00:20ff:fe8e:f3ad/64 up
```

To configure boot-time defaults for the interface `eri0`, place the following entry in the `/etc/hostname6.eri0` file:

```
addif 2001:0db8:3c4d:55:a00:20ff:fe8e:f3ad/64 up
```

#### Configuring IP-over-IP Tunnel Interfaces

An IP tunnel is conceptually comprised of two parts: a virtual link between two or more IP nodes, and an IP interface above this link which allows the system to transmit and receive IP packets encapsulated by the underlying link.

The `dladm(1M)` command is used to configure tunnel links, and `ifconfig` is used to configure IP interfaces over those tunnel links. An IPv4-over-IPv4 tunnel is created by plumbing an IPv4 interface over an IPv4 tunnel link. An IPv6-over-IPv4 tunnel is created by plumbing an IPv6 interface over an IPv6 tunnel link, and so forth.

When IPv6 interfaces are plumbed over IP tunnel links, their IPv6 addresses are automatically set. For IPv4 and IPv6 tunnels, source and destination link-local addresses of the form `fe80::interface-id` are configured. For IPv4 tunnels, the *interface-id* is the IPv4 tunnel source or destination address. For IPv6 tunnels, the *interface-id* is the last 64 bits of the IPv6 tunnel source or destination address. For example, for an IPv4 tunnel between 10.1.2.3 and 10.4.5.6, the IPv6 link-local source and destination addresses of the IPv6 interface would be `fe80::a01:203` and `fe80::a04:506`. For an IPv6 tunnel between `2000::1234:abcd` and `3000::5678:abcd`, the IPv6 link-local source and destination addresses of the interface would be `fe80::1234:abcd` and `fe80::5678:abcd`. These default link-local addresses can be overridden by specifying the addresses explicitly, as with any other point-to-point interface.

For 6to4 tunnels, a 6to4 global address of the form `2002:tsrc::1/16` is configured. The *tsrc* portion is the tunnel source IPv4 address. The prefix length of the 6to4 interface is automatically set to 16, as all 6to4 packets (destinations in the `2002::/16` range) are forwarded to the 6to4 tunnel interface. For example, for a 6to4 link with a tunnel source of 75.1.2.3, the IPv6 interface would have an address of `2002:4b01:203::1/16`.

Additional IPv6 addresses can be added using the `addif` option or by plumbing additional logical interfaces.

For backward compatibility, the plumbing of tunnel IP interfaces with special names will implicitly result in the creation of tunnel links without invoking `dladm create-iptun`. These tunnel names are:

<code>ip.tunN</code>	An IPv4 tunnel
<code>ip6.tunN</code>	An IPv6 tunnel
<code>ip.6to4tunN</code>	A 6to4 tunnel

These tunnels are “implicit tunnels”, denoted with the `i` flag in `dladm show-iptun` output. The tunnel links over which these special IP interfaces are plumbed are automatically created, and they are automatically deleted when the last reference is released (that is, when the last IP interface is unplumbed).

The `tsrc`, `tdst`, `encaplim`, and `hoplimit` options to `ifconfig` are obsolete and maintained only for backward compatibility. They are equivalent to their `dladm(1M)` counterparts.

**Display of Tunnel Security Settings** The `ifconfig` output for IP tunnel interfaces indicates whether IPsec policy is configured for the underlying IP tunnel link. For example, a line of the following form will be displayed if IPsec policy is present:

```
tunnel security settings --> use 'ipsecconf -ln -i ip.tun1'
```

If you do not set security policy, using either `ifconfig` or [ipsecconf\(1M\)](#), there is no tunnel security setting displayed.

### **Examples** EXAMPLE 1 Using the `ifconfig` Command

If your workstation is not attached to an Ethernet, the network interface, for example, `eri0`, should be marked “down” as follows:

```
example% ifconfig eri0 down
```

### EXAMPLE 2 Printing Addressing Information

To print out the addressing information for each interface, use the following command:

```
example% ifconfig -a
```

### EXAMPLE 3 Resetting the Broadcast Address

To reset each interface's broadcast address after the netmasks have been correctly set, use the next command:

```
example% ifconfig -a broadcast +
```

### EXAMPLE 4 Changing the Ethernet Address

To change the Ethernet address for interface `ce0`, use the following command:

```
example% ifconfig ce0 ether aa:1:2:3:4:5
```

### EXAMPLE 5 Configuring an IP-in-IP Tunnel

To configure an IP-in-IP tunnel, first create an IP tunnel link (`tunsrc` and `tundst` are hostnames with corresponding IPv4 entries in `/etc/hosts`):

```
example% dladm create-iptun -T ipv4 -s tunsrc -d tundst tun0
```

Then plumb a point-to-point interface, supplying the source and destination addresses (`mysrc` and `thedst` are hostnames with corresponding IPv4 entries in `/etc/hosts`):

```
example% ifconfig tun0 plumb mysrc thedst up
```

Use [ipsecconf\(1M\)](#), as described above, to configure tunnel security properties.

Configuring IPv6 tunnels is done by using a tunnel type of `ipv6` with `create-iptun`. IPv6 interfaces can also be plumbed over either type of tunnel.

**EXAMPLE 6** Configuring 6to4 Tunnels

To configure 6to4 tunnels, first create a 6to4 tunnel link (`myv4addr` is a hostname with a corresponding IPv4 entry in `/etc/hosts`):

```
example% dladm create-iptun -T 6to4 -s myv4addr my6to4tun0
```

Then an IPv6 interface is plumbed over this link:

```
example% ifconfig my6to4tun0 inet6 plumb up
```

The IPv6 address of the interface is automatically set as described above.

**EXAMPLE 7** Configuring IP Forwarding on an Interface

To enable IP forwarding on a single interface, use the following command:

```
example% ifconfig eri0 router
```

To disable IP forwarding on a single interface, use the following command:

```
example% ifconfig eri0 -router
```

**EXAMPLE 8** Configuring Source Address Selection Using a Virtual Interface

The following command configures source address selection such that every packet that is locally generated with no bound source address and going out on `qfe2` prefers a source address hosted on `vni0`.

```
example% ifconfig qfe2 usesrc vni0
```

The `ifconfig -a` output for the `qfe2` and `vni0` interfaces displays as follows:

```
qfe2: flags=1100843<UP,BROADCAST,RUNNING,MULTICAST,ROUTER,IPv4> mtu
 1500 index 4
 usesrc vni0
 inet 1.2.3.4 netmask ffffffff broadcast 1.2.3.255
 ether 0:3:ba:17:4b:e1
vni0: flags=2001110c1<UP,RUNNING,NOARP,NOXMIT,ROUTER,IPv4,VIRTUAL>
 mtu 0 index 5
 srcof qfe2
 inet 3.4.5.6 netmask ffffffff
```

Observe, above, the `usesrc` and `srcof` keywords in the `ifconfig` output. These keywords also appear on the logical instances of the physical interface, even though this is a per-physical interface parameter. There is no `srcof` keyword in `ifconfig` for configuring interfaces. This information is determined automatically from the set of interfaces that have `usesrc` set on them.

The following command, using the `none` keyword, undoes the effect of the preceding `ifconfig usesrc` command.

**EXAMPLE 8** Configuring Source Address Selection Using a Virtual Interface *(Continued)*

```
example% ifconfig qfe2 usesrc none
```

Following this command, `ifconfig -a` output displays as follows:

```
qfe2: flags=1100843<UP,BROADCAST,RUNNING,MULTICAST,ROUTER,IPv4> mtu
1500 index 4
inet 1.2.3.4 netmask ffffffff broadcast 1.2.3.255
ether 0:3:ba:17:4b:e1
vni0: flags=20011100c1<UP,RUNNING,NOARP,NOXMIT,ROUTER,IPv4,VIRTUAL>
mtu 0 index 5
inet 3.4.5.6 netmask ffffffff
```

Note the absence of the `usesrc` and `srcof` keywords in the output above.

**EXAMPLE 9** Configuring Source Address Selection for an IPv6 Address

The following command configures source address selection for an IPv6 address, selecting a source address hosted on `vni0`.

```
example% ifconfig qfe1 inet6 usesrc vni0
```

Following this command, `ifconfig -a` output displays as follows:

```
qfe1: flags=2000841<UP,RUNNING,MULTICAST,IPv6> mtu 1500 index 3
usesrc vni0
inet6 fe80::203:baff:fe17:4be0/10
ether 0:3:ba:17:4b:e0
vni0: flags=2002210041<UP,RUNNING,NOXMIT,NONUD,IPv6,VIRTUAL> mtu 0
index 5
srcof qfe1
inet6 fe80::203:baff:fe17:4444/128
vni0:1: flags=2002210040<RUNNING,NOXMIT,NONUD,IPv6,VIRTUAL> mtu 0
index 5
srcof qfe1
inet6 fec0::203:baff:fe17:4444/128
vni0:2: flags=2002210040<RUNNING,NOXMIT,NONUD,IPv6,VIRTUAL> mtu 0
index 5
srcof qfe1
inet6 2000::203:baff:fe17:4444/128
```

Depending on the scope of the destination of the packet going out on `qfe1`, the appropriately scoped source address is selected from `vni0` and its aliases.

**EXAMPLE 10** Using Source Address Selection with Shared-IP Zones

The following is an example of how the `usesrc` feature can be used with the `zones(5)` facility in Solaris. The following commands are invoked in the global zone:

**EXAMPLE 10** Using Source Address Selection with Shared-IP Zones *(Continued)*

```
example% ifconfig hme0 usesrc vni0
example% ifconfig eri0 usesrc vni0
example% ifconfig qfe0 usesrc vni0
```

Following the preceding commands, the `ifconfig -a` output for the virtual interfaces would display as:

```
vni0: flags=2001110c1<UP,RUNNING,NOARP,NOXMIT,ROUTER,IPv4,VIRTUAL>
 mtu 0 index 23
 srcof hme0 eri0 qfe0
 inet 10.0.0.1 netmask ffffffff
vni0:1:
 flags=2001110c1<UP,RUNNING,NOARP,NOXMIT,ROUTER,IPv4,VIRTUAL> mtu 0
 index 23
 zone test1
 srcof hme0 eri0 qfe0
 inet 10.0.0.2 netmask ffffffff
vni0:2:
 flags=2001110c1<UP,RUNNING,NOARP,NOXMIT,ROUTER,IPv4,VIRTUAL> mtu 0
 index 23
 zone test2
 srcof hme0 eri0 qfe0
 inet 10.0.0.3 netmask ffffffff
vni0:3:
 flags=2001110c1<UP,RUNNING,NOARP,NOXMIT,ROUTER,IPv4,VIRTUAL> mtu 0
 index 23
 zone test3
 srcof hme0 eri0 qfe0
 inet 10.0.0.4 netmask ffffffff
```

There is one virtual interface alias per zone (`test1`, `test2`, and `test3`). A source address from the virtual interface alias in the same zone is selected. The virtual interface aliases were created using [zonecfg\(1M\)](#) as follows:

```
example% zonecfg -z test1
zonecfg:test1> add net
zonecfg:test1:net> set physical=vni0
zonecfg:test1:net> set address=10.0.0.2
```

The `test2` and `test3` zone interfaces and addresses are created in the same way.

**EXAMPLE 11** Turning Off DHCPv6

The following example shows how to disable automatic use of DHCPv6 on all interfaces, and immediately shut down DHCPv6 on the interface named `hme0`. See [in.ndpd\(1M\)](#) and [ndpd.conf\(4\)](#) for more information on the automatic DHCPv6 configuration mechanism.

**EXAMPLE 11** Turning Off DHCPv6 *(Continued)*

```
example% echo ifdefault StatefulAddrConf false >> /etc/inet/ndpd.conf
example% kill -HUP -x in.ndpd
example% ifconfig hme0 dhcp release
```

**Files** /etc/netmasks  
Netmask data.

/etc/default/inet\_type  
Default Internet protocol type.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs
Interface Stability for command-line options	Committed
Interface Stability for command output	Uncommitted

*System Administration Guide: IP Services*

**Diagnostics** `ifconfig` sends messages that indicate if:

- the specified interface does not exist
- the requested address is unknown
- the user is not privileged and tried to alter an interface's configuration

**Notes** Do not select the names `broadcast`, `down`, `private`, `trailers`, `up` or other possible option names when you choose host names. If you choose any one of these names as host names, it can cause unusual problems that are extremely difficult to diagnose.

**Name** if\_mpadm – administer interfaces in an IP multipathing group

**Synopsis** if\_mpadm -d | -r *ifname*

**Description** The if\_mpadm utility administers IP interfaces that are part of an IP Multipathing (IPMP) group. Currently, administration is limited to offlining IP interfaces and undoing previous offline operations.

When an IP interface is taken offline, all IP data traffic that was flowing over the IP interface is moved to another IP interface in the IPMP group. In addition, all UP IP addresses hosted on the IP interface are brought down, causing `in.mpathd(1M)` to stop probe-based failure detection on the IP interface. As a result, an offline IP interface will not be used for any inbound or outbound IP traffic. Only IP interfaces that are in an IPMP group may be brought offline. If the IP interface is the last functioning interface in the IPMP group, the offline operation will fail.

When an offline operation is undone, any IP addresses hosted on that IP interface are brought UP and will be considered by `in.mpathd` for probe-based failure detection. In addition, provided the IP interface is otherwise active (see `in.mpathd(1M)`), it will again be used to send and receive IP data traffic for the IPMP group. Note that not all offline operations can be undone. For instance, `in.mpathd` may have offlined an IP interface because its hardware address was not unique within its IPMP group. The `ipmpstat` utility can be used to determine why an IP interface is offline, identify which IP interfaces in a group are being used for inbound and outbound IP traffic, and more; see `ipmpstat(1M)`.

**Options** The if\_mpadm utility supports the following options:

- d *ifname* Offline the IP interface specified by *ifname*. If *ifname* is not in an IPMP group, or the offline would cause the IPMP group to lose network connectivity, the operation will fail.
- r *ifname* Undo a previous offline of the IP interface specified by *ifname*. If *ifname* is not offline, the operation will fail.

**Examples** EXAMPLE 1 Offlining an IP Interface

The following command offlines the IP interface `under0`, causing any IP packets that were being sent and received through it to be handled by another IP interface in its group.

```
example% if_mpadm -d under0
```

EXAMPLE 2 Undoing a Previous Offline Operation

Use the following command to undo the operation in the previous example:

```
example% if_mpadm -r under0
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs
Interface Stability	Uncommitted

**See Also** [ifconfig\(1M\)](#), [in.mpathd\(1M\)](#), [impstat\(1M\)](#), [attributes\(5\)](#)

**Diagnostics** cannot offline: no other functioning interfaces are in its IPMP group.

**Description:** This message means that offlining the IP interface would leave the IPMP group without network connectivity.

cannot offline: not a physical interface or not in an IPMP group

**Description:** This means that the IP interface is not an underlying interface in an IPMP group, and therefore is not eligible to be offlined.

**Name** ifparse – parse ifconfig command line

**Synopsis** /sbin/ifparse [-fs] *addr\_family commands*

**Description** Use the ifparse command to parse the [ifconfig\(1M\)](#) command line options and output substrings, one per line, as appropriate. If no options are specified, ifparse returns the entire ifconfig command line as a series of substrings, one per line.

**Options** The ifparse command supports the following options:

- f Lists only substrings of the ifconfig command line that are relevant to IP network multipath failover
- s Lists only substrings of the ifconfig command line that are not relevant to IP network multipath failover

**Operands** The ifparse command *does not* support the *interface* operand of the ifconfig command.

**Examples** **EXAMPLE 1** Parsing Command Line Options Relevant to Failover

The following example shows the use of the ifparse command to parse the command line options relevant to IP network multipath failover:

```
example# ifparse -f inet 1.2.3.4 up group one addif 1.2.3.5 -failover up
set 1.2.3.4 up
```

**EXAMPLE 2** Parsing Command Line Options That Are Not Relevant to Failover

The following example shows the use of the ifparse command to parse the command line options that are not relevant to IP network multipath failover:

```
example# ifparse -s inet 1.2.3.4 up group one addif 1.2.3.5 -failover up
group one
addif 1.2.3.5 -failover up
```

**EXAMPLE 3** Parsing the Command Line For All Options

The following example shows the use of the ifparse command to parse the command line for all ifconfig options:

```
example# ifparse inet 1.2.3.4 up group one addif 1.2.3.5 -failover up
group one
set 1.2.3.4 up
addif 1.2.3.5 -failover up
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Obsolete

**See Also** [ifconfig\(1M\)](#), [attributes\(5\)](#)

**Diagnostics** usage: -fs <addr\_family> <commands>

**Description:** This message indicates an invalid command line.

ifparse: Not enough space

**Description:** This message indicates insufficient memory.

ifparse: dhcp not supported for inet6

**Description:** DHCP operations are not supported for the inet6 address family.

ifparse: Operation <operation> not supported for <addr\_family>

**Description:** Most operations cannot be used with all address families. For example, the broadcast operation is not supported on the inet6 address family.

ifparse: no argument for <operation>

**Description:** Some operations, for example broadcast, require an argument.

**Notes** The ifparse command is classified as an obsolete interface. It will likely be removed in a future release. You should not develop applications that depend upon this interface.

**Name** iiadm – command–line interface to control Sun StorageTek Availability Suite Point-in-Time Copy operations

**Synopsis** *iiadm -e {ind | shd} master\_vol shadow\_vol bitmap\_vol*  
*iiadm -ne ind master\_vol shadow\_vol bitmap\_vol*  
*iiadm [-p] [-n] {-c | -u} {s | m} volume\_set*  
*iiadm [-adDiLR] volume\_set*  
*iiadm [-p] [-n] -w volume\_set*  
*iiadm [-hiLLv]*  
*iiadm -P delay units volume\_set*  
*iiadm -P volume\_set*  
*iiadm -A overflow\_vol volume\_set*  
*iiadm [-OQ] overflow\_vol*  
*iiadm -E volume\_set*  
*iiadm [-IJ] volume\_set bitmap*  
*iiadm -g group\_name [-aAcDDeEiLLmPRuw]*  
*iiadm [-C] cluster\_tag [options]*

**Description** Point-in-Time Copy software is a point-in-time snapshot feature of the Solaris operating system.

A Point-in-Time Copy snapshot is an instantly-available, time-fixed, replicated view of a momentarily quiesced volume. Once a snapshot is taken, Point-in-Time Copy software allows immediate read/write access to both the master and shadow volume data.

Point-in-Time Copy software tracks the differences between the master and shadow volumes (caused by writes) from the moment that the snapshot was established. This capability allows applications accessing the master volume's data to move forward in time independently of applications accessing the shadow volume's data, and vice-versa.

The Point-in-Time Copy software's tracking of differences between the master and shadow volumes facilitates a fast resynchronization or a full copy at a later time. The volume resynchronization can occur from either shadow to master or master to shadow.

Instantly after the point-in-time is (re-)established (either when the CLI prompt returns or the next shell script command is read), the master volume can be remounted or the applications using them can be resumed. Also, the shadow volume can be mounted and immediately accessed.

The `iiadm` command line utility performs only one action per command invocation. Because of this, you cannot combine multiple options, except in combination with the following overall command modifiers:

- If no action item is entered, `iiadm` displays the list of Point-in-Time Copy sets (non-suspended) currently configured. If more than one action item, or an incorrectly specified action item is entered, `iiadm` displays the specific error message to `stderr`, followed by a brief usage summary.
- For the Point-in-Time Copy options `ENABLE (-e)`, `COPY (-c)` and `UPDATE (-u)`, there are two associated shadow volume selection qualifiers, `{ind|dep}`, that are used to specify the type of Point-in-Time Copy volume set to create.

An independent (`ind`) snapshot causes Point-in-Time Copy software to perform a full volume copy operation from the master to the shadow. When the copy completes, the shadow volume data is identical to the master volume data at the moment that it was established. Create an independent shadow if you require two physical copies of the data. An independent shadow volume must be the same size or greater than the size of the master volume. Sun recommends that the master and shadow volumes be the same size for environments where resynchronization from shadow to master is a consideration.

A dependent (`dep`) snapshot causes Point-in-Time Copy software not to perform a full volume copy. The resulting shadow volume relies on the master volume for all unmodified data blocks, which are not copied until requested. Create a dependent shadow when you do not require two physical copies of the data. A dependent shadow volume can be either the same size or smaller than the master volume. A smaller shadow volume is called a *Compact Dependent Shadow Volume*, and is typically used when the amount of change that occurs to a Point-in-Time Copy volume set is small compared to the entire size of the master volume.

The following syntax allows you to create an exportable independent shadow volume in a Sun Cluster environment:

```
iiadm -ne ind master shadow bitmap
```

An issue arises when using a Compact Dependent Shadow Volume in that its size is established at the time that the Point-in-Time Copy volume set is enabled. If the amount of change to the entire volume set over the duration of its usage exceeds the space allocated for the shadow volume, the shadow volume is marked as out of space. It is possible to read from the shadow volume even after it is out of space, until a portion of the data for which there was no room is requested. Once that happens, the read fails and the shadow volume is marked offline.

To address this issue, Point-in-Time Copy supports the ability to associate an *overflow* volume to an existing Point-in-Time Copy dependent volume set. Thus, if the size of the Compact Dependent Shadow Volume is too small, or an unscheduled amount of change occurs to the volume set, changed data can be redirected to the associated overflow volume. To facilitate efficient usage of this overflow volume, it can be associated with multiple Point-in-Time Copy volume sets on an as-needed basis.

**Considerations** Prior to invoking an Point-in-Time Copy enable, copy or update operation, Point-in-Time Copy assures that the shadow volume is not mounted, to prevent a file system panic from occurring. Also, it is suggested that you either unmount or suspend (quiesce) all applications using the master volume, for only the instant when the point-in-time snapshot is taken. This assures that an atomically consistent point-in-time snapshot is taken.

It is suggested that, if the master volume was suspended rather than unmounted, the new point-in-time shadow volume's integrity be validated using volume validation utilities, such as `fsck(1M)`. The reason is that Point-in-Time Copy has made a point-in-time copy of a mounted master volume to an unmounted shadow volume. During the mounting of the shadow volume, the file system detects that it is in the mounted state. Typically this state occurs only when a system crashes, so the file system attempts to validate the integrity of the volume assuming a system failure occurred, not an Point-in-Time Copy.

**ENVIRONMENT OPTIONS** The `ii_bitmap` variable in the `/usr/kernel/drv/ii.conf` configuration file determines the bitmap volume operational semantics as follows:

- `0` Indicates that the bitmap is maintained in memory only or resume operation.
- `1` Indicates that the bitmap is maintained in memory and on disk. This is the default value.

If a system failure occurs while using `ii_bitmap=0`, the shadow volume might be inconsistent and fast resynchronization would not be possible.

If Point-in-Time Copy is used in conjunction with the Network Storage component Remote Mirror or in a Sun Cluster, set `ii_bitmap=1`.

The `ii_debug` variable in the `/usr/kernel/drv/ii.conf` configuration file determines the amount of information logging that is output to the system console `/dev/console` during Point-in-Time Copy processing.

- `0` Indicates that no logging is sent to the system console.
- `1` Indicates that informational logging is sent to the system console.
- `2` Indicates that developmental logging is sent to the system console.

**Options** The `iiadm` utility supports the following options.

`-e{ind|dep} master_vol shadow_vol bitmap_vol`

Enable Point-in-Time Copy for the specified master, shadow, and bitmap volumes.

The enable shadow set processing assures that the specified volumes are accessible, that the `shadow_vol` is not mounted, and that the `bitmap_vol` is correctly sized for the type of shadow set being created. Additionally, it assures that the volumes are under control of the SV driver ( if they are not, it puts them there), initializes the bitmap volume, and, if the volume set is an independent shadow set, a full copy operation is initiated.

On a successful enable, Point-in-Time Copy stores the specified *master\_vol*, *shadow\_vol* and *bitmap\_vol* names, plus the enabling type (*ind* or *dep*), into the Point-in-Time Copy configuration store. The configuration store contains all currently configured Point-in-Time Copy Volume Sets and their associated configuration attributes. (See discussion above on independent and dependent shadow volume semantics.)

*master\_vol* is the volume from which a point-in-time snapshot is made.

*shadow\_vol* is the volume that contains the point-in-time snapshot.

*bitmap\_vol* is used for tracking differences between the shadow and master volumes. When Point-in-Time Copy shadow operations are suspended or resumed, the bitmap volume (maintained in kernel memory) can be stored in or retrieved from permanent storage. The storage associated with the bitmap volume should be as redundant as that of the shadow volume storage.

The *shadow\_vol* name is the name that the Point-in-Time Copy Shadow Set is known by for all *iiadm* options requiring specification of a *volume\_set* name.

**-d** *volume\_set*

Disable the Point-in-Time Copy volume set associated with the specified *volume\_set*.

If Point-in-Time Copy was running in *independent* mode as specified in the **-e** *ind* options, above, the shadow volume data contains the same data as it did before it was disabled (assuming no writes have occurred). Users can access the master and shadow volumes, as they are now standalone point-in-time copies.

During the time that the full copy is active, an *independent* volume operates as though it is a dependent volume. To assure that the volume is no longer in full copy mode, issue the following command to wait for the full copy to complete:

```
iiadm -w volume_set
```

**[-p]** **-u** *s volume\_set*

Update the shadow volume from the master.

Updates a point-in-time copy of the master volume to the shadow volume. *volume\_set* is the Point-in-Time Copy shadow set containing the master and shadow volumes. This option provides a fast resynchronization of the shadow volume, creating an incremental copy of the master. This update copies all 32KB segments flagged as different between the master and shadow volumes. It does not copy all master volume data, only changed data. While the data is being copied, the shadow is dependent upon the master volume.

Before using this option, momentarily quiesce the workload to the volumes; stop the host application from writing to the volumes. This ensures that the point-in-time data is consistent. You can visually check the status of this copy or update operation with *iiadm -i volume\_set*, or interactively (by means of a shell or script) with *iiadm -w volume\_set*, before using the target volume for any other operations.

This command supports PID (Process Identifier) locking, by using the option `-p`, `iiadm -p -u s`. Enabling this option prevents other processes from taking a new point-in-time snapshot, thus invalidating prior point-in-time data.

`[-p] [-n] -u m volume_set`

Updates a point-in-time copy of the master volume from the shadow. *volume\_set* is the Point-in-Time Copy volume set containing the master and shadow. This option provides a fast resynchronization of the master volume, creating an incremental copy of the shadow. This update copies all 32KB segments flagged as different between the master and shadow volumes. It does not copy all shadow volume data, only changed data. While the data is being copied, the master is dependent upon the shadow volume.

Before using this option, momentarily quiesce the workload to the volumes; stop the host application from writing to the volumes. This ensures that the point-in-time data is consistent. You can visually check the status of this copy or update operation with `iiadm -i volume_set`, or interactively (by means of a shell or script) with `iiadm -w volume_set`, before using the target volume for any other operations.

This command is query enabled to prevent accidentally overwriting the data on a master volume. When this command option is used in scripts, add the `-n` option to prevent the query from occurring.

This command supports PID (Process Identifier) locking, by using the option `-p`, `iiadm -p -u m`. Enabling this option prevents other processes from taking a new point-in-time snapshot, thus invalidating prior point-in-time data.

`[-p] -c s volume_set`

Copy the master volume to the shadow.

Creates a point-in-time copy of the master volume to the shadow volume. *volume\_set* is the Point-in-Time Copy volume set containing the master and shadow. This option writes all data in the point-in-time copy of the master volume to the shadow volume. While the data is being copied from master to shadow, the shadow is dependent on the master volume.

This option performs a full volume copy. Use `iiadm -u s` unless the integrity of the data on the independent shadow volume is in doubt. Otherwise, use this option to synchronize the master and shadow volumes; that is, make the data on each volume match.

Before using this option, momentarily quiesce the workload to the volumes; stop the host application from writing to the volumes. This ensures that the point-in-time data is consistent. You can visually check the status of this copy or update operation with `iiadm -i volume_set`, or interactively (by means of a shell or script) with `iiadm -w volume_set`, before using the target volume for any other operations.

This command supports PID (Process Identifier) locking, by using the `-p` option, `iiadm -p -c s`. Enabling this option prevents other processes from taking a new point-in-time snapshot, thus invalidating prior point-in-time data.

**-c m *volume\_set***

Copy the shadow volume to the master.

Creates a point-in-time copy of the shadow volume to the master volume. *volume\_set* is the Point-in-Time Copy volume set containing the master and shadow volumes. This option writes all data in the point-in-time copy of the shadow volume to the master volume. While the data is being copied from the shadow to the master, the master is dependent upon the shadow volume.

This option performs a full volume copy. Use `iiadm -u m` unless the integrity of the data on the independent master is in doubt. Otherwise, use this option to synchronize the master and shadow volumes; that is, make the data on each volume match.

Before using this option, momentarily quiesce the workload to the volumes; stop the host application from writing to the volumes. This ensures that the point-in-time data is consistent. You can visually check the status of this copy or update operation with `iiadm -i volume_set`, or interactively (by means of a shell or script) with `iiadm -w volume_set`, before using the target volume for any other operations.

This command is query-enabled to prevent accidentally overwriting the data on a master volume. When this command option is used in scripts, add the `-n` option to prevent the query from occurring.

This command supports PID (Process IDentifier) locking, by using the `-p` option, `iiadm -p -c m`. Enabling this option prevents other processes from taking a new point-in-time snapshot, thus invalidating prior point-in-time data.

**-a *volume\_set***

Abort any current copy operation that might be active between the master and shadow volumes. *volume\_set* is the Point-in-Time Copy volume set containing the master and shadow volumes. After executing `iiadm -a`, the update or copy to the target (master or shadow) volume is incomplete. The target volume is now a dependent copy of the source volume. Reissue the update or copy command option to resynchronize the volumes.

**[-p] [-n] -w *volume\_set***

Wait until any in-progress copy or update operation completes or is aborted. *volume\_set* is the Point-in-Time Copy volume set containing the master and shadow volumes.

This option waits until the current Point-in-Time Copy operation is complete, thus preventing a subsequent `iiadm` command (from a shell or script) from executing. Use this command option when you need to be sure the copy or update operation has completed.

This command supports PID (Process IDentifier) unlocking. If a prior copy or update, using a command `iiadm -p {-c|-u} {m|s}`, was invoked with the `-p` option, upon completion of the wait processing, if the current PID was the PID that locked the point-in-time data, this option unlocks the data.

-i *volume\_set*

Display status for the Point-in-Time Copy currently-enabled or -suspended volume set. *volume\_set* is the Point-in-Time Copy volume set containing the master and shadow volumes. If no *volume\_set* is specified, status is displayed for all Point-in-Time Copy volume sets that are configured.

-l

List all currently configured Point-in-Time Copy volumes.

-O *overflow\_vol*

This option causes Point-in-Time Copy to initialize the specified *overflow\_vol* for subsequent use as an overflow volume in conjunction with Compact Dependent Shadow Volumes. To facilitate efficient, shared usage of this overflow volume, it can be associated with multiple Point-in-Time Copy volume sets on an as-needed basis.

During initialization of the *overflow\_vol*, the initiator of this option, must answer the following question: “Initialize this overflow volume? yes/no” A response of either “yes/no” is required before proceeding.

This option supports the -n option, so that the requested action is performed without prompting. This option is useful for inclusion in a script. The -n option must be specified first. For example, “iiadm -nO vol” is valid; “iiadm -On vol” is not.

Make sure you want to initialize the data on the specified *overflow\_vol*, especially when using the -n option.

-A *overflow\_vol volume\_set*

This option enables the specified *overflow\_vol*, for subsequent use as an overflow volume in a situation where the size of the Compact Dependent Shadow Volume is too small, or an unscheduled amount of change occurs to the volume set. Overflow changed data would be redirected to the associated overflow volume. *volume\_set* is the Point-in-Time Copy volume set containing the master and shadow volumes.

If the *overflow\_vol* has not been initialized, this option initializes the *overflow\_vol* (see -O option), then attaches the *overflow\_vol* to the *volume\_set*.

If *overflow\_vol* was previously initialized, this option attaches the *overflow\_vol* to the *volume\_set*.

This option supports the -n option, so that the requested action is performed without prompting. This option is useful for inclusion in a script. The -n option must be specified first. For example, “iiadm -nA vol” is valid; “iiadm -An vol” is not.

Make sure you want to initialize the data on the specified *overflow\_vol*, especially when using the -n option.

**-D *volume\_set***

This option removes the overflow volume currently associated with the specified *volume\_set*. If the overflow volume is currently in use by the *volume\_set*, this operation fails with an “Overflow volume still in use” error message. To resolve this situation, perform one of the operations described below on the *volume\_set*. These operations momentarily clear out all overflow writes that are associated with this volume set.

**abort(-a)**

Abort copy operation.

**disable(-d)**

Dissolve the volume set.

**update(-u)**

Update the volume set.

**-L**

This option lists all overflow volumes which are associated with one or more volume sets.

**-Q *overflow\_vol***

This option displays the current status of the *overflow\_vol*.

**-E *volume\_set***

Export the independent shadow volume of the Point-in-Time Copy volume set specified by *volume\_set*. The shadow volume is to be made available to another host for read/write access, by means of an enabling technology, such as multi-ported devices. This other host is responsible for maintaining a bitmap of differences that is used to merge with locally recorded differences to the master when the shadow volume is rejoined to its master volume. While a shadow volume is exported it must not be subject to an update or copy operation. Perform an `iiadm -w volume_set` command prior to invoking an export command.

**-I *volume\_set bitmap\_vol***

Import the independent shadow volume of the Point-in-Time Copy volume set specified by *volume\_set*. The shadow volume must have been previously exported from a host by means of an enabling technology, such as multi-ported devices. The import operation causes this host to start maintaining a bitmap of differences as the volume is modified. The *bitmap\_vol* should not be the same as that used when the shadow volume was originally formed into a shadow group.

After the exported/imported independent shadow volume is no longer needed by the other node, you must enter a disable command so that the *bitmap\_vol* and its associated *shadow\_vol* are consistent, prior to performing a join operation. For example,

```
iiadm -d volume_set
```

**-J *volume\_set bitmap\_vol***

Join the *volume\_set*, using the *bitmap\_vol*, with the master volume set of the Point-in-Time Copy volume set. The bitmap volume supplied is read and merged with the original

volume to reconstruct the original volume set consisting of the master, shadow, and bitmap volumes. The *bitmap\_vol* to be merged is the one obtained on the node that had imported the independent shadow volume. There must be no write activity to the shadow volume on the importing machine from the time the bitmap is copied over until the shadow is once again imported.

`-g group_name -m volume_set [volume_set2 ...]`  
 Add one or more existing Point-in-Time Copy *volume\_set(s)* into a user specified *group\_name*. This association of one or more Point-in-Time Copy volume sets in a group allows the list of *iiadm* options shown below to be performed on all volume sets within the *group\_name* as a whole.

Only the commands COPY (-c) and UPDATE (-u) are performed atomically across all Point-in-Time Copy sets within the group. All other grouped, *iiadm* commands are performed sequentially on each member of the group.

The syntax of an *iiadm* group command is as follows:

```
iiadm -g group_name [options]
```

The *options* are as follows:

- a  
Abort copy operation on all sets within *group\_name*.
- A  
Attach *overflow\_vol* to all sets within *group\_name*.
- c {s | m}  
Copy shadow/master for all sets within *group\_name*.
- D  
Detach *overflow\_vol* from all sets within *group\_name*.
- d  
Disable all sets within *group\_name*.
- E  
Export all volume sets within *group\_name*.
- i  
Status of all volume sets within *group\_name*.
- l  
List all volume sets within *group\_name*.
- L  
List all groups.
- n  
Do not ask if an update of the master volume is what the user really intended.

- P  
Set parameters on all volume sets within *group\_name*.
  - R  
Reset all volume sets within *group\_name*.
  - u {s | m}  
Update shadow/master for all sets within *group\_name*.
  - w  
Wait for all volume sets within *group\_name*.
  - g -" " -m *volume\_set* [*volume\_set2* ...]  
Remove one or more existing Point-in-Time Copy *volume\_set(s)* from their currently associated *group\_name*. By default, or until moved into a user specified *group\_name*, all Point-in-Time Copy *volume\_set(s)* are in the blank (" ") group. This association allows all the previously documented *iiadm* group commands to be performed against the blank (" ") *iiadm group\_name*.
  - C *cluster\_tag*  
This Point-in-Time Copy option is a modifier that limits configuration operations to only those volumes belonging to a Sun Cluster Resource Group, or Disk Group.  
  
In a Sun Cluster where the volume manager is Sun Cluster-aware, *iiadm* automatically obtains the correct Disk Group information, therefore this option is typically not required unless the volumes are part of an encompassing Resource Group.  
  
In a Sun Cluster where the volumes are accessible on the local node only, the special *cluster\_tag* of `local` is used to indicate volumes that are not part of a Sun Cluster Resource Group or Disk Group.  
  
If "-L" is given as a the *cluster\_tag* argument, then *iiadm* lists all cluster tags associated with Point-in-Time Copy.  
  
This option is invalid when used on a Solaris system on which the Sun Cluster package has not been installed or configured.
  - h  
Prints the *iiadm* usage summary.
  - v  
Display the current version of the Point-in-Time Copy software components.
- Contact Sun Enterprise Services for assistance in using the remaining commands in this section.
- P *delay unit volume\_set*  
Alter the Point-in-Time Copy volume set tuning parameters for the specified *volume\_set* to *delay* ticks, every *unit* I/O's. Delay ranges from 2 to 10000 inclusive; unit ranges from 100 to 60000 inclusive.

**-R *volume***

After a volume has failed, Point-in-Time Copy places it offline. After replacing the volume, place it back online using this option. Associated dependent volumes in the Point-in-Time Copy volume set are also placed online. After the volume is placed online, this command also starts any necessary point-in-time volume updates.

**Exit Status** 0            Command completed successfully.  
 >0            An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTETYPE	ATTRIBUTEVALUE
Availability	storage/avs/point-in-time-copy, SUNWiuu
Interface Stability	Committed

**See Also** [dscfg\(1M\)](#), [svadm\(1M\)](#), [ds.log\(4\)](#), [rdc.cf\(4\)](#), [attributes\(5\)](#), [ii\(7D\)](#), [sv\(7D\)](#)

**Name** iicpbmp – copy Availability Suite Point-In-Time bitmap volumes

**Synopsis** `iicpbmp [-c] old_bitmap new_bitmap...`

**Description** The `iicpbmp` command copies an Availability Suite Point-in-Time bitmap volume, rewriting the bitmap header so that it is consistent with the new bitmap volume name. The configuration entry for the shadow set is rewritten to reflect the location of the new bitmap.

No checks on the current use of either the old or new bitmap volumes are made. The `iicpbmp` command should only be run when the Point-In-Time Copy shadow set using the old bitmap is suspended.

**Options** `-c` Do not attempt to update the Availability Suite configuration for the Point-in-Time shadow set that uses the bitmap. This option produces a duplicate of the bitmap but does not affect the shadow set using the old bitmap volume.

**Operands** `old_bitmap new_bitmap`  
The old and new Point-In-Time bitmap volumes.

**Warnings** The `iicpbmp` should be run only when a system is in single-user mode. `iicpbmp` makes no attempt to check if an Point-In-Time Copy set is in use at the time the copy is made. Running `iicpbmp` without the `-c` flag while Point-In-Time Copy is using the shadow set results in inconsistencies in the shadow set the next time Point-In-Time Copy is started.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/avs/point-in-time-copy, SUNWiiu
Interface Stability	Committed

**See Also** [iiadm\(1M\)](#), [iicpshd\(1M\)](#), [attributes\(5\)](#)

**Name** iicpshd – copy Availability Suite Point-in-Time shadow volume

**Synopsis** `iicpshd [-s] old_shadow new_shadow . . .`

**Description** The `iicpshd` command copies an Availability Suite Instant Image shadow volume, updating the bit map header and Availability Suite configuration to reflect the new shadow volume.

No checks on the current use of either the old or new shadow volumes are made. The `iicpshd` command should only be run when the Instant Image shadow set using the old shadow volume is suspended.

**Options** The `iicpshd` command supports the following option:

`-s` Update the StorageTek configuration information for the Point-in-Time shadow set, but do *not* copy data from the old shadow volume to the new shadow volume.

**Operands** A `iicpshd` command line has the following operands:

`old_shadow new_shadow`

`iicpshd` copies the data of the old Availability Suite Instant Image shadow volume to the new shadow volume and updates the bit map header and configuration data.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/avs/point-in-time-copy, SUNWuiu
Interface Stability	Committed

**See Also** [iiadm\(1M\)](#), [iicpbmp\(1M\)](#), [attributes\(5\)](#)

**Warnings** `iicpshd` should be run only when the system is in single-user mode. When you run `iicpshd`, the command makes no attempt to check if a Point-in-Time set is in use. Running `iicpshd` with the `-s` flag while Point-in-Time is using the old shadow volume can result in shadow volume data loss. If you use the `-s` option, you must manually copy the data on the old shadow volume to the new shadow volume.

**Name** ikeadm – manipulate Internet Key Exchange (IKE) parameters and state

**Synopsis** ikeadm [-np]

```
ikeadm [-np] get [debug | priv | stats | defaults]
ikeadm [-np] set [debug | priv] [level] [file]
ikeadm [-np] [get | del] [p1 | rule | preshared] [id]
ikeadm [-np] add [rule | preshared] { description }
ikeadm [-np] token [login | logout] PKCS#11_Token_Object
ikeadm [-np] [read | write] [rule | preshared | certcache] file
ikeadm [-np] dump [p1 | rule | preshared | certcache | groups
 | encralgs | authalgs]
ikeadm [-np] flush [p1 | certcache]
ikeadm help
 [get | set | add | del | read | write | dump | flush | token]
```

**Description** The `ikeadm` utility retrieves information from and manipulates the configuration of the Internet Key Exchange (IKE) protocol daemon, [in.iked\(1M\)](#).

`ikeadm` supports a set of operations, which may be performed on one or more of the supported object types. When invoked without arguments, `ikeadm` enters interactive mode which prints a prompt to the standard output and accepts commands from the standard input until the end-of-file is reached.

Because `ikeadm` manipulates sensitive keying information, you must be superuser to use this command. Additionally, some of the commands available require that the daemon be running in a privileged mode, which is established when the daemon is started.

For details on how to use this command securely see [Security](#).

**Options** The following options are supported:

-n

Prevent attempts to print host and network names symbolically when reporting actions. This is useful, for example, when all name servers are down or are otherwise unreachable.

-p

Paranoid. Do not print any keying material, even if saving Security Associations. Instead of an actual hexadecimal digit, print an X when this flag is turned on.

## Usage

**Commands** The following commands are supported:

**add**

Add the specified object. This option can be used to add a new policy rule or a new preshared key to the current (running) `in.iked` configuration. When adding a new preshared key, the command cannot be invoked from the command line, as it will contain keying material. The rule or key being added is specified using appropriate id-value pairs as described in the ID FORMATS section.

**del**

Delete a specific object or objects from `in.iked`'s current configuration. This operation is available for IKE (Phase 1) SAs, policy rules, and preshared keys. The object to be deleted is specified as described in the Id Formats.

**dump**

Display all objects of the specified type known to `in.iked`. This option can be used to display all Phase 1 SAs, policy rules, preshared keys, implemented Diffie-Helman groups, encryption and authentication algorithms available for Phase 1, or the certificate cache. A large amount of output might be generated by this command.

**flush**

Remove all IKE (Phase 1) SAs or cached certificates from `in.iked`.

Note that flushing the cert cache will also (as a side-effect) update IKE with any new certificates added or removed.

**get**

Lookup and display the specified object. May be used to view the current debug or privilege level, global statistics and default values for the daemon, or a specific IKE (Phase 1) SA, policy rule, or preshared key. The latter three object types require that identifying information be passed in; the appropriate specification for each object type is described below.

**help**

Print a brief summary of commands, or, when followed by a command, prints information about that command.

**read**

Update the current `in.iked` configuration by reading the policy rules or preshared keys from either the default location or from the file specified.

**set**

Adjust the current debug or privilege level. If the debug level is being modified, an output file may optionally be specified; the output file *must* be specified if the daemon is running in the background and is not currently printing to a file. When changing the privilege level, adjustments may only be made to lower the access level; it cannot be increased using `ikeadm`.

**write**

Write the current `in.iked` policy rule set or preshared key set to the specified file. A destination file must be specified. This command should not be used to overwrite the existing configuration files.

**token**

Log into a PKCS#11 token object and grant access to keying material or log out and invalidate access to keying material.

`token` can be run as a normal user with the following authorizations:

- `token login: solaris.network.ipsec.ike.token.login`
- `token logout: solaris.network.ipsec.ike.token.logout`

**Object Types** `debug`

Specifies the daemon's debug level. This determines the amount and type of output provided by the daemon about its operations. The debug level is actually a bitmask, with individual bits enabling different types of information.

Description	Flag	Nickname
Certificate management	0x0001	cert
Key management	0x0002	key
Operational	0x0004	op
Phase 1 SA creation	0x0008	phase1
Phase 2 SA creation	0x0010	phase2
PF_KEY interface	0x0020	pfkey
Policy management	0x0040	policy
Proposal construction	0x0080	prop
Door interface	0x0100	door
Config file processing	0x0200	config
Label processing	0x0400	label
All debug flags	0x07ff	all

When specifying the debug level, either a number (decimal or hexadecimal) or a string of nicknames may be given. For example, `88`, `0x58`, and `phase1+phase2+policy` are all equivalent, and will turn on debug for phase 1 sa creation, phase 2 sa creation, and policy management. A string of nicknames may also be used to remove certain types of information; `all-op` has the effect of turning on all debug *except* for operational messages; it is equivalent to the numbers `1019` or `0x3fb`.

## priv

Specifies the daemon's access privilege level. The possible values are:

Description	Level	Nickname
Base level	0	base
Access to preshared key info	1	modkeys
Access to keying material	2	keymat

By default, `in.iked` is started at the base level. A command-line option can be used to start the daemon at a higher level. `ikeadm` can be used to lower the level, but it cannot be used to raise the level.

Either the numerical level or the nickname may be used to specify the target privilege level.

In order to get, add, delete, dump, read, or write preshared keys, the privilege level must at least give access to preshared key information. However, when viewing preshared keys (either using the `get` or `dump` command), the key itself will only be available if the privilege level gives access to keying material. This is also the case when viewing Phase 1 SAs.

## stats

Global statistics from the daemon, covering both successful and failed Phase 1 SA creation.

Reported statistics include:

- Count of current P1 SAs which the local entity initiated
- Count of current P1 SAs where the local entity was the responder
- Count of all P1 SAs which the local entity initiated since boot
- Count of all P1 SAs where the local entity was the responder since boot
- Count of all attempted P1 SAs since boot, where the local entity was the initiator; includes failed attempts
- Count of all attempted P1 SAs since boot, where the local entity was the responder; includes failed attempts
- Count of all failed attempts to initiate a P1 SA, where the failure occurred because the peer did not respond
- Count of all failed attempts to initiate a P1 SA, where the peer responded
- Count of all failed P1 SAs where the peer was the initiator
- Whether a PKCS#11 library is in use, and if applicable, the PKCS#11 library that is loaded. See [Example 11](#).

## defaults

Display default values used by the `in.iked` daemon. Some values can be overridden in the daemon configuration file (see `ike.config(4)`); for these values, the token name is displayed in the `get defaults` output. The output will reflect where a configuration token has changed the default.

Default values might be ignored in the event a peer system makes a valid alternative proposal or they can be overridden by per-rule values established in `ike.config`. In such instances, a `get defaults` command continues to display the default values, not the values used to override the defaults.

**p1**

An IKE Phase 1 SA. A p1 object is identified by an IP address pair or a cookie pair; identification formats are described below.

**rule**

An IKE policy rule, defining the acceptable security characteristics for Phase 1 SAs between specified local and remote identities. A rule is identified by its label; identification formats are described below.

**preshared**

A preshared key, including the local and remote identification and applicable IKE mode. A preshared key is identified by an IP address pair or an identity pair; identification formats are described below.

**Id Formats** Commands like `add`, `del`, and `get` require that additional information be specified on the command line. In the case of the `delete` and `get` commands, all that is required is to minimally identify a given object; for the `add` command, the full object must be specified.

Minimal identification is accomplished in most cases by a pair of values. For IP addresses, the local `addr` and then the remote `addr` are specified, either in dot-notation for IPv4 addresses, colon-separated hexadecimal format for IPv6 addresses, or a host name present in the host name database. If a host name is given that expands to more than one address, the requested operation will be performed multiple times, once for each possible combination of addresses.

Identity pairs are made up of a local type-value pair, followed by the remote type-value pair. Valid types are:

**prefix**

An address prefix.

**fqdn**

A fully-qualified domain name.

**domain**

Domain name, synonym for `fqdn`.

**user\_fqdn**

User identity of the form `user@fqdn`.

**mailbox**

Synonym for `user_fqdn`.

A cookie pair is made up of the two cookies assigned to a Phase 1 Security Association (SA) when it is created; first is the initiator's, followed by the responder's. A cookie is a 64-bit number.

Finally, a label (which is used to identify a policy rule) is a character string assigned to the rule when it is created.

Formatting a rule or preshared key for the add command follows the format rules for the `in.iked` configuration files. Both are made up of a series of id-value pairs, contained in curly braces (`{` and `}`). See `ike.config(4)` and `ike.preshared(4)` for details on the formatting of rules and preshared keys.

**Security** The `ikeadm` command allows a privileged user to enter cryptographic keying information. If an adversary gains access to such information, the security of IPsec traffic is compromised. The following issues should be taken into account when using the `ikeadm` command.

- Is the TTY going over a network (interactive mode)?  
If it is, then the security of the keying material is the security of the network path for this TTY's traffic. Using `ikeadm` over a clear-text telnet or rlogin session is risky. Even local windows may be vulnerable to attacks where a concealed program that reads window events is present.
- Is the file accessed over the network or readable to the world (read/write commands)?  
A network-mounted file can be sniffed by an adversary as it is being read. A world-readable file with keying material in it is also risky.

If your source address is a host that can be looked up over the network, and your naming system itself is compromised, then any names used will no longer be trustworthy.

Security weaknesses often lie in misapplication of tools, not the tools themselves. It is recommended that administrators are cautious when using the `ikeadm` command. The safest mode of operation is probably on a console, or other hard-connected TTY.

For additional information regarding this subject, see the afterward by Matt Blaze in Bruce Schneier's *Applied Cryptography: Protocols, Algorithms, and Source Code in C*.

**Examples** EXAMPLE 1 Emptying out all Phase 1 Security Associations

The following command empties out all Phase 1 Security Associations:

```
example# ikeadm flush p1
```

EXAMPLE 2 Displaying all Phase 1 Security Associations

The following command displays all Phase 1 Security Associations:

```
example# ikeadm dump p1
```

EXAMPLE 3 Deleting a Specific Phase 1 Security Association

The following command deletes the specified Phase 1 Security Associations:

```
example# ikeadm del p1 local_ip remote_ip
```

**EXAMPLE 4** Adding a Rule From a File

The following command adds a rule from a file:

```
example# ikeadm add rule rule_file
```

**EXAMPLE 5** Adding a Preshared Key

The following command adds a preshared key:

```
example# ikeadm
ikeadm> add preshared { localidtype ip localid local_ip
 remoteidtype ip remoteid remote_ip ike_mode main
 key 1234567890abcdef1234567890abcdef }
```

**EXAMPLE 6** Saving All Preshared Keys to a File

The following command saves all preshared keys to a file:

```
example# ikeadm write preshared target_file
```

**EXAMPLE 7** Viewing a Particular Rule

The following command views a particular rule:

```
example# ikeadm get rule rule_label
```

**EXAMPLE 8** Reading in New Rules from `ike.config`

The following command reads in new rules from the `ike.config` file:

```
example# ikeadm read rules
```

**EXAMPLE 9** Lowering the Privilege Level

The following command lowers the privilege level:

```
example# ikeadm set priv base
```

**EXAMPLE 10** Viewing the Debug Level

The following command shows the current debug level

```
example# ikeadm get debug
```

**EXAMPLE 11** Using stats to Verify Hardware Accelerator

The following example shows how stats may include an optional line at the end to indicate if IKE is using a PKCS#11 library to accelerate public-key operations, if applicable.

