Address was found to conflict with another system's IP address by duplicate address detection (DAD) and cannot be used until the conflict is resolved. The system will periodically rerun DAD to determine if the conflict has been resolved. Alternatively, `refresh-addr` can be used to immediately rerun DAD.

inaccessible

Address cannot be used because the IP interface it is configured on has failed.

ok

Address is enabled, up, and functioning properly. The system will accept IP packets destined to this address, and will originate IP packets with this address in accordance with the configured IP source address selection policy.

tentative

Address is currently undergoing duplicate address detection (for example, as part of `up-addr` or `refresh-addr`).

CURRENT

For address objects in active configuration, it indicates any of the following flags. This field is not shown by default and will be shown only when `all` or `current` is specified with `-o`.

d (deprecated)

Will not be used as source address for outbound packets unless either there are no other addresses available on the interface or the application has explicitly bound to this address.

p (private)

Address not advertised by the routing daemon.

t (temporary)

Temporary IPv6 address as defined in RFC 3041.

U (up)

Address is marked up for use as a source/destination of outbound/inbound packets.

u (unnumbered)

Address matches the local address of some other link in the system.

PERSISTENT

Specifies the configuration that will be applied when the address object is instantiated on reboot or re-enabled using the `enable-addr` subcommand. It can be any or all of `u`, `p`, and `d` (see above).

ADDR

Numeric IPv4 or IPv6 address. In the case of point-to-point interfaces, the addresses of both the endpoints, are displayed (`laddr-->raddr`). For an address object of type `dhcp`, if the state of the address object is `disabled`, or if the address is `0.0.0.0` for IPv4 or `::` for IPv6, then a question mark (?) is displayed.

down-addr [-t] *addrobj*

The address identified by *addrobj* is marked down, so that it cannot be used as a source/destination of outbound/inbound packets. This command has no effect if the address object was already marked down prior to the `down-addr` invocation. If the address object is of type `addrconf`, the command returns an error.

-t, --temporary

Specifies that the configured address is temporary and changes apply only to the active configuration. This option is mandatory if the address object type is `dhcp`.

`up-addr [-t] addrobj`

The address identified by *addrobj* is marked up, so that it can be used as a source/destination of outbound/inbound packets. This subcommand has no effect if the address object has been marked down by the system because it is a duplicate address, or if the address was marked up prior to the `up-addr` invocation. If the address object is of type `addrconf`, the command returns an error.

-t, --temporary

Specifies that the configured address is temporary and changes apply only to the active configuration. This option is mandatory if the address object type is `dhcp`.

`refresh-addr [-i] addrobj`

If the *addrobj* is of the type `static` then DAD (Duplicate Address Detection) will be restarted (if necessary) on the address identified by the address object.

If the *addrobj* is of the type `dhcp`, then the lease duration obtained on the address will be extended by the DHCP client daemon.

If the *addrobj* is of the type `addrconf` then the command returns an error.

-i, --inform

For a specified IP address, obtains network configuration parameters from DHCP without obtaining a lease on it. This is useful in situations where an IP address is obtained through mechanisms other than DHCP.

`disable-addr -t addrobj`

Disables the address by removing it from the active configuration. If the address object was originally created persistently, then the persistent configuration is unchanged. To re-enable this *addrobj*, one should use `enable-addr`.

-t, --temporary

Specifies that the disabling is temporary and changes apply only to the active configuration.

`enable-addr -t addrobj`

Enables the given *addrobj* by reading the configuration from the persistent store. All the persistent address properties are applied to the address object. This subcommand requires that the interface on which the address object is being enabled be present. If the interface itself is missing in active configuration and is present in persistent store, that is, if the interface is disabled, then the user has to run `enable-if` before invoking `enable-addr`.

-t, --temporary

Specifies that the enabling is temporary and changes apply only to the active configuration.

`set -addrprop [-t] -p prop=value[...] addrobj`

Sets the value of a property on the *addrobj* specified. If the *addrobj* maps to several addresses, then property changes applies to all the addresses referenced by the *addrobj*. Only one property can be specified at a time. The properties supported on the *addrobj* and the property's possible values can be retrieved using `show -addrprop` subcommand. If the *addrobj* is of type `addrconf`, the command returns an error.

`-t, --temporary`

Specifies that the changes are temporary and changes apply only to the active configuration.

`-p prop=value[...], --prop prop=value[...]`

A property to set to the specified values.

`reset -addrprop [-t] -p prop addrobj`

Resets the given address property to its default value. If `-t` is not used, any persistent value of the property will be deleted. Only one property can be modified at a time. If the *addrobj* is of type `addrconf`, the command returns an error.

`-t, --temporary`

Specifies that the resets are temporary and changes apply only to the active configuration.

`-p prop, --prop prop`

A property to be reset.

`show -addrprop [[-c] -o field[...]] [-p prop,...] [addrobj]`

Show the current and persistent values of one or more properties, either for all the configured address objects or for the specified *addrobj*. Several properties of interest can be retrieved at one time by providing comma-separated property names to `-p` option. If the `-p` option is not specified, all available properties are displayed. If the *addrobj* is of type `addrconf`, the command returns an error.

`-o field[...], --output field[...]`

A case-insensitive, comma-separated list of output fields to display. The *field* name must be one of the fields listed below, or the special value `all` to display all fields. For each *addrobj*, the following fields can be displayed:

ADDROBJ

The name of the address object.

PROPERTY

The name of the property.

PERM

The read/write permissions of the property. The value shown will be `r` (read only), `w` (write only) or `rw` (read/write).

CURRENT

The current value of the property. For the disabled addresses, because the value is not set, the value displays as a double hyphen (--).

PERSISTENT

The persistent value of a property. Persistent values are the values that will be reapplied on reboot.

DEFAULT

The default value of the property. If the property has no default value, double hyphen (--) is shown.

POSSIBLE

A comma-separated list of the values a property can have. If the values span a numeric range, *min - max* might be shown as shorthand. If the possible values are unknown, a question mark (?) is displayed or if they are unbounded, double hyphen (--) will be shown.

-c, --parsable

Display using a stable machine-parsable format. The -o option is required with this option. See “Parsable Output Format”, below.

-p *prop*,..., --prop=*prop*

A comma-separated list of properties to display. See the sections on address object properties following subcommand descriptions.

set-prop [-t] -p prop[+|-]=*value*[...] *protocol*

Modifies the value of a protocol property to the *value* specified. If the property takes multiple values, the values should be specified with a comma as the delimiter. Only one property can be specified at a time. By default, the value is persistent and will be reapplied on reboot. The properties supported on a protocol and the property's possible values can be retrieved using the show-prop subcommand

The following protocols are supported: ip, ipv4, ipv6, icmp, tcp, udp and sctp.

Note that for some properties, it might be possible to set the value of the property both globally, and on a per-interface basis. The per-interface value can be set using the set-ifprop subcommand. In such cases, if the administrator chooses to customize the per-interface value of the property to be distinct from the global value, the per-interface value overrides the global setting for that interface.

-t, --temporary

Specifies that the changes to properties are temporary and changes apply only to the active configuration.

-p prop[+|-]=*value*[...], --prop prop[+|-]=*value*[...]

A property to set to the specified values. It also provides the following “qualifiers” to perform add and delete operations in addition to assignment.

- + Adds the given value to the current list of value(s).
- Removes the given value from the current list of value(s).
- = Makes a new assignment and removes all the current value(s).

See EXAMPLES for more information on how to use the qualifiers.

`reset-prop [-t] -p prop protocol`

Resets a property of the specified protocol to the default value of the property. If -t is not used, any persistent value of the property will be deleted. Only one property can be modified at a time.

`-t, --temporary`

Specifies that the resets are temporary and changes apply only to the active configuration.

`-p prop, --prop prop`

A property to be reset.

`show-prop [[-c] -o field[,...]] [-p prop,...] [protocol]`

Show the current and persistent values of one or more properties, either for all supported protocols or for the specified protocol. Several properties of interest can be retrieved at a time by providing comma-separated property names to -p option. If the -p option is not specified, all available properties are displayed.

`-o field[,...], --output field[,...]`

A case-insensitive, comma-separated list of output fields to display. The *field* name must be one of the fields listed below, or the special value `all` to display all fields. For each *protocol*, the following fields can be displayed:

PROTO

The name of the protocol.

PROPERTY

The name of the property.

PERM

The read/write permissions of the property. The value shown will be `r` (read only), `w` (write only) or `rw` (read/write).

CURRENT

The current value of the property. For the disabled addresses, because the value is not set, the value displays as a double hyphen (- -). If the value is unknown, it is displayed as a question mark (?). If the current value of the property is not in the set of listed POSSIBLE values, the keyword `custom` is displayed.

PERSISTENT

The persistent value of a property. Persistent values are the values that will be reapplied on reboot.

DEFAULT

The default value of the property. If the property has no default value, double hyphen (- -) is shown.

POSSIBLE

A comma-separated list of the values for the property setting to be used with the `set -prop` subcommand. If the values span a numeric range, *min - max* might be shown as shorthand. If the possible values are unknown, a question mark (?) is displayed or if they are unbounded, double hyphen (- -) will be shown.

-c, --parsable

Display using a stable machine-parsable format. The `-o` option is required with this option. See “Parsable Output Format”, below.

-p *prop*,..., --prop=*prop*

A comma-separated list of properties to display. See the sections on protocol properties following subcommand descriptions.

For the supported list of properties for every protocol, see “Protocol Properties” below.

Parsable Output Format

The `ipadm “show”` subcommands have an `-o` option that displays output in a machine-parsable format. The output format is one or more lines of colon (:) delimited fields. The fields displayed are specific to the subcommand used and are listed under the entry for the `-o` option for a given subcommand. Output includes only those fields requested by means of the `-o` option, in the order requested. Note that the `-o all` option, which displays all the fields for a given subcommand, cannot be used with parsable output option.

When you request multiple fields, any literal colon characters are escaped by a backslash (\) before being output. Similarly, literal backslash characters are also escaped (\\). This escape format is parsable by using shell [read\(1\)](#) functions with the environment variable set as `IFS=:`. Note that escaping is not done when you request only a single field.

Protocol Properties The following protocol properties are supported:

hostmodel (IPv4), hostmodel (IPv6)

Control send/receive behavior for IP packets on a multi-homed system. The value of `hostmodel` can be set to `strong` or `weak`, corresponding to the equivalent end-system model definitions of RFC 1122. In addition, a third value of `src-priority` is also supported. In the `src-priority` `hostmodel` scenario, a packet will be accepted on any interface, as long as the packet’s destination IP address is configured and marked UP on one of the host’s interfaces. When transmitting a packet, if multiple routes for the IP destination in the packet are available, the system will prefer routes where the IP source address in the packet is configured on the outgoing interface. If no such route is available, the system will fall back to selecting the “best” route, as with the weak ES case.

`ttl` (IPv4), `hoplimit` (IPv6)

Specifies the value that will be set for `ttl/hoplimit` field of an IPv4 or IPv6 header. Can be used to prevent the system from reaching other systems more than *N* hops away where *N* was the value specified.

`forwarding` (IPv4), `forwarding` (IPv6)

Enable/disable global IPv4 or IPv6 forwarding. All the configured interfaces will start/stop forwarding packets. Individual interfaces can override the global option using `set - ifprop`.

`recv_maxbuf` (TCP, SCTP, UDP, ICMP)

`send_maxbuf` (TCP, SCTP, UDP, ICMP)

Modifies the receive or send buffer sizes for the specified protocol.

`sack` (TCP)

Selective acknowledgment (SACK) allows recipients to selectively acknowledge out-of-sequence data and is intended to increase performance for data transfers over lossy links. See RFC 2018 for information on the SACK. Possible values and meanings:

`never`

Will neither accept SACK nor send out SACK information.

`passive`

Will accept SACK but not send out.

`active`

Will both accept SACK and send out SACK information.

`ecn` (TCP)

Explicit Congestion Control (see RFC 3168 for more information). Possible values are the same as above: `never`, `passive`, and `active`.

`smallest_anon_port` (TCP, SCTP, UDP)

`largest_anon_port` (TCP, SCTP, UDP)

These options define the upper and lower bounds on ephemeral ports. Ephemeral (means short-lived) ports are used when establishing outbound network connections.

`smallest_nonpriv_port` (TCP, SCTP, UDP)

This option define the start of non-privileged ports. The non-privileged port range normally starts at 1024. Any program that attempts to bind a non-privileged port does not have to run as root.

`extra_priv_ports` (TCP, SCTP, UDP)

This option define additional privileged ports outside of the 1-1023 range. Any program that attempts to bind the ports listed here must run as root. This prevents normal users from starting server processes on specific ports.

These ports can be added, removed, or assigned using the `set -prop` subcommand and the modifiers `+`, `-`, and `=`. See EXAMPLES below on usage.

Interface Properties The following interface properties are supported:

arp

Enables/disables the use of the Address Resolution Protocol (ARP) on an interface. ARP is used in mapping between network level addresses and link level addresses. This is currently implemented for mapping between IPv4 addresses and MAC addresses. Possible values are `on` or `off`. Default is `on`.

forwarding

Enables/disables IP forwarding on an interface. When enabled, the IP packets can be forwarded to and from the interface. Possible values are `on` or `off`. Default is `off`.

metric

Set the routing metric of the interface to *n*; if no value is specified, the default is 0. The routing metric is used by the routing protocol. Higher metrics have the effect of making a route less favorable. Metrics are counted as additional hops to the destination network or host.

mtu

Set the maximum transmission unit of the interface to *n*. For many types of networks, the MTU has an upper limit, for example, 1500 for Ethernet.

nud

Enables/disables the neighbor unreachability detection mechanism on a point-to-point physical interface. Possible values are `on` or `off`. Default is `on`.

usesrc

Specifies a physical or virtual interface to be used for source address selection. If the keyword `none` is used, then any previous selection is cleared. Default is Specifies a physical or virtual interface to be used for source address selection. If the keyword `none` is used, any previous selection is cleared. Default is `none`.

exchange_routes

Enables/disables exchanging of routing information on this interface. Possible values are `on` or `off`. Default is `off`.

Address Properties The address properties listed below are supported. Note that modifying address properties for `addrconf` address objects is not supported.

deprecated

The address should no longer be used as a source address in new communications, but packets addressed to this address are processed as expected. Possible values are `on` or `off`. Default is `off`. This property is not supported on an address object of type `dhcp`.

prefixlen

Specifies the number of left-most contiguous bits of the address that comprise the IPv6 prefix or IPv4 netmask of the address. The remaining low-order bits define the host part of the address. When `prefixlen` is converted to a text representation of the address, the address contains 1's for the bit positions that are to be used for the network part, and 0's for

the host part. The `prefixlen` must be specified as a single decimal number. This property is not supported on an address object of type `dhcp`.

private

Specifies that the addresses should not be advertised by the `in.routed` routing daemon. Possible values are `on` or `off`. Default is `off`.

transmit

Enables packets to be transmitted using the addresses referenced by the address object. This is the default behavior when the address is up. Possible values are `on` or `off`. Default is `on`.

zone

Specifies the zone in which all the addresses referenced by the address object should be placed. The named zone must be active in the kernel in the ready or running state. The interface is unplumbed when the zone is halted or rebooted. The zone must be configured to be an shared-IP zone. `zonecfg(1M)` is used to assign network interface names to exclusive-IP zones. To modify the zone assignment such that it persists across reboots, please use `zonecfg(1M)`. Possible values are the list of all the zones configured on the system. Default is `global`.

Operands Each `ipadm` subcommand operates on one of the following objects:

addrobj

An address configured on a network interface is identified by an *addrobj*. An *addrobj* consists of two parts. The first part is the name of the network interface on which the address is configured. The second part is a user-specified string that can use any of the alphanumeric characters and can be at-most 32 characters in length and must begin with a letter. The two parts of the *addrobj* are delimited by a slash (/). An address object always represents a unique set of address(es) in a system.

interface

Name of the underlying IP interface on which network address is configured.

protocol

Name of the TCP/IP Internet protocol family for which a property is to be configured. Following protocols are supported: `ip`, `ipv4`, `ipv6`, `icmp`, `tcp`, `sctp` and `udp`.

Examples **EXAMPLE 1** Creating IPv4 Static Addresses

The following command creates the address `10.2.3.4/24` on interface `bge1` and marks the address up, for use.

```
# ipadm create-addr -T static -a local=10.2.3.4/24 bge1/v4static1
```

The following command creates the address `10.2.3.5/24` on interface `bge1` but marks the address down until explicitly marked up.

```
# ipadm create-addr -T static -d -a 10.2.3.5/24 bge1/v4static2
```

EXAMPLE 1 Creating IPv4 Static Addresses *(Continued)*

Note that 10.2.3.5/24 is assumed to be the local address, because local was not used and there was only one address.

The following command marks the address object `bge1/v4static2` up that was previously marked down.

```
# ipadm up-addr bge1/v4static2
```

If the `DUPLICATE` flag was set on the address object, then `refresh-addr` will verify that the address is still a duplicate on the network. If it is not, the address will be marked up.

```
# ipadm refresh-addr bge1/v4static2
```

The following command lists the addresses that were configured. This shows that the address `bge1/v4static2` is not a duplicate.

```
# ipadm show-addr
ADDROBJ          TYPE    CURRENT    PERSISTENT  ADDR
lo0/v4           static  eU-----  ---         127.0.0.1/8
lo0/v6           static  eU-----  ---         ::/128
bge1/v4static1   static  eU-----  U--         10.2.3.4/24
bge1/v4static2   static  eU-----  U--         10.2.3.10/24
```

EXAMPLE 2 Creating DHCPv4-controlled Addresses

The following command obtains a DHCPv4 address on interface `bge1`.

```
# ipadm create-addr -T dhcp bge1/dhaddr
# ipadm show-addr bge1/dhaddr
ADDROBJ          TYPE    CURRENT    PERSISTENT  ADDR
bge1/dhaddr      dhcp    eU-----  ---         10.8.48.173/25
```

The following command extends the lease duration for the DHCPv4 address object `bge1/dhaddr`.

```
# ipadm refresh-addr bge1/dhaddr
```

EXAMPLE 3 Creating IPv6 Addresses

The following sequence of commands auto-configures IPv6 addresses on `bge1` using `in.ndpd` with the default interface ID. A link-local address is configured first, followed by `in.ndpd` adding the stateless and stateful auto-configured addresses.

```
# ipadm create-addr -T addrconf bge1/v6addr
```

The following command creates a IPv6 static address. To be able to configure an IPv6 address that is not a link-local address, the interface should already have a link-local address configured on it. It was accomplished by the previous step with `-T addrconf`.

```
# ipadm create-addr -T static -a local=2ff0::f3ad/64 bge1/v6static
```

EXAMPLE 3 Creating IPv6 Addresses (Continued)

The following command changes the prefix length of an IPv6 address.

```
# ipadm set-addrprop -p prefixlen=80 bge1/v6static
```

All the auto-configured addresses and the updated prefix length can be viewed by listing the addresses:

```
# ipadm show-addr
ADDROBJ      TYPE      CURRENT   PERSISTENT ADDR
lo0/v4       static    eU----- ---      127.0.0.1/8
lo0/v6       static    eU----- ---      ::/128
bge1/v6addr   addrconf eU----- ---      fe80::203:baff:fe94:2f01/10
bge1/v6addr   addrconf eU----- ---      2002:a08:39f0:1:203:baff:fe94:2f00/64
bge1/v6addr   addrconf eU----- ---      2001:db8:1:2::402f/128
bge1/v6static static    eU----- U--     2ff0::f3ad/80
```

EXAMPLE 4 Configuring an IPv4 Tunnel

The first command below (`ipadm`) creates the tunnel source address. Then, a `dladm` command creates the tunnel link. The final `ipadm` commands configure the IPv4 and IPv6 addresses on the tunnel IP interface.

```
# ipadm create-addr -T static -a local=10.2.3.4/24 bge1/v4static
# dladm create-iptun -T ipv4 -a local=10.2.3.4,remote=10.2.3.5 tun0
# ipadm create-addr -T static \
-a local=173.129.134.1,remote=173.129.134.2 tun0/v4tunaddr
# ipadm create-addr -T static \
-a local=2ff1::3344,remote=2ff1::3345 tun0/v6tunaddr
# ipadm show-addr
ADDROBJ      TYPE      CURRENT   PERSISTENT ADDR
lo0/v4       static    eU----- ---      127.0.0.1/8
lo0/v6       static    eU----- ---      ::/128
bge1/v4static static    eU----- U--     10.2.3.4/24
tun0/v4tunaddr static    eU----- U--     173.129.134.1->173.129.134.2
tun0/v6tunaddr static    eU----- U--     2ff1::3344->2ff1::3345
```

EXAMPLE 5 Viewing all of the Interfaces

The following command enables you to view all interfaces.

```
# ipadm show-if
IFNAME      STATE      CURRENT     PERSISTENT
lo0         ok         -m-v-----46 ---
e1000g0     ok         bm-----4- -46
e1000g1     disabled  ----- -46
ipmp0       failed    bm--I----46 -46
tun0       disabled  ----- --6
vni0       disabled  ---v-----46 -46
```

EXAMPLE 6 Displaying Interface Properties

The following command displays all interface properties for a specified interface.

```
# ipadm show-ifprop net0
IFNAME PROPERTY          PROTO PERM CURRENT PERSISTENT DEFAULT POSSIBLE
net0  arp                  ipv4  rw   on    --        on    on,off
net0  forwarding            ipv4  rw   off   on        off   on,off
net0  metric                  ipv4  rw   2     2        0     --
net0  mtu                     ipv4  rw   1500  --       1500  68-1500
net0  exchange_routes        ipv4  rw   off   --       off   on,off
net0  usesrc                  ipv4  rw   none  --       none  --
net0  forwarding            ipv6  rw   off   --       off   on,off
net0  metric                  ipv6  rw   2     2        0     --
net0  mtu                     ipv6  rw   1500  --       1500  1280-1500
net0  nud                     ipv6  rw   on    --       on    on,off
net0  exchange_routes        ipv6  rw   off   on       off   on,off
net0  usesrc                  ipv6  rw   none  --       none  --
```

EXAMPLE 7 Configuring per-Interface Properties

The following command sets the IPv4 MTU of the interface `net0` to `900`.

```
# ipadm set-ifprop -m ipv4 -p mtu=900 net0
```

The following command sets the IPv6 MTU of the interface `net0` to `1400`.

```
# ipadm set-ifprop -m ipv6 -p mtu 1400 net0
```

View the results:

```
# ipadm show-ifprop -p mtu net0
IFNAME PROPERTY          PROTO PERM CURRENT PERSISTENT DEFAULT POSSIBLE
net0  mtu                  ipv4  rw   900    900     1500    68-1500
net0  mtu                  ipv6  rw   1400   1400    1500    1280-1500

# ipadm show-ifprop -m ipv6 -p mtu net0
IFNAME PROPERTY          PROTO PERM CURRENT PERSISTENT DEFAULT POSSIBLE
net0  mtu                  ipv6  rw   1400   1400    1500    1280-1500
```

EXAMPLE 8 Displaying Supported Properties

The following command displays the properties supported on TCP.

```
# ipadm show-prop tcp
PROTO PROPERTY          PERM CURRENT PERSISTENT DEFAULT POSSIBLE
tcp  ecn                  rw   active  active    passive  never,passive,
                                         active
tcp  extra_priv_ports    rw   --      1,65535  2049,4045 1-65535
tcp  largest_anon_port    rw   32768   32768    65535     1024-65535
tcp  sack                 rw   active  --        active    never,passive,
                                         active
```

EXAMPLE 8 Displaying Supported Properties *(Continued)*

| | | | | | | |
|-----|-----------------------|----|-------|----|-------|-----------------|
| tcp | recv_maxbuf | rw | 29567 | -- | 49152 | 2048-1073741824 |
| tcp | send_maxbuf | rw | 21354 | -- | 49152 | 4096-1073741824 |
| tcp | smallest_anon_port | rw | 32768 | -- | 32768 | 1024-65535 |
| tcp | smallest_nonpriv_port | rw | 1024 | -- | 1024 | 1024-32768 |

EXAMPLE 9 Configuring Global IPv4 Forwarding

The following command sequence configures global IPv4 forwarding and overrides that setting for interface net0.

```
# ipadm set-prop -p forwarding=on ipv4
# ipadm set-ifprop -p forwarding=off -m ipv4 net0
# ipadm show-prop -p forwarding ipv4
```

| PROTO | PROPERTY | PERM | CURRENT | PERSISTENT | DEFAULT | POSSIBLE |
|-------|------------|------|---------|------------|---------|----------|
| ipv4 | forwarding | rw | on | on | off | on,off |

```
# show-ifprop -p forwarding -m ipv4 net0
```

| IFNAME | PROPERTY | PROTO | PERM | CURRENT | PERSISTENT | DEFAULT | POSSIBLE |
|--------|------------|-------|------|---------|------------|---------|----------|
| net0 | forwarding | ipv4 | rw | off | off | off | on,off |

EXAMPLE 10 Using Qualifiers in set -prop Subcommand

The following command sequence uses the plus and minus (+, -) qualifiers to add 1047, 1048, and 1049 as extra privileged ports for TCP.

```
# ipadm set-prop -p extra_priv_ports=1047 tcp
# ipadm set-prop -p extra_priv_ports+=1048 tcp
# ipadm set-prop -p extra_priv_ports+=1049 tcp
# ipadm set-prop -p extra_priv_ports+=1050 tcp
```

The following command deletes 1048 as extra privileged port.

```
# ipadm set-prop -p extra_priv_ports-=1048
```

The following command displays all the extra privileged ports for TCP.

```
# ipadm show-prop -p extra_priv_ports tcp
```

| PROTO | PROPERTY | PERM | CURRENT | PERSISTENT | DEFAULT | POSSIBLE |
|-------|------------------|------|--------------------|--------------------|-----------|----------|
| ipv4 | extra_priv_ports | rw | 1047,1049,
1050 | 1047,1049,
1050 | 2049,4045 | 1-65535 |

EXAMPLE 11 Enabling and Disabling Objects

The following command sequences enables and disables interface and address objects and display the results of those actions.

```
# ipadm create-addr -T static -a local=10.2.3.4/24 bge1/v4static
# ipadm set-addrprop -p private=yes bge1/v4static
# ipadm show-addr bge1/v4static
```

EXAMPLE 11 Enabling and Disabling Objects *(Continued)*

```

ADDROBJ      TYPE    CURRENT  PERSISTENT  ADDR
bge1/v4static  static eU-p----- Up-      10.2.3.4/24

```

The following command disables the address object `bge1/v4static`.

```

# ipadm disable-addr -t bge1/v4static
# ipadm show-addr bge1/v4static
ADDROBJ      TYPE    CURRENT  PERSISTENT  ADDR
bge1/v4static  static ----- Up-      10.2.3.4/24

```

The following command disables the interface object `bge1`.

```

# ipadm disable-if -t bge1
# ipadm show-if bge1
IFNAME      STATE      CURRENT      PERSISTENT
bge1        disabled  ----- -46

```

The following command enables the interface object from the persistent configuration.

```

# ipadm enable-if -t bge1
# ipadm show-if bge1
IFNAME      STATE      CURRENT      PERSISTENT
bge1        ok        bm-----46  -46

# ipadm show-addr bge1/v4static
ADDROBJ      TYPE    CURRENT  PERSISTENT  ADDR
bge1/v4static  static eU-p----- Up-      10.2.3.4/24

```

Note that when the interface object is enabled all the address objects configured on that interface are enabled also.

The following command creates persistent configuration for the `net0` interface in a non-global exclusive-IP zone so that the `net0` interface will be configured with the set of addresses made available through the `allowed-address` resource from the global zone on the next reboot.

```
# ipadm create-if net0
```

The `net0` interface can also be configured with the available set of `allowed-address` values in the non-global exclusive-IP zone without a reboot by executing the following commands:

```
# ipadm disable-if -t net0
# ipadm enable-if -t net0
```

Name ipf – alter packet filtering lists for IP packet input and output

Synopsis ipf [-6AdDEInoPRrsVyzZ] [-l block | pass | nomatch]
 [-T *optionlist*] [-F i | o | a | s | S] -f *filename*
 [-f *filename...*]

Description The ipf utility is part of a suite of commands associated with the Solaris IP Filter feature. See [ipfilter\(5\)](#).

The ipf utility opens the filenames listed (treating a hyphen (-) as stdin) and parses the file for a set of rules which are to be added or removed from the packet filter rule set.

If there are no parsing problems, each rule processed by ipf is added to the kernel's internal lists. Rules are added to the end of the internal lists, matching the order in which they appear when given to ipf.

ipf's use is restricted through access to /dev/ipauth, /dev/ipl, and /dev/ipstate. The default permissions of these files require ipf to be run as root for all operations.

Enabling Solaris IP Filter Feature Solaris IP Filter is installed with the Solaris operating system. However, packet filtering is not enabled by default. Use the following procedure to activate the Solaris IP Filter feature.

1. Assume a role that includes the IP Filter Management rights profile (see [rbac\(5\)](#)) or become superuser.
2. Configure system and services' firewall policies. See [svc.ipfd\(1M\)](#) and [ipf\(4\)](#).
3. (Optional) Create a network address translation (NAT) configuration file. See [ipnat.conf\(4\)](#).
4. (Optional) Create an address pool configuration file. See [ippool\(4\)](#).

Create an `ippool.conf` file if you want to refer to a group of addresses as a single address pool. If you want the address pool configuration file to be loaded at boot time, create a file called `/etc/ipf/ippool.conf` in which to put the address pool. If you do not want the address pool configuration file to be loaded at boot time, put the `ippool.conf` file in a location other than `/etc/ipf` and manually activate the rules.

5. Enable Solaris IP Filter, as follows:

```
# svcadm enable network/ipfilter
```

To re-enable packet filtering after it has been temporarily disabled either reboot the machine or enter the following command:

```
# svcadm enable network/ipfilter
```

...which essentially executes the following ipf commands:

1. Enable Solaris IP Filter:

```
# ipf -E
```

2. Load ippools:

```
# ippool -f <ippool configuration file>
```

See [ippool\(1M\)](#).

3. (Optional) Activate packet filtering:

```
ipf -f <ipf configuration file>
```

4. (Optional) Activate NAT:

```
ipnat -f <IPNAT configuration file>
```

See [ipnat\(1M\)](#).

Note – If you reboot your system, the IPfilter configuration is automatically activated.

Options The following options are supported:

-6

This option is required to parse IPv6 rules and to have them loaded. Loading of IPv6 rules is subject to change in the future.

-A

Set the list to make changes to the active list (default).

-d

Turn debug mode on. Causes a hex dump of filter rules to be generated as it processes each one.

-D

Disable the filter (if enabled). Not effective for loadable kernel versions.

-E

Enable the filter (if disabled). Not effective for loadable kernel versions.

-F i | o | a

Specifies which filter list to flush. The parameter should either be *i* (input), *o* (output) or *a* (remove all filter rules). Either a single letter or an entire word starting with the appropriate letter can be used. This option can be before or after any other, with the order on the command line determining that used to execute options.

-F s | S

To flush entries from the state table, use the -F option in conjunction with either *s* (removes state information about any non-fully established connections) or *S* (deletes the entire state table). You can specify only one of these two options. A fully established connection will show up in `ipfstat -s` output as 4/4, with deviations either way indicating the connection is not fully established.

-f *filename*

Specifies which files `ipf` should use to get input from for modifying the packet filter rule lists.

- I
Set the list to make changes to the inactive list.
- l *pass* | *block* | *nomatch*
Toggles default logging of packets. Valid arguments to this option are *pass*, *block* and *nomatch*. When an option is set, any packet which exits filtering and matches the set category is logged. This is most useful for causing all packets that do not match any of the loaded rules to be logged.
- n
Prevents *ipf* from making any *ioctl* calls or doing anything which would alter the currently running kernel.
- o
Force rules by default to be added/deleted to/from the output list, rather than the (default) input list.
- P
Add rules as temporary entries in the authentication rule table.
- R
Disable both IP address-to-hostname resolution and port number-to-service name resolution.
- r
Remove matching filter rules rather than add them to the internal lists.
- s
Swap the currently active filter list to be an alternative list.
- T *optionlist*
Allows run-time changing of IPFilter kernel variables. To allow for changing, some variables require IPFilter to be in a disabled state (-D), others do not. The *optionlist* parameter is a comma-separated list of tuning commands. A tuning command is one of the following:
 - list*
Retrieve a list of all variables in the kernel, their maximum, minimum, and current value.
 - single variable name*
Retrieve its current value.
 - variable name with a following assignment*
To set a new value.Examples follow:

```
# Print out all IPFilter kernel tunable parameters
ipf -T list
```

```
# Display the current TCP idle timeout and then set it to 3600
ipf -D -T fr_tcpidletimeout,fr_tcpidletimeout=3600 -E
```

```
# Display current values for fr_pass and fr_chksrc, then set
# fr_chksrc to 1.
ipf -T fr_pass,fr_chksrc,fr_chksrc=1
```

-v

Turn verbose mode on. Displays information relating to rule processing.

-V

Show version information. This will display the version information compiled into the ipf binary and retrieve it from the kernel code (if running or present). If it is present in the kernel, information about its current state will be displayed; for example, whether logging is active, default filtering, and so forth).

-y

Manually resync the in-kernel interface list maintained by IP Filter with the current interface status list.

-z

For each rule in the input file, reset the statistics for it to zero and display the statistics prior to them being zeroed.

-Z

Zero global statistics held in the kernel for filtering only. This does not affect fragment or state statistics.

Files /dev/ipauth

/dev/ipl

/dev/ipstate

Links to IP Filter pseudo devices.

/etc/ipf/ipf.conf

Location of ipf startup configuration file. See [ipf\(4\)](#).

/usr/share/ipfilter/examples/

Contains numerous IP Filter examples.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------|
| Availability | network/ipfilter |
| Interface Stability | Committed |

See Also [ipfstat\(1M\)](#), [ipmon\(1M\)](#), [ipnat\(1M\)](#), [ippool\(1M\)](#), [svcadm\(1M\)](#), [svc.ipfd\(1M\)](#), [ipf\(4\)](#), [ipnat.conf\(4\)](#), [ippool\(4\)](#), [attributes\(5\)](#), [ipfilter\(5\)](#)

System Administration Guide: IP Services

Diagnostics Needs to be run as root for the packet filtering lists to actually be affected inside the kernel.

Name ipfs – saves and restores information for NAT and state tables

Synopsis ipfs [-nv] -l
 ipfs [-nv] -u
 ipfs [-nv] [-d *dirname*] -R
 ipfs [-nv] [-d *dirname*] -W
 ipfs [-nNSv] [-f *filename*] -r
 ipfs [-nNSv] [-f *filename*] -w
 ipfs [-nNSv] -f *filename* -i <*if1*>,<*if2*>

Description The ipfs utility enables the saving of state information across reboots. Specifically, the utility allows state information created for NAT entries and rules using "keep state" to be locked (modification prevented) and then saved to disk. Then, after a reboot, that information is restored. The result of this state-saving is that connections are not interrupted.

Options The following options are supported:

- d Change the default directory used with -R and -W options for saving state information.
- n Do not take any action that would affect information stored in the kernel or on disk.
- v Provides a verbose description of ipfs activities.
- N Operate on NAT information.
- S Operate on filtering state information.
- u Unlock state tables in the kernel.
- l Lock state tables in the kernel.
- r Read information in from the specified file and load it into the kernel. This requires the state tables to have already been locked and does not change the lock once complete.
- w Write information out to the specified file and from the kernel. This requires the state tables to have already been locked and does not change the lock once complete.
- R Restores all saved state information, if any, from two files, ipstate.ipf and ipnat.ipf, stored in the /var/db/ipf directory. This directory can be changed with the -d option. The state tables are locked at the beginning of this operation and unlocked once complete.
- W Saves in-kernel state information, if any, out to two files, ipstate.ipf and ipnat.ipf, stored in the /var/db/ipf directory. This directory can be changed with the -d option. The state tables are locked at the beginning of this operation and unlocked once complete.

- Files**
- /var/db/ipf/ipstate.ipf
 - /var/db/ipf/ipnat.ipf
 - /dev/ipl
 - /dev/ipstate
 - /dev/ipnat

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------------|------------------|
| Availability | network/ipfilter |
| Interface Stability | Committed |

See Also [ipf\(1M\)](#), [ipmon\(1M\)](#), [ipnat\(1M\)](#), [attributes\(5\)](#)

Diagnostics Arguably, the -W and -R operations should set the locking and, rather than undo it, restore it to what it was previously.

Fragment table information is currently not saved.

Name ipfstat – reports on packet filter statistics and filter list

Synopsis ipfstat [-6aACdfghIilnoRstv]

ipfstat [-C] [-D *addrport*] [-P *protocol*] [-S *addrport*]
[-T *refreshtime*]

Description The ipfstat command is part of a suite of commands associated with the Solaris IP Filter feature. See [ipfilter\(5\)](#).

The ipfstat command examines /dev/kmem using the symbols `_fr_flags`, `_frstats`, `_filterin`, and `_filterout`. To run and work, it needs to be able to read both /dev/kmem and the kernel itself.

The default behavior of ipfstat is to retrieve and display the statistics which have been accumulated over time as the kernel has put packets through the filter.

The role of ipfstat is to display current kernel statistics gathered as a result of applying the filters in place (if any) to packets going in and out of the kernel. This is the default operation when no command line parameters are present. When supplied with either `-i` or `-o`, ipfstat will retrieve and display the appropriate list of filter rules currently installed and in use by the kernel.

ipfstat uses kernel device files to obtain information. The default permissions of these files require ipfstat to be run as root for all operations.

The ipfstat command supports the [kstat\(3KSTAT\)](#) kernel facility. Because of this support, as an alternative to ipfstat, you can use [kstat\(1M\)](#). For example:

```
# kstat -m ipf
```

Using the ipfstat `-t` option causes ipfstat to enter the state top mode. In this mode the state table is displayed similarly to the way the Unix top utility displays the process table. The `-C`, `-D`, `-P`, `-S` and `-T` command line options can be used to restrict the state entries that will be shown and to specify the frequency of display updates.

In state top mode, use the following keys to influence the displayed information:

- d Select information to display.
- l Redraw the screen.
- q Quit the program.
- s Switch between different sorting criteria.
- r Reverse the sorting criteria.

States can be sorted by protocol number, by number of IP packets, by number of bytes, and by time-to-live of the state entry. The default is to sort by the number of bytes. States are sorted in descending order, but you can use the `r` key to sort them in ascending order.

It is not possible to interactively change the source, destination, and protocol filters or the refresh frequency. This must be done from the command line.

The screen must have at least 80 columns for correct display. However, `ipfstat` does not check the screen width.

Only the first $X-5$ entries that match the sort and filter criteria are displayed (where X is the number of rows on the display). There is no way to see additional entries.

Options The following options are supported:

- 6 Display filter lists and states for IPv6, if available. This option might change in the future.
- a Display the accounting filter list and show bytes counted against each rule.
- A Display packet authentication statistics.
- C Valid only in combination with `-t`. Display “closed” states as well in the top. Normally, a TCP connection is not displayed when it reaches the `CLOSE_WAIT` protocol state. With this option enabled, all state entries are displayed.
- d Produce debugging output when displaying data.
- D *addrport* Valid only in combination with `-t`. Limit the state top display to show only state entries whose destination IP address and port match the *addrport* argument. The *addrport* specification is of the form *ipaddress*[,*port*]. The *ipaddress* and *port* should be either numerical or the string `any` (specifying any IP address and any port, in that order). If the `-D` option is not specified, it defaults to `-D any, any`.
- f Show fragment state information (statistics) and held state information (in the kernel) if any is present.
- g Show groups currently configured (both active and inactive).
- h Show per-rule the number of times each one scores a “hit”. For use in combination with `-i`.
- i Display the filter list used for the input side of the kernel IP processing.
- I Swap between retrieving `inactive`/`active` filter list details. For use in combination with `-i`.
- l When used with `-s`, show a list of active state entries (no statistics).
- n Show the rule number for each rule as it is printed.
- o Display the filter list used for the output side of the kernel IP processing.

- P *protocol* Valid only in combination with -t. Limit the state top display to show only state entries that match a specific protocol. The argument can be a protocol name (as defined in `/etc/protocols`) or a protocol number. If this option is not specified, state entries for any protocol are specified.
- R Disable both IP address-to-hostname resolution and port number-to-service name resolution.
- S *addrport* Valid only in combination with -t. Limit the state top display to show only state entries whose source IP address and port match the *addrport* argument. The *addrport* specification is of the form *ipaddress*[,*port*]. The *ipaddress* and *port* should be either numerical or the string any (specifying any IP address and any port, in that order). If the -S option is not specified, it defaults to -S any, any.
- s Show packet/flow state information (statistics only).
- T *refreshtime* Valid only in combination with -t. Specifies how often the state top display should be updated. The refresh time is the number of seconds between an update. Any positive integer can be used. The default (and minimal update time) is 1.
- t Show the state table in a way similar to the way the Unix utility, `top`, shows the process table. States can be sorted in a number of different ways.
- v Turn verbose mode on. Displays additional debugging information.

- Files**
- /dev/kmem
 - /dev/ksyms
 - /dev/ipl
 - /dev/ipstate

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

System Administration Guide: IP Services

Name ipmgmt – IP network interfaces and TCP/IP tunables management daemon

Synopsis /lib/inet/ipmgmt

svc:/network/ip-interface-management:default

Description ipmgmt is a system daemon that handles administrative events for network IP interfaces and IP/TCP/UDP/SCTP/ICMP tunables. It is controlled through the service management facility (SMF) service instance:

svc:/network/ip-interface-management:default

The ipmgmt daemon is started automatically by the SMF service and should not be invoked directly. It does not constitute an administrative or a programming interface. The administrative interface for managing IP interfaces and the aforementioned protocol tunables is through [ipadm\(1M\)](#).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcsr |
| Interface Stability | Private |

Name ipmon – monitors /dev/ipl for logged packets

Synopsis ipmon [-abDFhnpstvxX] [-N *device*] [[o] [NSI]] [-O [NSI]]
[-P *pidfile*] [-S *device*] [-f *device*] [*filename*]

Description The ipmon command is part of a suite of commands associated with the Solaris IP Filter feature. See [ipfilter\(5\)](#).

The ipmon command opens /dev/ipl for reading and awaits data to be saved from the packet filter. The binary data read from the device is reprinted in human readable form. However, IP addresses are not mapped back to hostnames, nor are ports mapped back to service names. The output goes to standard output, by default, or a filename, if specified on the command line. Should the -s option be used, output is sent instead to [syslogd\(1M\)](#). Messages sent by means of sys log have the day, month, and year removed from the message, but the time (including microseconds), as recorded in the log, is still included.

Messages generated by ipmon consist of whitespace-separated fields. Fields common to all messages are:

- The date of packet receipt. This is suppressed when the message is sent to sys log.
- The time of packet receipt. This is in the form *HH:MM:SS.F*, for hours, minutes, seconds, and fractions of a second (which can be several digits long).
- The name of the interface on which the packet was processed, for example, *ib1*.
- The group and rule number of the rule, for example, *@0:17*. These can be viewed with `ipfstat -in` for input rules or `ipfstat -o` for output rules. See [ipfstat\(1M\)](#).
- The action: *p* for passed, *b* for blocked, *s* for a short packet, *n* did not match any rules, or *L* for a log rule.
- The addresses. This is actually three fields: the source address and port (separated by a comma), the symbol \rightarrow , and the destination address and port. For example:
`209.53.17.22,80 → 198.73.220.17,1722.`
- *PR* followed by the protocol name or number, for example, *PR tcp*.
- *len* followed by the header length and total length of the packet, for example, *len 20 40*.

If the packet is a TCP packet, there will be an additional field starting with a hyphen followed by letters corresponding to any flags that were set. See [ipf.conf\(4\)](#) for a list of letters and their flags.

If the packet is an ICMP packet, there will be two fields at the end, the first always being *icmp*, the next being the ICMP message and submessage type, separated by a slash. For example, `icmp 3/3` for a port unreachable message.

Options The following options are supported:

-a

Open all of the device logfiles for reading log entries. All entries are displayed to the same output device (stderr or syslog).

- b
For rules which log the body of a packet, generate hex output representing the packet contents after the headers.
- D
Cause ipmon to turn itself into a daemon. Using subshells or backgrounding of ipmon is not required to turn it into an orphan so it can run indefinitely.
- f *device*
Specify an alternative device/file from which to read the log information for normal IP Filter log records.
- F
Flush the current packet log buffer. The number of bytes flushed is displayed, even if the result is zero.
- h
Displays usage information.
- n
IP addresses and port numbers will be mapped, where possible, back into hostnames and service names.
- N *device*
Set the logfile to be opened for reading NAT log records from or to *device*.
- o *letter*
Specify which log files from which to actually read data. N, NAT logfile; S, state logfile; I, normal IP Filter logfile. The -a option is equivalent to using -o NSI.
- O *letter*
Specify which log files you do not wish to read from. This is most commonly used in conjunction with the -a. Letters available as parameters are the same as for -o.
- p
Cause the port number in log messages always to be printed as a number and never attempt to look it up.
- P *pidfile*
Write the PD of the ipmon process to a file. By default this is /var/run/ipmon.pid.
- s
Packet information read in will be sent through syslogd rather than saved to a file. The default facility when compiled and installed is local0. The following levels are used:

LOG_INFO
Packets logged using the log keyword as the action rather than pass or block.

LOG_NOTICE
Packets logged that are also passed.

LOG_WARNING

Packets logged that are also blocked.

LOG_ERR

Packets that have been logged and that can be considered “short”.

-S device

Set the logfile to be opened for reading state log records from or to *device*.

-t

Read the input file/device in the way performed by [tail\(1\)](#).

-v

Show TCP window, ack, and sequence fields

-x

Show the packet data in hex.

-X

Show the log header record data in hex.

- Files**
- /dev/ipl
 - /dev/ipnat
 - /dev/ipstate

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |

System Administration Guide: IP Services

Diagnostics `ipmon` expects data that it reads to be consistent with how it should be saved and aborts if it fails an assertion which detects an anomaly in the recorded data.