```
example# ikeadm get stats
Phase 1 SA counts:
Current: initiator: 0 responder: 0
Total: initiator: 21 responder: 27
Attempted: initiator: 21 responder: 27
```

**EXAMPLE 11** Using stats to Verify Hardware Accelerator (Continued)

```
Failed: initiator: 0 responder: 0
 initiator fails include 0 time-out(s)
PKCS#11 library linked in from /opt/SUNWconn/lib/libpkcs11.so
example#
```

**EXAMPLE 12** Displaying the Certificate Cache

The following command shows the certificate cache and the status of associated private keys, if applicable:

```
example# ikeadm dump certcache
```

**EXAMPLE 13** Logging into a PKCS#11 Token

The following command shows logging into a PKCS#11 token object and unlocking private keys:

```
example# ikeadm token login "Sun Metaslot"
Enter PIN for PKCS#11 token:
ikeadm: PKCS#11 operation successful
```

**Exit Status** The following exit values are returned:

```
0 Successful completion.
non-zero An error occurred. Writes an appropriate error message to standard error.
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs
Interface Stability	Not an Interface

**See Also** [in.iked\(1M\)](#), [ike.config\(4\)](#), [ike.preshared\(4\)](#), [attributes\(5\)](#), [ipsec\(7P\)](#)

Schneier, Bruce, *Applied Cryptography: Protocols, Algorithms, and Source Code in C*, Second Edition, John Wiley & Sons, New York, NY, 1996.

**Notes** As `in.iked` can run only in the global zone and exclusive-IP zones, this command is not useful in shared-IP zones.

**Name** ikecert – manipulates the machine's on-filesystem public-key certificate databases

**Synopsis** ikecert certlocal  
 [-a | -e | -h | -k | -l | -r | -U | -C | -L]  
 [[-p] -T *PKCS#11 token identifier*]  
 [*option\_specific\_arguments*] . . .

ikecert certdb [-a | -e | -h | -l | -r | -U | -C | -L]  
 [[-p] -T *PKCS#11 token identifier*]  
 [*option\_specific\_arguments*] . . .

ikecert certrl db [-a | -e | -h | -l | -r]  
 [*option\_specific\_arguments*] . . .

ikecert tokens

**Description** The ikecert command manipulates the machine's on-filesystem public-key certificate databases. See the “Files” section, below.

ikecert has three subcommands, one for each of the three major repositories, plus one for listing available hardware tokens:

- certlocal deals with the private-key repository,
- certdb deals with the public-key repository, and:
- certrl db deals with the certificate revocation list (CRL) repository.
- tokens shows the available PKCS#11 tokens for a given PKCS#11 library.

The only supported PKCS#11 library and hardware is the Sun Cryptographic Accelerator 4000.

**Options** Except for tokens, each subcommand requires one option, possibly followed by one or more option-specific arguments.

The tokens subcommand lists all available tokens in the PKCS#11 library specified in `/etc/inet/ike/config`.

The following options are supported:

-a

#### certlocal

When specified with the certlocal subcommand, this option installs (adds) a private key into the Internet Key Exchange (IKE) local ID database. The key data is read from standard input, and is in either Solaris-only format or unencrypted PKCS#8 DER format. Key format is automatically

detected. PKCS#8 key files in PEM format and files in password protected, encrypted format are not recognized, but can be converted appropriately using tools available in OpenSSL.

This option cannot be used with PKCS#11 hardware objects when the corresponding public certificate is not already present in the IKE database. When importing both a public certificate and a private key, the public portion must be imported first using the `certdb` subcommand.

#### `certdb`

When specified with the `certdb` subcommand, this option reads a certificate from standard input and adds it to the IKE certificate database. The certificate must be a X.509 certificate in PEM Base64 or ASN.1 BER encoding. The certificate adopts the name of its identity.

This option can import a certificate into a PKCS#11 hardware key store one of two ways: Either a matching public key object *and* an existing private key object were created using the `cert local -kc` option, or if a PKCS#11 token is explicitly specified using the `-T` option.

#### `certrl db`

When specified with the `certrl db` subcommand, this option installs (adds) a CRL into the IKE database. The CRL reads from standard input.

-e [-f pkcs8] slot

#### certlocal

When specified with the `cert local` subcommand, this option extracts a private key from the IKE local ID database. The key data are written to standard output. The slot specifies which private key to extract. Private keys are only extracted in binary/ber format.

*Use this option with extreme caution.* See the “Security” section, below.

This option will not work with PKCS#11 hardware objects.

When used in conjunction with “-f pkcs8”, the private key is extracted in unencrypted PKCS#8 format.

-e [-f output-format] certspec

#### certdb

When specified with the `cert db` subcommand, this option extracts a certificate from the IKE certificate database which matches the `certspec` and writes it to standard output. The *output-format* option specifies the encoding format. Valid options are PEM and BER. This extracts the first matching identity. The default output format is PEM.

#### certrl db

When specified with the `cert rl db` subcommand, this option extracts a CRL from the IKE database. The key data are written to standard output. The `certspec` specifies which CRL that is extracted. The first one that matches in the database is extracted. See NOTES, below, for details on `certspec`

```
-kC -m keysize -t keytype -D dname -A altname[...]
[-S validity start_time][-F validity end_time]
[-T PKCS#11 token identifier]
```

patterns.

#### certlocal

When specified with the `cert local` subcommand, this option generates a IKE public/private key pair and adds it into the local ID database. It also generates a certificate request and sends that to standard output. For details on the above options see [Notes](#) for details on the *dname* argument and see ALTERNATIVE NAMES for details on the *altname* argument(s) to this command.

If `-T` is specified, the hardware token will generate the pair of keys.

If `-p` is specified with `-T`, the PKCS#11 token pin is stored in the clear on-disk, with root-protected file permissions. If not specified, one must unlock the token with [ikeadm\(1M\)](#) once [in.iked\(1M\)](#) is running.

```
-kS -m keysize -t keytype -D dname -A altname[...]
[-S validity start_time][-F validity end_time]
[-f output-format][[-p] -T PKCS#11 token identifier]
```

#### certlocal

When specified with the `cert local` subcommand, generates a public/private key pair and adds it into the local ID database. This option also generates a self-signed certificate and installs it into the certificate database. See NOTES, below, for details on the *dname* and *altname* arguments to this command.

-l [-v] [slot]

If -T is specified, the hardware token will generate the pair of keys, and the self-signed certificate will also be stored in the hardware.

#### certlocal

When specified with the `cert local` subcommand, this option lists private keys in the local ID database. The -v option switches output to a verbose mode where the entire certificate is printed.

*Use the -v option with extreme caution.* See the “Security” section, below. The -v option will not work with PKCS#11 hardware objects.

-l [-v] [certspec]

#### certdb

When specified with the `cert db` subcommand, this option lists certificates in the IKE certificate database matching the `certspec`, if any pattern is given. The list displays the identity string of the certificates, as well as, the private key if in the key database. The -v switches the output to a verbose mode where the entire certificate is printed.

If the matching certificate is on a hardware token, the token ID is also listed.

#### certrl db

When specified with the `cert rldb` subcommand, this option lists the CRLs in the IKE database along with any certificates that reside in the database and match the Issuer Name. `certspec` can be used to

specify to list a specific CRL. The `-v` option switches the output to a verbose mode where the entire certificate is printed. See NOTES, below, for details on `certspec` patterns.

`-r slot`

#### `certlocal`

When specified with the `certlocal` subcommand, deletes the local ID in the specified slot. If there is a corresponding public key, it is not be deleted. If this slot is deemed as “corrupted” or otherwise unrecognizable, it is deleted as well.

If this is invoked on a PKCS#11 hardware object, it will also delete the PKCS#11 public key and private key objects. If the public key object was already deleted by `certdb -r`, that is not a problem.

`-r certspec`

#### `certdb`

Removes certificates from the IKE certificate database. Certificates matching the specified certificate pattern are deleted. Any private keys in the `certlocal` database corresponding to these certificates are not deleted. This removes the first matching identity.

If the pattern specifies a slot and the slot is deemed as “corrupted” or otherwise unrecognizable, it is deleted as well.

If this is invoked on a PKCS#11 hardware object, it will also delete the certificate and the PKCS#11 public key object. If the public key

object was already deleted by `cert local -r`, that is not a problem.

#### `cert rldb`

When specified with the `cert rldb` subcommand, this option deletes the CRL with the given `certspec`.

`-U slot`

#### `cert local`

When specified with the `cert local` subcommand and the `-T` flag, this option unlinks a PKCS#11 private key object from the IKE database. There will be no attempt to access the hardware keystore or to validate or remove the on-token private key object. The object is simply disassociated from the IKE database.

#### `cert db`

When specified with the `cert db` subcommand and the `-T` flag, this option unlinks a PKCS#11 certificate object from the IKE database. There will be no attempt to access the hardware keystore or to validate or remove the on-token certificate or public key objects. The objects are simply disassociated from the IKE database.

`-C certspec`

#### `cert local`

When specified with the `cert local` subcommand, this option copies both the private key and its corresponding certificate and the public key from the on-disk keystore to the hardware keystore specified by its PKCS#11 token. This subcommand attempts

to create each of these components, even if one part fails. In all cases, the original on-disk private key and public certificate are still retained and must be deleted separately. Some hardware keystores, such as FIPS-140 compliant devices, may not support migration of private key objects in this manner.

#### certdb

When specified with the `certdb` subcommand, this option copies the certificate matching the given `certspec` and corresponding public key from the on-disk keystore to the hardware keystore specified by its PKCS#11 token. The original public certificate is still retained and must be deleted separately, if desired.

If `-p` is specified, the PKCS#11 token pin is stored in the clear on-disk, with root-protected file permissions. If not specified, one must unlock the token with [ikeadm\(1M\)](#) once [in.iked\(1M\)](#) is running.

-L pattern

#### certlocal

When specified with the `certlocal` subcommand, this option links an existing on-token private key object to the IKE database. The object itself remains on the token. This option simply lets the IKE infrastructure know that the object exists, as if it had been originally created on-token with the Solaris IKE utilities.

#### certdb

When specified with the `certdb` subcommand, this option links an

existing on-token certificate object to the IKE database. The object itself remains on the token. This option simply lets the IKE infrastructure know that the object exists, as if it had been originally created on-token with the Solaris IKE utilities.

If `-p` is specified, the PKCS#11 token pin is stored in the clear on-disk, with root-protected file permissions. If not specified, one must unlock the token with [ikeadm\(1M\)](#) once [in.iked\(1M\)](#) is running.

**Parameters** The following parameters are supported:

**certspec**

Specifies the pattern matching of certificate specifications. Valid certspecs are the Subject Name, Issuer Name, and Subject Alternative Names.

These can be specified as certificates that match the given certspec values and that do not match other certspec values. To signify a certspec value that is not supposed to be present in a certificate, place an `!` in front of the tag.

Valid certspecs are:

```
<Subject Names>
SUBJECT=<Subject Names>
ISSUER=<Issuer Names>
SLOT=<Slot Number in the certificate database>
```

```
Example:"ISSUER=C=US, O=SUN" IP=1.2.3.4 !DNS=example.com
Example:"C=US, O=CALIFORNIA" IP=5.4.2.1 DNS=example.com
```

Valid arguments to the alternative names are as follows:

```
IP=<IPv4 address>
DNS=<Domain Name Server address>
EMAIL=<email (RFC 822) address>
URI=<Uniform Resource Indicator value>
DN=<LDAP Directory Name value>
RID=<Registered Identifier value>
```

Valid Slot numbers can be specified without the keyword tag. Alternative name can also be issued with keyword tags.

- A  
Subject Alternative Names the certificate. The argument that follows the -A option should be in the form of *tag=value*. Valid tags are IP, DNS, EMAIL, URI, DN, and RID (See example below).
- D  
X. 509 distinguished name for the certificate subject. It typically has the form of: C=country, O=organization, OU=organizational unit, CN=common name. Valid tags are: C, O, OU, and CN.
- f  
Encoding output format. pem for PEM Base64 or ber for ASN.1 BER. If -f is not specified, pem is assumed.
- F *validity\_end\_time*  
Finish certificate validity time. If the -F flag is not specified, the validity end time is calculated at four years from the validity start time. See NOTES for an explanation for the validity date and time syntax.
- m  
Key size. It can be 512, 1024, 2048, 3072, or 4096. Use the following command to determine the key sizes supported by the Solaris Cryptographic Framework:
- ```
% cryptoadm list -vm
```
- The mechanisms displayed by the preceding command are described in [pkcs11_softtoken\(5\)](#). If your system has hardware acceleration, the mechanisms supported by the hardware will be listed in a separate section for each provider. Mechanisms can be any of:
- ```
CKM_RSA_PKCS_KEY_PAIR_GEN
CKM_DSA_KEY_PAIR_GEN
CKM_DH_PKCS_KEY_PAIR_GEN
```
- Note** – Some hardware does not support all key sizes. For example, the Sun Cryptographic Accelerator 4000's keystore (when using the -T option, below), supports only up to 2048-bit keys for RSA and 1024-bit keys for DSA.
- S *validity\_start\_time*  
Start certificate validity time. If the -S flag is not specified, the current date and time is used for the validity start time. See NOTES, below, for an explanation for the validity date and time syntax.
- t  
Key type. It can be rsa-sha1, rsa-md5, or dsa-sha1.
- T  
PKCS#11 token identifier for hardware key storage. This specifies a hardware device instance in conformance to the PKCS#11 standard. A PKCS#11 library must be specified in /etc/inet/ike/config. (See [ike.config\(4\)](#).)

A token identifier is a 32-character space-filled string. If the token given is less than 32 characters long, it will be automatically padded with spaces.

If there is more than one PKCS#11 library on a system, keep in mind that only one can be specified at a time in `/etc/inet/ike/config`. There can be multiple tokens (each with individual key storage) for a single PKCS#11 library instance.

**Security** This command can save private keys of a public-private key pair into a file. Any exposure of a private key may lead to compromise if the key is somehow obtained by an adversary.

The PKCS#11 hardware object functionality can address some of the shortcomings of on-disk private keys. Because IKE is a system service, user intervention at boot is not desirable. The token's PIN, however, is still needed. The PIN for the PKCS#11 token, therefore, is stored where normally the on-disk cryptographic keys would reside. This design decision is deemed acceptable because, with a hardware key store, *possession* of the key is still unavailable, only *use* of the key is an issue if the host is compromised. Beyond the PIN, the security of `ikecert` then reduces to the security of the PKCS#11 implementation. The PKCS#11 implementation should be scrutinized also.

Refer to the afterword by Matt Blaze in Bruce Schneier's *Applied Cryptography: Protocols, Algorithms, and Source Code in C* for additional information.

#### Examples EXAMPLE 1 Generating a Self-Signed Certificate

The following is an example of a self-signed certificate:

```
example# ikecert certlocal -ks -m 512 -t rsa-md5 -D "C=US, O=SUN" -A
IP=1.2.3.4
Generating, please wait...
Certificate generated.
Certificate added to database.
-----BEGIN X509 CERTIFICATE-----
MIIBRDCB76ADAgECAgEBMA0GCSqGSIb3DQEBAUAMBsxCzAJBgNVBAYTAlVTMQww
CgYDVQQKEwNTVU4wHhcNMDEwMzE0MDEzMDEwMzE0MDEzMDEwMzE0MDEzMDEw
CQYDVQQGEwJVUzEMMAoGA1UEChMDU1VOMFowDQYJKoZIhvcNAQEBBQADSAwRgJB
APDhqKggRoRUr6twTMTtSuNsReEnFoReVer!ztpXpQK6ybYLRH18JIqU/uCV/r
26R/cVXTy5qc5NbMwA40KzcCASOjIDAEmAsGA1UdDwQEAwIFoDAPBgNVHRECDAG
hwQBAgMEMA0GCSqGSIb3DQEBAUAA0EApTRD23KzN95GMvPD71hwwClukslKLVg8
f1xm9ZshLPJLRxHFwsqqjAad4j4wwwriiUmGAHLTGB0LJMl8xsgxag==
-----END X509 CERTIFICATE-----
```

#### EXAMPLE 2 Generating a CA Request

Generating a CA request appears the same as the self-signed certificate. The only differences between the two is the option `-c` instead of `-s`, and the certificate data is a CA request.

```
example# ikecert certlocal -kc -m 512 -t rsa-md5 \
-D "C=US, O=SUN" -A IP=1.2.3.4
```

**EXAMPLE 3** A CA Request Using a Hardware Key Store

The following example illustrates the specification of a token using the -T option.

```
example# # ikecert certlocal -kc -m 1024 -t rsa-md5 -T vca0-keystore \
-D "C=US, O=SUN" -A IP=1.2.3.4
```

**Exit Status** The following exit values are returned:

0

Successful completion.

non-zero

An error occurred. Writes an appropriate error message to standard error.

**Files** /etc/inet/secret/ike.privatekeys/\*

Private keys. A private key *must* have a matching public-key certificate with the same filename in /etc/inet/ike/publickeys/.

/etc/inet/ike/publickeys/\*

Public-key certificates. The names are only important with regard to matching private key names.

/etc/inet/ike/crls/\*

Public key certificate revocation lists.

/etc/inet/ike/config

Consulted for the pathname of a PKCS#11 library.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs
Interface Stability	Committed

**See Also** [ikeadm\(1M\)](#), [in.iked\(1M\)](#), [getdate\(3C\)](#), [ike.config\(4\)](#), [attributes\(5\)](#), [pkcs11\\_softtoken\(5\)](#)

Schneier, Bruce. *Applied Cryptography: Protocols, Algorithms, and Source Code in C*. Second Edition. John Wiley & Sons. New York, NY. 1996.

RSA Labs, PKCS#11 v2.11: *Cryptographic Token Interface Standards*, November 2001.

**Notes** The following is the validity date and time syntax when the -F or -S flags are used:

For relative dates, the syntax is as follows:

```
{+, -} [Ns] [Nm] [Nh] [Nd] [Nw] [NM] [Ny]
```

where:

N  
represents an integer

s  
represents seconds

m  
represents minutes

h  
represents hours

d  
represents days

w  
represents weeks

M  
represents months

y  
represents years

These parameters can be given in any order. For example, “+3d12h” is three and a half days from now, and “-3y2M” is three years and 2 months ago.

All parameters with fixed values can be added up in absolute seconds. Months and years, which have variable numbers of seconds, are calculated using calendar time. Months and years, which are not of fixed length, are defined such that adding a year or month means the same day next year or month. For instance, if it is Jan 26, 2005 and the certificate should expire 3 years and 1 month from today, the expiration (end validity time) date will be Feb 26, 2008. Overflows are dealt with accordingly. For example, one month from Jan 31, 2005 is March 3, 2005, since February has only 28 days.

For absolute dates, the syntax of the date formats included in the file `/etc/datemsk` are accepted (See [getdate\(3C\)](#) for details). Any date string prepended with a “+” or “-” is treated as a time relative to the current time, while others are treated as absolute dates. Sanity checking is also done to ensure that the end validity date is greater than the start validity date. For example, the following command would create a certificate with start date 1 day and 2 hours ago and an end date of Jan 22nd, 2007 at 12:00:00 local time.

```
ikecert certlocal -ks -t rsa-sha1 -m 1024 \
-D "CN=mycert, O=Sun, C=US" \
-S -1d2h -F "01/22/2007 12:00:00"
```

As in [iked\(1M\)](#) can run only in the global zone and exclusive-IP zones, this command is not useful in shared-IP zones.

**Name** ilbadm – establish and manipulate load balancing rules

**Synopsis** `ilbadm create-rule [-e] [-p] -i vip=value[,port=value[,protocol=value]  
 -m lbalg=value,type=value[,proxy-src=ip-range][,pmask=mask]  
 [-h hc-name=value[,hc-port=value]]  
 [-t [conn-drain=N][,nat-timeout=N],[persist-timeout=N]]  
 -o servergroup=value name`

`ilbadm show-rule [-e|-d] [-f |[-p] -o key[,key ...]] [name ...]`

`ilbadm delete-rule -a | name ...`

`ilbadm enable-rule [name ...]`

`ilbadm disable-rule [name ...]`

`ilbadm show-statistics [-p] -o field[,field] [-thAdvi]  
 [-r rulename] | [-s servername] [interval [count]]`

`ilbadm create-servergroup [-s server=hostspect[:portspec...]] groupname`

`ilbadm delete-servergroup groupname`

`ilbadm show-servergroup [-s|-f|[-p] -o field[,field]] [[-v] name]`

`ilbadm enable-server server ...`

`ilbadm disable-server server ...`

`ilbadm show-server [[-p] -o field[,field...]] [rulename...]`

`ilbadm add-server -s server=value[,value ... ] name`

`ilbadm remove-server -s server=value[,value ... ] name`

`ilbadm create-healthcheck [-n] -h hc-test=value  
 [,hc-timeout=value][,hc-count=value][,hc-interval=value] hcname`

`ilbadm delete-healthcheck hcname`

`ilbadm show-healthcheck [hcname ...]`

`ilbadm show-hc-result [rule-name]`

`ilbadm show-nat [count]`

`ilbadm show-persist [count]`

`ilbadm export-config filename`

`ilbadm import-config [-p] filename`

**Description** The `ilbadm` command manipulates or displays information about Integrated Load Balancer (ILB) rules using the subcommands described below.

Rule names are case insensitive, but case is preserved as it is entered. Rule names are limited in length to 19 characters. Server names cannot exceed 14 characters.

All parseable output (invoked with the `-p` option) requires that the fields to be printed or displayed be specified with the `-o` option. Fields will be displayed in the same order they are encountered on the command line. Multiple fields are separated by the colon (`:`) character. If a colon or backslash (`\`) occurs in the displayed string itself, it will be preceded by a backslash. No headers will be displayed for parseable output.

Server IDs are generated by the system when a server is added, using either the `create-servergroup` or the `add-server` subcommands.

Server IDs are guaranteed to be unique within the server group. A rule can be attached to only one server group, with the result that server IDs are unique for rules as well. Note that since more than one rule can attach to the same server group, the server ID alone is not sufficient to indicate a rule.

To be able to distinguish server IDs from hostnames, server IDs are prefixed with a leading underscore (`_`).

As noted below, the server group and healthcheck entities must be defined before they can be used in the `create-rule` subcommand.

**Sub-commands** Following are the `ilbadm` subcommands, along with their related options and operands. Note that subcommands have a normal and a short form; for example, `create-rule` and `create-rl`, saving you from having to type a few additional characters.

`create-rule|create-rl [-e] [-p] -i incoming -m method_attributes -o outgoing_spec [-h healthcheck] [-t timers] name`

Creates a rule *name* with a set of specified characteristics. *incoming* and *method\_attributes* are both specified as a set of *key=value* pairs. If *name* already exists, the command will fail. If a given tuple (virtual IP address, port(s), and protocol) matches another rule, the command will also fail. `create-rule` has the following options that control the overall effect of the command:

- e Enable the `create-rule` function. The default is that `create-rule` is disabled.
- p Create the rule as persistent (sticky). The default is that the rule exists only for the current session.

Keys and values are introduced by one-letter identifiers. These identifiers and their related keys and acceptable values are as follows.

-i Introduces the matching criteria for incoming packets.

vip  
(Virtual) destination IP address

- `port[-port]`  
Port number or name, for example, `telnet` or `dns`. A port can be specified by port number or symbolic name (as in `/etc/services`). Port number ranges are also supported.
- `protocol`  
TCP (the default) or UDP (see `/etc/services`).
- `-m`  
Specifies the keys describing how to handle a packet.
- `lbalg`  
The default is `roundrobin`, or its short form, `rr`. Other alternatives are: `hash-ip` (short form: `hip`), `hash-ip-port` (short form: `hipp`), `hash-ip-vip` (short form: `hipv`).
- `type`  
Refers to topology of network. Can be `DSR` (or `dsr` or `d`), `NAT` (or `n` or `nat`), `HALF-NAT` (or `h` or `half-nat`).
- `proxy-src`  
Required for full NAT only. Specifies the IP address range to use as the proxy source address range. The range is limited to ten IP addresses.
- `pmask`  
Optional. Has an alias of: `stickiness`. Specifies that this rule is to be persistent. The argument is a prefix length in CIDR notation; that is, 0–32 for IPv4 and 0–128 for IPv6. Use the `-p` option to specify this keyword.
- `-o`  
Specifies destination(s) for packets that match the criteria specified by the `-i` “clause”. This identifier has one well-known argument:
- `servergroup`    Specify a single server group as target. The server group must already have been created.
- `-h`  
The health check option has two arguments:
- `hc-name`  
Specifies the name of a predefined health check method
- `hc-port`  
Specifies the port(s) for the HC test program to check. The value can be keywords `ALL` or `ANY`, or a specific port number within the port range of the server group.
- `-t`  
Specifies customized timers, in seconds. A value of 0 means to use the system default value. The following are valid modifiers for `-t`:

**conn-drain**

If a server's type is NAT or HALF-TYPE, `conn-drain` is the timeout after which the server's connection state is deleted following the server's removal from a rule. This deletion occurs even if the server is not idle.

The default for TCP is that the connection state remains stable until the connection is gracefully shutdown. The default for UDP is that the connection state remains stable until the connection has been idle for the period `nat-timeout`.

**nat-timeout**

Applies only to NAT and half-NAT type connections. If such a connection is idle for the `nat-timeout` period, the connection state will be removed. The default is 120 for TCP and 60 UDP.

**persist-timeout**

When persistent mapping is enabled, if a numeric-only mapping has not been used for `persist-timeout` seconds, the mapping will be removed. The default is 60.

Note that server group and health check must be defined before they can be used in `create-rule`.

**delete-rule|delete-rl -a *name*[...]**

Remove all information pertaining to rule *name*. If *name* does not exist, command will fail. `delete-rule` has one option:

**-a**  
Delete all rules. (*name* is ignored.)

**enable-rule|enable-rl *name*[...]**

Enables a named rule, or all rules, if no name is specified). Enabling rules that are already enabled has no effect.

**disable-rule|disable-rl *name*[...]**

Disables a named rule, or all rules, if no name is specified. Disabling rules that are already disabled has no effect.

**show-statistics|show-stats [[-p] -o *field*[,...]] [-tv] [-A | -d] [[-i] -r *rulename* | -s *servername*] [*interval* [*count*]]**

Displays statistics, the output of which is subject to the use of the options described below. The syntax and semantics of this subcommand are modeled on [vmstat\(1M\)](#).

**-t**  
Prepend a timestamp with every sample.

**-d**  
Display the delta over entire interval. The default is changes per second. Cannot be used with the `-a` option.

- A  
Display absolute numbers. That is, numbers since module initialization, rule creation, and server addition. Cannot be used with the -d option.
- r *rulename*  
Display statistics only for the specified *rulename*. In combination with the -i option, display a line for each server.
- s *servername*  
Display statistics only for *server*. In combination with the -i option, display a line for each rule.
- i  
Itemize the information displayed by the -r and -s options. These are the only options with which -i is valid. Does not work with the -v option.
- v  
Display additional details for droppages. Note that, when the rule name is specified, drops are counted per rule and not per server. Does not work with the -i option.
- p  
Display parseable format. Requires use of -o option.
- o *field*  
Can be one or more from the list below. *field* can be uppercase or lowercase.
- |            |                                                                   |
|------------|-------------------------------------------------------------------|
| PKT_P      | Packets processed.                                                |
| BYTES_P    | Bytes processed.                                                  |
| PKT_U      | Unprocessed packets.                                              |
| BYTES_U    | Unprocessed bytes.                                                |
| PKT_D      | Packets dropped.                                                  |
| BYTES_D    | Bytes dropped.                                                    |
| ICMP_P     | ICMP echo requests processed.                                     |
| ICMP_D     | ICMP echo requests dropped.                                       |
| ICMP2BIG_P | ICMP fragmentation needed; message processed.                     |
| ICMP2BIG_D | Fragmentation needed; message dropped.                            |
| NOMEMP_D   | Packets dropped because of out-of-memory condition.               |
| NOORTP_D   | Packets dropped in NAT mode because no source port was available. |
- Note that when a question mark (?) is displayed as a column entry, it indicates that the proper value cannot be determined, most often because a rule or server was added or deleted.

Note that headers are displayed once for each ten samples. The timestamp format follows the [date\(1\)](#) format for the C locale. Neither the addition nor removal of a rule is detected.

`show-rule`|`show-r1` [-d|-e] [-f] [-p] -o *field*[,...] [*name*...]

Displays characteristics of the specified rules, or all, if no rule is specified. The subcommand has the following options:

- d  
Display only disabled rules.
- e  
Display only enabled rules.
- f  
Display a full list.
- o *field*[,...]  
Display output for *field*(s). Cannot be used with -f option.
- p  
Display parsable output in the format described in “Description”. Requires the -o option.

Note that the -o (with or without -p) and -f options are mutually exclusive.

`show-nat count`

Displays NAT table information. If *count* is specified, displays *count* entries from the NAT table. If no count is specified, displays the entire NAT table.

*count*

No assumptions should be made about the relative positions of elements in consecutive runs of this command. For example, executing `show-nat 10` twice is not guaranteed to display the same ten items twice, especially on a busy system.

Display format:

```
T: IP1 > IP2 >>> IP3 > IP4
```

These items are described as follows:

- T The transport protocol used in this entry.
- IP1 The client's IP address and port.
- IP2 The VIP and port.
- IP3 If half NAT mode, the client's IP address and port. If full NAT mode, the NAT'ed client's IP address and port.
- IP4 The backend server's IP address and port.

`show-persist`|`show-pt count`

Displays persistence table information. If *count* is specified, displays *count* entries from the table. If no count is specified, displays the entire persistence table.

No assumptions should be made about the relative positions of elements in consecutive runs of this command. For example, executing `show-persist 10` twice is not guaranteed to display the same ten items twice, especially on a busy system.

Display format:

R: IP1 --> IP2

These items are described as follows:

R

The rule this persistence entry is tied to.

IP1

The client's IP address and port.

IP2

The backend server's IP address.

`export-config`|`export-cf [filename]`

Exports the current configuration in a format suitable for re-import using `ilbadm import`. If no filename is specified, the subcommand writes to stdout.

`import-config`|`import-cf [-p] [filename]`

Reads configuration contents of a file. By default, this overrides any existing configuration. If no filename is specified, the subcommand reads from stdin. This subcommand has the following option:

-p

Preserve existing configuration and do incremental import.

`create-servergroup`|`create-sg [-s server=hostspec[:portspec...]] groupname`

Creates a server group. Additional servers can be added later using the `add-server` subcommand. Server groups are the only entity that can be used during rule creation to indicate back-end servers. If the specified server group is associated with one or more rules, the server is enabled when it is added. This subcommand has the following option and operands:

-s *server=hostspec[:portspec...]*

Specifies a list of servers to be added to the server group.

*hostspec* is a hostname or IP address. IPv6 addresses must be enclosed in brackets ([ ]) to distinguish them from “:*portspec*”

*portspec* is a service name or port number. If the port number is not specified, a number in the range 1–65535 is used.

`disable-server`|`disable-srv` *server*

Disable one or more server(s). That is, tell the kernel not to forward traffic to this server.

`disable-server` applies to all rules that are attached to the server group this server is part of.

*server* is a server ID.

`enable-server`|`enable-srv` *server...*

Reenables disabled servers.

`show-server`|`show-srv` [[-p] -o *field[,field...]*] [*rulename...*]

Displays servers associated with named rules, or all servers if no *rulename* is specified. The subcommand has the following options.

-o *field[,field...]*

Display only the specified fields.

-p

Display fields in parsable format. Requires the -o option.

`delete-servergroup`|`delete-sg` *groupname*

Deletes a server group.

`show-servergroup`|`show-sg` [[-p] -o *field[,...]*] [*name*]

Lists a server group, or all server groups, if no *name* is specified. The subcommand has the following options:

-o *field[,...]*

Display output for *field(s)*.

-p

Display parsable output in the format described in “Description”. Requires the -o option.

`add-server`|`add-srv` -s *server=value[, value...]* *servergroup*

Add specified server(s) to *servergroup*. See description of `create-servergroup` for definition of *value*.

-s

See `create-servergroup`.

Performing an `add-server` to a server group immediately after performing a `remove-server` on that server group might fail because of incomplete connection draining. Refer to the description of the `remove-server` subcommand for instructions on how to avoid this failure.

`remove-server`|`remove-srv` -s *server=value[, value...]* *servergroup*

Remove specified server(s) from *servergroup*.

-s

One or more of a server ID.

If a server is being used by a NAT/half-NAT rule, it is recommended that the server be disabled (using `disable-server`) before removal. By disabling a server, the server enters the connection-draining state. After all of the connections are drained, the server can then be removed by `remove-server`. If the `conn-drain` timeout value is set, the connection-draining state will be finished upon conclusion of the timeout period. Note that the default `conn-drain` timeout is 0, meaning it will keep waiting until a connection is gracefully shut down.

```
create-healthcheck|create-hc [-n] -h hc-test=value,hc-timeout=value,
hc-count=num_value,hc-interval=value hcname
```

Sets up a health check object for rules to use. All servers associated with a rule are checked using the same test. A health check event of a server consists of one to `hc-count` number of `hc-test` executions. If an `hc-test`'s result shows a server to be unresponsive, further `hc-test` checks are made, up to `hc-count` invocations, before a server is considered to be down.

-h

The `hc-test` is performed `hc-count` times until it succeeds or `hc-timeout` has expired. For a given rule, all servers are checked using the same test. The tests are as follows:

`hc-test`

PING, TCP, external method (script or binary). An external method should be specified with a full path name.

`hc-timeout`

Threshold at which a test is considered failed following interim failures of `hc-test`. If you kill an `hc-test` test, the result is considered a failure. The default value is five seconds.

`hc-count`

Maximum number of attempts to run `hc-test` before marking a server as down. The default value is three iterations.

`hc-interval`

Interval between invocations of `hc-test`. This value must be greater than `hc-timeout` times `hc-count`. The default value is 30 seconds.

The following arguments are passed to external methods:

\$1

VIP (literal IPv4 or IPv6 address).

\$2

Server IP (literal IPv4 or IPv6 address).

\$3

Protocol (UDP, TCP as a string).

\$4

The load balance mode, DSR, NAT, HALF\_NAT.

\$5

Numeric port.

\$6

Maximum time (in seconds) the method should wait before returning failure. If the method runs for longer, it can be killed, and the test considered failed.

External methods should return 0 (or the round-trip time to the back end server, in microseconds) for success and -1 if the server is considered down.

Before higher layer health check(s), TCP, UDP, and external tests start, a default ping test is performed first. The higher layer test will not be performed if ping fails. You can turn off the default ping check for these high layer health checks by through use of -n.

-n

Disable default ping test for high layer health check tests.

`delete-healthcheck|delete-hc hcname...`

Delete the named health check object(s) (*hcname*). If the given health check object is associated with enabled rule(s), deletion of the object will fail.

`show-healthcheck|show-hc [hcname...]`

List the health check information for the specified health check (*hcname*). If no health check is specified, list information for all existing health checks.

`show-hc-result|show-hc-res [rule-name]`

List the health check result for the servers that are associated with *rule-name*. If *rule-name* is not given, the health check results for all servers are displayed.

## Examples EXAMPLE 1 Configuring NAT Mode

The following commands create a rule with health check and timers set (port range shifting and session persistence).

```
ilbadm create-healthcheck -h hc-test=tcp,hc-timeout=2,hc-count=3, \
 hc-interval=10 hc1
ilbadm create-servergroup -s \
 server=60.0.0.10:6000-6009,60.0.0.11:7000-7009 sg1
ilbadm create-rule -e -i vip=81.0.0.10,port=5000-5009,protocol=tcp \
-m lbalg=rr,type=NAT,proxy-src=60.0.0.101-60.0.0.104, \
 pmask=24 \
-h hc-name=hc1 \
-t conn-drain=180,nat-timeout=180,persist-timeout=180 \
-o servergroup=sg1 rule1
```

The following command creates a rule with the default timer values and without health check.

```
ilbadm create-servergroup -s server=60.0.0.10 sg1
lbadm create-rule -e -i vip=81.0.0.10,port=5000 \
-m lbalg=rr,type=NAT,proxy-src=60.0.0.105 \
```

**EXAMPLE 1** Configuring NAT Mode *(Continued)*

```

 -o servergroup=sg1 rule1
ilbadm add-server -e -s server=60.0.0.11sg1
ilbadm enable-rule rule1

```

**EXAMPLE 2** Configuring Half-NAT Mode

The following command configures half-NAT mode and exemplifies port range collapsing.

```

ilbadm create-servergroup sg1
ilbadm create-rule -e -i vip=81.0.0.10,port=5000-5009 \
 -m lbalg=rr,type=h -o servergroup=sg1 rule1
ilbadm add-server -s server=60.0.0.10:6000,60.0.0.11:7000 sg1

```

**EXAMPLE 3** Configuring DSR Mode and Preparing Two Sets of Rules

The following command establishes two sets of rules to enable load balancing between HTTP and FTP traffic. Note both types of traffic traverse interface 60.0.0.10.

```

ilbadm create-servergroup -s servers=60.0.0.9,60.0.0.10 websg
ilbadm create-servergroup -s servers=60.0.0.10,60.0.0.11 ftpgroup

ilbadm create-rule -e -i vip=81.0.0.10,port=80 \
 -m lbalg=hash-ip-port,type=DSR \
 -o servergroup=websg webrule
ilbadm create-rule -e -i vip=81.0.0.10,port=ftp \
 -m lbalg=hash-ip-port,type=DSR,pmask=24 \
 -o servergroup=ftpgroup ftprule
ilbadm create-rule -e -p -i vip=81.0.0.10,port=ftp-data \
 -m lbalg=hash-ip-port,type=DSR,pmask=24 \
 -o servergroup=ftpgroup ftpdatarule

```

**EXAMPLE 4** Deleting Rule, Server Group, and Health Check

The following commands delete the rule, server group, and health check established in the first example.

```

ilbadm ilbadm delete-rule -a
ilbadm delete-servergroup sg1
ilbadm delete-healthcheck hc1

```

**EXAMPLE 5** Display a List of Rules

The following command displays a list of rules.

```

ilbadm show-rule
RULENAME STATUS LBALG TYPE PROTOCOL VIP PORT
r2 E hash-ip NAT TCP 45.0.0.10 81
r1 E hash-ip NAT TCP 45.0.0.10 80

```

**EXAMPLE 5** Display a List of Rules *(Continued)*

```
ilbadm show-rule -f
 RULENAME: rule1
 STATUS: E
 PORT: 80
 PROTOCOL: TCP
 LBALG: roundrobin
 TYPE: HALF-NAT
 PROXY-SRC: --
 PERSIST: --
 HC-NAME: hc1
 HC-PORT: ANY
 CONN-DRAIN: 0
 NAT-TIMEOUT: 120
 PERSIST-TIMEOUT: 60
 SERVERGROUP: sg1
 VIP: 80.0.0.2
 SERVERS: _sg1.0,_sg1.1
```

**EXAMPLE 6** Exporting and Importing Rules

The following commands show how to export rules to and import rules from stdout, and to/from a file.

```
ilbadm export-config

create-servergroup ftpgroup
add-server -s server=10.1.1.3:21 ftpgroup
add-server -s server=10.1.1.4:21 ftpgroup
create-servergroup webgroup_v6
add-server -s server=[2000::ff]:80 webgroup_v6
create-rule -e protocol=tcp,VIP=1.2.3.4,port=ftp \
 -m lbalg=roundrobin,type=DSR \
 -o servergroup=ftpgroup rule4
create-rule protocol=tcp,VIP=2003::1,port=ftp \
 -m lbalg=roundrobin,type=DSR \
 -o servergroup=ftpgroup6 rule3
create-rule -e protocol=tcp,VIP=2002::1,port=http \
 -m lbalg=roundrobin,type=DSR \
 -o servergroup=webgrp_v6 RULE-all
```

The following command exports rules to a file.

```
ilbadm export-config /tmp/ilbrules
```

Following this command, /tmp/ilbrules contains the output displayed in the previous command.

The following command imports rules from a file.

**EXAMPLE 6** Exporting and Importing Rules *(Continued)*

```
ilbadm import-config /tmp/ilbrules
```

This command replaces whatever rules were in place with the contents of /tmp/ilbrules.

The following command imports rules from stdin.

```
cat /tmp/ilbrules | ilbadm import-config
```

The effect of this command is identical to the effect of the preceding command.

**EXAMPLE 7** Creating a Single Health Check

The following command creates a single health check.

```
ilbadm create-healthcheck -h hc-timeout=3,hc-count=2,hc-interval=8,\
 hc-test=tcp hc1
```

**EXAMPLE 8** Listing All Healthchecks

The following command lists all extant health checks.

```
ilbadm show-healthcheck
```

HCNAME	TIMEOUT	COUNT	INTERVAL	DEF_PING	TEST
hc1	2	1	10	Y	tcp
hc2	2	1	10	N	/usr/local/bin/probe

**EXAMPLE 9** Deleting a Single Health Check

The following command deletes a single health check.

```
ilbadm delete-healthcheck hc1
```

**EXAMPLE 10** Displaying Statistics

The following command displays statistics at an interval of one seconds, for three iterations.

```
ilbadm show-stats -A 1 3
```

PKT_P	BYTES_P	PKT_U	BYTES_U	PKT_D	BYTES_D
0	0	0	0	4	196
0	0	0	0	4	196
0	0	0	0	4	196

The following is the command you would use to display statistics in verbose mode at intervals of one second. Output is too wide to fit within the page boundary.

```
ilbadm show-stats -v 1
```

The following command displays statistics for rule r1 at an interval of one second for three iterations.

**EXAMPLE 10** Displaying Statistics *(Continued)*

```
ilbadm show-stats -A -r r1 1 3
PKT_P BYTES_P PKT_U BYTES_U PKT_D BYTES_D
0 0 0 0 4 196
0 0 0 0 4 196
0 0 0 0 4 196
```

The following command displays statistics for rule r1 for each of its servers, for an interval of one second and a count of 3.

```
ilbadm show-stats -A -r r1 -i 1 3
SERVERNAME PKT_P BYTES_P
_sg1.0 0 0
_sg1.1 0 0
_sg1.2 0 0
_sg1.0 0 0
_sg1.1 0 0
_sg1.2 0 0
_sg1.0 0 0
_sg1.1 0 0
_sg1.2 0 0
```

The following command displays itemized statistics, with timestamps, for server `_sg1.0`, at an interval of one second and a count of 3.

```
ilbadm show-stats -A -s _sg1.0 -it 1 3
RULENAME PKT_P BYTES_P TIME
r1 0 0 2009-07-20:16.10.20
r1 0 0 2009-07-20:16.10.21
r1 0 0 2009-07-20:16.10.22
```

The following command displays statistics with specific option fields, at an interval of one second and a count of 3.

```
ilbadm show-stats -o BYTES_D,TIME 1 3
BYTES_D TIME
196 2009-07-20:16.14.25
0 2009-07-20:16.14.26
0 2009-07-20:16.14.27
```

**EXAMPLE 11** Displaying Health Check Results

The following command displays the results of a health check.

```
ilbadm show-hc-result rule1
RULENAME HCNAME SERVERID STATUS FAIL LAST NEXT RTT
rule1 hc1 _sg1.0 dead 6 04:45:17 04:45:30 698
rule1 hc1 _sg1.1 alive 0 04:45:11 04:45:25 260
rule1 hc1 _sg1.2 unreach 6 04:45:17 04:45:30 0
```

**EXAMPLE 12** Displaying the NAT Table

The following command displays the NAT table.

```
ilbadm show-nat 5
UDP: 124.106.235.150.53688>85.0.0.1.1024>>>82.0.0.39.4127>82.0.0.56.1024
UDP: 71.159.95.31.61528> 85.0.0.1.1024>>> 82.0.0.39.4146> 82.0.0.55.1024
UDP: 9.213.106.54.19787> 85.0.0.1.1024>>> 82.0.0.40.4114> 82.0.0.55.1024
UDP: 118.148.25.17.26676> 85.0.0.1.1024>>>82.0.0.40.4112> 82.0.0.56.1024
UDP: 69.219.132.153.56132>85.0.0.1.1024>>>82.0.0.39.4134> 82.0.0.55.1024
```

In actual ilbadm output, spaces are interspersed for greater readability.

**EXAMPLE 13** Displaying the Persistence Table

The following command displays the persistence table.

```
ilbadm show-persist 5
rule2: 124.106.235.150 --> 82.0.0.56
rule3: 71.159.95.31 --> 82.0.0.55
rule3: 9.213.106.54 --> 82.0.0.55
rule1: 118.148.25.17 --> 82.0.0.56
rule2: 69.219.132.153 --> 82.0.0.55
```

**EXAMPLE 14** Displaying Server Groups

The following command displays basic information about server groups.

```
ilbadm show-servergroup
sg1: id:sg1.2 35.0.0.4:80
sg1: id:sg1.1 35.0.0.3:80
sg1: id:sg1.0 35.0.0.2:80
sg2: id:sg2.3 35.0.0.5:81
sg2: id:sg2.2 35.0.0.4:81
sg2: id:sg2.1 35.0.0.3:81
sg2: id:sg2.0 35.0.0.2:81
```

The following command displays all available information about server groups.

```
ilbadm show-servergroup -o all
sgname serverID minport maxport IP_address
sg1 _sg1.0 -- -- 1.1.1.1
sg2 _sg2.1 -- -- 1.1.1.6
sg3 _sg3.0 9001 9001 1.1.1.1
sg3 _sg3.1 9001 9001 1.1.1.2
sg3 _sg3.2 9001 9001 1.1.1.3
sg3 _sg3.3 9001 9001 1.1.1.4
sg3 _sg3.4 9001 9001 1.1.1.5
sg3 _sg3.5 9001 9001 1.1.1.6
sg3 _sg3.6 9001 9001 1.1.1.11
sg3 _sg3.7 9001 9001 1.1.1.12
sg3 _sg3.8 9001 9001 1.1.1.13
```

**EXAMPLE 14** Displaying Server Groups *(Continued)*

```

sg3 _sg3.9 9001 9001 1.1.1.14
sg3 _sg3.10 9001 9001 1.1.1.15
sg3 _sg3.11 9001 9001 1.1.1.16
sg4 _sg4.0 9001 9006 1.1.1.1
sg4 _sg4.1 9001 9006 1.1.1.6

```

**EXAMPLE 15** List Servers Associated with a Rule

The following command lists the servers that are associated with a rule.

```

ilbadm show-server r1
SERVERID ADDRESS PORT RULENAME STATUS SERVERGROUP
_sg1.0 35.0.0.10 80 rule1 E sg1
_sg1.1 35.0.0.11 80 rule1 E sg1
_sg1.2 35.0.0.12 80 rule1 D sg1

```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTETYPE	ATTRIBUTEVALUE
Availability	SUNWilbu
Interface Stability	Committed

**See Also** [ilbd\(1M\)](#), [vmstat\(1M\)](#), [attributes\(5\)](#)

**Name** `ilbd` – ILB daemon

**Synopsis** `/usr/lib/inet/ilbd`

**Description** The Integrated Load Balancer (ILB) daemon, `ilbd`, provides user-level services for the ILB. It is a system daemon started by the Service Management Facility (see [smf\(5\)](#)). Its fault management resource identifier (FMRI) is:

```
svc:/network/loadbalancer/ilb:default
```

Note that `ilbd` is a Consolidation Private interface. See [attributes\(5\)](#).

`ilbd` provides no administrative interface. All ILB administration should be done through [ilbadm\(1M\)](#) or the programming library [libilb\(3LIB\)](#).

**Options** The `ilbd` daemon has no options.

**Examples** **EXAMPLE 1** Enabling the ILB Service

The following command enables the ILB service:

```
svcadm enable svc:/network/loadbalancer/ilb:default
```

**EXAMPLE 2** Disabling the ILB Service

The following command disables the ILB service:

```
svcadm disable svc:/network/loadbalancer/ilb:default
```

**Errors** The `ilbd` daemon uses [syslog\(3C\)](#) to report status and error messages. All of the messages are logged with the `LOG_DAEMON` facility. Error messages are logged with the `LOG_ERR` and `LOG_NOTICE` priorities, and informational messages are logged with the `LOG_INFO` priority. The default entries in the `/etc/syslog.conf` file log all of the `ilbd` daemon error messages to the `/var/adm/messages` log.

**Files** `/usr/lib/inet/ilbd`  
ILB daemon binary

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/load-balancer/ilb
Interface Stability	Project Private

**See Also** [svcs\(1\)](#), [ilbadm\(1M\)](#), [svcadm\(1M\)](#), [syslog\(3C\)](#), [libilb\(3LIB\)](#), [syslog.conf\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

**Notes** The `ilbd` service is managed by the service management facility, `smf(5)`, under the fault management resource identifier (FMRI):

```
svc:/network/loadbalancer/ilb:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command. To administer the service, the authorization `solaris.smf.manage.ilb` must be granted. Alternatively, the rights profile “ILB Management” can be granted.

The ILB service must be enabled for the `ilbadm(1M)` command and any other `libilb(3LIB)` client applications to function properly.

- Name** imqadmin – launch the Message Queue administration console
- Synopsis** `/usr/bin/imqadmin [-javahome path]`  
`/usr/bin/imqadmin -h`  
`/usr/bin/imqadmin -v`
- Description** imqadmin launches the graphical user interface application that performs most Message Queue administration tasks. These tasks include managing broker instances (including physical destinations) and administered objects.
- Options** The following options are supported:
- h Display usage help. The application is not launched.
  - javahome *path* Specify a path to an alternate Java 2 compatible runtime.
  - v Display version information.
- Environment Variables** The following environment variables affect the execution of this command:
- IMQ\_JAVAHOME Specify the Java 2 compatible runtime. When this environment variable is not set it defaults to `/usr/j2se`.
- Exit Status** The following exit values are returned:
- 0 Successful completion.
  - >0 An error occurred.
- Files** `$HOME/.imq/admin/brokerlist.properties`  
 Contains user settings, a list of broker instances being managed.
- `$HOME/.imq/admin/objectstorelist.properties`  
 Contains user settings, a list of object stores being managed.
- Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWiq

*Sun Java System Message Queue Administrator's Guide*

**Name** imqbrokerd – start a Message Queue broker instance

**Synopsis** /usr/bin/imqbrokerd [*option...*]

/usr/bin/imqbrokerd -h

**Description** imqbrokerd starts an instance of the Message Queue broker. The Message Queue broker is the main component of a Message Queue message server. The broker performs reliable delivery of messages to and from Java Message Service (JMS) clients.

imqbrokerd uses command line options to specify broker configuration properties.

**Options** The following options are supported:

-backup *fileName*

Back up a Master Broker's configuration change record to *fileName*. This option only applies to broker clusters.

-cluster *brokerList*

Specify the list of broker instances which are connected in a cluster. This list is merged with the list in the imq.cluster.brokerlist property. This option only applies to broker clusters.

*brokerList* is a comma-separated list of broker instances, each specified by *hostName:port* (the host on which the broker instance is running and the port number it is using) If you don't specify a value for *hostName*, localhost is used. If you don't specify a value for *port*, the value of 7676 is used. For example: host1:8899, host2, : 7878.

-dbpassword *password*

Specify the password for a plugged-in JDBC-compliant database used as a Message Queue data store.

-dbuser *userName*

Specify the user name for a plugged-in JDBC-compliant data store.

-D*property*=*value*

Set the specified broker configuration property to the *value*. The system does not validate either the configuration property or *value*. Therefore, spelling, formatting, and case is important. Message Queue can not set incorrect values passed using the -D option.

-force

Perform action without user confirmation. This option only applies when you use the - remove *instance* option, which normally requires confirmation.

---

-h	Display usage help. Execute nothing else on the command line.
-j <i>javahome path</i>	Specify the path to an alternate Java 2-compatible Java Development Kit (JDK) or Java Runtime Environment (JRE) The default is to use the runtime bundled with the operating system.
-ld <i>ldap password</i>	Specify the password for accessing an LDAP user repository when using an LDAP server (as opposed to a built-in flat-file repository) to authenticate users of a Message Queue message server.
-l <i>license [name]</i>	Specify the license to load, if different from the default for your Message Queue product edition. If you don't specify a license name, this lists all licenses installed on the system. Depending on the installed Message Queue edition, the values for <i>name</i> are <i>pe</i> (Platform Edition-basic features), <i>tr</i> (Platform Edition-90-day trial enterprise features), and <i>unl</i> (Enterprise Edition).
-log <i>level level</i>	Specify the logging level. Valid values for <i>level</i> are NONE, ERROR, WARNING, or INFO. The default value is INFO.
-m <i>metrics int</i>	Report metrics at a specific interval. Specify <i>int</i> as the number of seconds.
-n <i>name brokerName</i>	Specify the instance name of this broker and use the corresponding instance configuration file. If you do not specify a broker name, the name of the file is set to <i>imqbroker</i> . If you run more than one instance of a broker on the same host, each must have a unique name.
-p <i>passfile filename</i>	Specify the name of the file from which to read the passwords for the SSL keystore, LDAP user repository, or JDBC-compliant database.
-pw <i>password keypassword</i>	Specify the password for the SSL certificate keystore.
-port <i>number</i>	Specify the broker's Port Mapper port number. By default, this is set to 7676. To run two instances of a broker on the same server, each broker's Port

- Mapper must have a different port number. JMS clients connect to the broker instance using this port number.
- remove *instance* Remove the broker instance. Delete the instance configuration file, log files, data store, and other files and directories associated with the broker instance. This option requires user confirmation unless you also specify the -force option.
- reset store|messages|durables|props Reset the data store (or a subset of the store) or resets the configuration properties of the broker instance when the broker instance is started. The action depends on the argument provided.
- store Clear all persistent data in the data store, including messages, durable subscriptions, and transaction information store.
- messages Clear all persistent messages durable.
- durables Clear all durable subscriptions.
- props Clear all configuration information in the `config.props` instance configuration file. All properties assume default values.
- restore *filename* Replace the Master Broker's configuration change record with the specified backup file. This file must have been previously created using the -backup option. This option only applies to broker clusters.
- shared Specify that the jms connection service be implemented using the shared threadpool model, in which threads are shared among connections to increase the number of connections supported by a broker instance.
- silent Turn off logging to the console.
- tty Display all messages be to the console. WARNING and ERROR level messages are displayed on the console by default.

<code>-upgrade-store-nobackup</code>	Specify that an earlier, incompatible version Message Queue data store is automatically removed when migrating to Message Queue 3.5 format.  If you do not use this option, you must manually delete the earlier data store. This applies to both built-in (flat-file) persistence and plugged-in (JDBC-compliant) persistence. Migration of the earlier data store to a Message Queue 3.5 data store takes place the first time you start a Message Queue 3.5 broker instance on an earlier version data store.
<code>-version</code>	Display the version number of the installed product.
<code>-vmargs are [[arg]...]</code>	Specify arguments to pass to the Java VM. Separate arguments with spaces. If you want to pass more than one argument or if an argument contains a space, use enclosing quotation marks. For example:  <code>imqbrokerd -tty -vmargs "-Xmx128m -Xincgc"</code>

**Environment Variables** The following environment variables affect the execution of this command:

`IMQ_JAVAHOME` Specify the Java 2 compatible runtime. When this environment variable is not set it defaults to `/usr/j2se`.

**Exit Status** The following exit values are returned:

- `0` Successful completion.
- `>0` An error occurred.

**Files**

- `/etc/init.d/imq`  
Shell script for starting `imqbrokerd`. This file looks at the `/etc/imq/imqbrokerd.conf` file.
- `/etc/imq/imqbrokerd.conf`  
Configuration file which controls the behavior of the broker startup script.
- `/etc/imq/passwd`  
Flat file user repository for authenticating users.
- `/etc/imq/accesscontrol.properties`  
Controls client access to broker functionality.
- `/etc/imq/passfile.sample`  
Sample passfile used by the `-passfile` option.

`/var/imq/instances/brokerName/props/config.properties`  
Broker instance configuration file.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWiq

**See Also** [imqadmin\(1M\)](#), [imqcmd\(1M\)](#), [imqdbmgr\(1M\)](#), [imqkeytool\(1M\)](#), [imqobjmgr\(1M\)](#), [imqusermgr\(1M\)](#), [attributes\(5\)](#)

*Sun Java System Message Queue Administrator's Guide*

- 
- Name** imqcmd – manage Message Queue brokers
- Synopsis** `/usr/bin/imqcmd subcommand argument [option...]`  
`/usr/bin/imqcmd [-h | -H]`  
`/usr/bin/imqcmd -v`
- Description** imqcmd manages the Message Queue broker, including resources such as connection services, physical destinations, durable subscriptions, and transactions. The utility provides a number of subcommands for managing these resources.
- imqcmd supports many subcommands. Basic connection and authentication is required for the execution of every imqcmd subcommand. Use the `-secure` option to specify secure connections. Subcommands and their corresponding arguments and options follow the imqcmd command on the command line. See **USAGE** and **OPTIONS**.
- Options** The following options are supported:
- `-b hostName:port` Specify the name of the host on which the broker instance is running and the port number it is using.  
  
The default value is `localhost:7676`. If you do not specify the `-b` option, imqcmd uses the default.  
  
To specify port only, use: `-b :7878`. This is equivalent to `-b localhost:7878`  
  
To specify name only, use: `-b somehost`. This is equivalent to `-b somehost:7676`.
  - `-c clientID` Specify the ID of the durable subscriber to a topic.
  - `-d topicName` Specify the name of the topic.  
  
Use this option with the `list dur` and `destroy dur` subcommands.
  - `-f` Perform action without user confirmation.  
  
Use this option with any subcommand.
  - `-h` Display usage help. Execute nothing else on the command line.
  - `-H` Display usage help, attribute list, and examples. Execute nothing else on the command line.
  - `-int interval` Specify the interval, in seconds, at which the `metrics bkr`, `metrics dst`, and `metrics svc` subcommands display metrics output.  
  
Use this option with the `metrics` subcommand.
  - `-javahome` Specify an alternate Java 2 compatible runtime to use.

- m metricType* Specify the type of metric information to display.
- Use this option with the `metrics bkr`, `metrics dst`, and `metrics svc` subcommands. The value of *metricType* depends on whether the metrics are generated for a destination, a service, or a broker.
- Use one of the following values to specify *metricType*:
- `ttl` Total of messages in and out of the broker (default)
  - `rts` Provides the same information as `ttl`, but specifies the number of messages per second
  - `cxn` Connections, virtual memory heap, threads
- The following command displays connection, VM heap, and threads metric information for the default broker instance (`localhost:7676`) every five seconds:
- ```
imqcmd metrics bkr -m cxn -int 5
```
- msp numSamples* Specify the number of samples the `metrics bkr`, `metrics dst`, and `metrics svc` subcommands display in the metrics output.
- n argumentName* Specify the name of the subcommand argument. Depending on the subcommand, this might be the name of a service, a physical destination, a durable subscription, or a transaction ID.
- o attribute=value* Specify the value of an attribute. Depending on the subcommand argument, this might be the attribute of a broker, service, or destination.
- p password* Specify the administrator password.
- This option is deprecated. Use the `-passfile` option instead.
- passfile* Specify the administrator password.
- pst pauseType* Specify whether producers, consumers, or both are paused when pausing a destination.
- Use this option with the `pause dst` subcommand. Use one of the following values:
- `CONSUMERS` Pause delivery of messages to consumers.
 - `PRODUCERS` Pause delivery of messages from producers.
 - `ALL` Pause delivery of messages to consumers and from producers.

| | |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | If the <code>-pst</code> option is not specified, pauses both consumers and producers (the equivalent of <code>-pst ALL</code>). |
| <code>-rtm timeout</code> | Specify the timeout period in seconds of an <code>imqcmd</code> subcommand. The default value is 10. |
| <code>-rtr numRetries</code> | Specify the number of retries attempted after an <code>imqcmd</code> subcommand times out.

The default value is 5. |
| <code>-s</code> | Silent mode. No output is displayed.

Use this option with any subcommand. |
| <code>-secure</code> | Specify a secure administration connection to the broker instance. You must first configure the broker to enable a secure connection service.

Use this option whenever you want a secure communication with the broker. |
| <code>-svn serviceName</code> | Specify the service for which the connections are listed.

Use this option with the <code>list cxn</code> subcommand. |
| <code>-t destinationType</code> | Specify the type of a destination: <code>t</code> (topic) or <code>q</code> (queue). |
| <code>-tmp</code> | Include temporary destinations when listing destinations using the <code>list dst</code> subcommand. |
| <code>-u name</code> | Specify the administrator user name.

If you omit this value, you are prompted for it. |
| <code>-v</code> | Display version information. Execute nothing else on the command line. |

Usage

| | |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Subcommands and Options | The following subcommands and associated arguments and options are supported: |
| | <code>compact dst [-t type -n destName]</code>
Compact the flat-file data store for the destination of the specified type and name. If no type and name are specified, all destinations are compacted. Destinations must be paused before they can be compacted. |
| | <code>commit txn -n transaction_id</code>
Commit the specified transaction |

`create dst -t destinationType -n destName [-o attribute=value] [-o attribute=value1]...`

Create a destination of the specified type, with the specified name, and the specified attributes. Destination names must contain only alphanumeric characters (no spaces) and can begin with an alphabetic character or the underscore character (`_`).

`destroy dst -t destinationType -n destName`

Destroy the destination of the specified type and name.

`destroy dur -n subscrName -c client_id`

Destroy the specified durable subscription for the specified Client Identifier.

`list cxn [-s svn serviceName] [-b hostName:port]`

List all connections of the specified service name on the default broker or on a broker at the specified host and port. If the service name is not specified, all connections are listed.

`list dst [-t tmp]`

List all destinations, with option of listing temporary destinations as well.

`list dur -d destination`

List all durable subscriptions for the specified destination.

`list svc`

List all connection services on the broker instance.

`list txn`

List all transactions, being tracked by the broker.

`metrics bkr [-m metricType] [-i int interval] [-msp numSamples]`

Display broker metrics for the broker instance.

Use the `-m` option to specify the type of metric to display. Use one of the following values to specify *metricType*:

`ttl` Specifies the total of messages in and out of the broker (default).

`rts` Provides the same information as `ttl`, but specifies the number of messages per second.

`cxn` Connections, virtual memory heap, threads.

Use the `-i int` option to specify the interval (in seconds) at which to display the metrics. The default is 5 seconds.

Use the `-msp` option to specify the number of samples displayed in the output. A value of `-1` means an unlimited number. The default value is `-1`.

`metrics dst -t type -n destName [-m metricType] [-i int interval] [-msp numSamples]`

Displays metrics information for the destination of the specified type and name.

Use the `-m` option to specify the type of metrics to display. Use one of the following values to specify *metricType*:

- `ttl` Specifies the number of messages flowing in and out of the broker and residing in memory.
- `rts` Provides the same information as `ttl`, but specifies the number of messages per second.
- `con` Displays consumer related metrics.
- `dsk` Displays disk usage metrics.

Use the `-int` option to specify the interval (in seconds) at which to display the metrics. The default is 5 seconds.

Use the `-msp` option to specify the number of samples displayed in the output. A value of `-1` means an unlimited number. The default value is 5.

`metrics svc -n serviceName [-m metricType] [-int interval] [-msp numSamples]`

List metrics for the specified service on the broker instance. Use the `-m` option to specify the type of metric to display. Use one of the following values to specify *metricType*:

- `ttl` Total of messages in and out of the broker (default)
- `rts` Provides the same information as `ttl`, but specifies the number of messages per second
- `cxn` Connections, virtual memory heap, threads

Use the `-int` option to specify the interval (in seconds) at which to display the metrics. The default is 5 seconds.

Use the `-msp` option to specify the number of samples displayed in the output. A value of `-1` means an unlimited number. The default value is `-1`.

`pause bkr`

Pause the broker instance.

`pause dst [-t type -n destName] [-pst pauseType]`

Pause the delivery of messages to consumers (`-pst CONSUMERS`), or from producers (`-pst PRODUCERS`), or both (`-pst ALL`), for the destination of the specified type and name. If no destination type or name are specified, all destinations are paused.

`pause svc -n serviceName`

Pause the specified service running on the broker instance. You cannot pause the administrative service.

`purge dst -t destinationType -n destName`

Purge messages at the destination with the specified type and name.

`purge dur -n subscrName -c client_id`

Purge all messages for the specified client identifier.

query bkr

List the current settings of properties of the broker instance. Show the list of running brokers (in a multi-broker cluster) that are connected to the specified broker.

query dst -t *destinationType* -n *destName*

List information about the destination of the specified type and name.

query svc -n *serviceName*

Display information about the specified service running on the broker instance.

query txn -n *transaction_id*

List information about the specified transaction.

reload cls

Forces all the brokers in a cluster to reload the `imq.cluster.brokerList` property and update cluster information. This subcommand only applies to broker clusters.

restart bkr

Shut down and restart the broker instance. This command restarts the broker using the options specified when the broker was first started. If you want different options to be in effect, you must shut down the broker and then start it again, specifying the options you want.

resume bkr

Resume the broker instance.

resume dst [-t *type*] [-n -destName]

Resumes the delivery of messages for the paused destination of the specified type and name. If no destination type and name are specified, all destinations are resumed.

resume svc -n *serviceName*

Resume the specified service running on the broker instance.

rollback txn -n *transaction_id*

Roll back the specified transaction.

shutdown bkr

Shut down the broker instance

update bkr -o *attribute=value* [-o *attribute=value*]...

Change the specified attributes for the broker instance.

update dst -t *destinationType* -n *destName* -o *attribute=value* [-o *attribute=value1*]...

Update the value of the specified attributes at the specified destination..

update svc -n *serviceName* -o *attribute=value* [-o *attribute=value1*]...

Update the specified attribute of the specified service running on the broker instance.

Attribute Value Pairs You can specify attributes with the create and update subcommands. Applicable attributes depend on the subcommand arguments.

The following attributes are supported:

| | |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Queue (dst): | |
| maxTotalMsgBytes | Value: Integer (maximum total size of messages, in bytes)
Default: 0 (unlimited) |
| maxBytesPerMsg | Value: Integer (maximum size of a single message, in bytes)
Default: 0 (unlimited) |
| maxNumMsgs | Value: Integer (maximum total number of messages)
Default: 0 (unlimited) |
| consumerFlowLimit | Value: Integer Initial number of queued messages sent to active consumers before load-balancing starts A value of - 1 means an unlimited number.
Default: 1000 |
| isLocalOnly | Value: Boolean (destination limited to delivering messages to local consumers only) Default: false |
| limitBehavior | Value: Specify how broker responds when memory-limit is reached. Use one of the following values:
FLOW_CONTROL Slows down producers
REMOVE_OLDEST Purges oldest messages
REJECT_NEWEST Rejects the newest messages
Default: REJECT_NEWEST |
| localDeliveryPreferred | Value: Boolean Specify messages be delivered to remote consumers only if there are no consumers on the local broker. Requires that the destination not be restricted to local-only delivery (isLocalOnly = false)
Default: false |
| maxNumActiveConsumers | Value: Integer (maximum number of active consumers in load-balanced delivery) A value of - 1 means an unlimited number.
Default: 1 |
| maxNumBackupConsumers | Value: Integer (maximum number of backup consumers in load-balanced delivery) A value of - 1 means an unlimited number.
Default: 0 |

| | |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| maxNumProducers | Value: (maximum total number of producers) A value of - 1 means an unlimited number.

Default: - 1 |
| useDMQ | Specify whether a destination's dead messages are discarded or put on the dead message queue.

Default: t rue |
| Topic (dst): | |
| consumerFlowLimit | Value: Integer Maximum number of messages delivered to a consumer in a single batch. A value of - 1 means an unlimited number.

Default: 1000 |
| isLocalOnly | Value: Boolean (destination limited to delivering messages to local consumers only)

Default: f alse |
| limitBehavior | Value: Specify how broker responds when memory-limit is reached. Use one of the following values:

FLOW_CONTROL Slows down producers
REMOVE_OLDEST Purges the oldest messages
REJECT_NEWEST Rejects the newest messages

Default: REJECT_NEWEST |
| maxBytesPerMsg | Value: Integer (maximum size of a single message, in bytes)

Default: 0 (unlimited) |
| maxNumMsgs | Value: Integer (maximum total number of messages) A value of - 1 means an unlimited number.

Default: - 1 |
| maxNumProducers | Value: (maximum total number of producers)

Default: 0 (unlimited) |
| maxTotalMsgBytes | Value: Integer (maximum total size of messages, in bytes) A value of - 1 means an unlimited number.

Default: - 1 |

| | |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| useDMQ | Specify whether a destination's dead messages are discarded or put on the dead message queue. |
| | Default: <code>true</code> |
| Broker (bkr): | |
| imq.autocreate.destination.useDMQ | Value: Boolean. Set the <code>useDMQ</code> attribute to <code>true</code> to enable all autocreated physical destinations on a broker to use the dead message queue. Set the <code>useDMQ</code> attribute to <code>false</code> to disable all autocreated physical destinations on a broker from using the dead message queue. |
| | Default: <code>true</code> |
| imq.autocreate.queue | Value: Boolean |
| | Default: <code>true</code> |
| imq.autocreate.queue.maxNumActiveConsumers | Value: Integer (maximum number of consumers that can be active in load-balanced delivery from an autocreated queue destination) A value of - 1 means an unlimited number. |
| | Default: 1 |
| imq.autocreate.queue.maxNumBackupConsumers | Value: Integer (maximum number of backup consumers that can take the place of active consumers) A value of - 1 means an unlimited number. |
| | Default: 0 |
| imq.autocreate.topic | Value: Boolean |
| | Default: <code>true</code> |
| imq.cluster.url | Value: String (location of cluster configuration file) |
| | Default: <code>none</code> |
| imq.log.file.rolloverbytes | Value: Integer (maximum size of a log file, in bytes) |

| | |
|---------------------------|-------------------------------------------------------------|
| | Default: 0 (no rollover based on size) |
| imq.log.file.rolloversecs | Value: Integer (maximum age of a log file, in seconds) |
| | Default: 0 (no rollover based on age) |
| imq.log.level | Value: String (NONE, ERROR, WARNING, INFO) |
| | Default: INFO |
| imq.message.max_size | Value: Integer (maximum size of a single message, in bytes) |
| | Default: 70m |
| imq.portmapper.port | Value: Integer |
| | Default: 7676 |
| imq.system.max_count | Value: Integer (maximum total number of messages) |
| | Default: 0 (no limit) |
| imq.system.max_size | Value: Integer (maximum total size of messages, in bytes) |
| | Default: 0 (no limit) |
| Service (svc): | |
| maxThreads | Value: Integer (maximum threads assigned) |
| | Default: Depends on service |
| minThreads | Value: Integer (minimum threads assigned) |
| | Default: Depends on service |
| port | Value: Integer |
| | Default: 0 (dynamically allocated) |

Examples EXAMPLE 1 Shutting Down a Broker

The following command shuts down a broker for hostname myserver on port 7676:

```
mqcmd shutdown bkr -b myserver:7676
```

EXAMPLE 2 Restarting a Broker

The following command restarts a broker for hostname `myserver`:

```
imqcmd restart bkr -b myserver
```

EXAMPLE 3 Pausing a Service

The following command pauses a broker for hostname `localhost` on port `7676`, with a *serviceName* of `jms`:

```
imqcmd pause svc -n jms -b :7676
```

EXAMPLE 4 Resuming a Service

The following command resumes a service for hostname `localhost` on port `7676`, with a *serviceName* of `jms`:

```
imqcmd resume svc -n jms -b myserver:7676
```

EXAMPLE 5 Creating a Queue Destination

The following command creates a queue destination for hostname `myserver` on port `7676`, with a *destName* of `myFQ`, a *queueDeliveryPolicy* of `Failover`, and a *maxBytesPerMsg* of `10000`:

```
imqcmd create dst -n myFQ -t q -o "queueDeliveryPolicy=f" \  
-o "maxBytesPerMsg=10000" -b myserver:7676
```

EXAMPLE 6 Purging a Queue Destination

The following command purges a queue destination for hostname `myserver` on port `7676`, with a *destName* of `myFQ`:

```
imqcmd purge dst -n myFQ -t q -b myserver:7676
```

EXAMPLE 7 Listing Destinations on a Broker

The following command lists destinations for hostname `myserver` on port `7676`:

```
imqcmd list dst -b myserver:7676
```

EXAMPLE 8 Updating a Portmapper Port

The following command updates a portmapper port on hostname `myserver` from port `7676` to `7878`:

```
imqcmd update bkr -o "imq.portmapper.port=7878"
```

EXAMPLE 9 Updating the Maximum Number of Messages in the Queue

The following command updates the maximum number of messages in the queue to `2000` for `myserver` on port `8080` with a *destName* of `TestQueue`:

```
imqcmd update dst -b myserver:8080 -n TestQueue -t q -o "maxNumMsgs=2000"
```

EXAMPLE 10 Updating the Maximum Threads

The following command updates the maximum threads `jms` connection service to `200` for hostname `localhost` on port `7676`:

```
imqcmd update svc -n jms -o "minThreads=200"
```

EXAMPLE 11 Listing Durable Subscriptions

The following command lists durable subscriptions for a topic with hostname `localhost` on port `7676` with a `destName` of `myTopic`:

```
imqcmd list dur -d myTopic
```

EXAMPLE 12 Destroying Durable Subscriptions

The following command destroys subscriptions for hostname `localhost` on port `7676` with a `dursubName` of `myDurSub` and a `client_ID` of `111.222.333.444`:

```
imqcmd destroy dur -n myDurSub -c "111.222.333.444"
```

EXAMPLE 13 Listing All Transactions

The following command lists all transactions on a broker with hostname `localhost` on port `7676`:

```
imqcmd list txn
```

EXAMPLE 14 Displaying Information About a Transaction

The following command displays information about a transaction with hostname `localhost` on port `7676`, and a `transactionID` of `1234567890`

```
imqcmd query txn -n 1234567890
```

EXAMPLE 15 Committing a Transaction

The following command commits a transaction with hostname `localhost` on port `7676`, and a `transactionID` of `1234567890`:

```
imqcmd commit txn -n 1234567890
```

Environment Variables The following environment variables affect the execution of this command:

IMQ_JAVAHOME Specify the Java 2 compatible runtime. When this environment variable is not set it defaults to `/usr/j2se`.

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWiq |

See Also [imqadmin\(1M\)](#), [imqbrokerd\(1M\)](#), [imqdbmgr\(1M\)](#), [imqkeytool\(1M\)](#), [imqobjmgr\(1M\)](#), [imqusermgr\(1M\)](#), [attributes\(5\)](#)

Sun Java System Message Queue Administrator's Guide

Name imqdbmgr – manage a plugged-in JDBC-compliant Message Queue data store

Synopsis /usr/bin/imqdbmgr *subcommand argument* [*option...*]

/usr/bin/imqdbmgr -h | -help

/usr/bin/imqdbmgr -v | -version

Description The imqdbmgr utility creates and manages a Java DataBase Connectivity (JDBC) compliant database used for Message Queue persistent storage.

The database can be either embedded or external. To use a JDBC-compliant database (and the imqdbmgr utility), you need to first set a number of JDBC-related properties in the broker instance configuration file. See the *Sun Java System Message Queue Administrator's Guide* for additional information.

imqdbmgr supports four management subcommands. These *subcommands*, and their corresponding *arguments* and *options* follow the imqdbmgr command on the command line. See USAGE and OPTIONS.

The following subcommands are supported:

| | |
|----------|------------------------------------------------------------------------------------------------------------|
| create | Create a Message Queue database schema. |
| delete | Delete Message Queue database tables in the current data store. |
| recreate | Delete Message Queue database tables and recreate Message Queue database schema in the current data store. |
| reset | Reset the database table lock to allow other processes to access database tables. |

The imqdbmgr subcommands support the following arguments:

| | |
|--------|-------------------------------------------------------------------------------------|
| all | Indicates the subcommand applies to the data store, as well as the database tables. |
| lck | Indicates the subcommand applies to the database table lock. |
| oldtbl | Indicates the subcommand applies to an older version of the database tables. |
| tbl | Indicates the subcommand applies to the database tables only. |

Options The following options are supported:

| | |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -b <i>brokerName</i> | Specify the broker instance name and corresponding instance configuration properties. If this option is not specified, the default broker instance is assumed. |
| | Use this option with the create, delete, recreate, or reset subcommands. |
| -D <i>property=value</i> | Set system property <i>property</i> to <i>value</i> . |

| | |
|-----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| | Use this option with the <code>create</code> , <code>delete</code> , <code>recreate</code> , or <code>reset</code> subcommands. |
| <code>-h</code> <code>-help</code> | Display usage help. Execute nothing else on the command line. |
| <code>-p password</code> | Specify the database password. |
| | Use this option with the <code>create</code> , <code>delete</code> , <code>recreate</code> , or <code>reset</code> subcommands. |
| <code>-u userName</code> | Specify the database user name. |
| | Use this option with the <code>create</code> , <code>delete</code> , <code>recreate</code> , or <code>reset</code> subcommands. |
| <code>-v</code> <code>-version</code> | Display version information. Execute nothing else on the command line. |

Usage The following subcommands and associated arguments are supported:

| | |
|----------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>create all</code> | Create a new embedded data store and Message Queue database schema for a specified or default broker instance. |
| <code>create tbl [-u <i>userName</i>] [-p <i>password</i>]</code> | Create Message Queue database schema in an existing data store for a specified or default broker instance. |
| <code>delete tbl [-u <i>userName</i>] [-p <i>password</i>]</code> | Delete Message Queue database tables in the current data store for a specified or default broker instance. |
| <code>delete oldtbl [-u <i>userName</i>] [-p <i>password</i>]</code> | Delete the earlier version of Message Queue database tables. Used after the data store has been automatically migrated to the current version of Message Queue. |
| <code>recreate tbl [-u <i>userName</i>] [-p <i>password</i>]</code> | Delete Message Queue database tables and recreate Message Queue database schema in the current data store for a specified or default broker instance. |
| <code>reset lck</code> | Reset the database table lock to allow other processes to access database tables. |

Environment Variables The following environment variables affect the execution of this command:

| | |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <code>IMQ_JAVAHOME</code> | Specify the Java 2 compatible runtime. When this environment variable is not set it defaults to <code>/usr/j2se</code> . |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------|

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Files `/var/imq/instances/brokerName/dbstore` Recommended directory in which to create an embedded database.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWiq |

See Also [imqadmin\(1M\)](#), [imqbrokerd\(1M\)](#), [imqcmd\(1M\)](#), [imqusermgr\(1M\)](#), [imqkeytool\(1M\)](#), [imqobjmgr\(1M\)](#), [attributes\(5\)](#)

Sun Java System Message Queue Administrator's Guide

Name imqkeytool – generate a self-signed certificate for secure communication

Synopsis /usr/bin/imqkeytool [-broker] [-servlet *keystore_location*]
/usr/bin/imqkeytool -h

Description The imqkeytool utility generates a self-signed certificate for secure communication. The certificate can be used by a broker instance to establish a secure connection with a client, or by a Message Queue-supplied HTTPS servlet to establish a secure connection with a broker instance. An HTTPS servlet is an SSL-enabled variant of the HyperText Transfer Protocol that establishes a secure connection with a broker instance.

Without an option, imqkeytool generates a self-signed certificate for a broker instance.

imqkeytool uses command line options to specify whether the certificate is used by a broker instance or by a servlet.

Options The following options are supported:

| | |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -broker | Generate a self-signed certificate for the broker and places it in the Message Queue keystore. All broker instances running on a system must use the same certificate. |
| -h | Display usage help. Do not execute anything else on the command line. |
| -servlet <i>keystore_location</i> | Generate a self-signed certificate for an HTTPS servlet and places it in <i>keystore_location</i> .

<i>keystore_location</i> refers to the location of the keystore. You should move this keystore to a location where it is accessible and readable by the Message Queue HTTPS servlet to establish a secure connection with a broker. |

Environment Variables The following environment variables affect the execution of this command:

| | |
|--------------|------------------------------------------------------------------------------------------------------------|
| IMQ_JAVAHOME | Specify the Java 2 compatible runtime. When this environment variable is not set it defaults to /usr/j2se. |
|--------------|------------------------------------------------------------------------------------------------------------|

Exit Status The following exit values are returned:

| | |
|----|------------------------|
| 0 | Successful completion. |
| >0 | An error occurred. |

| | | |
|--------------|-------------------|---------------------------------------------------------------------------------------------------|
| Files | /etc/imq/keystore | Contains Message Queue keystore in which imqkeytool stores a self-signed certificate for brokers. |
|--------------|-------------------|---------------------------------------------------------------------------------------------------|

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWiq |

See Also [imqadmin\(1M\)](#), [imqbrokerd\(1M\)](#), [imqcmd\(1M\)](#), [imqdbmgr\(1M\)](#), [imqobjmgr\(1M\)](#), [imqusermgr\(1M\)](#), [attributes\(5\)](#)

Sun Java System Message Queue Administrator's Guide

Name imqobjmgr – manage Message Queue administered objects

Synopsis /usr/bin/imqobjmgr *subcommand* [[*option*]...]

/usr/bin/imqobjmgr -i *fileName*

/usr/bin/imqobjmgr -h | [-H] | -help | -Help

/usr/bin/imqobjmgr -v

Description imqobjmgr manages Message Queue administered objects in an object store accessible using JNDI. Administered objects allow JMS clients to be provider-independent by insulating them from provider-specific naming and configuration formats.

imqobjmgr supports five management subcommands. These *subcommands*, and their corresponding *options* follow the imqobjmgr command on the command line. See USAGE and OPTIONS.

The following subcommands are supported:

| | |
|--------|------------------------------------------------|
| add | Add a new administered object |
| delete | Delete an administered object |
| list | Display a list of administered objects |
| query | Display information about administered objects |
| update | Update administered objects |

You can use the -i option to specify the name of an input file that uses java property file syntax to represent all or part of any imqobjmgr subcommand clause. The -f, -s, and -pre options can be used with any imqobjmgr subcommand.

Options The following options are supported:

| | |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -f | Perform action without user confirmation. |
| -h -help | Display usage help. Execute nothing else on the command line. |
| -H -Help | Display usage help, attribute list, and examples. Execute nothing else on the command line. |
| -i <i>fileName</i> | Specify the name of an input file containing all or part of the subcommand clause, specifying object type, lookup name, object attributes, object store attributes, or other options. Use this option for repetitive information, such as object store attributes. |
| -j <i>attribute=value</i> | Specify attributes necessary to identify and access a JNDI object store. |
| -javahome | Specify an alternate Java 2 compatible runtime to use. imqobjmgr uses the runtime bundled with the operating system by default. |

| | |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -l <i>lookupName</i> | Specify the JNDI lookup name of an administered object. This name must be unique in the object store's context. |
| -o <i>attribute=value</i> | Specify the attributes of an administered object. |
| -pre | Run command in preview mode. Preview mode indicates what will be done without performing the command. |
| -r <i>read-only_state</i> | Specify if an administered object is a read-only object. A value of true indicates the administered object is a read-only object. JMS clients cannot modify the attributes of read-only administered objects. The read-only state is set to false by default. |
| -s | Silent mode. No output is displayed. |
| -t <i>type</i> | Specify the type of an administered object:
q = queue
t = topic
cf = ConnectionFactory
qf = queueConnectionFactory
tf = topicConnectionFactory
xcf = XA ConnectionFactory (distributed transactions)
xqf = XA queueConnectionFactory (distributed transactions)
xtf = XA topicConnectionFactory (distributed transactions)
e = SOAP endpoint (used to support SOAP messaging) |
| -v | Display version information. Execute nothing else on the command line. |

Usage This section provides information on subcommands, options, and attribute value pairs.

Subcommands and Options The following subcommands and corresponding options are supported:

add -t *type* -l *lookupName* [-o *attribute=value*]... -j *attribute=value*...

Add a new administered object of the specified type, lookup name, and object attributes to an object store.

delete -t *type* -l *lookupName* -j *attribute=value*...

Delete an administered object, of the specified type and lookup name from an object store.

list [-t *type*] -j *attribute=value*...

Display a list of administered objects of a specified type, or all administered objects, in an object store.

query -l *lookupName* -j *attribute=value*...

Display information about an administered object of a specified lookup name in an object store.

update -l *lookupName* [-o *attribute=value*]... -j *attribute=value*...

Update the specified attribute values of an administered object of the specified lookup name in an object store.

Attribute Value Pairs The following attribute value pairs are supported for the specified administered object types:

Type = ConnectionFactories: ConnectionFactory, TopicConnectionFactory, QueueConnectionFactory, XAConnectionFactory, XATopicConnectionFactory, and XAQueueConnectionFactory

imqAckOnAcknowledge

Value: String (true, false, not specified)

Default: not specified

imqAckOnProduce

Value: String (true, false, not specified)

Default: not specified

imqAckTimeout

Value: String (time in milliseconds)

Default: 0 (no timeout)

imqAddressList

Value: String

Default: not specified

imqAddressListBehavior

Value: String

Default: Priority

imqAddressListIterations

Value: Integer

Default: 1

imqBrokerHostName

Used if imqConnectionType is TCP or TLS. This attribute type is only supported in Message Queue 3.0.

Value: String

Default: localhost

imqBrokerHostPort

Used if imqConnectionType is TCP or TLS. This attribute type is only supported in Message Queue 3.0.

Value: Integer

Default: 7676

imqBrokerServicePort

Used if imqConnectionType is TCP or TLS. This attribute type is only supported in Message Queue 3.0.

Value: Integer

Default: 0

imqConfiguredClientID

Value: String (ID number)

Default: no ID specified

imqConnectionFlowCount

Value: Integer

Default: 100

imqConnectionFlowLimit

Value: Integer

Default: 1000

imqConnectionFlowLimitEnabled

Value: Boolean

Default: false

imqConnectionType

This attribute type is only supported in Message Queue 3.0.

Value: String (TCP, TLS, HTTP).

Default: TCP

imqConnectionURL

Used if imqConnectionType is HTTP. This attribute type is only supported in Message Queue 3.0.

Value: String

Default: `http://localhost/imq/tunnel`

imqConsumerFlowLimit

Value: Integer

Default: 1000

imqConsumerFlowThreshold
Value: Integer
Default: 50

imqDefaultPassword
Value: String
Default: guest

imqDefaultUsername
Value: String
Default: guest

imqDisableSetClientID
Value: Boolean
Default: false

imqJMSDeliveryMode
Value: Integer (1=non-persistent, 2=persistent)
Default: 2

imqJMSExpiration
Value: Long (time in milliseconds)
Default: 0 (does not expire)

imqJMSPriority
Value: Integer (0 to 9)
Default: 4

imqLoadMaxToServerSession
Value: Boolean
Default: true

imqOverrideJMSDeliveryMode
Value: Boolean
Default: false

imqOverrideJMSExpiration
Value: Boolean
Default: false

imqOverrideJMSHeadersToTemporaryDestinations
Value: Boolean
Default: false

imqOverrideJMSPriority
Value: Boolean
Default: false

imqQueueBrowserMaxMessagesPerRetrieve
Value: Integer
Default: 1000

imqBrowserRetrieveTimeout
Value: Long (time in milliseconds)
Default: 60,000

imqReconnectAttempts
Value: Integer
Default: 0

imqReconnectEnabled
Value: Boolean
Default: false

imqReconnectInterval
Value: Long (time in milliseconds)
Default: 3000

imqSetJMSXAppID
Value: Boolean
Default: false

imqSetJMSXConsumerTXID
Value: Boolean
Default: false

imqSetJMSXProducerTXID
Value: Boolean
Default: false

imqSetJMSXRcvTimestamp
Value: Boolean
Default: false

imqSetJMSXUserID
Value: Boolean
Default: false

imqSSLIsHostTrusted

Used if `imqConnectionType` is TLS. This attribute type is only supported in Message Queue 3.0.

Value: Boolean

Default: true

Type = Destinations: Topic and Queue

`imqDestinationDescription` Value: String

Default: no description

`imqDestinationName` Value: String

Default: `Untitled_Destination_Object`

Type = Endpoint (SOAP Endpoint)

`imqEndpointDescription` Value: String

Default: A description for the endpoint object

`imqEndpointName` Value: String

Default: `Untitled_Endpoint_Object`

`imqSOAPEndpointList` Value: String (one or more space-separated URLs)

Default: no url

Examples EXAMPLE 1 Adding a Topic Administered Object to an Object Store

Where JNDI lookup name=`myTopic` and `imqDestinationName=MyTestTopic`, the following command adds to an LDAP server object store:

```
imqobjmgr add -t t -l "cn=myTopic"\
-o "imqDestinationName=MyTestTopic"\
-j "java.naming.factory.initial=com.sun.jndi.ldap.LdapCtxFactory"\
-j "java.naming.provider.url=ldap://mydomain.com:389/o=imq"
```

Where JNDI lookup name=`myTopic` and `imqDestinationName=MyTestTopic`, the following command adds to a file system object store:

```
imqobjmgr add -t -l "cn=myTopic"\
-o "imqDestinationName=MyTestTopic"\
-j \
  "java.naming.factory.initial=com.sun.jndi.fscontext.RefFSContextFactory"\
-j "java.naming.provider.url=file:/home/foo/imq_admin_objects"
```

EXAMPLE 1 Adding a Topic Administered Object to an Object Store *(Continued)*

Where JNDI lookup name=`myTopic` and `imqDestinationName=MyTestTopic`, the following command adds to a file system object store, using an input file:

```
imqobjmgr -i inputfile
```

The associated input file consists of the following:

```
cmdtype=add
obj.type=t
obj.lookupName=cn=myTopic
obj.attrs.imqDestinationName=MyTestTopic
objstore.attrs.java.naming.factory.initial=com.sun.jndi.fscontext.\
  RefFSContextFactory
objstore.attrs.java.naming.provider.url=file:/home/foo/imq_admin_objects
```

EXAMPLE 2 Adding a QueueConnectionFactory Administered Object to an Object Store

Where JNDI lookup name=`myQCF`, read-only state=`true`, `imqAddressList=mq://foohost:777/jms`, the following command adds to an LDAP server object store:

```
imqobjmgr add -t qf -l "cn=myQCF" -r true\
-o "imqAddressList=mq://foohost:777/jms"\
-j "java.naming.factory.initial=com.sun.jndi.ldap.LdapCtxFactory"\
-j "java.naming.provider.url=ldap://mydomain.com:389/o=imq"
```

Where JNDI lookup name=`myQCF`, read-only state=`true`, `imqAddressList=mq://foohost:777/jms`, the following command adds to an LDAP server object store using an input file:

```
imqobjmgr -i inputfile
```

The associated input file consists of the following:

```
cmdtype=add
obj.type=qf
obj.lookupName=cn=myQCF
obj.readOnly=true
obj.attrs.imqAddressList=mq://foohost:777/jms
objstore.attrs.java.naming.factory.initial=com.sun.jndi.\
  ldap.LdapCtxFactory
objstore.attrs.java.naming.provider.url=ldap://mydomain.com:389/o=imq
```

Where JNDI lookup name=`myQCF`, read-only state=`true`, `imqAddressList=mq://foohost:777/jms`, the following command adds to an LDAP server object store, using both an input file and command options:

EXAMPLE 2 Adding a QueueConnectionFactory Administered Object to an Object Store
(Continued)

```
imqobjmgr add -t qf -l "cn=myQCF"\
-o "imqAddressList=mq://foohost:777/jms"\
-i inputfile
```

The associated input file consists of the following:

```
objstore.attrs.java.naming.factory.initial=com.sun.jndi.ldap.LdapCtxFactory
objstore.attrs.java.naming.provider.url=ldap://mydomain.com:389/o=imq
```

EXAMPLE 3 Deleting a Topic Administered Object from an Object Store

Where JNDI lookup name=myTopic and no confirmation is requested, the following command deletes from an LDAP server object store:

```
imqobjmgr delete -f -l "cn=myTopic"\
-j "java.naming.factory.initial=com.sun.jndi.ldap.LdapCtxFactory"\
-j "java.naming.provider.url=ldap://mydomain.com:389/o=imq"
```

EXAMPLE 4 Querying Information About a Topic Administered Object

Where JNDI lookup name=myTopic, the following command queries from an LDAP server object store using simple authentication scheme:

```
imqobjmgr query -l "cn=myTopic"\
-j "java.naming.factory.initial=com.sun.jndi.ldap.LdapCtxFactory"\
-j "java.naming.provider.url=ldap://mydomain.com:389/o=imq"\
-j "java.naming.security.authentication=simple"\
-j "java.naming.security.principal=uid=foo,ou=imqobjmgr,o=imq"\
-j "java.naming.security.credentials=foo"
```

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWiq |

See Also [imqadmin\(1M\)](#), [imqcmd\(1M\)](#), [imqbrokerd\(1M\)](#), [imqkeytool\(1M\)](#), [imqusermgr\(1M\)](#), [attributes\(5\)](#)

Sun Java System Message Queue Administrator's Guide

Name imqusermgr – command utility for managing a Message Queue user repository

Synopsis /usr/bin/imqusermgr *subcommand* [[*option*]. . .]

/usr/bin/imqusermgr -h

/usr/bin/imqusermgr -v

Description The imqusermgr utility manages a file-based user repository to authenticate and authorize users of a Message Queue message server.

imqusermgr provides subcommands for adding, deleting, updating, and listing user entries in the repository.

imqusermgr supports four management subcommands. These *subcommands*, and their corresponding *options* follow the imqusermgr command on the command line. See USAGE and OPTIONS.

The following subcommands are supported:

add Add a new user and associated password to the repository.

delete Delete a user from the repository.

list Display information users in the repository.

update Update the password or state of a user in the repository.

Options The following options are supported:

-a *active_state* Specify if user's state is active or inactive. An inactive user cannot create connections to the Message Queue message server.

Valid values for *active_state* are true or false. Specify true for active or false for inactive. the default is true.

Use this option with the update subcommand.

-f Perform action without user confirmation.

Use this option with the delete and update subcommands.

-g *group* Specify the group of the user.

Valid values for group are admin, user, and anonymous.

Use this option with the add subcommand.

-h Display usage help. Execute nothing else on the command line.

-i *brokerName* Specify the broker instance user repository to which the command applied. If you do not specify *brokerName*, the default *brokerName* is assumed.

- Use this option with the `add`, `delete`, `list`, and `update` subcommands.
- `-p password` Specify user password.
- Use this option with the `add` and `update` subcommands.
- `-s` Silent mode. Display no output
- Use this option with the `add`, `delete`, and `update` subcommands.
- `-u userName` Specify user name.
- userName* cannot contain the following characters: asterisk (*), colon (:), NEWLINE, or RETURN.
- Use this option with the `add`, `delete`, `update` and `list` subcommands.
- `-v` Display version information. Execute nothing else on the command line.

Usage The following subcommands and corresponding options are supported:

`add -u userName -p password [-g group] [-s] [-i brokerName]`

Add a new user and associated password to the repository, and optionally specify the user's group.

`delete -u userName [-s] [-f] [-i brokerName]`

Delete a user from the repository.

`list [-u user_name] [-i brokerName]`

Display information about the specified user in the repository. If no user is specified, all users are displayed.

`update -u userName -p password [-a state] [-s] [-f] [-i brokerName]`

`update -u userName -a state [-p password] [-s] [-f] [-i brokerName]`

Update the password or state (or both) of a user.

Environment Variables The following environment variables affect the execution of this command:

`IMQ_JAVAHOME` Specify the Java 2 compatible runtime. When this environment variable is not set, it defaults to `/usr/j2se`.

Exit Status The following exit values are returned:

`0` Successful completion.

`>0` An error occurred.

Files `/etc/imq/passwd` Flat-file user repository.

| Availability | SUNWiq |

See Also [imqadmin\(1M\)](#), [imqbrokerd\(1M\)](#), [imqcmd\(1M\)](#), [imqdbmgr\(1M\)](#), [imqkeytool\(1M\)](#), [imqobjmgr\(1M\)](#), [attributes\(5\)](#)

Sun Java System Message Queue Administrator's Guide

Name in.chargend – UDP or TCP character generator service daemon

Synopsis in.chargend

FMRI `svc:/internet/chargen:default`

Description FMRI stands for Fault Management Resource Identifier. It is used to identify resources managed by the Fault Manager. See [fmd\(1M\)](#) and [smf\(5\)](#).

The `in.chargend` service provides the server-side of the character-generator protocol. This protocol is used for debugging and bandwidth measurement and is available on both TCP and UDP transports, through port 19.

The `in.chargend` service is an [inetd\(1M\)](#) [smf\(5\)](#) delegated service. The `in.chargend` detects which transport is requested by examining the socket it is passed by the `inetd` daemon.

TCP-based service Once a connection is established, the `in.chargend` generates a stream of data. Any data received is discarded. The server generates data until the client program terminates the connection. Note that the data flow is limited by TCP flow control mechanisms.

UDP-based service The `in.chargend` listens for UDP datagrams. When a datagram is received, the server generates a UDP datagram in response containing a random number of ASCII characters (ranging from 0 to 512 characters). Any received data is ignored.

The `in.chargend` data consists of a pattern of 72 character lines containing the printable, 7-bit ASCII characters. Each line is terminated with a carriage return and a line feed character.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------------|
| Availability | service/network/legacy |
| Interface Stability | Committed |

See Also [inetd\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#)

RFC 864

Name in.comsat, comsat – biff server

Synopsis /usr/sbin/in.comsat

Description comsat is the server process which listens for reports of incoming mail and notifies users who have requested to be told when mail arrives. It is invoked as needed by [inetd\(1M\)](#), and times out if inactive for a few minutes.

comsat listens on a datagram port associated with the `biff` service specification (see [services\(4\)](#)) for one line messages of the form

user@mailbox - offset

If the *user* specified is logged in to the system and the associated terminal has the owner execute bit turned on (by a `biff y`), the *offset* is used as a seek offset into the appropriate mailbox file, and the first 7 lines or 560 characters of the message are printed on the user's terminal. Lines which appear to be part of the message header other than the From, To, Date, or Subject lines are not printed when displaying the message.

Files /var/adm/utmpx user access and administration information

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|---------------------------------|
| Availability | service/network/network-servers |

See Also [svcs\(1\)](#), [inetadm\(1M\)](#), [inetd\(1M\)](#), [svcadm\(1M\)](#), [services\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Notes The message header filtering is prone to error.

The `in.comsat` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/comsat:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). Responsibility for initiating and restarting this service is delegated to [inetd\(1M\)](#). Use [inetadm\(1M\)](#) to make configuration changes and to view configuration information for this service. The service's status can be queried using the [svcs\(1\)](#) command.

Name in.daytimed – UDP or TCP daytime protocol service daemon

Synopsis in.daytimed

FMRI `svc:/internet/daytime:default`

Description FMRI stands for Fault Management Resource Identifier. It is used to identify resources managed by the Fault Manager. See [fmd\(1M\)](#) and [smf\(5\)](#).

The `in.daytimed` service provides the server-side of the daytime protocol. This protocol is used for debugging and bandwidth measurement and is available on both TCP and UDP transports, through port 13.

The `in.daytimed` service is an [inetd\(1M\)](#) [smf\(5\)](#) delegated service. The `in.daytimed` detects which transport is requested by examining the socket it is passed by the `inetd` daemon.

TCP-based service Once a connection is established, the `in.daytimed` generates the current date and time in [ctime\(3C\)](#) format as 7-bit ASCII and sends it through the connection. The server then closes the connection. Any data received from the client side of the connection is discarded.

UDP-based service The `in.daytimed` listens for UDP datagrams. When a datagram is received, the server generates the current date and time in [ctime\(3C\)](#) format as 7-bit ASCII and inserts it in a UDP datagram sent in response to the client's request. Any received data is ignored.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------------|
| Availability | service/network/legacy |
| Interface Stability | Committed |

See Also [inetd\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#)

RFC 867

Name in.dhcpd – Dynamic Host Configuration Protocol server

Synopsis /usr/lib/inet/in.dhcpd [-denv] [-h relay_hops] [-i interface, ...]
 [-l syslog_local_facility] [-b automatic | manual]
 [-o DHCP_offer_time] [-t dhcptab_rescan_interval]

/usr/lib/inet/in.dhcpd [-dv] [-h relay_hops] [-i interface,]...
 [-l syslog_local_facility] -r IP_address | hostname, ...

Description in.dhcpd is a daemon that responds to Dynamic Host Configuration Protocol (DHCP) requests and optionally to BOOTP protocol requests. The daemon forks a copy of itself that runs as a background process. It must be run as root. The daemon has two run modes, DHCP server (with optional BOOTP compatibility mode) and BOOTP relay agent mode.

The first line in the SYNOPSIS section illustrates the options available in the DHCP/BOOTP server mode. The second line in the SYNOPSIS section illustrates the options available when the daemon is run in BOOTP relay agent mode.

The DHCP and BOOTP protocols are used to provide configuration parameters to Internet hosts. Client machines are allocated their IP addresses as well as other host configuration parameters through this mechanism.

The DHCP/BOOTP daemon manages two types of DHCP data tables: the dhcptab configuration table and the DHCP network tables.

See [dhcptab\(4\)](#) regarding the dhcptab configuration table and [dhcp_network\(4\)](#) regarding the DHCP network tables.

The dhcptab contains macro definitions defined using a termcap-like syntax which permits network administrators to define groups of DHCP configuration parameters to be returned to clients. However, a DHCP/BOOTP server always returns hostname, network broadcast address, network subnet mask, and IP maximum transfer unit (MTU) if requested by a client attached to the same network as the server machine. If those options have not been explicitly configured in the dhcptab, in.dhcpd returns reasonable default values.

The dhcptab is read at startup, upon receipt of a SIGHUP signal, or periodically as specified by the -t option. A SIGHUP (sent using the command `svcadm refresh network/dhcp-server`) causes the DHCP/BOOTP daemon to reread the dhcptab within an interval from 0-60 seconds (depending on where the DHCP daemon is in its polling cycle). For busy servers, users should run `svcadm restart network/dhcp-server` to force the dhcptab to be reread.

The DHCP network tables contain mappings of client identifiers to IP addresses. These tables are named after the network they support and the datastore used to maintain them.

The DHCP network tables are consulted during runtime. A client request received from a network for which no DHCP network table exists is ignored.

This command may change in future releases of Solaris software. Scripts, programs, or procedures that use this command might need modification when upgrading to future Solaris software releases. The command line options provided with the in.dhcpd daemon are used

only for the current session, and include only some of the server options you can set. The `dhcpsvc.conf(4)` contains all the server default settings, and can be modified by using the `dhcpgmr` utility. See `dhcpsvc.conf(4)` for more details.

Options The following options are supported:

- b *automatic | manual*
This option enables BOOTP compatibility mode, allowing the DHCP server to respond to BOOTP clients. The option argument specifies whether the DHCP server should automatically allocate permanent lease IP addresses to requesting BOOTP clients if the clients are not registered in the DHCP network tables (*automatic*) or respond only to BOOTP clients who have been manually registered in the DHCP network tables (*manual*). This option only affects DHCP server mode.
- d
Debugging mode. The daemon remains as a foreground process, and displays verbose messages as it processes DHCP and/or BOOTP datagrams. Messages are displayed on the current TTY. This option can be used in both DHCP/BOOTP server mode and BOOTP relay agent mode.
- h *relay_hops*
Specifies the maximum number of relay agent hops that can occur before the daemon drops the DHCP/BOOTP datagram. The default number of relay agent hops is 4. This option affects both DHCP/BOOTP server mode and BOOTP relay agent mode.
- i *interface, . . .*
Selects the network interfaces that the daemon should monitor for DHCP/BOOTP datagrams. The daemon ignores DHCP/BOOTP datagrams on network interfaces not specified in this list. This option is only useful on machines that have multiple network interfaces. If this option is not specified, then the daemon listens for DHCP/BOOTP datagrams on all network interfaces. The option argument consists of a comma-separated list of interface names. It affects both DHCP/BOOTP server and BOOTP relay agent run modes.
- l *syslog_local_facility*
The presence of this option turns on transaction logging for the DHCP server or BOOTP relay agent. The value specifies the `syslog` local facility (an integer from 0 to 7 inclusive) the DHCP daemon should use for tagging the transactions. Using a facility separate from the `LOG_DAEMON` facility allows the network administrator to capture these transactions separately from other DHCP daemon events for such

purposes as generating transaction reports. See [syslog\(3C\)](#), for details about local facilities. Transactions are logged using a record with 9 space-separated fields as follows:

1. Protocol:

Relay mode: "BOOTP"
 Server mode: "BOOTP" or "DHCP" based upon client type.

2. Type:

Relay mode: "RELAY-CLNT", "RELAY-SRVR"
 Server mode: "ASSIGN", "EXTEND", "RELEASE",
 "DECLINE", "INFORM", "NAK" "ICMP-ECHO."

3. Transaction time: absolute time in seconds (unix time)

4. Lease time:

Relay mode: Always 0.
 Server mode: 0 for ICMP-ECHO events, absolute time in seconds (unix time) otherwise

5. Source IP address: Dotted Internet form

Relay mode: Relay interface IP on RELAY-CLNT, INADDR_ANY on RELAY-SRVR.
 Server mode: Client IP.

6. Destination IP address: Dotted Internet form

Relay mode: Client IP on RELAY-CLNT, Server IP on RELAY-SRVR.
 Server mode: Server IP.

7. Client Identifier: Hex representation (0-9, A-F)

Relay mode: MAC address
 Server mode: BOOTP - MAC address; DHCP - client id

8. Vendor Class identifier (white space converted to periods (.)).

Relay mode: Always "N/A"
 Server mode: Vendor class ID tokenized by converting white space characters to periods (.)

9. MAC address: Hex representation (0-9, A-F)

Relay mode: MAC address

Server mode: MAC address

The format of this record is subject to change between releases.

Transactions are logged to the console if daemon is in debug mode (-d).

Logging transactions impact daemon performance.

It is suggested that you periodically rotate the DHCP transaction log file to keep it from growing until it fills the filesystem. This can be done in a fashion similar to that used for the general system message log `/var/adm/messages` and is best accomplished using the facilities provided by [logadm\(1M\)](#).

- `-n` Disable automatic duplicate IP address detection. When this option is specified, the DHCP server does not attempt to verify that an IP address it is about to offer a client is not in use. By default, the DHCP server pings an IP address before offering it to a DHCP/BOOTP client, to verify that the address is not in use by another machine.
- `-o DHCP_offer_time` Specifies the number of seconds the DHCP server should cache the offers it has extended to discovering DHCP clients. The default setting is 10 seconds. On slow network media, this value can be increased to compensate for slow network performance. This option affects only DHCP server mode.
- `-r IP_address | hostname, . . .` This option enables BOOTP relay agent mode. The option argument specifies a comma-separated list of IP addresses or hostnames of DHCP or BOOTP servers to which the relay agent is to forward BOOTP requests. When the daemon is started in this mode, any DHCP tables are ignored, and the daemon simply acts as a BOOTP relay agent.

A BOOTP relay agent listens to UDP port 68, and forwards BOOTP request packets received on this port to the destinations specified on the command line. It supports the BROADCAST flag described in RFC 1542. A BOOTP relay

agent can run on any machine that has knowledge of local routers, and thus does not have to be an Internet gateway machine.

Note that the proper entries must be made to the `netmasks` database so that the DHCP server being served by the BOOTP relay agents can identify the subnet mask of the foreign BOOTP/DHCP client's network. See [netmasks\(4\)](#) for the format and use of this database.

- `-t dhcptab_rescan_interval` Specifies the interval in minutes that the DHCP server should use to schedule the automatic rereading of the `dhcptab` information. Typically, you would use this option if the changes to the `dhcptab` are relatively frequent. Once the contents of the `dhcptab` have stabilized, you can turn off this option to avoid needless reinitialization of the server.
- `-v` Verbose mode. The daemon displays more messages than in the default mode. Note that verbose mode can reduce daemon efficiency due to the time taken to display messages. Messages are displayed to the current TTY if the debugging option is used; otherwise, messages are logged to the `syslogd` facility. This option can be used in both DHCP/BOOTP server mode and BOOTP relay agent mode.

Examples **EXAMPLE 1** Starting a DHCP Server in BOOTP Compatibility Mode

The following command starts a DHCP server in BOOTP compatibility mode, permitting the server to automatically allocate permanent IP addresses to BOOTP clients which are not registered in the server's table; limits the server's attention to incoming datagrams on network devices `le2` and `tr0`; drops BOOTP packets whose hop count exceeds 2; configures the DHCP server to cache extended DHCP offers for 15 seconds; and schedules `dhcptab` rescans to occur every 10 minutes:

```
# in.dhcpd -i le2,tr0 -h 2 -o 15 -t 10 -b automatic
```

EXAMPLE 2 Starting the Daemon in BOOTP Relay Agent Mode

The following command starts the daemon in BOOTP relay agent mode, registering the hosts `bladerunner` and `10.0.0.5` as relay destinations, with debugging and verbose modes enabled, and drops BOOTP packets whose hop count exceeds 5:

```
# in.dhcpd -d -v -h 5 -r bladerunner,10.0.0.5
```

Notes The `in.dhcpd` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/dhcp-server
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). Responsibility for initiating and restarting this service is delegated to [inetd\(1M\)](#). Use [inetadm\(1M\)](#) to make configuration changes and to view configuration information for this service. The service's status can be queried using the [svcs\(1\)](#) command.

Name in.discardd – UDP or TCP discard protocol service

Synopsis in.discardd

FMRI `svc:/internet/discard:default`

Description FMRI stands for Fault Management Resource Identifier. It is used to identify resources managed by the Fault Manager. See [fmd\(1M\)](#) and [smf\(5\)](#).

The `in.discardd` service provides the server-side of the discard protocol. This protocol is used for debugging and bandwidth measurement and is available on both TCP and UDP transports through port 9.

The `in.discardd` service is an [inetd\(1M\)](#) [smf\(5\)](#) delegated service. The `in.discardd` detects which transport is requested by examining the socket it is passed by the `inetd` daemon.

The discard service simply throws away any data it receives from the client.

TCP-based service Once a connection is established, the `in.discardd` discards any data received. No response is generated. The connection remains open until the client terminates it.

UDP-based service The `in.discardd` listens for UDP datagrams. When a datagram is received, the server discards it. No response is sent.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------------|
| Availability | service/network/legacy |
| Interface Stability | Committed |

See Also [inetd\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#)

RFC 863

Name in.echod – UDP or TCP echo protocol service daemon

Synopsis in.echod

FMRI `svc:/internet/echo:default`

Description FMRI stands for Fault Management Resource Identifier. It is used to identify resources managed by the Fault Manager. See [fmd\(1M\)](#) and [smf\(5\)](#).

The `in.echod` service provides the server-side of the echo protocol. This protocol is used for debugging and bandwidth measurement and is available on both TCP and UDP transports, through port 7.

The `in.echod` service is an [inetd\(1M\)](#) [smf\(5\)](#) delegated service. The `in.echod` detects which transport is requested by examining the socket it is passed by the `inetd` daemon.

TCP-based service Once a connection is established, the `in.echod` echoes any data received from the client back to the client. The server echoes data until the client program terminates the connection.

UDP-based service The `in.echod` listens for UDP datagrams. When a datagram is received, the server creates a UDP datagram containing the data it received and sends it to the client.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNW |
| Interface Stability | Committed |

RFC 862

Name inetadm – observe or configure inetd-controlled services

Synopsis inetadm

inetadm -?

inetadm -p

inetadm -l {FMRI | *pattern*}

inetadm -e {FMRI | *pattern*}

inetadm -d {FMRI | *pattern*}

inetadm -m {FMRI | *pattern*}... {*name=value*}...

inetadm -M {*name=value*}...

Description The `inetadm` utility provides the following capabilities for `inetd`-managed SMF services:

- Provides a list of all such services installed.
- Lists the services' properties and values.
- Allows enabling and disabling of services.
- Allows modification of the services' property values, as well as the default values provided by `inetd`.

See [smf\(5\)](#) for a description of an SMF service.

With no arguments, `inetadm` lists all services under `inetd(1M)` control, including such attributes as their current run state and whether or not they are enabled.

Options For options taking one or more FMRI operands (see [smf\(5\)](#) for a description of an FMRI), if the operand specifies a service (instead of a service instance), and that service has only a single instance, `inetadm` operates on that instance.

If a service name is supplied and it contains more than one instances or a pattern is supplied and it matches more than one instance, a warning message is displayed and that operand is ignored.

For those options taking `name=value` parameters, a description of each of the possible names and the allowed values is found in the `inetd(1M)` man page.

The following options are supported:

- | | |
|----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -? | Display a usage message. |
| -p | Lists all default <code>inet</code> service property values provided by <code>inetd</code> in the form of <code>name=value</code> pairs. If the value is of boolean type, it is listed as TRUE or FALSE. |

| | |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-l {FMRI pattern}...</code> | List all properties for the specified service instances as <i>name=value</i> pairs. In addition, if the property value is inherited from the default value provided by <code>inetd</code> , the <i>name=value</i> pair is identified by the token (default). Property inheritance occurs when properties do not have a specified service instance default. |
| <code>-e {FMRI pattern}...</code> | Enable the specified service instances. |
| <code>-d {FMRI pattern}...</code> | Disable the specified service instances. |
| <code>-m {FMRI pattern}...{name=value}...</code> | Change the values of the specified properties of the identified service instances. Properties are specified as whitespace-separated <i>name=value</i> pairs. To remove an instance-specific value and accept the default value for a property, simply specify the property without a value, for example, <code>name=</code> . |
| <code>-M {name=value}...</code> | Change the values of the specified <code>inetd</code> default properties. Properties are specified as whitespace-separated <i>name=value</i> pairs. |

Examples **EXAMPLE 1** Displaying Properties for a Service

The following command displays the properties for the `spray` service.

```
# inetadm -l network/rpc/spray:default
SCOPE    NAME=VALUE
         name="sprayd"
         endpoint_type="tli"
         proto="datagram_v"
         isrpc=TRUE
         rpc_low_version=1
         rpc_high_version=1
         wait=TRUE
         exec="/usr/lib/netsvc/spray/rpc.sprayd"
         user="root"
default  bind_addr=""
default  bind_fail_max=-1
default  bind_fail_interval=-1
default  max_con_rate=-1
default  max_copies=-1
default  con_rate_offline=-1
default  failrate_cnt=40
default  failrate_interval=60
default  inherit_env=TRUE
default  tcp_trace=FALSE
```

EXAMPLE 1 Displaying Properties for a Service *(Continued)*

```
default tcp_wrappers=FALSE
default connection_backlog=10
```

EXAMPLE 2 Displaying Default Properties

The following command displays default properties.

```
# inetadm -p
NAME=VALUE
bind_addr=""
bind_fail_max=-1
bind_fail_interval=-1
max_con_rate=-1
max_copies=-1
con_rate_offline=-1
failrate_cnt=40
failrate_interval=60
inherit_env=TRUE
tcp_trace=FALSE
tcp_wrappers=FALSE
default connection_backlog=10
```

EXAMPLE 3 Changing Property Values for a Service

The following command changes `rpc_high_version` to 3 and `tcp_trace` to TRUE for the `spray` service.

```
# inetadm -m network/rpc/spray:default \
    rpc_high_version=3 tcp_trace=TRUE
# inetadm -l network/rpc/spray:default
SCOPE  NAME=VALUE
       name="sprayd"
       endpoint_type="tli"
       proto="datagram_v"
       isrpc=TRUE
       rpc_low_version=1
       rpc_high_version=3
       wait=TRUE
       exec="/usr/lib/netsvc/spray/rpc.sprayd"
       user="root"
default bind_addr=""
default bind_fail_max=-1
default bind_fail_interval=-1
default max_con_rate=-1
default max_copies=-1
default con_rate_offline=-1
default failrate_cnt=40
```

EXAMPLE 3 Changing Property Values for a Service *(Continued)*

```

default failrate_interval=60
default inherit_env=TRUE
         tcp_trace=TRUE
default tcp_wrappers=FALSE
default connection_backlog=10

```

Exit Status The following exit values are returned:

- 0 Operation completed successfully.
- 1 A fatal error occurred. An accompanying error message will provide further information.
- 2 Invalid arguments were supplied, such as an ambiguous service FMRI or pattern.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | Committed |

See Also [inetd\(1M\)](#), [svccfg\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Name inetconv – convert `inetd.conf` entries into smf service manifests, import them into smf repository

Synopsis inetconv -?

```
inetconv [-f] [-n] [-i srcfile] [-o destdir]
```

```
inetconv -e [-n] [-i srcfile]
```

Description The `inetconv` utility converts a file containing records of `inetd.conf(4)` into `smf(5)` service manifests, and then import those manifests into the smf repository. Once the `inetd.conf` file has been converted, the only way to change aspects of an inet service is to use the `inetadm(1M)` utility.

There is a one-to-one correspondence between a service line in the input file and the manifest generated. By default, the manifests are named using the following template:

```
<svcname>-<proto>.xml
```

The `<svcname>` token is replaced by the service's name and the `<proto>` token by the service's protocol. Any slash (/) characters that exist in the source line for the service name or protocol are replaced with underscores (_).

The service line is recorded as a property of the converted service.

During the conversion process, if a service line is found to be malformed or to be for an internal `inetd` service, no manifest is generated and that service line is skipped.

The input file is left untouched by the conversion process.

Options The following options are supported:

- ? Display a usage message.
- e Enable smf services which are listed in the input file.
- f If a service manifest of the same name as the one to be generated is found in the destination directory, `inetconv` will overwrite that manifest if this option is specified. Otherwise, an error message is generated and the conversion of that service is not performed.
- i *srcfile* Permits the specification of an alternate input file *srcfile*. If this option is not specified, then the `inetd.conf(4)` file is used as input.
- n Turns off the auto-import of the manifests generated during the conversion process. Later, if you want to import a generated manifest into the `smf(5)` repository, you can do so through the use of the `svccfg(1M)` utility.

If the `-e` option is specified, the `-n` option only displays the smf services that would be enabled.

- o** Permits the specification of an alternate destination directory *destdir* for the generated manifests. If this option is not specified, then the manifests are placed in `/lib/svc/manifest/network/rpc`, if the service is a RPC service, or `/lib/svc/manifest/network` otherwise.

Examples **EXAMPLE 1** Generating smf Manifests from `inetd.conf`

The following command generates [smf\(5\)](#) manifests from `inetd.conf(4)` and places them in `/var/tmp`, overwriting any preexisting manifests of the same name, and then imports them into the smf repository.

```
# inetconv -f -o /var/tmp
100232/10 -> /var/tmp/100232_10-rpc_udp.xml
Importing 100232_10-rpc_udp.xml ...Done
telnet -> /var/tmp/telnet-tcp6.xml
Importing telnet-tcp6.xml ...Done
```

EXAMPLE 2 Generating Manifests from an Alternate Input File

The following command specifies a different input file and does not load the resulting manifests into the smf repository.

```
# inetconv -n -i /export/test/inet.svcs -o /var/tmp
100232/10 -> /var/tmp/100232_10-rpc_udp.xml
telnet -> /var/tmp/telnet-tcp6.xml
```

Exit Status The following exit values are returned:

- 0 Operation completed successfully (no errors).
- 1 Invalid options specified.
- 2 One or more service lines are malformed, and thus no manifest(s) were generated for them.
- 3 An error occurred importing one or more of the generated manifests.
- 4 A system error occurred.

Files `/lib/svc/manifest/network/{rpc}/<svcname>-<proto>.xml`
Default output manifest file name.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

Name inetd – Solaris Management Facility delegated restarter for inet services

Synopsis inetd [*configuration-file*] start | stop | refresh
 svc:/network/inetd:default

Description inetd is the delegated restarter for internet services for the Service Management Facility (SMF). Its basic responsibilities are to manage service states in response to administrative requests, system failures, and service failures; and, when appropriate, to listen for network requests for services.

Services are no longer managed by editing the inetd configuration file, `inetd.conf(4)`. Instead, you use `inetconv(1M)` to convert the configuration file content into SMF format services, then manage these services using `inetadm(1M)` and `svcadm(1M)`. Once a service has been converted by `inetconv`, any changes to the legacy data in the inetd config file will not become effective. However, `inetd` does alert the administrator when it notices change in the configuration file. See the start description under the “inetd Methods” section for further information.

Also note that the current `inetd` cannot be run from outside the SMF. This means it cannot be run from the command line, as was supported by the previous `inetd`. If you attempt to do this, a message is sent to `stderr` displaying mappings between the options supported by the previous `inetd` to the SMF version of `inetd`.

`inetd` listens for connections on behalf of all services that are in either the `online` or `degraded` state. A service enters one of these states when the service is enabled by the user and `inetd` manages to listen on its behalf. A listen attempt can fail if another server (whether standalone or a third-party internet service) is already listening on the same port. When this occurs, `inetd` logs this condition and continues trying to bind to the port at configured intervals a configured number of times. See the property `bind_fail_max` under “Service Properties,” below, for more details.

The configuration of all `inetd`'s managed SMF services is read when it is started. It is reread when `inetd` is refreshed, which occurs in response to an SMF request, or when it receives a `SIGHUP` signal. See the `refresh` description under “inetd Methods” for the behavior on configuration refresh.

You can use the `inetadm(1M)` or `svccfg(1M)` utilities to make configuration changes to Internet services within the SMF repository. `inetadm` has the advantage over `svccfg` in that it provides an Internet/RPC service context.

Service States As part of its service management duties, `inetd` implements a state machine for each of its managed services. The states in this machine are made up of the `smf(5)` set of states. The semantics of these states are as follows:

`uninitialized`
`inetd` has yet to process this service.

onLine

The service is handling new network requests and might have existing connections active.

degraded

The service has entered this state because it was able to listen and process requests for some, but not all, of the protocols specified for the service, having exhausted its listen retries. Existing network connections might be active.

offLine

Connections might be active, but no new requests are being handled. This is a transient state. A service might be offLine for any of the following reasons:

- The service's dependencies are unmet. When its dependencies become met the service's state will be re-evaluated.
- The service has exceeded its configured connection rate limit, `max_con_rate`. The service's state is re-evaluated when its connection offline timer, `con_rate_offline`, expires.
- The service has reached its allowed number of active connections, `max_copies`. The service's state is re-evaluated when the number of active connections drops below `max_copies`.
- `inetd` failed to listen on behalf of the service on all its protocols. As mentioned above, `inetd` retries up to a configured maximum number of times, at configured intervals. The service's state is re-evaluated when either a listen attempt is successful or the retry limit is reached.

disabled

The service has been turned off by an administrator, is not accepting new connections, and has none active. Administrator intervention is required to exit this state.

maintenance

A service is in this state because it is either malfunctioning and needs administrator attention or because an administrator has requested it.

Events constituting malfunctioning include: `inetd`'s inability to listen on behalf on any of the service's protocols before exceeding the service's bind retry limit, non-start methods returning with non-success return values, and the service exceeding its failure rate.

You request the maintenance state to perform maintenance on the service, such as applying a patch. No new requests are handled in this state, but existing connections might be active. Administrator intervention is required to exit this state.

Use `inetadm(1M)` to obtain the current state of a managed service.

Service Methods As part of certain state transitions `inetd` will execute, if supplied, one of a set of methods provided by the service. The set of supported methods are:

inetd_start

Executed to handle a request for an `online` or `degraded` service. Since there is no separate state to distinguish a service with active connections, this method is not executed as part of a state transition.

inetd_offline

Executed when a service is taken from the `online` or `degraded` state to the `offline` state. For a `wait`-type service that at the time of execution is performing its own listening, this method should result in it ceasing listening. This method will be executed before the `disable` method in the case an `online`/`degraded` service is disabled. This method is required to be implemented for a `wait`-type service.

inetd_online

Executed when a service transitions from the `offline` state to the `online` state. This method allows a service author to carry out some preparation prior to a service starting to handle requests.

inetd_disable

Executed when a service transitions from the `offline` state to the `disabled` state. It should result in any active connections for a service being terminated.

inetd_refresh

Executed when both of the following conditions are met:

- `inetd` is refreshed, by means of the framework or a `SIGHUP`, or a request comes in to refresh the service, and
- the service is currently in the `online` state and there are no configuration changes that would result in the service needing to be taken `offline` and brought back again.

The only compulsory method is the `inetd_start` method. In the absence of any of the others, `inetd` runs no method but behaves as if one was run successfully.

Service Properties Configuration for SMF-managed services is stored in the SMF repository. The configuration is made up of the basic configuration of a service, the configuration for each of the service's methods, and the default configuration applicable to all `inetd`-managed services.

For details on viewing and modifying the configuration of a service and the defaults, refer to [inetadm\(1M\)](#).

The basic configuration of a service is stored in a property group named `inetd` in the service. The properties comprising the basic configuration are as follows:

bind_addr

The address of the network interface to which the service should be bound. An empty string value causes the service to accept connections on any network interface.

bind_fail_interval

The time interval in seconds between a failed bind attempt and a retry. The values 0 and -1 specify that no retries are attempted and the first failure is handled the same as exceeding `bind_fail_max`.

bind_fail_max

The maximum number of times `inetd` retries binding to a service's associated port before giving up. The value -1 specifies that no retry limit is imposed. If none of the service's protocols were bound to before any imposed limit is reached, the service goes to the maintenance state; otherwise, if not all of the protocols were bound to, the service goes to the degraded state.

con_rate_offline

The time in seconds a service will remain offline if it exceeds its configured maximum connection rate, `max_con_rate`. The values 0 and -1 specify that connection rate limiting is disabled.

connection_backlog

The backlog queue size. Represents a limit on the number of incoming client requests that can be queued at the listening endpoints for servers.

endpoint_type

The type of the socket used by the service or the value `tl` to signify a TLI-based service. Valid socket type values are: `stream`, `dgram`, `raw`, `seqpacket`.

failrate_cnt

The count portion of the service's failure rate limit. The failure rate limit applies to `wait`-type services and is reached when *count* instances of the service are started within a given time. Exceeding the rate results in the service being transitioned to the maintenance state. This is different from the behavior of the previous `inetd`, which continued to retry every 10 minutes, indefinitely. The `failrate_cnt` check accounts for badly behaving servers that fail before consuming the service request and which would otherwise be continually restarted, taxing system resources. Failure rate is equivalent to the `-r` option of the previous `inetd`. The values 0 and -1 specify that this feature is disabled.

failrate_interval

The time portion in seconds of the service's failure rate. The values 0 and -1 specify that the failure rate limit feature is disabled.

inherit_env

If true, pass `inetd`'s environment on to the service's start method. Regardless of this setting, `inetd` will set the variables `SMF_FMRI`, `SMF_METHOD`, and `SMF_RESTARTER` in the start method's environment, as well as any environment variables set in the method context. These variables are described in [`smf_method\(5\)`](#).

isrpc

If true, this is an RPC service.

max_con_rate

The maximum allowed connection rate, in connections per second, for a `nowait`-type service. The values `0` and `-1` specify that that connection rate limiting is disabled.

max_copies

The maximum number of copies of a `nowait` service that can run concurrently. The values `0` and `-1` specify that copies limiting is disabled.

name

Can be set to one of the following values:

- a service name understood by `getservbyname(3SOCKET)`;
- if `isrpc` is set to `true`, a service name understood by `getrpcbyname(3NSL)`;
- if `isrpc` is set to `true`, a valid RPC program number.

proto

In the case of socket-based services, this is a list of protocols supported by the service. Valid protocols are: `tcp`, `tcp6`, `tcp6only`, `udp`, `udp6`, and `udp6only`. In the case of TLI services, this is a list of netids recognized by `getnetconfignt(3NSL)` supported by the service, plus the values `tcp6only` and `udp6only`. RPC/TLI services also support nettypes in this list, and `inetd` first tries to interpret the list member as a nettype for these service types. The values `tcp6only` and `udp6only` are new to `inetd`; these values request that `inetd` listen only for and pass on true IPv6 requests (not IPv4 mapped ones). See “Configuring Protocols for Sockets-Based Services,” below.

rpc_low_version

Lowest supported RPC version. Required when `isrpc` is set to `true`.

rpc_high_version

Highest supported RPC version. Required when `isrpc` is set to `true`.

tcp_keepalive

If `true`, enable the periodic transmission of messages on a connected socket. If the connected party fails to respond to these messages, the connection is considered broken. This applies only to services with `endpoint_type` set to `streams` and `wait` set to `false`.

tcp_trace

If `true`, and this is a `nowait`-type service, `inetd` logs the client's IP address and TCP port number, along with the name of the service, for each incoming connection, using the `syslog(3C)` facility. `inetd` uses the `syslog` facility code `daemon` and `notice` priority level. See `syslog.conf(4)` for a description of `syslog` codes and severity levels. This logging is separate from the logging done by the TCP wrappers facility.

`tcp_trace` is equivalent to the previous `inetd`'s `-t` option (and the `/etc/default/inetd` property `ENABLE_CONNECTION_LOGGING`).

tcp_wrappers

If `true`, enable TCP wrappers access control. This applies only to services with `endpoint_type` set to `streams` and `wait` set to `false`. The `syslog` facility code `daemon` is used to log allowed connections (using the `notice` severity level) and denied traffic (using

the warning severity level). See [syslog.conf\(4\)](#) for a description of sys log codes and severity levels. The Interface Stability of the TCP wrappers facility and its configuration files is Volatile. As the TCP wrappers facility is not controlled by Sun, intra-release incompatibilities are not uncommon. See [attributes\(5\)](#).

For more information about configuring TCP wrappers, you can refer to the [tcpd\(1M\)](#) and [hosts_access\(4\)](#) man pages, which are delivered as part of the Solaris operating system at `/usr/sfw/man`. These pages are not part of the standard Solaris man pages, available at `/usr/man`.

`tcp_wrappers` is equivalent to the previous `inetd`'s `/etc/default/inetd` property `ENABLE_TCPWRAPPERS`.

`wait`

If `true` this is a `wait`-type service, otherwise it is a `nowait`-type service. A `wait`-type service has the following characteristics:

- Its `inetd_start` method will take over listening duties on the service's bound endpoint when it is executed.
- `inetd` will wait for it to exit after it is executed before it resumes listening duties.

Datagram servers must be configured as being of type `wait`, as they are always invoked with the original datagram endpoint that will participate in delivering the service bound to the specified service. They do not have separate “listening” and “accepting” sockets. Connection-oriented services, such as TCP stream services can be designed to be either of type `wait` or `nowait`.

A number of the basic properties are optional for a service. In their absence, their values are taken from the set of default values present in the `defaults` property group in the `inetd` service. These properties, with their seed values, are listed below. Note that these values are configurable through [inetadm\(1M\)](#).

```
bind_fail_interval  -1
bind_fail_max      -1
con_rate_offline   -1
connection_backlog 10
failrate_count     40
failrate_time      60
inherit_env        true
max_con_rate       -1
max_copies         -1
tcp_keepalive      false
tcp_trace          false
tcp_wrappers       false
```

Each method specified for a service will have its configuration stored in the SMF repository, within a property group of the same name as the method. The set of properties allowable for

these methods includes those specified for the services managed by `svc.startd(1M)`. (See `svc.startd(1M)` for further details.) Additionally, for the `inetd_start` method, you can set the `arg0` property.

The `arg0` property allows external wrapper programs to be used with `inetd` services. Specifically, it allows the first argument, `argv[0]`, of the service's start method to be something other than the path of the server program.

In the case where you want to use an external wrapper program and pass arguments to the service's daemon, the arguments should be incorporated as arguments to the wrapper program in the `exec` property. For example:

```
exec='/path/to/wrapper/prog service_daemon_args'
arg0='/path/to/service/daemon'
```

In addition to the special method tokens mentioned in `smf_method(5)`, `inetd` also supports the `:kill_process` token for `wait`-type services. This results in behavior identical to that if the `:kill` token were supplied, except that the `kill` signal is sent only to the parent process of the `wait`-type service's `start` method, not to all members of its encompassing process contract (see `process(4)`).

Configuring Protocols for Sockets-Based Services

When configuring `inetd` for a sockets-based service, you have the choice, depending on what is supported by the service, of the alternatives described under the `proto` property, above. The following are guidelines for which `proto` values to use:

- For a service that supports only IPv4: `tcp` and `udp`
- For a service that supports only IPv6: `tcp6only` and `udp6only`
- For a service that supports both IPv4 and IPv6:
 - Obsolete and not recommended: `tcp6` and `udp6`
 - Recommended: use two separate entries that differ only in the `proto` field. One entry has `tcp` and the other has `tcp6only`, or `udp` plus `udp6only`.

See `EXAMPLES` for an example of a configuration of a service that supports both IPv4 and IPv6.

inetd Methods

`inetd` provides the methods listed below for consumption by the master restarter, `svc.startd(1M)`.

`start`

Causes `inetd` to start providing service. This results in `inetd` beginning to handle `smf` requests for its managed services and network requests for those services that are in either the `online` or `degraded` state.

In addition, `inetd` also checks if the `inetd.conf(4)`-format configuration file it is monitoring has changed since the last `inetconv(1M)` conversion was carried out. If it has, then a message telling the administrator to re-run `inetconv` to effect the changes made is logged in `syslog`.

stop

Causes `inetd` to stop providing service. At this point, `inetd` transitions each of its services that are not in either the `maintenance` or `disabled` states to the `offline` state, running any appropriate methods in the process.

refresh

Results in a refresh being performed for each of its managed services and the `inetd.conf(4)` format configuration file being checked for change, as in the `start` method. When a service is refreshed, its behavior depends on its current state:

- if it is in the `maintenance` or `disabled` states, no action is performed because the configuration will be read and consumed when the service leaves the state;
- if it is in the `offline` state, the configuration will be read and any changes consumed immediately;
- if it is in the `online` or `degraded` state and the configuration has changed such that a re-binding is necessary to conform to it, then the service will be transitioned to the `offline` state and back again, using the new configuration for the bind;
- if it is in the `online` state and a re-binding is not necessary, then the `inetd_refresh` method of the service, if provided, will be run to allow `online wait-type` services to consume any other changes.

Options No options are supported.

Operands *configuration-file*

Specifies an alternate location for the legacy service file (`inetd.conf(4)`).

`start|stop|refresh`

Specifies which of `inetd`'s methods should be run.

Examples **EXAMPLE 1** Configuring a Service that Supports Both IPv4 and IPv6

The following commands illustrate the existence of services that support both IPv4 and IPv6 and assign `proto` properties to those services.