Name ipmpstat – display IPMP subsystem status

Synopsis ipmpstat [-n] [-o *field*[,...]] [-P]] -a|-g|-i|-p|-t

Description The `ipmpstat` command concisely displays information about the IPMP subsystem. It supports five different output modes, each of which provides a different view of the IPMP subsystem (address, group, interface, probe, and target), described below. At most one output mode may be specified per invocation, and the displayed information is guaranteed to be self-consistent. It also provides a parseable output format which may be used by scripts to examine the state of the IPMP subsystem. Only basic privileges are needed to invoke `ipmpstat`, with the exception of probe mode which requires all privileges.

Options The following options are supported:

- a
Display IPMP data address information (“address” output mode).
- g
Display IPMP group information (“group” output mode).
- i
Display IP interface information (“interface” output mode).
- n
Display IP addresses numerically, rather than attempting to resolve them to hostnames. This option may be used in any output mode.
- o *field*[,...]
Display only the specified output fields, in order. The list of field names is case-insensitive and comma-separated. The field names that are supported depend on the selected output mode, described below. The special field name `all` may be used to display all fields for a given output mode.
- p
Display IPMP probe information (“probe” output mode).
- t
Display IPMP target information (“target” output mode).
- P
Display using a machine-parseable format, described below. If this option is specified, an explicit list of fields must be specified using the `-o` option.

Output Modes The `ipmpstat` utility supports the output modes listed below. Note that these modes map to some of the options described above.

Address Mode

Address mode displays the state of all IPMP data addresses on the system. The following output fields are supported:

ADDRESS

The hostname (or IP address) associated with the information. Note that because duplicate down addresses may exist, the address must be taken together with the **GROUP** to form a unique identity. For a given IPMP group, if duplicate addresses exist, at most one will be displayed, and an up address will always take precedence.

STATE

The state of the address. Either up if the address is **IFF_UP** (see [ifconfig\(1M\)](#)), or down if the address is not **IFF_UP**.

GROUP

The IPMP IP interface hosting the address.

INBOUND

The underlying IP interface that will receive packets for this address. This may change in response to external events such as IP interface failure. If this field is empty, then the system will not accept IP packets sent to this address (for example, because the address is down or because there are no active IP interfaces left in the IPMP group).

OUTBOUND

The underlying IP interfaces that will send packets using this source address. This may change in response to external events such as IP interface failure. If this field is empty, then the system will not send packets with this address as a source (for example, because the address is down or because there are no active IP interfaces left in the IPMP group).

If **-o** is not specified, all output fields are displayed.

Group Mode

Group mode displays the state of all IPMP groups on the system. The following output fields are supported:

GROUP

The IPMP IP interface name associated with the information. For the anonymous group (see [in.mpathd\(1M\)](#)), this field will be empty.

GROUPNAME

The IPMP group name. For the anonymous group, this field will be empty.

STATE

The state of the group:

| | |
|-----------------|--------------------------------------------------------|
| ok | All interfaces in the group are usable. |
| degraded | Some (but not all) interfaces in the group are usable. |
| failed | No interfaces in the group are usable. |

FDT

The probe-based failure detection time. If probe-based failure detection is disabled, this field will be empty.

INTERFACES

The list of underlying IP interfaces in the group. The list is divided into three parts:

1. Active interfaces are listed first and not enclosed in any brackets or parenthesis. Active interfaces are those being used by the system to send or receive data traffic.
2. INACTIVE interfaces are listed next and enclosed in parenthesis. INACTIVE interfaces are those that are functioning, but not being used according to administrative policy.
3. Unusable interfaces are listed last and enclosed in brackets. Unusable interfaces are those that cannot be used at all in their present configuration (for example, FAILED or OFFLINE).

If `-o` is not specified, all output fields are displayed.

Interface Mode

Interface mode displays the state of all IP interfaces that are tracked by `in.mpathd` on the system. The following output fields are supported:

INTERFACE

The IP interface name associated with the information.

ACTIVE

Either yes or no, depending on whether the IP interface is being used by the system for IP data traffic.

GROUP

The IPMP IP interface associated with the IP interface. For IP interfaces in the anonymous group (see `in.mpathd(1M)`), this field will be empty.

FLAGS

Assorted information about the IP interface:

- i Unusable due to being INACTIVE.
- s Marked STANDBY.
- m Nominated to send/receive IPv4 multicast for its IPMP group.
- b Nominated to send/receive IPv4 broadcast for its IPMP group.
- M Nominated to send/receive IPv6 multicast for its IPMP group.
- d Unusable due to being down.
- h Unusable due to being brought OFFLINE by `in.mpathd` because of a duplicate hardware address.

LINK

The state of link-based failure detection:

- up The link is up.

down

The link is down.

unknown

The network driver does not report link state changes.

PROBE

The state of probe-based failure detection:

ok

Probes detect no problems.

failed

Probes detect failure.

unknown

Probes cannot be sent since no suitable probe targets are known.

disabled

Probes have been disabled because a unique IP test address has not been configured.

STATE

The overall state of the interface:

ok

The interface is online and functioning properly based on the configured failure detection methods.

failed

The interface is online but has a link state of down or a probe state of failed.

offline

The interface is offline.

unknown

The interface is online but may or may not be functioning because the configured failure detection methods are in unknown states.

If -o is not specified, all output fields are displayed.

Probe Mode

Probe mode displays information about the probes being sent by `in.mpathd`. Unlike other output modes, this mode runs until explicitly terminated using Ctrl-C. The following output fields are supported:

TIME

The time the probe was sent, relative to when `ipmpstat` was started. If the probe was sent prior to starting `ipmpstat`, the time will be negative.

PROBE

An identifier representing the probe. The identifier will start at zero and will monotonically increment for each probe sent by `in.mpathd` over a given interface. To enable more detailed analysis by packet monitoring tools, this identifier matches the `icmp_seq` field of the ICMP probe packet.

INTERFACE

The IP interface the probe was sent on.

TARGET

The hostname (or IP address) of the target the probe was sent to.

NETRTT

The network round-trip-time for the probe. This is the time between when the IP module sends the probe and when the IP module receives the acknowledgment. If `in.mpathd` has concluded that the probe has been lost, this field will be empty.

RTT

The total round-trip-time for the probe. This is the time between when `in.mpathd` starts executing the code to send the probe, and when it completes processing the ack. If `in.mpathd` has concluded that the probe has been lost, this field will be empty. Spikes in the total round-trip time that are not present in the network round-trip time indicate that the local system itself is overloaded.

RTTAVG

The average round-trip-time to **TARGET** over **INTERFACE**. This aids identification of slow targets. If there is insufficient data to calculate the average, this field will be empty.

RTTDEV

The standard deviation for the round-trip-time to **TARGET** over **INTERFACE**. This aids identification of jittery targets. If there is insufficient data to calculate the standard deviation, this field will be empty.

If `-o` is not specified, all fields except for **RTTAVG** and **RTTDEV** are displayed.

Target Mode

Target mode displays IPMP probe target information. The following output fields are supported:

INTERFACE

The IP interface name associated with the information.

MODE

The probe target discovery mode:

- | | |
|------------------------|--------------------------------------------------------|
| <code>routes</code> | Probe targets found by means of the routing table. |
| <code>multicast</code> | Probe targets found by means of multicast ICMP probes. |
| <code>disabled</code> | Probe-based failure detection is disabled. |

TESTADDR

The hostname (or IP address) that will be used for sending and receiving probes. If a unique test address has not been configured, this field will be empty. Note that if an IP interface is configured with both IPv4 and IPv6 test addresses, probe target information will be displayed separately for each test address.

TARGETS

A space-separated list of probe target hostnames (or IP addresses), in firing order. If no probe targets could be found, this field will be empty.

If `-o` is not specified, all output fields are displayed.

Output Format By default, `ipmpstat` uses a human-friendly tabular format for its output modes, where each row contains one or more fields of information about a given object, which is in turn uniquely identified by one or more of those fields. In this format, a header identifying the fields is displayed above the table (and after each screenful of information), fields are separated by whitespace, empty fields are represented by `--` (double hyphens), and other visual aids are used. If the value for a field cannot be determined, its value will be displayed as `“?”` and a diagnostic message will be output to standard error.

Machine-parseable format also uses a tabular format, but is designed to be efficient to programmatically parse. Specifically, machine-parseable format differs from human-friendly format in the following ways:

- No headers are displayed.
- Fields with empty values yield no output, rather than showing `--`.
- Fields are separated by a single colon (`:`), rather than variable amounts of whitespace.
- If multiple fields are requested, and a literal `:` or a backslash (`\`) occur in a field's value, they are escaped by prefixing them with `\`.

Examples **EXAMPLE 1** Obtaining Failure Detection Time of a Specific Interface

The following code uses the machine-parseable output format to create a `ksh` function that outputs the failure detection time of a given IPMP IP interface:

```
getfdt() {
    ipmpstat -gP -o group,fdt | while IFS=: read group fdt; do
        [[ "$group" = "$1" ]] && { echo "$fdt"; return; }
    done
}
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

`/usr/sbin/ipmpstat:`

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|--------------------------|------------------|
| Availability | SUNWcs |
| Interface Stability | Committed |
| Machine-Parseable Format | Committed |
| Human-Friendly Format | Not-an-Interface |

/sbin/ipmpstat is not a Committed interface.

Name ipnat – user interface to the NAT subsystem

Synopsis ipnat [-CdFhLnRrsv] -f *filename*

Description The ipnat utility opens a specified file (treating - as stdin) and parses it for a set of rules that are to be added or removed from the IP NAT.

If there are no parsing problems, each rule processed by ipnat is added to the kernel's internal lists. Rules are appended to the internal lists, matching the order in which they appear when given to ipnat.

ipnat's use is restricted through access to /dev/ipauth, /dev/ip1, and /dev/ipstate. The default permissions of these files require ipnat to be run as root for all operations.

ipnat's use is restricted through access to /dev/ipnat. The default permissions of /dev/ipnat require ipnat to be run as root for all operations.

Options The following options are supported:

- C Delete all entries in the current NAT rule listing (NAT rules).
- d Turn debug mode on. Causes a hex dump of filter rules to be generated as it processes each one.
- F Delete all active entries in the current NAT translation table (currently active NAT mappings).
- f *filename* Parse specified file for rules to be added or removed from the IP NAT. *filename* can be stdin.
- h Print number of hits for each MAP/Redirect filter.
- l Show the list of current NAT table entry mappings.
- n Prevents ipf from doing anything, such as making ioctl calls, which might alter the currently running kernel.
- R Disable both IP address-to-hostname resolution and port number-to-service name resolution.
- r Remove matching NAT rules rather than add them to the internal lists.
- s Retrieve and display NAT statistics.
- v Turn verbose mode on. Displays information relating to rule processing and active rules/table entries.

| | |
|-------------------------|-------------------------------------------------------------|
| Files /dev/ipnat | Link to IP Filter pseudo device. |
| /dev/kmem | Special file that provides access to virtual address space. |
| /etc/ipf/ipnat.conf | Location of ipnat startup configuration file. |

`/usr/share/ipfilter/examples/` Contains numerous IP Filter examples.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------|
| Availability | network/ipfilter |
| Interface Stability | Committed |

Name ippool – user interface to the IP Filter pools

Synopsis ippool -a [-dnv] [-m *poolname*] [-o *role*] -i *ipaddr*
 [/netmask]
 ippool -A [-dnv] [-m *poolname*] [-o *role*] [-S *seed*]
 [-t *type*]
 ippool -f *file* [-dnuv]
 ippool -F [-dv] [-o *role*] [-t *type*]
 ippool -h [-dv] [-m *poolname*] [-t *type*]
 ippool -l [-dv] [-m *poolname*] [-t *type*]
 ippool -r [-dnv] [-m *poolname*] [-o *role*] -i *ipaddr*
 [/netmask]
 ippool -R [-dnv] [-m *poolname*] [-o *role*] [-t *type*]
 ippool -s [-dtv] [-M *core*] [-N *namelist*]

Description The ippool utility is used to manage information stored in the IP pools subsystem of IP Filter software. Configuration file information can be parsed and loaded into the kernel and currently configured pools can be removed, changed, or inspected.

ippool's use is restricted through access to /dev/ippool. The default permissions of /dev/ippool require ippool to be run as root for all operations.

The command line options used are divided into two sections: the global options and the instance-specific options.

ippool's use is restricted through access to /dev/ipauth, /dev/ipL, and /dev/ipstate. The default permissions of these files require ippool to be run as root for all operations.

Options ippool supports the option categories described below.

Global Options The following global options are supported:

- d Toggle debugging of processing the configuration file.
- n Prevents ippool from doing anything, such as making ioctl calls, that would alter the currently running kernel.
- v Turn verbose mode on.

Instance-Specific Options The following instance-specific options are supported:

- a Add a new data node to an existing pool in the kernel.
- A Add a new (empty) pool to the kernel.
- f *file* Read in IP pool configuration information from *file* and load it into the kernel.
- F Flush loaded pools from the kernel.

- h Display a list of pools of the type: hash loaded in the kernel.
- l Display a list of pools of the type: tree loaded in the kernel.
- r Remove an existing data node from a pool in the kernel.
- R Remove an existing pool from within the kernel.
- s Display IP pool statistical information.

Other Options The following, additional options are supported:

- i *ipaddr[/netmask]* Sets the IP address for the operation being undertaken with an all-one's mask or, optionally, a specific netmask, given in either dotted-quad notation or as a single integer.
- m *poolname* Sets the pool name for the current operation.
- M *core* Specify an alternative path to /dev/kmem from which to retrieve statistical information.
- N *namelist* Specify an alternative path to lookup symbol name information when retrieving statistical information.
- o *role* Sets the role with which this pool is to be used. Currently only ipf, auth, and count are accepted as arguments to this option.
- S *seed* Sets the hashing seed to the number specified. For use with hash-type pools only.
- t *type* Sets the type of pool being defined. Must be one of pool, hash, or group-map.
- u When parsing a configuration file, rather than load new pool data into the kernel, unload it.

| | | |
|--------------|----------------------|-------------------------------------------------------------|
| Files | /dev/ippool | Link to IP Filter pseudo device. |
| | /dev/kmem | Special file that provides access to virtual address space. |
| | /etc/ipf/ippool.conf | Location of ippool startup configuration file. |

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------|
| Availability | network/ipfilter |
| Interface Stability | Committed |

See Also [ipf\(1M\)](#), [ipfstat\(1M\)](#), [ippool\(4\)](#), [attributes\(5\)](#)

Name ipqosconf – configure the IPQoS facility

Synopsis /usr/sbin/ipqosconf

/usr/sbin/ipqosconf -a *conf_file* [-vs]

/usr/sbin/ipqosconf -c

/usr/sbin/ipqosconf -f

/usr/sbin/ipqosconf -l

/usr/sbin/ipqosconf -L

Description The `ipqosconf` utility configures the Quality of Service facility of the Internet Protocol (IP). Only superusers can use this command.

Without arguments, `ipqosconf` displays the actual IPQoS configuration.

Configuration is not preserved across reboot. You must apply the configuration every time that the machine reboots. To apply the configuration early in the boot phase, you can populate the `/etc/inet/ipqosinit.conf` file, which is then read from the `svc:/network/initial:default` service.

Options The following options are supported:

-a *conf_file* Apply the configuration in *conf_file*. If the *conf_file* is `-`, `ipqosconf` reads from standard input.

-c Populate the boot file with the current configuration.

-f Flush the configuration.

-l List the current applied configuration.

-L List the current configuration in verbose mode.

In addition to the information that the `-l` option provides, the `-L` option provides filters and classes configured through other means than the `ipqosconf` command. This option also provides the full set of filters that were created by `ipqosconf` by representing a multi-homed host in a configuration file

-s Log messages to `syslog` during an `-a` operation.

-v Toggle verbose mode during an `-a` operation.

The `-v` option causes all messages to go to the console in addition to their normal destination. Messages intended to go to `syslog`, because the `-s` flag is set or because it is a log message, still go to `syslog` as well as the console.

Configuration File The configuration file is composed of a format version and a succession of configuration (action) blocks. There are different configuration blocks for each type of action that is being configured.

Format Version The first line of the configuration file specifies the format version contained in the configuration file.

The following entry specifies the format version:

```
fmt_version x.x
```

where *x.x* is the format version. 1.0 is the only supported version.

Configuration Blocks Following the format version, are a succession of configuration (action) blocks that are different for each type of action being configured. A configuration block always has the following structure:

```
action {
    name action_name
    module module_name
    params_clause | ""
    cf_clauses
}

action_name      ::= string
module_name      ::= ipgpc | dlcosmk | dscpmk | flowacct | tswtclmt |
                  tokenmt

params_clause    ::= params {
                    parameters
                    params_stats | ""
                  }

parameters       ::= prm_name_value parameters | ""

prm_name_value   ::= param_name param_value
```

Modules The *param_name* and the types of *param_value* are specific to a given module.

```
params_stats     ::= global_stats boolean

cf_clauses       ::= class_clause cf_clauses |
                  filter_clause cf_clauses | ""

class_clause     ::= class {
                    name class_name
                    next_action next_action_name
                    class_stats | ""
                  }
```

```

class_name      ::= string
next_action_name ::= string
class_stats     ::= enable_stats boolean
boolean        ::= TRUE | FALSE

filter_clause   ::= filter {
                    name filter_name
                    class class_name
                    parameters
                }

filter_name     ::= string

```

There must be exactly one configuration block belonging to module `ipgpc`. The action must be named `ipgpc.classify`. All other actions should be reachable from `ipgpc` by way of parameters of type action or the `next_action` of a class.

The set of types that are used for parameters of the different modules are:

```

action         ::= string
protocol       ::= 1..255
port           ::= 1..65535
uint8          ::= 0..255
uint32         ::= 0..4294967296
int32          ::= -2147483648..2147483648
address        ::= <see the description section>
ifname        ::= <interface name recognized by SIOGLIFINDEX ioctl>
enum           ::= string | { string_list }
boolean        ::= TRUE | FALSE
integer_array ::= { range_value_list }
map_index      ::= uint32
address        ::= ip_address | ip_node_name
user           ::= uid | username
uid            ::= 0..65535
username       ::= string
string_list    ::= string sl_entries
sl_entries     ::= ',' string sl_entries | ""
range_value_list ::= range_value_entry range_value_entries
range_value_entry ::= range ':' integer_array_value
range          ::= uint32 '-' uint32
integer_array_value ::= string | integer_array_number
integer_array_number ::= uint8 | uint32
range_value_entries ::= ';' range_value_entry range_value_entries | ""
ip_node_name   ::= string
ip_address     ::= v4_address | v6_address
v4_address     ::= v4_ip_address / v4_cidr_mask |
v4_ip_address

```

```

v4_cidr_mask      ::= 1-32
v6_address        ::= v6_ip_address / v6_cidr_mask |
v6_ip_address
v6_cidr_mask      ::= 1-128

```

METER module tokenmt configuration syntax:

```

red_action_name    action
yellow_action_name action
green_action_name  action
committed_rate     uint32
committed_burst    uint32
peak_rate          uint32
<if present this signifies that this will be a two rate meter, not
  a single rate meter>
peak_burst         uint32
<this is the 'peak' burst size for a two rate meter, but
  the 'excess' burst size for a single rate meter>
color_aware       boolean
color_map         integer_array
global_stats      boolean

```

METER module tswtclmt configuration syntax:

```

red_action_name    action
yellow_action_name action
green_action_name  action
committed_rate     uint32
peak_rate          uint32
window            uint32
global_stats      boolean

```

MARKER module dscpmk configuration syntax:

```

next_action        action
dscp_map           int_array
dscp_detailed_stats boolean
global_stats       boolean

```

MARKER module dlcosmk configuration syntax:

```

next_action        action
cos                map_index
global_stats       boolean

```

CLASSIFIER module ipgpc configuration syntax:

```

user              user
projid            int32
if_name           ifname

```

```

direction      enum {
                LOCAL_IN,
                LOCAL_OUT,
                FWD_IN,
                FWD_OUT}
protocol       protocol
dsfield        uint8
dsfield_mask   uint8
saddr          address
daddr          address
sport          port
dport          port
priority       uint32
precedence     uint32
ip_version     enum {
                V4,
                V6 }
global_stats   boolean

```

ACCOUNTING module flowacct configuration syntax:

```

next_action    action
timer          uint32
timeout        uint32
max_limit      uint32

```

| | | |
|-------|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Types | <i>action</i> | A string of characters with a matching action definition. The character string can be up to twenty three characters in length. To allow for spaces the string needs to be enclosed in quotes and cannot span lines. Two special actions are pre-defined and can not have an explicit action definition. The two pre-defined actions are <code>continue</code> and <code>drop</code> . <code>continue</code> causes the packet that is passed to it to continue normal processing. <code>drop</code> causes the packet that is passed to it to be dropped. |
| | <i>address</i> | A machine name or address recognized by <code>getipnodebyname(3SOCKET)</code> . If a machine name is specified, and <code>ip_version</code> has been defined, the query is done using that address family. If a machine name is not specified and <code>ip_version</code> has not been defined, the query is done using the <code>AI_DEFAULT</code> flag to <code>getipnodebyname()</code> (<code>. . AF_INET6 . .</code>). CIDR address masks following an IP address are allowed. Specify the CIDR address masks as 1-32 (for v4) or 1-128 (for v6). CIDR addresses are disallowed for node names. |
| | <i>enum</i> | Either one of the supported values or comma delimited list of support values, enclosed in curly braces. |
| | <i>ifname</i> | A non-NULL, existing interface name recognized by the <code>SIOGLIFINDEX</code> socket ioctl. |
| | <i>integer_array</i> | A comma delimited set of <i>range/value</i> pairs, enclosed in curly braces. |

Specify *range* in the format *x-y*, where *x* and *y* are integers that denote the range of array indexes to which the value applies. The minimum value for both *x* and *y* is 0. The maximum value for *x* is particular to the parameter. Any array indexes not referred to in the set of ranges are left at their previous value.

| | |
|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>map_index</i> | A non-negative integer used as an index into any maps associated with a parameter of this type.

The maximum value of this type is dictated by the number of entries in the associated maps. The index starts at 0. |
| <i>port</i> | Either a service name recognized by <code>getservbyname(3SOCKET)</code> or an integer 1-65535. |
| <i>protocol</i> | Either a protocol name recognized by <code>getprotobyname(3SOCKET)</code> or an integer 1-255. |
| <i>string</i> | A character string. Enclose <i>string</i> in quotes. <i>string</i> cannot span multiple lines. |
| <i>user</i> | Either a valid user ID or username for the system that is being configured. |

Parameters The configuration file can contain the following parameters

| | |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>color_aware</i> | A value of TRUE or FALSE, indicating whether or not the configured action takes account of the previous packet coloring when classifying. |
| <i>color_map</i> | An integer array that defines which values of the <code>dscp</code> field correspond with which colors for when the <code>color_aware</code> parameter is set to TRUE. |
| <i>committed_burst</i> | The committed burst size in bits. |
| <i>committed_rate</i> | The committed rate in bits per second. |
| <i>cos</i> | The value used to determine the underlying driver level priority applied to the packet which is defined in <code>802.1D</code> . |
| <i>daddr</i> | The destination address of the datagram. |
| <i>direction</i> | The value used to build a filter matching only part of the traffic.

This parameter is of type <code>enum</code> with valid values of <code>LOCAL_IN</code> (local bound traffic), <code>LOCAL_OUT</code> (local sourced traffic), <code>FWD_IN</code> (forwarded traffic entering the system), and <code>FWD_OUT</code> (forwarded traffic exiting the system). |
| <i>dport</i> | The destination port of the datagram. |

| | |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| dscp_detailed_stats | A value of TRUE or FALSE that determines whether detailed statistics are switched on for this dscp action.

Specify TRUE to switch on or FALSE to switch off. |
| dscp_map | The <i>integer_array</i> that supplies the values that IP packets with a given dscp value have their dscp re-marked with.

The existing value is used to index into the array where the new value is taken from. The array is of size 64, meaning valid indexes are 0-63 and valid values are also 0-63. |
| dsfield | The DS field of the IP datagram header. This is an 8-bit value, with each bit position corresponding with the same one in the header; this enables matches to be done on the CU bits. If you specify this parameter, you must also specify the <code>dsfield_mask</code> parameter. |
| dsfield_mask | The mask applied to the <code>dsfield</code> parameter to determine the bits against which to match. This is an 8-bit value, with each bit position corresponding with the same one in the <code>dsfield</code> parameter. |
| global_stats | A value of TRUE or FALSE to enable or disable the statistic collection for this action. |
| green_action_name | The action to be executed for packets that are deemed to be green. |
| if_name | The name of an interface recognized by the SIOGLIFINDEX ioctl. This parameter is of type <code>ifname</code> . |
| ip_version | This parameter is of type <code>enum</code> and has valid values of V4 and V6.

If it is set to V4 only then only ipv4 addresses are requested for a specified hostname. If it is set to V6, only ipv6 addresses are returned if there are any, otherwise v4 mapped v6 addresses are returned. If both V4 and V6 are specified, or if <code>ip_version</code> is not specified, then both ipv4 and ipv6 addresses are requested for a specified hostname. |
| max_limit | The maximum number of flow entries present at one time in the <code>flowacct</code> actions in the memory resident table. |
| next_action | The action to be executed when the current action is complete.

This value can be either the name of an action defined in the configuration file, or one of the two special action types: <code>drop</code> and <code>continue</code> . |
| peak_burst | The peak burst size, for a two rate meter, or excess burst size, for a single rate meter, in bits. |
| peak_rate | The peak rate in bits per second. |

| | |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| precedence | An integer that is used to order filters. If there are two matching filters that have the same priority value, the one with the lower precedence value is the one matched. This parameter should be used because the order of the filters in a configuration file has no influence on their relative precedence. |
| priority | An integer that represents the relative priority of a filter. If there are two matching filters, the one with the higher priority value is the one matched. Multiple filters can have the same priority. |
| projid | The project ID of the process sending the data. This value is always -1 for received traffic. |
| protocol | The Upper Layer Protocol against which this entry is matched. |
| red_action_name | The action to be executed for packets that are determined to be red. |
| saddr | The source address of the datagram. |
| sport | The source port of the datagram. |
| timeout | The timeout in milliseconds after which flows are written to the accounting file. |
| timer | The period in milliseconds at which timed-out flows are checked for. |
| user | The user ID or username of the process sending the data. This value is always -1 for received traffic. |
| window | The window size in ms. |
| yellow_action_name | The action to be executed for packets that are determined to be yellow. |

Security None.

Examples **EXAMPLE 1** Sending All Traffic From eng to the AF 1 Class of Service

This example sends all traffic from eng to the AF 1 class of service. It is documented in four separate steps:

The following step creates a tokenmt action with three outcomes:

```
#meter for class 1.
action {
    name AF_CL1
    module tokenmt
    params{
        committed_rate 64
        committed_burst 75
        peak_burst 150
    }
}
```

EXAMPLE 1 Sending All Traffic From eng to the AF 1 Class of Service (Continued)

```
        global_stats TRUE
        red_action_name drop
        yellow_action_name markAF12
        green_action_name markAF11
    }
}
```

The following step creates two dscpmk actions:

```
#class 1, low drop precedence.
action {
    name markAF11
    module dscpmk
    params{
        dscp_map {0-63:28}
        dscp_detailed_stats TRUE
        global_stats TRUE
        next_action acct1
    }
}
#class 1, medium drop precedence.
action {
    name markAF12
    module dscpmk
    params {
        dscp_map {0-63:30}
        dscp_detailed_stats TRUE
        global_stats TRUE
        next_action acct1
    }
}
```

The following step creates an accounting action:

```
#billing for transmitted class 1 traffic.
action {
    name acct1
    module flowacct
    params {
        timer 10
        timeout 30
        global_stats TRUE
    }
    max_limit 1024
    next_action continue
}
}
```

EXAMPLE 1 Sending All Traffic From eng to the AF 1 Class of Service (Continued)

The following step creates an ipgpc action:

```
#traffic from eng sent, traffic from ebay dropped.
action {
    name ipgpc.classify
    module ipgpc
    class {
        name from_eng
        enable_stats TRUE
        next_action AF_CL1
    }
    class {
        name from_ebay
        enable_stats TRUE
        next_action drop
    }

    filter {
        name from_eng
        saddr eng-subnet
        class from_eng
    }
    filter {
        name from_ebay
        saddr ebay-subnet
        class from_ebay
    }
}
```

| | | |
|--------------|------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| Files | /etc/inet/ipqosinit.conf | Contains the IPQoS configuration loaded at boot time. If this file exists, it is read from the network/initial:default service. |
| | /etc/inet/ipqosconf.1.sample | Sample configuration file for an application server |
| | /etc/inet/ipqosconf.2.sample | Sample configuration file that meters the traffic for a specified application |
| | /etc/inet/ipqosconf.3.sample | Sample configuration file that marks the ethernet headers of web traffic with a given user priority |

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|----------------------|
| Availability | system/network/ipqos |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Committed |

See Also `syslog(3C)`, `getipnodebyname(3SOCKET)`, `getprotobyname(3SOCKET)`, `getservbyname(3SOCKET)`, `attributes(5)`, `d1cosmk(7ipp)`, `dscpmk(7ipp)`, `flowacct(7ipp)`, `ipgpc(7ipp)`, `ipqos(7ipp)`, `tokenmt(7ipp)`, `tswtclmt(7ipp)`

Diagnostics `ipqosconf` sends messages to `syslog` of facility `user`, severity `notice` when any changes are made to the IPQoS configuration.

Errors that occur during an `ipqosconf` operation send an error message to the console by default. For the application of a new configuration if the `-s` option is set then these messages are sent to `syslog` as facility `user`, severity `error` instead. If the `-v` option is present during an application then all error and change notification messages are sent to the console as well as their default destination.

Name ipsecalgs – configure the IPsec protocols and algorithms table

Synopsis ipsecalgs

ipsecalgs -l

ipsecalgs -s

ipsecalgs -a [-P *protocol-number* | -p *protocol-name*] -k *keylen-list*
 [-i *inc*] [-K *default-keylen*] -b *blocklen-list* -n *alg-names*
 -N *alg-number* -m *mech-name* [-f] [-s]

ipsecalgs -P *protocol-number* -p *protocol-name*
 [-e *exec-mode*] [-f] [-s]

ipsecalgs -r -p *protocol-name* [] -n *alg-name* [-s]

ipsecalgs -r -p *protocol-name* [] -N *alg-number* [-s]

ipsecalgs -R -P *protocol-number* [-s]

ipsecalgs -R -p *protocol-name* [-s]

ipsecalgs -e *exec-mode* -P *protocol-number* [-s]

ipsecalgs -e *exec-mode* -p *protocol-name* [-s]

Description Use the ipsecalgs command to query and modify the IPsec protocol and algorithms stored in /etc/inet/ipsecalgs. You can use the ipsecalgs command to do the following:

- list the currently defined IPsec protocols and algorithms
- modify IPsec protocols definitions
- modify IPsec algorithms definitions

Never edit the /etc/inet/ipsecalgs file manually. The valid IPsec protocols and algorithms are described by the ISAKMP DOI. See *RFC 2407*. In the general sense, a Domain of Interpretation (DOI) defines data formats, network traffic exchange types, and conventions for naming security-relevant information such as security policies or cryptographic algorithms and modes. For ipsecalgs, the DOI defines naming and numbering conventions for algorithms and the protocols they belong to. These numbers are defined by the Internet Assigned Numbers Authority (IANA). Each algorithm belongs to a protocol. Algorithm information includes supported key lengths, block or MAC length, and the name of the cryptographic mechanism corresponding to that algorithm. This information is used by the IPsec modules, [ipsecesp\(7P\)](#) and [ipsecah\(7P\)](#), to determine the authentication and encryption algorithms that can be applied to IPsec traffic.

The following protocols are predefined:

| | |
|-----------------|-----------------------------------------------------------------------------------------------------------|
| IPSEC_PROTO_ESP | Defines the encryption algorithms (transforms) that can be used by IPsec to provide data confidentiality. |
| IPSEC_PROTO_AH | Defines the authentication algorithms (transforms) that can be used by IPsec to provide authentication. |

The mechanism name specified by an algorithm entry must correspond to a valid Solaris Cryptographic Framework mechanism. You can obtain the list of available mechanisms by using the [cryptoadm\(1M\)](#) command.

Applications can retrieve the supported algorithms and their associated protocols by using the functions [getipsecalgbyname\(3NSL\)](#), [getipsecalgbynum\(3NSL\)](#), [getipsecprotobyname\(3NSL\)](#) and [getipsecprotobynum\(3NSL\)](#).

Modifications to the protocols and algorithm by default update only the contents of the `/etc/inet/ipsecalg` configuration file. In order for the new definitions to be used for IPsec processing, the changes must be communicated to the kernel using the `-s` option. See NOTES for a description of how the `ipsecalg` configuration is synchronized with the kernel at system restart.

When invoked without arguments, `ipsecalg` displays the list of mappings that are currently defined in `/etc/inet/ipsecalg`. You can obtain the corresponding kernel table of protocols and algorithms by using the `-l` option.

Options `ipsecalg` supports the following options:

`-a`

Adds an algorithm of the protocol specified by the `-P` option. The algorithm name(s) are specified with the `-n` option. The supported key lengths and block sizes are specified with the `-k`, `-i`, and `-b` options.

`-b`

Specifies the block or MAC lengths of an algorithm, in bytes. Set more than one block length by separating the values with commas.

`-e`

Designates the execution mode of cryptographic requests for the specified protocol in the absence of cryptographic hardware provider. See [cryptoadm\(1M\)](#). *exec-mode* can be one of the following values:

`sync` Cryptographic requests are processed synchronously in the absence of a cryptographic hardware provider. This execution mode leads to better latency when no cryptographic hardware providers are available

`async` Cryptographic requests are always processed asynchronously in the absence of cryptographic hardware provider. This execution can improve the resource utilization on a multi-CPU system, but can lead to higher latency when no cryptographic hardware providers are available.

This option can be specified when defining a new protocol or to modify the execution mode of an existing protocol. By default, the `sync` execution mode is used in the absence of a cryptographic hardware provider.

- f
Used with the -a option to force the addition of an algorithm or protocol if an entry with the same name or number already exists.
- i
Specifies the valid key length increments in bits. This option must be used when the valid key lengths for an algorithm are specified by a range with the -k option.
- K
Specifies the default key lengths for an algorithm, in bits. If the -K option is not specified, the minimum key length will be determined as follows:
- If the supported key lengths are specified by range, the default key length will be the minimum key length.
 - If the supported key lengths are specified by enumeration, the default key length will be the first listed key length.
- k
Specifies the supported key lengths for an algorithm, in bits. You can designate the supported key lengths by enumeration or by range.
- Without the -i option, -k specifies the supported key lengths by enumeration. In this case, *keylen-list* consists of a list of one or more key lengths separated by commas, for example:
- ```
128,192,256
```
- The listed key lengths need not be increasing, and the first listed key length will be used as the default key length for that algorithm unless the -K option is used.
- With the -i option, -k specifies the range of supported key lengths for the algorithm. The minimum and maximum key lengths must be separated by a dash ('-') character, for example:
- ```
32-448
```
- l
Displays the kernel algorithm tables.
- m
Specifies the name of the cryptographic framework mechanism name corresponding to the algorithm. Cryptographic framework mechanisms are described in the [cryptoadm\(1M\)](#) man page.
- N
Specifies an algorithm number. The algorithm number for a protocol must be unique. IANA manages the algorithm numbers. See *RFC 2407*.
- n
Specifies one or more names for an algorithm. When adding an algorithm with the -a option, *alg-names* contains a string or a comma-separated list of strings, for example:

des - cbs, des

When used with the `-r` option to remove an algorithm, *alg-names* contains one of the valid algorithm names.

`-P`

Adds a protocol of the number specified by *protocol-number* with the name specified by the `-p` option. This option is also used to specify an IPsec protocol when used with the `-a` and the `-R` options. Protocol numbers are managed by the IANA. See *RFC 2407*.

`-p`

Specifies the name of the IPsec protocol.

`-R`

Removes an IPsec protocol from the algorithm table. The protocol can be specified by number by using the `-P` option or by name by using the `-p` option. The algorithms associated with the protocol are removed as well.

`-r`

Removes the mapping for an algorithm. The algorithm can be specified by algorithm number using the `-N` option or by algorithm name using the `-A` option.

`-s`

Synchronizes the kernel with the contents of `/etc/inet/ipsecalgs`. The contents of `/etc/inet/ipsecalgs` are always updated, but new information is not passed on to the kernel unless the `-s` is used. See *NOTES* for a description of how the `ipsecalgs` configuration is synchronized with the kernel at system restart.

The following options allow optional parameters to be configured. These are currently only used for combined mode algorithms, that is, algorithms that provide encryption and authentication in a single operation.

`-I`

The length of the Initialization Vector (IV) in bytes. The default IV length is the same as the block length.

`-M`

The length of the MAC or ICV in bytes for combined mode algorithms.

`-S`

The number of bytes of salt needed by the algorithm. The salt needs to be provided by the key management mechanism.

`-F`

Algorithm flags. These influence the way in which the kernel handles security tasks, especially authentication, in the kernel. They are also used by [ipseckey\(1M\)](#) and [ipsecconf\(1M\)](#). Flags can be specified as a comma-separated list of tokens; see the example below. The following tokens are supported:

COUNTERMODE

The algorithm uses counter mode.

COMBINED

The algorithm provides encryption and authentication in the same operation.

CCM

The cryptographic framework mechanism needs a CK_AES_CCM_PARAMS structure.

GCM

The cryptographic framework mechanism needs a CK_AES_GCM_PARAMS structure.

The algorithm flags can be displayed with the `-l` option.

Examples **EXAMPLE 1** Adding a Protocol for IPsec Encryption

The following example shows how to add a protocol for IPsec encryption:

```
example# ipsecalgs -P 3 -p "IPSEC_PROTO_ESP"
```

EXAMPLE 2 Adding the Blowfish Algorithm

The following example shows how to add the Blowfish algorithm:

```
example# ipsecalgs -a -P 3 -k 32-488 -K 128 -i 8 -n "blowfish" \
  -b 8 -N 7 -m CKM_BF_CBC
```

EXAMPLE 3 Updating the Kernel Algorithm Table

The following example updates the kernel algorithm table with the currently defined protocol and algorithm definitions:

```
example# svcadm refresh ipsecalgs
```

EXAMPLE 4 Adding the AES Galois/Counter Mode (GCM) Algorithm

The following command adds this algorithm.

```
example# ipsecalgs -a -P3 -k 128-256 -K 128 -i 64 -N 20 -b 16 \
  -n "aes-gcm16,aes-gcm" -m CKM_AES_GCM -M 16 -I 8 -S 4 \
  -F GCM,COMBINED,COUNTER
```

Files `/etc/inet/ipsecalgs`

File that contains the configured IPsec protocols and algorithm definitions. Never edit this file manually.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Committed |

See Also [cryptoadm\(1M\)](#), [ipsecconf\(1M\)](#), [ipseckey\(1M\)](#), [svcadm\(1M\)](#), [getipsecalgbyname\(3NSL\)](#), [getipsecprotobyname\(3NSL\)](#), [ike.config\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#), [ipsecah\(7P\)](#), [ipsecesp\(7P\)](#)

Piper, Derrell, *RFC 2407, The Internet IP Security Domain of Interpretation for ISAKMP*. Network Working Group. November 1998.

Notes When protocols or algorithm definitions that are removed or altered, services that rely upon these definitions can become unavailable. For example, if the IPSEC_PROTO_ESP protocol is removed, then IPsec cannot encrypt and decrypt packets.

Synchronization of the `ipsecalgs` configuration with the kernel at system startup is provided by the following [smf\(5\)](#) service:

```
svc:/network/ipsec/ipsecalgs:default
```

The IPsec services are delivered as follows:

```
svc:/network/ipsec/policy:default (enabled)
svc:/network/ipsec/ipsecalgs:default (enabled)
svc:/network/ipsec/manual-key:default (disabled)
svc:/network/ipsec/ike:default (disabled)
```

Services that are delivered disabled are delivered that way because the system administrator must create configuration files for those services before enabling them. See [ipseckey\(1M\)](#) and [ike.config\(4\)](#). The default policy for the `policy` service is to allow all traffic to pass without IPsec protection. See [ipsecconf\(1M\)](#).

The correct administrative procedure is to create the configuration file for each service, then enable each service using [svcadm\(1M\)](#), as shown in the following example:

```
example# svcadm enable ipsecalgs
```

The service's status can be queried using the [svcs\(1\)](#) command.

If the `ipsecalgs` configuration is modified, the new configuration should be resynchronized as follows:

```
example# svcadm refresh ipsecalgs
```

Administrative actions on this service, such as enabling, disabling, refreshing, and requesting restart can be performed using [svcadm\(1M\)](#). A user who has been assigned the authorization shown below can perform these actions:

```
solaris.smf.manage.ipsec
```

See [auths\(1\)](#), [user_attr\(4\)](#), [rbac\(5\)](#).

The `ipsecalg` [smf\(5\)](#) service does not have any user-configurable properties.

The `smf(5)` framework records any errors in the service-specific log file. Use any of the following commands to examine the `logfile` property:

```
example# svcs -l ipsecalg
example# svccprop ipsecalg
example# svccfg -s ipsecalg listprop
```

This command requires `sys_ip_config` privilege to operate and thus can run in the global zone and in exclusive-IP zones. All shared-IP zones share the same available set of algorithms; however, you can use [ipseconf\(1M\)](#) to set up system policy that uses differing algorithms for various shared-IP zones. All exclusive-IP zones have their own set of algorithms.

Name ipsecconf – configure system wide IPsec policy

Synopsis /usr/sbin/ipsecconf
/usr/sbin/ipsecconf -a *file* [-q]
/usr/sbin/ipsecconf -c *file*
/usr/sbin/ipsecconf -d [-i *tunnel-name*] {*index*, *tunnel-name*, *index*}
/usr/sbin/ipsecconf -f [-i *tunnel-name*]
/usr/sbin/ipsecconf -F
/usr/sbin/ipsecconf -Fa *file* [-q]
/usr/sbin/ipsecconf -l [-i *tunnel-name*] [-n]
/usr/sbin/ipsecconf -L [-n]
/usr/sbin/ipsecconf -r *file* [-q]

Description The ipsecconf utility configures the IPsec policy for a host or for one of its tunnels. Once the policy is configured, all outbound and inbound datagrams are subject to policy checks as they exit and enter the host or tunnel. For the host policy, if no entry is found, no policy checks will be completed, and all the traffic will pass through. For a tunnel, if no entry is found and there is at least one entry for the tunnel, the traffic will automatically drop. The difference in behavior is because of the assumptions about IPsec tunnels made in many implementations. Datagrams that are being forwarded will not be subjected to policy checks that are added using this command. See [ifconfig\(1M\)](#) and [dladm\(1M\)](#) for information on how to protect forwarded packets. Depending upon the match of the policy entry, a specific action will be taken.

This command can be run only by superuser.

Each entry can protect traffic in either one direction (requiring a pair of entries) or by a single policy entry which installs the needed symmetric sadb rules.

When the command is issued without any arguments, the list of file policy entries loaded are shown. To display the (spd p.e.s) use the -l option. Both will display the index number for the entry. To specify a single tunnel's SPD, use the -i option in combination with -l. To specify all SPDs, both host and for all tunnels, use -L.

Note, since one file policy entry (FPE) can generate multiple SPD pol entries (SPEs), the list of FPEs may not show all the actual entries. However, it is still useful in determining what rules have been added to get the spd into its current state.

You can use the -d option with the index to delete a given policy in the system. If the -d option removes an FPE entry that produces multiple SPEs, only then SPD with the same policy index as the FPE will be removed. This can produce a situation where there may be SPEs when there are no FPEs.

As with -l, -d can use the -i flag to indicate a tunnel. An alternate syntax is to specify a tunnel name, followed by a comma (,), followed by an index. For example, ip.tun0,1.

With no options, the entries are displayed in the order that they were added, which is not necessarily the order in which the traffic match takes place.

To view the order in which the traffic match will take place, use the `-l` option. The rules are ordered such that all bypass rules are checked first, then ESP rules, then AH rules. After that, they are checked in the order entered.

Policy entries are not preserved across system restarts. Permanent policy entries should be added to `/etc/inet/ipsecinit.conf`. This file is read by the following `smf(5)` service:

```
svc:/network/ipsec/policy
```

See **NOTES** for more information on managing IPsec security policy and **SECURITY** for issues in securing `/etc/inet/ipsecinit.conf`.

Options `ipsecconf` supports the following options:

`-a file`

Add the IPsec policy to the system as specified by each entry in the file. An IPsec configuration file contains one or more entries that specify the configuration. Once the policy is added, all outbound and inbound datagrams are subject to policy checks.

Entries in the files are described in the **Operands** section below. Examples can be found in the **Examples** section below.

Policy is latched for TCP/UDP sockets on which a `connect(3SOCKET)` or `accept(3SOCKET)` is issued. So, the addition of new policy entries may not affect such endpoints or sockets. However, the policy will be latched for a socket with an existing non-null policy. Thus, make sure that there are no preexisting connections that will be subject to checks by the new policy entries.

The feature of policy latching explained above may change in the future. It is not advisable to depend upon this feature.

The default behavior is to append new rules to the existing policy. If a new rule conflicts with an existing rule, an error is reported, the new rule will not be added.

To add a new rule that conflicts with an existing rule, the existing rule must be removed (see below) or the existing policy flushed. If the policy is flushed, IPsec will not protect any network traffic until a new policy is added.

The `-F` (flush) flag can be combined with `-a` to perform an atomic policy replacement; the existing policy will be replaced by the new policy described in the config file. By combining these two flags, there is not even a small window when the system is without a policy, which is the case when the flush and add commands are run sequentially.

`-c file`

Check the syntax of the configuration file and report any errors without making any changes to the policy. This option is useful when debugging configurations and when `smf(5)` reports a configuration error. See **SECURITY**.

-d *index*

Delete the host policy denoted by the *index*. The *index* is obtained by invoking `ipsecconf` without any arguments, or with the `-l` option. See DESCRIPTION for more information. Once the entry is deleted, all outbound and inbound datagrams affected by this policy entry will not be subjected to policy checks. Be advised that with connections for which the policy has been latched, packets will continue to go out with the same policy, even if it has been deleted. It is advisable to use the `-l` option to find the correct policy *index*.

-d *name,index*

Delete the policy entry denoted by *index* on a tunnel denoted by *name*. Since tunnels affect traffic that might originate off-node, latching does not apply as it does in the host policy case. Equivalent to: `-d index -i name`.

-f

Flush all the policies in the system. Constraints are similar to the `-d` option with respect to latching and host versus per-tunnel behavior.

-F

Flush all policies on all tunnels and also flush all host policies. See discussion of combining the `-F` and `-a` options, under `-a`, above.

-i *name*

Specify a tunnel interface name for use with the `-d`, `-f`, or `-l` flags.

-l

Listing of a single policy table, defaulting to the host policy. When `ipsecconf` is invoked without any arguments, a complete list of policy entries with indexes added by the user since boot is displayed. The current table can differ from the previous one if, for example, a multi-homed entry was added or policy reordering occurred, or if a single rule entry generates two `spd` rules. In the case of a multi-homed entry, all the addresses are listed explicitly. If a mask was not specified earlier but was instead inferred from the address, it will be explicitly listed here. This option is used to view policy entries in the correct order. The outbound and inbound policy entries are listed separately.

-L

Lists all policy tables, including host policy and all tunnel instances (including configured but unplumbed).

If `-i` is specified, `-L` lists the policy table for a specific tunnel interface.

-n

Show network addresses, ports, protocols in numbers. The `-n` option may only be used with the `-l` option.

-q

Quiet mode. Suppresses the warning message generated when adding policies.

`-r file`

Remove IPsec policy rules from the system as specified by each entry in *file*. The format of the file contents is the same as is specified with the `-a` option. The file could be created with `ipsecconf -l` and then modified with an editor.

Operands Each policy entry contains three parts specified as follows:

```
{pattern} action {properties}
```

or

```
{pattern} action {properties} ["or" action {properties}]*
```

Every policy entry begins on a new line and can span multiple lines. If an entry exceeds the length of a line, you should split it only within a “braced” section or immediately before the first (left-hand) brace of a braced section. Avoid using the backslash character (`\`). See EXAMPLES.

The *pattern* section, as shown in the syntax above, specifies the traffic pattern that should be matched against the outbound and inbound datagrams. If there is a match, a specific *action* determined by the second argument will be taken, depending upon the *properties* of the policy entry.

If there is an `or` in the rule (multiple action-properties for a given pattern), a transmitter will use the first action-property pair that works, while a receiver will use any that are acceptable.

pattern and *properties* are name-value pairs where name and value are separated by a `<space>`, `<tab>` or `<newline>`. Multiple name-value pairs should be separated by `<space>`, `<tab>` or `<newline>`. The beginning and end of the pattern and properties are marked by `{` and `}` respectively.

Files can contain multiple policy entries. An unspecified name-value pair in the *pattern* will be considered as a wildcard. Wildcard entries match any corresponding entry in the datagram.

One thing to remember is that UDP port 500 is always bypassed regardless of any policy entries. This is a requirement for `in.iked(1M)` to work.

File can be commented by using a `#` as the first character. Comments may be inserted either at the beginning or the end of a line.

The complete syntax of a policy entry is:

```
policy ::= { <pattern1> } <action1> { <properties1> } |
        { <pattern2> } <action2> { <properties2> }
        [ 'or' <action2> { <properties2> } ]*

pattern1 ::= <pattern_name_value_pair1>*

pattern2 ::= <pattern_name_value_pair2>*
```

```
action1 ::= apply | permit | bypass | pass
action2 ::= bypass | pass | drop | ipsec

properties1 ::= {<prop_name_value_pair1>}
properties2 ::= {<prop_name_value_pair2>}

pattern_name_value_pair1 ::=
  saddr <address>/<prefix> |
  src <address>/<prefix> |
  srcaddr <address>/<prefix> |
  smask <mask> |
  sport <port> |
  daddr <address>/<prefix> |
  dst <address>/<prefix> |
  dstaddr <address>/<prefix> |
  dmask <mask> |
  dport <port> |
  ulp <protocol> |
  proto <protocol> |
  type <icmp-type> |
  type <number>-<number> |
  code <icmp-code>
  code <number>-<number>
  tunnel <interface-name> |
  negotiate <tunnel,transport>

pattern_name_value_pair2 ::=
  raddr <address>/<prefix> |
  remote <address>/<prefix> |
  rport <port> |
  laddr <address>/<prefix> |
  local <address>/<prefix> |
  lport <port> |
  ulp <protocol> |
  type <icmp-type> |
  type <number>-<number> |
  code <icmp-code> |
  code <number>-<number>
  proto <protocol> |
  tunnel <interface-name> |
  negotiate <tunnel,transport> |
  dir <dir_val2>

address ::= <IPv4 dot notation> | <IPv6 colon notation> |
  <String recognized by gethostbyname>|
  <String recognized by getnetbyname>
```

```

prefix ::= <number>

mask ::= <0xhexdigit[hexdigit]> | <0Xhexdigit[hexdigit]> |
        <IPv4 dot notation>

port ::= <number>| <String recognized by getservbyname>

protocol ::= <number>| <String recognized by getprotobyname>

prop_name_value_pair1 ::=
    auth_algs <auth_alg> |
    encr_algs <encr_alg> |
    encr_auth_algs <auth_alg> |
    sa <sa_val> |
    dir <dir_val1>

prop_name_value_pair2 ::=
    auth_algs <auth_alg> |
    encr_algs <encr_alg> |
    encr_auth_algs <auth_alg> |
    sa <sa_val>

auth_alg ::= <auth_algname> ['(' <keylen> ')']
auth_algname ::= any | md5 | hmac-md5 | sha | sha1 | hmac-sha |
                hmac-sha1 | hmac-sha256 | hmac-sha384 |
                hmac-sha512 |<number>

encr_alg ::= <encr_algname> ['(' <keylen> ')']
encr_algname ::= any | aes | aes-cbc | des | des-cbc | 3des |
                3des-cbc | blowfish | blowfish-cbc | aes-ccm |
                aes-gcm | <number>

keylen ::= <number> | <number>'..' | '..'<number> | <number>'..' \
<number>

sa_val ::= shared | unique

dir_val1 ::= out | in
dir_val2 ::= out | in | both

number ::= < 0 | 1 | 2 ... 9> <number>
icmp-type ::= <number> | unreachable | echo | echorep | squench |
              redir | timex | paramprob | timest | timestrep |
              inforeq | inforep | maskreq | maskrep | unreachable6 |
              pkttoobig6 | timex6 | paramprob6 | echo6 | echorep6 |
              router-sol6 | router-ad6 | neigh-sol6 | neigh-ad6 |
              redir6

```

```

icmp-code ::= <number> | net-unr | host-unr | proto-unr | port-unr |
needfrag | srcfail | net-unk | host-unk | isolate |
net-prohib | host-prohib | net-tos | host-tos |
filter-prohib | host-preced | cutoff-preced |
no-route6 | adm-prohib6 | addr-unr6 | port-unr6 |
hop-limex6 | frag-re-timex6 | err-head6 | unrec-head6 |
unreq-opt6

```

Policy entries may contain the following (name value) pairs in the *pattern* field. Each (name value) pair may appear only once in given policy entry.

laddr/plen

local/plen

The value that follows is the local address of the datagram with the prefix length. Only *plen* leading bits of the source address of the packet will be matched. *plen* is optional. Local means destination on incoming and source on outgoing packets. The source address value can be a hostname as described in [getaddrinfo\(3SOCKET\)](#) or a network name as described in [getnetbyname\(3XNET\)](#) or a host address or network address in the Internet standard dot notation. See [inet_addr\(3XNET\)](#). If a hostname is given and [getaddrinfo\(3SOCKET\)](#) returns multiple addresses for the host, then policy will be added for each of the addresses with other entries remaining the same.

raddr/plen

remote/plen

The value that follows is the remote address of the datagram with the prefix length. Only *plen* leading bits of the remote address of the packet will be matched. *plen* is optional. Remote means source on incoming packets and destination on outgoing packets. The remote address value can be a hostname as described in [getaddrinfo\(3SOCKET\)](#) or a network name as described in [getnetbyname\(3XNET\)](#) or a host address or network address in the Internet standard dot notation. See [inet_addr\(3XNET\)](#). If a hostname is given and [getaddrinfo\(3SOCKET\)](#) returns multiple addresses for the host, then policy will be added for each of the addresses with other entries remaining the same.

src/plen

srcaddr/plen

saddr/plen

The value that follows is the source address of the datagram with the prefix length. Only *plen* leading bits of the source address of the packet will be matched. *plen* is optional.

The source address value can be a hostname as described in [getaddrinfo\(3SOCKET\)](#) or a network name as described in [getnetbyname\(3XNET\)](#) or a host address or network address in the Internet standard dot notation. See [inet_addr\(3XNET\)](#).

If a hostname is given and [getaddrinfo\(3SOCKET\)](#) returns multiple addresses for the host, then policy will be added for each of the addresses with other entries remaining the same.

daddr/plen

dest/plen

dstaddr/plen

The value that follows is the destination address of the datagram with the prefix length. Only *plen* leading bits of the destination address of the packet will be matched. *plen* is optional.

See *saddr* for valid values that can be given. If multiple source and destination addresses are found, then a policy entry that covers each source address-destination address pair will be added to the system.

smask

For IPv4 only. The value that follows is the source mask. If prefix length is given with *saddr*, this should not be given. This can be represented either in hexadecimal number with a leading 0x or 0X, for example, 0xffff0000, 0Xffff0000 or in the Internet decimal dot notation, for example, 255.255.0.0 and 255.255.255.0. The mask should be contiguous and the behavior is not defined for non-contiguous masks.

smask is considered only when *saddr* is given.

For both IPv4 and IPv6 addresses, the same information can be specified as a *slen* value attached to the *saddr* parameter.

dmask

Analogous to *smask*.

lport

The value that follows is the local port of the datagram. This can be either a port number or a string searched with a NULL proto argument, as described in [getservbyname\(3XNET\)](#)

rport

The value that follows is the remote port of the datagram. This can be either a port number or a string searched with a NULL proto argument, as described in [getservbyname\(3XNET\)](#)

sport

The value that follows is the source port of the datagram. This can be either a port number or a string searched with a NULL proto argument, as described in [getservbyname\(3XNET\)](#)

dport

The value that follows is the destination port of the datagram. This can be either a port number or a string as described in [getservbyname\(3XNET\)](#) searched with NULL proto argument.

proto ulp

The value that follows is the Upper Layer Protocol that this entry should be matched against. It could be a number or a string as described in [getprotobyname\(3XNET\)](#). If no *smask* or *plen* is specified, a *plen* of 32 for IPv4 or 128 for IPv6 will be used, meaning a host. If the *ulp* is *icmp* or *ipv6-icmp*, any action applying IPsec must be the same for all *icmp* rules.

type *num* or *num-num*

The value that follows is the ICMP type that this entry should be matched against. *type* must be a number from 0 to 255, or one of the appropriate `icmp-type` keywords. Also, *ulp* must be present and must specify either `icmp` or `ipv6-icmp`. A range of types can be specified with a hyphen separating numbers.

code *num* or *num-num*

The value that follows is the ICMP code that this entry should be matched against. The value following the keyword `code` must be a number from 0 to 254 or one of the appropriate `icmp-code` keywords. Also, *type* must be present. A range of codes can be specified with a hyphen separating numbers.

tunnel *name*

Specifies a tunnel network interface, as configured with `ifconfig(1M)`. If a tunnel of *name* does not yet exist, the policy entries are added anyway, and joined with the tunnel state when it is created. If a tunnel is unplumbed, its policy entries disappear.

negotiate *tunnel***negotiate** *transport*

For per-tunnel security, specify whether the IPsec SAs protecting the traffic should be tunnel-mode SAs or transport-mode SAs. If transport-mode SAs are specified, no addresses can appear in the policy entry. Transport-mode is backward compatible with Solaris 9, and tunnel IPsec policies configured with `ifconfig(1M)` will show up as transport mode entries here.

Policy entries may contain the following (name-value) pairs in the properties field. Each (name-value) pair may appear only once in a given policy entry.

auth_algs

An acceptable value following this implies that IPsec AH header will be present in the outbound datagram. Values following this describe the authentication algorithms that will be used while applying the IPsec AH on outbound datagrams and verified to be present on inbound datagrams. See *RFC 2402*.

This entry can contain either a string or a decimal number.

string

This should be either MD5 or HMAC-MD5 denoting the HMAC-MD5 algorithm as described in *RFC 2403*, and SHA1, or HMAC-SHA1 or SHA or HMAC-SHA denoting the HMAC-SHA algorithm described in *RFC 2404*. You can use the `ipsecalgs(1M)` command to obtain the complete list of authentication algorithms.

The string can also be ANY, which denotes no-preference for the algorithm. Default algorithms will be chosen based upon the SAs available at this time for manual SAs and the key negotiating daemon for automatic SAs. Strings are not case-sensitive.

number

A number in the range 1-255. This is useful when new algorithms can be dynamically loaded.

If *auth_algs* is not present, the AH header will not be present in the outbound datagram, and the same will be verified for the inbound datagram.

encr_algs

An acceptable value following this implies that IPsec ESP header will be present in the outbound datagram. The value following this describes the encryption algorithms that will be used to apply the IPsec ESP protocol to outbound datagrams and verify it to be present on inbound datagrams. See *RFC 2406*.

This entry can contain either a string or a decimal number. Strings are not case-sensitive.

string

Can be one of the following:

| string value: | Algorithm Used: | See RFC: |
|-----------------------------|-----------------|----------|
| DES or DES-CBC | DES-CBC | 2405 |
| 3DES or 3DES-CBC | 3DES-CBC | 2451 |
| BLOWFISH or
BLOWFISH-CBC | BLOWFISH-CBC | 2451 |
| AES or AES-CBC | AES-CBC | 2451 |
| AES-CCM | AES-CCM | 4309 |
| AES-GCM | AES_GCM | 4106 |

You can use the [ipsecalgs\(1M\)](#) command to obtain the complete list of authentication algorithms.

The value can be NULL, which implies a NULL encryption, pursuant to *RFC 2410*. This means that the payload will not be encrypted. The string can also be ANY, which indicates no-preference for the algorithm. Default algorithms will be chosen depending upon the SAs available at the time for manual SAs and upon the key negotiating daemon for automatic SAs. Strings are not case-sensitive.

number

A decimal number in the range 1-255. This is useful when new algorithms can be dynamically loaded.

encr_auth_algs

An acceptable value following *encr_auth_algs* implies that the IPsec ESP header will be present in the outbound datagram. The values following *encr_auth_algs* describe the

authentication algorithms that will be used while applying the IPsec ESP protocol on outbound datagrams and verified to be present on inbound datagrams. See *RFC 2406*. This entry can contain either a string or a number. Strings are case-insensitive.

string

Valid values are the same as the ones described for `auth_algs` above.

number

This should be a decimal number in the range 1-255. This is useful when new algorithms can be dynamically loaded.

If `encr_algs` is present and `encr_auth_algs` is not present in a policy entry, the system will use an ESP SA regardless of whether the SA has an authentication algorithm or not.

If `encr_algs` is not present and `encr_auth_algs` is present in a policy entry, null encryption will be provided, which is equivalent to `encr_algs` with `NULL`, for outbound and inbound datagrams.

If both `encr_algs` and `encr_auth_algs` are not present in a policy entry, ESP header will not be present for outbound datagrams and the same will be verified for inbound datagrams.

If both `encr_algs` and `encr_auth_algs` are present in a policy entry, ESP header with integrity checksum will be present on outbound datagrams and the same will be verified for inbound datagrams.

For `encr_algs`, `encr_auth_algs`, and `auth_algs` a key length specification may be present. This is either a single value specifying the only valid key length for the algorithm or a range specifying the valid minimum and/or maximum key lengths. Minimum or maximum lengths may be omitted.

dir

Values following this decides whether this entry is for outbound or inbound datagram. Valid values are strings that should be one of the following:

out

This means that this policy entry should be considered only for outbound datagrams.

in

This means that this policy entry should be considered only for inbound datagrams.

both

This means that this policy entry should be considered for both inbound and outbound datagrams

This entry is not needed when the action is “apply”, “permit” or “ipsec”. But if it is given while the action is “apply” or “permit”, it should be “out” or “in” respectively. This is mandatory when the action is “bypass”.

sa

Values following this decide the attribute of the security association. Value indicates whether a unique security association should be used or any existing SA can be used. If there is a policy requirement, SAs are created dynamically on the first outbound datagram using the key management daemon. Static SAs can be created using `ipseckey(1M)`. The values used here determine whether a new SA will be used/obtained. Valid values are strings that could be one of the following:

unique

Unique Association. A new/unused association will be obtained/used for packets matching this policy entry. If an SA that was previously used by the same 5 tuples, that is, {Source address, Destination address, Source port, Destination Port, Protocol (for example, TCP/UDP)} exists, it will be reused. Thus uniqueness is expressed by the 5 tuples given above. The security association used by the above 5 tuples will not be used by any other socket. For inbound datagrams, uniqueness will not be verified.

For tunnel-mode tunnels, `unique` is ignored. SAs are assigned per-rule in tunnel-mode tunnels. For transport-mode tunnels, `unique` is implicit, because the enforcement happens only on the outer-packet addresses and protocol value of either IPv4-in-IP or IPv6-in-IP.

shared

Shared association. If an SA exists already for this source-destination pair, it will be used. Otherwise a new SA will be obtained. This is the default.

This is mandatory only for outbound policy entries and should not be given for entries whose action is “bypass”. If this entry is not given for inbound entries, for example, when “dir” is in or “action” is permit, it will be assumed to be shared.

Action follows the pattern and should be given before properties. It should be one of the following and this field is mandatory.

ipsec

Use IPsec for the datagram as described by the properties, if the pattern matches the datagram. If `ipsec` is given without a `dir spec`, the pattern is matched to incoming and outgoing datagrams.

apply

Apply IPsec to the datagram as described by the properties, if the pattern matches the datagram. If `apply` is given, the pattern is matched only on the outbound datagram.

permit

Permit the datagram if the pattern matches the incoming datagram and satisfies the constraints described by the properties. If it does not satisfy the properties, discard the datagram. If `permit` is given, the pattern is matched only for inbound datagrams.

bypass**pass**

Bypass any policy checks if the pattern matches the datagram. `dir` in the properties decides whether the check is done on outbound or inbound datagrams. All the `bypass` entries are checked before checking with any other policy entry in the system. This has the highest precedence over any other entries. `dir` is the only field that should be present when action is `bypass`.

`drop`

Drop any packets that match the pattern.

If the file contains multiple policy entries, for example, they are assumed to be listed in the order in which they are to be applied. In cases of multiple entries matching the outbound and inbound datagram, the first match will be taken. The system will reorder the policy entry, that is, add the new entry before the old entry, only when:

The level of protection is “stronger” than the old level of protection.

Currently, strength is defined as:

AH and ESP > ESP > AH

The standard uses of AH and ESP were what drove this ranking of “stronger”. There are flaws with this. ESP can be used either without authentication, which will allow cut-and-paste or replay attacks, or without encryption, which makes it equivalent or slightly weaker than AH. An administrator should take care to use ESP properly. See [ipsecesp\(7P\)](#) for more details.

If the new entry has `bypass` as action, `bypass` has the highest precedence. It can be added in any order, and the system will still match all the `bypass` entries before matching any other entries. This is useful for key management daemons which can use this feature to bypass IPsec as it protects its own traffic.

Entries with both AH (`auth_algs` present in the policy entry) and ESP (`encr_auth_algs` or `encr_auth_algs` present in the policy entry) protection are ordered after all the entries with AH and ESP and before any AH-only and ESP-only entries. In all other cases the order specified by the user is not modified, that is, newer entries are added at the end of all the old entries. See [Examples](#).

A new entry is considered duplicate of the old entry if an old entry matches the same traffic pattern as the new entry. See [Examples](#) for information on duplicates.

Security If, for example, the policy file comes over the wire from an NFS mounted file system, an adversary can modify the data contained in the file, thus changing the policy configured on the machine to suit his needs. Administrators should be cautious about transmitting a copy of the policy file over a network.

To prevent non-privileged users from modifying the security policy, ensure that the configuration file is writable only by trusted users.

The configuration file is defined by a property of the policy `smf(5)` service. The default configuration file, is `/etc/inet/ipsecinit.conf`. This can be changed using the `svccprop(1)` command. See NOTES for more details.

The policy description language supports the use of tokens that can be resolved by means of a name service, using functions such as `gethostbyname(3NSL)`. While convenient, these functions are only secure as the name service the system is configured to use. Great care should be taken to secure the name service if it is used to resolve elements of the security policy.

If your source address is a host that can be looked up over the network and your naming system itself is compromised, then any names used will no longer be trustworthy.

If the name switch is configured to use a name service that is not local to the system, bypass policy entries might be required to prevent the policy from preventing communication to the name service. See `nsswitch.conf(4)`.

Policy is latched for TCP/UDP sockets on which a `connect(3SOCKET)` or `accept(3SOCKET)` has been issued. Adding new policy entries will not have any effect on them. This feature of latching may change in the future. It is not advisable to depend upon this feature.

The `ipsecconf` command can only be run by a user who has sufficient privilege to open the `pf_key(7P)` socket. The appropriate privilege can be assigned to a user with the Network IPsec Management profile. See `profiles(1)`, `rbac(5)`, `prof_attr(4)`.

Make sure to set up the policies before starting any communications, as existing connections may be affected by the addition of new policy entries. Similarly, do not change policies in the middle of a communication.

Note that certain `ndd` tunables affect how policies configured with this tool are enforced; see `ipsecesp(7P)` for more details.

Examples **EXAMPLE 1** Protecting Outbound TCP Traffic With ESP and the AES Algorithm

The following example specified that any TCP packet from `spiderweb` to `arachnid` should be encrypted with AES, and the SA could be a shared one. It does not verify whether or not the inbound traffic is encrypted.

```
#
# Protect the outbound TCP traffic between hosts spiderweb
# and arachnid with ESP and use AES algorithm.
#
{
    laddr spiderweb
    raddr arachnid
    ulp tcp
    dir out
} ipsec {
```

EXAMPLE 1 Protecting Outbound TCP Traffic With ESP and the AES Algorithm *(Continued)*

```

        encr_algs AES
    }

```

EXAMPLE 2 Verifying Whether or Not Inbound Traffic is Encrypted

Example 1 does not verify whether or not the inbound traffic is encrypted. The entry in this example protects inbound traffic:

```

#
# Protect the TCP traffic on inbound with ESP/DES from arachnid
# to spiderweb
#
{
    laddr spiderweb
    raddr arachnid
    ulp tcp
    dir in
} ipsec {
    encr_algs AES
}

```

sa can be absent for inbound policy entries as it implies that it can be a shared one. Uniqueness is not verified on inbound. Note that in both the above entries, authentication was never specified. This can lead to cut and paste attacks. As mentioned previously, though the authentication is not specified, the system will still use an ESP SA with encr_auth_alg specified, if it was found in the SA tables.

EXAMPLE 3 Protecting All Traffic Between Two Hosts

The following example protects both directions at once:

```

{
    laddr spiderweb
    raddr arachnid
    ulp tcp
} ipsec {
    encr_algs AES
}

```

EXAMPLE 4 Authenticating All Inbound Traffic to the Telnet Port

This entry specifies that any inbound datagram to telnet port should come in authenticated with the SHA1 algorithm. Otherwise the datagram should not be permitted. Without this entry, traffic destined to port number 23 can come in clear. sa is not specified, which implies that it is shared. This can be done only for inbound entries. You need to have an equivalent entry to protect outbound traffic so that the outbound traffic is authenticated as well, remove the dir.

EXAMPLE 4 Authenticating All Inbound Traffic to the Telnet Port *(Continued)*

```

#
# All the inbound traffic to the telnet port should be
# authenticated.
#
{
    lport telnet
    dir in
} ipsec {
    auth_algs sha1
}

```

EXAMPLE 5 Verifying Inbound Traffic is Null-Encrypted

The first entry specifies that any packet with address host-B should not be checked against any policies. The second entry specifies that all inbound traffic from network-B should be encrypted with a NULL encryption algorithm and the MD5 authentication algorithm. NULL encryption implies that ESP header will be used without encrypting the datagram. As the first entry is bypass it need not be given first in order, as bypass entries have the highest precedence. Thus any inbound traffic will be matched against all bypass entries before any other policy entries.

```

#
# Make sure that all inbound traffic from network-B is NULL
# encrypted, but bypass for host-B alone from that network.
# Add the bypass first.
{
    raddr host-B
    dir in
} bypass {}

# Now add for network-B.
{
    raddr network-B/16
    dir in
} ipsec {
    encr_algs NULL
    encr_auth_algs md5
}

```

EXAMPLE 6 Entries to Bypass Traffic from IPsec

The first two entries provide that any datagram leaving the machine with source port 53 or coming into port number 53 should not be subjected to IPsec policy checks, irrespective of any other policy entry in the system. Thus the latter two entries will be considered only for ports other than port number 53.

EXAMPLE 6 Entries to Bypass Traffic from IPsec *(Continued)*

```
#
# Bypass traffic for port no 53
#
{lport 53} bypass {}
{rport 53} bypass {}
{raddr spiderweb } ipsec {encr_algs any sa unique}
```

EXAMPLE 7 Protecting Outbound Traffic

```
#
# Protect the outbound traffic from all interfaces.
#
{raddr spiderweb dir out} ipsec {auth_algs any sa unique}
```

If the `gethostbyname(3XNET)` call for spiderweb yields multiple addresses, multiple policy entries will be added for all the source address with the same properties.

```
{
  laddr arachnid
  raddr spiderweb
  dir in
} ipsec {auth_algs any sa unique}
```

If the `gethostbyname(3XNET)` call for spiderweb and the `gethostbyname(3XNET)` call for arachnid yield multiple addresses, multiple policy entries will be added for each (`saddr daddr`) pair with the same properties. Use `ipsecconf -l` to view all the policy entries added.

EXAMPLE 8 Bypassing Unauthenticated Traffic

```
#
# Protect all the outbound traffic with ESP except any traffic
# to network-b which should be authenticated and bypass anything
# to network-c
#
{raddr network-b/16 dir out} ipsec {auth_algs any}
{dir out} ipsec {encr_algs any}
{raddr network-c/16 dir out} bypass {} # NULL properties
```

Note that `bypass` can be given anywhere and it will take precedence over all other entries. `NULL` pattern matches all the traffic.

EXAMPLE 9 Encrypting IPv6 Traffic with 3DES and MD5

The following entry on the host with the link local address `fe80::a00:20ff:fe21:4483` specifies that any outbound traffic between the hosts with IPv6 link-local addresses `fe80::a00:20ff:fe21:4483` and `fe80::a00:20ff:felf:e346` must be encrypted with 3DES and MD5.

EXAMPLE 9 Encrypting IPv6 Traffic with 3DES and MD5 *(Continued)*

```

{
  laddr fe80::a00:20ff:fe21:4483
  raddr fe80::a00:20ff:fe1f:e346
  dir out
} ipsec {
  encr_algs 3DES
  encr_auth_algs MD5
}

```

EXAMPLE 10 Verifying IPv6 Traffic is Authenticated with SHA1

The following two entries require that all IPv6 traffic to and from the IPv6 site-local network fec0:abcd::0/32 be authenticated with SHA1.

```
{raddr fec0:abcd::0/32} ipsec { auth_algs SHA1 }
```

EXAMPLE 11 Key Lengths

```

# use aes at any key length
{raddr spiderweb} ipsec {encr_algs aes}

# use aes with a 192 bit key
{raddr spiderweb} ipsec {encr_algs aes(192)}

# use aes with any key length up to 192 bits
# i.e. 192 bits or less
{raddr spiderweb} ipsec {encr_algs aes(..192)}

# use aes with any key length of 192 or more
# i.e. 192 bits or more
{raddr spiderweb} ipsec {encr_algs aes(192..)}

#use aes with any key from 192 to 256 bits
{raddr spiderweb} ipsec {encr_algs aes(192..256)}

#use any algorithm with a key of 192 bits or longer
{raddr spiderweb} ipsec {encr_algs any(192..)}

```

EXAMPLE 12 Correct and Incorrect Policy Entries

The following are examples of correctly formed policy entries:

```

{ raddr that_system rport telnet } ipsec { encr_algs 3des encr_auth_algs
sha1 sa shared}

{
  raddr that_system
  rport telnet
}

```

EXAMPLE 12 Correct and Incorrect Policy Entries (Continued)

```

} ipsec {
    encr_algs 3des
    encr_auth_algs sha1
    sa shared
}

{ raddr that_system rport telnet } ipsec
  { encr_algs 3des encr_auth_algs sha1 sa shared}

{ raddr that_system rport telnet } ipsec
  { encr_algs 3des encr_auth_algs sha1 sa shared} or ipsec
  { encr_algs aes encr_auth_algs sha1 sa shared}

```

...and the following is an incorrectly formed entry:

```

{ raddr that_system rport telnet } ipsec
  { encr_algs 3des encr_auth_algs sha1 sa shared}
  or ipsec { encr_algs aes encr_auth_algs sha1 sa shared}

```

In the preceding, incorrect entry, note that the third line begins with “or ipsec”. Such an entry causes ipsecconf to return an error.

EXAMPLE 13 Allowing Neighbor Discovery to Occur in the Clear

The following two entries require that all IPv6 traffic to and from the IPv6 site-local network fec0:abcd::0/32 be authenticated with SHA1. The second entry allows neighbor discovery to operate correctly.

```

{raddr fec0:abcd::0/32} ipsec { auth_algs SHA1 }
{raddr fec0:abcd::0/32 ulp ipv6-icmp type 133-137 dir both }
  pass { }

```

EXAMPLE 14 Using “or”

The following entry allows traffic using the AES or Blowfish algorithms from the remote machine spiderweb:

```

{raddr spiderweb} ipsec {encr_algs aes} or ipsec {encr_algs blowfish}

```

EXAMPLE 15 Configuring a Tunnel to be Backward-Compatible with Solaris 9

The following example is equivalent to “encr_algs aes encr_auth_algs md5” in [ifconfig\(1M\)](#):

```

{tunnel ip.tun0 negotiate transport} ipsec {encr_algs aes
                                           encr_auth_algs md5}

```

EXAMPLE 16 Configuring a Tunnel to a VPN client with an Assigned Address

The following example assumes a distinct “inside” network with its own topology, such that a client’s default route goes “inside”.

```
# Unlike route(1m), the default route has to be spelled-out.
{tunnel ip.tun0 negotiate tunnel raddr client-inside/32
 laddr 0.0.0.0/0} ipsec {encr_algs aes encr_auth_algs sha1}
```

EXAMPLE 17 Transit VPN router between Two Tunnelled Subnets and a Third

The following example specifies a configuration for a VPN router that routes between two tunnelled subnets and a third subnet that is on-link. Consider remote-site A, remote-site B, and local site C, each with a /24 address allocation.

```
# ip.tun0 between me (C) and remote-site A.
# Cover remote-site A to remote-site B.
{tunnel ip.tun0 negotiate tunnel raddr A-prefix/24 laddr
 B-prefix/24} ipsec {encr_algs 3des encr_auth_algs md5}

# Cover remote-site A traffic to my subnet.
{tunnel ip.tun0 negotiate tunnel raddr A-prefix/24 laddr
 C-prefix/24} ipsec {encr_algs 3des encr_auth_algs md5}

# ip.tun1 between me (C) and remote-site B.
# Cover remote-site B to remote-site A.
{tunnel ip.tun1 negotiate tunnel raddr B-prefix/24 laddr
 A-prefix/24} ipsec {encr_algs aes encr_auth_algs sha1}

# Cover remote-site B traffic to my subnet.
{tunnel ip.tun1 negotiate tunnel raddr B-prefix/24 laddr
 C-prefix/24} ipsec {encr_algs aes encr_auth_algs md5}
```

EXAMPLE 18 Using Combined Mode Ciphers

Combined mode ciphers provide data privacy and message authentication in a single operation. They are treated as special versions of `encr_algs`. They provide message authentication without the need to specify `encr_auth_algs`. The two combined mode ciphers supported are:

`aes-ccm`

AES CCM Mode(Counter with CBC-MAC)

`aes-gcm`

AES GCM Mode (Galois/Counter)

The parameters used are the same as any other `encr_algs` value. In both examples, the number in the algorithm token indicates the length of the Integrity Check Vector (ICV). See [ipsecalgs\(1M\)](#).

EXAMPLE 18 Using Combined Mode Ciphers (Continued)

```
# simple example using transport mode
{laddr 192.168.99.2 raddr 192.168.99.3} ipsec
  {encr_algs aes-gcm sa shared}
# simple example using CCM mode and 128 bit keys
{laddr 192.168.99.100 raddr 192.168.99.200} ipsec
  {encr_algs aes-ccm(128) sa shared}
```

Files /var/run/ipsecpolicy.conf

Cache of IPsec policies currently configured for the system, maintained by ipsecconf command. Do not edit this file.

/etc/inet/ipsecinit.conf

File containing IPsec policies to be installed at system restart by the policy [smf\(5\)](#) service. See NOTES for more information.

/etc/inet/ipsecinit.sample

Sample input file for ipsecconf.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------------|----------------|
| Availability | SUNWcs |
| Interface Stability | Committed |

See Also [auths\(1\)](#), [profiles\(1\)](#), [svccprop\(1\)](#), [svcs\(1\)](#), [in.iked\(1M\)](#), [init\(1M\)](#), [ifconfig\(1M\)](#), [ipsecalgs\(1M\)](#), [ipseckey\(1M\)](#), [svccadm\(1M\)](#), [svccfg\(1M\)](#), [gethostbyname\(3NSL\)](#), [accept\(3SOCKET\)](#), [connect\(3SOCKET\)](#), [gethostbyname\(3XNET\)](#), [getnetbyname\(3XNET\)](#), [getprotobyname\(3XNET\)](#), [getservbyname\(3XNET\)](#), [getaddrinfo\(3SOCKET\)](#), [socket\(3SOCKET\)](#), [ike.config\(4\)](#), [nsswitch.conf\(4\)](#), [prof_attr\(4\)](#), [user_attr\(4\)](#), [attributes\(5\)](#), [rbac\(5\)](#), [smf\(5\)](#), [ipsecah\(7P\)](#), [ipsecesp\(7P\)](#), [pf_key\(7P\)](#)

Diagnostics Bad “string” on line *N*.

Duplicate “string” on line *N*.

string refers to one of the names in pattern or properties. A Bad string indicates that an argument is malformed; a Duplicate string indicates that there are multiple arguments of a similar type, for example, multiple Source Address arguments.

Interface name already selected

Dual use of `-i name` and `name,index` for an index.

Error before or at line *N*.

Indicates parsing error before or at line *N*.

Non-existent index

Reported when the *index* for delete is not a valid one.

spd_msg return: File exists

Reported when there is already a policy entry that matches the traffic of this new entry.

Notes IPsec manual keys are managed by the service management facility, [smf\(5\)](#). The services listed below manage the components of IPsec. These services are delivered as follows:

```
svc:/network/ipsec/policy:default (enabled)
svc:/network/ipsec/ipsecalgs:default (enabled)
svc:/network/ipsec/manual-key:default (disabled)
svc:/network/ipsec/ike:default (disabled)
```

The manual-key service is delivered disabled. The system administrator must create manual IPsec Security Associations (SAs), as described in [ipseckey\(1M\)](#), before enabling that service.

The policy service is delivered enabled, but without a configuration file, so that, as a starting condition, packets are not protected by IPsec. After you create the configuration file `/etc/inet/ipsecinit.conf`, as described in this man page, and refresh the service (`svcadm refresh`, see below), the policy contained in the configuration file is applied. If there is an error in this file, the service enters maintenance mode.

Services that are delivered disabled are delivered that way because the system administrator must create configuration files for those services before enabling them. See [ike.config\(4\)](#) for the `ike` service.

See [ipsecalgs\(1M\)](#) for the `ipsecalgs` service.

The correct administrative procedure is to create the configuration file for each service, then enable each service using [svcadm\(1M\)](#).

If the configuration needs to be changed, edit the configuration file then refresh the service, as follows:

```
example# svcadm refresh policy
```

The [smf\(5\)](#) framework will record any errors in the service-specific log file. Use any of the following commands to examine the log file property:

```
example# svcs -l policy  
example# svcprop policy  
example# svccfg -s policy listprop
```

The following property is defined for the `policy` service:

```
config/config_file
```

This property can be modified using [svccfg\(1M\)](#) by users who have been assigned the following authorization:

```
solaris.smf.value.ipsec
```

See [auths\(1\)](#), [user_attr\(4\)](#), [rbac\(5\)](#).

The service needs to be refreshed using [svcadm\(1M\)](#) before the new property is effective. General non-modifiable properties can be viewed with the [svcprop\(1\)](#) command.

```
# svccfg -s ipsec/policy setprop config/config_file = /new/config_file  
# svcadm refresh policy
```

Administrative actions on this service, such as enabling, disabling, refreshing, and requesting restart can be performed using [svcadm\(1M\)](#). A user who has been assigned the authorization shown below can perform these actions:

```
solaris.smf.manage.ipsec
```

The service's status can be queried using the [svcs\(1\)](#) command.

The `ipsecconf` command is designed to be managed by the `policy` [smf\(5\)](#) service. While the `ipsecconf` command can be run from the command line, this is discouraged. If the `ipsecconf` command is to be run from the command line, the `policy` [smf\(5\)](#) service should be disabled first. See [svcadm\(1M\)](#).

Name ipseckey – manually manipulate an IPsec Security Association Database (SADB)

Synopsis ipseckey [-nvp]
 ipseckey [-nvp] -f *filename*
 ipseckey -c *filename*
 ipseckey [-nvp] [delete | delete-pair | get] SA_TYPE {EXTENSION *value...*}
 ipseckey [-np] [monitor | passive_monitor | pmonitor]
 ipseckey [-nvp] flush {SA_TYPE}
 ipseckey [-nvp] dump {SA_TYPE}
 ipseckey [-nvp] save SA_TYPE {*filename*}
 ipseckey [-nvp] -s *filename*

Description The ipseckey command is used to manually manipulate the security association databases of the network security services, [ipsecah\(7P\)](#) and [ipsecesp\(7P\)](#). You can use the ipseckey command to set up security associations between communicating parties when automated key management is not available.

While the ipseckey utility has only a limited number of general options, it supports a rich command language. The user may specify requests to be delivered by means of a programmatic interface specific for manual keying. See [pf_key\(7P\)](#). When ipseckey is invoked with no arguments, it will enter an interactive mode which prints a prompt to the standard output and accepts commands from the standard input until the end-of-file is reached. Some commands require an explicit security association (“SA”) type, while others permit the SA type to be unspecified and act on all SA types.

ipseckey uses a PF_KEY socket and the message types SADB_ADD, SADB_DELETE, SADB_GET, SADB_UPDATE, SADB_FLUSH, and SADB_X_PROMISC. Thus, you must be a superuser to use this command.

ipseckey handles sensitive cryptographic keying information. Please read the [Security](#) section for details on how to use this command securely.

Options -c [*filename*]
 Analogous to the -f option (see following), except that the input is not executed but only checked for syntactical correctness. Errors are reported to `stderr`. This option is provided to debug configurations without making changes. See [SECURITY](#) and “Service Management Facility” for more information.

-f [*filename*]
 Read commands from an input file, *filename*. The lines of the input file are identical to the command line language. The load command provides similar functionality. The -s option or the save command can generate files readable by the -f argument.

- n
Prevent attempts to print host and network names symbolically when reporting actions. This is useful, for example, when all name servers are down or are otherwise unreachable.
- p
Paranoid. Do not print any keying material, even if saving SAs. Instead of an actual hexadecimal digit, print an X when this flag is turned on.
- s [*filename*]
The opposite of the -f option. If '-' is given for a *filename*, then the output goes to the standard output. A snapshot of all current SA tables will be output in a form readable by the -f option. The output will be a series of add commands, but with some names not used. This occurs because a single name may often indicate multiple addresses.
- v
Verbose. Print the messages being sent into the PF_KEY socket, and print raw seconds values for lifetimes.

Commands add

Add an SA. Because it involves the transfer of keying material, it cannot be invoked from the shell, lest the keys be visible in [ps\(1\)](#) output. It can be used either from the interactive ipseckey> prompt or in a command file specified by the -f command. The add command accepts all extension-value pairs described below.

update

Update SA lifetime, and in the cases of larval SAs (leftover from aborted automated key management), keying material and other extensions. Like add, this command cannot be invoked from the shell because keying material would be seen by the [ps\(1\)](#) command. It can be used either from the interactive ipseckey> prompt or in a command file specified by the -f command. The update command accepts all extension-value pairs, but normally is only used for SA lifetime updates.

update-pair

As update, but apply the update to the SA and its paired SA, if there is one.

delete

Delete a specific SA from a specific SADB. This command requires the spi extension, and the dest extension for IPsec SAs. Other extension-value pairs are superfluous for a delete message. If the SA to be deleted is paired with another SA, the SA is deleted and the paired SA is updated to indicate that it is now unpaired.

delete-pair

Delete a specific SA from a specific SADB. If the SA is paired with another SA, delete that SA too. This command requires the spi extension and the dest extension for the IPsec SA, or its pair.

get

Lookup and display a security association from a specific SADB. Like delete, this command only requires spi and dest for IPsec.

flush

Remove all SA for a given SA_TYPE, or all SA for all types.

monitor

Continuously report on any PF_KEY messages. This uses the SADB_X_PROMISC message to enable messages that a normal PF_KEY socket would not receive to be received. See [pf_key\(7P\)](#).

passive_monitor

Like monitor, except that it does not use the SADB_X_PROMISC message.

pmonitor

Synonym for passive_monitor.

dump

Will display all SAs for a given SA type, or will display all SAs. Because of the large amount of data generated by this command, there is no guarantee that all SA information will be successfully delivered, or that this command will even complete.

save

Is the command analog of the -s option. It is included as a command to provide a way to snapshot a particular SA type, for example, esp or ah.

help

Prints a brief summary of commands.

SA_TYPE all

Specifies all known SA types. This type is only used for the flush and dump commands. This is equivalent to having no SA type for these commands.

ah

Specifies the IPsec Authentication Header (“AH”) SA.

esp

Specifies the IPsec Encapsulating Security Payload (“ESP”) SA.

Extension Value Types

Commands like add, delete, get, and update require that certain extensions and associated values be specified. The extensions will be listed here, followed by the commands that use them, and the commands that require them. Requirements are currently documented based upon the IPsec definitions of an SA. Required extensions may change in the future. <number> can be in either hex (0xnnn), decimal (nnn) or octal (0nnn). <string> is a text string. <hexstr> is a long hexadecimal number with a bit-length. Extensions are usually paired with values; however, some extensions require two values after them.

spi <number>

Specifies the security parameters index of the SA. This extension is required for the add, delete, get and update commands.

`pair-spi <number>`

When `pair-spi` is used with the `add` or `update` commands, the SA being added or updated will be paired with the SA defined by `pair-spi`. A pair of SAs can be updated or deleted with a single command.

The two SAs that make up the pair need to be in opposite directions from the same pair of IP addresses. The command will fail if either of the SAs specified are already paired with another SA.

If the `pair-spi` token is used in a command and the SA defined by `pair-spi` does not exist, the command will fail. If the command was `add` and the pairing failed, the SA to be added will instead be removed.

`inbound | outbound`

These optional flags specify the direction of the SA. When the `inbound` or `outbound` flag is specified with the `add` command, the kernel will insert the new SA into the specified hash table for faster lookups. If the flag is omitted, the kernel will decide into which hash table to insert the new SA based on its knowledge the IP addresses specified with the `src` and `dst` extensions.

When these flags are used with the `update`, `delete`, `update-pair` or `get` commands, the flags provide a hint as to the hash table in which the kernel should find the SA.

`replay <number>`

Specifies the replay window size. If not specified, the replay window size is assumed to be zero. It is not recommended that manually added SAs have a replay window. This extension is used by the `add` and `update` commands.

`replay_value <number>`

Specifies the replay value of the SA. This extension is used by the `add` and `update` commands.

`state <string>|<number>`

Specifies the SA state, either by numeric value or by the strings “larval”, “mature”, “dying” or “dead”. If not specified, the value defaults to `mature`. This extension is used by the `add` and `update` commands.

`auth_alg <string>|<number>`

`authalg <string>|<number>`

Specifies the authentication algorithm for an SA, either by numeric value, or by strings indicating an algorithm name. Current authentication algorithms include:

 HMAC-MD5

 md5, hmac-md5

 HMAC-SH-1

 sha, sha-1, hmac-sha1, hmac-sha

HMAC-SHA-256

sha256, sha-256, hmac-sha256, hmac-sha-256

HMAC-SHA-384

sha384, sha-384, hmac-sha384, hmac-sha-384

HMAC-SHA-512

sha512, sha-512, hmac-sha512, hmac-sha-512

Often, algorithm names will have several synonyms. This extension is required by the `add` command for certain SA types. It is also used by the `update` command.

Use the `ipsecalgs(1M)` command to obtain the complete list of authentication algorithms.

`encr_alg <string>|<number>`

`encr_alg <string>|<number>`

Specifies the encryption algorithm for an SA, either by numeric value, or by strings indicating an algorithm name. Current encryption algorithms include DES (“des”), Triple-DES (“3des”), Blowfish (“blowfish”), and AES (“aes”). This extension is required by the `add` command for certain SA types. It is also used by the `update` command.

Use the `ipsecalgs(1M)` command to obtain the complete list of encryption algorithms.

The next six extensions are lifetime extensions. There are two varieties, “hard” and “soft”. If a `hard` lifetime expires, the SA will be deleted automatically by the system. If a `soft` lifetime expires, an `SADB_EXPIRE` message will be transmitted by the system, and its state will be downgraded to `dying` from `mature`. See `pf_key(7P)`. The `monitor` command to `key` allows you to view `SADB_EXPIRE` messages.

`idle_addtime <number>`

`idle_usetime <number>`

Specifies the number of seconds that this SA can exist if the SA is not used before the SA is revalidated. If this extension is not present, the default value is half of the `hard_addtime` (see below). This extension is used by the `add` and `update` commands.

`soft_bytes <number>`

`hard_bytes <number>`

Specifies the number of bytes that this SA can protect. If this extension is not present, the default value is zero, which means that the SA will not expire based on the number of bytes protected. This extension is used by the `add` and `update` commands.

`soft_addtime <number>`

`hard_addtime <number>`

Specifies the number of seconds that this SA can exist after being added or updated from a larval SA. An update of a mature SA does not reset the initial time that it was added. If this extension is not present, the default value is zero, which means the SA will not expire based on how long it has been since it was added. This extension is used by the `add` and `update` commands.

`soft_usetime <number>`

`hard_usetime <number>`

Specifies the number of seconds this SA can exist after first being used. If this extension is not present, the default value is zero, which means the SA will not expire based on how long it has been since it was added. This extension is used by the `add` and `update` commands.

`saddr address | name`

`srcaddr address | name`

`saddr6 IPv6 address`

`srcaddr6 IPv6 address`

`src address | name`

`src6 IPv6 address`

`srcaddr address` and `src address` are synonyms that indicate the source address of the SA. If unspecified, the source address will either remain unset, or it will be set to a wildcard address if a destination address was supplied. To not specify the source address is valid for IPsec SAs. Future SA types may alter this assumption. This extension is used by the `add`, `update`, `get` and `delete` commands.

`daddr <address>|<name>`

`dstaddr <address>|<name>`

`daddr6 <IPv6 address>|<name>`

`dstaddr6 <IPv6 address>|<name>`

`dst <addr>|<name>`

`dst6 <IPv6 address>|<name>`

`dstaddr <addr>` and `dst <addr>` are synonyms that indicate the destination address of the SA. If unspecified, the destination address will remain unset. Because IPsec SAs require a specified destination address and `spi` for identification, this extension, with a specific value, is required for the `add`, `update`, `get` and `delete` commands.

If a name is given, `ipseckey` will attempt to invoke the command on multiple SAs with all of the destination addresses that the name can identify. This is similar to how `ipseconf` handles addresses.

If `dst6` or `dstaddr6` is specified, only the IPv6 addresses identified by a name are used.

`sport <portnum>`

`sport` specifies the source port number for an SA. It should be used in combination with an upper-layer protocol (see below), but it does not have to be.

`dport <portnum>`

`dport` specifies the destination port number for an SA. It should be used in combination with an upper-layer protocol (see below), but it does not have to be.

`encap <protocol>`

Identifies the protocol used to encapsulate NAT-traversal IPsec packets. Other NAT-traversal parameters (`nat_*`) are below. The only acceptable value for `<protocol>` currently is `udp`.

proto <protocol number>

ulp <protocol number>

proto, and its synonym ulp, specify the IP protocol number of the SA.

nat_loc <address>|<name>

If the local address in the SA (source or destination) is behind a NAT, this extension indicates the NAT node's globally-routable address. This address can match the SA's local address if there is a nat_lport (see below) specified.

nat_rem <address>|<name>

If the remote address in the SA (source or destination) is behind a NAT, this extension indicates that node's internal (that is, behind-the-NAT) address. This address can match the SA's local address if there is a nat_rport (see below) specified.

nat_lport <portnum>

Identifies the local UDP port on which encapsulation of ESP occurs.

nat_rport <portnum>

Identifies the remote UDP port on which encapsulation of ESP occurs.

isrc <address> | <name>[/<prefix>]

innersrc <address> | <name>[/<prefix>]

isrc6 <address> | <name>[/<prefix>]

innersrc6 <address> | <name>[/<prefix>]

proxyaddr <address> | <name>[/<prefix>]

proxy <address> | <name>[/<prefix>]

isrc <address>[/<prefix>] and innersrc <address>[/<prefix>] are synonyms. They indicate the inner source address for a tunnel-mode SA.

An inner-source can be a prefix instead of an address. As with other address extensions, there are IPv6-specific forms. In such cases, use only IPv6-specific addresses or prefixes.

Previous versions referred to this value as the proxy address. The usage, while deprecated, remains.

idst <address> | <name>[/<prefix>]

innerdst <address> | <name>[/<prefix>]

idst6 <address> | <name>[/<prefix>]

innerdst6 <address> | <name>[/<prefix>]

idst <address>[/<prefix>] and innerdst <address>[/<prefix>] are synonyms. They indicate the inner destination address for a tunnel-mode SA.

An inner-destination can be a prefix instead of an address. As with other address extensions, there are IPv6-specific forms. In such cases, use only IPv6-specific addresses or prefixes.

innersport <portnum>

isport <portnum>

`innersport` specifies the source port number of the inner header for a tunnel-mode SA. It should be used in combination with an upper-layer protocol (see below), but it does not have to be.

`innerdport` <portnum>

`idport` <portnum>

`innerdport` specifies the destination port number of the inner header for a tunnel-mode SA. It should be used in combination with an upper-layer protocol (see below), but it does not have to be.

`ipproto` <protocol number>`iuip` <protocol number>

`ipproto`, and its synonym `iuip`, specify the IP protocol number of the inner header of a tunnel-mode SA.

`authkey` <hexstring>

Specifies the authentication key for this SA. The key is expressed as a string of hexadecimal digits, with an optional `/` at the end, for example, `123/12`. Bits are counted from the most-significant bits down. For example, to express three '1' bits, the proper syntax is the string `"e/3"`. For multi-key algorithms, the string is the concatenation of the multiple keys. This extension is used by the `add` and `update` commands.

`encrkey` <hexstring>

Specifies the encryption key for this SA. The syntax of the key is the same as `authkey`. A concrete example of a multi-key encryption algorithm is `3des`, which would express itself as a 192-bit key, which is three 64-bit parity-included DES keys. This extension is used by the `add` and `update` commands.

`reserved_bits` <number>

The last <number> bits of the `encrkey` string are marked as reserved in the `PF_KEY` message. This option is only for testing certain encryption algorithms.

Certificate identities are very useful in the context of automated key management, as they tie the SA to the public key certificates used in most automated key management protocols. They are less useful for manually added SAs. Unlike other extensions, `srcidtype` takes two values, a *type*, and an actual *value*. The type can be one of the following:

`prefix`

An address prefix.

`fqdn`

A fully-qualified domain name.

`domain`

Domain name, synonym for `fqdn`.

`user_fqdn`

User identity of the form `user@fqdn`.

`mailbox`

Synonym for `user_fqdn`.

The *value* is an arbitrary text string that should identify the certificate.

`srcidtype <type, value>`

Specifies a source certificate identity for this SA. This extension is used by the `add` and `update` commands.

`dstidtype <type, value>`

Specifies a destination certificate identity for this SA. This extension is used by the `add` and `update` commands

Label extensions are used on Trusted Extensions to associate sensitivity labels with the traffic carried inside a security association. These extensions are not allowed unless Trusted Extensions is enabled.

`label label`

Defines the sensitivity label of traffic carried by this SA. Disallowed on systems not using Trusted Extensions.

`outer-label label`

Defines the sensitivity of the ciphertext traffic belonging to this SA; this label will appear in the outer packet header. Disallowed on systems not using Trusted Extensions. Incorrect use of this extension might allow label policy to be circumvented.

`implicit-label label`

Defines the sensitivity of the ciphertext traffic belonging to this SA and request that this SA not contain an explicit on-the-wire label. Disallowed on systems not using Trusted Extensions. Incorrect use of this extension might allow label policy to be circumvented.

Tunnel Mode versus
Transport Mode SAs

An IPsec SA is a Tunnel Mode SA if the “proto” value is either 4 (ipip) or 41 (ip6) *and* there is an inner-address or inner-port value specified. Otherwise, the SA is a Transport Mode SA.

Security

Keying material is very sensitive and should be generated as randomly as possible. Some algorithms have known weak keys. IPsec algorithms have built-in weak key checks, so that if a weak key is in a newly added SA, the `add` command will fail with an invalid value.

The `ipseckey` command allows a privileged user to enter cryptographic keying information. If an adversary gains access to such information, the security of IPsec traffic is compromised. The following issues should be taken into account when using the `ipseckey` command.

1. Is the TTY going over a network (interactive mode)?
 - If it is, then the security of the keying material is the security of the network path for this TTY’s traffic. Using `ipseckey` over a clear-text `telnet` or `rlogin` session is risky.
 - Even local windows might be vulnerable to attacks where a concealed program that reads window events is present.
2. Is the file accessed over the network or readable to the world (`-f` option)?
 - A network-mounted file can be sniffed by an adversary as it is being read.
 - A world-readable file with keying material in it is also risky.

- The `ipseckey` command is designed to be managed by the `manual-key smf(5)` service. Because the `smf(5)` log files are world-readable, the `ipseckey` does not record any syntax errors in the log files, as these errors might include secret information.

If a syntax error is found when the `manual-key smf(5)` service is enabled, the service enters maintenance mode. The log file will indicate that there was a syntax error, but will not specify what the error was.

The administrator should use `ipseckey -c filename` from the command line to discover the cause of the errors. See `OPTIONS`.

If your source address is a host that can be looked up over the network and your naming system itself is compromised, then any names used will not be trustworthy.

Security weaknesses often lie in misapplication of tools, not in the tools themselves. Administrators are urged to be cautious when using `ipseckey`. The safest mode of operation is probably on a console or other hard-connected TTY.

For further thoughts on this subject, see the afterward by Matt Blaze in Bruce Schneier's *Applied Cryptography: Protocols, Algorithms, and Source Code in C*.

Service Management Facility IPsec manual keys are managed by the service management facility, `smf(5)`. The services listed below manage the components of IPsec. These services are delivered as follows:

```
svc:/network/ipsec/policy:default (enabled)
svc:/network/ipsec/ipsecalgs:default (enabled)
svc:/network/ipsec/manual-key:default (disabled)
svc:/network/ipsec/ike:default (disabled)
```

The `manual-key` service is delivered disabled. The system administrator must create manual IPsec Security Associations (SAs), as described in this man page, before enabling that service.

The `policy` service is delivered enabled, but without a configuration file, so that, as a starting condition, packets are not protected by IPsec. After you create the configuration file `/etc/inet/ipsecinit.conf` and refresh the service (`svcadm refresh`, see below), the policy contained in the configuration file is applied. If there is an error in this file, the service enters maintenance mode. See `ipseconf(1M)`.

Services that are delivered disabled are delivered that way because the system administrator must create configuration files for those services before enabling them. See `ike.config(4)` for the `ike` service.

See `ipsecalgs(1M)` for the `ipsecalgs` service.

The correct administrative procedure is to create the configuration file for each service, then enable each service using `svcadm(1M)`.

If the configuration needs to be changed, edit the configuration file then refresh the service, as follows:

```
example# svcadm refresh manual-key
```

Warning: To prevent ipseckey complaining about duplicate Associations, the ipseckey command flushes the Security Association Data Base (SADB) when the ipseckey command is run from [smf\(5\)](#), before adding any new Security Associations defined in the configuration file. This differs from the command line behavior where the SADB is not flushed before adding new Security Associations.

The [smf\(5\)](#) framework will record any errors in the service-specific log file. Use any of the following commands to examine the logfile property:

```
example# svcs -l manual-key
example# svcprop manual-key
example# svccfg -s manual-key listprop
```

The following property is defined for the manual-key service:

```
config/config_file
```

This property can be modified using [svccfg\(1M\)](#) by users who have been assigned the following authorization:

```
solaris.smf.value.ipsec
```

See [auths\(1\)](#), [user_attr\(4\)](#), [rbac\(5\)](#).

The service needs to be refreshed using [svcadm\(1M\)](#) before the new property is effective. General non-modifiable properties can be viewed with the [svcprop\(1\)](#) command.

```
# svccfg -s ipsec/manual-key setprop config/config_file = \
/new/config_file
# svcadm refresh manual-key
```

Administrative actions on this service, such as enabling, disabling, refreshing, and requesting restart can be performed using [svcadm\(1M\)](#). A user who has been assigned the authorization shown below can perform these actions:

```
solaris.smf.manage.ipsec
```

The service's status can be queried using the [svcs\(1\)](#) command.

The ipseckey command is designed to be run under [smf\(5\)](#) management. While the ipsecconf command can be run from the command line, this is discouraged. If the ipseckey command is to be run from the command line, the manual-key [smf\(5\)](#) service should be disabled first. See [svcadm\(1M\)](#).

Examples

EXAMPLE 1 Emptying Out All SAs

To empty out all SA:

```
example# ipseckey flush
```

EXAMPLE 2 Flushing Out IPsec AH SAs Only

To flush out only IPsec AH SAs:

```
example# ipseckey flush ah
```

EXAMPLE 3 Saving All SAs To Standard Output

To save all SAs to the standard output:

```
example# ipseckey save all
```

EXAMPLE 4 Saving ESP SAs To The File /tmp/snapshot

To save ESP SAs to the file /tmp/snapshot:

```
example# ipseckey save esp /tmp/snapshot
```

EXAMPLE 5 Deleting an IPsec SA

To delete an IPsec SA, only the SPI and the destination address are needed:

```
example# ipseckey delete esp spi 0x2112 dst 224.0.0.1
```

An alternative would be to delete the SA and the SAs pair if it has one:

```
example# ipseckey delete-pair esp spi 0x2112 dst 224.0.0.1
```

EXAMPLE 6 Getting Information on an IPsec SA

Likewise, getting information on a SA only requires the destination address and SPI:

```
example# ipseckey get ah spi 0x5150 dst mypeer
```

EXAMPLE 7 Adding or Updating IPsec SAs

Adding or updating SAs requires entering interactive mode:

```
example# ipseckey
ipseckey> add ah spi 0x90125 src me.domain.com dst you.domain.com \
    authalg md5 authkey 1234567890abcdef1234567890abcdef
ipseckey> update ah spi 0x90125 dst you.domain.com hard_bytes \
    16000000
ipseckey> exit
```

Adding two SAs that are linked together as a pair:

```
example# ipseckey
ipseckey> add esp spi 0x2345 src me.domain.com dst you.domain.com \
    authalg md5 authkey bde359723576fdea08e56cbe876e24ad \
    encralg des encrkey be02938e7def2839
ipseckey> add esp spi 0x5432 src me.domain.com dst you.domain.com \
    authalg md5 authkey bde359723576fdea08e56cbe876e24ad \
    encralg des encrkey be02938e7def2839 pair-spi 0x2345
```

EXAMPLE 7 Adding or Updating IPsec SAs (Continued)

```
ipseckey> exit
```

EXAMPLE 8 Adding an SA in the Opposite Direction

In the case of IPsec, SAs are unidirectional. To communicate securely, a second SA needs to be added in the opposite direction. The peer machine also needs to add both SAs.

```
example# ipseckey
ipseckey> add ah spi 0x2112 src you.domain.com dst me.domain.com \
          authalg md5 authkey bde359723576fdea08e56cbe876e24ad \
          hard_bytes 16000000
ipseckey> exit
```

EXAMPLE 9 Monitoring PF_KEY Messages

Monitoring for PF_KEY messages is straightforward:

```
example# ipseckey monitor
```

EXAMPLE 10 Using Commands in a File

Commands can be placed in a file that can be parsed with the `-f` option. This file may contain comment lines that begin with the “#” symbol. For example:

```
# This is a sample file for flushing out the ESP table and
# adding a pair of SAs.

flush esp

### Watch out! I have keying material in this file. See the
### SECURITY section in this manual page for why this can be
### dangerous .

add esp spi 0x2112 src me.domain.com dst you.domain.com \
          authalg md5 authkey bde359723576fdea08e56cbe876e24ad \
          encralg des encrkey be02938e7def2839 hard_usetime 28800
add esp spi 0x5150 src you.domain.com dst me.domain.com \
          authalg md5 authkey 930987dbe09743ade09d92b4097d9e93 \
          encralg des encrkey 8bd4a52e10127deb hard_usetime 28800

## End of file - This is a gratuitous comment
```

EXAMPLE 11 Adding SAs for IPv6 Addresses

The following commands from the interactive-mode create an SA to protect IPv6 traffic between the site-local addresses

```
example # ipseckey
ipseckey> add esp spi 0x6789 src6 fec0:bbbb::4483 dst6 fec0:bbbb::7843\
          authalg md5 authkey bde359723576fdea08e56cbe876e24ad \
```

EXAMPLE 11 Adding SAs for IPv6 Addresses (Continued)

```
encralg des encrkey be02938e7def2839 hard_usetime 28800
ipseckey>exit
```

EXAMPLE 12 Linking Two SAs as a Pair

The following command links two SAs together, as a pair:

```
example# ipseckey update esp spi 0x123456 dst 192.168.99.2 \
pair-spi 0x654321
```

Files /etc/inet/secret/ipseckeys

Default configuration file used at boot time. See “Service Management Facility” and SECURITY for more information.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | Committed |

See Also [ps\(1\)](#), [svccprop\(1\)](#), [svcs\(1\)](#), [ipseconf\(1M\)](#), [ipsecalgs\(1M\)](#), [route\(1M\)](#), [svcadm\(1M\)](#), [svccfg\(1M\)](#), [ike.config\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#), [ipsec\(7P\)](#), [ipsecah\(7P\)](#), [ipsecesp\(7P\)](#), [pf_key\(7P\)](#)

Schneier, B., *Applied Cryptography: Protocols, Algorithms, and Source Code in C*. Second ed. New York, New York: John Wiley & Sons, 1996.

Diagnostics The ipseckey command parses the configuration file and reports any errors. In the case of multiple errors, ipseckey reports as many of these as possible.

The ipseckey command does not attempt to use a COMMAND that has a syntax error. A COMMAND might be syntactically correct but can nevertheless generate an error because the kernel rejected the request made to [pf_key\(7P\)](#). This might occur because a key had an invalid length or because an unsupported algorithm was specified.

If there are any errors in the configuration file, ipseckey reports the number of valid COMMANDS and the total number of COMMANDS parsed.

Parse error on line N.

If an interactive use of ipseckey would print usage information, this would print instead. Usually preceded by another diagnostic. Because COMMANDS can cover more than a single line in the configuration file by using the backslash character to delimit lines, its not always possible to pinpoint in the configuration file the exact line that caused the error.

Unexpected end of command line.

An additional argument was expected on the command line.

Unknown

A value for a specific extension was unknown.

Address type *N* not supported.

A name-to-address lookup returned an unsupported address family.

N is not a bit specifier

bit length *N* is too big for

string is not a hex string

Keying material was not entered appropriately.

Can only specify single

A duplicate extension was entered.

Don't use extension for *<string>* for *<command>*.

An extension not used by a command was used.

One of the entered values is incorrect: Diagnostic code *NN*: *<msg>*

This is a general invalid parameter error. The diagnostic code and message provides more detail about what precise value was incorrect and why.

Notes In spite of its IPsec-specific name, ipseckey is analogous to [route\(1M\)](#), in that it is a command-line interface to a socket-based administration engine, in this case, PF_KEY. PF_KEY was originally developed at the United States Naval Research Laboratory.

To have machines communicate securely with manual keying, SAs need to be added by all communicating parties. If two nodes wish to communicate securely, both nodes need the appropriate SAs added.

In the future ipseckey may be invoked under additional names as other security protocols become available to PF_KEY.

This command requires `sys_ip_config` privilege to operate and thus can run in the global zone and in exclusive-IP zones. The global zone can set up security associations with ipseckey to protect traffic for shared-IP zones on the system.

Name iscsiadm – enable management of iSCSI initiators

Synopsis `iscsiadm subcommand direct-object [options] [operand]`

Description The `iscsiadm` command enables management of the iSCSI (Internet SCSI) initiator on a host. `iscsiadm` is implemented as a set of subcommands, many with their own options, which are described in the section for that subcommand. Options not associated with a particular subcommand are described under **OPTIONS**.

`iscsiadm` works only when the following service is online:

```
svc:/network/iscsi/initiator:default
```

The `iscsiadm` command supports the following subcommands, which are described in detail in subsections that follow:

`add` Adds element(s) to an object.
`list` Lists element(s) of an object.
`modify` Modifies attributes of an object.
`remove` Removes an element from an object.

The `iscsiadm` subcommands operate on a *direct-object*. These are described in the section for each subcommand.

The `iscsiadm` command supports the Internet Storage Name Service (iSNS) for the discovery of iSCSI targets. The command supports the Challenge Handshake Authentication Protocol (CHAP) for authentication.

add Subcommand The syntax for the `add` subcommand is:

```
# iscsiadm add direct_object [operands...]
```

The `add` subcommand adds the following *direct_objects*:

```
discovery-address discovery-address [...]
```

Adds a target to a list of discovery addresses. A discovery address (as in the syntax shown below) is an IP *address:port* combination used in a `SendTargets` discovery session. Using this discovery approach, a target device can inform an initiator of the target address and target name of each target exposed by that device. Connection to a target is not attempted unless the `SendTargets` method of discovery has been enabled on the host. You enable this method with the `modify` subcommand.

The *discovery-address* parameter is formatted as:

```
<IP address>[:port]
```

If *port* is not specified, the default of 3260 will be used.

`isns-server isns-server [...]`

Add an iSNS server to the list of iSNS server addresses. An iSNS server address (specified in the syntax shown below) is an IP address-port combination used in an iSNS discovery session. By using iSNS discovery, an iSNS server can provide an initiator with information about a portal and the name of each target that belongs to the same discovery domain as that of the initiator. Connection to the iSNS server is not attempted unless the iSNS method of discovery has been enabled on the host. You enable this method with the `modify` subcommand, described below.

The `isns-server` parameter is formatted as:

`IP_address[:port]`

If a port is not specified, the default of 3205 is used.

`static-config static_target [...]`

Adds a target to the list of statically configured targets. A connection to the target will not be attempted unless the static configuration method of discovery has been enabled.

The `static_target` parameter is formatted as:

`<target-name>, <target address>[:port-number] [, tpgt]`

`<target-name>` can be up to 223 characters.

`list` Subcommand The syntax for the `list` subcommand is:

```
# iscsiadm list direct-object [options]
```

The `list` subcommand displays data for the following *direct-objects*:

`discovery`

Lists the discovery methods and their current activation state, enabled or disabled. Discovery methods are:

- iSNS (Internet Storage Name Service)
- Static
- SendTargets

`initiator-node`

Lists information for the initiator node on the host. The iSCSI initiator node represents a logical HBA and is a logical host connection point for iSCSI targets. The parameter values listed in the response are default parameter settings for the initiator. Each connected target for an initiator can have parameter values that differ from the parameter values on the initiator node.

`static-config [static_target[, ...]]`

Lists the target name and address for specified targets or, if no static targets are specified, all statically discovered targets.

`target [-S] [-v] [target[, ...]]`

Lists a target's current parameters, connection state, and which method was used for the target's discovery. Reports information for specified targets or, if no targets are specified, all targets that have been discovered or have had parameters modified by the `modify target` subcommand.

When used with the `-S` option for a specified target, this subcommand returns:

- target name
- logical unit number
- vendor ID
- product ID
- OS device name (for example, `/dev/rdisk/c0t2d0s0`)

The `-v` options gives more details, such as the current login parameters, the detailed connection information, and the discovery method used to discover the target.

A return of `NA` as the discovery method parameter indicates that the target was created with a `iscsiadm modify target-param` command and does not exist as a discovered object. To remove such targets, use `iscsiadm remove target-param`.

`target-param [-v] target [...]`

Lists a target's default and user-defined parameters.

`discovery-address [-v] [discovery-address[, ...]]`

Lists the `discovery-address` objects that have been added using the `iscsiadm add discovery-address` subcommand.

When used with the `-v` option, lists all known targets at a specified `discovery-address`. The `-v` option returns one or more target names along with zero or more target addresses and associated target portal group tags (TPGT), if applicable.

`isns-server [-v] [isns-server[, ...]]`

Lists the `isns-server` objects that have been added using the `iscsiadm add isns-server` subcommand.

When used with the `-v` option, this subcommand lists all known targets at a specified `isns-server` address. The `-v` option returns one or more target names along with zero or more target addresses and associated target portal group tags, if applicable.

`modify` Subcommand The syntax for the `modify` subcommand is:

```
# iscsiadm modify direct_object [options]
```

The `modify` subcommand supports the following `direct_objects`:

`discovery` [*options*]

Enabling a discovery method initiates a discovery using that method. Disabling a discovery method that is currently enabled does not affect connections to any targets that have already been discovered by that method.

Options for modify discovery are as follows:

- i, -iSNS enable | disable
Enable or disable iSNS discovery.
- s, --static enable | disable
Enable or disable static discovery.
- t, --sendtargets enable | disable
Enable or disable SendTargets discovery.

`initiator-node` [*options*]

Modifies an initiator's properties. If a target is currently connected, this operation can succeed. However, the modified set of parameters will not be in effect for that target until an existing connection session no longer exists and a new connection has been established. The options `-C` and `--CHAP-secret` require a CHAP secret entry in response to a prompt.

For iSCSI booting when the Solaris I/O multipathing feature (formerly known as Sun StorEdge Traffic Manager [STMS] or MPxIO) is disabled, you can modify only the following initiator-node options:

- `-r, --radius-server`
- `-R, --radius-access`
- `-P, --radius-shared-secret`

For iSCSI booting when the Solaris I/O multipathing feature is enabled, you can modify only the following initiator-node options:

- `-h, --headerdigest`
- `-d, --datadigest`
- `-c, --configured-sessions`

Options for modify `initiator-node` are as follows:

- A, --node-alias <*initiator node alias*>
Modifies the initiator node alias. Maximum length of 223 characters.
- a, --authentication chap | none
Sets the authentication mode.
- C, --CHAP-secret
Sets the CHAP secret value. There is no default value. Maximum length is 16 characters; minimum required length is 12 characters.
- c, --configured-sessions <*num_sessions*> | <*IP address*>[,<*IP address*>...]
Sets the number of configured iSCSI sessions that will be created for each iSCSI target. The feature should be used in combination with the Solaris I/O multipathing feature described in [scsi_vhci\(7D\)](#).
- d, --datadigest none | CRC32
Sets whether CRC32 is enabled to check SCSI data transfers.

- H, --CHAP-name *CHAP name*
Specifies a CHAP username. If you do not use this option, upon initialization, the CHAP name is set to the initiator node name. When the authentication method is set to CHAP (see -a/--authentication option, above), the CHAP username is displayed with the command `iscsiadm list initiator-node`.
- h, --headerdigest none | CRC32
Sets whether CRC32 is enabled to check SCSI packet headers.
- N, --node-name <*initiator node name*>
Modifies the initiator node name. Maximum of 223 characters.
- Note** – During Solaris installation, the initiator node name is set to a globally unique value. Changing this value can adversely affect operation within the iSCSI network.
- P, --radius-shared-secret (exclusive)
Sets the RADIUS shared secret.
- R, --radius-access enable | disable
Sets whether a RADIUS server will be used.
- r, --radius-server <*IP address*>[:<*port*>]
Sets the IP address and port of the radius server to be used.
- T, --tunable-param <<*tunable-prop*>=<*value*>, ...>
Specify one or more tunable parameters for all targets that initiator node connected.

Note – These values should only be modified by an administrator with a good working knowledge of the parameter's impact within the iSCSI network.

Supported tunable-prop options are:

`recv-login-rsp-timeout`
Session Login Response Time

The `recv-login-rsp-timeout` option specifies how long iSCSI initiator will wait for the response of iSCSI session login request from the iSCSI target. Valid value is from 0 to 60*60, default to 60 seconds.

`conn-login-max`
Maximized Connection Retry Time

The `conn-login-max` option lets the iSCSI initiator reestablish the connection to the target in case of IO timeout or connection failure during the given time window. Valid value is from 0 to 60*60, default to 180 seconds.

`polling-login-delay`
Login Retry Time Interval

The `polling-login-delay` option specifies the time interval between each login retry when iSCSI initiator to target IO timeout or connection failure. Valid value is from 0 to 60*60, default to 60 seconds.

`target-param [options] target`

Modifies a target's parameters. If a target is currently connected, the modify operation will succeed, although the modified settings might not take effect for a few seconds. To confirm that these settings are active, use `iscsiadm list target -v`. If a specified target is not associated with any discovery method, a target object is created with the specified parameters. After using this command to modify a target's parameters, the new parameters will persist until they are modified or removed with a `iscsiadm remove target-param` command on that target. The options `-C` and `--CHAP-secret` require a CHAP secret entry in response to a prompt.

Options for modify `target-param` are as follows:

- B, `--bi-directional-authentication enable | disable`
Sets the bidirectional option. If set to enable, the initiator performs bidirectional authentication for the specified target.
- C, `--CHAP-secret`
Sets the target's CHAP secret value. There is no default value. Maximum acceptable length is 16 characters.
- c, `--configured-sessions <num_sessions> | <IP address>[,<IP address>...]`
Sets the number of configured iSCSI sessions that will be created for each iSCSI target. The feature should be used in combination with the Solaris I/O multipathing feature described in [scsi_vhci\(7D\)](#).
- d, `--datadigest none | CRC32`
Sets whether CRC32 is enabled or disabled for the data.
- H, `--CHAP-name CHAP name`
Sets a CHAP username. If you do not use this option, upon initialization, the CHAP name is set to the target name. When the authentication method is set to CHAP (see `-a/--authentication` option, under the `initiator-node` direct object, above), the CHAP username is displayed with the command `iscsiadm list initiator-node`.
- h, `--headerdigest none | CRC32`
Sets whether CRC32 is enabled or disabled for the header.
- p, `--login-param`
Specify one or more login parameter settings.

Note – These values should only be modified by an administrator with a good working knowledge of the parameter's impact within the iSCSI network.

The login parameters are derived from iSCSI proposed standard RFC 3720. Valid values are:

| | |
|--------------------|-------------------|
| dataseqinorder | yes or no |
| defaulttime2retain | 0–3600 |
| defaulttime2wait | 0–3600 |
| firstburstlength | 512 to 2^{24-1} |
| immediatedata | yes or no |
| initialr2t | yes or no |
| maxburstlength | 512 to 2^{24-1} |
| datapduinorder | yes or no |
| maxoutstandingr2t | 1 to 65535 |
| maxrecvdataseglen | 512 to 2^{24-1} |

-T, --tunable-param <<*tunable-prop*>=<*value*>, ...>

Specify one or more tunable parameters for all targets that initiator node connected.

Note – Tunable values should only be modified by an administrator with a good working knowledge of the parameter's impact within the iSCSI network.

Supported *tunable-prop* options are:

recv-login-rsp-timeout

Session Login Response Time

The `recv-login-rsp-timeout` option specifies how long iSCSI initiator will wait for the response of iSCSI session login request from the iSCSI target. Valid value is from 0 to 60*60, default to 60 seconds.

conn-login-max

Maximized Connection Retry Time

The `conn-login-max` option lets the iSCSI initiator reestablish the connection to the target in case of IO timeout or connection failure during the given time window. Valid value is from 0 to 60*60, default to 180 seconds.

polling-login-delay

Login Retry Time Interval

The `polling-login-delay` option specifies the time interval between each login retry when iSCSI initiator to target IO timeout or connection failure. Valid value is from 0 to 60*60, default to 60 seconds.

remove Subcommand The syntax for the remove subcommand is:

```
# iscsiadm remove direct_object
```

The remove subcommand supports the following *direct_objects*:

`discovery-address` *discovery-address*, ...

Removes a target device from the list of discovery addresses. A discovery address (as in the syntax shown below) is an IP address-port combination used in a SendTargets discovery session. Using this discovery approach, a target device can inform an initiator of the target address and target name of each target exposed by that device. If any target exposed by the discovery address is currently mounted or there is active I/O on the device, an error of “logical unit in use” is returned and the operation fails. If the associated devices are not in use, they are removed.

discovery-address must be formatted as:

`<IP address>[:<port>]`

There are no options associated with this direct object.

`isns-server` *isns-server*, ...

Removes an iSNS server from the list of iSNS server addresses. An iSNS server address (specified in the syntax shown below) is an IP address-port combination used in an iSNS discovery session. By using iSNS discovery, an iSNS server can provide an initiator with information about a portal and the name of each target that belongs to the same discovery domain as that of the initiator. If any target discovered by means of iSNS is currently mounted or there is active I/O on the device, an error of “logical unit in use” is returned and the operation fails. If the associated devices are not in use, they are removed.

isns-server must be formatted as:

`IP_address[:port]`

There are no options associated with this direct object.

`static-config` *static_target*, ...

Removes a target from the list of statically discovered targets. If the target being removed is currently mounted or there is active I/O on the device, an error of “logical unit in use” is returned and the operation fails. If a device is not in use, it will be removed.

static_target must be formatted as:

`<target-name>, <target-address>[:port-number][, tpgt]`

There are no options associated with this direct object.

`target-param` *target-name*

Removes target specified by *target-name*. The target name is formatted as:

`<target-name>`

There are no options associated with this direct object. For iSCSI booting when the Solaris I/O multipathing feature (formerly known as Sun StorEdge Traffic Manager [STMS] or MPxIO) is enabled, you cannot remove the target.

Proper Use of Discovery Methods Do not configure a target to be discovered by both static and dynamic discovery methods. The consequence of using redundant discovery methods might be slow performance when communicating with the iSCSI target device.

Options The following generic options are supported:

- V, --version Displays version information. Stops interpretation of subsequent arguments.
- ?, --help Displays help information. Can be used following an `iscsiadm` command with no arguments, following a subcommand, or following a subcommand-direct object combination. Responds with help information appropriate for your entry. For example, if you enter:

```
# iscsiadm modify initiator-node --help
```

...`iscsiadm` responds with a display of the options available for that combination of subcommand and direct object.

Examples EXAMPLE 1 Adding a Discovery Address

The following command uses the `add` subcommand to add a discovery address.

```
# iscsiadm add discovery-address 10.0.0.1:3260 10.0.0.2:3260
```

EXAMPLE 2 Adding a Static Target

The following command uses the `add` subcommand to add a static target.

```
# iscsiadm add static-config \  
iqn.1999-08.com.array:sn.01234567,10.0.0.1:3260
```

EXAMPLE 3 Listing Current Discovery Settings

The following command uses the `list` subcommand to list current discovery settings.

```
# iscsiadm list discovery  
Discovery:  
Static: enabled  
Send Targets: disabled  
iSNS: enabled
```

EXAMPLE 4 Obtaining Verbose Discovery Output

The following commands uses the `-v` option (one with, one without) with the `list` subcommand to obtain verbose output.

```
# iscsiadm list discovery-address  
Discovery Address: 10.0.0.1:3260  
Discovery Address: 10.0.0.2:3260  
  
# iscsiadm list discovery-address -v 10.0.0.1:3260
```

EXAMPLE 4 Obtaining Verbose Discovery Output *(Continued)*

```

Discovery Address: 10.0.0.1:3260
  Target name: eui.210000203787d1f7
    Target address: 10.0.0.1:3260
  Target name: eui.210000203787a693
    Target address: 10.0.0.1:3260

```

EXAMPLE 5 Displaying Information on the Initiator

The following command uses the `list` subcommand to display information on the initiator.

```

# iscsiadm list initiator-node
Initiator node name: iqn.1986-03.com.company.central.interopv20-1
Initiator node alias: interopv20-1
  Login Parameters (Default/Configured):
    Header Digest: NONE/NONE
    Data Digest: NONE/NONE
  Authentication Type: CHAP
    CHAP Name: iqn.1986-03.com.company.central.interopv20-1
  RADIUS Server: NONE
  RADIUS access: disabled
  Tunable Parameters (Default/Configured):
    Session Login Response Time: 60/-
    Maximum Connection Retry Time: 180/-
    Login Retry Time Interval: 60/-
  Configured Sessions: 1

```

EXAMPLE 6 Displaying Static Configuration Information

The following command uses the `list` subcommand to display information about static configurations.

```

# iscsiadm list static-config
  Static target: eui.210000203787a693,10.0.0.1:3260

```

EXAMPLE 7 Displaying Target Information

The following commands show the use of the `list` subcommand with various options to display information about targets.

```

# iscsiadm list target
Target: iqn.2004-05.com.abcStorage:Tgt-1
  Alias: -
  TPGT: 12288
  ISID: 4000002a0000
  Connections: 1# iscsiadm list target -v iqn.2004-05.com.abcStorage:Tgt-1
Target: iqn.2004-05.com.abcStorage:Tgt-1
  Alias: -
  TPGT: 12288

```

EXAMPLE 7 Displaying Target Information (Continued)

```

ISID: 4000002a0000
Connections: 1
  CID: 0
    IP address (Local): 10.4.52.158:32803
    IP address (Peer): 10.4.49.70:3260
    Discovery Method: SendTargets
    Login Parameters (Negotiated):
      Data Sequence In Order: yes
      Data PDU In Order: yes
      Default Time To Retain: 20
      Default Time To Wait: 2
      Error Recovery Level: 0
      First Burst Length: 65536
      Immediate Data: yes
      Initial Ready To Transfer (R2T): yes
      Max Burst Length: 262144
      Max Outstanding R2T: 1
      Max Receive Data Segment Length: 65536
      Max Connections: 1
      Header Digest: NONE
      Data Digest: NONE
# iscsiadm list target -S iqn.2004-05.com.abcStorage:Tgt-1
Target: iqn.2004-05.com.abcStorage:Tgt-1
  Alias: -
  TPGT: 12288
  ISID: 4000002a0000
  Connections: 1
  LUN: 6
    Vendor: ABCStorage
    Product: iSCSI Target
    OS Device Name: /dev/rdisk/c3t1d0s2
  LUN: 5
    Vendor: ABCStorage
    Product: iSCSI Target
    OS Device Name: /dev/rdisk/c3t0d0s2

```

EXAMPLE 8 Displaying Target Parameter Information

The following command uses the `list` subcommand to display target information for a specific target.

```

# iscsiadm list target-param -v iqn.2004-05.com.abcStorage:Tgt-1
Target: iqn.2004-05.com.abcStorage:Tgt-1
  Alias: -
  Bi-directional Authentication: disabled
  Authentication Type: NONE

```

EXAMPLE 8 Displaying Target Parameter Information (Continued)

```

Login Parameters (Default/Configured):
  Data Sequence In Order: yes/-
  Data PDU In Order: yes/-
  Default Time To Retain: 20/-
  Default Time To Wait: 2/-
  Error Recovery Level: 0/-
  First Burst Length: 65536/-
  Immediate Data: yes/-
  Initial Ready To Transfer (R2T): yes/-
  Max Burst Length: 262144/-
  Max Outstanding R2T: 1/-
  Max Receive Data Segment Length: 65536/-
  Max Connections: 1/-
  Header Digest: NONE/-
  Data Digest: NONE/-
Tunable Parameters (Default/Configured):
  Session Login Response Time: 60/-
  Maximum Connection Retry Time: 180/-
  Login Retry Time Interval: 60/-
Configured Sessions: 1

```

EXAMPLE 9 Enabling Static Discovery Method

The following command uses the `modify` subcommand to enable the static discovery method.

```
# iscsiadm modify discovery --static enable
```

EXAMPLE 10 Setting the IP Address for the Radius Server

The following command uses the `modify` subcommand to set the IP address for the radius server, which will be used for CHAP authentication.

```
# iscsiadm modify initiator --radius-server 10.0.0.1
```

EXAMPLE 11 Setting the Node Name for Initiator

The following command uses the `modify` subcommand to set the node name for the initiator node.

```
# iscsiadm modify initiator-node -N iqn.2004-10.com.SUN.host-1
```

EXAMPLE 12 Changing Target Parameters

The following command uses the `modify` subcommand to change the target parameters for a specified target.

```
# iscsiadm modify target-param -d none -h none eui.210000203787a693
```

EXAMPLE 13 Removing a Discovery Address

The following command uses the `remove` subcommand to remove a discovery address.

```
# iscsiadm remove discovery-address 10.0.0.1:3260
```

EXAMPLE 14 Removing Target Parameters

The following command uses the `remove` subcommand to remove a set of target parameters.

```
# iscsiadm remove target-param eui.210000203787a693
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

System Administration Guide: Devices and File Systems

Name isns – Internet Storage Name Service

Synopsis /usr/sbin/isns

Description The Internet Storage Name Service (iSNS) provides consolidated discovery services for Internet SCSI (iSCSI) and Internet Fibre Channel Protocol (iFCP) devices in an IP network. iSNS uses a client/server mechanism: servers store configuration information for clients, and provide that information upon a client's request. IETF RFC 4171 describes the protocols between the server and client.

This man page provides a summary of the Solaris iSNS server implementation. The current implementation does not support iFCP devices.

Solaris iSNS server is implemented as the daemon `isns`, which binds to the well-known port 3205 to service client requests. The daemon is started by the service management facility (`smf(5)`), using the fault management resource identifier (FMRI):

```
svc:/network/isns_server
```

Use `svcadm(1M)` to enable `isns`. Enabling the service means that it starts and runs automatically whenever the operating system is booted. The state of service can be displayed with the `svcs(1)` command.

The service properties listed below can be managed using `svccfg(1M)`. The default value is assigned per RFC 4171 and implementation choice.

`data_store_location`

Configuration data store location. The default location is `/etc/isns/isnsdata.xml`.

`ESI_retry_threshold_count`

Entity Status Inquiry retry threshold counter. The default count is 3.

`Management_SCNs_Enabled`

Boolean that determines whether Management State Change Notification is enabled. The default is yes.

`Authorized_Control_Nodes`

Control node names.

After changing a property value, you must use `svcadm(1M)` `refresh` to enable `isns` to recognize the new value. If you change the `data_store_location` property, you must enter a `svcadm restart` command for the change to take effect.

RFC 4171 defines the default discovery domain, the default domain set, and the “Default DD/DDS” setting with the intent of managing clients that have not been assigned to any user-defined discovery domain. The server adopts the following behaviors with respect to the default discovery domain and domain set:

- An unassigned client is added to the default discovery domain. A newly registered client or a client that was removed from its last discovery domain membership is considered to be an unassigned client.

- When a client gets assigned to a user-defined discovery domain, the server will remove the client from the default discovery domain.
- The default discovery domain set is allowed to be administratively activated or deactivated in order to let the administrator control discovery among clients in the default discovery domain.
- It is not allowed to administratively add a client to the default discovery domain, nor to administratively add a user-defined discovery domain to the default discovery domain set.
- The default state of the Default discovery domain set is inactive.

The `isns` server supports certain `rbac(5)` authorizations that allow you to administer `isns` activity. These authorizations include the following `auth_attr(4)` privileges:

`solaris.isnsmgr.write`

Required to create a discovery domain or domain set, to enable/disable a discovery domain set and to change grouping of iSNS clients in a discovery domain or grouping of discovery domains in a discovery domain set.

`solaris.smf.manage.isns`

Required to manage the `isns` server through the `smf(5)`.

`solaris.smf.value.isns`

Required to change the SMF service properties associated with `isns`.

The iSNS Server Management profile (see `prof_attr(4)`) includes all of the preceding authorizations. See `rbac(5)` for an overview of roles and authorizations.

Options There are no options supported by the `isns` daemon.

Examples EXAMPLE 1 Starting an `isns` Server

The following command starts the `isns` server.

```
# svcadm enable svc:/network/isns_server
```

EXAMPLE 2 Stopping an `isns` Server

The following command stops the `isns` server.

```
# svcadm disable svc:/network/isns_server
```

EXAMPLE 3 Changing an `isns` Property

The following sequence of commands changes the value of the `ESI_retry_threshold_count` property.

```
# svccfg -s svc:/network/isns_server setprop \
config/ESI_retry_threshold_count = 6
# svcadm refresh svc:/network/isns_server
```

Files /usr/sbin/isns
iSNS daemon binary.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------------------------|
| Availability | service/storage/isns |
| Interface Stability | Committed |
| Standard | See standards(5) . |

See Also [svcs\(1\)](#), [isnsadm\(1M\)](#), [svcadm\(1M\)](#), [svccfg\(1M\)](#), [auth_attr\(4\)](#), [prof_attr\(4\)](#), [attributes\(5\)](#), [rbac\(5\)](#), [smf\(5\)](#)

Notes It is strongly recommended that you restart the server (`svcadm restart`) after a service property is changed. This allows the server to apply a uniform setting for existing and new clients.

A control node, as described in RFC 4171, is not required to administer the server. Control node operations can be achieved through the [isnsadm\(1M\)](#) command interface on the local host. For example, `isnsadm` enables you to create a discovery domain and a discovery domain set and to add a member to it, in order to create discovery domain and discovery domain set associations.

Name isnsadm – administer the internet Storage Name Server (iSNS) server

Synopsis *isnsadm options*

isnsadm subcommand [subcommand_options] [operand]

Description The *isnsadm* command is the command-line interface to the Internet Storage Name Service (iSNS) server. *isnsadm* comprises a set of subcommands, described in their own section, each of which accomplishes one of the iSNS server management functions.

For any operations that will change the iSNS configurations the `solaris.isnsmgr.write` authorization is required. Refer to [isns\(1M\)](#). For read operations, the command does not require special authorizations.

isnsadm has a set of general options and a set of subcommand-specific options. The first category is described under **OPTIONS**; the second category is described in the context of each subcommand description.

Options The following options are supported:

`-?`, `--help`

Displays context help. Stops interpretation of any subsequent arguments.

`-V`, `--version`

Displays version information. Stops interpretation of any subsequent arguments.

Operands The following operands are used by one or more *isnsadm* subcommands.

iscsi-node-name

iSCSI target or iSCSI initiator symbolic name. A string with a maximum length of 223 characters.

discovery-domain-name

Discovery domain symbolic name. A string with a maximum length of 256 characters.

discovery-domain-set-name

Discovery domain set symbolic name. A string with a maximum length of 256 characters.

Subcommands The *isnsadm* command supports the subcommands described below.

`add-dd` The `add-dd` subcommand adds a discovery domain to a discovery domain set.