```
example# svcs -a | grep mysvc
online      15:48:29 svc:/network/mysvc:dgram4
online      15:48:29 svc:/network/mysvc:dgram6
online      15:51:47 svc:/network/mysvc:stream4
online      15:52:10 svc:/network/mysvc:stream6

# inetadm -M network/rpc/mysvc:dgram4 proto=udp
# inetadm -M network/rpc/mysvc:dgram6 proto=udp6only
# inetadm -M network/rpc/mysvc:stream4 proto=tcp
# inetadm -M network/rpc/mysvc:stream6 proto=tcp6only
```

See `svcs(1)` and `inetadm(1M)` for descriptions of those commands.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | Committed |

See Also [fmd\(1M\)](#), [inetadm\(1M\)](#), [inetconv\(1M\)](#), [svcadm\(1M\)](#), [svccfg\(1M\)](#), [svcs\(1\)](#), [svc.startd\(1M\)](#), [syslog\(3C\)](#), [getnetconfigent\(3NSL\)](#), [getrpcbyname\(3NSL\)](#), [getservbyname\(3SOCKET\)](#), [inetd.conf\(4\)](#), [process\(4\)](#), [syslog.conf\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#), [smf_method\(5\)](#)

Notes The `inetd` daemon performs the same function as, but is implemented significantly differently from, the daemon of the same name in Solaris 9 and prior Solaris operating system releases. In the current Solaris release, `inetd` is part of the Solaris Management Facility (see [smf\(5\)](#)) and will run only within that facility.

The `/etc/default/inetd` file has been deprecated. The functionality represented by the properties `ENABLE_CONNECTION_LOGGING` and `ENABLE_TCP_WRAPPERS` are now available as the `tcp_trace` and `tcp_wrappers` properties, respectively. These properties are described above, under “Service Properties”.

Name in.fingerd, fingerd – remote user information server

Synopsis /usr/sbin/in.fingerd

Description `fingerd` implements the server side of the Name/Finger protocol, specified in *RFC 742*. The Name/Finger protocol provides a remote interface to programs which display information on system status and individual users. The protocol imposes little structure on the format of the exchange between client and server. The client provides a single command line to the finger server which returns a printable reply.

`fingerd` waits for connections on TCP port 79. Once connected, it reads a single command line terminated by RETURN-LINEFEED and passes the arguments to `finger(1)`, prepended with `-s`. `fingerd` closes its connections as soon as the output is finished.

Files

| | |
|------------------|----------------------------------|
| /var/adm/utmpx | User and accounting information. |
| /etc/passwd | System password file. |
| /var/adm/lastlog | Last login times. |
| \$HOME/.plan | User's plans. |
| \$HOME/.project | User's projects. |

Usage `fingerd` and `in.fingerd` are IPv6-enabled. See [ip6\(7P\)](#).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|---------------------------------|
| Availability | service/network/network-servers |

See Also [finger\(1\)](#), [svcs\(1\)](#), [inetadm\(1M\)](#), [inetd\(1M\)](#), [svcadm\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#), [ip6\(7P\)](#)

Harrenstien, Ken, *RFC 742, NAME/FINGER*, Network Information Center, SRI International, Menlo Park, Calif., December 1977.

Notes Connecting directly to the server from a TIP or an equally narrow-minded TELNET-protocol user program can result in meaningless attempts at option negotiation being sent to the server, which foul up the command line interpretation. `fingerd` should be taught to filter out IAC's and perhaps even respond negatively (IAC does not) to all option commands received.

The `in.fingerd` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/finger:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). Responsibility for initiating and restarting this service is

delegated to [inetd\(1M\)](#). Use [inetadm\(1M\)](#) to make configuration changes and to view configuration information for this service. The service's status can be queried using the [svcs\(1\)](#) command.

Name infocmp – compare or print out terminfo descriptions

Synopsis /usr/bin/infocmp [-d] [-c] [-n] [-I] [-L] [-C] [-r] [-u]
 [-s | d | i | l | c] [-v] [-V] [-1] [-w *width*]
 [-A *directory*] [-B *directory*] [*termname*]. . .

Description infocmp compares a binary terminfo entry with other terminfo entries, rewrites a terminfo description to take advantage of the use= terminfo field, or prints out a terminfo description from the binary file (*term*) in a variety of formats. It displays boolean fields first, then numeric fields, followed by the string fields. If no options are specified and zero, or one *termname* is specified, the -I option is assumed. If more than one *termname* is specified, the -d option is assumed.

Options The -d , -c , and -n options can be used for comparisons. infocmp compares the terminfo description of the first terminal *termname* with each of the descriptions given by the entries for the other terminal's *termname*. If a capability is defined for only one of the terminals, the value returned will depend on the type of the capability: F for boolean variables, -1 for integer variables, and NULL for string variables.

- d Produce a list of each capability that is different between two entries. This option is useful to show the difference between two entries, created by different people, for the same or similar terminals.
- c Produce a list of each capability that is common between two entries. Capabilities that are not set are ignored. This option can be used as a quick check to see if the -u option is worth using.
- n Produce a list of each capability that is in neither entry. If no *termname* is given, the environment variable TERM will be used for both of the *termnames*. This can be used as a quick check to see if anything was left out of a description.

The -I , -L , and -C options will produce a source listing for each terminal named.

- I Use the terminfo names.
- L Use the long C variable name listed in < term.h >.
- C Use the termcap names. The source produced by the -C option may be used directly as a termcap entry, but not all of the parameterized strings may be changed to the termcap format. infocmp will attempt to convert most of the parameterized information, but anything not converted will be plainly marked in the output and commented out. These should be edited by hand.
- r When using -C , put out all capabilities in termcap form.

If no *termname* is given, the environment variable TERM will be used for the terminal name.

All padding information for strings will be collected together and placed at the beginning of the string where termcap expects it. Mandatory padding (padding information with a trailing '/') will become optional.

All `termcap` variables no longer supported by `terminfo`, but are derivable from other `terminfo` variables, will be displayed. Not all `terminfo` capabilities will be translated; only those variables which were part of `termcap` will normally be displayed. Specifying the `-r` option will take off this restriction, allowing all capabilities to be displayed in `termcap` form.

Note that because padding is collected to the beginning of the capability, not all capabilities are displayed. Mandatory padding is not supported. Because `termcap` strings are not as flexible, it is not always possible to convert a `terminfo` string capability into an equivalent `termcap` format. A subsequent conversion of the `termcap` file back into `terminfo` format will not necessarily reproduce the original `terminfo` source.

Some common `terminfo` parameter sequences, their `termcap` equivalents, and some terminal types which commonly have such sequences, are:

| <code>terminfo</code> | <code>termcap</code> | Representative Terminals |
|---------------------------------------------|------------------------------------------|--------------------------|
| <code>%p1%c</code> | <code>%. adm</code> | |
| <code>%p1%d</code> | <code>%d hp, ANSI standard, vt100</code> | |
| <code>%p1%'x'%'%+%c</code> | <code>%+x concept</code> | |
| <code>%i</code> | <code>%i ANSI standard, vt100</code> | |
| <code>%p1?%'x'%'%>%t%p1%'y'%'%+%;</code> | <code>%>xy concept</code> | |
| <code>%p2 is printed before %p1</code> | <code>%r hp</code> | |

`-u` Produce a `terminfo` source description of the first terminal *termname* which is relative to the sum of the descriptions given by the entries for the other terminals' *termnames*. It does this by analyzing the differences between the first *termname* and the other *termnames* and producing a description with `use=` fields for the other terminals. In this manner, it is possible to retrofit generic `terminfo` entries into a terminal's description. Or, if two similar terminals exist, but were coded at different times, or by different people so that each description is a full description, using `infocmp` will show what can be done to change one description to be relative to the other.

A capability is displayed with an at-sign (`@`) if it no longer exists in the first *termname*, but one of the other *termname* entries contains a value for it. A capability's value is displayed if the value in the first *termname* is not found in any of the other *termname* entries, or if the first of the other *termname* entries that has this capability gives a different value for that capability.

The order of the other *termname* entries is significant. Since the `terminfo` compiler `tic` does a left-to-right scan of the capabilities, specifying two `use=` entries that contain differing entries for the same capabilities will produce different results, depending on the order in which the entries are given. `infocmp` will flag any such inconsistencies between the other *termname* entries as they are found.

Alternatively, specifying a capability *after* a `use=` entry that contains, it will cause the second specification to be ignored. Using `infocmp` to recreate a description can be a useful check to make sure that everything was specified correctly in the original source description.

Another error that does not cause incorrect compiled files, but will slow down the compilation time, is specifying superfluous `use=` fields. `infocmp` will flag any superfluous `use=` fields.

- s Sorts the fields within each type according to the argument below:
 - d Leave fields in the order that they are stored in the `terminfo` database.
 - i Sort by `terminfo` name.
 - l Sort by the long C variable name.
 - c Sort by the `termcap` name.

If the `-s` option is not given, the fields are sorted alphabetically by the `terminfo` name within each type, except in the case of the `-C` or the `-L` options, which cause the sorting to be done by the `termcap` name or the long C variable name, respectively.

- v Print out tracing information on standard error as the program runs.
- V Print out the version of the program in use on standard error and exit.
- l Print the fields one to a line. Otherwise, the fields are printed several to a line to a maximum width of 60 characters.
- width* Changes the output to *width* characters.

The location of the compiled `terminfo` database is taken from the environment variable `TERMINFO`. If the variable is not defined, or the terminal is not found in that location, the system `terminfo` database, usually in `/usr/share/lib/terminfo`, is used. The options `-A` and `-B` may be used to override this location.

- A* *directory* Set `TERMINFO` for the first *termname*.
- B* *directory* Set `TERMINFO` for the other *termnames*. With this, it is possible to compare descriptions for a terminal with the same name located in two different databases. This is useful for comparing descriptions for the same terminal created by different people.

Files `/usr/share/lib/terminfo/??/*` Compiled terminal description database.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

Name in.ftpd, ftpd – File Transfer Protocol Server

Synopsis in.ftpd [-4] [-A] [-a] [-C] [-d] [-I] [-i] [-K] [-L] [-l]
 [-o] [-P *dataport*] [-p *ctrlport*] [-Q] [-q]
 [-r *rootdir*] [-S] [-s] [-T *maxtimeout*] [-t *timeout*]
 [-u *umask*] [-V] [-v] [-W] [-w] [-X]

Description in.ftpd is the Internet File Transfer Protocol (FTP) server process. The server may be invoked by the Internet daemon [inetd\(1M\)](#) each time a connection to the FTP service is made or run as a standalone server. See [services\(4\)](#).

Options in.ftpd supports the following options:

- 4 When running in standalone mode, listen for connections on an AF_INET type socket. The default is to listen on an AF_INET6 type socket.
- a Enables use of the [ftpaccess\(4\)](#) file.
- A Disables use of the [ftpaccess\(4\)](#) file. Use of ftpaccess is disabled by default.
- C Non-anonymous users need local credentials (for example, to authenticate to remote file servers). So they should be prompted for a password unless they forwarded credentials as part of authentication.
- d Writes debugging information to [syslogd\(1M\)](#).
- i Logs the names of all files received by the FTP Server to [xferlog\(4\)](#). You can override the -i option through use of the [ftpaccess\(4\)](#) file.
- I Disables the use of AUTH and ident to determine the username on the client. See *RFC 931*. The FTP Server is built not to use AUTH and ident.
- K Connections are only allowed for users who can authenticate through the ftp AUTH mechanism. (Anonymous ftp may also be allowed if it is configured.) ftpd will ask the user for a password if one is required.
- l Logs each FTP session to [syslogd\(1M\)](#).
- L Logs all commands sent to in.ftpd to [syslogd\(1M\)](#). When the -L option is used, command logging will be on by default, once the FTP Server is invoked. Because the FTP Server includes USER commands in those logged, if a user accidentally enters a password instead of the username, the password will be logged. You can override the -L option through use of the [ftpaccess\(4\)](#) file.
- o Logs the names of all files transmitted by the FTP Server to [xferlog\(4\)](#). You can override the -o option through use of the [ftpaccess\(4\)](#) file.
- P *dataport* The FTP Server determines the port number by looking in the [services\(4\)](#) file for an entry for the ftp-data service. If there is no entry,

- the daemon uses the port just prior to the control connection port. Use the `-P` option to specify the data port number.
- `-p ctrlport` When run in standalone mode, the FTP Server determines the control port number by looking in the `services(4)` file for an entry for the `ftp` service. Use the `-p` option to specify the control port number.
 - `-Q` Disables PID files. This disables user limits. Large, busy sites that do not want to impose limits on the number of concurrent users can use this option to disable PID files.
 - `-q` Uses PID files. The `limit` directive uses PID files to determine the number of current users in each access class. By default, PID files are used.
 - `-r rootdir` `chroot(2)` to `rootdir` upon loading. Use this option to improve system security. It limits the files that can be damaged should a break in occur through the daemon. This option is similar to anonymous FTP. Additional files are needed, which vary from system to system.
 - `-S` Places the daemon in standalone operation mode. The daemon runs in the background. This is useful for startup scripts that run during system initialization. See `init.d(4)`.
 - `-s` Places the daemon in standalone operation mode. The daemon runs in the foreground. This is useful when run from `/etc/inittab` by `init(1M)`.
 - `-T maxtimeout` Sets the maximum allowable timeout period to `maxtimeout` seconds. The default maximum timeout limit is 7200 second (two hours). You can override the `-T` option through use of the `ftpaccess(4)` file.
 - `-t timeout` Sets the inactivity timeout period to `timeout` seconds. The default timeout period is 900 seconds (15 minutes). You can override the `-t` option through use of the `ftpaccess(4)` file.
 - `-u umask` Sets the default `umask` to `umask`.
 - `-V` Displays copyright and version information, then terminate.
 - `-v` Writes debugging information to `syslogd(1M)`.
 - `-W` Does not record user `login` and `logout` in the `wtmpx(4)` file.
 - `-w` Records each user `login` and `logout` in the `wtmpx(4)` file. By default, logins and logouts are recorded.
 - `-X` Writes the output from the `-i` and `-o` options to the `syslogd(1M)` file instead of `xferlog(4)`. This allows the collection of output from several hosts on one central `loghost`. You can override the `-X` option through use of the `ftpaccess(4)` file.

| | |
|----------|-------------------------------------------------------------------------------------------------------------------|
| Requests | The FTP Server currently supports the following FTP requests. Case is not distinguished. |
| ABOR | Abort previous command. |
| ADAT | Send an authentication protocol message. |
| ALLO | Allocate storage (vacuously). |
| AUTH | Specify an authentication protocol to be performed. Currently only “GSSAPI” is supported. |
| APPE | Append to a file. |
| CCC | Set the command channel protection mode to “clear” (no protection). Not allowed if data channel is protected. |
| CDUP | Change to parent of current working directory. |
| CWD | Change working directory. |
| DELE | Delete a file. |
| ENC | Send a privacy and integrity protected command (given in argument). |
| EPRT | Specify extended address for the transport connection. |
| EPSV | Extended passive command request. |
| HELP | Give help information. |
| LIST | Give list files in a directory (ls -lA). |
| LPRT | Specify long address for the transport connection. |
| LPSV | Long passive command request. |
| MIC | Send an integrity protected command (given in argument). |
| MKD | Make a directory. |
| MDTM | Show last time file modified. |
| MODE | Specify data transfer <i>mode</i> . |
| NLST | Give name list of files in directory (ls). |
| NOOP | Do nothing. |
| PASS | Specify password. |
| PASV | Prepare for server-to-server transfer. |
| PBSZ | Specify a protection buffer size. |
| PROT | Specify a protection level under which to protect data transfers. Allowed arguments:
clear No protection. |

| | | |
|------|---------|----------------------------------------------------------------------------|
| | safe | Integrity protection |
| | private | Integrity and encryption protection |
| PORT | | Specify data connection port. |
| PWD | | Print the current working directory. |
| QUIT | | Terminate session. |
| REST | | Restart incomplete transfer. |
| RETR | | Retrieve a file. |
| RMD | | Remove a directory. |
| RNFR | | Specify rename-from file name. |
| RNTO | | Specify rename-to file name. |
| SITE | | Use nonstandard commands. |
| SIZE | | Return size of file. |
| STAT | | Return status of server. |
| STOR | | Store a file. |
| STOU | | Store a file with a unique name. |
| STRU | | Specify data transfer <i>structure</i> . |
| SYST | | Show operating system type of server system. |
| TYPE | | Specify data transfer type. |
| USER | | Specify user name. |
| XCUP | | Change to parent of current working directory. This request is deprecated. |
| XCWD | | Change working directory. This request is deprecated. |
| XMKD | | Make a directory. This request is deprecated. |
| XPWD | | Print the current working directory. This request is deprecated. |
| XRMD | | Remove a directory. This request is deprecated. |

The following nonstandard or UNIX specific commands are supported by the SITE request:

| | |
|-------------|------------------------------------------------------|
| ALIAS | List aliases. |
| CDPATH | List the search path used when changing directories. |
| CHECKMETHOD | List or set the checksum method. |
| CHECKSUM | Give the checksum of a file. |

| | |
|--------|----------------------------------------------------------------------|
| CHMOD | Change mode of a file. For example, SITE CHMOD 755 <i>filename</i> . |
| EXEC | Execute a program. For example, SITE EXEC program params |
| GPASS | Give special group access password. For example, SITE GPASS bar. |
| GROUP | Request special group access. For example, SITE GROUP foo. |
| GROUPS | List supplementary group membership. |
| HELP | Give help information. For example, SITE HELP. |
| IDLE | Set idle-timer. For example, SITE IDLE 60. |
| UMASK | Change umask. For example, SITE UMASK 002. |

The remaining FTP requests specified in *RFC 959* are recognized, but not implemented.

The FTP server will abort an active file transfer only when the ABOR command is preceded by a Telnet “Interrupt Process” (IP) signal and a Telnet “Synch” signal in the command Telnet stream, as described in *RFC 959*. If a STAT command is received during a data transfer that has been preceded by a Telnet IP and Synch, transfer status will be returned.

`in.ftpd` interprets file names according to the “globbing” conventions used by `cs(1)`. This allows users to utilize the metacharacters: * ? [] { } ~

`in.ftpd` authenticates users according to the following rules:

First, the user name must be in the password data base, the location of which is specified in `nsswitch.conf(4)`. An encrypted password (an authentication token in PAM) must be present. A password must always be provided by the client before any file operations can be performed. For non-anonymous users, the PAM framework is used to verify that the correct password was entered. See SECURITY below.

Second, the user name must not appear in either the `/etc/ftpusers` or the `/etc/ftpd/ftpusers` file. Use of the `/etc/ftpusers` files is deprecated, although it is still supported.

Third, the users must have a standard shell returned by `getusershell(3C)`.

Fourth, if the user name is anonymous or ftp, an anonymous ftp account must be present in the password file for user ftp. Use `ftpconfig(1M)` to create the anonymous ftp account and home directory tree.

Fifth, if the GSS-API is used to authenticate the user, then `gss_auth_rules(5)` determines user access without a password needed.

The FTP Server supports virtual hosting, which can be configured by using `ftppdhost(1M)`.

The FTP Server does not support sublogins.

General FTP Extensions The FTP Server has certain extensions. If the user specifies a filename that does not exist with a RETR (retrieve) command, the FTP Server looks for a conversion to change a file or directory that does into the one requested. See [ftpconversions\(4\)](#).

By convention, anonymous users supply their email address when prompted for a password. The FTP Server attempts to validate these email addresses. A user whose FTP client hangs on a long reply, for example, a multiline response, should use a dash (-) as the first character of the user's password, as this disables the Server's `lreply()` function.

The FTP Server can also log all file transmission and reception. See [xferlog\(4\)](#) for details of the log file format.

The SITE EXEC command may be used to execute commands in the `/bin/ftp-exec` directory. Take care that you understand the security implications before copying any command into the `/bin/ftp-exec` directory. For example, do not copy in `/bin/sh`. This would enable the user to execute other commands through the use of `sh -c`. If you have doubts about this feature, do not create the `/bin/ftp-exec` directory.

Security For non-anonymous users, `in.ftpd` uses [pam\(3PAM\)](#) for authentication, account management, and session management, and can use Kerberos v5 for authentication.

The PAM configuration policy, listed through `/etc/pam.conf`, specifies the module to be used for `in.ftpd`. Here is a partial `pam.conf` file with entries for the `in.ftpd` command using the UNIX authentication, account management, and session management module.

```
ftp  auth      requisite    pam_authok_get.so.1
ftp  auth      required    pam_dhkeys.so.1
ftp  auth      required    pam_unix_auth.so.1

ftp  account   required    pam_unix_roles.so.1
ftp  account   required    pam_unix_projects.so.1
ftp  account   required    pam_unix_account.so.1

ftp  session   required    pam_unix_session.so.1
```

If there are no entries for the `ftp` service, then the entries for the “other” service will be used. Unlike `login`, `passwd`, and other commands, the `ftp` protocol will only support a single password. Using multiple modules will prevent `in.ftpd` from working properly.

To use Kerberos for authentication, a `host/<FQDN>` Kerberos principal must exist for each Fully Qualified Domain Name associated with the `in.ftpd` server. Each of these `host/<FQDN>` principals must have a keytab entry in the `/etc/krb5/krb5.keytab` file on the `in.ftpd` server. An example principal might be:

```
host/bigmachine.eng.example.com
```

See [kadmin\(1M\)](#) or [gkadmin\(1M\)](#) for instructions on adding a principal to a `krb5.keytab` file. See *System Administration Guide: Security Services* for a discussion of Kerberos authentication.

For anonymous users, who by convention supply their email address as a password, `in.ftpd` validates passwords according to the `passwd-check` capability in the `ftpaccess` file.

Usage The `in.ftpd` command is IPv6-enabled. See [ip6\(7P\)](#).

| | | |
|--------------|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| Files | <code>/etc/ftpd/ftpaccess</code> | FTP Server configuration file |
| | <code>/etc/ftpd/ftpconversions</code> | FTP Server conversions database |
| | <code>/etc/ftpd/ftpgroups</code> | FTP Server enhanced group access file |
| | <code>/etc/ftpd/ftphosts</code> | FTP Server individual user host access file |
| | <code>/etc/ftpd/ftpservers</code> | FTP Server virtual hosting configuration file. |
| | <code>/etc/ftpd/ftpusers</code> | File listing users for whom FTP login privileges are disallowed. |
| | <code>/etc/ftpusers</code> | File listing users for whom FTP login privileges are disallowed. This use of this file is deprecated. |

Horowitz, M., Lunt, S., *FTP Security Extensions, RFC 2228*. The Internet Society, October 1997.

Diagnostics `in.ftpd` logs various errors to `syslogd(1M)`, with a facility code of daemon.

Notes The anonymous FTP account is inherently dangerous and should be avoided when possible.

The FTP Server must perform certain tasks as the superuser, for example, the creation of sockets with privileged port numbers. It maintains an effective user ID of the logged in user, reverting to the superuser only when necessary.

The FTP Server no longer supports the `/etc/default/ftpd` file. Instead of using `UMASK=nnn` to set the umask, use the `defumask` capability in the `ftppass` file. The banner greeting text capability is also now set through the `ftppass` file by using the `greeting` text capability instead of by using `BANNER="..."`. However, unlike the `BANNER` string, the greeting text string is not passed to the shell for evaluation. See `ftppass(4)`.

The `pam_unix(5)` module is no longer supported. Similar functionality is provided by `pam_authok_check(5)`, `pam_authok_get(5)`, `pam_authok_store(5)`, `pam_dhkeys(5)`, `pam_passwd_auth(5)`, `pam_unix_account(5)`, `pam_unix_auth(5)`, and `pam_unix_session(5)`.

The `in.ftpd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/ftp
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. Responsibility for initiating and restarting this service is delegated to `inetd(1M)`. Use `inetadm(1M)` to make configuration changes and to view configuration information for this service. The service's status can be queried using the `svcs(1)` command.

- Name** in.iked – daemon for the Internet Key Exchange (IKE)
- Synopsis** /usr/lib/inet/in.iked [-d] [-f *filename*] [-p *level*]
/usr/lib/inet/in.iked -c [-f *filename*]
- Description** in.iked performs automated key management for IPsec using the Internet Key Exchange (IKE) protocol.
- in.iked implements the following:
- IKE authentication with either pre-shared keys, DSS signatures, RSA signatures, or RSA encryption.
 - Diffie-Hellman key derivation using either 768, 1024, 1536, 2048, 3072, or 4096-bit public key moduli, or 256, 384, or 521-bit elliptic curve moduli.
 - Authentication protection with cipher choices of AES, DES, Blowfish, or 3DES, and hash choices of either HMAC-MD5 or HMAC-SHA-1. Encryption in in.iked is limited to the IKE authentication and key exchange. See [ipsecesp\(7P\)](#) for information regarding IPsec protection choices.
- in.iked is managed by the following [smf\(5\)](#) service:
- ```
svc:/network/ipsec/ike
```
- This service is delivered disabled because the configuration file needs to be created before the service can be enabled. See [ike.config\(4\)](#) for the format of this file.
- See “Service Management Facility” for information on managing the [smf\(5\)](#) service.
- in.iked listens for incoming IKE requests from the network and for requests for outbound traffic using the PF\_KEY socket. See [pf\\_key\(7P\)](#).
- in.iked has two support programs that are used for IKE administration and diagnosis: [ikeadm\(1M\)](#) and [ikecert\(1M\)](#).
- The [ikeadm\(1M\)](#) command can read the /etc/inet/ike/config file as a rule, then pass the configuration information to the running in.iked daemon using a doors interface.
- ```
example# ikeadm read rule /etc/inet/ike/config
```
- Refreshing the [ike smf\(5\)](#) service provided to manage the in.iked daemon sends a SIGHUP signal to the in.iked daemon, which will (re)read /etc/inet/ike/config and reload the certificate database.
- The preceding two commands have the same effect, that is, to update the running IKE daemon with the latest configuration. See “Service Management Facility” for more details on managing the in.iked daemon.

When Trusted Extensions are enabled (see [labeld\(1M\)](#)), `in.iked` can be used in the global zone to negotiate labeled security associations. On labeled systems using `in.iked`, UDP ports 500 and 4500 must be configured as multi-level ports for the global zone in the `tnzonecfg` file (see `tnzonecfg(4)`, part of the *Solaris Trusted Extensions Reference Manual*). See [ike.config\(4\)](#) for more information on configuring `in.iked` to be label-aware.

Service Management Facility The IKE daemon (`in.iked`) is managed by the service management facility, [smf\(5\)](#). The following group of services manage the components of IPsec:

```
svc:/network/ipsec/ipsecalgs    (See ipsecalgs(1M))
svc:/network/ipsec/policy      (See ipsecconf(1M))
svc:/network/ipsec/manual-key  (See ipseckey(1M))
svc:/network/ipsec/ike        (see ike.config(4))
```

The `manual-key` and `ike` services are delivered disabled because the system administrator must create configuration files for each service, as described in the respective man pages listed above.

The correct administrative procedure is to create the configuration file for each service, then enable each service using [svcadm\(1M\)](#).

The `ike` service has a dependency on the `ipsecalgs` and `policy` services. These services should be enabled before the `ike` service. Failure to do so results in the `ike` service entering maintenance mode.

If the configuration needs to be changed, edit the configuration file then refresh the service, as follows:

```
example# svcadm refresh ike
```

The following properties are defined for the `ike` service:

`config/admin_privilege`

Defines the level that [ikeadm\(1M\)](#) invocations can change or observe the running `in.iked`. The acceptable values for this property are the same as those for the `-p` option. See the description of `-p` in `OPTIONS`.

`config/config_file`

Defines the configuration file to use. The default value is `/etc/inet/ike/config`. See [ike.config\(4\)](#) for the format of this file. This property has the same effect as the `-f` flag. See the description of `-f` in `OPTIONS`.

`config/debug_level`

Defines the amount of debug output that is written to the `debug_logfile` file, described below. The default value for this is `op` or operator. This property controls the recording of information on events such as re-reading the configuration file. Acceptable values for `debug_level` are listed in the [ikeadm\(1M\)](#) man page. The value `all` is equivalent to the `-d` flag. See the description of `-d` in `OPTIONS`.

config/debug_logfile

Defines where debug output should be written. The messages written here are from debug code within `in.iked`. Startup error messages are recorded by the `smf(5)` framework and recorded in a service-specific log file. Use any of the following commands to examine the `logfile` property:

```
example# svcs -l ike
example# svcprop ike
example# svccfg -s ike listprop
```

The values for these log file properties might be different, in which case both files should be inspected for errors.

config/ignore_errors

A boolean value that controls `in.iked`'s behavior should the configuration file have syntax errors. The default value is `false`, which causes `in.iked` to enter maintenance mode if the configuration is invalid.

Setting this value to `true` causes the IKE service to stay online, but correct operation requires the administrator to configure the running daemon with `ikeadm(1M)`. This option is provided for compatibility with previous releases.

These properties can be modified using `svccfg(1M)` by users who have been assigned the following authorization:

```
solaris.smf.value.ipsec
```

PKCS#11 token objects can be unlocked or locked by using `ikeadm` token login and `ikeadm` token logout, respectively. Availability of private keying material stored on these PKCS#11 token objects can be observed with: `ikeadm dump cert cache`. The following authorizations allow users to log into and out of PKCS#11 token objects:

```
solaris.network.ipsec.ike.token.login
solaris.network.ipsec.ike.token.logout
```

See `auths(1)`, `ikeadm(1M)`, `user_attr(4)`, `rbac(5)`.

The service needs to be refreshed using `svcadm(1M)` before a new property value is effective. General, non-modifiable properties can be viewed with the `svcprop(1)` command.

```
# svccfg -s ipsec/ike setprop config/config_file = \
/new/config_file
# svcadm refresh ike
```

Administrative actions on this service, such as enabling, disabling, refreshing, and requesting restart can be performed using `svcadm(1M)`. A user who has been assigned the authorization shown below can perform these actions:

```
solaris.smf.manage.ipsec
```

The service's status can be queried using the `svcs(1)` command.

The `in.iked` daemon is designed to be run under `smf(5)` management. While the `in.iked` command can be run from the command line, this is discouraged. If the `in.iked` command is to be run from the command line, the `ike smf(5)` service should be disabled first. See `svcadm(1M)`.

Options The following options are supported:

- c Check the syntax of a configuration file.
- d Use debug mode. The process stays attached to the controlling terminal and produces large amounts of debugging output. This option is deprecated. See “Service Management Facility” for more details.
- f *filename* Use *filename* instead of `/etc/inet/ike/config`. See `ike.config(4)` for the format of this file. This option is deprecated. See “Service Management Facility” for more details.
- p *level* Specify privilege level (*level*). This option sets how much `ikeadm(1M)` invocations can change or observe about the running `in.iked`.

Valid *levels* are:

- 0 Base level
- 1 Access to preshared key info
- 2 Access to keying material

If `-p` is not specified, *level* defaults to 0.

This option is deprecated. See “Service Management Facility” for more details.

Security This program has sensitive private keying information in its image. Care should be taken with any core dumps or system dumps of a running `in.iked` daemon, as these files contain sensitive keying information. Use the `coreadm(1M)` command to limit any corefiles produced by `in.iked`.

| | | |
|--------------|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| Files | <code>/etc/inet/ike/config</code> | Default configuration file. |
| | <code>/etc/inet/secret/ike.privatekeys/*</code> | Private keys. A private key <i>must</i> have a matching public-key certificate with the same filename in <code>/etc/inet/ike/publickeys/</code> . |
| | <code>/etc/inet/ike/publickeys/*</code> | Public-key certificates. The names are only important with regard to matching private key names. |
| | <code>/etc/inet/ike/crls/*</code> | Public key certificate revocation lists. |
| | <code>/etc/inet/secret/ike.preshared</code> | IKE pre-shared secrets for Phase I authentication. |

| Name | init, telinit – process control initialization |
| Synopsis | <pre>/sbin/init [0123456abcQqSs] /etc/telinit [0123456abcQqSs]</pre> |
| Description | <p>init is the default primordial user process. (Options given to the kernel during boot may result in the invocation of an alternative primordial user process, as described on kernel(1M)). init initiates the core components of the service management facility, svc.configd(1M) and svc.startd(1M), and restarts these components if they fail. For backwards compatibility, init also starts and restarts general processes according to /etc/inittab, as described below.</p> <p>The run levels and system booting descriptions given below are provided for compatibility purposes only, and otherwise made obsolete by the service management facility, smf(5).</p> <p>init Failure If init exits for any reason other than system shutdown, it will be restarted with process-ID 1.</p> <p>Run Level Defined At any given time, the system is in one of eight possible run levels. A run level is a software configuration under which only a selected group of processes exists. Processes spawned by init for each of these run levels are defined in /etc/inittab. init can be in one of eight run levels, 0–6 and S or s (S and s are identical). The run level changes when a privileged user runs /sbin/init.</p> <p>init and System Booting When the system is booted, init is invoked and the following occurs. First, it reads /etc/default/init to set environment variables. This is typically where TZ (time zone) and locale-related environments such as LANG or LC_CTYPE get set. (See the FILES section at the end of this page.) init then looks in /etc/inittab for the <code>initdefault</code> entry (see inittab(4)). If the <code>initdefault</code> entry:</p> <ul style="list-style-type: none"> exists <ul style="list-style-type: none"> init usually uses the run level specified in that entry as the initial run level to enter only if the <code>options/milestone</code> property has not been specified for svc.startd(1M). does not exist <ul style="list-style-type: none"> The service management facility, smf(5), examines its configuration specified in svc.startd(1M), and enters the milestone specified by the <code>options/milestone</code> property. <p>The <code>initdefault</code> entry in /etc/inittab corresponds to the following run levels:</p> <ul style="list-style-type: none"> S or s <ul style="list-style-type: none"> init goes to the single-user state. In this state, the system console device (/dev/console) is opened for reading and writing and the command /sbin/su, (see su(1M)), is invoked. Use either <code>init</code> or <code>telinit</code> to change the run level of the system. Note that if the shell is terminated (using an end-of-file), init only re-initializes to the single-user state if /etc/inittab does not exist. 0-6 <ul style="list-style-type: none"> init enters the corresponding run level. Run levels 0, 5, and 6 are reserved states for shutting the system down. Run levels 2, 3, and 4 are available as multi-user operating states. |

If this is the first time since power up that `init` has entered a run level other than single-user state, `init` first scans `/etc/inittab` for `boot` and `powerwait` entries (see [inittab\(4\)](#)). These entries are performed before any other processing of `/etc/inittab` takes place, providing that the run level entered matches that of the entry. In this way any special initialization of the operating system, such as mounting file systems, can take place before users are allowed onto the system. `init` then scans `/etc/inittab` and executes all other entries that are to be processed for that run level.

To spawn each process in `/etc/inittab`, `init` reads each entry and for each entry that should be respawned, it forks a child process. After it has spawned all of the processes specified by `/etc/inittab`, `init` waits for one of its descendant processes to die, a `powerfail` signal, or a signal from another `init` or `telinit` process to change the system's run level. When one of these conditions occurs, `init` re-examines `/etc/inittab`.

inittab Additions New entries can be added to `/etc/inittab` at any time; however, `init` still waits for one of the above three conditions to occur before re-examining `/etc/inittab`. To get around this, `init Q` or `init q` command wakes `init` to re-examine `/etc/inittab` immediately.

When `init` comes up at boot time and whenever the system changes from the single-user state to another run state, `init` sets the [ioctl\(2\)](#) states of the console to those modes saved in the file `/etc/ioctl.syscon`. `init` writes this file whenever the single-user state is entered.

Run Level Changes When a run level change request is made, `init` or a designate sends the warning signal (SIGTERM) to all processes that are undefined in the target run level. A minimum interval of five seconds is observed before `init` or its designate forcibly terminates these processes by sending a kill signal (SIGKILL). Additionally, `init` informs [svc.startd\(1M\)](#) that the run level is changing. [svc.startd\(1M\)](#) then restricts the system to the set of services which the milestone corresponding to the run-level change depends on.

When `init` receives a signal telling it that a process it spawned has died, it records the fact and the reason it died in `/var/adm/utmpx` and `/var/adm/wtmpx` if it exists (see [who\(1\)](#)). A history of the processes spawned is kept in `/var/adm/wtmpx`.

If `init` receives a `powerfail` signal (SIGPWR) it scans `/etc/inittab` for special entries of the type `powerfail` and `powerwait`. These entries are invoked (if the run levels permit) before any further processing takes place. In this way `init` can perform various cleanup and recording functions during the powerdown of the operating system.

Environment Variables in /etc/default/init You can set default values for environment variables, for such items as timezone and character formatting, in `/etc/default/init`. See the FILES section, below, for a list of these variables.

telinit `telinit`, which is linked to `/sbin/init`, is used to direct the actions of `init`. It takes a one-character argument and signals `init` to take the appropriate action.

Security `init` uses `pam(3PAM)` for session management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the session management module to be used for `init`. Here is a partial `pam.conf` file with entries for `init` using the UNIX session management module.

```
init    session    required    pam_unix_session.so.1
```

If there are no entries for the `init` service, then the entries for the “other” service will be used.

Options 0

Go into firmware.

1

Put the system in system administrator mode. All local file systems are mounted. Only a small set of essential kernel processes are left running. This mode is for administrative tasks such as installing optional utility packages. All files are accessible and no users are logged in on the system.

This request corresponds to a request for `smf(5)` to restrict the system milestone to `svc:/milestone/single-user:default`.

2

Put the system in multi-user mode. All multi-user environment terminal processes and daemons are spawned. This state is commonly referred to as the multi-user state.

This request corresponds to a request for `smf(5)` to restrict the system milestone to `svc:/milestone/multi-user:default`.

3

Extend multi-user mode by making local resources available over the network.

This request corresponds to a request for `smf(5)` to restrict the system milestone to `svc:/milestone/multi-user-server:default`.

4

Is available to be defined as an alternative multi-user environment configuration. It is not necessary for system operation and is usually not used.

5

Shut the machine down so that it is safe to remove the power. Have the machine remove power, if possible.

6

Stop the operating system and reboot to the state defined by the `initdefault` entry in `/etc/inittab`.

The service `svc:/system/boot-config:default` is enabled by default. When the `config/fastreboot_default` property is set to `true`, `init 6` will bypass certain firmware initialization and test steps, depending on the specific capabilities of the system.

a,b,c

Process only those `/etc/inittab` entries having the a, b, or c run level set. These are pseudo-states, which may be defined to run certain commands, but which do not cause the current run level to change.

Q,q

Re-examine `/etc/inittab`.

S, s

Enter single-user mode. This is the only run level that doesn't require the existence of a properly formatted `/etc/inittab` file. If this file does not exist, then by default, the only legal run level that `init` can enter is the single-user mode. When in single-user mode, the filesystems required for basic system operation will be mounted. When the system comes down to single-user mode, these file systems will remain mounted (even if provided by a remote file server), and any other local filesystems will also be left mounted. During the transition down to single-user mode, all processes started by `init` or `init.d` scripts that should only be running in multi-user mode are killed. In addition, any process that has a `utmpx` entry will be killed. This last condition insures that all port monitors started by the SAC are killed and all services started by these port monitors, including `ttymon` login services, are killed.

This request corresponds to a request for [smf\(5\)](#) to restrict the system milestone to `svc:/milestone/single-user:default`.

Files `/dev/console`

System console device.

`/etc/default/init`

Contains environment variables and their default values. For example, for the `timezone` variable, `TZ`, you might specify `TZ=US/Pacific`. The variables are:

`TZ`

Either specifies the timezone information (see [ctime\(3C\)](#)) or the name of a timezone information file `/usr/share/lib/zoneinfo`.

Refer to the [TIMEZONE\(4\)](#) man page before changing this setting.

`CMASK`

The mask (see [umask\(1\)](#)) that `init` uses and that every process inherits from the `init` process. If not set, `init` uses the mask it inherits from the kernel. Note that `init` always attempts to apply a `umask` of `022` before creating a file, regardless of the setting of `CMASK`.

`LC_CTYPE`

Character characterization information

`LC_MESSAGES`

Message translation

`LC_MONETARY`

Monetary formatting information

LC_NUMERIC

Numeric formatting information

LC_TIME

Time formatting information

LC_ALL

If set, all other LC_* environmental variables take-on this value.

LANG

If LC_ALL is not set, and any particular LC_* is also not set, the value of LANG is used for that particular environmental variable.

/etc/inittab

Controls process dispatching by `init`.

/etc/ioctl.syscon

ioctl states of the console, as saved by `init` when single-user state is entered.

/etc/svc/volatile/init.state

`init` state necessary to recover from failure.

/var/adm/utmpx

User access and administration information.

/var/adm/wtmpx

History of user access and administration information.

/var/run/initpipe

A named pipe used for internal communication.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [login\(1\)](#), [sh\(1\)](#), [stty\(1\)](#), [who\(1\)](#), [kernel\(1M\)](#), [shutdown\(1M\)](#), [su\(1M\)](#), [svc.configd\(1M\)](#), [svc.startd\(1M\)](#), [ttypmon\(1M\)](#), [ioctl\(2\)](#), [kill\(2\)](#), [ctime\(3C\)](#), [pam\(3PAM\)](#), [init.d\(4\)](#), [inittab\(4\)](#), [pam.conf\(4\)](#), [TIMEZONE\(4\)](#), [utmpx\(4\)](#), [attributes\(5\)](#), [pam_unix_session\(5\)](#), [smf\(5\)](#), [termio\(7I\)](#)

Diagnostics If `init` finds that it is respawning an entry from `/etc/inittab` more than ten times in two minutes, it assumes that there is an error in the command string in the entry and generates an error message on the system console. It then refuses to respawn this entry until either five minutes has elapsed or it receives a signal from a user-spawned `init` or `telinit` command. This prevents `init` from eating up system resources when someone makes a typographical error in the `inittab` file, or a program is removed that is referenced in `/etc/inittab`.

Notes `init` and `telinit` can be run only by a privileged user.

The `S` or `s` state must not be used indiscriminately in `/etc/inittab`. When modifying this file, it is best to avoid adding this state to any line other than `initdefault`.

If a default state is not specified in the `initdefault` entry in `/etc/inittab`, state 6 is entered. Consequently, the system will loop by going to firmware and rebooting continuously.

If the `utmpx` file cannot be created when booting the system, the system will boot to state “`s`” regardless of the state specified in the `initdefault` entry in `/etc/inittab`. This can occur if the `/var` file system is not accessible.

When a system transitions down to the `S` or `s` state, the `/etc/nologin` file (see [nologin\(4\)](#)) is created. Upon subsequent transition to run level 2, this file is removed.

`init` uses `/var/run/initpipe`, a named pipe, for internal communication.

The `pam_unix(5)` module is no longer supported. Similar functionality is provided by [pam_unix_session\(5\)](#).

Name init.sma – start and stop the snmpd daemon

Synopsis /etc/init.d/init.sma start | stop | restart | status

Description The `init.sma` utility is run automatically during installation and each time the system is rebooted. This utility manages the `snmpd`.

Options The following options are supported:

`start` Starts the `snmpd` daemon.
`stop` Stops the `snmpd` daemon.
`restart` Stops then starts the `snmpd` daemon.
`status` Reports the `snmpd` daemon's status.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWsmagt |
| Interface Stability | Uncommitted |

See Also [attributes\(5\)](#)

Name init.wbem – start and stop the CIM Boot Manager

Synopsis svccfg svc:/application/management/wbem start | stop

Description The `init.wbem` utility is run automatically during installation, each time the system is rebooted, and by means of the `svccfg(1M)` command. This method manipulates the CIM Object Manager (CIMOM) and the Solaris Management Console server, both of which run combined in a single process. `init.wbem` can be used to start, stop, or retrieve status from the server.

CIM Object Manager The CIM Object Manager manages CIM objects on a WBEM-enabled system. A CIM object is a computer representation, or model, of a managed resource, such as a printer, disk drive, or CPU. CIM objects are stored internally as Java classes.

When a WBEM client application accesses information about a CIM object, the CIM Object Manager contacts either the appropriate provider for that object or the CIM Object Manager Repository. Providers are classes that communicate with managed objects to access data.

When a WBEM client application requests data from a managed resource that is not available from the CIM Object Manager Repository, the CIM Object Manager forwards the request to the provider for that managed resource. The provider dynamically retrieves the information.

At startup, the CIM Object Manager performs the following functions:

- Listens for RMI connections on RMI port 5987 and for XML/HTTP connections on HTTP port 5988.
- Sets up a connection to the CIM Object Manager Repository.
- Waits for incoming requests.

During normal operations, the CIM Object Manager performs the following functions:

- Performs security checks to authenticate user login and authorization to access namespaces.
- Performs syntactical and semantic checking of CIM data operations to ensure that they comply with the latest CIM Specification.
- Routes requests to the appropriate provider or to the CIM Object Manager Repository.
- Delivers data from providers and from the CIM Object Manager Repository to WBEM client applications.

A WBEM client application contacts the CIM Object Manager to establish a connection when it needs to perform WBEM operations, such as creating a CIM class or updating a CIM instance. When a WBEM client application connects to a CIM Object Manager, it gets a reference to the CIM Object Manager, which it then uses to request services and operations.

Solaris Management Console Server The Solaris Management Console server is the back end to the front end console, [smc\(1M\)](#). It provides tools for the console to download and performs common services for the console and its tools to use, such as authentication, authorization, logging, messaging, and persistence.

System Booting The `init.wbem` script is installed in the `/etc/init.d` directory.

Options The `init.wbem` function is implemented as a service management facility (SMF) method and is controlled by means of the [svcadm\(1M\)](#) command using the fault management resource identifier (FMRI) `svc:/application/management/wbem`.

The following options are supported through [svcadm\(1M\)](#):

`start` Starts the CIMOM and Solaris Management Console server on the local host.
`stop` Stops the CIMOM and Solaris Management Console server on the local host.
`status` Gets the status of the CIMOM and Solaris Management Console server on the local host.

The SMF property options/`tcp_listen` is used to control whether CIMOM and the Solaris Management console server will respond to requests from remote systems.

The specification:

```
svc:/application/management/wbem/options/tcp_listen = true
```

...allows remote access and `false` disallows remote access. `false` is the default value.

Examples EXAMPLE 1 Allowing Access to Remote Systems

The following commands enable CIMOM and the Solaris Management Console server to allow access from remote systems.

```
# svccfg -s \  
svc:/application/management/wbem setprop options/tcp_listen = true  
# svcadm refresh svc:/application/management/wbem
```

Notes When the `init.wbem` script is invoked by SMF, it does not run the CIMOM and Solaris Management Console server directly. The server process is in Java and is too heavyweight to be run immediately at system boot time. Instead, three lightweight processes listen on three different ports that the CIMOM and the Solaris Management Console server normally use. This acts similarly to [inetd\(1M\)](#).

Because Java programs cannot inherit file descriptors as other programs can, there is a small time period from when the first connection is made until the server is fully operational where client connections may be dropped. WBEM clients are immune to this, as they will retry until the server comes online. Solaris Management Console clients are not immune, and it may be necessary to manually reconnect, though this should not happen in the common case.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

Name `inityp2l` – create NIS (YP) to LDAP configuration files

Synopsis `/usr/lib/netsvc/yp/inityp2l [-m mapping_file_name]
[-c config_file_name]`

Description The `inityp2l` utility assists with creation of the `NISLDAPmapping` and `ypserv` files. See [NISLDAPmapping\(4\)](#) and [ypserv\(4\)](#). `inityp2l` examines the NIS maps on a system, and through a dialogue with the user, determines which NIS to (and from) LDAP mappings are required. A `NISLDAPmapping` file is then created based on this information. The utility asks users about their LDAP server configuration and a `ypserv` file is created based on this information.

The `inityp2l` utility handles mappings for standard NIS maps and the `auto.*` series of maps. If requested, it creates default mappings for custom maps, with each map entry represented as a single DIT string. `inityp2l` does not handle full custom mapping, but if requested, `inityp2l` will insert comments into the `NISLDAPmapping` file that indicate where these should be added.

To write to the `NISLDAPmapping` or `ypserv` files is potentially dangerous. `inityp2l` warns the user and asks for confirmation before:

1. it overwrites either file
2. it writes to the default `NISLDAPmapping` file location, if this file did not previously exist. This is important because the existence of a file in this location causes NIS components to work NIS to LDAP (N2L) mode when next restarted, rather than to traditional NIS mode.

`inityp2l` assists with rapid creation of a simple N2L configuration files. It is not a general purpose tool for the management of these files. An advanced user who would like to maintain the files or use custom mappings should examine the output of `inityp2l` and customize it by using a standard text editor.

Options `inityp2l` supports the following options:

- c Specify the name of the generated `ypserv` file. The default location is described in [Files](#).
- m Specify the name of the generated `NISLDAPmapping` file. The default is described in [Files](#).

| | | |

Name in.lpd – BSD print protocol adaptor

Synopsis /usr/lib/print/in.lpd

Description in.lpd implements the network listening service for the BSD print protocol specified in RFC 1179. The BSD print protocol provides a remote interface for systems to interact with a local spooling system. The protocol defines five standard requests from the client to the server: starting queue processing, transferring print jobs, retrieving terse status, retrieving verbose status, and canceling print jobs.

The in.lpd service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/lp
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). Responsibility for initiating and restarting this service is delegated to [inetd\(1M\)](#). Use [inetadm\(1M\)](#) to make configuration changes and to view configuration information for this service. The service's status can be queried using the [svcs\(1\)](#) command.

in.lpd uses the `config/log_from_remote` property to allow or disallow remote access. The default value of this property, `localhost`, disallows remote access.

inetd waits for connections on TCP port 515. Upon receipt of a connect request, in.lpd is started to service the connection. Once the request has been filled, in.lpd closes the connection and exits.

Examples **EXAMPLE 1** Allowing Remote Access

The following command allows remote access to in.lpd.