The `add-dd` subcommand has the following syntax:

```
# isnsadm add-dd option discovery-domain-name, ...
```

`add-dd` has the following option:

`-s` *discovery-domain-set-name*

Specifies a discovery domain set.

add-node The **add-node** subcommand adds a node to a specified discovery-domain.

The **add-node** subcommand has the following syntax:

```
# isnsadm add-node option iscsi-node-name,...
```

add-node has the following options:

-d, -dd *discovery-domain-name*
Specifies a discovery domain.

create-dd The **create-dd** subcommand creates a discovery domain with the name you specify.

The **create-dd** subcommand has the following syntax:

```
# isnsadm create-dd discovery-domain-name, ...
```

create-dd has no options.

create-dd-set The **create-dd-set** subcommand creates a discovery domain set with the name you specify.

The **create-dd-set** subcommand has the following syntax:

```
# isnsadm create-dd-set discovery-domain-set-name, ...
```

create-dd-set has no options.

delete-dd The **delete-dd** subcommand deletes a discovery domain of the name you specify.

The **delete-dd** subcommand has the following syntax:

```
# isnsadm delete-dd discovery-domain-name, ...
```

delete-dd has no options.

delete-dd-set The **delete-dd-set** subcommand deletes a discovery domain set of the name you specify.

The **delete-dd-set** subcommand has the following syntax:

```
# isnsadm delete-dd-set discovery-domain-set-name, ...
```

delete-dd-set has no options.

disable-dd-set The **disable-dd-set** subcommand disables a discovery domain set.

The **disable-dd-set** subcommand has the following syntax:

```
# isnsadm disable-dd-set discovery-domain-set-name, ...
```

disable-dd-set has no options.

`enable-dd-set` The `enable-dd-set` subcommand enables a discovery domain set.

The `enable-dd-set` subcommand has the following syntax:

```
# isnsadm enable-dd-set discovery-domain-set-name, ...
```

`enable-dd-set` has no options.

`list-dd` The `list-dd` subcommand displays information about discovery domains. If no operand is specified, it lists all discovery domains that currently exist on the iSNS server.

The `list-dd` subcommand has the following syntax:

```
# isnsadm list-dd [option] [discovery-domain-name, ...]
```

`list-dd` supports the following option:

`-v, --verbose`

Displays the member contents of the discovery domain(s).

`list-dd-set` The `list-dd-set` subcommand lists the discovery domain sets, both enabled and disabled, that exist on the iSNS server. Note that there is no `dd-set` registration. If no operand is specified, it lists all of the discovery domain sets.

The `list-dd-set` subcommand has the following syntax:

```
# isnsadm list-dd-set [option] [discovery-domain-set-name, ...]
```

`list-dd-set` supports the following option:

`-v, --verbose`

Shows all discovery domains within the discovery domain set.

`list-node` The `list-node` subcommand displays information about nodes that are currently registered with the iSNS server or that are not registered and belong to non-default discovery-domain(s). For the latter case, the node has its type field shown as unknown. If no operand is specified, `list-node` lists all nodes known by the iSNS server.

The `list-node` subcommand has the following syntax:

```
# isnsadm list-node [options] [iscsi-node-name, ...]
```

`list-node` supports the following options:

`-t, --target`

Filters the list to display only iSCSI target nodes.

`-i, --initiator`

Filters the list to display only iSCSI initiator nodes.

`-v, --verbose`

Displays details about a node. Without this option, only the name, alias, and type information are displayed.

modify-dd The **modify-dd** subcommand modifies an attribute of a specified discovery domain.

The **modify-dd** subcommand has the following syntax:

```
# isnsadm modify-dd option discovery-domain-name
```

modify-dd has the following option:

-n *discovery-domain-name*
Specifies the new name of a discovery domain to be applied to an existing discovery-domain.

modify-dd-set The **modify-dd-set** subcommand modifies a discovery domain set.

The **modify-dd-set** subcommand has the following syntax:

```
# isnsadm modify-dd-set option discovery-domain-set-name
```

modify-dd-set has the following option:

-n *discovery-domain-set-name*
Specifies the new name of a discovery domain set to be applied to an existing discovery-domain-set.

remove-dd The **remove-dd** subcommand removes the association with a specified discovery domain set.

The **remove-dd** subcommand has the following syntax:

```
# isnsadm remove-dd option discovery-domain-name, ...
```

remove-dd has the following option:

-s *discovery-domain-set-name*
Specifies the discovery domain set from which the discovery domain will be removed.

remove-node The **remove-node** subcommand removes a node.

The **remove-node** subcommand has the following syntax:

```
# isnsadm remove-node option iscsi-node-name, ...
```

remove-node has the following option:

-d *discovery-domain-name*
Specifies the discovery domain from which a node will be removed.

show-config The **show-config** subcommand displays the iSNS server administrative settings. Note that the setting can be modified by means of the service management facility (see [smf\(5\)](#)). Refer to [isns\(1M\)](#).

The **show-config** subcommand has the following syntax:

```
# isnsadm show-config
```

show-config has no options.

Examples EXAMPLE 1 Displaying Clients

The following use of the `list -node` subcommand displays clients.

```
# isnsadm list-node -v
iSCSI Name: iqn.1986-03.com.sun:01:000e0c9f10da.45173FEA.engr
  Alias: STK5320_NAS
  Type: Target
  Network Entity: SE5310
  Portal: 172.20.57.95:3260
    Portal Group: 1
  Portal: 172.20.56.95:3260
    Portal Group: 1
  DD Name: Default
iSCSI Name: iqn.1986-03.com.sun:01:000e0c9f10da.454F00A2.acct
  Alias:
  Type: Target
  Network Entity: SE5310
  Portal: 172.20.57.95:3260
    Portal Group: 1
  Portal: 172.20.56.95:3260
    Portal Group: 1
  DD Name: Default
iSCSI Name: iqn.1986-03.com.sun:01:e00000000000.46fd8e2b
  Alias: host-x2100
  Type: Initiator
  Network Entity: iqn.1986-03.com.sun:01:e00000000000.46fd8e2b
  Portal: 172.20.236.123:58530
    Portal Group: 1
  DD Name: Default
```

EXAMPLE 2 Displaying a Discovery Domain

The following use of the `list -dd` subcommand displays discovery domains.

```
# isnsadm list-dd -v
DD name: Default
  DD set(s): Default
    iSCSI Name: iqn.1986-03.com.sun:01:000e0c9f10da.45173FEA.engr
    iSCSI Name: iqn.1986-03.com.sun:01:000e0c9f10da.454F00A2.acct
    iSCSI name: iqn.1986-03.com.sun:01:e00000000000.46fd8e2b
  DD name: acct-dd
  DD name: engineering-dd
```

EXAMPLE 3 Adding a Node

The following use of the `add -node` subcommand adds a node to a discovery domain, creating a discovery domain membership.

EXAMPLE 3 Adding a Node *(Continued)*

```
# isnsadm add-node -d engineering-dd \  
iqn.1986-03.com.sun:01:000e0c9f10da.454F00A2.engr
```

EXAMPLE 4 Removing a Node

The following use of the `remove-node` subcommand removes a node from a discovery domain, thereby removing a discovery domain membership.

```
# isnsadm remove-node -d acct-dd \  
iqn.1986-03.com.sun:01:000e0c9f10da.454F00A2.acct
```

EXAMPLE 5 Creating a Discovery Domain Set

The following use of the `create-dd-set` subcommand creates a discovery domain set.

```
# isnsadm create-dd-set operation-dd-set
```

EXAMPLE 6 Displaying a Discovery Domain Set

The following use of the `list-dd-set` subcommand displays discovery domain sets.

```
# isnsadm list-dd-set -v  
DD Set name: Default  
    State: Disabled  
    DD Name: Default  
DD Set name: operation-dd-set  
    State: Disabled
```

EXAMPLE 7 Adding a Discovery Domain

The following use of the `add-dd` subcommand adds a discovery domain to a discovery domain set.

```
# isnsadm add-dd -s operation-dd-set engineering-dd
```

EXAMPLE 8 Displaying a Discovery Domain Set

The following use of the `list-dd-set` displays the attributes of a discovery domain set.

```
# isnsadm list-dd-set  
DD Set name: Default  
    State: Disabled  
    DD Name: Default  
DD Set name: operation-dd-set  
    State: Disabled  
    DD Name: engineering-dd
```

EXAMPLE 9 Enabling a Discovery Domain Set

The following use of the `enable-dd-set` subcommand enables a discovery domain set.

```
# isnsadm enable-dd-set Default
```

EXAMPLE 10 Disabling a Discovery Domain Set

The following use of the `disable-dd-set` subcommand disables a discovery domain set.

```
# isnsadm disable-dd-set Default
```

EXAMPLE 11 Displaying Administrative Settings

The following use of the `show-config` subcommand displays current administrative settings.

```
# isnsadm show-config
  Data Store Location: /etc/isns/isnsdata.xml
  Entity Status Inquiry Non-Response Threshold: 3
  Management SCN Enabled: yes
  Authorized Control Node Names: -
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------|
| Availability | service/storage/isns |
| Interface Stability | Volatile |

See Also [iscsiadm\(1M\)](#), [isns\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Notes When a subcommand is invoked with multiple operands and there are failures on one or more, but not all, operands, `isnsadm` displays a generic message indicating partial failure, with list of failed operands. An error on a specific operand can be found by issuing the same subcommand on the failing operand.

Name itadm – administer iSCSI targets

Synopsis `itadm create-target [-a,--auth-method radius | chap | none | default] [-s,--chap-secret] [-S,--chap-secret-file path] [-u,--chap-user chap-user-name] [-n,--node-name target_node_name] [-l,--alias alias] [-t,--tpg tpg-name[,tpg-name]]`

`itadm modify-target [-a,--auth-method radius | chap | none | default] [-s,--chap-secret] [-S,--chap-secret-file path] [-u,--chap-user chap-user-name] [-n,--node-name new_target_node_name] [-l,--alias alias] [-t,--tpg tpg-name[,tpg-name]] target_node_name`

`itadm delete-target [-f,--force] target_node_name`

`itadm list-target [-v,--verbose] [target_node_name]`

`itadm create-tpg tpg_name IP-address[:port] [IP-address[:port]]. . .`

`itadm list-tpg [-v,--verbose] [tpg_name]`

`itadm delete-tpg [-f,--force] tpg_name`

`itadm create-initiator [-s,--chap-secret] [-S,--chap-secret-file path] [-u,--chap-user chap-user-name] initiator_node_name`

`itadm modify-initiator [-s,--chap-secret] [-S,--chap-secret-file path] [-u,--chap-user chap-user-name] initiator_node_name`

`itadm list-initiator [-v,--verbose] initiator_node_name`

`itadm delete-initiator initiator_node_name`

`itadm modify-defaults [-a,--auth-method radius | chap | none] [-r,--radius-server IP-address[:port]] [-d,--radius-secret] [-D,--radius-secret-file path][-i,--isns enable | disable] [-I,--isns-server IP-address[:port] [,IP-address[:port]]]`

`itadm list-defaults`

Description The `itadm` command manages Internet SCSI (iSCSI) target nodes within the SCSI Target Mode Framework described in [stmfadm\(1M\)](#) and [libstmf\(3LIB\)](#). This allows the iSCSI initiators to access STMF logical units using the iSCSI protocol. In addition to iSCSI target nodes, `itadm` manages two other classes of managed objects: iSCSI Target Portal Groups, and iSCSI Initiator Node Contexts.

`itadm` is implemented as a set of subcommands with options and operands for each subcommand. These subcommands are described in their own section, below. In addition to its subcommands, `itadm` has a help command, which displays the utility's usage information. The help command is invoked with the `-?` option.

iSCSI Target Portal Groups An iSCSI Target Network Portal is an IP address and TCP port that can be used by an initiator node to connect to an iSCSI target. A collection of these portals is called a Target Portal Group (TPG). You can use a TPG to limit access to an iSCSI target. Use the `itadm modify -t`

command to bind a specific iSCSI target to the TPG. An iSCSI listener is created on each IP address that belongs to the TPG, and listens for connections to the iSCSI target.

A TPG is identified by a unique name provided when the TPG is created. A numerical “Target Portal Group Tag” from the range 2-65535 is automatically generated when the TPG is created. The Target Portal Group Tag 1 is reserved for the “default” target portal group that is used when no explicit Target Portal Groups are set on the target. The portal for the default TPG matches requests from all network interfaces on port 3260.

iSCSI Initiator Node Contexts Certain operations such as authentication by means of Challenge Handshake Authentication Protocol (CHAP) require parameters associated with a remote iSCSI Initiator Node. These parameters are associated with an iSCSI Initiator Node Context. An iSCSI Initiator Node Context is identified by its Initiator Node Name, formatted in either IQN or EUI format (see RFC 3720). For example:

```
iqn.1986-03.com.sun:01:e00000000000.47d55444
eui.02004567A425678D
```

Specifying IP Addresses A number of `itadm` subcommands require that you specify one or more IP addresses with optional port numbers. For IPv4, use standard dotted decimal notation. For IPv6, enclose addresses in square brackets. The following are example specifications.

```
IPv4:  10.2.4.1
        10.2.4.1:3260
IPv6:  [1080:0:0:0:8:800:200C:417A]
        [1080:0:0:0:8:800:200C:417A]:3260
```

Sub-commands The following are the `itadm` subcommands with their options.

```
itadm create-target [-a,--auth-method radius | chap | none | default]
                    [-s,--chap-secret]
                    [-S,--chap-secret-file path] [-u,--chap-user chap-user-name]
                    [-n,--node-name target_node_name] [-l,--alias alias]
                    [-t,--tpg tpg-name[,tpg-name,...]]
```

Create a iSCSI target with the specified options. Options are as follows.

-a,--auth-method radius | chap | none | default

Specifies the authentication method to use for the target. Valid values are `radius`, `chap`, and `none`. `chap` indicates that initiators connecting to this target must be authenticated using the Challenge Handshake Authentication Protocol (CHAP). `radius` indicates initiators should also be authenticated by means of CHAP but the required authentication parameters should be obtained from a central RADIUS server (see the `radius-server` and `radius-secret` options). `none` means that no authentication is required to connect to the target. `default` means the target will use the global setting of this property. (See the `modify-defaults` subcommand.)

-s,--chap-secret

The CHAP secret to send during mutual CHAP authentication. There is no default for this property. Maximum length is 255 characters; minimum required length is 12 characters.

- S, --chap-secret-file *path*
Path to a temporary file containing the CHAP secret as described in the -s option.
- u, --chap-user *chap-user-name*
Specifies the CHAP username for a target for use in mutual CHAP authentication. This value is allowed only for targets, cannot be set globally, and is used only when the initiator node is configured to use mutual CHAP authentication. If no value is specified then the target node name is used as the username. See [iscsiadm\(1M\)](#).
- n, --node-name *target_node_name*
An iSCSI Target Node is identified by its Target Node Name, formatted in either IQN or EUI format (see RFC 3720). This option establishes that name.
- l, --alias *alias*
An alternate identifier associated with a target node. The identifier does not need to be unique.
- t, --tpg *tpg-name[,tpg-name,...]*
A list of Target Portal Group (TPG) identifiers that specifies the TPGs that an initiator can use to access a specific target or the keyword default. If default is specified, the target will use the default portal, INADDR_ANY:3260.

```

itadm modify-target [-a,--auth-method radius | chap | none | default]
                    [-s,--chap-secret] [-S,--chap-secret-file path]
                    [-u,--chap-user chap-user-name] [-n,--node-name new_tgt_node_name]
                    [-l,--alias alias] [-t,--tpg tpg-name[,tpg-name]] target_node_name

```

Modify an iSCSI target according to the specified options. Options are as follows.

- a, --auth-method *radius | chap | none | default*
As described under the create-target subcommand, above.
- s, --chap-secret
As described under the create-target subcommand, above.
- S, --chap-secret-file *path*
As described under the create-target subcommand, above.
- u, --chap-user *chap-user-name*
As described under the create-target subcommand, above. To remove an explicitly set CHAP username use -u none.
- n, --node-name *target_node_name*
Renames the target. See also the description of -n under the create-target subcommand, above.
- l, --alias *alias*
As described under the create-target subcommand, above. To remove an explicitly set alias use -l none.

`-t, --tpg tpg-name[,tpg-name,...]`

As described under the `create-target` subcommand, above.

`itadm list-target` `itadm list-target [-v, --verbose] [target_node_name]`

List information about the configured targets. If `target_node_name` is specified, list only the information for that target. Option is as follows.

`-v, --verbose`

Verbose mode.

`itadm delete-target` `itadm delete-target [-f, --force] target_node_name`

Delete the target specified by `target_node_name`. The target must be offline before it can be deleted. Option is as follows.

`-f, --force`

If the target persists in an online state, this option attempts to offline the target before deleting it.

`itadm create-tpg` `itadm create-tpg tpg_name IP-address[:port]...`

Create an iSCSI target portal group made up of the specified portals and assign it the identifier `tpg_name`. Each portal is an IP address and port pair. IPv4 portals are specified in dotted address notation, for example, `172.31.255.255`. IPv6 portal addresses must be enclosed in square brackets.

This subcommand has no options.

`itadm list-tpg` `itadm list-tpg [-v, --verbose] [tpg_name]`

List information about the configured target portal group. If `tpg_name` is specified then list only the information about the target portal group associated with that `tpg_name`. Option is as follows.

`-v, --verbose`

Verbose mode.

`itadm delete-tpg` `itadm delete-tpg [-f, --force] tpg_name`

Delete the target portal group associated with `tpg_name`. Option is as follows.

`-f, --force`

If the TPG is associated with any targets, the request to delete will be denied unless this option is specified.

`itadm create-initiator` `itadm create-initiator [-s, --chap-secret] [-S, --chap-secret-file path] [-u, --chap-user chap-user-name] initiator_node_name`

Configure parameters associated with the remote initiator named `initiator_node_name`. Options are as follows.

`-s,--chap-secret`
As described under the `create-target` subcommand, above.

`-S,--chap-secret-file path`
As described under the `create-target` subcommand, above.

`-u,--chap-user chap-user-name`
Specifies the CHAP username for an initiator, for use in CHAP authentication. If no value is specified then the initiator node name is used as the username.

```
itadm itadm modify-initiator [-s,--chap-secret] [-S,--chap-secret-file path]
modify-initiator [-u,--chap-user chap-user-name] initiator_node_name
```

Modify parameters associated with the remote initiator named *initiator_node_name*. Options are as follows.

`-s,--chap-secret`
As described under the `create-target` subcommand, above.

`-S,--chap-secret-file path`
As described under the `create-target` subcommand, above.

`-u,--chap-user chap-user-name`
Specifies the CHAP username for an initiator, for use in CHAP authentication. If no value is specified then the initiator node name is used as the username.

```
itadm itadm delete-initiator initiator_node_name
delete-initiator
```

Delete parameters associated with the remote initiator named *initiator_node_name*. This subcommand has no options.

```
itadm itadm list-initiator [-v,--verbose] initiator_node_name
list-initiator
```

List parameters associated with the initiator named *initiator_node_name*. Option is as follows.

`-v,--verbose`
Verbose mode.

```
itadm itadm modify-defaults [-a,--auth-method radius | chap | none]
modify-defaults [-r,--radius-server IP-address[:port]] [-d,--radius-secret]
[-D,--radius-secret-file path][-i,--isns enable | disable]
[-I,--isns-server IP-address[:port]][,IP-address[:port]]
```

Modify default parameters. Options are as follows.

`-a,--auth-method radius | chap | none`
Specifies the default authentication method to use for all targets. Valid values are `radius`, `chap`, and `none`. `chap` indicates that initiators connecting to this target must be authenticated using Challenge Handshake Authentication Protocol (CHAP). `radius` indicates initiators should also be authenticated by means of CHAP, but the required authentication parameters should be obtained from a central RADIUS server. (See

--radius-server and --radius-secret options.) none means that no authentication is required to connect to the target. Individual targets can override this global setting using the -a option of the create-target and modify-target subcommands.

-d,--radius-secret

RADIUS Shared Secret for centralized CHAP authentication.

-D,--radius-secret-file *path*

Path to a temporary file containing the CHAP secret as described in the -d option.

-i,--sns enable | disable

Specifies whether targets should be registered with the set of defined iSCSI Name Service (iSNS) servers.

-I,--isns-server *IP-address[:port][,IP-address[:port],...]*

Defines a list of iSNS servers with which iSCSI target nodes will be registered when the isns option associated with the respective target is set. Up to eight iSNS servers can be specified. To remove all iSNS servers, use -I none.

-r,--radius-server *IP-address[:port]*

Specify the IP address of the RADIUS server used for centralized CHAP authentication.

```
itadm list-defaults
itadm list-defaults
```

List information about the default properties. This subcommand has no options.

Examples EXAMPLE 1 Creating a Target

The following command creates a target.

```
# itadm create-target
Target iqn.1986-03.com.sun:02:72e1b181-7bce-c0e6-851e-ec0d8cf14b7a
successfully created
```

EXAMPLE 2 Creating a Target with a Specific Name

The following command creates a target with a specific IQN.

```
# itadm create-target -n eui.20387ab8943ef7548
or:
# itadm create-target \
-n iqn.1986-03.com.sun:02:a9a366f8-cc2b-f291-840948c7f29e
```

EXAMPLE 3 Changing a Name

The following command changes an IQN for an existing target.

```
# itadm modify-target -n eui.20387ab8943ef7548 \
iqn.1986-03.com.sun:02:a9a366f8-909b-cc2b-f291-840948c7f29e
```

EXAMPLE 4 Setting up CHAP Authentication

The following command sets up CHAP authentication for a target using the default CHAP username.

```
# itadm modify-initiator -s iqn.1986-03.com.sun:01:e00000000000.47d55444
Enter CHAP secret: *****
Re-enter secret: *****

# itadm modify-target -a chap eui.20387ab8943ef7548
```

EXAMPLE 5 Creating Target Portal Groups

The following command creates two target portal groups, A and B, using port 8000 for the addresses in TPG 2.

```
# itadm create-tpg A 192.168.0.1 192.168.0.2
# itadm create-tpg B 192.168.0.2:8000 192.168.0.2:8000
```

EXAMPLE 6 Configuring a Target to Use TPGs

The following command configures a target to use TPGs A and B.

```
# itadm modify-target -t A,B eui.20387ab8943ef7548
```

EXAMPLE 7 Setting up RADIUS Authentication for Specific Target

The following command sets up RADIUS authentication for a specific target.

```
# itadm modify-defaults -r 192.168.10.1 -d
Enter RADIUS secret: *****
Re-enter secret: *****

# itadm modify-target -a radius eui.20387ab8943ef7548
```

EXAMPLE 8 Setting up RADIUS Authentication for All Targets

The following command sets up RADIUS authentication for all targets.

```
# itadm modify-defaults -d -r 192.168.10.1 -a radius
Enter RADIUS secret: *****
Re-enter secret: *****
```

The preceding command assumes all targets were created with `-a default`.

EXAMPLE 9 Listing Default Properties

The following command lists default properties.

```
# itadm list-defaults
iSCSI Target Default Properties:
```

```
alias:          none
```

EXAMPLE 9 Listing Default Properties (Continued)

```

auth:          none
radiusserver:  none
radiussecret:  unset
isns:          disabled
isnsserver:    2.3.4.5,4.5.6.7

```

EXAMPLE 10 Listing Targets

The following command lists targets.

```

# itadm list-target
TARGET NAME                                STATE    SESSIONS
iqn.1986-03.com.sun:02:72e1b181-7bce-c0e6-851e-ec0d8cf14b7a  online  0
iqn.1986-03.com.sun:02:2cb0c526-c05a-e279-e396-a367006f4227  online  0
iqn.1986-03.com.sun:02:d14125bb-1c9d-c28d-97b0-f89259b642f3  online  0
iqn.1986-03.com.sun:02:03ff9fc5-794a-e9b4-a081-bb82917c292a  online  0

```

EXAMPLE 11 Listing Targets (Verbose)

The following command lists targets with the verbose option.

```

# itadm list-target -v
TARGET NAME                                STATE    SESSIONS
iqn.1986-03.com.sun:02:d23e68d8-2d79-c988-98e7-a6361689d33c  online  0
    alias:                                  -
    auth:                                    none (defaults)
    targetchapuser:                          -
    targetchapsecret:                        unset
    tpg-tags:                                default
iqn.1986-03.com.sun:02:94ec46d4-c8e1-6993-ef03-ffc1dcd66606  online  1
    alias:                                  -
    auth:                                    chap
    targetchapuser:                          -
    targetchapsecret:                        unset
    tpg-tags:                                nge1_ipv4 = 3

```

EXAMPLE 12 Listing a Specific Target

The following command lists targets with the verbose option.

```

# itadm list-target -v \
iqn.1986-03.com.sun:02:2cb0c526-c05a-e279-e396-a367006f4227
TARGET NAME                                STATE    SESSIONS
iqn.1986-03.com.sun:02:2cb0c526-c05a-e279-e396-a367006f4227  online  1
    alias:                                  -
    auth:                                    chap
    targetchapuser:                          -
    targetchapsecret:                        unset
    tpg-tags:                                nge1_ipv4 = 3

```

Name `itu` – convert packages to Driver Update format and patch Solaris install media for Install Time Update

Synopsis `itu makedu -r solaris_release [-v] [-f] [-d output_dir] [-o iso_file]`
`[-l iso_label] package [package...]`

`itu updatemedia -R media_root [-v] [-f] [-o iso_file]`
`[-l iso_label] pkg_or_patch [pkg_or_patch...]`

`itu makeiso -o iso_file [-v] [-l iso_label] media_root`

Description The `itu` utility converts driver packages to Driver Update (DU) format and patches a Solaris install media with driver packages and patches for Install Time Update (ITU). `itu` has three subcommands: `makedu`, `updatemedia` and `makeiso`.

Options The following options are supported:

`-d output_dir`

Directory where the Driver Update directory is to be created.

`-f`

If `output_dir/DU` or `iso_file` already exists, remove it without asking first.

`-l iso_label`

Label/volume name of the ISO image (if `-o` option is specified).

`-o iso_file`

Path of the ISO image file to be created. For subcommands `updatemedia` and `makeiso`, it will be a bootable ISO image. This option must be specified for subcommand `makeiso`.

`-R media_root`

Top-level directory of on-disk image of Solaris installation media. This option must be specified for subcommand `updatemedia`.

`-r solaris_release`

Solaris release number for which the Driver Update is intended. It takes the form of the output of `uname -r`, for example, `5.10`. This option must be specified for subcommand `makedu`.

`-v`

Verbose. Multiple `-v` options increase verbosity.

Sub-commands The `itu` subcommands are described as follows.

makedu The `makedu` subcommand takes one or more driver packages as input and converts them to DU format. At the beginning of an interactive Solaris installation session, these driver updates can be applied to the running kernel, which will then also automatically apply them to the newly installed Solaris at the end of the installation process.

The `-r` option is required to specify the Solaris release number for which the driver updates apply. The `solaris_release` option argument takes the form `uname -r` output, for example, `5.10` or `5.11`.

If the `-d` option is specified, the resulting DU directory tree is placed in the directory *output_dir*.

If the `-o` option is specified, a (non-bootable) ISO image of the DU directory tree is written in the file *iso_file*. This ISO image can be burned onto a CD/DVD using `cdrw(1)` or `cdrecord(1)` (not a SunOS man page). See the “Examples” section below for an example of creating a DU on a floppy.

At least one of `-d` and `-o` option must be specified. If both are specified, then both an ISO image and a directory tree are generated.

updatemedia The `updatemedia` subcommand takes a list of driver packages and patches as input and applies them to the miniroot of a Solaris install media. It also places them in a subdirectory called ITUs under the Solaris install media's top-level directory:

media_root/ITUs

When booting a system from the updated media, the patches and packages will be part of the booted Solaris image. They will also be applied to the target system being installed at the end of the installation process.

The `-R` option must be entered on the command line to specify the Solaris install media. Note that the install media must be on a location that is writable by `it tu`.

If the `-o` option is specified, a bootable ISO image of the patched install media is also created in the file *iso_file*. The ISO image can then be burned onto a CD or DVD.

makeiso The `makeiso` subcommand runs `mkisofs(8)` to create a bootable Solaris ISO image of the Solaris install media *media_root* and writes it to the file *iso_file*. The ISO image file can then be burned onto a CD or DVD with utilities such as `cdrw(1)` or `cdrecord(1)`. (Note that `mkisofs(8)` and `cdrecord(1)` are not SunOS man pages.)

Caution – The Solaris install media *media-root* must contain the file `boot/grub/stage2_eltorito`, which will be written to the media boot sectors. This file will be modified with some boot information, thus it has to be writable. If necessary, first save a copy, prior to running this subcommand.

Operands The following operands are supported:

package [*package...*]

One or more driver packages.

pkg_or_patch [*pkg_or_patch...*]

One or more patches or packages.

media_root

The top-level directory of a Solaris install media.

Examples EXAMPLE 1 Creating a DU CD/DVD

The following commands create a Driver Update CD/DVD containing the packages SAMPLEpkg1 and SAMPLEpkg2.

```
# itu makedu -r 5.10 -o my.iso SAMPLEpkg1 SAMPLEpkg2
# cdrw -i my.iso
```

EXAMPLE 2 Creating a DU Floppy

The following commands create a Driver Update floppy containing the driver package MYdriver.

```
# rmformat -F quick /dev/rdiskette
# mkfs -F pcfs /dev/rdiskette
# mount -F pcfs /dev/diskette /mnt
# /usr/bin/itu makedu -r 5.10 -d /mnt /export/MYdriver
# umount /mnt
# dd if=/dev/rdiskette of=floppy.dd
```

The `itu` command above creates the DU directly onto the floppy mounted on `/mnt`. The `dd` invocation stores an image of the floppy in the file `floppy.dd`. This is useful for distributing a DU floppy in file form. From the file, the floppy can then be recreated as follows:

```
# dd if=floppy.dd of=/dev/rdiskette
```

EXAMPLE 3 Patching the Solaris Install Media

The following command patches the Solaris install media in `/export/s10u1` with patch `/opt/patches/123456-07` and driver package `/opt/pkg/MYdriver`. The command also creates a bootable ISO image with ISO label “MyS10U1” in the file `/tmp/dvd.iso`.

```
# /usr/bin/itu updatemedia -R /export/s10u1 -o /tmp/dvd.iso -l MyS10U1 \
    /opt/patches/123456-07 /opt/pkg/MYdriver
```

EXAMPLE 4 Creating a Bootable ISO Image

The following commands create the bootable ISO image `mydvd.iso` of the Solaris install image `/export/solaris-10u1` with ISO label “Special-S10”.

```
# /usr/bin/itu makeiso -o mydvd.iso -l "Special-S10" \
    /export/solaris-10u1
# cdrw -i mydvd.iso
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | Committed |

See Also [cdrw\(1\)](#), [pkgadd\(1M\)](#), [attributes\(5\)](#)

[mkisofs\(8\)](#), (`/usr/share/man/man8/mkisofs.8`), in the SUNWfsman package (not a SunOS man page)

Name k5srvutil – host key table (keytab) manipulation utility

Synopsis /usr/sbin/k5srvutil *operation* [-ik] [-f *filename*]

Description The `k5srvutil` command allows a system manager to list or change keys currently in his keytab or to add new keys to the keytab.

The operand *operation* must be one of the following:

- `list` Lists the keys in a keytab, showing version number and principal name.
- `change` Changes all the keys in the keytab to new randomly-generated keys, updating the keys in the Kerberos server's database to match those by using the `kadmin` protocol. If a key's version number does not match the version number stored in the Kerberos server's database, the operation fails. The old keys are retained so that existing tickets continue to work. If the `-i` flag is specified, `k5srvutil` prompts for yes or no before changing each key. If the `-k` option is used, the old and new keys are displayed.
- `delold` Deletes keys that are not the most recent version from the keytab. This operation should be used at some point after a `change` operation to remove old keys. If the `-i` flag is specified, `k5srvutil` asks the user whether the old keys associated with each principal should be removed.
- `delete` Deletes particular keys in the keytab, interactively prompting for each key.

In all cases, the default keytab file is `/etc/krb5.keytab` file unless this is overridden by the `-f` option.

`k5srvutil` uses the `kadmin(1M)` program to edit the keytab in place. However, old keys are retained, so they are available in case of failure.

Options The following options are supported:

- `-f filename` Specify a keytab file other than the default file, `/etc/krb5.keytab`.
- `-i` Prompts user before changing keys when using the `change` or `delold` operands.
- `-k` Displays old and new keys when using the `change` operand.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

Name kadb – a kernel debugger

Synopsis

SPARC ok boot *device_specifier* kadb [-d] [*boot-flags*]

x86 select (b)oot or (i)nterpreter: b kadb [-d] [*boot-flags*]

Description kadb, an interactive kernel debugger, has been replaced by [kmdb\(1\)](#). For backwards compatibility, the methods used to load kadb will be interpreted as requests to load [kmdb\(1\)](#). Unlike with the compatibility link from [adb\(1\)](#) to [mdb\(1\)](#), [kmdb\(1\)](#) will always load in its native user interface mode, regardless of the name used to load it.

[kmdb\(1\)](#) is based on [mdb\(1\)](#), and thus shares mdb's user interface style and feature set. The [mdb\(1\)](#) man page describes the features and operation of mdb. The [kmdb\(1\)](#) man page describes the differences between mdb and kmdb. This man page describes the major changes and incompatibilities between kadb and kmdb.

Consult the *Solaris Modular Debugger Guide* for a detailed description of both mdb and kmdb.

Major changes This section briefly lists the major differences between kadb and kmdb. It is not intended to be exhaustive.

Debugger Loading and Unloading [kmdb\(1\)](#) may be loaded at boot, as with kadb. It may also be loaded after boot, thus allowing for kernel debugging and execution control without requiring a system reboot. If [kmdb\(1\)](#) is loaded after boot, it may be unloaded.

mdb Feature Set The features introduced by [mdb\(1\)](#), including access to kernel type data, debugger commands (dcmds), debugger modules (dmods), and enhanced execution control facilities, are available under [kmdb\(1\)](#). Support for changing the representative CPU (:x) is available for both SPARC and x86. Furthermore, full execution-control facilities are available after the representative CPU has been changed.

Significant Incompatibilities This section lists the significant features that have changed incompatibly between kadb and [kmdb\(1\)](#). It is not intended to be exhaustive. All [kmdb\(1\)](#) commands referenced here are fully described in the [kmdb\(1\)](#) man page. A description as well as examples can be found in the *Solaris Modular Debugger Guide*.

Deferred Breakpoints The kadb-style “module#symbol:b” syntax is not supported under [kmdb\(1\)](#). Instead, use “::bp module‘symbol”.

Watchpoints The ::wp dcmd is the preferred way to set watchpoint with kmdb. Various options are available to control the type of watchpoint set, including -p for physical watchpoints

(SPARC only), and `-i` for I/O port watchpoints (x86 only). `$l` is not supported, therefore, the watchpoint size must be specified for each watchpoint created.

Access to I/O Ports (x86 only)

The commands used to access I/O ports under `kadb` have been replaced with the `::in` and `::out` dcmts. These two dcmts allow both read and write of all I/O port sizes supported by `kadb`.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------|--------------------------|
| Availability | system/library/processor |

Solaris Modular Debugger Guide

Name kadmin, kadmin.local – Kerberos database administration program

Synopsis /usr/sbin/kadmin [-r *realm*] [-p *principal*] [-q *query*]
 [-s *admin_server* [:*port*]] [[-c *credential_cache*]
 | [-k [-t *keytab*]] | [-w *password*]] [-x *db_args*]. . .
 /usr/sbin/kadmin.local [-r *realm*] [-p *principal*]
 [-q *query*] [-d *dbname*] [-e "*enc:salt...*"] [-m] [-D]

Description kadmin and kadmin.local are interactive command-line interfaces to the Kerberos V5 administration system. They provide for the maintenance of Kerberos principals, policies, and service key tables (keytabs). kadmin and kadmin.local provide identical functionality; the difference is that kadmin.local can run only on the master KDC and does not use Kerberos authentication.

Except as explicitly noted otherwise, this man page uses kadmin to refer to both versions.

By default, both versions of kadmin attempt to determine your user name and perform operations on behalf of your “*username/admin*” instance. Operations performed are subject to privileges granted or denied to this user instance by the Kerberos ACL file (see [kadm5.acl\(4\)](#)). You may perform administration as another user instance by using the -p option.

The remote version, kadmin, uses Kerberos authentication and an encrypted RPC to operate securely from anywhere on the network. It normally prompts for a password and authenticates the user to the Kerberos administration server, kadmind, whose service principal is kadmin/*fqdn*. Some options specific to the remote version permit the password prompt to be bypassed. The -c option searches the named credentials cache for a valid ticket for the kadmin/*fqdn* service and uses it to authenticate the user to the Kerberos admin server without a password. The -k option searches a keytab for a credential to authenticate to the kadmin/*fqdn* service, and again no password is collected. If kadmin has collected a password, it requests a kadmin/*fqdn* Kerberos service ticket from the KDC, and uses that service ticket to interact with kadmind.

The local version, kadmin.local, must be run with an effective UID of root, and normally uses a key from the /var/krb5/.k5.*realm* stash file (see [kdb5_util\(1M\)](#)) to decrypt information from the database rather than prompting for a password. The -m option will bypass the .k5.*realm* stash file and prompt for the master password.

Options The following options are supported:

-c *credentials_cache*

Search *credentials_cache* for a service ticket for the kadmin/*fqdn* service; it can be acquired with the [kinit\(1\)](#) program. If this option is not specified, kadmin requests a new service ticket from the KDC, and stores it in its own temporary credentials cache.

-d *dbname*

Specify a non-standard database name. [Local only]

-D

Turn on debug mode. [Local only]

-
- e "*enc:salt ...*"
Specify a different encryption type and/or key salt. [Local only]
 - k [-t *keytab*]
Use the default keytab (-k) or a specific keytab (-t *keytab*) to decrypt the KDC response instead of prompting for a password. In this case, the default principal will be `host/hostname`. This is primarily used for keytab maintenance.
 - m
Accept the database master password from the keyboard rather than using the `/var/krb5/.k5.realm` stash file. [Local only]
 - p *principal*
Authenticate *principal* to the `kadmin/fqdn` service. Otherwise, `kadmin` will append `/admin` to the primary principal name of the default credentials cache, the value of the `USER` environment variable, or the username as obtained with `getpwnid`, in that order of preference.
 - q *query*
Pass *query* directly to `kadmin`, which will perform *query* and then exit. This can be useful for writing scripts.
 - r *realm*
Use *realm* as the default database realm.
 - s *admin_server[:port]*
Administer the specified *admin* server at the specified port number (*port*). This can be useful in administering a realm not known to your client.
 - w *password*
Use *password* instead of prompting for one. Note that placing the password for a Kerberos principal with administration access into a shell script can be dangerous if unauthorized users gain read access to the script or can read arguments of this command through `ps(1)`.
 - x *db_args*
Pass database-specific arguments to `kadmin`. Supported arguments are for LDAP and the Berkeley-db2 plug-in. These arguments are:
 - `binddn=binddn`
LDAP simple bind DN for authorization on the directory server. Overrides the `ldap_kadmind_dn` parameter setting in `krb5.conf(4)`.
 - `bindpwd=bindpwd`
Bind password.
 - `dbname=name`
For the Berkeley-db2 plug-in, specifies a name for the Kerberos database.
 - `nconns=num`
Maximum number of server connections.

`port=num`

Directory server connection port.

Commands `list_requests`

Lists all the commands available for `kadmin`. Aliased by `lr` and `?`.

`get_privs`

Lists the current Kerberos administration privileges (ACLs) for the principal that is currently running `kadmin`. The privileges are based on the `/etc/krb5/kadm5.acl` file on the master KDC. Aliased by `getprivs`.

`add_principal [options] newprinc`

Creates a new principal, *newprinc*, prompting twice for a password. If the `-policy` option is not specified and a policy named `default` exists, then the `default` policy is assigned to the principal; note that the assignment of the `default` policy occurs automatically only when a principal is first created, so the `default` policy must already exist for the assignment to occur. The automatic assignment of the `default` policy can be suppressed with the `-clearpolicy` option. This command requires the `add` privilege. Aliased by `addprinc` and `ank`. The options are:

`-expire expdate`

Expiration date of the principal. See the `Time Formats` section for the valid absolute time formats that you can specify for *expdate*.

`-pwexpire pwexpdate`

Password expiration date. See the `Time Formats` section for the valid absolute time formats that you can specify for *pwexpdate*.

`-maxlife maxlife`

Maximum ticket life for the principal. See the `Time Formats` section for the valid time duration formats that you can specify for *maxlife*.

`-maxrenewlife maxrenewlife`

Maximum renewable life of tickets for the principal. See the `Time Formats` section for the valid time duration formats that you can specify for *maxrenewlife*.

`-kvno kvno`

Explicitly set the key version number.

`-policy policy`

Policy used by the principal. If both the `-policy` and `-clearpolicy` options are not specified, the `default` policy is used if it exists; otherwise, the principal will have no policy. Also note that the password and principal name must be different when you add a new principal with a specific policy or the `default` policy.

`-clearpolicy`

`-clearpolicy` prevents the `default` policy from being assigned when `-policy` is not specified. This option has no effect if the `default` policy does not exist.

`{-|+}allow_postdated`
-allow_postdated prohibits the principal from obtaining postdated tickets. (Sets the KRB5_KDB_DISALLOW_POSTDATED flag.) +allow_postdated clears this flag.

`{-|+}allow_forwardable`
-allow_forwardable prohibits the principal from obtaining forwardable tickets. (Sets the KRB5_KDB_DISALLOW_FORWARDABLE flag.) +allow_forwardable clears this flag.

`{-|+}allow_renewable`
-allow_renewable prohibits the principal from obtaining renewable tickets. (Sets the KRB5_KDB_DISALLOW_RENEWABLE flag.) +allow_renewable clears this flag.

`{-|+}allow_proxiabile`
-allow_proxiabile prohibits the principal from obtaining proxiabile tickets. (Sets the KRB5_KDB_DISALLOW_PROXIABLE flag.) +allow_proxiabile clears this flag.

`{-|+}allow_dup_skey`
-allow_dup_skey disables user-to-user authentication for the principal by prohibiting this principal from obtaining a session key for another user. (Sets the KRB5_KDB_DISALLOW_DUP_SKEY flag.) +allow_dup_skey clears this flag.

`{-|+}requires_preauth`
+requires_preauth requires the principal to preauthenticate before being allowed to kinit. (Sets the KRB5_KDB_REQUIRES_PRE_AUTH flag.) -requires_preauth clears this flag.

`{-|+}requires_hwauth`
+requires_hwauth requires the principal to preauthenticate using a hardware device before being allowed to kinit. (Sets the KRB5_KDB_REQUIRES_HW_AUTH flag.)
-requires_hwauth clears this flag.

`{-|+}allow_svr`
-allow_svr prohibits the issuance of service tickets for the principal. (Sets the KRB5_KDB_DISALLOW_SVR flag.) +allow_svr clears this flag.

`{-|+}allow_tgs_req`
-allow_tgs_req specifies that a Ticket-Granting Service (TGS) request for a service ticket for the principal is not permitted. This option is useless for most things.
+allow_tgs_req clears this flag. The default is +allow_tgs_req. In effect,
-allow_tgs_req sets the KRB5_KDB_DISALLOW_TGT_BASED flag on the principal in the database.

`{-|+}allow_tix`
-allow_tix forbids the issuance of any tickets for the principal. +allow_tix clears this flag. The default is +allow_tix. In effect, -allow_tix sets the KRB5_KDB_DISALLOW_ALL_TIX flag on the principal in the database.

{-|+}needchange

+needchange sets a flag in attributes field to force a password change; -needchange clears it. The default is -needchange. In effect, +needchange sets the KRB5_KDB_REQUIRES_PWCHANGE flag on the principal in the database.

{-|+}password_changing_service

+password_changing_service sets a flag in the attributes field marking this as a password change service principal (useless for most things).

-password_changing_service clears the flag. This flag intentionally has a long name. The default is -password_changing_service. In effect, +password_changing_service sets the KRB5_KDB_PWCHANGE_SERVICE flag on the principal in the database.

-randkey

Sets the key of the principal to a random value.

-pw *password*

Sets the key of the principal to the specified string and does not prompt for a password. Note that using this option in a shell script can be dangerous if unauthorized users gain read access to the script.

-e "enc:salt ..."

Override the list of enctype:salttype pairs given in `kdc.conf(4)` for setting the key of the principal. The quotes are necessary if there are multiple enctype:salttype pairs. One key for each similar enctype and same salttype will be created and the first one listed will be used. For example, in a list of two similar encetypes with the same salt, "des-cbc-crc:normal des-cbc-md5:normal", one key will be created and it will be of type des-cbc-crc:normal.

Example:

```
kadmin: addprinc tlyu/admin
WARNING: no policy specified for "tlyu/admin@ACME.COM";
defaulting to no policy.
Enter password for principal tlyu/admin@ACME.COM:
Re-enter password for principal tlyu/admin@ACME.COM:
Principal "tlyu/admin@ACME.COM" created.
kadmin:
```

Errors:

KADM5_AUTH_ADD (requires add privilege)

KADM5_BAD_MASK (should not happen)

KADM5_DUP (principal exists already)

KADM5_UNK_POLICY (policy does not exist)

KADM5_PASS_Q_* (password quality violations)

delete_principal [-force] *principal*

Deletes the specified principal from the database. This command prompts for deletion, unless the -force option is given. This command requires the delete privilege. Aliased by delprinc.

Example:

```
kadmin: delprinc mwm_user
Are you sure you want to delete the principal
"mwm_user@ACME.COM"? (yes/no): yes
Principal "mwm_user@ACME.COM" deleted.
Make sure that you have removed this principal from
all kadmin ACLs before reusing.
kadmin:
```

Errors:

KADM5_AUTH_DELETE (requires delete privilege)

KADM5_UNK_PRINC (principal does not exist)

modify_principal [*options*] *principal*

Modifies the specified principal, changing the fields as specified. The options are as above for add_principal, except that password changing is forbidden by this command. In addition, the option -clearpolicy will clear the current policy of a principal. This command requires the modify privilege. Aliased by modprinc.

Errors:

KADM5_AUTH_MODIFY (requires modify privilege)

KADM5_UNK_PRINC (principal does not exist)

KADM5_UNK_POLICY (policy does not exist)

KADM5_BAD_MASK (should not happen)

change_password [*options*] *principal*

Changes the password of *principal*. Prompts for a new password if neither -randkey or -pw is specified. Requires the changepw privilege, or that the principal that is running the program to be the same as the one changed. Aliased by cpw. The following options are available:

-randkey

Sets the key of the principal to a random value.

-pw *password*

Sets the password to the specified string. Not recommended.

-e “enc:salt ...”

Override the list of enctype:salttype pairs given in `kdc.conf(4)` for setting the key of the principal. The quotes are necessary if there are multiple enctype:salttype pairs. For each key, the first matching similar enctype and same salttype in the list will be used to set the new key(s).

-keepold

Keeps the previous kvno's keys around. There is no easy way to delete the old keys, and this flag is usually not necessary except perhaps for TGS keys as it will allow existing valid TGTs to continue to work.

Example:

```
kadmin: cpw systest
Enter password for principal systest@ACME.COM:
Re-enter password for principal systest@ACME.COM:
Password for systest@ACME.COM changed.
kadmin:
```

Errors:

KADM5_AUTH_MODIFY (requires the modify privilege)

KADM5_UNK_PRINC (principal does not exist)

KADM5_PASS_Q_* (password policy violation errors)

KADM5_PASS_REUSE (password is in principal's password history)

KADM5_PASS_TOOsoon (current password minimum life not expired)

`get_principal [-terse] principal`

Gets the attributes of *principal*. Requires the inquire privilege, or that the principal that is running the program to be the same as the one being listed. With the `-terse` option, outputs fields as quoted tab-separated strings. Aliased by `getprinc`.

Examples:

```
kadmin: getprinc tlyu/admin
Principal: tlyu/admin@ACME.COM
Expiration date: [never]
Last password change: Thu Jan 03 12:17:46 CET 2008
Password expiration date: [none]
Maximum ticket life: 24855 days 03:14:07
Maximum renewable life: 24855 days 03:14:07
Last modified: Thu Jan 03 12:17:46 CET 2008 (root/admin@ACME.COM)
Last successful authentication: [never]
Last failed authentication: [never]
Failed password attempts: 0
Number of keys: 5
Key: vno 2, AES-256 CTS mode with 96-bit SHA-1 HMAC, no salt
```

```

Key: vno 2, AES-128 CTS mode with 96-bit SHA-1 HMAC, no salt
Key: vno 2, Triple DES cbc mode with HMAC/sha1, no salt
Key: vno 2, ArcFour with HMAC/md5, no salt
Key: vno 2, DES cbc mode with RSA-MD5, no salt
Attributes: REQUIRES_PRE_AUTH
Policy: [none]
kadmin: getprinc -terse tlyu/admin
"tlyu/admin@ACME.COM"  0      1199359066      0      2147483647
"root/admin@ACME.COM" 1199359066      128     2      0      "[none]"      21474836
47      0      0      0      5      1      2      18     0      1      2
17      0      1      2      16     0      1      2      23     0      12
      3      0
kadmin:

```

Errors:

KADM5_AUTH_GET (requires the get [inquire] privilege)

KADM5_UNK_PRINC (principal does not exist)

list_principals [*expression*]

Retrieves all or some principal names. *expression* is a shell-style glob expression that can contain the wild-card characters ?, *, and []. All principal names matching the expression are printed. If no expression is provided, all principal names are printed. If the expression does not contain an "@" character, an "@" character followed by the local realm is appended to the expression. Requires the list privilege. Aliased by listprincs, get_principals, and getprincs.

Examples:

```

kadmin: listprincs test*
test3@ACME.COM
test2@ACME.COM
test1@ACME.COM
testuser@ACME.COM
kadmin:

```

add_policy [*options*] *policy*

Adds the named policy to the policy database. Requires the add privilege. Aliased by addpol. The following options are available:

-maxlife *maxlife*

sets the maximum lifetime of a password. See the Time Formats section for the valid time duration formats that you can specify for *maxlife*.

-minlife *minlife*

sets the minimum lifetime of a password. See the Time Formats section for the valid time duration formats that you can specify for *minlife*.

-minlength *length*

sets the minimum length of a password.

`-minclasses` *number*

sets the minimum number of character classes allowed in a password. The valid values are:

1

only letters (himom)

2

both letters and numbers (hi2mom)

3

letters, numbers, and punctuation (hi2mom!)

`-history` *number*

sets the number of past keys kept for a principal.

Errors:

KADM5_AUTH_ADD (requires the add privilege)

KADM5_DUP (policy already exists)

`delete_policy` [`-force`] *policy*

Deletes the named policy. Unless the `-force` option is specified, prompts for confirmation before deletion. The command will fail if the policy is in use by any principals. Requires the delete privilege. Aliased by `delpol`.

Example:

```
kadmin: del_policy guests
Are you sure you want to delete the
policy "guests"? (yes/no): yes
Policy "guests" deleted.
kadmin:
```

Errors:

KADM5_AUTH_DELETE (requires the delete privilege)

KADM5_UNK_POLICY (policy does not exist)

KADM5_POLICY_REF (reference count on policy is not zero)

`modify_policy` [*options*] *policy*

Modifies the named policy. Options are as above for `add_policy`. Requires the modify privilege. Aliased by `modpol`.

Errors:

KADM5_AUTH_MODIFY (requires the modify privilege)

KADM5_UNK_POLICY (policy does not exist)

`get_policy [-terse] policy`

Displays the values of the named policy. Requires the `inquire` privilege. With the `-terse` flag, outputs the fields as quoted strings separated by tabs. Aliased by `getpol`.

Examples:

```
kadmin: get_policy admin
Policy: admin
Maximum password life: 180 days 00:00:00
Minimum password life: 00:00:00
Minimum password length: 6
Minimum number of password character classes: 2
Number of old keys kept: 5
Reference count: 17
kadmin: get_policy -terse
admin admin 15552000 0 6 2 5 17
kadmin:
```

Errors:

KADM5_AUTH_GET (requires the `get` privilege)

KADM5_UNK_POLICY (policy does not exist)

`list_policies [expression]`

Retrieves all or some policy names. *expression* is a shell-style glob expression that can contain the wild-card characters `?`, `*`, and `[]`'s. All policy names matching the expression are printed. If no expression is provided, all existing policy names are printed. Requires the `list` privilege. Aliased by `listpols`, `get_policies`, and `getpols`.

Examples:

```
kadmin: listpols
test-pol dict-only once-a-min test-pol-nopw
kadmin: listpols t*
test-pol test-pol-nopw kadmin:
```

`ktadd [-k keytab] [-q] [-e enctype:salt]`

Adds a principal or all principals matching *princ-exp* to a keytab, randomizing each principal's key in the process.

`ktadd` requires the `inquire` and `changepw` privileges. An entry for each of the principal's unique encryption types is added, ignoring multiple keys with the same encryption type but different `salt` types. If the `-k` argument is not specified, the default keytab file, `/etc/krb5/krb5.keytab`, is used.

The “`-e enctype:salt”` option overrides the list of *enctypes* given in `krb5.conf(4)`, in the `permitted_enctypes` parameter. If “`-e enctype:salt”` is not used and `permitted_enctypes` is not defined in `krb5.conf(4)`, a key for each *enctype* supported by the system on which `kadmin` is run will be created and added to the keytab. Restricting the

enctypes of keys in the keytab is useful when the system for which keys are being created does not support the same set of *enctypes* as the KDC. Note that `ktadd` modifies the *enctype* of the keys in the principal database as well.

If the `-q` option is specified, less status information is displayed. Aliased by `xst`. The `-glob` option requires the `list` privilege. Also, note that if you use `-glob` to create a keytab, you need to remove `/etc/krb5/kadm5.keytab` and create it again if you want to use `-p */admin` with `kadmin`.

`princ-exp`

princ-exp follows the same rules described for the `list_principals` command.

Example:

```
kadmin: ktadd -k /tmp/new-keytab nfs/chicago
Entry for principal nfs/chicago with kvno 2,
encryption type DES-CBC-CRC added to keytab
WRFILE:/tmp/new-keytab.
kadmin:
```

`ktremove [-k keytab] [-q] principal [kvno | all | old]`

Removes entries for the specified principal from a keytab. Requires no privileges, since this does not require database access. If `all` is specified, all entries for that principal are removed; if `old` is specified, all entries for that principal except those with the highest `kvno` are removed. Otherwise, the value specified is parsed as an integer, and all entries whose `kvno` match that integer are removed. If the `-k` argument is not specified, the default keytab file, `/etc/krb5/krb5.keytab`, is used. If the `-q` option is specified, less status information is displayed. Aliased by `ktrem`.

Example:

```
kadmin: ktremove -k /tmp/new-keytab nfs/chicago
Entry for principal nfs/chicago with kvno 2
removed from keytab
WRFILE:/tmp/new-keytab.
kadmin:
```

`quit`

Quits `kadmin`. Aliased by `exit` and `q`.

Time Formats Various commands in `kadmin` can take a variety of time formats, specifying time durations or absolute times. The `kadmin` option variables *maxrenewlife*, *maxlife*, and *minlife* are time durations, whereas *expdate* and *pwexpdate* are absolute times.

Examples:

```
kadmin: modprinc -expire "12/31 7pm" jdb
kadmin: modprinc -maxrenewlife "2 fortnight" jdb
kadmin: modprinc -pwexpire "this sunday" jdb
kadmin: modprinc -expire never jdb
```

```
kadmin: modprinc -maxlife "7:00:00pm tomorrow" jdb
```

Note that times which do not have the “ago” specifier default to being absolute times, unless they appear in a field where a duration is expected. In that case, the time specifier will be interpreted as relative. Specifying “ago” in a duration can result in unexpected behavior.

The following time formats and units can be combined to specify a time. The time and date format examples are based on the date and time of July 2, 1999, 1:35:30 p.m.

| Time Format | Examples |
|--------------------------------------|------------------------|
| <i>hh[:mm][:ss][am/pm/a.m./p.m.]</i> | 1p.m., 1:35, 1:35:30pm |

| Variable | Description |
|-----------|---------------------------------------------------------------|
| <i>hh</i> | hour (12-hour clock, leading zero permitted but not required) |
| <i>mm</i> | minutes |
| <i>ss</i> | seconds |

| Date Format | Examples |
|------------------------|-----------------------|
| <i>mm/dd[/yy]</i> | 07/02, 07/02/99 |
| <i>yyyy-mm-dd</i> | 1999-07-02 |
| <i>dd-month-yyyy</i> | 02-July-1999 |
| <i>month [,yyyy]</i> | Jul 02, July 02,1999 |
| <i>dd month[yyyy]</i> | 02 JULY, 02 july 1999 |

| Variable | Description |
|--------------|--------------------------------------------------------------------|
| <i>dd</i> | day |
| <i>mm</i> | month |
| <i>yy</i> | year within century (00-38 is 2000 to 2038; 70-99 is 1970 to 1999) |
| <i>yyyy</i> | year including century |
| <i>month</i> | locale's full or abbreviated month name |

| Time Units | Examples |
|------------|----------|
|------------|----------|

| | |
|-------------------|-----------------|
| [+ - #] year | "-2 year" |
| [+ - #] month | "2 months" |
| [+ - #] fortnight | |
| [+ - #] week | |
| [+ - #] day | |
| [+ - #] hour | |
| [+ - #] minute | |
| [+ - #] min | |
| [+ - #] second | |
| [+ - #] sec | |
| tomorrow | |
| yesterday | |
| today | |
| now | |
| this | "this year" |
| last | "last saturday" |
| next | "next month" |
| sunday | |
| monday | |
| tuesday | |
| wednesday | |
| thursday | |
| friday | |
| saturday | |
| never | |

You can also use the following time modifiers: first, second, third, fourth, fifth, sixth, seventh, eighth, ninth, tenth, eleventh, twelfth, and ago.

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of kadmin:

PAGER

The command to use as a filter for paging output. This can also be used to specify options. The default is [more\(1\)](#).

Files `/var/krb5/principal`

Kerberos principal database.

`/var/krb5/principal.ulog`

The update log file for incremental propagation.

`/var/krb5/principal.kadm5`

Kerberos administrative database. Contains policy information.

`/var/krb5/principal.kadm5.lock`

Lock file for the Kerberos administrative database. This file works backwards from most other lock files (that is, `kadmin` will exit with an error if this file does *not* exist).

`/var/krb5/kadm5.dict`

Dictionary of strings explicitly disallowed as passwords.

`/etc/krb5/kadm5.acl`

List of principals and their `kadmin` administrative privileges.

`/etc/krb5/kadm5.keytab`

Keytab for `kadmin` principals: `kadmin/fqdn`, `changew/fqdn`, and `kadmin/changew`.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------------|
| Availability | system/security/kerberos-5 |
| Interface Stability | Committed |

See Also [kpasswd\(1\)](#), [more\(1\)](#), [gkadmin\(1M\)](#), [kadmin\(1M\)](#), [kdb5_util\(1M\)](#), [kdb5_ldap_util\(1M\)](#), [kproplog\(1M\)](#), [kadm5.acl\(4\)](#), [kdc.conf\(4\)](#), [krb5.conf\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [kerberos\(5\)](#), [krb5envvar\(5\)](#)

History The `kadmin` program was originally written by Tom Yu at MIT, as an interface to the OpenVision Kerberos administration program.

Diagnostics The `kadmin` command is currently incompatible with the MIT `kadmin` daemon interface, so you cannot use this command to administer an MIT-based Kerberos database. However, clients running the Solaris implementation of Kerberos can still use an MIT-based KDC.

Name kadmind – Kerberos administration daemon

Synopsis /usr/lib/krb5/kadmind [-d] [-m] [-p *port-number*] [-r *realm*]
-x *db_args*...

Description kadmind runs on the master key distribution center (KDC), which stores the principal and policy databases. kadmind accepts remote requests to administer the information in these databases. Remote requests are sent, for example, by [kpasswd\(1\)](#), [gkadmin\(1M\)](#), and [kadmin\(1M\)](#) commands, all of which are clients of kadmind. When you install a KDC, kadmind is set up in the `init` scripts to start automatically when the KDC is rebooted.

kadmind requires a number of configuration files to be set up for it to work:

`/etc/krb5/kdc.conf`

The KDC configuration file contains configuration information for the KDC and the Kerberos administration system. kadmind understands a number of configuration variables (called relations) in this file, some of which are mandatory and some of which are optional. In particular, kadmind uses the `acl_file`, `dict_file`, `admin_keytab`, and `kadmind_port` relations in the `[realms]` section. Refer to the [kdc.conf\(4\)](#) man page for information regarding the format of the KDC configuration file.

`/etc/krb5/kadm5.keytab`

kadmind requires a keytab (key table) containing correct entries for the `kadmin/fqdn`, `kadmin/changepw` and `kadmin/changepw` principals for every realm that kadmind answers requests. The keytab can be created with the [kadmin\(1M\)](#) or [kdb5_util\(1M\)](#) command. The location of the keytab is determined by the `admin_keytab` relation in the `kdc.conf(4)` file.

`/etc/krb5/kadm5.acl`

kadmind uses an ACL (access control list) to determine which principals are allowed to perform Kerberos administration actions. The path of the ACL file is determined by the `acl_file` relation in the `kdc.conf` file. See [kdc.conf\(4\)](#). For information regarding the format of the ACL file, refer to [kadm5.acl\(4\)](#).

The kadmind daemon will need to be restarted to reread the `kadm5.acl` file after it has been modified. You can do this, as root, with the following command:

```
# svcadm restart svc:/network/security/kadmin:default
```

After kadmind begins running, it puts itself in the background and disassociates itself from its controlling terminal.

kadmind can be configured for incremental database propagation. Incremental propagation allows slave KDC servers to receive principal and policy updates incrementally instead of receiving full dumps of the database. These settings can be changed in the [kdc.conf\(4\)](#) file:

```
sunw_dbprop_enable = [true | false]
```

Enable or disable incremental database propagation. Default is `false`.

```
sunw_dbprop_master_ulogsize = N
```

Specifies the maximum amount of log entries available for incremental propagation to the slave KDC servers. The maximum value that this can be is 2500 entries. Default value is 1000 entries.

The `kiprop/<hostname>@<REALM>` principal must exist in the master's `kadm5.keytab` file to enable the slave to authenticate incremental propagation from the master. In the principal syntax above, `<hostname>` is the master KDC's host name and `<REALM>` is the realm in which the master KDC resides.

Kerberos client machines can automatically migrate Unix users to the default Kerberos realm specified in the local `krb5.conf(4)`, if the user does not have a valid kerberos account already. You achieve this by using the `pam_krb5_migrate(5)` service module for the service in question. The Kerberos service principal used by the client machine attempting the migration needs to be validated using the `u` privilege in `kadm5.acl(4)`. When using the `u` privilege, `kadmind` validates user passwords using PAM, specifically using a `PAM_SERVICE` name of `k5migrate` by calling `pam_authenticate(3PAM)` and `pam_acct_mgmt(3PAM)`.

A suitable PAM stack configuration example for `k5migrate` would look like:

```
k5migrate      auth      required      pam_unix_auth.so.1
k5migrate      account  required      pam_unix_account.so.1
```

Options The following options are supported:

`-d`

Specifies that `kadmind` does not put itself in the background and does not disassociate itself from the terminal. In normal operation, you should use the default behavior, which is to allow the daemon to put itself in the background.

`-m`

Specifies that the master database password should be retrieved from the keyboard rather than from the stash file. When using `-m`, the `kadmind` daemon receives the password prior to putting itself in the background. If used in combination with the `-d` option, you must explicitly place the daemon in the background.

`-p port-number`

Specifies the port on which the `kadmind` daemon listens for connections. The default is controlled by the `kadmind_port` relation in the `kdc.conf(4)` file.

`-r realm`

Specifies the default realm that `kadmind` serves. If `realm` is not specified, the default `realm` of the host is used. `kadmind` answers requests for any realm that exists in the local KDC database and for which the appropriate principals are in its keytab.

`-x db_args`

Pass database-specific arguments to `kadmind`. Supported arguments are for LDAP and the Berkeley-db2 plug-in. These arguments are:

binddn=binddn

LDAP simple bind DN for authorization on the directory server. Overrides the `ldap_kadmin_dn` parameter setting in `krb5.conf(4)`.

bindpwd=bindpwd

Bind password.

dbname=name

For the Berkeley-db2 plug-in, specifies a name for the Kerberos database.

nconns=num

Maximum number of server connections.

port=num

Directory server connection port.

Files `/var/krb5/principal`

Kerberos principal database.

`/var/krb5/principal.ulong`

The update log file for incremental propagation.

`/var/krb5/principal.kadm5`

Kerberos administrative database containing policy information.

`/var/krb5/principal.kadm5.lock`

Kerberos administrative database lock file. This file works backwards from most other lock files (that is, `kadmin` exits with an error if this file does not exist).

`/var/krb5/kadm5.dict`

Dictionary of strings explicitly disallowed as passwords.

`/etc/krb5/kadm5.acl`

List of principals and their `kadmin` administrative privileges.

`/etc/krb5/kadm5.keytab`

Keytab for `kadmin` principals: `kadmin/fqdn`, `changepw/fqdn`, and `kadmin/changepw`.

`/etc/krb5/kdc.conf`

KDC configuration information.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------------|
| Availability | system/security/kerberos-5 |
| Interface Stability | Committed |

See Also [kpasswd\(1\)](#), [svcs\(1\)](#), [gkadmin\(1M\)](#), [kadmin\(1M\)](#), [kadmin\(1M\)](#), [kdb5_util\(1M\)](#), [kdb5_ldap_util\(1M\)](#), [kproplog\(1M\)](#), [svcadm\(1M\)](#), [pam_acct_mgmt\(3PAM\)](#), [pam_authenticate\(3PAM\)](#), [kadm5.acl\(4\)](#), [kdc.conf\(4\)](#), [krb5.conf\(4\)](#), [attributes\(5\)](#), [kerberos\(5\)](#), [krb5envvar\(5\)](#), [pam_krb5_migrate\(5\)](#), [smf\(5\)](#)

Notes The Kerberos administration daemon (`kadmin`) is now compliant with the change-password standard mentioned in RFC 3244, which means it can now handle change-password requests from non-Solaris Kerberos clients.

The `kadmin` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/security/kadmin
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Name kcfcd – kernel-level cryptographic framework daemon

Synopsis kcfcd

Description The kcfcd daemon helps in managing CPU usage by cryptographic operations performed in software by kernel threads. The system utilization associated with these threads is charged to the kcfcd process. It also does module verification for kernel cryptographic modules.

Only a privileged user can run this daemon.

The kcfcd daemon is automatically invoked in run level 1, after /usr is mounted. A previously invoked kcfcd daemon that is still running must be stopped before invoking another kcfcd command.

Manually starting and restarting kcfcd is not recommended. If it is necessary to do so, use the [cryptoadm\(1M\)](#) start and stop subcommands.

Exit Status The following exit values are returned:

0 Daemon started successfully.

> 1 Daemon failed to start.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------|
| Availability | SUNWcsl/SUNWcslx |
| Interface Stability | Committed |

See Also [cryptoadm\(1M\)](#), [attributes\(5\)](#)

Name kclient – set up a machine as a Kerberos client

Synopsis /usr/sbin/kclient [-n] [-R *realm*] [-k *kdc*] [-a *adminuser*]
 [-c *filepath*] [-d *dnsarg*] [-f *fqdn_list*] [-h *logical_host_name*]
 [-k *kdc_list*] [-m *master_kdc*] [-p *profile*] [-s *pam_service*]
 [-T *kdc_vendor*]

Description By specifying the various command options, you can use the `kclient` utility to:

- Configure a machine as a Kerberos client for a specified realm and for KDC by setting up `krb5.conf(4)`.
- Add the Kerberos host principal to the local host's keytab file (`/etc/krb5/krb5.keytab`).
- Set up the machine to do kerberized NFS.
- Bring over a master `krb5.conf` copy from a specified pathname.
- Setup a machine to do server and/or host/domain name-to-realm mapping lookups by means of DNS.
- Configure a Kerberos client to use an MS Active Directory server. This generates a keytab file with the Kerberos client's service keys populated.
- Setup a Kerberos client that has no service keys. This is useful when the client does not require service keys, because the client does not wish to host a service that uses Kerberos for security.
- Configure a Kerberos client that is part of a cluster. This option requires the logical host name of the cluster so that the proper service keys are created and populated in the client's keytab file.
- Setup a Kerberos client to join an environment that consists of Kerberos servers that are non-Solaris and non-MS Active Directory servers.
- Configure `pam.conf(4)` to use Kerberos authentication for specified services.
- Configure the client as a simple NTP broadcast/multicast client.
- Specify custom domain/host name-to-realm name mappings.
- Setup the Kerberos client to use multiple KDC servers.

The `kclient` utility needs to be run on the client machine with root permission and can be run either interactively or non-interactively. In the non-interactive mode, the user feeds in the required inputs by means of a profile, command-line options, or a combination of profile and command-line options. The user is prompted for “required” parameter values (`realm` and `adminuser`), if found missing in the non-interactive run. The interactive mode is invoked when the utility is run without any command-line arguments.

Both the interactive and non-interactive forms of `kclient` can add the `host/fqdn` entry to the local host's keytab file. They also can require the user to enter the password for the administrative user requested, to obtain the Kerberos Ticket Granting Ticket (TGT) for `adminuser`. The `host/fqdn`, `nfs/fqdn`, and `root/fqdn` principals can be added to the KDC database (if not already present) before their possible addition to the local host's keytab.

The `kclient` utility assumes that the local host has been setup for DNS and requires the presence of a valid `resolv.conf(4)`. Also, `kclient` can fail if the localhost time is not synchronized with that of the KDC. For Kerberos to function the localhost time must be within five minutes of that of the KDC. It is advised that both systems run some form of time synchronization protocol, such as the Network Time Protocol (NTP). See the `ntpd` man page, delivered in the `SUNWntpu` package (not a SunOS man page).

Options The non-interactive mode supports the following options:

-n

Set up the machine for kerberized NFS. This involves making changes to `krb5*` security flavors in `nfssec.conf(4)`. This option will also add `nfs/fqdn` and `root/fqdn` entries to the local host's keytab file if the `-K` option has not been specified.

-R [*realm*]

Specifies the Kerberos realm.

-k *kdc_list*

The `-k` option specifies the KDC host names for the Kerberos client. *kdc_list* is a comma-separated list of KDCs. If the `-m` option is not used, it is assumed that the first (or only) host in *kdc_list* is the master KDC host name. Note that the list specified is used verbatim. This is helpful when specifying non-fully qualified KDC host names that can be canonicalized by DNS.

-a [*adminuser*]

Specifies the Kerberos administrative user.

-T *kdc_vendor*

Configure the Kerberos client to associate with a third party server. Valid *kdc_vendor* currently supported are:

`ms_ad`

Microsoft Active Directory

`mit`

MIT KDC server

`heimdal`

Heimdal KDC server

`shishi`

Shishi KDC server

Knowing the administrative password will be required to associate the client with the server if the `ms_ad` option is specified.

-c [*filepath*]

Specifies the pathname to the `krb5.conf(4)` master file, to be copied over to the local host. The path specified normally points to a master copy on a remote host and brought over to the local host by means of NFS.

-d [*dnsarg*]

Specifies the DNS lookup option to be used and specified in the `krb5.conf(4)` file. Valid *dnsarg* entries are: `none`, `dns_lookup_kdc`, `dns_lookup_realm` and `dns_fallback`. Any other entry is considered invalid. The latter three *dnsarg* values assume the same meaning as those described in `krb5.conf`. `dns_lookup_kdc` implies DNS lookups for the KDC and the other servers. `dns_lookup_realm` is for host/domain name-to-realm mapping by means of DNS. `dns_fallback` is a superset and does DNS lookups for both the servers and the host/domain name-to-realm mapping. A lookup option of `none` specifies that DNS is not be used for any kind of mapping lookup.

-D *domain_list*

Specifies the host and/or domain names to be mapped to the Kerberos client's default realm name. *domain_list* is a comma-separated list, for example “`example.com,host1.example.com`”. If the `-D` option is not used, then only the client's domain is used for this mapping. For example, if the client is `host1.eng.example.com`, then the domain that is mapped to the `EXAMPLE.COM` realm is `example.com`.

-K

Configure the Kerberos client without service keys, which are usually stored in `/etc/krb5/krb5.keytab`. This is useful in the following scenarios:

- The client IP address is dynamically assigned and therefore does not host Kerberized services.
- Client has a static IP address, but does not want to host any Kerberized services.
- Client has a static IP address, but the local administrator does not currently have service keys available for the machine. It is expected that, at a later time, these keys will be installed on the machine.

-f [*fqdn_list*]

This option creates a service principal entry (`host/nfs/root`) associated with each of the listed *fqdn*'s, if required, and subsequently adds the entries to the local host's keytab.

fqdn_list is a comma-separated list of one or more fully qualified DNS domain names.

This option is especially useful in Kerberos realms having systems offering kerberized services, but situated in multiple different DNS domains.

-h *logical_host_name*

Specifies that the Kerberos client is a node in a cluster. The *logical_host_name* is the logical host name given to the cluster. The resulting `/etc/krb5/krb5.conf` and `/etc/krb5/krb5.keytab` files must be manually copied over to the other members of the cluster.

-m *master_kdc*

This option specifies the master KDC to be used by the Kerberos client. *master_kdc* is the host name of the master KDC for the client. If the `-m` option is not used, then it is assumed that the first KDC host name listed with the `-k` option is the master KDC.

-p [*profile*]

Specifies the profile to be used to enable the reading in of the values of all the parameters required for setup of the machine as a Kerberos client.

The profile should have entries in the format:

PARAM <*value*>

Valid *PARAM* entries are: REALM, KDC, ADMIN, FILEPATH, NFS, DNSLOOKUP, FQDN, NOKEY, NOSOL, LHN, KDCVENDOR, RMAP, MAS, and PAM.

These profile entries correspond to the **-R** [*realm*], **-k** [*kdc*], **-a** [*adminuser*], **-c** [*filepath*], **-n**, **-d** [*dnsarg*], **-f** [*fqdn_list*], **-K**, **-h** [*logical_host_name*], **-T** [*kdc_vendor*], **-D** [*domain_list*], **-m** [*master_kdc*], and **-s** [*pam_service*] command-line options, respectively. Any other *PARAM* entry is considered invalid and is ignored.

The NFS profile entry can have a value of 0 (do nothing) or 1 (operation is requested). Any other value is considered invalid and is ignored.

Keep in mind that the command line options override the *PARAM* values listed in the profile.

-s *pam_service*

Specifies that the PAM service names, listed in *pam_service*, are authenticated through Kerberos before any other type of authentication. Using this option updates [pam.conf\(4\)](#) to include [pam_krb5\(5\)](#) to existing authentication stacks for the specified service(s) in *pam_service*. An example of a possible *pam_service* value is: `gdm, sshd - kbdint`.

Examples **EXAMPLE 1** Setting Up a Kerberos Client Using Command-Line Options

To setup a Kerberos client using the `clntconfig/admin` administrative principal for realm 'ABC.COM', `kdc 'example1.com'` and that also does kerberized NFS, enter:

```
# /usr/sbin/kclient -n -R ABC.COM -k example1.com -a clntconfig
```

Alternatively, to set up a Kerberos client using the `clntconfig/admin` administrative principal for the realm 'EAST.ABC.COM', `kdc 'example2.east.abc.com'` and that also needs service principal(s) created and/or added to the local keytab for multiple DNS domains, enter:

```
# /usr/sbin/kclient -n -R EAST.ABC.COM -k example2.east.abc.com \
-f west.abc.com,central.abc.com -a clntconfig
```

Note that the `krb5` administrative principal used by the administrator needs to have only `add`, `inquire`, `change-pwd` and `modify` privileges (for the principals in the KDC database) in order for the `kclient` utility to run. A sample [kadm5.acl\(4\)](#) entry is:

```
clntconfig/admin@ABC.COM acmi
```

EXAMPLE 2 Setting Up a Kerberos Client Using the Profile Option

To setup a Kerberos client using the `clntconfig/admin` administrative principal for realm 'ABC.COM', kdc 'example1.com' and that also copies over the master `krb5.conf` from a specified location, enter:

```
# /usr/sbin/kclient -p /net/example1.com/export/profile.krb5
```

The contents of `profile.krb5`:

```
REALM ABC.COM
KDC example1
ADMIN clntconfig
FILEPATH /net/example1.com/export/krb5.conf
NFS 0
DNSLOOKUP none
```

EXAMPLE 3 Setting Up a Kerberos Client That Has a Dynamic IP Address

In this example a Kerberos client is a DHCP client that has a dynamic IP address. This client does not wish to host any Kerberized services and therefore does not require a keytab (`/etc/krb5/krb5.keytab`) file.

For this type of client the administrator would issue the following command to configure this machine to be a Kerberos client of the ABC.COM realm with the KDC server `kdc1.example.com`:

```
# /usr/sbin/kclient -K -R EXAMPLE.COM -k kdc1.example.com
```

- Files**
- `/etc/krb5/kadm5.acl`
Kerberos access control list (ACL) file.
 - `/etc/krb5/krb5.conf`
Default location for the local host's configuration file.
 - `/etc/krb5/krb5.keytab`
Default location for the local host's keytab file.
 - `/etc/nfssec.conf`
File listing NFS security modes.
 - `/etc/resolv.conf`
DNS resolver configuration file.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------------|
| Availability | system/security/kerberos-5 |
| Interface Stability | Committed |

See Also `encrypt(1)`, `ksh93(1)`, `ldapdelete(1)`, `ldapmodify(1)`, `ldapsearch(1)`, `dd(1M)`, `smbadm(1M)`, `kadm5.acl(4)`, `krb5.conf(4)`, `nfssec.conf(4)`, `pam.conf(4)`, `resolv.conf(4)`, `attributes(5)`, `pam_krb5(5)`

Notes `fqn` stands for the Fully Qualified Domain Name of the local host. The `kclient` utility saves copies of both the `krb5.conf(4)` and `nfssec.conf(4)` files to files with corresponding names and `.sav` extensions. The optional copy of the `krb5.conf(4)` master file is neither encrypted nor integrity-protected and it takes place over regular NFS.

-
- Name** kdb5_ldap_util – Kerberos configuration utility
- Synopsis** kdb5_ldap_util [-D *user_dn* [-w *passwd*]] [-H *ldap_uri*] *command*
[*command_options*]
- Description** The kdb5_ldap_util utility allows an administrator to manage realms, Kerberos services, and ticket policies. The utility offers a set of general options, described under OPTIONS, and a set of commands, which, in turn, have their own options. Commands and their options are described in their own subsections, below.
- Options** kdb5_ldap_util has a small set of general options that apply to the kdb5_ldap_util utility itself and a larger number of options that apply to specific commands. A number of these command-specific options apply to multiple commands and are described in their own section, below.
- General Options** The following general options are supported:
- D *user_dn*
Specifies the distinguished name (DN) of a user who has sufficient rights to perform the operation on the LDAP server.
 - H *ldap_uri*
Specifies the URI of the LDAP server.
 - w *passwd*
Specifies the password of *user_dn*. This option is not recommended.
- Common Command-specific Options** The following options apply to a number of kdb5_ldap_util commands.
- subtrees *subtree_dn_list*
Specifies the list of subtrees containing the principals of a realm. The list contains the DNs of the subtree objects separated by a colon.
 - sscope *search_scope*
Specifies the scope for searching the principals under a subtree. The possible values are 1 or one (one level), 2 or sub (subtrees).
 - containerref *container_reference_dn*
Specifies the DN of the container object in which the principals of a realm will be created. If the container reference is not configured for a realm, the principals will be created in the realm container.
 - maxttl *max_ticket_life*
Specifies maximum ticket life for principals in this realm.
 - maxrenewlife *max_renewable_ticket_life*
Specifies maximum renewable life of tickets for principals in this realm.
 - r *realm*
Specifies the Kerberos realm of the database; by default the realm returned by krb5_default_local_realm(3) is used.

kdb5_ldap_util Commands The `kdb5_ldap_util` utility comprises a set of commands, each with its own set of options. These commands are described in the following subsections.

The `create` Command The `create` command creates a realm in a directory. The command has the following syntax:

```
create \
[-subtrees subtree_dn_list]
[-sscope search_scope]
[-containerref container_reference_dn]
[-k mkeytype]
[-m|-P password] -sf stashfilename]
[-s]
[-r realm]
[-maxtktlife max_ticket_life]
[-kdcdn kdc_service_list]
[-admin dn admin_service_list]
[-maxrenewlife max_renewable_ticket_life]
[ticket_flags]
```

The `create` command has the following options:

- subtree *subtree_dn_list*
See “Common Command-specific Options,” above.
- sscope *search_scope*
See “Common Command-specific Options,” above.
- containerref *container_reference_dn*
See “Common Command-specific Options,” above.
- k *mkeytype*
Specifies the key type of the master key in the database; the default is that given in `kdc.conf(4)`.
- m
Specifies that the master database password should be read from the TTY rather than fetched from a file on the disk.
- P *password*
Specifies the master database password. This option is not recommended.
- sf *stashfilename*
Specifies the stash file of the master database password.
- s
Specifies that the stash file is to be created.
- maxtktlife *max_ticket_life*
See “Common Command-specific Options,” above.
- maxrenewlife *max_renewable_ticket_life*
See “Common Command-specific Options,” above.

-r realm
See “Common Command-specific Options,” above.

ticket_flags

Specifies the ticket flags. If this option is not specified, by default, none of the flags are set. This means all the ticket options will be allowed and no restriction will be set. See “Ticket Flags” for a list and descriptions of these flags.

The `modify` Command The `modify` command modifies the attributes of a realm. The command has the following syntax:

```
modify \
[-subtrees subtree_dn_list]
[-sscope search_scope]
[-containerref container_reference_dn]
[-r realm]
[-maxtktlife max_ticket_life]
[-maxrenewlife max_renewable_ticket_life]
[ticket_flags]
```

The `modify` command has the following options:

-subtree subtree_dn_list
See “Common Command-specific Options,” above.

-sscope search_scope
See “Common Command-specific Options,” above.

-containerref container_reference_dn
See “Common Command-specific Options,” above.

-maxtktlife max_ticket_life
See “Common Command-specific Options,” above.

-maxrenewlife max_renewable_ticket_life
See “Common Command-specific Options,” above.

-r realm
See “Common Command-specific Options,” above.

ticket_flags

Specifies the ticket flags. If this option is not specified, by default, none of the flags are set. This means all the ticket options will be allowed and no restriction will be set. See “Ticket Flags” for a list and descriptions of these flags.

The `view` Command The `view` command displays the attributes of a realm. The command has the following syntax:

```
view [-r realm]
```

The `view` command has the following option:

-r realm

See “Common Command-specific Options,” above.

The `destroy` Command The `destroy` command destroys a realm, including the master key stash file. The command has the following syntax:

```
destroy [-f] [-r realm]
```

The `destroy` command has the following options:

-f

If specified, `destroy` does not prompt you for confirmation.

-r realm

See “Common Command-specific Options,” above.

The `list` Command The `list` command displays the names of realms. The command has the following syntax:

```
list
```

The `list` command has no options.

The `stashesrvpw` Command The `stashesrvpw` command enables you to store the password for service object in a file so that a KDC and Administration server can use it to authenticate to the LDAP server. The command has the following syntax:

```
stashesrvpw [-f filename] servicedn
```

The `stashesrvpw` command has the following option and argument:

-f filename

Specifies the complete path of the service password file. The default is:

```
/var/krb5/service_passwd
```

servicedn

Specifies the distinguished name (DN) of the service object whose password is to be stored in file.

The `create_policy` Command The `create_policy` command creates a ticket policy in a directory. The command has the following syntax:

```
create_policy \  
[-r realm]  
[-maxtktlife max_ticket_life]  
[-maxrenewlife max_renewable_ticket_life]  
[ticket_flags]  
policy_name
```

The `create_policy` command has the following options:

-r realm

See “Common Command-specific Options,” above.

`-maxttl` *max_ticket_life*

See “Common Command-specific Options,” above.

`-maxrenewlife` *max_renewable_ticket_life*

See “Common Command-specific Options,” above.

ticket_flags

Specifies the ticket flags. If this option is not specified, by default, none of the flags are set.

This means all the ticket options will be allowed and no restriction will be set. See “Ticket Flags” for a list and descriptions of these flags.

policy_name

Specifies the name of the ticket policy.

The `modify_policy` Command The `modify_policy` command modifies the attributes of a ticket policy. The command has the following syntax:

```
modify_policy \
[-r realm]
[-maxttl max_ticket_life]
[-maxrenewlife max_renewable_ticket_life]
[ticket_flags]
policy_name
```

The `modify_policy` command has the same options and argument as those for the `create_policy` command.

The `view_policy` Command The `view_policy` command displays the attributes of a ticket policy. The command has the following syntax:

```
view_policy [-r realm] policy_name
```

The `view_policy` command has the following options:

`-r` *realm*

See “Common Command-specific Options,” above.

policy_name

Specifies the name of the ticket policy.

The `destroy_policy` Command The `destroy_policy` command destroys an existing ticket policy. The command has the following syntax:

```
destroy_policy [-r realm] [-force] policy_name
```

The `destroy_policy` command has the following options:

`-r` *realm*

See “Common Command-specific Options,” above.

-force

Forces the deletion of the policy object. If not specified, you will be prompted for confirmation before the policy is deleted. Enter yes to confirm the deletion.

policy_name

Specifies the name of the ticket policy.

The `list_policy` Command The `list_policy` command lists the ticket policies in the default or a specified realm. The command has the following syntax:

```
list_policy [-r realm]
```

The `list_policy` command has the following option:

-r *realm*

See “Common Command-specific Options,” above.

Ticket Flags A number of `kdb5_ldap_util` commands have `ticket_flag` options. These flags are described as follows:

{-|+}allow_dup_skey

-allow_dup_skey disables user-to-user authentication for principals by prohibiting principals from obtaining a session key for another user. This setting sets the `KRB5_KDB_DISALLOW_DUP_SKEY` flag. +allow_dup_skey clears this flag.

{-|+}allow_forwardable

-allow_forwardable prohibits principals from obtaining forwardable tickets. This setting sets the `KRB5_KDB_DISALLOW_FORWARDABLE` flag. +allow_forwardable clears this flag.

{-|+}allow_postdated

-allow_postdated prohibits principals from obtaining postdated tickets. This setting sets the `KRB5_KDB_DISALLOW_POSTDATED` flag. +allow_postdated clears this flag.

{-|+}allow_proxiable

-allow_proxiable prohibits principals from obtaining proxiable tickets. This setting sets the `KRB5_KDB_DISALLOW_PROXIABLE` flag. +allow_proxiable clears this flag.

{-|+}allow_renewable

-allow_renewable prohibits principals from obtaining renewable tickets. This setting sets the `KRB5_KDB_DISALLOW_RENEWABLE` flag. +allow_renewable clears this flag.

{-|+}allow_svr

-allow_svr prohibits the issuance of service tickets for principals. This setting sets the `KRB5_KDB_DISALLOW_SVR` flag. +allow_svr clears this flag.

{-|+}allow_tgs_req

-allow_tgs_req specifies that a Ticket-Granting Service (TGS) request for a service ticket for principals is not permitted. This option is useless for most purposes. +allow_tgs_req clears this flag. The default is +allow_tgs_req. In effect, -allow_tgs_req sets the `KRB5_KDB_DISALLOW_TGT_BASED` flag on principals in the database.

`{- |+}allow_tix`
`-allow_tix` forbids the issuance of any tickets for principals. `+allow_tix` clears this flag. The default is `+allow_tix`. In effect, `-allow_tix` sets the `KRB5_KDB_DISALLOW_ALL_TIX` flag on principals in the database.

`{- |+}needchange`
`+needchange` sets a flag in the attributes field to force a password change; `-needchange` clears that flag. The default is `-needchange`. In effect, `+needchange` sets the `KRB5_KDB_REQUIRES_PWCHANGE` flag on principals in the database.

`{- |+}password_changing_service`
`+password_changing_service` sets a flag in the attributes field marking a principal as a password-change-service principal (a designation that is most often not useful).
`-password_changing_service` clears the flag. That this flag has a long name is intentional. The default is `-password_changing_service`. In effect, `+password_changing_service` sets the `KRB5_KDB_PWCHANGE_SERVICE` flag on principals in the database.

`{- |+}requires_hwauth`
`+requires_hwauth` requires principals to preauthenticate using a hardware device before being allowed to `kinit(1)`. This setting sets the `KRB5_KDB_REQUIRES_HW_AUTH` flag.
`-requires_hwauth` clears this flag.

`{- |+}requires_preauth`
`+requires_preauth` requires principals to preauthenticate before being allowed to `kinit(1)`. This setting sets the `KRB5_KDB_REQUIRES_PRE_AUTH` flag. `-requires_preauth` clears this flag.

Examples EXAMPLE 1 Using create

The following is an example of the use of the create command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
create -subtrees o=org -sscope SUB -r ATHENA.MIT.EDU
Password for "cn=admin,o=org": password entered
Initializing database for realm 'ATHENA.MIT.EDU'
You will be prompted for the database Master Password.
It is important that you NOT FORGET this password.
Enter KDC database master key: master key entered
Re-enter KDC database master key to verify: master key re-enteredjjjjjj
```

EXAMPLE 2 Using modify

The following is an example of the use of the modify command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
modify +requires_preauth -r ATHENA.MIT.EDU
Password for "cn=admin,o=org": password entered
Password for "cn=admin,o=org": password entered
```

EXAMPLE 3 Using view

The following is an example of the use of the view command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
view -r ATHENA.MIT.EDU
    Password for "cn=admin,o=org":
                Realm Name: ATHENA.MIT.EDU
                Subtree: ou=users,o=org
                Subtree: ou=servers,o=org
                SearchScope: ONE
                Maximum ticket life: 0 days 01:00:00
                Maximum renewable life: 0 days 10:00:00
                Ticket flags: DISALLOW_FORWARDABLE REQUIRES_PWCHANGE
```

EXAMPLE 4 Using destroy

The following is an example of the use of the destroy command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
destroy -r ATHENA.MIT.EDU
Password for "cn=admin,o=org": password entered
Deleting KDC database of 'ATHENA.MIT.EDU', are you sure?
(type 'yes' to confirm)? yes
OK, deleting database of 'ATHENA.MIT.EDU'...
```

EXAMPLE 5 Using list

The following is an example of the use of the list command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu list
Password for "cn=admin,o=org": password entered
Re-enter Password for "cn=admin,o=org": password re-entered
ATHENA.MIT.EDU
OPENLDAP.MIT.EDU
MEDIA-LAB.MIT.EDU
```

EXAMPLE 6 Using stashesrvpw

The following is an example of the use of the stashesrvpw command.

```
# kdb5_ldap_util stashesrvpw -f \
/home/andrew/conf_keyfile cn=service-kdc,o=org
Password for "cn=service-kdc,o=org": password entered
Re-enter password for "cn=service-kdc,o=org": password re-entered
```

EXAMPLE 7 Using create_policy

The following is an example of the use of the create_policy command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
create_policy -r ATHENA.MIT.EDU \
-maxtktlife "1 day" -maxrenewLife "1 week" \
```

EXAMPLE 7 Using `create_policy` (Continued)

```
-allow_postdated +needchange -allow_forwardable tktpolicy
Password for "cn=admin,o=org": password entered
```

EXAMPLE 8 Using `modify_policy`

The following is an example of the use of the `modify_policy` command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
modify_policy -r ATHENA.MIT.EDU \
-maxtktlife "60 minutes" -maxrenewlife "10 hours" \
+allow_postdated -requires_preauth tktpolicy
Password for "cn=admin,o=org": password entered
```

EXAMPLE 9 Using `view_policy`

The following is an example of the use of the `view_policy` command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
view_policy -r ATHENA.MIT.EDU tktpolicy
Password for "cn=admin,o=org": password entered
    Ticket policy: tktpolicy
    Maximum ticket life: 0 days 01:00:00
    Maximum renewable life: 0 days 10:00:00
    Ticket flags: DISALLOW_FORWARDABLE REQUIRES_PWCHANGE
```

EXAMPLE 10 Using `destroy_policy`

The following is an example of the use of the `destroy_policy` command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
destroy_policy -r ATHENA.MIT.EDU tktpolicy
Password for "cn=admin,o=org": password entered
This will delete the policy object 'tktpolicy', are you sure?
(type 'yes' to confirm)? yes
** policy object 'tktpolicy' deleted.
```

EXAMPLE 11 Using `list_policy`

The following is an example of the use of the `list_policy` command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
list_policy -r ATHENA.MIT.EDU
Password for "cn=admin,o=org": password entered
tktpolicy
tmpolicy
userpolicy
```

EXAMPLE 12 Using `setsrvpw`

The following is an example of the use of the `setsrvpw` command.