```
# inetadm -m svc:/application/print/rfc1179:default bind_addr=""
```

Exit Status The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

Name in.mpathd – IP multipathing daemon

Synopsis /usr/lib/inet/in.mpathd

Description The `in.mpathd` daemon performs failure and repair detection for IP interfaces that have been placed into an IPMP group (or optionally, for all IP interfaces on the system). It also controls which IP interfaces in an IPMP group are “active” (being used by the system to send or receive IP data traffic) in a manner that is consistent with the administrator's configured policy.

The `in.mpathd` daemon can detect IP interface failure and repair through two methods: by monitoring the `IFF_RUNNING` flag for each IP interface (link-based failure detection), and by sending and receiving ICMP probes on each IP interface (probe-based failure detection). Link-based failure detection is instantaneous and is always enabled (provided the network driver supports the feature); probe-based failure detection must be enabled through the configuration of one or more test addresses (described below), but tests the entire IP interface send and receive path. The `impstat(1M)` utility can be used to check which failure detection methods are enabled.

If only link-based failure detection is enabled, then the health of the interface is determined solely from the state of the `IFF_RUNNING` flag. Otherwise, the interface is considered failed if either of the two methods indicate a failure, and repaired once both methods indicate the failure has been corrected. Not all interfaces in a group need to be configured with the same failure detection methods.

As mentioned above, to perform probe-based failure detection `in.mpathd` requires a test address on each IP interface for the purpose of sending and receiving probes. Each address must be marked `NOFAILOVER` (see `ifconfig(1M)`) and `in.mpathd` will be limited to probing targets on the same subnet. Each address may be configured statically or acquired by means of DHCP. To find targets, `in.mpathd` first consults the routing table for routes on the same subnet, and uses the specified next-hop. If no routes match, it sends all-hosts ICMP probes and selects a subset of the systems that respond. Thus, for probe-based failure detection to operate, there must be at least one neighbor on each subnet that responds to ICMP echo request probes. The `impstat(1M)` utility can be used to display both the current probe target information and the status of sent probes.

Both IPv4 and IPv6 are supported. If an IP interface is plumbed for IPv4 and an IPv4 test address is configured then `in.mpathd` will start sending ICMPv4 probes over that IP interface. Similarly, if an IP interface is plumbed for IPv6 and an IPv6 test address is configured, then `in.mpathd` will start sending ICMPv6 probes over that IP interface. However, note that `in.mpathd` will ignore IPv6 test addresses that are not link-local. If both IPv4 and IPv6 are plumbed, it is sufficient to configure only one of the two, that is, either an IPv4 test address or an IPv6 test address. If both IPv4 and IPv6 test addresses are configured, `in.mpathd` probes using both ICMPv4 and ICMPv6.

As mentioned above, `in.mpathd` also controls which IP interfaces in an IPMP group are “active” (used by the system to send and receive IP data traffic). Specifically, `in.mpathd` tracks the administrative configuration of each IPMP group and attempts to keep the number of

active IP interfaces in each group consistent with that configuration. Therefore, if an active IP interface fails, `in.mpathd` will activate an `INACTIVE` interface in the group, provided one exists (it will prefer `INACTIVE` interfaces that are also marked `STANDBY`). Likewise, if an IP interface repairs and the resulting repair leaves the IPMP group with more active interfaces than the administrative configuration specifies, `in.mpathd` will deactivate one of the interfaces (preferably one marked `STANDBY`), except when the `FAILBACK` variable is used, as described below. Similar adjustments will be made by `in.mpathd` when offlining IP interfaces (for instance, in response to [if_mpadm\(1M\)](#)).

The `in.mpathd` daemon accesses three variable values in `/etc/default/mpathd`: `FAILURE_DETECTION_TIME`, `FAILBACK` and `TRACK_INTERFACES_ONLY_WITH_GROUPS`.

The `FAILURE_DETECTION_TIME` variable specifies the probe-based failure detection time. The shorter the failure detection time, the more probe traffic. The default value of `FAILURE_DETECTION_TIME` is 10 seconds. This means that IP interface failure will be detected by `in.mpathd` within 10 seconds. The IP interface repair detection time is always twice the value of `FAILURE_DETECTION_TIME`. Note that failures and repairs detected by link-based failure detection are acted on immediately, though `in.mpathd` may ignore link state changes if it suspects that the link state is flapping due to defective hardware; see [DIAGNOSTICS](#).

By default, `in.mpathd` limits failure and repair detection to IP interfaces that are configured as part of a named IPMP group. Setting `TRACK_INTERFACES_ONLY_WITH_GROUPS` to `no` enables failure and repair detection on all IP interfaces, even if they are not part of a named IPMP group. IP interfaces that are tracked but not part of a named IPMP group are considered to be part of the “anonymous” IPMP group. In addition to having no name, this IPMP group is special in that its IP interfaces are not equivalent and thus cannot take over for one another in the event of an IP interface failure. That is, the anonymous IPMP group can only be used for failure and repair detection, and provides no high-availability or load-spreading.

As described above, when `in.mpathd` detects that an IP interface has repaired, it activates it so that it will again be used to send and receive IP data traffic. However, if `FAILBACK` is set to `no`, then the IP interface will only be activated if no other active IP interfaces in the group remain. However, the interface may subsequently be activated if another IP interface in the group fails.

Files `/etc/default/mpathd` Contains default values used by the `in.mpathd` daemon.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

System Administration Guide: IP Services

Diagnostics IP interface *interface_name* has a hardware address which is not unique in group *group_name*; offlining

Description: For probe-based failure detection, load-spreading, and other code IPMP features to work properly, each IP interface in an IPMP group must have a unique hardware address. If this requirement is not met, in .mpathd will automatically offline all but one of the IP interfaces with duplicate hardware addresses.

IP interface *interface_name* now has a unique hardware address in group *group_name*; onlining

Description: The previously-detected duplicate hardware address is now unique, and therefore in .mpathd has brought *interface_name* back online.

Test address *address* is not unique in group; disabling probe-based failure detection on *interface_name*

Description: For in .mpathd to perform probe-based failure detection, each test address in the group must be unique.

No test address configured on interface *interface_name* disabling probe-based failure detection on it

Description: For in .mpathd to perform probe-based failure detection on an IP interface, it must be configured with a test address: IPv4, IPv6, or both.

IP *interface_name* in group *group_name* is not plumbed for IPv[4|6], affecting IPv[4|6] connectivity

Description: All IP interfaces in a multipathing group must be homogeneously plumbed. For example, if one IP interface is plumbed for IPv4, then all IP interfaces in the group must be plumbed for IPv4, or IPv4 packets will not be able to be reliably sent and received. The STREAMS modules pushed on all IP interfaces must also be identical.

The link has come up on *interface_name* more than 2 times in the last minute; disabling repair until it stabilizes.

Description: To limit the impact of interfaces with intermittent hardware (such as a bad cable), in .mpathd will not consider an IP interface with a frequently changing link state as repaired until the link state stabilizes.

Invalid failure detection time of *time*, assuming default 10000 ms

Description: An invalid value was encountered for FAILURE_DETECTION_TIME in the /etc/default/mpathd file.

Too small failure detection time of *time*, assuming minimum of 100 ms

Description: The minimum value that can be specified for FAILURE_DETECTION_TIME is currently 100 milliseconds.

Invalid value for FAILBACK *value*

Description: Valid values for the boolean variable FAILBACK are yes or no.

Invalid value for TRACK_INTERFACES_ONLY_WITH_GROUPS *value*

Description: Valid values for the boolean variable TRACK_INTERFACES_ONLY_WITH_GROUPS are yes or no.

Cannot meet requested failure detection time of *time* ms on (inet[6] *interface_name*) new failure detection time for group *group_name* is *time* ms

Description: The round trip time for ICMP probes is higher than necessary to maintain the current failure detection time. The network is probably congested or the probe targets are loaded. in.mpathd automatically increases the failure detection time to whatever it can achieve under these conditions.

Improved failure detection time *time* ms on (inet[6] *interface_name*) for group *group_name*

Description: The round trip time for ICMP probes has now decreased and in.mpathd has lowered the failure detection time correspondingly.

IP interface failure detected on *interface_name*

Description: in.mpathd has detected a failure on *interface_name*, and has set the IFF_FAILED flag on *interface_name*, ensuring that it will not be used for IP data traffic.

IP interface repair detected on *interface_name*

Description: in.mpathd has detected a repair on *interface_name*, and has cleared the IFF_FAILED flag. Depending on the administrative configuration, the *interface_name* may again be used for IP data traffic.

All IP interfaces in group *group* are now unusable

Description: in.mpathd has determined that none of the IP interfaces in *group* can be used for IP data traffic, breaking network connectivity for the group.

At least 1 IP interface (*interface_name*) in group *group* is now usable

Description: in.mpathd has determined that at least one of the IP interfaces in *group* can again be used for IP data traffic, restoring network connectivity for the group.

The link has gone down on *interface_name*

Description: in.mpathd has detected that the IFF_RUNNING flag for *interface_name* has been cleared, indicating that the link has gone down.

The link has come up on *interface_name*

Description: in.mpathd has detected that the IFF_RUNNING flag for *interface_name* has been set, indicating that the link has come up.

Name in.ndpd – daemon for IPv6 autoconfiguration

Synopsis /usr/lib/inet/in.ndpd [-adt] [-f *config_file*]

Description in.ndpd provides both the host and router autoconfiguration components of Neighbor Discovery for IPv6 and Stateless and Stateful Address Autoconfiguration for IPv6. In particular, in.ndpd implements:

- router discovery;
- prefix discovery;
- parameter discovery;
- invocation of stateful address autoconfiguration;
- stateless address autoconfiguration; and
- privacy extensions for stateless address autoconfiguration.

Other aspects of Neighbor Discovery are implemented by [ip6\(7P\)](#), including:

- address resolution;
- neighbor unreachability detection; and
- redirect.

The duplicate address detection function is implemented by the system kernel.

in.ndpd is managed by the service management facility (SMF), by means of the service identifier:

```
svc:/network/routing/ndp:default
```

If the `/etc/inet/ndpd.conf` file does not exist or does not set the variable `AdvSendAdvertisements` to true for a network interface, then in.ndpd will make the node a host for that interface, that is, sending router solicitation messages and then using router advertisement messages it receives to autoconfigure the node. Note that in.ndpd only autoconfigures the addresses of global or site-local scope from the prefix advertisement.

If `AdvSendAdvertisements` is set to true for an interface, then in.ndpd will perform router functions on that interface, that is, sending router advertisement messages to autoconfigure the attached hosts, but not use any advertisements it receives for autoconfiguration. However, when sending advertisements, in.ndpd will use the advertisements it sends itself to autoconfigure its prefixes.

Stateless autoconfiguration requires no manual configuration of hosts, minimal (if any) configuration of routers, and no additional servers. The stateless mechanism enables a host to generate its own addresses and uses local information as well as non-local information that is advertised by routers to generate the addresses. in.ndpd will plumb logical interfaces for each of these addresses.

Stateful autoconfiguration involves the [dhcpgent\(1M\)](#) daemon and the use of the DHCPv6 protocol. The dhcpgent daemon is responsible for plumbing the logical interfaces for the acquired addresses, maintaining the leases, and handling duplicate addresses. in.ndpd starts

the `dhcpgent` daemon automatically and signals when DHCPv6 should be started. `in.ndpd` also detects when `dhcpgent` configures the logical interfaces, and sets the appropriate prefix length on each according to received Routing Advertisement messages. `in.ndpd` will not stop `dhcpgent`; use [ifconfig\(1M\)](#) to control `dhcpgent` if necessary.

Temporary addresses that are autoconfigured for an interface can also be implemented. A temporary address token is enabled for one or more interfaces on a host. However, unlike standard, autoconfigured IPv6 addresses, a temporary address consists of the site prefix and a randomly generated 64 bit number. This random number becomes the interface ID segment of the IPv6 address. A link-local address is not generated with the temporary address as the interface ID.

If the kernel detects a duplicate temporary address, `in.ndpd` will automatically choose another.

Routers advertise all prefixes that have been assigned on the link. IPv6 hosts use Neighbor Discovery to obtain a subnet prefix from a local router. Hosts automatically create IPv6 addresses by combining the subnet prefix with an interface IDs that is generated from an interface's MAC address. In the absence of routers, a host can generate only link-local addresses. Link-local addresses can only be used for communication with nodes on the same link.

For information on how to enable IPv6 address autoconfiguration, see [System Administration Guide: IP Services](#)

Options Supported options and equivalent SMF service properties are listed below. SMF service properties are set using a command of the form:

```
# routeadm -m ndp:default key=value
```

-a

Turn off stateless and stateful address auto configuration. When set, the daemon does not autoconfigure any addresses and does not renumber any addresses. This option does the same thing as the following lines in `ndpd.conf(4)`:

```
ifdefault StatefulAddrConf off
ifdefault StatelessAddrConf off
```

Use of this option is equivalent to setting the `stateless_addr_conf` property to false.

-d

Turn on large amounts of debugging output on `stdout`. When set, the program runs in the foreground and stays attached to the controlling terminal. Use of this option is equivalent to setting the `debug` property to true.

-f *config_file*

Use *config_file* for configuration information instead of the default `/etc/inet/ndpd.conf`. Use of this option is equivalent to setting the `config_file` property to the configuration file to be used.

-t

Turn on tracing (printing) of all sent and received packets to stdout. When set, the program runs in the foreground and stays attached to the controlling terminal. As such, this option cannot be run under the SMF.

Files /etc/inet/ndpd.conf Configuration file. This file is not necessary on a host, but it is required on a router to enable in.ndpd to advertise autoconfiguration information to the hosts.

System Administration Guide: IP Services

Narten, T., Nordmark, E., Simpson, W. *RFC 2461, Neighbor Discovery for IP Version 6 (IPv6)*. The Internet Society. December 1998.

Thomson, S., Narten, T. *RFC 2462, IPv6 Stateless Address Autoconfiguration*. The Internet Society. December 1998.

Narten, T., and Draves, R. *RFC 3041, Privacy Extensions for Stateless Address Autoconfiguration in IPv6*. The Internet Society. January 2001.

Diagnostics Receipt of a SIGHUP signal will make in.ndpd restart and reread /etc/inet/ndpd.conf.

Notes The in.ndpd daemon service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/routing/ndp:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#) or [routeadm\(1M\)](#).

Name in.rarpd, rarpd – DARPA Reverse Address Resolution Protocol server

Synopsis /usr/sbin/in.rarpd [-d] -a
 /usr/sbin/in.rarpd [-d] *device unit*

Description in.rarpd starts a daemon that responds to Reverse Address Resolution Protocol (RARP) requests. The daemon forks a copy of itself that runs in background. It must be run as root.

RARP is used by machines at boot time to discover their Internet Protocol (IP) address. The booting machine provides its Ethernet address in a RARP request message. Using the ethers and hosts databases, in.rarpd maps this Ethernet address into the corresponding IP address which it returns to the booting machine in an RARP reply message. The booting machine must be listed in both databases for in.rarpd to locate its IP address. in.rarpd issues no reply when it fails to locate an IP address.

in.rarpd uses the STREAMS-based Data Link Provider Interface (DLPI) message set to communicate directly with the datalink device driver.

Options The following options are supported:

- a Get the list of available network interfaces from IP using the SIOCGIFADDR ioctl and start a RARP daemon process on each interface returned.
- d Print assorted debugging messages while executing.

Examples **EXAMPLE 1** Starting An in.rarpd Daemon For Each Network Interface Name Returned From /dev/ip:
 The following command starts an in.rarpd for each network interface name returned from /dev/ip:

```
example# /usr/sbin/in.rarpd -a
```

EXAMPLE 2 Starting An in.rarpd Daemon On The Device /dev/le With The Device Instance Number 0
 The following command starts one in.rarpd on the device /dev/le with the device instance number 0.

```
example# /usr/sbin/in.rarpd le 0
```

Files /etc/ethers File or other source, as specified by [nsswitch.conf\(4\)](#).

| Availability | system/boot/network |

See Also [svcs\(1\)](#), [boot\(1M\)](#), [ifconfig\(1M\)](#), [svcadm\(1M\)](#), [ethers\(4\)](#), [hosts\(4\)](#), [netconfig\(4\)](#), [nsswitch.conf\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#), [dlpi\(7P\)](#)

Finlayson, R., Mann, T., Mogul, J., and Theimer, M., *RFC 903, A Reverse Address Resolution Protocol*, Network Information Center, SRI International, June 1984.

Notes The `in.rarpd` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/rarp
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

-
- Name** in.rdisc, rdisc – network router discovery daemon
- Synopsis** /usr/sbin/in.rdisc [-a] [-f] [-s] [*send-address*] [*receive-address*]
 /usr/sbin/in.rdisc -r [-p *preference*] [-T *interval*]
 [*send-address*] [*receive-address*]
- Description** in.rdisc remains part of the software distribution of the Solaris Operating Environment. It is, however, not used by default. [in.routed\(1M\)](#) includes the functionality provided by in.rdisc. See [routeadm\(1M\)](#) for details of how to specify the IPV4 routing daemon.
- in.rdisc implements the ICMP router discovery protocol. The first form of the command is used on hosts and the second form is used on routers.
- in.rdisc can be invoked in either the first form (host mode) or second form (router mode).
- On a host, in.rdisc populates the network routing tables with default routes. On a router, advertises the router to all the hosts.
- in.rdisc is managed by the service management facility (SMF), by means of the service identifier:
- ```
svc:/network/routing/rdisc:default
```
- Host (First Form)** On a host, in.rdisc listens on the ALL\_HOSTS (224.0.0.1) multicast address for ROUTER\_ADVERTISE messages from routers. The received messages are handled by first ignoring those listed router addresses with which the host does not share a network. Among the remaining addresses, the ones with the highest preference are selected as default routers and a default route is entered in the kernel routing table for each one of them.
- Optionally, in.rdisc can avoid waiting for routers to announce themselves by sending out a few ROUTER\_SOLICITATION messages to the ALL\_ROUTERS (224.0.0.2) multicast address when it is started.
- A timer is associated with each router address. The address will no longer be considered for inclusion in the routing tables if the timer expires before a new *advertise* message is received from the router. The address will also be excluded from consideration if the host receives an *advertise* message with the preference being maximally negative or with a lifetime of zero.
- Router (Second Form)** When in.rdisc is started on a router, it uses the SIOCIFCONF [ioctl\(2\)](#) to find the interfaces configured into the system and it starts listening on the ALL\_ROUTERS multicast address on all the interfaces that support multicast. It sends out *advertise* messages to the ALL\_HOSTS multicast address advertising all its IP addresses. A few initial *advertise* messages are sent out during the first 30 seconds and after that it will transmit *advertise* messages approximately every 600 seconds.
- When in.rdisc receives a *solicitation* message, it sends an *advertise* message to the host that sent the *solicitation* message.

When `in.rdisc` is terminated by a signal, it sends out an *advertise* message with the preference being maximally negative.

**Options** Supported options and equivalent SMF service properties are listed below. SMF service properties are set using a command of the form:

```
routeadm -m rdisc:default key=value
```

- a Accept all routers independent of the preference they have in their *advertise* messages. Normally, `in.rdisc` only accepts (and enters in the kernel routing tables) the router or routers with the highest preference. Use of this option is equivalent to setting the `accept_all` property to true.
- f Run `in.rdisc` forever even if no routers are found. Normally, `in.rdisc` gives up if it has not received any *advertise* message after soliciting three times, in which case it exits with a non-zero exit code. If `-f` is not specified in the first form then `-s` must be specified. For SMF execution, this option is required.
- r Act as a router, rather than a host. Use of this option is equivalent to setting the `act_as_router` property to true.
- s Send three *solicitation* messages initially to quickly discover the routers when the system is booted. When `-s` is specified, `in.rdisc` exits with a non-zero exit code if it can not find any routers. This can be overridden with the `-f` option. This option is not compatible with SMF execution and is not supported for the `rdisc` service.
- p *preference* Set the preference transmitted in the *solicitation* messages. The default is zero. Use of this option is equivalent to setting the `preference` property.
- T *interval* Set the interval between transmitting the *advertise* messages. The default time is 600 seconds. Use of this option is equivalent to setting the `transmit_interval` property.

The `send-address` and `receive-address` daemon options can be set by means of the `send_address` and `receive_address` properties.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/routing

**See Also** [in.routed\(1M\)](#), [routeadm\(1M\)](#), [svcadm\(1M\)](#), [ioctl\(2\)](#), [gateways\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#), [icmp\(7P\)](#), [inet\(7P\)](#)

**Name** in.rexecd, rexecd – remote execution server

**Synopsis** in.rexecd

**Description** in.rexecd is the server for the [rexec\(3SOCKET\)](#) routine. The server provides remote execution facilities with authentication based on user names and passwords. It is invoked automatically as needed by [inetd\(1M\)](#), and then executes the following protocol:

1. The server reads characters from the socket up to a null (`\0`) byte. The resultant string is interpreted as an ASCII number, base 10.
2. If the number received in step 1 is non-zero, it is interpreted as the port number of a secondary stream to be used for the `stderr`. A second connection is then created to the specified port on the client's machine.
3. A null terminated user name of at most 16 characters is retrieved on the initial socket.
4. A null terminated password of at most 16 characters is retrieved on the initial socket.
5. A null terminated command to be passed to a shell is retrieved on the initial socket. The length of the command is limited by the upper bound on the size of the system's argument list.
6. rexecd then validates the user as is done at login time and, if the authentication was successful, changes to the user's home directory, and establishes the user and group protections of the user. If any of these steps fail the connection is aborted and a diagnostic message is returned.
7. A null byte is returned on the connection associated with the `stderr` and the command line is passed to the normal login shell of the user. The shell inherits the network connections established by rexecd.

**Usage** in.rexecd and rexecd are IPv6-enabled. See [ip6\(7P\)](#).

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/network-servers

**See Also** [svcs\(1\)](#), [inetd\(1M\)](#), [inetadm\(1M\)](#), [svcadm\(1M\)](#), [rexec\(3SOCKET\)](#), [attributes\(5\)](#), [smf\(5\)](#), [ip6\(7P\)](#)

**Diagnostics** All diagnostic messages are returned on the connection associated with the `stderr`, after which any network connections are closed. An error is indicated by a leading byte with a value of 1 (0 is returned in step 7 above upon successful completion of all the steps prior to the command execution).

username too long	The name is longer than 16 characters.
password too long	The password is longer than 16 characters.

command too long	The command line passed exceeds the size of the argument list (as configured into the system).
Login incorrect.	No password file entry for the user name existed.
Password incorrect.	The wrong password was supplied.
No remote directory.	The <code>chdir</code> command to the home directory failed.
Try again.	A fork by the server failed.
<code>/usr/bin/sh: ...</code>	The user's login shell could not be started.

**Notes** The `in.rexecd` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/rexec:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). Responsibility for initiating and restarting this service is delegated to [inetd\(1M\)](#). Use [inetadm\(1M\)](#) to make configuration changes and to view configuration information for this service. The service's status can be queried using the [svcs\(1\)](#) command.

- 
- Name** in.ripngd – network routing daemon for IPv6
- Synopsis** /usr/sbin/in.ripngd [-s] [-q] [-t] [-p *n*] [-P] [-v ]  
[*logfile*]
- Description** in.ripngd is the IPv6 equivalent of [in.routed\(1M\)](#). It is invoked at boot time to manage the network routing tables. The routing daemon uses the Routing Information Protocol for IPv6.
- in.ripngd is managed by the service management facility (SMF), by means of the service identifier:
- ```
svc:/network/routing/ripng:default
```
- In normal operation, in.ripngd listens on the [udp\(7P\)](#) socket port 521 for routing information packets. If the host is an internetwork router, it periodically supplies copies of its routing tables to any directly connected hosts and networks.
- When in.ripngd is started, it uses the [SIOCGLIFCONF ioctl\(2\)](#) to find those directly connected IPv6 interfaces configured into the system and marked “up”; the software loopback interface is ignored. If multiple interfaces are present, it is assumed the host will forward packets between networks. in.ripngd then multicasts a request packet on each IPv6 interface and enters a loop, listening for request and response packets from other hosts.
- When a request packet is received, in.ripngd formulates a reply based on the information maintained in its internal tables. The response packet contains a list of known routes. With each route is a number specifying the number of bits in the prefix. The prefix is the number of bits in the high order part of an address that indicate the subnet or network that the route describes. Each route reported also has a “*hop count*” metric. A count of 16 or greater is considered “infinity.” The metric associated with each route returned provides a metric relative to the sender.
- The request packets received by in.ripngd are used to update the routing tables if one of the following conditions is satisfied:
- No routing table entry exists for the destination network or host, and the metric indicates the destination is “reachable”, that is, the *hop count* is not infinite.
 - The source host of the packet is the same as the router in the existing routing table entry. That is, updated information is being received from the very internetwork router through which packets for the destination are being routed.
 - The existing entry in the routing table has not been updated for a period of time, defined to be 90 seconds, and the route is at least as cost-effective as the current route.
 - The new route describes a shorter route to the destination than the one currently stored in the routing tables; this is determined by comparing the metric of the new route against the one stored in the table.

When an update is applied, `in.ripngd` records the change in its internal tables and generates a response packet to all directly connected hosts and networks. To allow possible unstable situations to settle, `in.ripngd` waits a short period of time (no more than 30 seconds) before modifying the kernel's routing tables.

In addition to processing incoming packets, `in.ripngd` also periodically checks the routing table entries. If an entry has not been updated for 3 minutes, the entry's metric is set to infinity and marked for deletion. Deletions are delayed an additional 60 seconds to insure the invalidation is propagated throughout the internet.

Hosts acting as internetwork routers gratuitously supply their routing tables every 30 seconds to all directly connected hosts and networks.

Options `in.ripngd` supports the options listed below. Listed with the options are the equivalent SMF property values. These are set for the `ripng:default` service with a command of the form:

```
# routeadm -m ripng:default key=value
```

- p *n* Send and receive the routing packets from other routers using the UDP port number *n*. Use of this option is equivalent to setting the `udp_port` property.
- P Do not use poison reverse. Use of this option is equivalent to setting the `poison_reverse` property to false.
- q Do not supply routing information. Use of this option is equivalent to setting the `quiet_mode` property to true.
- s Force `in.ripngd` to supply routing information whether it is acting as an internetwork router or not. Use of this option is equivalent to setting the `supply_routes` property to true.
- t Print all packets sent or received to standard output. `in.ripngd` will not divorce itself from the controlling terminal. Accordingly, interrupts from the keyboard will kill the process. Not supported by the `ripng` service.
- v Print all changes made to the routing tables to standard output with a timestamp. Use of this option is equivalent to setting the `verbose` property to true.

Any other argument supplied to this option is interpreted as the name of the file in which the actions of `in.ripngd`, as specified by this option or by `-t`, should be logged instead of being sent to standard output.

The logfile can be specified for the `ripng` service by means of the `log_file` property.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|------------------------|
| Availability | system/network/routing |

See Also [in.routed\(1M\)](#), [routeadm\(1M\)](#), [svcadm\(1M\)](#), [ioctl\(2\)](#), [attributes\(5\)](#), [smf\(5\)](#), [udp\(7P\)](#)

G. Malkin, R. Minnear, *RFC 2080, RIPng for IPv6*, January 1997.

Notes The kernel's routing tables may not correspond to those of `in.ripngd` for short periods of time while processes that utilize existing routes exit; the only remedy for this is to place the routing process in the kernel.

`in.ripngd` currently does not support all of the functionality of [in.routed\(1M\)](#). Future releases may support more if appropriate.

`in.ripngd` initially obtains a routing table by examining the interfaces configured on a machine. It then sends a request on all directly connected networks for more routing information. `in.ripngd` does not recognize or use any routing information already established on the machine prior to startup. With the exception of interface changes, `in.ripngd` does not see any routing table changes that have been done by other programs on the machine, for example, routes added, deleted or flushed by means of the [route\(1M\)](#) command. Therefore, these types of changes should not be done while `in.ripngd` is running. Rather, shut down `in.ripngd`, make the changes required, and then restart `in.ripngd`.

Name in.rlogind, rlogind – remote login server

Synopsis /usr/sbin/in.rlogind [-k5eExXciPp] [-s *tos*] [-S *keytab*]
[-M *realm*]

Description in.rlogind is the server for the [rlogin\(1\)](#) program. The server provides a remote login facility with authentication based on Kerberos V5 or privileged port numbers.

in.rlogind is invoked by [inetd\(1M\)](#) when a remote login connection is established. When Kerberos V5 authentication is required (see option -k below), the authentication sequence is as follows:

- Check Kerberos V5 authentication.
- Check authorization according to the rules in [krb5_auth_rules\(5\)](#).
- Prompt for a password if any checks fail and /etc/pam.conf is configured to do so.

In order for Kerberos authentication to work, a host/<FQDN> Kerberos principal must exist for each Fully Qualified Domain Name associated with the in.rlogind server. Each of these host/<FQDN> principals must have a keytab entry in the /etc/krb5/krb5.keytab file on the in.rlogind server. An example principal might be:

```
host/bigmachine.eng.example.com
```

See [kadmin\(1M\)](#) or [gkadmin\(1M\)](#) for instructions on adding a principal to a krb5.keytab file. See *System Administration Guide: Security Services* for a discussion of Kerberos authentication.

If Kerberos V5 authentication is not enabled, then the authentication procedure follows the standard rlogin protocol:

- The server checks the client's source port. If the port is not in the range 512-1023, the server aborts the connection.
- The server checks the client's source address. If an entry for the client exists in both /etc/hosts and /etc/hosts.equiv, a user logging in from the client is not prompted for a password. If the address is associated with a host for which no corresponding entry exists in /etc/hosts, the user is prompted for a password, regardless of whether or not an entry for the client is present in /etc/hosts.equiv. See [hosts\(4\)](#) and [hosts.equiv\(4\)](#).

Once the source port and address have been checked, in.rlogind allocates a pseudo-terminal and manipulates file descriptors so that the slave half of the pseudo-terminal becomes the stdin, stdout, and stderr for a login process. The login process is an instance of the [login\(1\)](#) program, invoked with the -r.

The login process then proceeds with the [pam\(3PAM\)](#) authentication process. See SECURITY below. If automatic authentication fails, it reprompts the user to login.

The parent of the login process manipulates the master side of the pseudo-terminal, operating as an intermediary between the login process and the client instance of the `rlogin` program. In normal operation, a packet protocol is invoked to provide Ctrl-S and Ctrl-Q type facilities and propagate interrupt signals to the remote programs. The login process propagates the client terminal's baud rate and terminal type, as found in the environment variable, `TERM`.

Options The following options are supported:

- 5 Same as `-k`, for backwards compatibility.
- c Requires Kerberos V5 clients to present a cryptographic checksum of initial connection information like the name of the user that the client is trying to access in the initial authenticator. This checksum provides additional security by preventing an attacker from changing the initial connection information. This option is mutually exclusive with the `-i` option.
- e Creates an encrypted session.
- E Same as `-e`, for backwards compatibility.
- i Ignores authenticator checksums if provided. This option ignores authenticator checksums presented by current Kerberos clients to protect initial connection information. Option `-i` is the opposite of option `-c`.
- k Allows Kerberos V5 authentication with the `.k5login` access control file to be trusted. If this authentication system is used by the client and the authorization check is passed, then the user is allowed to log in.
- M *realm* Uses the indicated Kerberos V5 realm. By default, the daemon will determine its realm from the settings in the `krb5.conf(4)` file.
- p Prompts for authentication only if other authentication checks fail.
- P Prompts for a password in addition to other authentication methods.
- s *tos* Sets the IP TOS option.
- S *keytab* Sets the KRB5 keytab file to use. The `/etc/krb5/krb5.keytab` file is used by default.
- x Same as `-e`, for backwards compatibility.
- X Same as `-e`, for backwards compatibility.

Usage `rlogind` and `in.rlogind` are IPv6-enabled. See [ip6\(7P\)](#). IPv6 is not currently supported with Kerberos V5 authentication.

Typically, Kerberized `rlogin` service runs on port 543 (`klogin`) and Kerberized, encrypted `rlogin` service runs on port 2105 (`eklogin`). The corresponding FMRI entries are:

```
svc:/network/login:klogin (rlogin with kerberos)
svc:/network/login:eklogin (rlogin with kerberos and encryption)
```

Security `in.rlogind` uses [pam\(3PAM\)](#) for authentication, account management, and session management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the modules to be used for `in.rlogind`. Here is a partial `pam.conf` file with entries for the `rlogin` command using the “rhosts” and UNIX authentication modules, and the UNIX account, session management, and password management modules.

```

rlogin      auth sufficient      pam_rhosts_auth.so.1
rlogin      auth requisite          pam_authtok_get.so.1
rlogin      auth required           pam_dhkeys.so.1
rlogin      auth required           pam_unix_auth.so.1

rlogin      account required     pam_unix_roles.so.1
rlogin      account required     pam_unix_projects.so.1
rlogin      account required     pam_unix_account.so.1

rlogin      session required      pam_unix_session.so.1

```

With this configuration, the server checks the client’s source address. If an entry for the client exists in both `/etc/hosts` and `/etc/hosts.equiv`, a user logging in from the client is not prompted for a password. If the address is associated with a host for which no corresponding entry exists in `/etc/hosts`, the user is prompted for a password, regardless of whether or not an entry for the client is present in `/etc/hosts.equiv`. See [hosts\(4\)](#) and [hosts.equiv\(4\)](#).

When running a Kerberized `rlogin` service (with or without the encryption option), the `pam` service name that should be used is “`krlogin`”.

If there are no entries for the `rlogin` service, then the entries for the “other” service will be used. If multiple authentication modules are listed, then the user may be prompted for multiple passwords. Removing the `pam_rhosts_auth.so.1` entry will disable the `/etc/hosts.equiv` and `~/.rhosts` authentication protocol and the user would always be forced to type the password. The *sufficient* flag indicates that authentication through the `pam_rhosts_auth.so.1` module is sufficient to authenticate the user. Only if this authentication fails is the next authentication module used.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|---------------------------------|
| Availability | service/network/network-servers |

See Also [login\(1\)](#), [svcs\(1\)](#), [rlogin\(1\)](#), [gkadmin\(1M\)](#), [in.rshd\(1M\)](#), [inetadm\(1M\)](#), [inetd\(1M\)](#), [kadmin\(1M\)](#), [svcadm\(1M\)](#), [pam\(3PAM\)](#), [hosts\(4\)](#), [hosts.equiv\(4\)](#), [krb5.conf\(4\)](#), [pam.conf\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [krb5_auth_rules\(5\)](#), [pam_authtok_check\(5\)](#), [pam_authtok_get\(5\)](#), [pam_authtok_store\(5\)](#), [pam_dhkeys\(5\)](#), [pam_passwd_auth\(5\)](#), [pam_unix_account\(5\)](#), [pam_unix_auth\(5\)](#), [pam_unix_session\(5\)](#), [smf\(5\)](#)

System Administration Guide: Security Services

Diagnostics All diagnostic messages are returned on the connection associated with the `stderr`, after which any network connections are closed. An error is indicated by a leading byte with a value of 1.

Hostname for your address unknown. No entry in the host name database existed for the client's machine.

Try again. A *fork* by the server failed.

/usr/bin/sh: ... The user's login shell could not be started.

Notes The authentication procedure used here assumes the integrity of each client machine and the connecting medium. This is insecure, but it is useful in an "open" environment.

A facility to allow all data exchanges to be encrypted should be present.

The `pam_unix(5)` module is no longer supported. Similar functionality is provided by [pam_authtok_check\(5\)](#), [pam_authtok_get\(5\)](#), [pam_authtok_store\(5\)](#), [pam_dhkeys\(5\)](#), [pam_passwd_auth\(5\)](#), [pam_unix_account\(5\)](#), [pam_unix_auth\(5\)](#), and [pam_unix_session\(5\)](#).

The `in.rlogind` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/login:rlogin (rlogin)
svc:/network/login:klogin (rlogin with kerberos)
svc:/network/login:eklogin (rlogin with kerberos and encryption)
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). Responsibility for initiating and restarting this service is delegated to [inetd\(1M\)](#). Use [inetadm\(1M\)](#) to make configuration changes and to view configuration information for this service. The service's status can be queried using the [svcs\(1\)](#) command.

Name in.routed, routed – network routing daemon

Synopsis /usr/sbin/in.routed [-AdghmnqsStVz] [-T *tracefile* [-v]]
[-F *net*[/mask][,metric]] [-P *params*]

Description The daemon `in.routed`, often referred to as `routed`, is invoked at boot time to manage the network routing tables. It uses Routing Information Protocol, RIPv1 (RFC 1058), RIPv2 (RFC 2453), and Internet Router Discovery Protocol (RFC 1256) to maintain the kernel routing table. The RIPv1 protocol is based on the reference 4.3BSD daemon.

`in.routed` is managed by means of the service management facility (SMF), using the fault management resource identifier (FMRI):

```
svc:/network/routing/route:default
```

The daemon listens on a udp socket for the `route` service (see [services\(4\)](#)) for Routing Information Protocol packets. It also sends and receives multicast Router Discovery ICMP messages. If the host is a router, `in.routed` periodically supplies copies of its routing tables to any directly connected hosts and networks. It also advertises or solicits default routes using Router Discovery ICMP messages.

When started (or when a network interface is later turned on), `in.routed` uses an `AF_ROUTE` address family facility to find those directly connected interfaces configured into the system and marked “up”. It adds necessary routes for the interfaces to the kernel routing table. Soon after being first started, and provided there is at least one interface on which RIP has not been disabled, `in.routed` deletes all pre-existing non-static routes in the kernel table. Static routes in the kernel table are preserved and included in RIP responses if they have a valid RIP metric (see [route\(1M\)](#)).

If more than one interface is present (not counting the loopback interface), it is assumed that the host should forward packets among the connected networks. After transmitting a RIP request and Router Discovery Advertisements or Solicitations on a new interface, the daemon enters a loop, listening for RIP request and response and Router Discovery packets from other hosts.

When a request packet is received, `in.routed` formulates a reply based on the information maintained in its internal tables. The response packet generated contains a list of known routes, each marked with a “hop count” metric (a count of 16 or greater is considered “infinite”). Advertised metrics reflect the metric associated with an interface (see [ifconfig\(1M\)](#)), so setting the metric on an interface is an effective way to steer traffic.

Responses do not include routes with a first hop on the requesting network, to implement in part split-horizon. Requests from query programs such as [rtquery\(1M\)](#) are answered with the complete table.

The routing table maintained by the daemon includes space for several gateways for each destination to speed recovery from a failing router. RIP response packets received are used to

update the routing tables, provided they are from one of the several currently recognized gateways or advertise a better metric than at least one of the existing gateways.

When an update is applied, `in.routed` records the change in its own tables and updates the kernel routing table if the best route to the destination changes. The change in the kernel routing table is reflected in the next batch of response packets sent. If the next response is not scheduled for a while, a flash update response containing only recently changed routes is sent.

In addition to processing incoming packets, `in.routed` also periodically checks the routing table entries. If an entry has not been updated for 3 minutes, the entry's metric is set to infinity and marked for deletion. Deletions are delayed until the route has been advertised with an infinite metric to insure the invalidation is propagated throughout the local internet. This is a form of poison reverse.

Routes in the kernel table that are added or changed as a result of ICMP Redirect messages are deleted after a while to minimize black-holes. When a TCP connection suffers a timeout, the kernel tells `in.routed`, which deletes all redirected routes through the gateway involved, advances the age of all RIP routes through the gateway to allow an alternate to be chosen, and advances the age of any relevant Router Discovery Protocol default routes.

Hosts acting as internetwork routers gratuitously supply their routing tables every 30 seconds to all directly connected hosts and networks. These RIP responses are sent to the broadcast address on nets that support broadcasting, to the destination address on point-to-point links, and to the router's own address on other networks. If RIPv2 is enabled, multicast packets are sent on interfaces that support multicasting.

If no response is received on a remote interface, if there are errors while sending responses, or if there are more errors than input or output (see [netstat\(1M\)](#)), then the cable or some other part of the interface is assumed to be disconnected or broken, and routes are adjusted appropriately.

The Internet Router Discovery Protocol is handled similarly. When the daemon is supplying RIP routes, it also listens for Router Discovery Solicitations and sends Advertisements. When it is quiet and listening to other RIP routers, it sends Solicitations and listens for Advertisements. If it receives a good Advertisement and it is not multi-homed, it stops listening for broadcast or multicast RIP responses. It tracks several advertising routers to speed recovery when the currently chosen router dies. If all discovered routers disappear, the daemon resumes listening to RIP responses. It continues listening to RIP while using Router Discovery if multi-homed to ensure all interfaces are used.

The Router Discovery standard requires that advertisements have a default “lifetime” of 30 minutes. That means should something happen, a client can be without a good route for 30 minutes. It is a good idea to reduce the default to 45 seconds using `-P rdisc_interval=45` on the command line or `rdisc_interval=45` in the `/etc/gateways` file. See [gateways\(4\)](#).

While using Router Discovery (which happens by default when the system has a single network interface and a Router Discover Advertisement is received), there is a single default route and a variable number of redirected host routes in the kernel table. On a host with more than one network interface, this default route will be via only one of the interfaces. Thus, multi-homed hosts running with `-q` might need the `no_rdisc` argument described below.

To support “legacy” systems that can handle neither RIPv2 nor Router Discovery, you can use the `pm_rdisc` parameter in the `/etc/gateways`. See [gateways\(4\)](#).

By default, neither Router Discovery advertisements nor solicitations are sent over point-to-point links (for example, PPP). The Solaris OE uses a netmask of all ones (255.255.255.255) on point-to-point links.

`in.routed` supports the notion of “distant” passive or active gateways. When the daemon is started, it reads the file `/etc/gateways` to find such distant gateways that cannot be located using only information from a routing socket, to discover if some of the local gateways are passive, and to obtain other parameters. Gateways specified in this manner should be marked passive if they are not expected to exchange routing information, while gateways marked active should be willing to exchange RIP packets. Routes through passive gateways are installed in the kernel's routing tables once upon startup and are not included in transmitted RIP responses.

Distant active gateways are treated like network interfaces. RIP responses are sent to the distant active gateway. If no responses are received, the associated route is deleted from the kernel table and RIP responses are advertised via other interfaces. If the distant gateway resumes sending RIP responses, the associated route is restored.

Distant active gateways can be useful on media that do not support broadcasts or multicasts but otherwise act like classic shared media, such as some ATM networks. One can list all RIP routers reachable on the HIPPI or ATM network in `/etc/gateways` with a series of “host” lines. Note that it is usually desirable to use RIPv2 in such situations to avoid generating lists of inferred host routes.

Gateways marked external are also passive, but are not placed in the kernel routing table, nor are they included in routing updates. The function of external entries is to indicate that another routing process will install such a route if necessary, and that other routes to that destination should not be installed by `in.routed`. Such entries are required only when both routers might learn of routes to the same destination.

Options Listed below are available options. Any other argument supplied is interpreted as the name of a file in which the actions of `in.routed` should be logged. It is better to use `-T` (described below) instead of appending the name of the trace file to the command. Associated SMF properties for these options are described, and can be set by means of a command of the form:

```
# routeadm -m route:default name=value
```

-
- A
Do not ignore RIPv2 authentication if we do not care about RIPv2 authentication. This option is required for conformance with RFC 2453. However, it makes no sense and breaks using RIP as a discovery protocol to ignore all RIPv2 packets that carry authentication when this machine does not care about authentication. This option is equivalent to setting the `ignore_auth` property value to `false`.
- d
Do not run in the background. This option is meant for interactive use and is not usable under the SMF.
- F *net* [*/mask*] [*,metric*]
Minimize routes in transmissions via interfaces with addresses that match *net* (network number)/*mask* (netmask), and synthesizes a default route to this machine with the *metric*. The intent is to reduce RIP traffic on slow, point-to-point links, such as PPP links, by replacing many large UDP packets of RIP information with a single, small packet containing a “fake” default route. If *metric* is absent, a value of 14 is assumed to limit the spread of the “fake” default route. This is a dangerous feature that, when used carelessly, can cause routing loops. Notice also that more than one interface can match the specified network number and mask. See also -g. Use of this option is equivalent to setting the `minimize_routes` property.
- g
Used on internetwork routers to offer a route to the “default” destination. It is equivalent to -F 0/0, 1 and is present mostly for historical reasons. A better choice is -P `pm_rdisc` on the command line or `pm_rdisc` in the `/etc/gateways` file. A larger metric will be used with the latter alternatives, reducing the spread of the potentially dangerous default route. The -g (or -P) option is typically used on a gateway to the Internet, or on a gateway that uses another routing protocol whose routes are not reported to other local routers. Note that because a metric of 1 is used, this feature is dangerous. Its use more often creates chaos with a routing loop than solves problems. Use of this option is equivalent to setting the `offer_default_route` property to `true`.
- h
Causes host or point-to-point routes not to be advertised, provided there is a network route going the same direction. That is a limited kind of aggregation. This option is useful on gateways to LANs that have other gateway machines connected with point-to-point links such as SLIP. Use of this option is equivalent to setting the `advertise_host_routes` property to `false`.
- m
Cause the machine to advertise a host or point-to-point route to its primary interface. It is useful on multi-homed machines such as NFS servers. This option should not be used except when the cost of the host routes it generates is justified by the popularity of the server. It is effective only when the machine is supplying routing information, because there is more than one interface. The -m option overrides the -q option to the limited extent

of advertising the host route. Use of this option is equivalent to setting the `advertise_host_routes_primary` property to true.

-n

Do not install routes in kernel. By default, routes are installed in the kernel. Use of this option is equivalent to setting the `install_routes` property to false.

-P *params*

Equivalent to adding the parameter line *params* to the `/etc/gateways` file. Can also be set by means of the `parameters` property.

-q

Opposite of the `-s` option. This is the default when only one interface is present. With this explicit option, the daemon is always in “quiet mode” for RIP and does not supply routing information to other computers. Use of this option is equivalent to setting the `quiet_mode` property to true.

-s

Force `in.routed` to supply routing information. This is the default if multiple network interfaces are present on which RIP or Router Discovery have not been disabled, and if the `/dev/ip` ndd variable `ip_forwarding` is set to 1. Use of this option is equivalent to setting the `supply_routes` property to true.

-S

If `in.routed` is not acting as an internetwork router, instead of entering the whole routing table in the kernel, it enters only a default route for each internetwork router. This reduces the memory requirements without losing any routing reliability. This option is provided for compatibility with the previous, RIPv1-only `in.routed`. Use of this option is generally discouraged. Use of this option is equivalent to setting the `default_routes_only` property to true.

-t

Runs in the foreground (as with `-d`) and logs the contents of the packets received (as with `-zz`). This is for compatibility with prior versions of Solaris and has no SMF equivalent.

-T *tracefile*

Increases the debugging level to at least 1 and causes debugging information to be appended to the trace file. Because of security concerns, do not to run `in.routed` routinely with tracing directed to a file. Use of this option is equivalent to setting the `log_file` property to `trace file path`.

-v

Enables debug. Similar to `-z`, except, where `-z` increments `trace_level`, `-v` sets `trace_level` to 1. Also, `-v` requires the `-T` option. Use of this option is equivalent to setting the `debug` property to true.

-V

Displays the version of the daemon.

-z

Increase the debugging level, which causes more information to be logged on the tracefile specified with -T or stdout. The debugging level can be increased or decreased with the SIGUSR1 or SIGUSR2 signals or with the `rtquery(1M)` command.

Files `/etc/defaultrouter` If this file is present and contains the address of a default router, the system startup script does not run `in.routed`. See `defaultrouter(4)`.

`/etc/gateways` List of distant gateways and general configuration options for `in.routed`. See `gateways(4)`.

Attributes See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------|------------------------|
| Availability | system/network/routing |

See Also `route(1M)`, `routeadm(1M)`, `rtquery(1M)`, `svcadm(1M)`, `ioctl(2)`, `inet(3SOCKET)`, `defaultrouter(4)`, `gateways(4)`, `attributes(5)`, `icmp(7P)`, `inet(7P)`, `udp(7P)`

Internet Transport Protocols, X SIS 028112, Xerox System Integration Standard

Routing Information Protocol, v2 (RFC 2453, STD 0056, November 1998)

RIP-v2 MD5 Authentication (RFC 2082, January 1997)

Routing Information Protocol, v1 (RFC 1058, June 1988)

ICMP Router Discovery Messages (RFC 1256, September 1991)

Notes In keeping with its intended design, this daemon deviates from RFC 2453 in two notable ways:

- By default, `in.routed` does not discard authenticated RIPv2 messages when RIP authentication is not configured. There is little to gain from dropping authenticated packets when RIPv1 listeners will gladly process them. Using the -A option causes `in.routed` to conform to the RFC in this case.
- Unauthenticated RIP requests are never discarded, even when RIP authentication is configured. Forwarding tables are not secret and can be inferred through other means such as test traffic. RIP is also the most common router-discovery protocol, and hosts need to send queries that will be answered.

`in.routed` does not always detect unidirectional failures in network interfaces, for example, when the output side fails.

Name in.rshd, rshd – remote shell server

Synopsis in.rshd [-k5eciU] [-s *tos*] [-S *keytab*] [-M *realm*]
[-L *env_var*] *host.port*

Description in.rshd is the server for the [rsh\(1\)](#) program. The server provides remote execution facilities with authentication based on Kerberos V5 or privileged port numbers.

in.rshd is invoked by [inetd\(1M\)](#) each time a shell service is requested.

When Kerberos V5 authentication is required (this can be set with Kerberos-specific options listed below), the following protocol is initiated:

1. Check Kerberos V5 authentication.
2. Check authorization according to rules in [krb5_auth_rules\(5\)](#).
3. A null byte is returned on the initial socket and the command line is passed to the normal login shell of the user. (The PATH variable is set to `/usr/bin`.) The shell inherits the network connections established by in.rshd.

In order for Kerberos authentication to work, a host/*<FQDN>* Kerberos principal must exist for each Fully Qualified Domain Name associated with the in.rshd server. Each of these host/*<FQDN>* principals must have a keytab entry in the `/etc/krb5/krb5.keytab` file on the in.rshd server. An example principal might be:

```
host/bigmachine.eng.example.com
```

See [kadmin\(1M\)](#) or [gkadmin\(1M\)](#) for instructions on adding a principal to a `krb5.keytab` file. See *System Administration Guide: Security Services* for a discussion of Kerberos authentication.

If Kerberos V5 authentication is not enabled, then in.rshd executes the following protocol:

1. The server checks the client's source port. If the port is not in the range 512-1023, the server aborts the connection. The client's host address (in hex) and port number (in decimal) are the arguments passed to in.rshd.
2. The server reads characters from the socket up to a null (`\0`) byte. The resultant string is interpreted as an ASCII number, base 10.
3. If the number received in step 2 is non-zero, it is interpreted as the port number of a secondary stream to be used for the `stderr`. A second connection is then created to the specified port on the client's machine. The source port of this second connection is also in the range 512-1023.
4. A null-terminated user name of at most 16 characters is retrieved on the initial socket. This user name is interpreted as the user identity on the *client's* machine.
5. A null terminated user name of at most 16 characters is retrieved on the initial socket. This user name is interpreted as a user identity to use on the *server's* machine.

6. A null terminated command to be passed to a shell is retrieved on the initial socket. The length of the command is limited by the upper bound on the size of the system's argument list.
7. `in.rshd` then validates the user according to the following steps. The remote user name is looked up in the password file and a `chdir` is performed to the user's home directory. If the lookup fails, the connection is terminated. If the `chdir` fails, it does a `chdir` to `/` (root). If the user is not the superuser, (user ID 0), and if the `pam_rhosts_auth` PAM module is configured for authentication, the file `/etc/hosts.equiv` is consulted for a list of hosts considered "equivalent". If the client's host name is present in this file, the authentication is considered successful. See the SECURITY section below for a discussion of PAM authentication.

If the lookup fails, or the user is the superuser, then the file `.rhosts` in the home directory of the remote user is checked for the machine name and identity of the user on the client's machine. If this lookup fails, the connection is terminated

8. A null byte is returned on the initial connection and the command line is passed to the normal login shell of the user. The `PATH` variable is set to `/usr/bin`. The shell inherits the network connections established by `in.rshd`.

Options The following options are supported:

- 5 Same as `-k`, for backwards compatibility
- c Requires Kerberos V5 clients to present a cryptographic checksum of initial connection information like the name of the user that the client is trying to access in the initial authenticator. This checksum provides additional security by preventing an attacker from changing the initial connection information. This option is mutually exclusive with the `-i` option.
- e Requires the client to encrypt the connection.
- i Ignores authenticator checksums if provided. This option ignores authenticator checksums presented by current Kerberos clients to protect initial connection information. Option `-i` is the opposite of option `-c`.
- k Allows Kerberos V5 authentication with the `.k5login` access control file to be trusted. If this authentication system is used by the client and the authorization check is passed, then the user is allowed to log in.
- L *env_var* List of environment variables that need to be saved and passed along.
- M *realm* Uses the indicated Kerberos V5 realm. By default, the daemon will determine its realm from the settings in the `krb5.conf(4)` file.
- s *tos* Sets the IP TOS option.
- S *keytab* Sets the KRB5 keytab file to use. The `/etc/krb5/krb5.keytab` file is used by default.

-U Refuses connections that cannot be mapped to a name through the [getnameinfo\(3SOCKET\)](#) function.

Usage rshd and in.rshd are IPv6-enabled. See [ip6\(7P\)](#). IPv6 is not currently supported with Kerberos V5 authentication.

The Kerberized rshd service runs on port 544 (kshell). The corresponding FMRI entry is :
 svc:/network/shell:kshell (rshd with kerberos (ipv4 only))

Security in.rshd uses [pam\(3PAM\)](#) for authentication, account management, and session management. The PAM configuration policy, listed through /etc/pam.conf, specifies the modules to be used for in.rshd. Here is a partial pam.conf file with entries for the rsh command using rhosts authentication, UNIX account management, and session management module.

| | | | |
|-----|---------|----------|------------------------|
| rsh | auth | required | pam_rhosts_auth.so.1 |
| rsh | account | required | pam_unix_roles.so.1 |
| rsh | session | required | pam_unix_projects.so.1 |
| rsh | session | required | pam_unix_account.so.1 |
| rsh | session | required | pam_unix_session.so.1 |

If there are no entries for the rsh service, then the entries for the “other” service are used. To maintain the authentication requirement for in.rshd, the rsh entry must always be configured with the pam_rhosts_auth.so.1 module.

in.rshd can authenticate using Kerberos V5 authentication or [pam\(3PAM\)](#). For Kerberized rsh service, the appropriate PAM service name is krsh.

Files /etc/hosts.equiv

\$HOME/.k5login File containing Kerberos principals that are allowed access.

/etc/krb5/krb5.conf Kerberos configuration file.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|---------------------------------|
| Availability | service/network/network-servers |

See Also [rsh\(1\)](#), [svcs\(1\)](#), [gkadmin\(1M\)](#), [inetadm\(1M\)](#), [inetd\(1M\)](#), [kadmin\(1M\)](#), [svcadm\(1M\)](#), [pam\(3PAM\)](#), [getnameinfo\(3SOCKET\)](#), [hosts\(4\)](#), [krb5.conf\(4\)](#), [pam.conf\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [krb5_auth_rules\(5\)](#), [pam_authtok_check\(5\)](#), [pam_authtok_get\(5\)](#), [pam_authtok_store\(5\)](#), [pam_dhkeys\(5\)](#), [pam_passwd_auth\(5\)](#), [pam_rhosts_auth\(5\)](#), [pam_unix_account\(5\)](#), [pam_unix_auth\(5\)](#), [pam_unix_session\(5\)](#), [smf\(5\)](#), [ip6\(7P\)](#)

System Administration Guide: Security Services

Diagnostics The following diagnostic messages are returned on the connection associated with `stderr`, after which any network connections are closed. An error is indicated by a leading byte with a value of 1 in step 8 above (0 is returned above upon successful completion of all the steps prior to the command execution).

| | |
|------------------------------------|------------------------------------------------------------------------------------------------|
| locuser too long | The name of the user on the client's machine is longer than 16 characters. |
| remuser too long | The name of the user on the remote machine is longer than 16 characters. |
| command too long | The command line passed exceeds the size of the argument list (as configured into the system). |
| Hostname for your address unknown. | No entry in the host name database existed for the client's machine. |
| Login incorrect. | No password file entry for the user name existed. |
| Permission denied. | The authentication procedure described above failed. |
| Can't make pipe. | The pipe needed for the <code>stderr</code> was not created. |
| Try again. | A <i>fork</i> by the server failed. |

Notes The authentication procedure used here assumes the integrity of each client machine and the connecting medium. This is insecure, but it is useful in an “open” environment.

A facility to allow all data exchanges to be encrypted should be present.

The `pam_unix(5)` module is no longer supported. Similar functionality is provided by [pam_authtok_check\(5\)](#), [pam_authtok_get\(5\)](#), [pam_authtok_store\(5\)](#), [pam_dhkeys\(5\)](#), [pam_passwd_auth\(5\)](#), [pam_unix_account\(5\)](#), [pam_unix_auth\(5\)](#), and [pam_unix_session\(5\)](#).

The `in.rshd` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/shell:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). Responsibility for initiating and restarting this service is delegated to [inetd\(1M\)](#). Use [inetadm\(1M\)](#) to make configuration changes and to view configuration information for this service. The service's status can be queried using the [svcs\(1\)](#) command.

Name in.rwhod, rwhod – system status server

Synopsis /usr/sbin/in.rwhod [-m *[ttl]*]

Description in.rwhod is the server which maintains the database used by the [rwho\(1\)](#) and [ruptime\(1\)](#) programs. Its operation is predicated on the ability to broadcast or multicast messages on a network.

in.rwhod operates as both a producer and consumer of status information. As a producer of information it periodically queries the state of the system and constructs status messages which are broadcast or multicast on a network. As a consumer of information, it listens for other in.rwhod servers' status messages, validating them, then recording them in a collection of files located in the directory `/var/spool/rwho`.

The rwho server transmits and receives messages at the port indicated in the rwho service specification, see [services\(4\)](#). The messages sent and received are defined in `/usr/include/protocols/rwhod.h` and are of the form:

```
struct outmp {
    char    out_line[8];    /* tty name */
    char    out_name[8];    /* user id */
    long    out_time;      /* time on */
};
struct whod {
    char    wd_vers;
    char    wd_type;
    char    wd_fill[2];
    int     wd_sendtime;
    int     wd_recvtime;
    char    wd_hostname[32];
    int     wd_loadav[3];
    int     wd_bovertime;
    struct  whoent {
        struct outmp we_utmp;
        int     we_idle;
    } wd_we[1024 / sizeof (struct whoent)];
};
```

All fields are converted to network byte order prior to transmission. The load averages are as calculated by the [w\(1\)](#) program, and represent load averages over the 1, 5, and 15 minute intervals prior to a server's transmission. The host name included is that returned by the [uname\(2\)](#) system call. The array at the end of the message contains information about the users who are logged in to the sending machine. This information includes the contents of the [utmpx\(4\)](#) entry for each non-idle terminal line and a value indicating the time since a character was last received on the terminal line.

Messages received by the `rwho` server are discarded unless they originated at a `rwho` server's port. In addition, if the host's name, as specified in the message, contains any unprintable ASCII characters, the message is discarded. Valid messages received by `in.rwhod` are placed in files named `whod.hostname` in the directory `/var/spool/rwho`. These files contain only the most recent message, in the format described above.

Status messages are generated approximately once every 3 minutes.

Options The following options are supported:

`-m [ttl]` Use the `rwho` IP multicast address (224.0.1.3) when transmitting. Receive announcements both on this multicast address and on the IP broadcast address. If `ttl` is not specified in `.rwhod` multicasts on all interfaces but with the IP TimeToLive set to 1 (that is, packets are not forwarded by multicast routers.) If `ttl` is specified in `.rwhod` only transmits packets on one interface and setting the IP TimeToLive to the specified `ttl`.

Files `/var/spool/rwho/whod.*` information about other machines

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|---------------------------------|
| Availability | service/network/network-servers |

See Also [ruptime\(1\)](#), [rwho\(1\)](#), [w\(1\)](#), [uname\(2\)](#), [services\(4\)](#), [utmpx\(4\)](#), [attributes\(5\)](#)

Warnings This service can cause network performance problems when used by several hosts on the network. It is not run at most sites by default. If used, include the `-m` multicast option.

Notes This service takes up progressively more network bandwidth as the number of hosts on the local net increases. For large networks, the cost becomes prohibitive.

`in.rwhod` should relay status information between networks. People often interpret the server dying as a machine going down.

Name install – install commands

Synopsis /usr/sbin/install -c *dira* [-m *mode*] [-u *user*] [-g *group*]
 [-o] [-s] *file*

/usr/sbin/install -f *dirb* [-m *mode*] [-u *user*] [-g *group*]
 [-o] [-s] *file*

/usr/sbin/install -n *dirc* [-m *mode*] [-u *user*] [-g *group*]
 [-o] [-s] *file*

/usr/sbin/install -d | -i [-m *mode*] [-u *user*] [-g *group*]
 [-o] [-s] *dirx...*

/usr/sbin/install [-m *mode*] [-u *user*] [-g *group*] [-o] [-s] *file*
 [*dirx*]...

Description install is most commonly used in “makefiles” (see [make\(1S\)](#)) to install a file in specific locations, or to create directories within a file system. Each file is installed by copying it into the appropriate directory.

install uses no special privileges to copy files from one place to another. The implications of this are:

- You must have permission to read the files to be installed.
- You must have permission to copy into the destination directory.
- You must have permission to change the modes on the final copy of the file if you want to use the -m option.
- You must be super-user if you want to specify the ownership of the installed file with the -u or -g options. If you are not the super-user, the installed file is owned by you, regardless of who owns the original.

Note that if the ROOT environment variable is set, each of the default directory paths are prefixed by its value (for example, \$ROOT/bin and so on).

install prints messages telling the user exactly what files it is replacing or creating and where they are going.

If no options or directories (*dirx...*) are given, install searches a set of default directories (/bin, /usr/bin, /etc, /lib, and /usr/lib, in that order) for a file with the same name as *file*. When the first occurrence is found, install issues a message saying that it is overwriting that file with *file*, and proceeds to do so. If the file is not found, the program states this and exits.

If one or more directories (*dirx...*) are specified after *file*, those directories are searched before the default directories.

This version of install (/usr/sbin/install) is not compatible with the install binaries in many versions of Unix other than Solaris. For a higher degree of compatibility with other Unix versions, use /usr/ucb/install, which is described in the [install\(1B\)](#) man page.

Options The following options are supported:

- c *dira* Install *file* in the directory specified by *dira*, if *file* does not yet exist. If it is found, *install* issues a message saying that the file already exists, and exits without overwriting it.
- f *dirb* Force *file* to be installed in given directory, even if the file already exists. If the file being installed does not already exist, the mode and owner of the new file is set to 755 and *bin*, respectively. If the file already exists, the mode and owner is that of the already existing file.
- n *dirc* If *file* is not found in any of the searched directories, it is put in the directory specified in *dirc*. The mode and owner of the new file is set to 755 and *bin*, respectively.
- d Create a directory. Missing parent directories are created as required as in *mkdir -p*. If the directory already exists, the owner, group and mode is set to the values given on the command line.
- i Ignore default directory list, searching only through the given directories (*dirx ...*).
- m *mode* The mode of the new file is set to *mode*. Set to 0755 by default.
- u *user* The owner of the new file is set to *user*. Only available to the super-user. Set to *bin* by default.
- g *group* The group id of the new file is set to *group*. Only available to the super-user. Set to *bin* by default.
- o If *file* is found, save the “found” file by copying it to *OLDfile* in the directory in which it was found. This option is useful when installing a frequently used file such as */bin/sh* or */lib/saf/ttymon*, where the existing file cannot be removed.
- s Suppress printing of messages other than error messages.

Usage See [largefile\(5\)](#) for the description of the behavior of *install* when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [chgrp\(1\)](#), [chmod\(1\)](#), [chown\(1\)](#), [cp\(1\)](#), [install\(1B\)](#), [make\(1S\)](#), [mkdir\(1\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

- Name** installboot – install bootblocks in a disk partition
- Synopsis** `installboot [-F zfs|ufs|hsfs] bootblk raw-disk-device`
- Description** The `boot(1M)` program, `ufsboot`, is loaded from disk by the bootblock program which resides in the boot area of a disk partition. This program is filesystem-specific, and must match the type of filesystem on the disk to be booted.
- The boot objects are platform-dependent and reside in the `/usr/platform/platform-name/lib/fs/file-system` directory. The platform name can be found using the `-i` option of `uname(1)`. The filesystem type can be found using:
- ```
% fstyp raw-disk-device
```
- See `fstyp(1M)`.
- The `installboot` utility is a SPARC only program. It is not supported on the x86 architecture. x86 users should use `installgrub(1M)` instead.
- Options** The following option is supported:
- ```
-F zfs|ufs|hsfs
```
- Specifies the file system type of the boot block to be installed. Required if you wish to specify `zfs` or `hsfs`. The default is `ufs`.
- Operands** *bootblk*
The name of the bootblock code.
- raw-disk-device*
The name of the disk device onto which the bootblock code is to be installed; it must be a character device which is readable and writable. Naming conventions for a SCSI or IPI drive are `c?t?d?s?` and `c?d?s?` for an IDE drive.
- Examples** **EXAMPLE 1** Installing UFS Boot Block
- To install a `ufs` boot block on slice 0 of target 0 on controller 1 of the platform where the command is being run, use:
- ```
installboot /usr/platform/'uname -i'/lib/fs/ufs/bootblk \
 /dev/rdisk/c1t0d0s0
```
- EXAMPLE 2** Installing ZFS Boot Block
- To install a `ZFS` boot block on slice 0 of target 0 on controller 1 of the platform where the command is being run, use syntax such as the following:
- ```
# installboot -F zfs /usr/platform/'uname -i'/lib/fs/zfs/bootblk \  
  /dev/rdisk/c1t1d0s0
```

Files /usr/platform/*platform-name*/lib/fs/ Directory where boot objects reside.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [kmdb\(1\)](#), [od\(1\)](#), [uname\(1\)](#), [boot\(1M\)](#), [fstyp\(1M\)](#), [init\(1M\)](#), [kernel\(1M\)](#), [monitor\(1M\)](#), [reboot\(1M\)](#), [rpc.bootparamd\(1M\)](#), [init.d\(4\)](#), [attributes\(5\)](#)

Warnings The `installboot` utility fails if the *bootblk* or *openfirmware* files do not exist or if the raw disk device is not a character device.

Name installer – Solaris Web Start installer utility

Synopsis `installer [-locales list] [-nodisplay] [-noconsole]`
`[-debug]`

Description The `installer` utility invokes a Web Start install wizard sequence which will lead the user through a sequence of installation panels. This installer utility is found on many CDs that are shipped with Solaris and it will be found among the top level files of these CDs.

When the installer is on a CD being accessed from a desktop file manager, the installer can be double clicked to start the installation sequence. If the user is not currently the system's root user, the root user password will be requested.

The installer utility can also be run from other UNIX scripts. Usually, a script is used in conjunction with the utility's `-nodisplay` option. Add the `-noconsole` option for non-interactive scripts.

Options The following options are supported:

`-locales list` Selects product translations for install, corresponding to the specified list of locales if the specified locale translations are present on the installation media. Locales are supplied in a comma-separated list following the `-locales` option. An example *list* would appear as follows:

```
installer -locales fr,de,it
```

This would install products with translations for the French, German, and Italian locales.

`-nodisplay` Runs the install without a graphical user interface. Use the default product install unless it was modified by the `-locales` options.

`-noconsole` Run the install without any interactive text console device. Useful when paired with `-nodisplay` for non-interactive UNIX script use.

`-debug` Outputs extra information about what the install is doing. Mainly for install diagnostic purposes.

Files `/var/sadm/install/logs` location of installation log files

See Also [prodreg\(1M\)](#)

Name installf – add a file to the software installation database

Synopsis `installf [-c class] [[-M] -R root_path] [-V fs_file] pkginst pathname`
`[ftype [major minor] [mode owner group]]`

`installf [-c class] [[-M] -R root_path] [-V fs_file] pkginst -`

`installf -f [-c class] [[-M] -R root_path] [-V fs_file] pkginst`

Description `installf` informs the system that a pathname not listed in the `pkgmap(4)` file is being created or modified. It should be invoked before any file modifications have occurred.

When the second synopsis is used, the pathname descriptions will be read from standard input. These descriptions are the same as would be given in the first synopsis but the information is given in the form of a list. The descriptions should be in the form:

```
pathname [ftype [ major minor ] [ mode owner group ] ]
```

After all files have been appropriately created and/or modified, `installf` should be invoked with the `-f` synopsis to indicate that installation is final. Links will be created at this time and, if attribute information for a pathname was not specified during the original invocation of `installf`, or was not already stored on the system, the current attribute values for the pathname will be stored. Otherwise, `installf` verifies that attribute values match those given on the command line, making corrections as necessary. In all cases, the current content information is calculated and stored appropriately.

Package commands are `largefile(5)`-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, `pkgadd(1M)`, `pkgtrans(1)` and other package commands can process a datastream of up to 4 GB.

- Options**
- `-c class` Class to which installed objects should be associated. Default class is none.
 - `-f` Indicates that installation is complete. This option is used with the final invocation of `installf` (for all files of a given class).
 - `-M` Instruct `installf` not to use the `$root_path/etc/vfstab` file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.
 - `-R root_path` Define the full path name of a directory to use as the `root_path`. All files, including package system information files, are relocated to a directory tree starting in the specified `root_path`. The `root_path` can be specified when installing to a client from a server (for example, `/export/root/client1`).
- `installf` inherits the value of the `PKG_INSTALL_ROOT` environment variable. (See ENVIRONMENT VARIABLES, below.) If `PKG_INSTALL_ROOT` is set, such as when the `-R` option is used with `pkgadd(1M)` or `pkgrm(1M)`

| | | |
|-----------------|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | | Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5) . |
| | <i>-V fs_file</i> | Specify an alternative <i>fs_file</i> to map the client's file systems. For example, used in situations where the <i>\$root_path/etc/vfstab</i> file is non-existent or unreliable. |
| Operands | <i>pkginst</i> | Name of package instance with which the pathname should be associated. |
| | <i>pathname</i> | Pathname that is being created or modified. |
| | <i>ftype</i> | A one-character field that indicates the file type. Possible file types include: <ul style="list-style-type: none"> b block special device c character special device d directory e a file to be edited upon installation or removal f a standard executable or data file l linked file p named pipe s symbolic link v volatile file (one whose contents are expected to change) x an exclusive directory |
| | <i>major</i> | The major device number. The field is only specified for block or character special devices. |
| | <i>minor</i> | The minor device number. The field is only specified for block or character special devices. |
| | <i>mode</i> | The octal mode of the file (for example, 0664). A question mark (?) indicates that the mode will be left unchanged, implying that the file already exists on the target machine. This field is not used for linked or symbolically linked files. |
| | <i>owner</i> | The owner of the file (for example, bin or root). The field is limited to 14 characters in length. A question mark (?) indicates that the owner will be left unchanged, implying that the file already exists on the target machine. This field is not used for linked or symbolically linked files. |
| | <i>group</i> | The group to which the file belongs (for example, bin or sys). The field is limited to 14 characters in length. A question mark (?) indicates that the group will be left unchanged, implying that the file already exists on the target |

machine. This field is not used for linked or symbolically linked files.

Examples **EXAMPLE 1** Basic Usage

The following example shows the use of `installf`, invoked from an optional pre-install or post-install script:

```
# create /dev/xt directory
# (needs to be done before drvininstall)
installf $PKGINST /dev/xt d 755 root sys ||
    exit 2
majno='/usr/sbin/drvininstall -m /etc/master.d/xt
    -d $BASEDIR/data/xt.o -v1.0' ||
    exit 2
i=00
while [ $i -lt $limit ]
do
    for j in 0 1 2 3 4 5 6 7
    do
        echo /dev/xt$i$j c $majno 'expr $i ? 8 + $j'
        644 root sys |
        echo /dev/xt$i$j=/dev/xt/$i$j
    done
    i='expr $i + 1'
    [ $i -le 9 ] && i="0$i" #add leading zero
done | installf $PKGINST - || exit 2
# finalized installation, create links
installf -f $PKGINST || exit 2
```

Environment Variables `installf` inherits the value of the following environment variable. This variable is set when `pkgadd(1M)` or `pkgrm(1M)` is invoked with the `-R` option.

PKG_INSTALL_ROOT If present, defines the full path name of a directory to use as the system's `PKG_INSTALL_ROOT` path. All product and package information files are then looked for in the directory tree, starting with the specified `PKG_INSTALL_ROOT` path. If not present, the default system path of `/` is used.

Exit Status `0` Successful operation.
`>0` An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [pkginfo\(1\)](#), [pkgmk\(1\)](#), [pkgparam\(1\)](#), [pkgproto\(1\)](#), [pkgtrans\(1\)](#), [pkgadd\(1M\)](#), [pkgask\(1M\)](#), [pkgchk\(1M\)](#), [pkgrm\(1M\)](#), [removef\(1M\)](#), [pkgmap\(4\)](#), [space\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

Application Packaging Developer's Guide

Notes When *f*type is specified, all applicable fields, as shown below, must be defined:

| <i>f</i> type | Required Fields |
|---------------------|------------------------------|
| p, x, d, f, v, or e | mode owner group |
| c or b | major minor mode owner group |

The `installf` command will create directories, named pipes and special devices on the original invocation. Links are created when `installf` is invoked with the `-f` option to indicate installation is complete.

Links should be specified as *path1=path2*. *path1* indicates the destination and *path2* indicates the source file.

Files installed with `installf` will be placed in the class `none`, unless a class is defined with the command. Subsequently, they will be removed when the associated package is deleted. If this file should not be deleted at the same time as the package, be certain to assign it to a class which is ignored at removal time. If special action is required for the file before removal, a class must be defined with the command and an appropriate class action script delivered with the package.

When classes are used, `installf` must be used in one of the following forms:

```
installf -c class1 . . .
installf -f -c class1 . . .
installf -c class2 . . .
installf -f -c class2 . . .
```

Name installgrub – install GRUB in a disk partition

Synopsis /sbin/installgrub [-fm] *stage1 stage2 raw-device*

Description The `installgrub` command is an x86-only program. GRUB stands for GRand Unified Bootloader.

`installgrub` installs GRUB stage 1 and stage 2 files on the boot area of a disk partition. If you specify the `-m` option, `installgrub` installs the stage 1 file on the master boot sector of the disk.

Options The `installgrub` command accepts the following options:

- f Suppresses interaction when overwriting the master boot sector.
- m Installs GRUB *stage1* on the master boot sector interactively. You must use this option if Solaris is installed on an extended partition.

Operands The `installgrub` command accepts the following operands:

- stage1* The name of the GRUB stage 1 file.
- stage2* The name of the GRUB stage 2 file.
- raw-device* The name of the device onto which GRUB code is to be installed. It must be a character device that is readable and writable. For disk devices, specify the slice where the GRUB menu file is located. (For Solaris it is the root slice.)

Examples EXAMPLE 1 Installing GRUB on a Hard Disk Slice

The following command installs GRUB on a system where the root slice is `c0d0s0`:

```
example# /sbin/installgrub /boot/grub/stage1 \
        /boot/grub/stage2 /dev/rdisk/c0d0s0
```

Files /boot/grub Directory where GRUB files reside.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | Uncommitted |

See Also [boot\(1M\)](#), [fdisk\(1M\)](#), [fmthard\(1M\)](#), [kernel\(1M\)](#), [attributes\(5\)](#)

Warnings Installing GRUB on the master boot sector (`-m` option) overrides any boot manager currently installed on the machine. The system will always boot the GRUB in the Solaris partition regardless of which `fdisk` partition is active.

Name `install_scripts`, `add_install_client`, `add_to_install_server`, `rm_install_client`, `setup_install_server`, `check` – scripts used to install the Solaris software

Synopsis `media-mnt-pt/Solaris_XX/Tools/add_install_client`

`media-mnt-pt/Solaris_XX/Tools/setup_install_server [-b]`
`[-t install_boot_image_path] [-w wanboot_image_path] install_dir_path`

Description These commands are located on slice 0 of the Solaris Software and Solaris Installer CDs or DVDs. (The terms “CD” and “DVD” are hereafter referred to as “installation media”.) If the Solaris installation media has been copied to a local disk, `media_mnt_pt` is the path to the copied Solaris installation media. They can be used for a variety of installation tasks.

The `XX` in `Solaris_XX` is the version number of the Solaris release being used.

There are three versions of the `add_install_client` command. See SYNOPSIS.

Use the following version of the `add_install_client` command to add clients for network installation (these commands update the `bootparams(4)` file). The `add_install_client` command must be run from the install server's Solaris installation image (a mounted Solaris

installation media or a Solaris installation media copied to disk) or the boot server's boot directory (if a boot server is required). The Solaris installation image or the boot directory must be the same Solaris release that you want installed on the client.

```
media-mnt-pt/Solaris_XX/Tools/add_install_client
  [-i IP_address]
  [-e Ethernet_address] [-s server_name : path]
  [-c server_name : path]
  [-n [server] : name_service [( netmask)]]
  [-p server_name : path] [-t install_boot_image_path]
  host_name platform_group
```

Use the following version of the `add_install_client` command to add support for instances of a platform within a platform group to the install server. This group is booted and configured using DHCP. The script performs the necessary configuration steps on the server, and prints the data that the user needs to add to the DHCP server for the group.

```
media-mnt-pt/Solaris_XX/Tools/add_install_client -d
  [-s server:path]
  [-c server:path] [-p server:path]
  [-t install_boot_image_path]
  [-t install_boot_image_path] [-f boot_file_name]
  platform_name platform_group
```

Use the following version of the `add_install_client` command to add a single client to the install server. This client is booted and configured using DHCP. The script performs the necessary configuration steps on the server, and prints the data that the user needs to add to the DHCP server for the client. The `-f` flag used above needs to be added to the existing usage as well. `-f` allows the user to specify a boot file name to be used for a given client.

```
media-mnt-pt/Solaris_XX /Tools/add_install_client -d
  [-s server_name:path]
  [-c server_name:path] [-p server_name:path]
  [-t install_boot_image_path] [-f boot_file_name]
  -e Ethernet_address platform_group
  [-b property=value] platform_group
```

Always use the `-d` option when registering x86 Architecture Pre-boot eXecution Environment (PXE) clients. These clients use DHCP for their configuration.

Use `add_to_install_server` to merge other Solaris installation media with an existing image on a Net Install Server. Each installation media that can be merged (each OS CD or DVD, and the Language CD or DVD) has its own `add_to_install_server` script. Do not use `add_to_install_server` scripts with installation media other than the ones with which they were delivered.

Use `check` to validate the rules in a `rules` file (this is only necessary if a custom JumpStart installation is being set up).

Use `rm_install_client` to remove clients for network installation (these commands update the `bootparams(4)` file).

Use `setup_install_server` to copy the Solaris installation media to a disk (to set up an install server), to build a WANboot miniroot image (to set up a WANboot install server), or to copy just the boot software of the Solaris installation media to a disk (to set up a boot server). An install server is required to install clients over the network. A boot server is also required for network installations if the install server and clients to be installed are on different subnets (the boot server must be located on the client's subnet).

Options The `add_install_client` supports the following options:

`-b property=value`

Set a property value in the client-specific menu. `lst` file located on the boot server's TFTP directory, `/tftpboot` by default. Use this option to set boot properties that are specific to this client.

Use this option only with an x86 client and only in conjunction with the `-d` and `-e` options.

`-c server_name:path`

This option is required only to specify a JumpStart directory for a custom JumpStart installation. `server_name` is the host name of the server with a JumpStart directory. `path` is the absolute path to the JumpStart directory.

`-d`

Specify as a DHCP client.

`-e Ethernet_address`

Specify the Ethernet address of the system to be installed.

`-f`

Specify the `boot_file_name` of the client to be installed.

`-i IP_address`

Specify the IP address of the client to be installed.

`-n [server]: name_service[(netmask)]`

This option specifies which name service should be used during system configuration. This sets the `ns` keyword in the `bootparams(4)` file.

name_service

Valid entries are `nis` and `none`.

netmask

A series of four numbers separated by periods, specifying which portion of an IP address is the network part, and which is the host part.

server

The name of the server or IP address of the specified name service. If the server specified is on a different subnet, then the `netmask` may be needed to enable the client to contact

the server.

-p *server_name: path*

This option is used to specify the NFS or ZFS shared directory that contains the user-defined `sysidcfg` file. When a client is booted, it attempts to read a file specifically named `sysidcfg` in this directory to obtain answers to the system and network identification questions. *server_name* is either a valid host name or IP address. *path* is the absolute pathname of the directory on the file server that contains the `sysidcfg` file.

-s *server_name: path*

This option is required only when using `add_install_client` from a boot server. Specify the name of the server and the absolute path of the Solaris installation image that is used for this installation. *path* is either the path to a mounted Solaris installation media or a path to a directory with a copy of the Solaris installation media.

-t

Allows you to specify an alternate miniroot

The `add_to_install_server` command supports the following options:

-p

Specifies the location of the installation media (containing the supplemental products) to be copied.

-s

Allows users to select from a list only the products needing installation.

The `check` command supports the following options:

-p *install_dir_path*

Validates the rules file by using the `check` script from a specified Solaris installation image, instead of the `check` script from the system you are using. *install_dir_path* is the path to a Solaris installation image on a local disk or a mounted Solaris installation media.

Use this option to run the most recent version of `check` if your system is running a previous version of Solaris.

-r *rulesfile*

Specifies a rules file other than the one named `rules`. Using this option, the validity of a rule can be tested before integrating it into the rules file. `check` reports whether or not the rule is valid, but it does not create the `rules.ok` file necessary for a custom JumpStart installation.

The `rm_install_client` command supports the following options:

-e *Ethernet_address*

Specify the Ethernet address of the system to be removed.

-f

Specify the *boot_file_name* of the client to be removed.

The `setup_install_server` command supports the following options:

- b
This option sets up the server only as a boot server.
- t
This option allows an alternate miniroot to be specified.
- w
This option builds a WANboot miniroot image.

Operands The `add_install_client` command supports the following operands:

host_name

This is the name of the client to be installed.

platform_group

Vendor-defined grouping of hardware platforms for the purpose of distributing specific software. Examples of valid platform groups are:

| System | Platform Group |
|---------------|----------------|
| x86 | i86pc |
| Sun Fire 4800 | sun4u |

Use the `uname(1)` command (with the `-m` option) to determine a system's platform group.

platform_name

Use the `uname(1)` command (with the `-i` option) to determine a system's platform name.

The following example shows the use of the `uname` command to determine the system platform name for an Ultra 10:

```
uname -i
```

The system responds with:

```
SUNW,Ultra-5_10
```

Therefore, the system's platform name is `SUNW,Ultra-5_10`.

The following command calls `add_install_client` for Ultra 10s:

```
add_install_client -d SUNW,Ultra-5_10 sun4u
```

For IA32 platforms, the platform name is always `SUNW.i86pc`.

The following command calls `add_install_client` for IA32 platforms:

```
add_install_client -d SUNW.i86pc i86pc
```

install_boot_image_path

Pathname of alternate miniroot, specified with -t option.

The `rm_install_client` command supports the following operands:

host_name

Name of the client to be removed.

platform_name

The platform name of the client to be removed. See the description of this operand above.

Ethernet_address

Ethernet address of the client to be removed.

boot_file_name

Name of the boot file to be removed.

The `setup_install_server` command supports the following operands:

install_dir_path

The absolute path of the directory in which the Solaris software is to be copied. The directory must be empty.

wanboot_image_path

The absolute path of the directory in which the file containing the WANboot miniroot image is to be created.

install_boot_image_path

Pathname of alternate miniroot, specified with -t option.

Examples EXAMPLE 1 Using `add_install_client`

The following `add_install_client` commands add clients for network installation from a mounted Solaris installation media:

```
example# cd /cdrom/cdrom0/s0/Solaris_10/Tools
example# ./add_install_client system_2/sun4u
```

EXAMPLE 2 Using `add_install_client`

The following `add_install_client` commands add clients for network installation from a mounted Solaris installation media on an install server. The -c option specifies a server and path to a JumpStart directory that has a rules file and a profile file for performing a custom JumpStart installation. Also, the Solaris installation media has been copied to the `/export/install` directory:

```
example# cd /export/install/Solaris_10/Tools
example# /add_install_client
          -c install_server:/jumpstart system_1 i86pc\
example# ./add_install_client -c install_server:/jumpstart\
          system_2 i86pc
```

EXAMPLE 3 Using `add_install_client`

The following `add_install_client` command adds support for a specific sun4u platform machine (8:0:20:99:88:77) using the boot file: `sun4u.solaris10`.

```
example# add_install_client -d -f sun4u.solaris10\  
      -e 8:0:20:99:88:77 sun4u
```

EXAMPLE 4 Using `add_install_client`

The following `add_install_client` command adds x86 clients that use the PXE standard for network booting:

```
example# add_install_client -d -s svrname:/mnt/export/root\  
      SUNW.i86pc i86p
```

EXAMPLE 5 Using `add_to_install_server`

The following `add_to_install_server` command copies the packages in all the installation media's products directories to an existing install server:

```
example# cd /cdrom/cdrom0/s0  
example# ./add_to_install_server /export/Solaris_10
```

EXAMPLE 6 Using `check`

The following `check` command validates the syntax of the rules file used for a custom JumpStart installation:

```
example# cd jumpstart_dir_path  
example# ./check -p /cdrom/cdrom0/s0
```

EXAMPLE 7 Using `rm_install_client`

The following `rm_install_client` commands remove clients for network installation:

```
example# cd /export/install/Solaris_10/Tools  
example# ./rm_install_client holmes  
example# ./rm_install_client watson
```

EXAMPLE 8 Using `setup_install_server`

The following `setup_install_server` command copies the mounted Solaris installation media to a directory named `/export/install` on the local disk:

```
example# cd /cdrom/cdrom0/s0/Solaris_10/Tools  
example# ./setup_install_server /export/install
```

EXAMPLE 9 Using `setup_install_server`

The following `setup_install_server` command copies the boot software of a mounted Solaris installation media to a directory named `/boot_dir` on a system that is going to be a boot server for a subnet:

EXAMPLE 9 Using `setup_install_server` (Continued)

```
example# cd /cdrom/cdrom0/s0/Solaris_10/Tools
example# ./setup_install_server -b /boot_dir
```

EXAMPLE 10 Using `setup_install_server`

By default, `setup_install_server` looks for an installation boot directory at the Solaris `../Tools/Boot` location of the mount Solaris distribution disc.

If an alternate boot directory is required, such as one saved on a network boot server by way of an earlier `./setup_install_server -b /boot_dir` command, the `-t` option can be used.

```
example# cd /cdrom/cdrom0/s0/Solaris_10/Tools
example# ./setup_install_server -t /boot_dir /export/install
```

EXAMPLE 11 Using `setup_install_server` with WANboot Option

The following `setup_install_server` command creates an image of the WANboot miniroot file system and stores it in the file `/wanboot_dir/miniroot`.

```
example# cd /cdrom/cdrom0/s0/Solaris_10/Tools
example# ./setup_install_server -w /wanboot_dir /export/install
```

EXAMPLE 12 x86: Specifying a Serial Console to Use During a Network Installation (from Installation Media)

The following example illustrates how to add an x86 install client to an install server and specify a serial console to use during the installation. This example sets up the install client in the following manner:

- The `-d` option indicates that the client is set up to use DHCP to set installation parameters.
- The `-e` option indicates that this installation occurs only on the client with the ethernet address `00:07:e9:04:4a:bf`.
- The first and second uses of the `-b` option instruct the installation program to use the serial port `ttya` as an input and an output device.

```
install server# cd /export/boot/Solaris_10/Tools
install server# ./add_install_client -d -e "00:07:e9:04:4a:bf" \
    -b "input-device=ttya" -b "output-device=ttya" \
    i86pc
```

For a complete description of the boot property variables and values you can use with the `-b` option, see [eeprom\(1M\)](#).

EXAMPLE 13 Specifying a Boot Device to Use During a Network Installation (from Installation Media)

The following example illustrates how to add an x86 install client to an install server and specify a boot device to use during the installation. If you specify the boot device when you set up the install client, you are not prompted for this information by the Device Configuration Assistant during the installation.

This example sets up the install client in the following manner:

- The `-d` option indicates that the client is set up to use DHCP to set installation parameters
- The `-e` option indicates that this installation occurs only on the client with the ethernet address `00:07:e9:04:4a:bf`.
- The first and second uses of the `-b` option instruct the installation program to use the serial port `ttya` as an input and an output device.
- The third use of the `-b` option instructs the installation program to use a specific boot device during the installation.
- The value of the boot device path varies based on your hardware..
- The `i86pc` platform name indicates that the client is an x86-based system.

```
install server# cd /export/boot/Solaris_10/Tools
install server# ./add_install_client -d -e "00:07:e9:04:4a:bf" \
    -b "input-device=ttya" -b "output-device=ttya" \
    -b "bootpath=/pci@0,0/pci108e,16a8@8" i86pc
```

For a complete description of the boot property variables and values you can use with the `-b` option, see [eeprom\(1M\)](#).

Exit Status The following exit values are returned:

- 0
Successful completion.
- 1

Name install-solaris – install the Solaris operating system

Synopsis install-solaris

Description `install-solaris` invokes the Solaris Install program. Depending on graphical capability and available memory at the time of invocation, `install-solaris` invokes either a text-based installer or a graphical installer.

The following minimum requirements for physical memory dictate which features are available during installation:

For SPARC machines:

128 MB Minimum physical memory for all installation types

228 MB Minimum physical memory required to display a window

512 MB Minimum physical memory required for graphical-based installation

For x86 machines:

256 MB Minimum physical memory for all installation types

256 MB Minimum physical memory required for windowing system

512 MB Minimum physical memory required for graphical-based installation

In some cases, even if the minimum physical memory is present, available virtual memory after system startup can limit the number of features available.

`install-solaris` exists only on the Solaris installation media (CD or DVD) and should be invoked only from there. Refer to the for more details.

`install-solaris` allows installation of the operating system onto any standalone system. `install-solaris` loads the software available on the installation media. Refer to the for disk space requirements.

Usage Refer to the for more information on the various menus and selections.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------------------------|
| Availability | SUNWcdrom (Solaris installation media) |
| Interface Stability | Committed |

See Also [pkginfo\(1\)](#), [install\(1M\)](#), [pkgadd\(1M\)](#), [attributes\(5\)](#)

Notes It is advisable to exit `install-solaris` by means of the exit options in the `install-solaris` menus.

Name in.stdiscover – Service Tag Discovery Daemon

Synopsis /usr/lib/inet/in.stdiscover

Description The `in.stdiscover` daemon allows a mechanism for discovering the location of the Service Tag Listener. By default, the `in.stdiscover` daemon listens for discovery probes (using a minimal built-in protocol) on UDP port 6481.

The daemon is under control of the service management facility, [smf\(5\)](#), under its `inetd` framework. It only runs upon demand and exits when no longer in use.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-------------------------------|
| Availability | system/management/service-tag |
| Interface Stability | Private |

See Also [in.stlisten\(1M\)](#), [stclient\(1M\)](#)

Name in.stlisten – Service Tag Listener

Synopsis /usr/lib/inet/in.stlisten

Description The `in.stlisten` daemon allows a mechanism for discovering the location of the Service Tag. By default, the `in.stlisten` daemon listens for discovery probes (using a minimal built-in protocol) on TCP port 6481.

The daemon is under control of the service management facility, `smf(5)`, under its `inetd` framework. It only runs upon demand and exits when no longer in use.

Attributes See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-------------------------------|
| Availability | system/management/service-tag |
| Interface Stability | Private |

See Also `in.stdiscover(1M)`, `stclient(1M)`, `svccfg(1M)`, `attributes(5)`, `environ(5)`, `smf(5)`

Notes In open networks where the participants may not always be trusted, it is recommended that you deploy this daemon with the `passphrase-encryption` option. In `smf(5)` environments, the following command can be used to set the *passphrase*:

```
< prepare a text file "passfile" containing the passphrase >
# chown svctag:daemon passfile
# chmod 600 passfile
svccfg -s svc:/network/stlisten \
    setprop servicetag/passphrase=passfile
```

where *passfile* is the path of a file containing the intended *passphrase*.

This *passphrase* can be subsequently cleared as follows:

```
svccfg -s svc:/network/stlisten \
    setprop servicetag/passphrase=""
```

Name in.talkd, talkd – server for talk program

Synopsis in.talkd

Description talkd is a server used by the [talk\(1\)](#) program. It listens at the UDP port indicated in the “talk” service description; see [services\(4\)](#). The actual conversation takes place on a TCP connection that is established by negotiation between the two machines involved.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|---------------------------------|
| Availability | service/network/network-servers |

See Also [svcs\(1\)](#), [talk\(1\)](#), [inetadm\(1M\)](#), [inetd\(1M\)](#), [svcadm\(1M\)](#), [services\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Notes The protocol is architecture dependent.

The in.talkd service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/talk
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). Responsibility for initiating and restarting this service is delegated to [inetd\(1M\)](#). Use [inetadm\(1M\)](#) to make configuration changes and to view configuration information for this service. The service's status can be queried using the [svcs\(1\)](#) command.

Name in.telnetd, telnetd – DARPA TELNET protocol server

Synopsis /usr/sbin/in.telnetd [-a *authmode*] [-EXUh] [-s *tos*]
[-S *keytab*] [-M *realm*]

Description in.telnetd is a server that supports the DARPA standard TELNET virtual terminal protocol. in.telnetd is normally invoked in the internet server (see [inetd\(1M\)](#)), for requests to connect to the TELNET port as indicated by the /etc/services file (see [services\(4\)](#)).

in.telnetd operates by allocating a pseudo-terminal device for a client, then creating a login process which has the slave side of the pseudo-terminal as its standard input, output, and error. in.telnetd manipulates the master side of the pseudo-terminal, implementing the TELNET protocol and passing characters between the remote client and the login process.

When a TELNET session starts up, in.telnetd sends TELNET options to the client side indicating a willingness to do *remote echo* of characters, and to *suppress go ahead*. The pseudo-terminal allocated to the client is configured to operate in “cooked” mode, and with XTABS, ICRNL and ONLCR enabled. See [termio\(7I\)](#).

in.telnetd is willing to do: *echo*, *binary*, *suppress go ahead*, and *timing mark*. in.telnetd is willing to have the remote client do: *binary*, *terminal type*, *terminal size*, *logout option*, and *suppress go ahead*.

in.telnetd also allows environment variables to be passed, provided that the client negotiates this during the initial option negotiation. The DISPLAY environment variable may be sent this way, either by the TELNET general environment passing methods, or by means of the XDISPLOC TELNET option. DISPLAY can be passed in the environment option during the same negotiation where XDISPLOC is used. Note that if you use both methods, use the same value for both. Otherwise, the results may be unpredictable.

These options are specified in Internet standards *RFC 1096*, *RFC 1408*, *RFC 1510*, *RFC 1571*, *RFC 2941*, *RFC 2942*, *RFC 2946*, and *RFC 1572*. The following Informational draft is also supported: *RFC 2952*.

The banner printed by in.telnetd is configurable. The default is (more or less) equivalent to ‘uname -sr’ and will be used if no banner is set in /etc/default/telnetd. To set the banner, add a line of the form

```
BANNER="..."
```

to /etc/default/telnetd. Nonempty banner strings are fed to shells for evaluation. The default banner may be obtained by

```
BANNER="\r\n\r\n'uname -s' 'uname -r'\r\n\r\n"
```

and no banner will be printed if /etc/default/telnetd contains

```
BANNER=""
```

Options The following options are supported:

- a *authmode* This option may be used for specifying what mode should be used for authentication. There are several valid values for *authmode*:
 - valid Only allows connections when the remote user can provide valid authentication information to identify the remote user, and is allowed access to the specified account without providing a password.
 - user Only allows connections when the remote user can provide valid authentication information to identify the remote user. The `login(1)` command will provide any additional user verification needed if the remote user is not allowed automatic access to the specified account.
 - none This is the default state. Authentication information is not required. If no or insufficient authentication information is provided, then the `login(1)` program provides the necessary user verification.
 - off This disables the authentication code. All user verification happens through the `login(1)` program.
- E Disables encryption support negotiation.
- h Disables displaying host specific information before login has been completed.
- M *realm* Uses the indicated Kerberos V5 realm. By default, the daemon will determine its realm from the settings in the `krb5.conf(4)` file.
- s *tos* Sets the IP TOS option.
- S *keytab* Sets the KRB5 keytab file to use. The `/etc/krb5/krb5.keytab` file is used by default.
- U Refuses connections that cannot be mapped to a name through the `getnameinfo(3SOCKET)` function.
- X Disables Kerberos V5 authentication support negotiation.

Usage `telnetd` and `in.telnetd` are IPv6-enabled. See [ip6\(7P\)](#).

Security `in.telnetd` can authenticate using Kerberos V5 authentication, [pam\(3PAM\)](#), or both. By default, the telnet server will accept valid Kerberos V5 authentication credentials from a telnet client that supports Kerberos. `in.telnetd` can also support an encrypted session from such a client if the client requests it.

The telnet protocol only uses single DES for session protection—clients request service tickets with single DES session keys. The KDC must know that host service principals that offer the telnet service support single DES, which, in practice, means that such principals must have single DES keys in the KDC database.

In order for Kerberos authentication to work, a host/<FQDN> Kerberos principal must exist for each Fully Qualified Domain Name associated with the telnetd server. Each of these host/<FQDN> principals must have a keytab entry in the /etc/krb5/krb5.keytab file on the telnetd server. An example principal might be:

```
host/bigmachine.eng.example.com
```

See [kadmin\(1M\)](#) or [gkadmin\(1M\)](#) for instructions on adding a principal to a krb5.keytab file. See *System Administration Guide: Security Services* for a discussion of Kerberos authentication.

in.telnetd uses [pam\(3PAM\)](#) for authentication, account management, session management, and password management. The PAM configuration policy, listed through /etc/pam.conf, specifies the modules to be used for in.telnetd. Here is a partial pam.conf file with entries for the telnet command using the UNIX authentication, account management, session management, and password management modules.

```
telnet  auth requisite      pam_authok_get.so.1
telnet  auth required       pam_dhkeys.so.1
telnet  auth required       pam_unix_auth.so.1

telnet  account requisite   pam_roles.so.1
telnet  account required    pam_projects.so.1
telnet  account required    pam_unix_account.so.1

telnet  session required    pam_unix_session.so.1

telnet  password required   pam_dhkeys.so.1
telnet  password requisite  pam_authok_get.so.1
telnet  password requisite  pam_authok_check.so.1
telnet  password required   pam_authok_store.so.1
```

If there are no entries for the telnet service, then the entries for the "other" service will be used. If multiple authentication modules are listed, then the user may be prompted for multiple passwords.

For a Kerberized telnet service, the correct PAM service name is ktelnet.

Files /etc/default/telnetd

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|------------------------|
| Availability | service/network/telnet |

See Also [login\(1\)](#), [svcs\(1\)](#), [telnet\(1\)](#), [gkadmin\(1M\)](#), [inetadm\(1M\)](#), [inetd\(1M\)](#), [kadmin\(1M\)](#), [svcadm\(1M\)](#), [pam\(3PAM\)](#), [getnameinfo\(3SOCKET\)](#), [issue\(4\)](#), [krb5.conf\(4\)](#), [pam.conf\(4\)](#), [services\(4\)](#), [attributes\(5\)](#), [pam_authtok_check\(5\)](#), [pam_authtok_get\(5\)](#), [pam_authtok_store\(5\)](#), [pam_dhkeys\(5\)](#), [pam_passwd_auth\(5\)](#), [pam_unix_account\(5\)](#), [pam_unix_auth\(5\)](#), [pam_unix_session\(5\)](#), [smf\(5\)](#), [ip6\(7P\)](#), [termio\(7I\)](#)

System Administration Guide: Security Services

Alexander, S. *RFC 1572, TELNET Environment Option*. Network Information Center, SRI International, Menlo Park, Calif., January 1994.

Borman, Dave. *RFC 1408, TELNET Environment Option*. Network Information Center, SRI International, Menlo Park, Calif., January 1993.

Borman, Dave. *RFC 1571, TELNET Environment Option Interoperability Issues*. Network Information Center, SRI International, Menlo Park, Calif., January 1994.

Crispin, Mark. *RFC 727, TELNET Logout Option*. Network Information Center, SRI International, Menlo Park, Calif., April 1977.

Marcy, G. *RFC 1096, TELNET X Display Location Option*. Network Information Center, SRI International, Menlo Park, Calif., March 1989.

Postel, Jon, and Joyce Reynolds. *RFC 854, TELNET Protocol Specification*. Network Information Center, SRI International, Menlo Park, Calif., May 1983.

Waitzman, D. *RFC 1073, TELNET Window Size Option*. Network Information Center, SRI International, Menlo Park, Calif., October 1988.

Kohl, J., Neuman, C., *The Kerberos Network Authentication Service (V5), RFC 1510*. September 1993.

Ts'o, T. and J. Altman, *Telnet Authentication Option, RFC 2941*. September 2000.

Ts'o, T., *Telnet Authentication: Kerberos Version 5, RFC 2942*. September 2000.

Ts'o, T., *Telnet Data Encryption Option, RFC 2946*. September 2000.

Ts'o, T., *Telnet Encryption: DES 64 bit Cipher Feedback, RFC 2952*. September 2000.

Notes Some TELNET commands are only partially implemented.

Binary mode has no common interpretation except between similar operating systems.

The terminal type name received from the remote client is converted to lower case.

The *packet* interface to the pseudo-terminal should be used for more intelligent flushing of input and output queues.

`in.telnetd` never sends TELNET *go ahead* commands.

The `pam_unix(5)` module is no longer supported.. Similar functionality is provided by `pam_authok_check(5)`, `pam_authok_get(5)`, `pam_authok_store(5)`, `pam_dhkeys(5)`, `pam_passwd_auth(5)`, `pam_unix_account(5)`, `pam_unix_auth(5)`, and `pam_unix_session(5)`.

The `in.telnetd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/telnet
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. Responsibility for initiating and restarting this service is delegated to `inetd(1M)`. Use `inetadm(1M)` to make configuration changes and to view configuration information for this service. The service's status can be queried using the `svcs(1)` command.

Name in.tftpd, tftpd – Internet Trivial File Transfer Protocol server

Synopsis in.tftpd [-d] [-T *rextmval*] [-s] [*homedir*]

Description tftpd is a server that supports the Internet Trivial File Transfer Protocol (TFTP).

Before responding to a request, the server attempts to change its current directory to *homedir*; the default directory is /tftpboot.

The use of tftp does not require an account or password on the remote system. Due to the lack of authentication information, in.tftpd will allow only publicly readable files to be accessed. Files may be written only if they already exist and are publicly writable. Note that this extends the concept of “public” to include all users on all hosts that can be reached through the network. This may not be appropriate on all systems, and its implications should be considered before enabling this service.

in.tftpd runs with the user ID and group ID set to [GU]ID_NOBODY under the assumption that no files exist with that owner or group. However, nothing checks this assumption or enforces this restriction.

Options

- d Debug. When specified it sets the SO_DEBUG socket option.
- s Secure. When specified, the directory change to *homedir* must succeed. The daemon also changes its root directory to *homedir*.
- T *rextmval* Specifies the value of the retransmission timeout in seconds. This also affects the maximum session timeout in that the latter is set to five times the retransmission timeout value.

Usage The in.tftpd server is IPv6-enabled. See [ip6\(7P\)](#).

in.tftpd supports transfers of greater than 32 MB, per RFC 2348.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|----------------------|
| Availability | service/network/tftp |

See Also [svcs\(1\)](#), [tftp\(1\)](#), [inetadm\(1M\)](#), [inetd\(1M\)](#), [svcadm\(1M\)](#), [netconfig\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#), [ip6\(7P\)](#)

Malkin, G. and Harkin, A. *RFC 2347, TFTP Option Extension*. The Internet Society. May 1998

Malkin, G. and Harkin, A. *RFC 2348, TFTP Blocksize Option*. The Internet Society. May 1998

Malkin, G. and Harkin, A. *RFC 2349, TFTP Timeout Interval and Transfer Size Options*. The Internet Society. May 1998

Sollins, K.R. *RFC 1350, The TFTP Protocol (Revision 2)*. Network Working Group. July 1992.

Notes The `tftpd` server only acknowledges the transfer size option that is sent with a read request when the octet transfer mode is specified.

The `in.tftpd.1m` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/tftp/udp6:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). Responsibility for initiating and restarting this service is delegated to [inetd\(1M\)](#). Use [inetadm\(1M\)](#) to make configuration changes and to view configuration information for this service. The service's status can be queried using the [svcs\(1\)](#) command.

Unlike most [smf\(5\)](#) services, a manifest for the `tftp` service is not included in the system. To create one and enable this service, the administrator should:

1. Edit `/etc/inet/inetd.conf` and uncomment the `tftp` entry.
2. Run `/usr/sbin/inetconv`.

After you run `inetconv`, the `svc:/network/tftp/udp6:default` service is created and enabled.

Name in.timed – UDP or TCP time protocol service daemon

Synopsis in.timed

FMRI svc:/internet/time:default

Description FMRI stands for Fault Management Resource Identifier. It is used to identify resources managed by the Fault Manager. See [fmd\(1M\)](#) and [smf\(5\)](#).

The `in.timed` service provides the server-side of the time protocol. The time server sends to requestors the time in seconds since midnight, January 1, 1900. The time protocol is available on both TCP and UDP transports through port 37.

The `in.timed` service is an [inetd\(1M\)](#) [smf\(5\)](#) delegated service. The `in.timed` detects which transport is requested by examining the socket it is passed by the `inetd` daemon.

TCP-based service Once a connection is established, the `in.timed` sends the time as a 32-bit binary number and closes the connection. Any received data is ignored.

UDP-based service The `in.timed` listens for UDP datagrams. When a datagram is received, the server generates a UDP datagram containing the time as a 32-bit binary number and sends it to the client. Any received data is ignored.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------------|
| Availability | service/network/legacy |
| Interface Stability | Committed |

See Also [inetd\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#)

RFC 868

Name intrd – interrupt distribution daemon

Synopsis /usr/lib/intrd

Description The `intrd` daemon is started at boot time to monitor the assignments between interrupts and CPUs. If `intrd` decides that the current assignments are imbalanced and harmful to system performance, it will generate and implement new assignments.

Any notifications will be delivered via [syslogd\(1M\)](#).

Because `intrd` dynamically monitors a system for optimal performance, it consumes a small amount of CPU time, even on an otherwise idle system. This behavior is normal.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|---------------------|
| Availability | system/kernel/power |
| Interface Stability | Uncommitted |

See Also [svcs\(1\)](#), [svcadm\(1M\)](#), [syslogd\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Notes The interrupt distribution daemon is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/intrd:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Name intrstat – report interrupt statistics

Synopsis /usr/sbin/intrstat [-c *cpulist* | -C *processor_set_id*] [-T u | d]
[-x *opt[=val]*] [*interval* [*count*]]

Description The `intrstat` utility gathers and displays run-time interrupt statistics. The output is a table of device names and CPU IDs, where each row of the table denotes a device, and each column of the table denotes a CPU. Each cell in the table contains both the raw number of interrupts for the given device on the given CPU, and the percentage of absolute time spent in that device's interrupt handler on that CPU.

The device name is given in the form of `{name}#{instance}`. The name is the normalized driver name, and typically corresponds to the name of the module implementing the driver. See [ddi_driver_name\(9F\)](#). Many Sun-delivered drivers have their own manual pages. See [Intro\(7\)](#).

If standard output is a terminal, the table contains as many columns of data as can fit within the terminal width. If standard output is not a terminal, the table contains at most four columns of data. By default, data is gathered and displayed for all CPUs. If the data cannot fit in a single table, it is printed across multiple tables. The set of CPUs for which data is displayed can be optionally specified with the `-c` or `-C` option.

By default, `intrstat` displays data once per second and runs indefinitely. Both of these behaviors can be optionally controlled with the `interval` and `count` parameters, respectively. See [OPERANDS](#).

Because `intrstat` uses dynamic discovery, it reports only on devices that raise interrupts while the command is running. Any devices that are silent while `intrstat` is running are not displayed.

`intrstat` induces a small system-wide performance degradation. As a result, only the super-user can run `intrstat` by default. The *Solaris Dynamic Tracing Guide* explains how administrators can grant privileges to other users to permit them to run `intrstat`.

Options The following options are supported:

`-c cpulist`

Displays data for the CPUs specified by *cpulist*.

cpulist can be a single processor ID (for example, 4), a range of processor IDs (for example, 4-6), or a comma separated list of processor IDs or processor ID ranges (for example, 4,5,6 or 4,6-8).

`-C processor_set_id`

Displays data for the CPUs in the processor set specified by *processor_set_id*.

`intrstat` modifies its output to always reflect the CPUs in the specified processor set. If a CPU is added to the set, `intrstat` modifies its output to include the added CPU. If a CPU is removed from the set, `intrstat` modifies its output to exclude the removed CPU. At most one processor set can be specified.

`-T u | d`

Display a time stamp.

Specify `u` for a printed representation of the internal representation of time. See [time\(2\)](#).

Specify `d` for standard date format. See [date\(1\)](#).

`-x opt[=val]`

Enable or modify a DTrace runtime option or D compiler option. The list of options is found in the *Solaris Dynamic Tracing Guide*. A boolean option is enabled by specifying its name. Options with values are set by separating the option name and value with an equal sign (=)

Operands The following operands are supported:

count

Indicates the number of intervals to execute before exiting.

interval

Indicates the number of seconds to be executed before exiting.

Examples **EXAMPLE 1** Using `intrstat` Without Options

Without options, `intrstat` displays a table of trap types and CPUs. At most, four columns can fit in the default terminal width. If there are more than four CPUs, multiple tables are displayed.

The following example runs `intrstat` on a uniprocessor Intel IA/32-based laptop:

```
example# intrstat
      device |      cpu0 %tim
-----+-----
      ata#0 |      166 0.4
      ata#1 |       0 0.0
audioi810#0 |       6 0.0
      i8042#0 |      281 0.7
      iprb#0 |       6 0.0
      uhci#1 |       6 0.0
      uhci#2 |       6 0.0

      device |      cpu0 %tim
-----+-----
      ata#0 |      161 0.5
      ata#1 |       0 0.0
audioi810#0 |       6 0.0
      i8042#0 |      303 0.6
```

EXAMPLE 1 Using intrstat Without Options *(Continued)*

```

iprb#0 |          6  0.0
uhci#1 |          6  0.0
uhci#2 |          6  0.0

```

...

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------|
| Availability | developer/dtrace |
| Interface Stability | See below. |

The command-line syntax is Committed. The human-readable output is Uncommitted.

Solaris Dynamic Tracing Guide

Name in.uucpd, uucpd – UUCP server

Synopsis /usr/sbin/in.uucpd [-n]

Description in.uucpd is the server for supporting UUCP connections over networks.

in.uucpd is invoked by [inetd\(1M\)](#) when a UUCP connection is established, that is, a connection to the port indicated in the “uucp” service specification, and executes the following protocol. See [services\(4\)](#):

1. The server prompts with `login: .` The [uucico\(1M\)](#) process at the other end must supply a username.
2. Unless the username refers to an account without a password, the server then prompts with `Password: .` The `uucico` process at the other end must supply the password for that account.

If the username is not valid, or is valid but refers to an account that does not have `/usr/lib/uucp/uucico` as its login shell, or if the password is not the correct password for that account, the connection is dropped. Otherwise, `uucico` is run, with the user ID, group ID, group set, and home directory for that account, with the environment variables `USER` and `LOGNAME` set to the specified username, and with a `-u` flag specifying the username. Unless the `-n` flag is specified, entries are made in `/var/adm/utmpx`, `/var/adm/wtmpx`, and `/var/adm/lastlog` for the username. `in.uucpd` must be invoked by a user with appropriate privilege (usually `root`) in order to be able to verify that the password is correct.

Security in.uucpd uses [pam\(3PAM\)](#) for authentication, account management, and session management. The PAM configuration policy, listed through `/etc/pam.conf`, specifies the modules to be used for in.uucpd. Here is a partial `pam.conf` file with entries for uucp using the UNIX authentication, account management, and session management module.

```
uucp    auth requisite      pam_authok_get.so.1
uucp    auth required        pam_dhkeys.so.1
uucp    auth required        pam_unix_auth.so.1

uucp    account requisite   pam_roles.so.1
uucp    account required    pam_projects.so.1
uucp    account required    pam_unix_account.so.1

uucp    session required    pam_unix_session.so.1
```

If there are no entries for the `uucp` service, then the entries for the “other” service will be used. If multiple authentication modules are listed, then the peer may be prompted for multiple passwords.

Files

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|----------------------|
| Availability | service/network/uucp |

See Also [svcs\(1\)](#), [inetadm\(1M\)](#), [inetd\(1M\)](#), [svcadm\(1M\)](#), [uucico\(1M\)](#), [pam\(3PAM\)](#), [pam.conf\(4\)](#), [services\(4\)](#), [attributes\(5\)](#), [pam_authtok_check\(5\)](#), [pam_authtok_get\(5\)](#), [pam_authtok_store\(5\)](#), [pam_dhkeys\(5\)](#), [pam_passwd_auth\(5\)](#), [pam_unix_account\(5\)](#), [pam_unix_auth\(5\)](#), [pam_unix_session\(5\)](#), [smf\(5\)](#)

Diagnostics All diagnostic messages are returned on the connection, after which the connection is closed.

| | |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| user read | An error occurred while reading the username. |
| passwd read | An error occurred while reading the password. |
| Login incorrect. | The username is invalid or refers to an account with a login shell other than <code>/usr/lib/uucp/uucico</code> , or the password is not the correct password for the account. |

Notes The `in.uucpd` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/uucp
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). Responsibility for initiating and restarting this service is delegated to [inetd\(1M\)](#). Use [inetadm\(1M\)](#) to make configuration changes and to view configuration information for this service. The service's status can be queried using the [svcs\(1\)](#) command.

The `pam_unix(5)` module is no longer supported. Similar functionality is provided by [pam_authtok_check\(5\)](#), [pam_authtok_get\(5\)](#), [pam_authtok_store\(5\)](#), [pam_dhkeys\(5\)](#), [pam_passwd_auth\(5\)](#), [pam_unix_account\(5\)](#), [pam_unix_auth\(5\)](#), and [pam_unix_session\(5\)](#).

Name iostat – report I/O statistics

Synopsis /usr/bin/iostat [-cCdDeEiImMnpPrstxXYZ] [-l *n*] [-T *u* | *d*]
 [*disk*]... [*interval* [*count*]]

Description The `iostat` utility iteratively reports terminal, disk, and tape I/O activity, as well as CPU utilization. The first line of output is for all time since boot; each subsequent line is for the prior interval only.

To compute this information, the kernel maintains a number of counters. For each disk, the kernel counts reads, writes, bytes read, and bytes written. The kernel also takes hi-res time stamps at queue entry and exit points, which allows it to keep track of the residence time and cumulative residence-length product for each queue. Using these values, `iostat` produces highly accurate measures of throughput, utilization, queue lengths, transaction rates and service time. For terminals collectively, the kernel simply counts the number of input and output characters.

During execution of the kernel status command, the state of the system can change. If relevant, a state change message is included in the `iostat` output, in one of the following forms:

```
<<device added: sd0>>
<<device removed: sd0>>
<<partition added: sd0,a>>
<<partition removed: sd0,a>>
<<NFS mounted: nfs1>>
<<NFS unmounted: nfs1>>
<<multi-path added: ssd4>>
<<multi-path removed: ssd4>>
<<controller added: c1>>
<<controller removed: c1>>
<<processors added: 1, 3>>
<<processors removed: 1, 3>>
```

Note that the names printed in these state change messages are affected by the `-n` and `-m` options as appropriate.

For more general system statistics, use [sar\(1\)](#), [sar\(1M\)](#), or [vmstat\(1M\)](#).

Output The output of the `iostat` utility includes the following information.

| | |
|--------|---------------------------|
| device | name of the disk |
| r/s | reads per second |
| w/s | writes per second |
| kr/s | kilobytes read per second |

| | |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | The average I/O size during the interval can be computed from kr/s divided by r/s . |
| kw/s | kilobytes written per second |
| | The average I/O size during the interval can be computed from kw/s divided by w/s . |
| wait | average number of transactions waiting for service (queue length) |
| | This is the number of I/O operations held in the device driver queue waiting for acceptance by the device. |
| actv | average number of transactions actively being serviced (removed from the queue but not yet completed) |
| | This is the number of I/O operations accepted, but not yet serviced, by the device. |
| svc_t | average response time of transactions, in milliseconds |
| | The <code>svc_t</code> output reports the overall <i>response</i> time, rather than the <i>service</i> time, of a device. The overall time includes the time that transactions are in queue and the time that transactions are being serviced. The time spent in queue is shown with the <code>-x</code> option in the <code>wsvc_t</code> output column. The time spent servicing transactions is the true service time. Service time is also shown with the <code>-x</code> option and appears in the <code>asvc_t</code> output column of the same report. |
| %w | percent of time there are transactions waiting for service (queue non-empty) |
| %b | percent of time the disk is busy (transactions in progress) |
| wsvc_t | average service time in wait queue, in milliseconds |
| asvc_t | average service time of active transactions, in milliseconds |
| wt | the I/O wait time is no longer calculated as a percentage of CPU time, and this statistic will always return zero. |

Options The following options are supported:

- c Report the percentage of time the system has spent in user mode, in system mode, waiting for I/O, and idling. See the NOTES section for more information.
- C When the `-x` option is also selected, report extended disk statistics aggregated by *controller id*.
- d For each disk, report the number of kilobytes transferred per second, the number of transfers per second, and the average service time in milliseconds.
- D For each disk, report the reads per second, writes per second, and percentage disk utilization.

- e Display device error summary statistics. The total errors, hard errors, soft errors, and transport errors are displayed.
- E Display all device error statistics.
- i In -E output, display the Device ID instead of the Serial No. The Device Id is a unique identifier registered by a driver through `ddi_devid_register(9F)`.
- I Report the counts in each interval, rather than rates (where applicable).
- l n Limit the number of disks included in the report to *n*; the disk limit defaults to 4 for -d and -D, and unlimited for -x. Note: disks explicitly requested (see *disk* below) are not subject to this disk limit.
- m Report file system mount points. This option is most useful if the -P or -p option is also specified or used in conjunction with -Xn or -en. The -m option is useful only if the mount point is actually listed in the output. This option can only be used in conjunction with the -n option.
- M Display data throughput in MB/sec instead of KB/sec.
- n Display names in descriptive format. For example, cXtYdZ, rmt/N, server:/export/path.

By default, disks are identified by instance names such as `ssd23` or `md301`. Combining the -n option with the -x option causes disk names to display in the cXtYdZsN format which is more easily associated with physical hardware characteristics. The cXtYdZsN format is particularly useful in FibreChannel (FC) environments where the FC World Wide Name appears in the t field.
- p For each disk, report per-partition statistics in addition to per-device statistics.
- P For each disk, report per-partition statistics only, no per-device statistics.
- r Display data in a comma-separated format.
- s Suppress messages related to state changes.
- t Report the number of characters read and written to terminals per second.
- T u | d Display a time stamp.

Specify u for a printed representation of the internal representation of time. See [time\(2\)](#). Specify d for standard date format. See [date\(1\)](#).
- X For disks under `scsi_vhci(7D)` control, in addition to disk *lun* statistics, also report statistics for *lun.controller*.
- x Report extended disk statistics. By default, disks are identified by instance names such as `ssd23` or `md301`. Combining the x option with the -n option causes disk names to display in the cXtYdZsN format, more easily associated with physical

hardware characteristics. Using the `cXtYdZsN` format is particularly helpful in the FibreChannel environments where the FC World Wide Name appears in the `t` field.

If no output display is requested (no `-x`, `-e`, `-E`), `-x` is implied.

-Y For disks under `scsi_vhci(7D)` control, in addition to disk `lun` statistics, also report statistics for `lun.targetport` and `lun.targetport.controller`.

In `-n` (descriptive) mode the `targetport` is shown in using the `target-port` property of the path. Without `-n` the `targetport` is shown using the shorter `port-id`. All target ports with the same `target-port` property value share the same `port-id`. The `target-port-to-port-id` association does not persist across reboot.

If no output display is requested (no `-x`, `-e`, `-E`), `-x` is implied.

-z Do not print lines whose underlying data values are all zeros.

The option set `-xcnXTdz interval` is particularly useful for determining whether disk I/O problems exist and for identifying problems.

Operands The following operands are supported:

count Display only *count* reports.

disk Explicitly specify the disks to be reported; in addition to any explicit disks, any active disks up to the disk limit (see `-l` above) will also be reported.

interval Report once each *interval* seconds.

Examples **EXAMPLE 1** Using `iostat` to Generate User and System Operation Statistics

The following command displays two reports of extended device statistics, aggregated by *controller id*, for user (`us`) and system (`sy`) operations. Because the `-n` option is used with the `-x` option, devices are identified by controller names.

```
example% iostat -xcnXTdz 5
```

```
Mon Nov 24 14:58:36 2003
```

```
cpu
```

```
us sy wt id
```

```

```

EXAMPLE 2 Using iostat to Generate TTY Statistics

The following command displays two reports on the activity of five disks in different modes of operation. Because the -x option is used, disks are identified by instance names.

```
example% iostat -x tc 5 2
```

```

          extended device statistics          tty          cpu
device r/s  w/s kr/s kw/s wait actv svc_t %w  %b tin tout us sy wt id
sd0    0.4 0.3 10.4  8.0 0.0  0.0 36.9  0  1  0  10  0  0  0 99
sd1    0.0 0.0  0.3  0.4 0.0  0.0 35.0  0  0
sd6    0.0 0.0  0.0  0.0 0.0  0.0  0.0  0  0
nfs1   0.0 0.0  0.0  0.0 0.0  0.0  0.0  0  0
nfs2   0.0 0.0  0.0  0.1 0.0  0.0 35.6  0  0

          extended device statistics          tty          cpu
device r/s  w/s kr/s kw/s wait actv svc_t %w  %b tin tout us sy wt id
sd0    0.0 0.0  0.0  0.0 0.0  0.0  0.0  0  0  0 155  0  0  0 100
sd1    0.0 0.0  0.0  0.0 0.0  0.0  0.0  0  0
sd6    0.0 0.0  0.0  0.0 0.0  0.0  0.0  0  0
nfs1   0.0 0.0  0.0  0.0 0.0  0.0  0.0  0  0
nfs2   0.0 0.0  0.0  0.0 0.0  0.0  0.0  0  0

```

EXAMPLE 3 Using iostat to Generate Partition and Device Statistics

The following command generates partition and device statistics for each disk. Because the -n option is used with the -x option, disks are identified by controller names.

```
example% iostat -xnp
```

```

          extended device statistics
r/s  w/s  kr/s kw/s wait actv wsvc_t asvc_t  %w  %b device
0.4  0.3  10.4  7.9  0.0  0.0   0.0  36.9  0  1 c0t0d0
0.3  0.3   9.0  7.3  0.0  0.0   0.0  37.2  0  1 c0t0d0s0
0.0  0.0   0.1  0.5  0.0  0.0   0.0  34.0  0  0 c0t0d0s1

```

EXAMPLE 3 Using `iostat` to Generate Partition and Device Statistics *(Continued)*

```
0.0 0.0 0.0 0.1 0.0 0.0 0.6 35.0 0 0 fuji:/export/home/user3
```

EXAMPLE 4 Show Translation from Instance Name to Descriptive Name

The following example illustrates the use of `iostat` to translate a specific instance name to a descriptive name.

```
example% iostat -xn sd1
                extended device statistics
r/s   w/s   kr/s  kw/s wait actv wsvc_t asvc_t %w  %b device
0.0   0.0   0.0   0.0  0.0  0.0  0.0   0.0  0  0 c8t1d0
```

EXAMPLE 5 Show Target Port and Controller Activity for a Specific Disk

In the following example, there are four controllers, all connected to the same target port.

```
# iostat -Y ssd22
                extended device statistics
device          r/s   w/s   kr/s  kw/s wait actv  svc_t  %w  %b
ssd22            0.2   0.0   1.5   0.0  0.0  0.0   0.7  0  0
ssd22.t2        0.2   0.0   1.5   0.0  0.0  0.0   0.0  0  0
ssd22.t2.fp0    0.0   0.0   0.4   0.0  0.0  0.0   0.0  0  0
ssd22.t2.fp1    0.0   0.0   0.4   0.0  0.0  0.0   0.0  0  0
ssd22.t2.fp2    0.0   0.0   0.4   0.0  0.0  0.0   0.0  0  0
ssd22.t2.fp3    0.0   0.0   0.4   0.0  0.0  0.0   0.0  0  0
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | See below. |

Invocation is evolving. Human readable output is unstable.

See Also [date\(1\)](#), [sar\(1\)](#), [sar\(1M\)](#), [mpstat\(1M\)](#), [vmstat\(1M\)](#), [time\(2\)](#), [attributes\(5\)](#), [scsi_vhci\(7D\)](#)

Notes The sum of CPU utilization might vary slightly from 100 because of rounding errors in the production of a percentage figure.

The `svc_t` response time is not particularly significant when the I/O (`r/s+w/s`) rates are under 0.5 per second. Harmless spikes are fairly normal in such cases.

The `mpstat` utility reports the same `wt`, `usr`, and `sys` statistics. See [mpstat\(1M\)](#) for more information.

When executed in a zone and if the pools facility is active, `iostat(1M)` will only provide information for those processors in the processor set of the pool to which the zone is bound.

Name ipaddrsel – configure IPv6 default address selection

Synopsis /usr/sbin/ipaddrsel
/usr/sbin/ipaddrsel -f *file*
/usr/sbin/ipaddrsel -d

Description Use the `ipaddrsel` utility to configure the IPv6 default address selection policy table. The policy table is a longest-matching-prefix lookup table that is used for IPv6 source address selection and for destination address ordering when resolving names to `AF_INET6` addresses. For a description of how the policy table is used for source address selection, see [inet6\(7P\)](#). For a description of how the policy table is used for destination address ordering, see [getaddrinfo\(3SOCKET\)](#).

The unmodified policy table is valid for all typical IPv6 deployments. Modify the table only if a circumstance exists for which the default behavior of the IPv6 source address selection or destination address ordering mechanism is unsatisfactory. See the [Examples](#) section for examples of such circumstances. You should carefully consider your addressing strategy before you change the table from the provided default.

When the `ipaddrsel` command is issued without any arguments, the address selection policy currently in use is printed. The format of the output is compatible with the format of the configuration file that the `-f` option accepts.

Note – If the `usesrc` subcommand to [ifconfig\(1M\)](#) is applied to a particular physical interface, the selection policy specified by `usesrc` overrides the source address selection policies specified by `ipaddrsel`. This is true for packets that are locally generated and for applications that do not choose a non-zero source address using [bind\(3SOCKET\)](#).

The Configuration File The configuration file that the `-f` option accepts can contain either comment lines or policy entries. Comment lines have a '#' character as the first non-blank character, and they are ignored by the `ipaddrsel` utility. Policy entry lines have the following format:

```
prefix/prefix_length precedence label [# comment]
```

The *prefix* must be an IPv6 prefix in a format consistent with [inet\(3SOCKET\)](#). The *prefix_length* is an integer ranging from 0 to 128. The IPv6 source address selection and destination address ordering algorithms determine the precedence or label of an address by doing a longest-prefix-match lookup using the prefixes in this table, much like next-hop determination for a destination is done by doing a longest-prefix-match lookup using an IP routing table.

The precedence is a non-negative integer that represents how the destination address ordering mechanism will sort addresses returned from name lookups. In general, addresses with a higher precedence will be in front of addresses with a lower precedence. Other factors, such as destinations with undesirable source addresses can, however, override these precedence values.

The label is a string of at most fifteen characters, not including the NULL terminator. The label allows particular source address prefixes to be used with destination prefixes of the same label. Specifically, for a particular destination address, the IPv6 source address selection algorithm prefers source addresses whose label is equal that of the destination.

The label may be followed by an optional comment.

The file must contain a default policy entry, which is an entry with `::0/0` as its *prefix* and *prefix_length*. This is to ensure that all possible addresses match a policy.

Options The `ipaddrsel` utility supports the following options:

- f *file* Replace the address selection policy table with the policy specified in the *file*.
- d Revert the kernel's address selection policy table back to the default table. Invoking `ipaddrsel` in this way only changes the currently running kernel's policy table, and does not alter the configuration file `/etc/inet/ipaddrsel.conf`. To revert the configuration file back to its default settings, use `ipaddrsel -d`, then dump the contents of the table to the configuration file by redirecting the output of `ipaddrsel` to `/etc/inet/ipaddrsel.conf`.

```
example# ipaddrsel -d
example# ipaddrsel > /etc/inet/ipaddrsel.conf
```

Examples **EXAMPLE 1** The Default Policy in `/etc/inet/ipaddrsel.conf`

The following example is the default policy that is located in `/etc/inet/ipaddrsel.conf`:

```
# Prefix                Precedence Label
::1/128                 50 Loopback
::/96                   20 IPv4_Compatible
::ffff:0.0.0.0/96      10 IPv4
2002::/16               30 6to4
::/0                    40 Default
```

EXAMPLE 2 Assigning a Lower Precedence to Link-local and Site-local Addresses

By default, the destination address ordering rules sort addresses of smaller scope before those of larger scope. For example, if a name resolves to a global and a site-local address, the site local address would be ordered before the global address. An administrator can override this ordering rule by assigning a lower precedence to addresses of smaller scope, as the following table demonstrates.

```
# Prefix                Precedence Label
::1/128                 50 Loopback
::/0                    40 Default
2002::/16               30 6to4
fec0::/10               27 Site-Local
fe80::/10               23 Link-Local
::/96                   20 IPv4_Compatible
```

EXAMPLE 2 Assigning a Lower Precedence to Link-local and Site-local Addresses *(Continued)*

```
::ffff:0.0.0.0/96                10 IPv4
```

EXAMPLE 3 Assigning Higher Precedence to IPv4 Destinations

By default, IPv6 addresses are ordered in front of IPv4 addresses in name lookups.

::ffff:0.0.0.0/96 has the lowest precedence in the default table. In the following example, IPv4 addresses are assigned higher precedence and are ordered in front of IPv6 destinations:

```
# Prefix                Precedence Label
::1/128                 50 Loopback
::/0                    40 Default
2002::/16               30 6to4
::/96                   20 IPv4_Compatible
::ffff:0.0.0.0/96     60 IPv4
```

EXAMPLE 4 Ensuring that a Particular Source Address is Used

This example ensures that a particular source address is used only when communicating with destinations in a particular network.

The following policy table assigns a label of 5 to a particular source address on the local system, 2001:1111:1111::1. The table assigns the same label to a network, 2001:2222:2222::/48. The result of this policy is that the 2001:1111:1111::1 source address will only be used when communicating with destinations contained in the 2001:2222:2222::/48 network. For this example, this network is the ClientNet, which could represent a particular client's network.

```
# Prefix                Precedence Label
::1/128                 50 Loopback
2001:1111:1111::1/128  40 ClientNet
2001:2222:2222::/48    40 ClientNet
::/0                    40 Default
2002::/16               30 6to4
::/96                   20 IPv4_Compatible
::ffff:0.0.0.0/96     10 IPv4
```

This example assumes that the local system has one physical interface, and that all global prefixes are assigned to that physical interface.

Exit Status ipaddrsel returns the following exit values:

- 0 ipaddrsel successfully completed.
- >0 An error occurred. If a failure is encountered, the kernel's current policy table is unchanged.

Files `/etc/inet/ipaddrsel.conf` The file that contains the IPv6 default address selection policy to be installed at boot time. This file is loaded before any Internet services are started.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

Notes The ipnodes cache kept by [nscd\(1M\)](#) contains addresses that are ordered using the destination address ordering algorithm, which is one of the reasons why `ipaddrsel` is called before `nscd` in the boot sequence. If `ipaddrsel` is used to change the address selection policy after `nscd` has started, you should invalidate the `nscd` ipnodes cache invalidated by invoking the following command:

```
example# /usr/sbin/nscd -i ipnodes
```

Name ipadm – configure Internet Protocol network interfaces and TCP/IP tunables

Synopsis ipadm create-if [-t] *interface*
 ipadm delete-if *interface*
 ipadm show-if [[-p] -o *field[,...]*] [*interface*]
 ipadm disable-if -t *interface*
 ipadm enable-if -t *interface*

ipadm set-ifprop [-t] -m *protocol* -p prop=*value[,...]* *interface*
 ipadm reset-ifprop [-t] -m *protocol* -p *prop* *interface*
 ipadm show-ifprop [[-c] -o *field[,...]*] [-p *prop[,...]*]
 [-m *protocol*] [*interface*]

ipadm create-addr [-t] -T static [-d]
 -a {local|remote}=*addr[/prefixlen]*,... *addrobj*
 ipadm create-addr [-t] -T dhcp [-w *seconds* | forever] *addrobj*
 ipadm create-addr [-t] -T addrconf [-i *interface-id*]
 [-p {stateful|stateless}={yes|no},...] *addrobj*

ipadm delete-addr [-r] *addrobj*
 ipadm show-addr [[-p] -o *field[,...]*] [*addrobj*]
 ipadm up-addr [-t] *addrobj*
 ipadm down-addr [-t] *addrobj*
 ipadm refresh-addr [-i] *addrobj*
 ipadm disable-addr -t *addrobj*
 ipadm enable-addr -t *addrobj*

ipadm set-addrprop [-t] -p prop=*value[,...]* *addrobj*
 ipadm reset-addrprop [-t] -p prop=*value[,...]* *addrobj*
 ipadm show-addrprop [[-c] -o *field[,...]*] [-p *prop[,...]*] [*addrobj*]

ipadm set-prop [-t] -p prop=*value[,...]* *protocol*
 ipadm reset-prop [-t] -p *prop* *protocol*
 ipadm show-prop [[-c] -o *field[,...]*] [-p *prop[,...]*] [*protocol*]

Description The ipadm command provides a set of subcommands that can be used to:

manage interfaces:

- create and delete interfaces
- modify interface properties
- display interface configuration

manage addresses:

- create and delete addresses
- modify address properties
- display address configuration

manage TCP/IP protocol properties:

- modify TCP/IP properties
- display TCP/IP properties

The various operands to `ipadm` subcommands are described in the “Operands” section, which follows “Subcommands”.

Sub-commands The following subcommands are supported:

`create-if [-t] interface`

Create an IP interface that handles both IPv4 and IPv6 packets. The address of the IPv4 interface will be set to `0.0.0.0` and the address of the IPv6 interface will be set to `::`. This subcommand, by default, causes the information to persist, so that on the next reboot this interface will be instantiated.

An interface is implicitly enabled for IPv4 and IPv6 when it is created. See the `disable-if` and `enable-if` subcommands below, to disable or enable an interface.

Note that `lo0` is a special interface, called the loopback interface. It is a virtual IP interface and is not associated with any physical hardware. It is one of the first IP interfaces to be created on the system, with IPv4 address of `127.0.0.1` and IPv6 address of `::1/128`.

`-t, --temporary`

Specifies that the operation is temporary and must not persist. The operation affects only the active configuration.

`delete-if interface`

Deletes the interface from active configuration. All addresses configured on the interface will be torn down. Further, all the persistent information related to the interface will be removed from the persistent data store and, for this reason, *interface* will not be instantiated upon reboot. To disable an interface from active configuration (rather than delete the interface), use the `disable-if` subcommand.

`show-if [[-p] -o field[,...]] [interface]`

Show network interface configuration information, either for all the network interfaces configured on the system, including the ones that are only in the persistent configuration, or for the specified network interface.

`-o field[,...], --output field[,...]`

A case-insensitive, comma-separated list of output fields to display. The *field* name must be one of the fields listed below, or the special value `all` to display all fields. For each network interface, the following fields can be displayed:

IFNAME

The name of the IP interface.

STATE

Indicates one of the following for the displayed interface.

ok

Indicates that the required resources for an interface are allocated. For some interfaces this also indicates that the link is up.

offline

The interface is offline and thus cannot send or receive IP data traffic. See [if_mpadm\(1M\)](#).

failed

Indicates that the datalink is down. If the interface is part of an IPMP group it could also mean that the interface has failed (that is, IFF_FAILED is set). Failed interfaces will not be used to send or receive IP data traffic. If this is set on a physical IP interface in an IPMP group, IP data traffic will continue to flow over other usable IP interfaces in the IPMP group. If this is set on an IPMP IP interface, the entire group has failed and no data traffic can be sent or received over any interfaces in that group. See [in.ndpd\(1M\)](#).

down

Indicates that the interface is administratively down, preventing any IP packets from being sent or received through it.

disabled

Indicates that the interface has been disabled from the active configuration using the `disable-if` subcommand.

CURRENT

For interface objects, in active configuration, it indicates any of the following flags.

b

interface supports broadcast

m

interface supports multicast

p

interface is a point-to-point link

v

interface is a virtual interface (for example, [vni\(7d\)](#), loopback), that is, the physical interface has no underlying hardware.

I

IPMP meta interface

s

IPMP interface is marked standby administratively. See [in.ndpd\(1M\)](#).

i

IPMP interface is inactive. See [in.ndpd\(1M\)](#).

V

interface is a VRRP interface

a

VRRP interface is in accept mode (`~IFF_NOACCEPT`)

Z

Layer-3 protection of IP addresses for the interface has been administratively enforced.

4

interface can handle IPv4 packets

6

interface can handle IPv6 packets

Note that `b` and `p` are mutually exclusive.

PERSISTENT

Specifies the configuration that will be applied when the interface object is instantiated on reboot or re-enabled using the `enable-if` subcommand. It can be any or all of `s`, `4`, and `6` (see above).

`-p, --parsable`

Display using a stable machine-parsable format. The `-o` option is required with this option. See “Parsable Output Format”, below.

`disable-if -t interface`

Disables the specified *interface* by removing it from the active configuration. All the addresses configured on the interface will be disabled. If the interface object was created persistently to begin with, then the persistent configuration is unchanged. To re-enable this interface, one should use `enable-if`.

`-t, --temporary`

Specifies that the disable is temporary and changes apply only to the active configuration.

`enable-if -t interface`

Enables the given interface by reading the configuration from the persistent store. All the persistent interface properties, if any, are applied and all the persistent addresses, if any, on the given interface will be enabled.

`-t, --temporary`

Specifies that the enable is temporary and changes apply only to the active configuration.

`set-ifprop [-t] -m protocol -p prop=value[...] interface`

Modifies an interface property to the value specified by the user. If the property takes multiple values then the values should be specified with a comma as the delimiter. Only one property can be specified at a time. The properties supported on an interface and the property's possible values can be retrieved using `show-ifprop` subcommand. Only one property at a time can be modified.

`-t, --temporary`

Specifies that the changes are temporary and changes apply only to the active configuration.

-m protocol, *--module protocol*

Identifies whether property should be applied for IPv4 or IPv6 packets.

-p prop=value[...], *--prop prop=value[...]*

A property to set to the specified values.

reset -i fprop [-t] -m protocol -p prop interface

Resets a property of the specified interface to its default value. If *-t* is not used, any persisted value of the property will be deleted. Only one property can be modified at a time.

-t, *--temporary*

Specifies that the resets are temporary and changes apply only to the active configuration.

-m protocol, *--module protocol*

Identifies whether the property being reset affects either IPv4 or IPv6 packets.

-p prop, *--prop prop*

A property to set to the specified values.

show -i fprop [[-c] -o field[...]] [-p prop,...] [-m protocol] [interface]

Show the current and persistent values of one or more properties, either for all the created interfaces or for the specified interface. Several properties of interest can be retrieved at one time by providing comma-separated property names to *-p* option. If the *-p* option is not specified, all available interface properties are displayed.

-o field[...], *--output field[...]*

A case-insensitive, comma-separated list of output fields to display. The *field* name must be one of the fields listed below, or the special value `all` to display all fields. For each interface, the following fields can be displayed:

IFNAME

The name of the interface.

PROPERTY

The name of the property.

PROTO

The name of the protocol the property belongs to. The protocols currently supported are IPv4 and IPv6.

PERM

The read/write permissions of the property. The value shown will be `r` (read-only), `w` (write-only) or `rw` (read-and-write).

CURRENT

The current value of the property. For disabled interfaces, because a value is not set, it will be shown as `--`.

PERSISTENT

The persistent value of the property. Persistent values are the values that will be reapplied on reboot.

DEFAULT

The default value of the property. If the property has no default value, - is displayed.

POSSIBLE

A comma-separated list of the values the property can have. If the values span a numeric range, *min - max* might be displayed as shorthand. If the possible values are unknown, ? is displayed or if they are unbounded, - is displayed.

-c, -parsable

Display using a stable machine-parsable format. The -o option is required with this option. See “Parsable Output Format”, below.

-p prop,..., --prop=prop

A comma-separated list of properties to display. See the sections on interface properties following subcommand descriptions.

-m protocol, -module protocol

Displays properties matching the given protocol. Valid values are *ipv4* and *ipv6*.

For the supported list of interface properties, see “Interface Properties” below.

create-addr [-t] -T static [-d] -a {local | remote}=addr[/prefixlen],... addrobj

Creates a static IPv4 or IPv6 address on the interface specified in *addrobj*. If the interface on which the address is created is not plumbed, this subcommand will implicitly plumb the interface. The created static address will be identified by *addrobj*.

By default, a configured address will be marked up, so that it can be used as a source or destination of or for outbound and inbound packets.

All address objects are enabled when they are created. See the *disable-addr* and *enable-addr* subcommands for instructions on disabling or enabling an address object.

A persistent operation cannot be performed on a temporary object. That is, if the interface is temporarily created, then one cannot create the address object persistently.

-t, -temporary

Specifies that the configured address is temporary and changes apply only to the active configuration.

-d, -down

Specifies that the configured address should be marked down, that is, the address will not be used as a source or destination of IP packets.

-a {local | remote}=addr[/prefixlen],...**--address {local | remote}=addr[/prefixlen],...**

addr indicates a literal IP address or a hostname corresponding to the local or remote end-point (for point-to-point interfaces).

If a hostname is specified its numeric value is uniquely obtained using the entry in `/etc/hosts`. If no numeric IP address is defined in the file, then the numeric value is uniquely obtained using the resolver order specified for `hosts` or `ipnodes` in `nsswitch.conf(4)`. If there are multiple entries for a given hostname, an error will be generated. Because IP addresses are created before naming services have been brought online during the boot process, it is important that any hostname used be included in `/etc/hosts`.

If the *prefixlen* is not explicitly specified in the command-line, the netmask for the address is obtained by following the search in the order listed below:

1. using the order specified for netmasks in `nsswitch.conf(4)`
2. interpreting IPv4 address using Classful subnetting semantics defined in RFC 791, and interpreting IPv6 addresses using the definitions in RFC 4291.

For point-to-point interfaces, along with the address of the local end-point the address of the remote end-point must be specified (for example, `-a local=laddr,remote=raddr`). If *prefixlen* for the remote end-point is specified, an error will be returned.

Note that if the interface requires only a local address, specify it directly with the `-a` option as follows: `-a addr[/prefixlen]`. The address will automatically be considered a local address.

```
create-addr [-t] -T dhcp [-w seconds | forever] addrobj
```

Creates a DHCP-controlled IPv4 address on an interface specified in *addrobj*. The created IPv4 address will be identified by *addrobj*.

All the address objects are enabled when they are created. See the `disable-addr` and `enable-addr` subcommands for instructions on disabling and enabling an address object.

A persistent operation cannot be performed on a temporary object. That is, if the interface is temporarily created, one cannot create the address object persistently.

`-t, --temporary`

Specifies that the configured address is temporary and changes apply only to the active configuration.

`-w seconds | forever, --wait seconds | forever`

Specifies the amount of time, in seconds, to wait until the operation completes. If no wait interval is given, and the operation is one that cannot complete immediately, `ipadm` will, by default, wait 120 seconds for the requested operation to complete. Note that the default wait time is subject to change in future releases. The symbolic value `forever` can be used as well, with obvious meaning.

`create-addr [-t] -T addrconf [-i interface-id] [-p {stateful | stateless}={yes | no},..] addrobj`
 Creates an auto-configured IPv6 address on an interface specified in *addrobj*. The created IPv6 addresses will be identified by *addrobj*.

The system uses the default interface ID (for the media-type Ethernet, the Interface ID is the MAC address of the interface) to generate auto-configured addresses. This behavior can be overridden using `-i` option.

By default:

- IPv6 addresses will be auto-configured based on prefixes advertised by routers as described in RFC 4862 and...
- IPv6 addresses will be auto-configured on the specified interface using the IPv6 address offered by DHCPv6 server as described in RFC 3315. (That is, `-p stateful=yes, stateless=yes` is the default option.)

All the address objects are enabled when they are created. See the `disable-addr` and `enable-addr` subcommands for instructions on disabling and enabling an address object.

A persistent operation cannot be performed on a temporary object. That is, if the interface is temporarily created, then one cannot create the address object persistently.

`-t, --temporary`

Specifies that the configured address is temporary and changes apply only to the active configuration.

`-i interface-id, --interface-id interface-id`

Specifies the interface ID to be used for generating auto-configured addresses.

`-p {stateful | stateless}={yes | no},..`

`--prop {stateful | stateless}={yes | no},..`

Specifies if stateful or stateless or both methods of auto-configuration should be enabled or not.

If `-p stateful=no` is specified, then stateful auto-configuration based on DHCPv6-specified IPv6 addresses will not be performed.

If `-p stateless=no` is specified, then stateless auto-configuration based on the router-advertised prefixes will not be performed.

If `-p stateful=no, stateless=no` is specified, then both the methods of auto-configuration will not be performed.

With the `-T addrconf` option, `-p stateful=yes, stateless=yes` is used by default.

`delete-addr [-r] addrobj`

Deletes all the addresses identified by *addrobj* on the interface specified in the *addrobj*. It also removes these addresses from the persistent data-store; thus, these addresses will not be instantiated on reboot.

If the address object is a DHCP-controlled address, `delete-addr` removes the address from the system without notifying the DHCP server, and records the current lease for later use.

`-r, --release`

If the *addrobj* is a DHCP-controlled address, this option brings about the relinquishing of the DHCP-controlled IP addresses on the interface by notifying the server and the discarding of the current lease.

`show-addr` `[[-p] -o field[,...]] [addrobj | interface]`

Show address information, either for the given *addrobj* or all the address objects configured on the specified interface, including the address objects that are only in the persistent configuration.

`-p, --parsable`

Display using a stable machine-parsable format. The `-o` option is required with this option. See “Parsable Output Format”, below.

`-o field[,...], --output field[,...]`

A case-insensitive, comma-separated list of output fields to display. The *field* name must be one of the fields listed below, or the special value `all` to display all fields. For each interface, the following fields can be displayed:

ADDROBJ

The name of the address object.

TYPE

Type of the address object. It will be one of: `from-gz`, `static`, `dhcp`, or `addrconf`. The `static`, `dhcp`, and `addrconf` types correspond to the type of the address object specified by the `-T` option of `create-addr`. The `from-gz` type will only be displayed in non-global zones, and indicates that the address was configured based on the `allowed-address` property configured for the non-global exclusive-IP zone from the global zone.

STATE

State of the address object. This field is shown only when `all` is specified with `-o`. This indicates one of the following values:

disabled

Address is not part of the active configuration (see `disable-addr` and `disable-if`).

down

Address is administratively down (see `down-addr`).

duplicate