EXAMPLE 12 Using `setsrvpw` (Continued)

```
# kdb5_ldap_util setsrvpw -D cn=admin,o=org setsrvpw \
-fileonly -f /home/andrew/conf_keyfile cn=service-kdc,o=org
Password for "cn=admin,o=org": password entered
Password for "cn=service-kdc,o=org": password entered
Re-enter password for "cn=service-kdc,o=org": password re-entered
```

EXAMPLE 13 Using `create_service`

The following is an example of the use of the `create_service` command.

```
# kdb5_ldap_util -D cn=admin,o=org create_service \
-kdc -randpw -f /home/andrew/conf_keyfile cn=service-kdc,o=org
Password for "cn=admin,o=org": password entered
File does not exist. Creating the file /home/andrew/conf_keyfile...
```

EXAMPLE 14 Using `modify_service`

The following is an example of the use of the `modify_service` command.

```
# kdb5_ldap_util -D cn=admin,o=org modify_service \
-realm ATHENA.MIT.EDU cn=service-kdc,o=org
Password for "cn=admin,o=org": password entered
Changing rights for the service object. Please wait ... done
```

EXAMPLE 15 Using `view_service`

The following is an example of the use of the `view_service` command.

```
# kdb5_ldap_util -D cn=admin,o=org view_service \
cn=service-kdc,o=org
Password for "cn=admin,o=org": password entered
      Service dn: cn=service-kdc,o=org
      Service type: kdc
      Service host list:
      Realm DN list: cn=ATHENA.MIT.EDU,cn=Kerberos,cn=Security
```

EXAMPLE 16 Using `destroy_service`

The following is an example of the use of the `destroy_service` command.

```
# kdb5_ldap_util -D cn=admin,o=org destroy_service \
cn=service-kdc,o=org
Password for "cn=admin,o=org": password entered
This will delete the service object 'cn=service-kdc,o=org', are you sure?
(type 'yes' to confirm)? yes
** service object 'cn=service-kdc,o=org' deleted.
```

EXAMPLE 17 Using `list_service`

The following is an example of the use of the `list_service` command.

EXAMPLE 17 Using `list_service` (Continued)

```
# kdb5_ldap_util -D cn=admin,o=org list_service
Password for "cn=admin,o=org": password entered
cn=service-kdc,o=org
cn=service-adm,o=org
cn=service-pwd,o=org
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------------------|
| Availability | service/security/kerberos-5 |
| Interface Stability | Volatile |

See Also [kinit\(1\)](#), [kadmin\(1M\)](#), [kdc.conf\(4\)](#), [attributes\(5\)](#)

Name kdb5_util – Kerberos Database maintenance utility

Synopsis /usr/sbin/kdb5_util [-d *dbname*] [-f *stashfile_name*]
[-k *mkeytype*] [-m] [-M *mkeyname*] [-P *password*] [-r *realm*]
[-x *db_args*]... *cmd*

Description The `kdb5_util` utility enables you to create, dump, load, and destroy the Kerberos V5 database. You can also use `kdb5_util` to create a stash file containing the Kerberos database master key.

Options The following options are supported:

-d *dbname*

Specify the database name. `.db` is appended to whatever name is specified. You can specify an absolute path. If you do not specify the `-d` option, the default database name is `/var/krb5/principal`.

-f *stashfile_name*

Specify the stash file name. You can specify an absolute path.

-k *mkeytype*

Specify the master key type. Valid values are `des3-cbc-sha1`, `des-cbc-crc`, `des-cbc-md5`, `des-cbc-raw`, `arcfour-hmac-md5`, `arcfour-hmac-md5-exp`, `aes128-cts-hmac-sha1-96`, and `aes256-cts-hmac-sha1-96`.

-m

Enter the master key manually.

-M *mkeyname*

Specify the master key name.

-P *password*

Use the specified *password* instead of the stash file.

-r *realm*

Use *realm* as the default database realm.

-x *db_args*

Pass database-specific arguments to `kadmin`. Supported arguments are for LDAP and the Berkeley-db2 plug-in. These arguments are:

`binddn=binddn`

LDAP simple bind DN for authorization on the directory server. Overrides the `ldap_kadmin_dn` parameter setting in `krb5.conf(4)`.

`bindpwd=bindpwd`

Bind password.

`dbname=name`

For the Berkeley-db2 plug-in, specifies a name for the Kerberos database.

`nconns=num`

Maximum number of server connections.

`port=num`

Directory server connection port.

Operands The following operands are supported:

cmd

Specifies whether to create, destroy, dump, or load the database, or to create a stash file.

You can specify the following commands:

`create -s`

Creates the database specified by the `-d` option. You will be prompted for the database master password. If you specify `-s`, a stash file is created as specified by the `-f` option. If you did not specify `-f`, the default stash file name is `/var/krb5/.k5.realm`. If you use the `-f`, `-k`, or `-M` options when you create a database, then you must use the same options when modifying or destroying the database.

`destroy`

Destroys the database specified by the `-d` option.

`stash`

Creates a stash file. If `-f` was not specified, the default stash file name is `/var/krb5/.k5.realm`. You will be prompted for the master database password. This command is useful when you want to generate the stash file from the password.

`dump [-old] [-b6] [-b7] [-ov] [-verbose] [-mkey_convert] [-new_mkey_file mkey_file] [-rev] [-recurse] [filename [principals...]]`

Dumps the current Kerberos and KADM5 database into an ASCII file. By default, the database is dumped in current format, “`kdb5_util load_dumpversion 5`”. If *filename* is not specified or is the string “-”, the dump is sent to standard output. Options are as follows:

`-old`

Causes the dump to be in the Kerberos 5 Beta 5 and earlier dump format (“`kdb5_edit load_dump version 2.0`”).

`-b6`

Causes the dump to be in the Kerberos 5 Beta 6 format (“`kdb5_edit load_dump version 3.0`”).

`-b7`

Causes the dump to be in the Kerberos 5 Beta 7 format (“`kdb5_util load_dump version 4`”). This was the dump format produced on releases prior to 1.2.2.

`-ov`

Causes the dump to be in `ovsec_adm_export` format.

-verbose

Causes the name of each principal and policy to be displayed as it is dumped.

-mkey_convert

Prompts for a new master key. This new master key will be used to re-encrypt the key data in the dumpfile. The key data in the database will not be changed.

-new_mkey_file *mkey_file*

The filename of a stash file. The master key in this stash file will be used to re-encrypt the key data in the dumpfile. The key data in the database will not be changed.

-rev

Dumps in reverse order. This might recover principals that do not dump normally, in cases where database corruption has occurred.

-recurse

Causes the dump to walk the database recursively (bt ree only). This might recover principals that do not dump normally, in cases where database corruption has occurred. In cases of such corruption, this option will probably retrieve more principals than will the -rev option.

load [-old] [-b6] [-b7] [-ov] [-hash] [-verbose] [-update] *filename dbname*
[*admin_dbname*]

Loads a database dump from *filename* into *dbname*. Unless the -old or -b6 option is specified, the format of the dump file is detected automatically and handled appropriately. Unless the -update option is specified, load creates a new database containing only the principals in the dump file, overwriting the contents of any existing database. The -old option requires the database to be in the Kerberos 5 Beta 5 or earlier format (“kdb5_edit load_dump version 2.0”).

-b6

Requires the database to be in the Kerberos 5 Beta 6 format (“kdb5_edit load_dump version 3.0”).

-b7

Requires the database to be in the Kerberos 5 Beta 7 format (“kdb5_util load_dump version 4”).

-ov

Requires the database to be in ovsec_adm_import format. Must be used with the -update option.

-hash

Requires the database to be stored as a hash. If this option is not specified, the database will be stored as a bt ree. This option is not recommended, as databases stored in hash format are known to corrupt data and lose principals.

-verbose

Causes the name of each principal and policy to be displayed as it is dumped.

-update

Records from the dump file are added to or updated in the existing database. Otherwise, a new database is created containing only what is in the dump file and the old one is destroyed upon successful completion.

filename

Required argument that specifies a path to a file containing database dump.

dbname

Required argument that overrides the value specified on the command line or overrides the default.

admin_dbname

Optional argument that is derived from *dbname* if not specified.

Examples EXAMPLE 1 Creating File that Contains Information about Two Principals

The following example creates a file named `slavedata` that contains the information about two principals, `jdb@ACME.COM` and `pak@ACME.COM`.

```
# /usr/krb5/bin/kdb5_util dump -verbose slavedata
jdb@ACME.COM pak@ACME.COM
```

Files /var/krb5/principal

Kerberos principal database.

/var/krb5/principal.kadm5

Kerberos administrative database. Contains policy information.

/var/krb5/principal.kadm5.lock

Lock file for the Kerberos administrative database. This file works backwards from most other lock files (that is, `kadmin` exits with an error if this file does not exist).

/var/krb5/principal.uolog

The update log file for incremental propagation.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------------|
| Availability | system/security/kerberos-5 |
| Interface Stability | Committed |

See Also [kpasswd\(1\)](#), [gkadmin\(1M\)](#), [kadmin\(1M\)](#), [kadmin\(1M\)](#), [kadmin.local\(1M\)](#), [kdb5_ldap_util\(1M\)](#), [kproplog\(1M\)](#), [kadm5.acl\(4\)](#), [kdc.conf\(4\)](#), [attributes\(5\)](#), [kerberos\(5\)](#)

Name kdcmgr – set up a Kerberos Key Distribution Center (KDC)

Synopsis /usr/sbin/kdcmgr [-a *admprincipal*] [-e *enctype*]
[-h] [-p *pwfile*] [-r *realm*] *subcommand*

Description Use the kdcmgr utility to do the following:

- Configure a master Key Distribution Center (KDC) server.
- Configure a slave KDC. This assumes that a master KDC has already been configured. The default propagation method configured is incremental propagation. See [kpropd\(1M\)](#).
- Specify a list of slave KDCs to configure service principals and create access control list for those slaves on the master KDC.

If you specify no options, kdcmgr prompts you for required information, including a password to generate the master key and a password for the administrative principal. When you specify sufficient options, you are still prompted for these passwords, unless you specified the -p *pwfile* option.

The kdcmgr utility must be run as superuser or by someone who has the Primary Administrator role. The command must be run on the server from which it is invoked.

Note that kdcmgr requires the user to enter sensitive information, such as the password used to generate the database's master key and the password for the administrative principal. Great care must be taken to ensure that the connection to the server is secured over the network, by using a protocol such as [ssh\(1\)](#).

You must also exercise great care when selecting the administrative and master key passwords. They should be derived from non-dictionary words and a long string of characters consisting of all of the following character classes:

- special characters (for example, !@#\$%^&*)
- numerals (0-9)
- uppercase letters
- lowercase letters

Options The following options are supported:

-a *admprincipal*

When creating a master KDC, specifies the administrative principal, *admprincipal*, that will be created.

When creating a slave KDC, *admprincipal* is used to authenticate as the administrative principal.

If you omit -a, the suggested default administrative principal name is the output of [logname\(1\)](#) appended by /admin.

-e *enctype*

Specifies the encryption type to be used when creating the key for the master key, which is used to encrypt all principal keys in the database. The set of valid encryption types used here are described in [krb5.conf\(4\)](#) under the `permitted_encypes` option. Note that the encryption type specified here must be supported on all KDCs or else they will not be able to decrypt any of the principal keys. Solaris 9 and earlier releases support only the `des-cbc-crc` encryption type for the master key. Therefore, if any of the master or slave KDCs are of these older releases, then `-e des-cbc-crc` would need to be specified on all KDCs configured with `kdcmgr`.

The default encryption type is `aes128-cts-hmac-sha1-96`.

-h

Displays usage information for `kdcmgr`.

-p *pwfile*

Provides the location of the password file that contains the password used to create the administrative principal and/or master key.

Warning: This option should be used with great care. Make sure that this *pwfile* is accessible only by a privileged user and on a local file system. Once the KDC has been configured, you should remove *pwfile*.

-r *realm*

Set the default realm for this server.

If the `-r` option is not specified, `kdcmgr` attempts to obtain the machine's local domain name by submitting the canonical form of the machine's host name to DNS and using the return value to derive the domain name. If successful, the domain name is converted to uppercase and proposed as the default realm name.

Subcommands The following subcommands are supported:

`create [master]`

`create [-m masterkdc] slave`

Creates a KDC. If no option is specified, an attempt to create a master KDC is made.

`create [master]`

Create a master KDC. Upon successful configuration the [krb5kdc\(1M\)](#) and [kadmind\(1M\)](#) are enabled on the machine.

`create [-m masterkdc] slave`

Configures a slave KDC. After configuration, the [krb5kdc\(1M\)](#) and [kpropd\(1M\)](#) services are enabled on the machine.

masterkdc specifies the master KDC to authenticate and with which to perform administrative tasks. If the `-m` option is not specified, you are prompted for a master KDC host name.

destroy

Remove all Kerberos configuration and database files associated with the KDC server. A confirmation is required before these files are deleted.

status

Determines the role of the KDC, master or slave, and outputs this and the state of such associated processes as:

- [krb5kdc\(1M\)](#)
- [kadmind\(1M\)](#)
- [kpropd\(1M\)](#)

The subcommand also displays information on incremental propagation if the configuration has this feature enabled, as well as any issues with dependent files.

Examples EXAMPLE 1 Setting up a Master KDC

The following command configures a master KDC with the administrative principal `user1/admin` and with the realm name `EXAMPLE.COM`:

```
$ kdcmgr -a user1/admin -r EXAMPLE.COM create
```

Note that a password will be required to assign to the newly created `user1/admin` principal. The password for the master key will also need to be provided.

EXAMPLE 2 Setting up a Slave KDC

The following command configures a slave KDC, authenticates with the administrative principal `user1/admin`, specifies `kdc1` as the master, and uses the `EXAMPLE.COM` realm name:

```
$ kdcmgr -a user1/admin -r EXAMPLE.COM create -m kdc1 slave
```

Note that you must enter the correct password for `user1/admin` and that the master KDC must already have been created before entering this command. The correct password for the master key is also required.

Files `/etc/krb5/krb5.conf`
Main Kerberos configuration file.

`/etc/krb5/kdc.conf`
KDC configuration, used by both master and slave servers.

`/etc/krb5/krb5.keytab`
Default location of the local host's service keys.

`/etc/krb5/kadm5.acl`
Kerberos administrative access control list (ACL).

`/etc/krb5/kadm5.keytab`
Service keys specific to [kadmind\(1M\)](#).

`/var/krb5/principal`
Kerberos principal database.

`/var/krb5/principal.kadm5`
Kerberos policy database.

`/etc/krb5/kpropd.acl`
Used by slaves to indicate from which server to receive updates.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------------|
| Availability | system/security/kerberos-5 |
| Interface Stability | See below |

The command line interface (CLI) is Uncommitted. The CLI output is Not an Interface.

See Also [logname\(1\)](#), [ssh\(1\)](#), [kadmin\(1M\)](#), [kadmind\(1M\)](#), [kdb5_util\(1M\)](#), [kdb5_ldap_util\(1M\)](#), [kpropd\(1M\)](#), [krb5kdc\(1M\)](#), [ping\(1M\)](#), [svcadm\(1M\)](#), [kdc.conf\(4\)](#), [krb5.conf\(4\)](#), [attributes\(5\)](#)

Name kernel – UNIX system executable file containing basic operating system services

Synopsis kernel-name [-asrvx] [-m *smf_options*] [-i *altinit*]

Description The operating system image, or kernel, is the collection of software comprising the image files (`unix` and `genunix`) and the modules loaded at any instant in time. The system will not function without a kernel to control it.

The kernel is loaded by the [boot\(1M\)](#) command in a machine-specific way. The kernel may be loaded from disk, CD-ROM, or DVD (`diskfull boot`) or over the network (`diskless boot`). In either case, the directories under `/platform` and `/kernel` must be readable and must contain executable code which is able to perform the required kernel service. If the `-a` flag is given, the user is able to supply different pathnames for the default locations of the kernel and modules. See [boot\(1M\)](#) for more information on loading a specific kernel.

The `moddir` variable contains a list of module directories separated by whitespace. `moddir` can be set in the `/etc/system` file. The minimal default is:

```
/platform/platform-name/kernel /kernel /usr/kernel
```

This default can be supplemented by a specific platform. It is common for many SPARC systems to override the default path with:

```
/platform/platform-name/kernel:/platform/hardware-class-name\  
/kernel:/kernel:/usr/kernel
```

where *platform-name* can be found using the `-i` option of [uname\(1\)](#), and *hardware-class-name* can be found using the `-m` option of [uname\(1\)](#).

The kernel configuration can be controlled using the `/etc/system` file (see [system\(4\)](#)).

`genunix` is the platform-independent component of the base kernel.

Options The following options are supported:

`-a`

Asks the user for configuration information, such as where to find the system file, where to mount root, and even override the name of the kernel itself. Default responses will be contained in square brackets ([]), and the user may simply enter RETURN to use the default response (note that RETURN is labeled ENTER on some keyboards). To help repair a damaged `/etc/system` file, enter `/dev/null` at the prompt that asks for the pathname of the system configuration file. See [system\(4\)](#).

`-i altinit`

Select an alternative executable to be the primordial process. *altinit* must be a valid path to an executable. The default primordial process is [init\(1M\)](#).

`-m smf_options`

The *smf_options* include two categories of options to control booting behavior of the service management facility: recovery options and messages options.

Message options determine the type and amount of messages that [smf\(5\)](#) displays during boot. Service options determine the services which are used to boot the system.

Recovery options

debug

Prints standard per-service output and all `svc.startd` messages to log.

milestone=[milestone]

Boot with some SMF services temporarily disabled, as indicated by *milestone*. *milestone* can be “none”, “single-user”, “multi-user”, “multi-user-server”, or “all”. See the `milestone` subcommand of [svcadm\(1M\)](#).

Messages options

quiet

Prints standard per-service output and error messages requiring administrative intervention.

verbose

Prints standard per-service output with more informational messages.

-r

Reconfiguration boot. The system will probe all attached hardware devices and configure the logical namespace in `/dev`. See [add_drv\(1M\)](#) and [rem_drv\(1M\)](#) for additional information about maintaining device drivers.

-s

Boots only to init level 's'. See [init\(1M\)](#).

-v

Boots with verbose messages enabled. If this flag is not given, the messages are still printed, but the output is directed to the system logfile. See [syslogd\(1M\)](#).

-x

Does not boot in clustered mode. This option only has an effect when a version of Sun Cluster software that supports this option has been installed.

Examples See [boot\(1M\)](#) for examples and instructions on how to boot.

Files /kernel

Contains kernel components common to all platforms within a particular instruction set that are needed for booting the system. of the core image file.

/platform/*platform-name*/kernel

The platform-specific kernel components.

/platform/*hardware-class-name*/kernel

The kernel components specific to this hardware class.

/usr/kernel

Contains kernel components common to all platforms within a particular instruction set.

The directories in this section can potentially contain the following subdirectories:

drv

Loadable device drivers

exec

The modules that execute programs stored in various file formats.

fs

File system modules

misc

Miscellaneous system-related modules

sched

Operating system schedulers

strmod

System V STREAMS loadable modules

sys

Loadable system calls

SPARC cpu

Processor specific modules

tod

Time-Of-Day hardware interface modules

As only 64-bit SPARC platforms are supported, all SPARC executable modules are contained within `sparcv9` directories in the directories listed above.

x86 mach

x86 hardware support

Modules comprising the 32-bit x86 kernel are contained in the above directories, with the 64-bit x86 kernel components contained within `amd64` subdirectories.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------------------------------------------|
| Availability | system/library/processor, system/library/processorx |

See Also [kmdb\(1\)](#), [uname\(1\)](#), [isainfo\(1\)](#), [add_drv\(1M\)](#), [boot\(1M\)](#), [init\(1M\)](#), [rem_drv\(1M\)](#), [savecore\(1M\)](#), [svc.startd\(1M\)](#), [svcadm\(1M\)](#), [syslogd\(1M\)](#), [system\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#), [devfs\(7FS\)](#)

SPARC Only `monitor(1M)`

Diagnostics The kernel gives various warnings and error messages. If the kernel detects an unrecoverable fault, it will panic or halt.

Notes Reconfiguration boot will, by design, not remove /dev entries for some classes of devices that have been physically removed from the system.

Name keyserv – server for storing private encryption keys

Synopsis keyserv [-c] [-d | -e] [-D] [-n] [-s *sizespec*]

Description keyserv is a daemon that is used for storing the private encryption keys of each user logged into the system. These encryption keys are used for accessing secure network services such as secure NFS.

Normally, root's key is read from the file `/etc/.rootkey` when the daemon is started. This is useful during power-fail reboots when no one is around to type a password.

keyserv does not start up if the system does not have a secure rpc domain configured. Set up the domain name by using the `/usr/bin/domainname` command. Usually the `svc:/system/identity:domain` service reads the domain from `/etc/defaultdomain`. Invoking the `domainname` command without arguments tells you if you have a domain set up.

The `/etc/default/keyserv` file contains the following default parameter settings. See [Files](#).

`ENABLE_NOBODY_KEYS` Specifies whether default keys for nobody are used.
`ENABLE_NOBODY_KEYS=NO` is equivalent to the `-d` command-line option. The default value for `ENABLE_NOBODY_KEYS` is `YES`.

Options The following options are supported:

- c Do not use disk caches. This option overrides any `-s` option.
- D Run in debugging mode and log all requests to keyserv.
- d Disable the use of default keys for nobody. See [Files](#).
- e Enable the use of default keys for nobody. This is the default behavior. See [Files](#).
- n Root's secret key is not read from `/etc/.rootkey`. Instead, keyserv prompts the user for the password to decrypt root's key stored in the `publickey` database and then stores the decrypted key in `/etc/.rootkey` for future use. This option is useful if the `/etc/.rootkey` file ever gets out of date or corrupted.
- s *sizespec* Specify the size of the extended Diffie-Hellman common key disk caches. The *sizespec* can be one of the following forms:
 - mechtype=size* *size* is an integer specifying the maximum number of entries in the cache, or an integer immediately followed by the letter *M*, denoting the maximum size in MB.
 - size* This form of *sizespec* applies to all caches.

Note that the `des` mechanism, `AUTH_DES`, does not use a disk cache.

Files /etc/.rootkey

/etc/default/keyserv Contains default settings. You can use command-line options to override these settings.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [keylogin\(1\)](#), [svcs\(1\)](#), [keylogout\(1\)](#), [svcadm\(1M\)](#), [publickey\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Notes The keyserv service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/rpc/keyserv:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Name killall – kill all active processes

Synopsis /usr/sbin/killall [*signal*]

Description killall is used by [shutdown\(1M\)](#) to kill all active processes not directly related to the shutdown procedure.

killall terminates all processes with open files so that the mounted file systems will be unbusy and can be unmounted.

killall sends *signal* (see [kill\(1\)](#)) to the active processes. If no *signal* is specified, a default of 15 is used.

The killall command can be run only by the super-user.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [kill\(1\)](#), [ps\(1\)](#), [fuser\(1M\)](#), [shutdown\(1M\)](#), [signal\(3C\)](#), [attributes\(5\)](#)

Name kmscfg – configure the PKCS#11 KMS provider

Synopsis kmscfg

```
kmscfg -p[rofile] Profile_Name
kmscfg -a[gent] Agent_ID
kmscfg -i[paddr] Agent_Address
kmscfg -t[imeout] Transaction_Timeout
kmscfg -f[ailover] Failover_Limit
kmscfg -d[iscovery] Discovery_Freq
```

Description The `kmscfg` command is used to initialize a PKCS#11 KMS provider (`pkcs11_kms`) for use with the Solaris Cryptographic Framework. In order for the KMS provider to communicate with the KMS, it must have some configuration information available. This configuration data contains information such as the name of the profile to be used, the name of the KMS Agent, the IP address of the KMS server, and some other parameters (see SYNOPSIS).

By default, `kmscfg` stores the configuration information in `/var/kms/$USERNAME`. This directory will be created if it is not already present. If the configuration is already detected, the user will be given the option to override the existing data. The default location can be overridden by using the `KMSTOKEN_DIR` environment variable, which must be set prior to invoking `kmscfg`.

Prior to running `kmscfg`, the KMS administrator must have performed the required initialization and configuration steps on the KMS itself to setup the individual Profiles and Agents that PKCS11 KMS consumers will use. The instructions for configuring a KMS are available in the *KMS 2.2 Administration Guide* (<http://docs.sun.com/app/docs/doc/316195103AA>).

Once the administrator has configured the KMS, the necessary identification information (profile name, agent ID, IP address) must be provided to be able to run `kmscfg` and initialize the provider on the Oracle Solaris client.

Options The options listed below are supported. Note that if the profile, agent id, or agent address are not specified on the command line, `kmscfg` prompts you to provide these items.

-a *Agent_ID*

The user agent ID to be used for the KMS token being configured. It is not unusual for the Profile and Agent ID to be the same, for example, `MyAgent`.

-d *Discovery_Freq*

Frequency with which the client will try to discover the availability of other KMS servers. If not specified, `Discovery_Freq` defaults to 10.

-f *Failover_Limit*

The number of times communications to the KMS can fail before the client gives up. If not specified, `Failover_Limit` defaults to 3.

-i Agent_Addr

Address of the KMS. This can be an IPv4 address (*xxx.xxx.xxx.xxx*) or an IPv6 address. If an IPv6 address is used, it must be enclosed in brackets. For example:

[2001:0DB8:AC10:FE01] A fully qualified host name can also be used, as long as that name can be resolved by the name service configured on the client.

-p Profile_Name

The name of the KMS profile to be used for the KMS token being configured.

-t Transaction_Timeout

Timeout period for individual KMS commands, in seconds. If not specified, this value defaults to 10.

Exit Status After completing the requested operation, `kmscfg` exits with one of the following status values.

0

Successful termination.

1

Failure. The requested operation could not be completed.

Files `/var/kms/$USERNAME`

Default KMS token configuration directory.

`${KMSTOKEN_DIR}`

Alternate KMS token configuration directory.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|--------------------------------------------|
| Availability | /system/library/security/crypto/pkcs11_kms |
| Interface Stability | Volatile |

See Also [pktool\(1\)](#), [attributes\(5\)](#), [pkcs11_kms\(5\)](#)

KMS 2.2 Administration Guide (<http://docs.sun.com/app/docs/doc/316195103AA>)

Name kprop – Kerberos database propagation program

Synopsis /usr/lib/krb5/kprop [-d] [-f *file*] [-p *port-number*]
[-r *realm*] [-s *keytab*] [*host*]

Description kprop is a command-line utility used for propagating a Kerberos database from a master KDC to a slave KDC. This command must be run on the master KDC. See the *Solaris System Administration Guide, Vol. 6* on how to set up periodic propagation between the master KDC and slave KDCs.

To propagate a Kerberos database, the following conditions must be met:

- The slave KDCs must have an /etc/krb5/kpropd.ac1 file that contains the principals for the master KDC and all the slave KDCs.
- A keytab containing a host principal entry must exist on each slave KDC.
- The database to be propagated must be dumped to a file using [kdb5_util\(1M\)](#).

Options The following options are supported:

-d Enable debug mode. Default is debug mode disabled.

-f *file* File to be sent to the slave KDC. Default is the /var/krb5/slave_datatrans file.

-p *port-number* Propagate *port-number*. Default is port 754.

-r *realm* Realm where propagation will occur. Default *realm* is the local realm.

-s *keytab* Location of the keytab. Default location is /etc/krb5/krb5.keytab.

Operands The following operands are supported:

host Name of the slave KDC.

Examples EXAMPLE 1 Propagating the Kerberos Database

The following example propagates the Kerberos database from the /tmp/slave_data file to the slave KDC london. The machine london must have a host principal keytab entry and the kpropd.ac1 file must contain an entry for the all the KDCs.

```
# kprop -f /tmp/slave_data london
```

| | | |
|--------------|---------------------------|----------------------------------------------------------------|
| Files | /etc/krb5/kpropd.ac1 | List of principals of all the KDCs; resides on each slave KDC. |
| | /etc/krb5/krb5.keytab | Keytab for Kerberos clients. |
| | /var/krb5/slave_datatrans | Kerberos database propagated to the KDC slaves. |

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|----------------------------|
| Availability | system/security/kerberos-5 |

See Also [kpasswd\(1\)](#), [svcs\(1\)](#), [gkadmin\(1M\)](#), [inetadm\(1M\)](#), [inetd\(1M\)](#), [kadmind\(1M\)](#), [kadmin.local\(1M\)](#), [kdb5_util\(1M\)](#), [svcadm\(1M\)](#), [kadm5.acl\(4\)](#), [kdc.conf\(4\)](#), [attributes\(5\)](#), [kerberos\(5\)](#), [smf\(5\)](#)

System Administration Guide: Security Services

Name kpropd – Kerberos propagation daemon for slave KDCs

Synopsis /usr/lib/krb5/kpropd [-d] [-f *temp_dbfile*] [-F *dbfile*]
 [-p *kdb_util*] [-P *port_number*] [-r *realm*]
 [-s *srv_tabfile*] [-S] [-a *acl_file*]

Description The kpropd command runs on the slave KDC server. It listens for update requests made by [kprop\(1M\)](#) from the master KDC and periodically requests incremental updates from the master KDC.

When the slave receives a kprop request from the master, kpropd copies principal data to a temporary text file. Next, kpropd invokes [kdb5_util\(1M\)](#) (unless a different database utility is selected) to load the text file in database format.

When the slave periodically requests incremental updates, kpropd update its `principal.ulong` file with any updates from the master. [kproplog\(1M\)](#) can be used to view a summary of the update entry log on the slave KDC.

kpropd is not configured for incremental database propagation by default. These settings can be changed in the `kdc.conf(4)` file:

| | |
|--------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| <code>sunw_dbprop_enable = [true false]</code> | Enables or disables incremental database propagation. Default is <code>false</code> . |
| <code>sunw_dbprop_slave_poll = N[s, m, h]</code> | Specifies how often the slave KDC polls for any updates that the master might have. Default is 2m (two minutes). |

The `kprop/<hostname>@<REALM>` principal must exist in the slave's `keytab` file to enable the master to authenticate incremental propagation requests from the slave. In this syntax, `<hostname>` is the slave KDC's host name and `<REALM>` is the realm in which the slave KDC resides.

Options The following options are supported:

| | |
|------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <code>-d</code> | Enable debug mode. Default is debug mode disabled. |
| <code>-f <i>temp_dbfile</i></code> | The location of the slave's temporary principal database file. Default is <code>/var/krb5/from_master</code> . |
| <code>-F <i>dbfile</i></code> | The location of the slave's principal database file. Default is <code>/var/krb5/principal</code> . |
| <code>-p <i>kdb_util</i></code> | The location of the Kerberos database utility used for loading principal databases. Default is <code>/usr/sbin/kdb5_util</code> . |
| <code>-P <i>port_number</i></code> | Specifies the port number on which kpropd will listen. Default is 754 (service name: <code>krb5_prop</code>). |
| <code>-r <i>realm</i></code> | Specifies from which Kerberos realm kpropd will receive information. Default is specified in <code>/etc/krb5/krb5.conf</code> . |

- s *srv_tabfile* The location of the service table file used to authenticate the kpropd daemon.
- S Run the daemon in standalone mode, instead of having *inetd* listen for requests. Default is non-standalone mode.
- a *acl_file* The location of the kpropd's access control list to verify if this server can run the kpropd daemon. The file contains a list of principal name(s) that will be receiving updates. Default is `/etc/krb5/kpropd.acl`.

| | | |
|--------------|--------------------------------------------------|------------------------------------------------------------------------------|
| Files | <code>/var/krb5/principal</code> | Kerberos principal database. |
| | <code>/var/krb5/principal.u^log</code> | The update log file. |
| | <code>/etc/krb5/kdc.conf</code> | KDC configuration information. |
| | <code>/etc/krb5/kpropd.acl</code> | List of principals of all the KDCs; resides on each slave KDC. |
| | <code>/var/krb5/from_master</code> | Temporary file used by kpropd before loading this to the principal database. |

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------------|
| Availability | system/security/kerberos-5 |
| Interface Stability | Committed |

See Also [kdb5_util\(1M\)](#), [kprop\(1M\)](#), [kproplog\(1M\)](#), [kdc.conf\(4\)](#), [krb5.conf\(4\)](#), [attributes\(5\)](#), [kerberos\(5\)](#)

Notes The kprop service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/security/krb5_prop:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). Responsibility for initiating and restarting this service is delegated to [inetd\(1M\)](#). Use [inetadm\(1M\)](#) to make configuration changes and to view configuration information for this service. The service's status can be queried using the [svcs\(1\)](#) command.

Name kproplog – display the contents of the Kerberos principal update log

Synopsis /usr/sbin/kproplog [-h | -e *num*]

Description The kproplog displays the contents of the Kerberos principal update log to standard output. This command can be used to keep track of the incremental updates to the principal database, which is enabled by default. The /var/krb5/principal.u`log` file contains the update log maintained by the `kadmind(1M)` process on the master KDC server and the `kpropd(1M)` process on the slave KDC servers. When updates occur, they are logged to this file. Subsequently any KDC slave configured for incremental updates will request the current data from the master KDC and update their `principal.ulog` file with any updates returned.

The kproplog command can only be run on a KDC server by someone with privileges comparable to the superuser. It will display update entries for that server only.

If no options are specified, the summary of the update log is displayed. If invoked on the master, all of the update entries are also displayed. When invoked on a slave KDC server, only a summary of the updates are displayed, which includes the serial number of the last update received and the associated time stamp of the last update.

Options The following options are supported:

- h Display a summary of the update log. This information includes the database version number, state of the database, the number of updates in the log, the time stamp of the first and last update, and the version number of the first and last update entry.
- e *num* Display the last *num* update entries in the log. This is useful when debugging synchronization between KDC servers.
- v Display individual attributes per update. An example of the output generated for one entry:

```
Update Entry
  Update serial # : 4
  Update operation : Add
  Update principal : test@EXAMPLE.COM
  Update size : 424
  Update committed : True
  Update time stamp : Fri Feb 20 23:37:42 2004
  Attributes changed : 6
    Principal
    Key data
    Password last changed
    Modifying principal
    Modification time
    TL data
```

Files /var/krb5/principal.u`log` The update log file for incremental propagation.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------------|
| Availability | system/security/kerberos-5 |
| Interface Stability | Committed |

See Also [kpasswd\(1\)](#), [gkadmin\(1M\)](#), [kadmin\(1M\)](#), [kadmin\(1M\)](#), [kadmin\(1M\)](#), [kdb5_util\(1M\)](#), [kprop\(1M\)](#), [kpropd\(1M\)](#), [kadm5.acl\(4\)](#), [kdc.conf\(4\)](#), [attributes\(5\)](#), [kerberos\(5\)](#)

Name krb5kdc – KDC daemon

Synopsis /usr/lib/krb5/krb5kdc [-d *dbpath*] [-r *realm*] [-m]
 [-k *masterenctype*] [-M *masterkeyname*]
 [-p *port*] [-n] [-x *db_args*]. . .

Description krb5kdc is the daemon that runs on the master and slave KDCs to process the Kerberos tickets. For Kerberos to function properly, krb5kdc must be running on at least one KDC that the Kerberos clients can access. Prior to running krb5kdc, you must initialize the Kerberos database using [kdb5_util\(1M\)](#). See the *System Administration Guide: Security Services* for information regarding how to set up KDCs and initialize the Kerberos database.

Options The following options are supported:

- d *dbpath*
Specify the path to the database; default value is /var/krb5.
- k *masterenctype*
Specify the encryption type for encrypting the database. The default value is des-cbc-crc. des3-cbc-sha1, arcfour-hmac-md5, arcfour-hmac-md5-exp, aes128-cts-hmac-sha1-96, and aes256-cts-hmac-sha1-96 are also valid.
- m
Specify that the master key for the database is to be entered manually.
- M *masterkeyname*
Specify the principal to retrieve the master Key for the database.
- n
Specify that krb5kdc should not detach from the terminal.
- p *port*
Specify the port that will be used by the KDC to listen for incoming requests.
- r *realm*
Specify the realm name; default is the local realm name.
- x *db_args*
Pass database-specific arguments to kadmin. Supported arguments are for the LDAP plug-in. These arguments are:
 - binddn=binddn*
Specifies the DN of the object used by the KDC server to bind to the LDAP server. This object should have the rights to read the realm container, principal container and the subtree that is referenced by the realm. Overrides the `ldap_kdc_dn` parameter setting in [krb5.conf\(4\)](#).
 - bindpwd=bindpwd*
Specifies the password for the above-mentioned *binddn*. It is recommended not to use this option. Instead, the password can be stashed using the `stashesrvpw` command of [kdb5_ldap_util\(1M\)](#).

`nconns=num`

Specifies the number of connections to be maintained per LDAP server.

`host=ldapuri`

Specifies, by an LDAP URI, the LDAP server to which to connect.

Files `/var/krb5/principal.db`
Kerberos principal database.

`/var/krb5/principal.kadm5`
Kerberos administrative database. This file contains policy information.

`/var/krb5/principal.kadm5.lock`
Kerberos administrative database lock file. This file works backwards from most other lock files (that is, `kadmin` will exit with an error if this file does *not* exist).

`/etc/krb5/kdc.conf`
KDC configuration file. This file is read at startup.

`/etc/krb5/kprop.acl`
File that defines the access control list for propagating the Kerberos database using `kprop`.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|----------------------------|
| Availability | system/security/kerberos-5 |

See Also [kill\(1\)](#), [kpasswd\(1\)](#), [gkadmin\(1M\)](#), [kadmind\(1M\)](#), [kadmin.local\(1M\)](#), [kdb5_util\(1M\)](#), [kdb5_ldap_util\(1M\)](#), [logadm\(1M\)](#), [krb5.conf\(4\)](#), [attributes\(5\)](#), [krb5envvar\(5\)](#), [kerberos\(5\)](#),

System Administration Guide: Security Services

Notes The following signal has the specified effect when sent to the server process using the [kill\(1\)](#) command:

SIGHUP

`krb5kdc` closes and re-opens log files that it directly opens. This can be useful for external log-rotation utilities such as [logadm\(1M\)](#). If this method is used for log file rotation, set the [krb5.conf\(4\)](#) `kdc_rotate` period relation to `never`.

Name ksslcfg – enable and configure SMF instance of Kernel SSL

Synopsis ksslcfg create -f pkcs11 -T *token_label* -C *certificate_label*
 [-d *softtoken_directory*]
 [-p *password_file* [-u *username*]]
 [-h *ca_certchain_file*] [-c *ciphersuites*]
 [-t *ssl_session_cache_timeout*]
 [-z *ssl_session_cache_size*] [-v] -x *proxy_port* [*host*] *ssl_port*

ksslcfg create -f pkcs12 -i *cert_and_key_pk12file*
 [-p *password_file* [-u *username*]]
 [-c *ciphersuites*] [-t *ssl_session_cache_timeout*]
 [-z *ssl_session_cache_size*] [-v] -x *proxy_port* [*host*] *ssl_port*

ksslcfg create -f pem -i *cert_and_key_pemfile*
 [-p *password_file* [-u *username*]]
 [-c *ciphersuites*] [-t *ssl_session_cache_timeout*]
 [-z *ssl_session_cache_size*] [-v] -x *proxy_port* [*host*] *ssl_port*

ksslcfg delete [-v] [*host*] *ssl_port*

ksslcfg -V

ksslcfg -?

Description ksslcfg manages [smf\(5\)](#) instances for the Kernel SSL proxy module. An SSL-enabled web server can use the services of its Kernel SSL proxy to improve the performance of the HTTPS packets processing. It does so by creating an instance of the Kernel SSL service, specifying the SSL proxy port and parameters, and by listening on the proxy port.

The `create` subcommand creates an instance and enables the service for the given address and SSL port.

The `delete` subcommand disables the service for the given address and port, if it is enabled, and deletes the instance from the SMF repository.

ksslcfg can be run as root or by other users assigned to the Network Security profile. See [rbac\(5\)](#) and [user_attr\(4\)](#). You must run ksslcfg to configure your Kernel SSL proxy before you start your application.

ksslcfg allows you to specify an *ssl_port* operand, described under OPERANDS, and, with the `-x` option, a *proxy_port* value. When specified for use with the Kernel SSL proxy, these values cannot also be configured for the Solaris Network Cache and Acceleration (NCA) feature. See [nca\(1\)](#) for a description of the NCA feature.

The Fault Managed Resource Identifier (FMRI) for the kernel SSL proxy instances is `svc://network/ssl/proxy`. ksslcfg creates an instance of that service unique to the combination of host and SSL port. Instance FMRI for particular proxy entries can be found with [svcs\(1\)](#) and used for dependencies of other services.

Options The following options are supported:

- c *ciphersuites*** Set of ciphers a client is allowed to negotiate in a sorted order. The supported SSL version3 and TLS ciphers are listed below. Note that the names are case-insensitive.

```
rsa_rc4_128_sha
rsa_rc4_128_md5
rsa_aes_256_cbc_sha
rsa_aes_128_cbc_sha
rsa_3des_edc_cbc_sha
rsa_des_cbc_sha
```
- f *key_format*** Uses the certificate/key format specified in *key_format*. The supported options are pkcs11, pkcs12, and pem.
- i *key_and_certificate_file*** When pkcs12 or pem is specified with the -f option, reads a key and a certificate of the web server from *key_and_certificate_file*. This file can also contain any intermediate CA certificates that form the certificate chain to the root CA for the server certificate. These certificates must follow the server certificate in the file and the order must be bottom up: lowest level CA certificate followed by the next higher level CA certificate, and so on.
- C *certificate_label*** PKCS#11 can store multiple certificates in single token. This option enables you to specify a single certificate, identified by *certificate_label*. This label must match the CKA_LABEL on the certificate object in the token specified by -T. This option is to be used only with -f pkcs11.
- d *softtoken_directory*** This option is applicable only with the pkcs11 key format, when the token label is the Sun Software PKCS#11 softtoken. Use this option to override the default location of the PKCS#11 softtoken directory (\$HOME/.sunw). See [pkcs11_softtoken\(5\)](#).
- h *ca_certchain_file*** When pkcs11 is specified with the -f option, reads a set of intermediate CA certificates that form the certificate chain to the root CA for the server certificate (specified with the -C option), from *ca_certchain_file*. The file must be in PEM format.
- p *password_file*** Obtains the password used to encrypt the private key from *password_file*. When using the pkcs11 option (see -f, above), the password is used to authenticate the user to the PKCS #11 token.

| | |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-t ssl_session_cache_timeout</code> | The timeout value, in seconds, for an SSL session. It corresponds to <code>SSL3SessionTimeout</code> of the Sun ONE web server configuration or <code>SSLSessionCacheTimeout</code> of <code>mod_ssl</code> . |
| <code>-T token_label</code> | When <code>pkcs11</code> is specified with <code>-f</code> , uses the PKCS#11 token specified in <code>token_label</code> . Use <code>cryptoadm list -v</code> to display all PKCS#11 tokens available. |
| <code>-u username</code> | The username of the user who owns the password file. If omitted, the system will try to read the password file as root. |
| <code>-v</code> | Verbose mode. |
| <code>-V</code> | Displays the version. |
| <code>-x proxy_port</code> | The SSL proxy port. The port number is designated exclusively for clear-text HTTP communication between the web server and the kernel SSL proxy module. No external HTTP packets are delivered to this port. |
| <code>-z ssl_session_cache_size</code> | The maximum number of SSL sessions that can be cached. It corresponds to <code>SSLCacheEntries</code> of the Sun ONE web server configuration. When this option is not specified, the default is 5000 entries. |
| <code>-?</code> | Displays the usage of the command. |

Operands `[host] [ssl_port]` The address and the port of the web server for which the kernel SSL entry is created. If `host` is omitted, the entry will be used for all requests that arrived at the `ssl_port`, regardless of the destination address. Both a host name and an IP address are acceptable forms for `host`. `ssl_port` is required. Typically, this has a value of 443.

Examples EXAMPLE 1 Create and Enable a Kernel SSL Instance

The following command creates and enables a Kernel SSL instance using a certificate and a key in PKCS#11 format.

```
# ksslcfg create -f pkcs11 -T "Sun Software PKCS#11 softtoken" \
-C "Server-Cert" -p /some/directory/password -u webservd \
-x 8080 www.mysite.com 443

% svcs svc:/network/ssl/proxy
STATE          STIME      FMRI
online         Sep_27    svc:/network/ssl/proxy:kssl-www-mysite-com-443
```

EXAMPLE 2 Create and Enable a Default Instance for All Addresses

The following command creates and enables a default instance for all addresses from a certificate and key in a pkcs#12 file.

```
# ksslcfg create -x 8888 -f pkcs12 -i /some/directory/keypair.p12 \
  -p /some/directory/password -u webservd 443
```

EXAMPLE 3 Create and Enable an Instance with Specific Cipher Suites

The following command creates and enables an instance with specific cipher suites.

```
# ksslcfg create -x 8080 -f pem \
  -i /some/directory/keypair.pem -p /some/directory/password \
  -c "rsa_rc4_128_md5,rsa_rc4_128_sha" \
  209.249.116.195 443
```

EXAMPLE 4 Disable and Delete an Instance

The following command disables and deletes an instance.

```
# ksslcfg delete www.mysite.com 443
```

Exit Status 0 Successful completion.

>0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWksslu |
| Interface Stability | See below. |

Command line options and the utility name are Committed. The command output, the FMRI service name (svc://network/ssl/proxy), and the FMRI instance's name format are Uncommitted

See Also [nca\(1\)](#), [svcprop\(1\)](#), [svcs\(1\)](#), [cryptoadm\(1M\)](#), [svcadm\(1M\)](#), [svccfg\(1M\)](#), [user_attr\(4\)](#), [attributes\(5\)](#), [pkcs11_softtoken\(5\)](#), [rbac\(5\)](#), [smf\(5\)](#)

Notes `ksslcfg create` without an host argument creates an `INADDR_ANY` smf instance. `ksslcfg delete` without an host argument deletes only the `INADDR_ANY` instance. `ksslcfg delete` needs a host argument to delete any non-`INADDR_ANY` instance.

On a system with [zones\(5\)](#) installed, the `ksslcfg` command can be used only in the global zone at this time.

Name kstat – display kernel statistics

Synopsis kstat [-lpq] [-T u | d] [-c *class*] [-m *module*]
 [-i *instance*] [-n *name*] [-s *statistic*]
 [interval [count]]

kstat [-lpq] [-T u | d] [-c *class*]
 [*module:instance:name:statistic*]...
 [interval [count]]

Description The kstat utility examines the available kernel statistics, or kstats, on the system and reports those statistics which match the criteria specified on the command line. Each matching statistic is printed with its module, instance, and name fields, as well as its actual value.

Kernel statistics may be published by various kernel subsystems, such as drivers or loadable modules; each kstat has a module field that denotes its publisher. Since each module might have countable entities (such as multiple disks associated with the [sd\(7D\)](#) driver) for which it wishes to report statistics, the kstat also has an instance field to index the statistics for each entity; kstat instances are numbered starting from zero. Finally, the kstat is given a name unique within its module.

Each kstat may be a special kstat type, an array of name-value pairs, or raw data. In the name-value case, each reported value is given a label, which we refer to as the statistic. Known raw and special kstats are given statistic labels for each of their values by kstat; thus, all published values can be referenced as *module:instance:name:statistic*.

When invoked without any module operands or options, kstat will match all defined statistics on the system. Example invocations are provided below. All times are displayed as fractional seconds since system boot.

Options The tests specified by the following options are logically ANDed, and all matching kstats will be selected. A regular expression containing shell metacharacters must be protected from the shell by enclosing it with the appropriate quotes.

The argument for the -c, -i, -m, -n, and -s options may be specified as a shell glob pattern, or a Perl regular expression enclosed in '/' characters.

- c *class* Displays only kstats that match the specified class. *class* is a kernel-defined string which classifies the “type” of the kstat.
- i *instance* Displays only kstats that match the specified instance.
- l Lists matching kstat names without displaying values.
- m *module* Displays only kstats that match the specified module.
- n *name* Displays only kstats that match the specified name.
- p Displays output in parseable format. All example output in this document is given in this format. If this option is not specified, kstat produces output in a human-readable, table format.

- q Displays no output, but return appropriate exit status for matches against given criteria.
- s *statistic* Displays only kstats that match the specified statistic.
- T d | u Displays a time stamp before each statistics block, either in [date\(1\)](#) format (d) or as an alphanumeric representation of the value returned by [time\(2\)](#) (u).

Operands The following operands are supported:

- module:instance:name:statistic* Alternate method of specifying module, instance, name, and statistic as described above. Each of the module, instance, name, or statistic specifiers may be a shell glob pattern or a Perl regular expression enclosed by '/' characters. It is possible to use both specifier types within a single operand. Leaving a specifier empty is equivalent to using the '*' glob pattern for that specifier.
- interval* The number of seconds between reports.
- count* The number of reports to be printed.

Examples In the following examples, all the command lines in a block produce the same output, as shown immediately below. The exact statistics and values will of course vary from machine to machine.

EXAMPLE 1 Using the kstat Command

```
example$ kstat -p -m unix -i 0 -n system_misc -s 'avenrun*'
example$ kstat -p -s 'avenrun*'
example$ kstat -p 'unix:0:system_misc:avenrun*'
example$ kstat -p '::::avenrun*'
example$ kstat -p '::::/^avenrun_\d+min$/'
```

```
unix:0:system_misc:avenrun_15min        3
unix:0:system_misc:avenrun_1min        4
unix:0:system_misc:avenrun_5min        2
```

EXAMPLE 2 Using the kstat Command

```
example$ kstat -p -m cpu_stat -s 'intr*'
example$ kstat -p cpu_stat:::/^intr/
```

```
cpu_stat:0:cpu_stat0:intr                29682330
cpu_stat:0:cpu_stat0:intrblk            87
cpu_stat:0:cpu_stat0:intrthread        15054222
cpu_stat:1:cpu_stat1:intr                426073
cpu_stat:1:cpu_stat1:intrblk            51
cpu_stat:1:cpu_stat1:intrthread        289668
```

EXAMPLE 2 Using the kstat Command *(Continued)*

```

cpu_stat:2:cpu_stat2:intr      134160
cpu_stat:2:cpu_stat2:intrblk   0
cpu_stat:2:cpu_stat2:intrthread 131
cpu_stat:3:cpu_stat3:intr      196566
cpu_stat:3:cpu_stat3:intrblk   30
cpu_stat:3:cpu_stat3:intrthread 59626

```

EXAMPLE 3 Using the kstat Command

```

example$ kstat -p :::state '::::avenrun*'
example$ kstat -p :::state :::/^avenrun/

```

```

cpu_info:0:cpu_info0:state     on-line
cpu_info:1:cpu_info1:state     on-line
cpu_info:2:cpu_info2:state     on-line
cpu_info:3:cpu_info3:state     on-line
unix:0:system_misc:avenrun_15min      4
unix:0:system_misc:avenrun_1min 10
unix:0:system_misc:avenrun_5min 3

```

EXAMPLE 4 Using the kstat Command

```

example$ kstat -p 'unix:0:system_misc:avenrun*' 1 3
unix:0:system_misc:avenrun_15min      15
unix:0:system_misc:avenrun_1min 11
unix:0:system_misc:avenrun_5min 21

```

```

unix:0:system_misc:avenrun_15min      15
unix:0:system_misc:avenrun_1min 11
unix:0:system_misc:avenrun_5min 21

```

```

unix:0:system_misc:avenrun_15min      15
unix:0:system_misc:avenrun_1min 11
unix:0:system_misc:avenrun_5min 21

```

EXAMPLE 5 Using the kstat Command

```

example$ kstat -p -T d 'unix:0:system_misc:avenrun*' 5 2
Thu Jul 22 19:39:50 1999
unix:0:system_misc:avenrun_15min      12
unix:0:system_misc:avenrun_1min 0
unix:0:system_misc:avenrun_5min 11

```

```

Thu Jul 22 19:39:55 1999
unix:0:system_misc:avenrun_15min      12
unix:0:system_misc:avenrun_1min 0
unix:0:system_misc:avenrun_5min 11

```

EXAMPLE 6 Using the kstat Command

```
example$ kstat -p -T u 'unix:0:system_misc:avenrun*'
932668656
unix:0:system_misc:avenrun_15min      14
unix:0:system_misc:avenrun_1min      5
unix:0:system_misc:avenrun_5min     18
```

Exit Status The following exit values are returned:

- 0 One or more statistics were matched.
- 1 No statistics were matched.
- 2 Invalid command line options were specified.
- 3 A fatal error occurred.

Files /dev/kstat kernel statistics driver

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [date\(1\)](#), [sh\(1\)](#), [time\(2\)](#), [gmatch\(3GEN\)](#), [kstat\(3KSTAT\)](#), [attributes\(5\)](#), [kstat\(7D\)](#), [sd\(7D\)](#), [kstat\(9S\)](#)

Notes If the pattern argument contains glob or Perl RE metacharacters which are also shell metacharacters, it will be necessary to enclose the pattern with appropriate shell quotes.

Name kttk_warnd – Kerberos warning daemon

Synopsis /usr/lib/krb5/kttk_warnd

Description kttk_warnd is a daemon on Kerberos clients that can warn users when their Kerberos tickets are about to expire or renew the tickets before they expire. It is invoked by `inetd` when a ticket-granting ticket (TGT) is obtained for the first time, such as after using the `kinit` command. kttk_warnd can be configured through the `/etc/krb5/warn.conf` file on the client. In `warn.conf`, you can specify that you be supplied notice, through `syslog` or terminal or mail, of ticket expiration or to renew the TGT.

Files /etc/krb5/warn.conf Kerberos warning configuration file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Committed |

See Also [svcs\(1\)](#), [inetadm\(1M\)](#), [inetd\(1M\)](#), [svcadm\(1M\)](#), [warn.conf\(4\)](#), [attributes\(5\)](#), [kerberos\(5\)](#), [smf\(5\)](#)

Notes The kttk_warnd service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/security/kttk_warn:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). Responsibility for initiating and restarting this service is delegated to [inetd\(1M\)](#). Use [inetadm\(1M\)](#) to make configuration changes and to view configuration information for this service. The service's status can be queried using the [svcs\(1\)](#) command.

Name labeld – Trusted Extensions label daemon

Synopsis /usr/lib/labeld

Description The labeld daemon is a system daemon which is started at boot time when Trusted Extensions is enabled. This daemon is started automatically and should not be invoked directly. It does not constitute a programming interface.

To enable Trusted Extensions, enter the following at the command line:

```
% svcadm enable svc:/system/labeld
```

Because Trusted Extensions affects the initialization and operation of zones, all zones must be removed before enabling Trusted Extensions. After enabling, the system should be rebooted to allow Trusted Extensions to come up properly initialized.

Enabling or disabling Trusted Extensions can only be done by a user or role with the `solaris.smf.manage.labels` authorization. (For example, a user or role that has either the Information Security or Object Label Management Rights Profile, or superuser.)

Other configuration steps are needed before using Trusted Extensions functionality. For more information, see the *Solaris Trusted Extensions Installation and Configuration Guide*.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | system/trusted |
| Interface Stability | Uncommitted |

See Also [svcs\(1\)](#), [svcadm\(1M\)](#), [syslogd\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Solaris Trusted Extensions Administrator's Procedures

Notes The [labels\(5\)](#) service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/labeld:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

-
- Name** labelit – list or provide labels for file systems
- Synopsis** labelit [-F *FSType*] [-V] [-o *FSType-specific-options*] *special*
[*operands*]
- Description** The labelit utility is used to write or display labels on unmounted disk file systems.
- Options** The following options are supported:
- F *FSType* Specify the *FSType* on which to operate. The *FSType* should either be specified here or be determinable from `/etc/vfstab` by matching the *special* with an entry in the table. If no matching entry is found, the default file system type specified in `/etc/default/fs` will be used.
 - V Echo complete command line. This option may be used to verify and validate the command line. Additional information obtained using a `/etc/vfstab` lookup is included in the output. The command is not executed.
 - o Specify *FSType*-specific options. See the manual page for the labelit module specific to the file system type.
- Operands** The following operands are supported. If no operands are specified, labelit will display the value of the labels.
- special* The disk partition (for example, `/dev/rdsk/c0t3d0s6`). The device may not be on a remote machine.
 - operands* *FSType*-specific operands. Consult the manual page of the *FSType*-specific labelit command for detailed descriptions.
- Usage** See [largefile\(5\)](#) for the description of the behavior of labelit when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).
- Exit Status** The following exit values are returned:
- 0 Write or display of labels was successful.
 - non-zero An error occurred.
- Files**
- `/etc/vfstab` List of default parameters for each file system.
 - `/etc/default/fs` Default local file system type. Default values can be set for the following flags in `/etc/default/fs`. For example:
 - LOCAL=*ufs*
 - LOCAL The default partition for a command if no *FSType* is specified.
- Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [labelit_hfs\(1M\)](#), [labelit_udfs\(1M\)](#), [labelit_ufs\(1M\)](#), [volcopy\(1M\)](#), [vfstab\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

Notes This utility may not be supported for all *FSTypes*.

Name labelit_hfs – provide and print labels for hfs file systems

Synopsis /usr/sbin/labelit -F hfs [*generic_options*]
[-o *specific_options*] *special*

Description labelit can be used to provide labels for unmounted CD-ROM images (CD-ROMs may not be labeled, as they are read-only media).

generic_options are options supported by the generic labelit command.

If no *specific_options* are specified, labelit prints the current value of all label fields.

The *special* name should be the physical disk section (for example, /dev/dsk/c0d0s6).

Options -o Use one or more of the following *name=value* pairs separated by commas (with no intervening spaces) to specify values for specific label fields. According to the ISO 9660 specification, only certain sets of characters may be used to fill in these labels. Thus, “d-characters” below refers to the characters ‘A’ through ‘Z’, the digits ‘0’ through ‘9’, and the ‘_’ (underscore) character. “a-characters” below refers to ‘A’ through ‘Z’, ‘0’ through ‘9’, space, and the following characters: !"%&'()*+,-./:;<=>?_.

absfile= Abstract file identifier, d-characters, 37 characters maximum.

applid= Application identifier, d-characters, 128 characters maximum.

bibfile= Bibliographic file identifier, d-characters, 37 characters maximum.

copyfile= Copyright file identifier, d-characters, 128 maximum.

prepid= Data preparer identifier, d-characters, 128 maximum.

pubid= Publisher identifier, d-characters, 128 maximum.

sysid= System identifier, a-characters, 32 maximum.

volid= Volume identifier, d-characters, 32 maximum.

volsetid= Volume set identifier, d-characters, 128 maximum.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [labelit\(1M\)](#), [volcopy\(1M\)](#), [attributes\(5\)](#)

Name labelit_udfs – provide and print labels for udf file systems

Synopsis labelit -F udfs [*generic_options*] [-o *specific_options*] *special*
[*fsname volume*]

Description The labelit command writes labels on an unmounted disk that contains a universal disk file (udf) system. These labels can be used to identify volumes.

Options The following options are supported:

generic_options Specify *generic_options* supported by the generic labelit command. See labelit(1M) for descriptions of supported options.

-o *specific_options* Specify udfs-file-system-specific options in a comma-separated list with no intervening spaces. The following *specific_options* are available:

lvinfo1=*string* Specify information to be inserted in the LVInfo1 field of the Implementation Use Volume Descriptor. Information in LVInfo1 is generally used to identify the person creating the file system. The maximum length of the string specified is 35 bytes.

lvinfo2=*string* Specify information to be inserted into the LVInfo2 field of the Implementation Use Volume Descriptor. Information in LVInfo2 is generally used to identify the organization responsible for creating the file system. The maximum length of the string specified is 35 bytes.

lvinfo3=*string* Specify information to be inserted into the LVInfo3 field of the Implementation Use Volume Descriptor. Information in LVInfo3 is generally used to identify the contact information for the medium. The maximum length of the string specified is 35 bytes.

Operands The following operands are supported:

special Specify *special* as the physical disk slice, for example, /dev/rdisk/c0t0d0s6. The device can not be on a remote machine.

fsname Specify *fsname* as the mount point, (for example, root, u1, and so forth), of the file system.

volume Specify *volume* as the physical volume name.

If none of the options (*fsname*, *volume*, *specific_options*) is specified, labelit prints the current values of *fsname*, *volume*, LVInfo1, LVInfo2 and LVInfo3.

Exit Status The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------|
| Availability | system/file-system/udfs |

See Also [labelit\(1M\)](#), [attributes\(5\)](#)

Name labelit_ufs – provide and print labels for ufs file systems

Synopsis labelit -F ufs [*generic_options*] *special* [*fsname* *volume*]

Description labelit is used to write labels on unmounted disk file systems. Such labels may be used to uniquely identify volumes and are used by volume-oriented programs such as [volcopy\(1M\)](#).

Options The following option is supported:

generic_options options supported by the generic labelit command. See [labelit\(1M\)](#).

Operands The following operands are supported:

special name should be the physical disk section (for example, /dev/dsk/c0d0s6). The device may not be on a remote machine.

fsname represents the mount point (for example, root, u1, and so on) of the file system.

volume may be used to represent the physical volume name.

If *fsname* and *volume* are not specified, labelit prints the current values of these labels. Both *fsname* and *volume* are limited to six or fewer characters.

Exit Status The following exit values are returned:

0 Write or display of labels was successful.

non-zero An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [labelit\(1M\)](#), [volcopy\(1M\)](#), [attributes\(5\)](#), [ufs\(7FS\)](#)

Name latencytop – report latency-related statistics in system and in applications

Synopsis latencytop [-t *interval*] [-o *log_file*] [-k *log_level*]
 [-f [no]*feature*,...] [-l *log_interval*] [-h]
 [-s pid=*PID* | pgid=*PGID*]

Description LatencyTOP is an observability tool that reports statistics about latencies in the system and in applications. The tool reports statistics about where and what kind of latencies are happening in the system and in the applications that are running on the system. The statistics then can be used to improve performance throughput of applications and system, as you remove the identified latencies.

The tool analyzes system activity periodically and displays the data in the output window. Two types of latencies are tracked: an LWP going in and out of sleep and an LWP spinning order to acquire a synchronization object. The tool uses the Solaris DTrace framework to collect the statistics corresponding to these two scenarios of inactivity of the system and application LWPs.

The output window is divided into two sections. An upper part displays the system-wide statistics, while the lower part displays statistics about individual processes. The user can navigate the list of processes (using the left- and right-arrow keys) and select the list they are interested in. The tool will then display statistics about that selected process in the lower part of the window. If the t or T key is pressed, the tool displays the LWP-specific view of that selected process. The t or T key can be used to toggle between the process-view and the thread-view.

During execution, a user can force a refresh of the analysis by pressing the r or R key. The interval time is restored to the default or to a specified value (if -t was used). To quit the application, the user must press the q or Q key.

Options The following options are supported:

-f, --feature [no]*feature1*,[no]*feature2*,...

Enables/disables features in LatencyTOP. Features can be only one of the following:

[no]filter

Filter large interruptible latencies, for example, sleep. The default is off.

[no]sched

Monitors sched (PID=0). The default is off.

[no]sobj

Monitors synchronize objects. The default is on.

[no]low

Lower overhead by sampling small latencies. Enabling this feature will lower CPU utilization by estimating small latencies statistically. Use it for heavy workloads such as a very busy web server. The default is off.

- h
Displays the command's usage.
- k *log_level*
Specifies the level of logging in the log file. Valid values are:
 - 0 none (default)
 - 1 unknown
 - 2 all
- l [*log_interval*]
Writes data to the log file every *log_interval* seconds; *log_interval* must be greater than 60.
- o *log_file*
Specifies the log file where output will be written. The default log file is `/var/log/latencytop.log`.
- s *pid=PID | pgid=PGID*
Tracks only the specified process or the specified process group and displays data related only to that process or the process group.
- t *interval*
Specifies the interval, in seconds, at which the tool collects statistics from the system. The possible values are between 1 and 60; the default is 5 seconds.

Examples EXAMPLE 1 Running the Tool

The following command launches the tool with default values for options.

```
% latencytop
```

EXAMPLE 2 Setting the Interval

The following command sets the sampling interval to two seconds.

```
% latencytop -t 2
```

EXAMPLE 3 Specifying the Log File

The following command sets the log file to `/tmp/latencytop.log`.

```
% latencytop -o /tmp/latencytop.log
```

EXAMPLE 4 Specifying the Log Level

The following command sets the log level to `all`.

```
% latencytop -l 2
```

EXAMPLE 5 Enabling Tracing of Latencies

The following command enables the tracing of latencies caused by synchronization objects.

```
% latencytop -f subj
```

EXAMPLE 6 Displaying Data for a Process Group

The following command displays trace data for processes belonging to Process Group 630.

```
% latencytop -s pgid=630
```

Exit Status 0

Successful operation.

1

An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------------|
| Architecture | x86, SPARC |
| Availability | diagnostic/latencytop |
| Interface Stability | Volatile |

See Also [dtrace\(1M\)](#), [kstat\(1M\)](#), [attributes\(5\)](#)

Usage You must have DTrace privileges to run LatencyTOP.

Name ldapaddent – create LDAP entries from corresponding /etc files

Synopsis ldapaddent [-cpv] [-a *authenticationMethod*] [-b *baseDN*]
 -D *bindDN* [-w *bind_password*] [-j *passwdFile*] [-f *filename*]
database

ldapaddent [-cpv] -a *sasl/GSSAPI* [-b *baseDN*] [-f *filename*]
database

ldapaddent -d [-v] [-a *authenticationMethod*] [-D *bindDN*]
 [-w *bind_password*] [-j *passwdFile*] *database*

ldapaddent [-cpv] -h *LDAP_server[:serverPort]* [-M *domainName*]
 [-N *profileName*] [-P *certifPath*] [-a *authenticationMethod*]
 [-b *baseDN*] -D *bindDN* [-w *bind_password*] [-f *filename*]
 [-j *passwdFile*] *database*

ldapaddent [-cpv] -h *LDAP_server[:serverPort]* [-M *domainName*]
 [-N *profileName*] [-P *certifPath*] [-a *authenticationMethod*]
 [-b *baseDN*] [-f *filename*] *database*

ldapaddent -d [-v] -h *LDAP_server[:serverPort]* [-M *domainName*]
 [-N *profileName*] [-P *certifPath*] [-a *authenticationMethod*]
 [-b *baseDN*] -D *bindDN* [-w *bind_password*] [-j *passwdFile*]
database

Description ldapaddent creates entries in LDAP containers from their corresponding /etc files. This operation is customized for each of the standard containers that are used in the administration of Solaris systems. The *database* argument specifies the type of the data being processed. Legal values for this type are one of *aliases*, *auto_**, *bootparams*, *ethers*, *group*, *hosts* (including both IPv4 and IPv6 addresses), *ipnodes* (alias for *hosts*), *netgroup*, *netmasks*, *networks*, *passwd*, *shadow*, *protocols*, *publickey*, *rpc*, and *services*. In addition to the preceding, the *database* argument can be one of the RBAC-related files (see [rbac\(5\)](#)):

- /etc/user_attr
- /etc/security/auth_attr
- /etc/security/prof_attr
- /etc/security/exec_attr

By default, ldapaddent reads from the standard input and adds this data to the LDAP container associated with the database specified on the command line. An input file from which data can be read is specified using the -f option.

If you specify the -h option, ldapaddent establishes a connection to the server indicated by the option in order to obtain a *DUAProfile* specified by the -N option. The entries will be stored in the directory described by the configuration obtained.

By default (if the -h option is not specified), entries will be stored in the directory based on the client's configuration. To use the utility in the default mode, the Solaris LDAP client must be set up in advance.

The location where entries are to be written can be overridden by using the `-b` option.

If the entry to be added exists in the directory, the command displays an error and exits, unless the `-c` option is used.

Although, there is a shadow database type, there is no corresponding shadow container. Both the shadow and the passwd data is stored in the `people` container itself. Similarly, data from `networks` and `netmasks` databases are stored in the `networks` container.

The `user_attr` data is stored by default in the `people` container. The `prof_attr` and `exec_attr` data is stored by default in the `SolarisProfAttr` container.

You must add entries from the passwd database before you attempt to add entries from the shadow database. The addition of a shadow entry that does not have a corresponding passwd entry will fail.

The passwd database must precede the user_attr database.

For better performance, the recommended order in which the databases should be loaded is as follows:

- passwd database followed by shadow database
- networks database followed by netmasks database
- bootparams database followed by ethers database

Only the first entry of a given type that is encountered will be added to the LDAP server. The `ldapaddent` command skips any duplicate entries.

Options The `ldapaddent` command supports the following options:

`-a authenticationMethod`

Specify authentication method. The default value is what has been configured in the profile. The supported authentication methods are:

```
simple
sasl/CRAM-MD5
sasl/DIGEST-MD5
sasl/GSSAPI
tls:simple
tls:sasl/CRAM-MD5
tls:sasl/DIGEST-MD5
```

Selecting `simple` causes passwords to be sent over the network in clear text. Its use is strongly discouraged. Additionally, if the client is configured with a profile which uses no authentication, that is, either the `credentialLevel` attribute is set to `anonymous` or `authenticationMethod` is set to `none`, the user must use this option to provide an authentication method. If the authentication method is `sasl/GSSAPI`, `bindDN` and `bindPassword` is not required and the `hosts` and `ipnodes` fields of `/etc/nsswitch.conf` must be configured as:

hosts: dns files
ipnodes: dns files

See [nsswitch.conf\(4\)](#).

- b *baseDN*
Create entries in the *baseDN* directory. *baseDN* is not relative to the client's default search base, but rather, it is the actual location where the entries will be created. If this parameter is not specified, the first search descriptor defined for the service or the default container will be used.
- c
Continue adding entries to the directory even after an error. Entries will not be added if the directory server is not responding or if there is an authentication problem.
- D *bindDN*
Create an entry which has write permission to the *baseDN*. When used with -d option, this entry only needs read permission.
- d
Dump the LDAP container to the standard output in the appropriate format for the given database.
- f *filename*
Indicates input file to read in an `/etc/` file format.
- h *LDAP_server[:serverPort]*
Specify an address (or a name) and an optional port of the LDAP server in which the entries will be stored. The current naming service specified in the `nsswitch.conf` file is used. The default value for the port is 389, except when TLS is specified as the authentication method. In this case, the default LDAP server port number is 636.
- j *passwdFile*
Specify a file containing the password for the bind DN or the password for the SSL client's key database. To protect the password, use this option in scripts and place the password in a secure file. This option is mutually exclusive of the -w option.
- M *domainName*
The name of a domain served by the specified server. If not specified, the default domain name will be used.
- N *profileName*
Specify the DUAProfile name. A profile with such a name is supposed to exist on the server specified by -h option. Otherwise, a default DUAProfile will be used. The default value is `default`.

-P *certifPath*

The certificate path for the location of the certificate database. The value is the path where security database files reside. This is used for TLS support, which is specified in the `authenticationMethod` and `serviceAuthenticationMethod` attributes. The default is `/var/ldap`.

-p

Process the password field when loading password information from a file. By default, the password field is ignored because it is usually not valid, as the actual password appears in a shadow file.

-w *bindPassword*

Password to be used for authenticating the *bindDN*. If this parameter is missing, the command will prompt for a password. NULL passwords are not supported in LDAP.

When you use `-w bindPassword` to specify the password to be used for authentication, the password is visible to other users of the system by means of the `ps` command, in script files or in shell history.

If you supply “-” (hyphen) as a password, you will be prompted to enter a password.

-v

Verbose.

Operands The following operands are supported:

database

The name of the database or service name. Supported values are: `aliases`, `auto_*`, `bootparams`, `ethers`, `group`, `hosts` (including IPv6 addresses), `netgroup`, `netmasks`, `networks`, `passwd`, `shadow`, `protocols`, `publickey`, `rpc`, and `services`. Also supported are `auth_attr`, `prof_attr`, `exec_attr`, `user_attr`, and `projects`.

Examples **EXAMPLE 1** Adding Password Entries to the Directory Server

The following example shows how to add password entries to the directory server:

```
example# ldapaddent -D "cn=directory manager" -w secret \
    -f /etc/passwd passwd
```

EXAMPLE 2 Adding Group Entries

The following example shows how to add group entries to the directory server using `sasl/CRAM-MD5` as the authentication method:

```
example# ldapaddent -D "cn=directory manager" -w secret \
    -a "sasl/CRAM-MD5" -f /etc/group group
```

EXAMPLE 3 Adding `auto_master` Entries

The following example shows how to add `auto_master` entries to the directory server:

EXAMPLE 3 Adding auto_master Entries (Continued)

```
example# ldapaddent -D "cn=directory manager" -w secret \
-f /etc/auto_master auto_master
```

EXAMPLE 4 Dumping passwd Entries from the Directory to File

The following example shows how to dump password entries from the directory to a file foo:

```
example# ldapaddent -d passwd > foo
```

EXAMPLE 5 Adding Password Entries to a Specific Directory Server

The following example shows how to add password entries to a directory server that you specify:

```
example# ldapaddent -h 10.10.10.10:3890 \
-M another.domain.name -N special_duaprofile \
-D "cn=directory manager" -w secret \
-f /etc/passwd passwd
```

Exit Status The following exit values are returned:

- 0
Successful completion.
- >0
An error occurred.

Files /var/ldap/ldap_client_file
/var/ldap/ldap_client_cred
Files containing the LDAP configuration of the client. These files are not to be modified manually. Their content is not guaranteed to be human readable. Use [ldapclient\(1M\)](#) to update these files.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|--------------------|
| Availability | system/network/nis |
| Interface Stability | Committed |

See Also [ldap\(1\)](#), [ldaplist\(1\)](#), [ldapmodify\(1\)](#), [ldapmodrdn\(1\)](#), [ldapsearch\(1\)](#), [idsconfig\(1M\)](#), [ldapclient\(1M\)](#), [suninstall\(1M\)](#), [nsswitch.conf\(4\)](#), [attributes\(5\)](#)

System Administration Guide: Security Services

Caution Currently StartTLS is not supported by `libldap.so.5`, therefore the port number provided refers to the port used during a TLS open, rather than the port used as part of a StartTLS sequence. For example:

```
-h foo:1000 -a tls:simple
```

The preceding refers to a raw TLS open on host `foo` port `1000`, not an open, StartTLS sequence on an unsecured port `1000`. If port `1000` is unsecured the connection will not be made.

Name ldap_cachemgr – LDAP daemon to manage client configuration for LDAP based Network Information Service lookups

Synopsis /usr/lib/ldap/ldap_cachemgr [-l *log-file*] [-g]

Description The ldap_cachemgr daemon is a process that provides an up-to-date configuration cache for LDAP naming services. It is started during multi-user boot.

The ldap_cachemgr utility provides caching for all parameters as specified and used by the LDAP naming service clients. The ldap_cachemgr utility uses the cache files which are originally created by executing the ldapclient(1M) utility, as cold start files. Updates to the cache files take place dynamically if profiles are used to configure the client. See the init option to ldapclient(1M).

The ldap_cachemgr utility helps improve the performance of the clients that are using LDAP as the Naming service repository. In order for the LDAP naming services to function properly, the ldap_cachemgr daemon must be running. ldap_cachemgr also improves system security by making the configuration files readable by superuser only.

The cache maintained by this daemon is shared by all the processes that access LDAP Naming information. All processes access this cache through a door call. On startup, ldap_cachemgr initializes the cache from the cache files. See ldapclient(1M). Thus, the cache survives machine reboots.

The ldap_cachemgr daemon also acts as its own administration tool. If an instance of ldap_cachemgr is already running, commands are passed transparently to the running version.

Options The following options are supported:

-g

Print current configuration and statistics to standard output. This is the only option executable without superuser privileges.

-l *log-file*

Cause ldap_cachemgr to use a log file other than the default /var/ldap/cachemgr.log.

Examples EXAMPLE 1 Stopping and Restarting the ldap_cachemgr Daemon

The following example shows how to stop and to restart the ldap_cachemgr daemon.

```
example# svcadm disable network/ldap/client
example# svcadm enable network/ldap/client
```

EXAMPLE 2 Forcing ldap_cachemgr to Reread Configuration Files

The following example shows how to force ldap_cachemgr to reread the /var/ldap/ldap_client_file and /var/ldap/ldap_client_cred files

```
example# pkill -HUP ldap_cachemgr
```

Files /var/ldap/cachemgr.log

Default log file.

/var/ldap/ldap_client_file

/var/ldap/ldap_client_cred

Files containing the LDAP configuration of the client. These files are not to be modified manually. Their content is not guaranteed to be human readable. Use [ldapclient\(1M\)](#) to update these files.

Warnings The `ldap_cachemgr` utility is included in the current Solaris release on an uncommitted basis only. It is subject to change or removal in a future minor release.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|--------------------|
| Availability | system/network/nis |

See Also [ldap\(1\)](#), [ldapadd\(1\)](#), [ldapdelete\(1\)](#), [ldaplist\(1\)](#), [ldapmodify\(1\)](#), [ldapmodrdn\(1\)](#), [ldapsearch\(1\)](#), [pkill\(1\)](#), [svcs\(1\)](#), [idsconfig\(1M\)](#), [ldapaddent\(1M\)](#), [ldapclient\(1M\)](#), [suninstall\(1M\)](#), [svcadm\(1M\)](#), [signal.h\(3HEAD\)](#), [resolv.conf\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Notes The `ldap_cachemgr` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/ldap/client
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Name ldapclient – initialize LDAP client machine or output an LDAP client profile in LDIF format

Synopsis /usr/sbin/ldapclient [-v | -q] init [-a profileName=profileName]
 [-a domainName=domain] [-a proxyDN=proxyDN]
 [-a proxyPassword=password]
 [-a authenticationMethod=authenticationMethod]
 [-a enableShadowUpdate=true | false]
 [-a adminDN=adminDN]
 [-a adminPassword=adminPassword]
 [-a certificatePath=path] [-d bindDN] [-w bindPassword]
 [-j passwdFile] [-y passwdFile]
 [-z adminrPasswdFile] LDAP_server[:port_number]
 /usr/sbin/ldapclient [-v | -q] manual [-a attrName=attrVal]
 /usr/sbin/ldapclient [-v | -q] mod [-a attrName=attrVal]
 /usr/sbin/ldapclient [-v | -q] list
 /usr/sbin/ldapclient [-v | -q] uninit
 /usr/sbin/ldapclient [-v | -q] genprofile -a profileName=profileName
 [-a attrName=attrVal]

Description The ldapclient utility can be used to:

- initialize LDAP client machines
- restore the network service environment on LDAP clients
- list the contents of the LDAP client cache in human readable format.

The `init` form of the `ldapclient` utility is used to initialize an LDAP client machine, using a profile stored on an LDAP server specified by `LDAP_server`. The LDAP client will use the attributes in the specified profile to determine the configuration of the LDAP client. Using a configuration profile allows for easy installation of LDAP client and propagation of configuration changes to LDAP clients. The `ldap_cachemgr(1M)` utility will update the LDAP client configuration when its cache expires by reading the profile. For more information on the configuration profile refer to IETF document *A Configuration Schema for LDAP Based Directory User Agents*.

The `manual` form of the `ldapclient` utility is used to initialize an LDAP client machine manually. The LDAP client will use the attributes specified on the command line. Any unspecified attributes will be assigned their default values. At least one server must be specified in the `defaultServerList` or the `preferredServerList` attributes. The `domainName` attribute must be specified if the client's `domainName` is not set.

The `mod` form of the `ldapclient` utility is used to modify the configuration of an LDAP client machine that was setup manually. This option modifies only those LDAP client configuration attributes specified on the command line. The `mod` option should only be used on LDAP clients that were initialized using the `manual` option.

Regardless of which method is used for initialization, if a client is to be configured to use a `proxy credentialLevel`, proxy credentials must be provided using `-a proxyDN=proxyDN` and `-a proxyPassword=proxyPassword` options. However, if `-a proxyPassword=proxyPassword` is not specified, `ldapclient` will prompt for it. Note that NULL passwords are not allowed in LDAP. If a `self credentialLevel` is configured, `authenticationMethod` must be `sasl/GSSAPI`.

Similarly, if a client is to be configured to enable shadow information update and use a proxy `credentialLevel`, administrator credentials must be provided using `-a adminDN=adminDN` and `-a adminPassword=adminPassword`. However, the shadow information update does not need the administrator credentials if a `self credentialLevel` is configured.

If any file is modified during installation, it will be backed up to `/var/ldap/restore`. The files that are typically modified during initialization are:

- `/etc/nsswitch.conf`
- `/etc/defaultdomain` (if it exists)
- `/var/yp/binding/'domainname'` (for a NIS(YP) client)
- `/var/nis/NIS_COLD_START` (for a NIS+ client)
- `/var/ldap/ldap_client_file` (for an existing LDAP client)
- `/var/ldap/ldap_client_cred` (for an existing LDAP client)

`ldapclient` does not set up a client to resolve hostnames using DNS. It simply copies `/etc/nsswitch.ldap` to `/etc/nsswitch.conf`. If you prefer to use DNS for host resolution, please refer to the DNS documentation for information on setting up DNS. See [`resolv.conf\(4\)`](#). If you want to use `sasl/GSSAPI` as the authentication method, you have to use DNS for hosts and ipnodes resolution.

The `list` form of the `ldapclient` utility is used to list the LDAP client configuration. The output will be human readable. LDAP configuration files are not guaranteed to be human readable. Note that for security reason, the values for `adminDN` and `adminPassword` will not be displayed.

The `uninit` form of the `ldapclient` utility is used to uninitialized the network service environment, restoring it to the state it was in prior to the last execution of `ldapclient` using `init` or `manual`. The restoration will succeed only if the machine was initialized with the `init` or `manual` form of `ldapclient`, as it uses the backup files created by these options.

The `genprofile` option is used to write an LDIF formatted configuration profile based on the attributes specified on the command line to standard output. This profile can then be loaded into an LDAP server to be used as the client profile, which can be downloaded by means of the `ldapclient init` command. Loading the LDIF formatted profile to the directory server can be done through [`ldapadd\(1\)`](#), or through any server specific import tool. Note that the attributes `proxyDN`, `proxyPassword`, `certificatePath`, `domainName`, `enableShadowUpdate`, `adminDN`, and `adminPassword` are not part of the configuration profile and thus are not permitted.

You must have superuser privileges to run the `ldapclient` command, except with the `genprofile` option.

To access the information stored in the directory, clients can either authenticate to the directory, or use an unauthenticated connection. The LDAP client is configured to have a credential level of either anonymous or proxy. In the first case, the client does not authenticate to the directory. In the second case, client authenticates to the directory using a proxy identity for read access, and using an administrator identity for write access if `enableShadowUpdate` is configured. In the third case, client authenticates to the directory using a Kerberos principal that is mapped to an LDAP identity by the LDAP server. Refer to the chapter on implementing security in the *System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)* or your appropriate directory server documentation for identity mapping details.

If a client is configured to use an identity, you can configure which authentication method the client will use. The LDAP client supports the following authentication methods:

```
none
simple
sasl/CRAM-MD5
sasl/DIGEST-MD5
sasl/GSSAPI
tls:simple
tls:sasl/CRAM-MD5
tls:sasl/DIGEST-MD5
```

Note that some directory servers may not support all of these authentication methods. For `simple`, be aware that the bind password will be sent in the clear to the LDAP server. For those authentication methods using TLS (transport layer security), the entire session is encrypted. You will need to install the appropriate certificate databases to use TLS.

Commands The following commands are supported:

```
init
    Initialize client from a profile on a server.

manual
    Manually initialize client with the specified attribute values.

mod
    Modify attribute values in the configuration file after a manual initialization of the client.

list
    Write the contents of the LDAP client cache to standard output in human readable form.

uninit
    Uninitialize an LDAP client, assuming that ldapclient was used to initialize the client.
```

genprofile

Generate a configuration profile in LDIF format that can then be stored in the directory for clients to use, with the `init` form of this command.

Attributes The following attributes are supported:

adminDN

Specify the Bind Distinguished Name for the administrator identity that is used for shadow information update. This option is required if the credential level is `proxy`, and `enableShadowUpdate` is set to `true`. There is no default value.

adminPassword

Specify the administrator password. This option is required if the credential level is `proxy`, and `enableShadowUpdate` is set to `true`. There is no default value.

attributeMap

Specify a mapping from an attribute defined by a service to an attribute in an alternative schema. This can be used to change the default schema used for a given service. The syntax of `attributeMap` is defined in the profile IETF draft. This option can be specified multiple times. The default value for all services is `NULL`. In the example,

```
attributeMap: passwd:uid=employeeNumber
```

the LDAP client would use the LDAP attribute `employeeNumber` rather than `uid` for the `passwd` service. This is a multivalued attribute.

authenticationMethod

Specify the default authentication method used by all services unless overridden by the `serviceAuthenticationMethod` attribute. Multiple values can be specified by using a semicolon-separated list. The default value is `none`. For those services that use `credentialLevel` and `credentialLevel` is `anonymous`, this attribute is ignored. Services such as `pam_ldap` will use this attribute, even if `credentialLevel` is `anonymous`. The supported authentication methods are described above. If the `authenticationMethod` is `sasl/GSSAPI`, the `hosts` and `ipnodes` of `/etc/nsswitch.conf` must be configured with DNS support, for example:

```
hosts: dns files
ipnodes: dns files
```

bindTimeLimit

The maximum time in seconds that a client should spend performing a bind operation. Set this to a positive integer. The default value is 30.

certificatePath

The certificate path for the location of the certificate database. The value is the path where security database files reside. This is used for TLS support, which is specified in the `authenticationMethod` and `serviceAuthenticationMethod` attributes. The default is `/var/ldap`.

credentialLevel

Specify the credential level the client should use to contact the directory. The credential levels supported are either `anonymous` or `proxy`. If a proxy credential level is specified, then the `authenticationMethod` attribute must be specified to determine the authentication mechanism. Also, if the credential level is `proxy` and at least one of the authentication methods require a bind DN, the `proxyDN` and `proxyPassword` attribute values must be set. In addition, if `enableShadowUpdate` is set to `true`, the `adminDN` and `adminPassword` values must be set. If a self credential level is specified, the `authenticationMethod` must be `sasl/GSSAPI`.

defaultSearchBase

Specify the default search base DN. There is no default. The `serviceSearchDescriptor` attribute can be used to override the `defaultSearchBase` for given services.

defaultSearchScope=one | sub

Specify the default search scope for the client's search operations. This default can be overridden for a given service by specifying a `serviceSearchDescriptor`. The default is one level search.

defaultServerList

A space separated list of server names or server addresses, either IPv4 or IPv6. If you specify server names, be sure that the LDAP client can resolve the name without the LDAP name service. You must resolve the LDAP servers' names by using either `files` or `dns`. If the LDAP server name cannot be resolved, your naming service will fail.

The port number is optional. If not specified, the default LDAP server port number 389 is used, except when TLS is specified in the authentication method. In this case, the default LDAP server port number is 636.

The format to specify the port number for an IPv6 address is:

```
[ipv6_addr]:port
```

To specify the port number for an IPv4 address, use the following format:

```
ipv4_addr:port
```

If the host name is specified, use the format:

```
host_name:port
```

If you use TLS, the LDAP server's hostname must match the hostname in the TLS certificate. Typically, the hostname in the TLS certificate is a fully qualified domain name. With TLS, the LDAP server host addresses must resolve to the hostnames in the TLS certificate. You must use `files` or `dns` to resolve the host address.

domainName

Specify the DNS domain name. This becomes the default domain for the machine. The default is the current domain name. This attribute is only used in client initialization.

`enableShadowUpdate=true | false`

Specify whether the client is allowed to update shadow information. If set to `true` and the credential level is `proxy`, `adminDN` and `adminPassword` must be specified.

`followReferrals=true | false`

Specify the referral setting. A setting of `true` implies that referrals will be automatically followed and `false` would result in referrals not being followed. The default is `true`.

`objectClassMap`

Specify a mapping from an `objectClass` defined by a service to an `objectClass` in an alternative schema. This can be used to change the default schema used for a given service. The syntax of `objectClassMap` is defined in the profile IETF draft. This option can be specified multiple times. The default value for all services is `NULL`. In the example,

```
objectClassMap=passwd:posixAccount=unixAccount
```

the LDAP client would use the LDAP `objectClass` of `unixAccount` rather than the `posixAccount` for the `passwd` service. This is a multivalued attribute.

`preferredServerList`

Specify the space separated list of server names or server addresses, either IPv4 or IPv6, to be contacted before servers specified by the `defaultServerList` attribute. If you specify server names, be sure that the LDAP client can resolve the name without the LDAP name service. You must resolve the LDAP servers' names by using either `files` or `dns`. If the LDAP server name cannot be resolved, your naming service will fail.

The port number is optional. If not specified, the default LDAP server port number 389 is used, except when TLS is specified in the authentication method. In this case, the default LDAP server port number is 636.

The format to specify the port number for an IPv6 address is:

```
[ipv6_addr]:port
```

To specify the port number for an IPv4 address, use the following format:

```
ipv4_addr:port
```

If the host name is specified, use the format:

```
host_name:port
```

If you use TLS, the LDAP server's hostname must match the hostname in the TLS certificate. Typically, the hostname in the TLS certificate is a fully qualified domain name. With TLS, the LDAP server host addresses must resolve to the hostnames in the TLS certificate. You must use `files` or `dns` to resolve the host address.

`profileName`

Specify the profile name. For `ldapclient init`, this attribute is the name of an existing profile which may be downloaded periodically depending on the value of the `profileTTL` attribute. For `ldapclient genprofile`, this is the name of the profile to be generated. The default value is `default`.

profileTTL

Specify the TTL value in seconds for the client information. This is only relevant if the machine was initialized with a client profile. If you do not want `ldap_cachemgr(1M)` to attempt to refresh the LDAP client configuration from the LDAP server, set `profileTTL` to 0 (zero). Valid values are either zero 0 (for no expiration) or a positive integer in seconds. The default value is 12 hours.

proxyDN

Specify the Bind Distinguished Name for the proxy identity. This option is required if the credential level is proxy, and at least one of the authentication methods requires a bind DN. There is no default value.

proxyPassword

Specify client proxy password. This option is required if the credential level is proxy, and at least one of the authentication methods requires a bind DN. There is no default.

searchTimeLimit

Specify maximum number of seconds allowed for an LDAP search operation. The default is 30 seconds. The server may have its own search time limit.

serviceAuthenticationMethod

Specify authentication methods to be used by a service in the form `servicename:authenticationmethod`, for example:

```
pam_ldap:tls:simple
```

For multiple authentication methods, use a semicolon-separated list. The default value is no service authentication methods, in which case, each service would default to the `authenticationMethod` value. The supported authentications are described above.

Three services support this feature: `passwd - cmd`, `key serv`, and `pam_ldap`. The `passwd - cmd` service is used to define the authentication method to be used by `passwd(1)` to change the user's password and other attributes. The `key serv` service is used to identify the authentication method to be used by the `chkey(1)` and `newkey(1M)` utilities. The `pam_ldap` service defines the authentication method to be used for authenticating users when `pam_ldap(5)` is configured. If this attribute is not set for any of these services, the `authenticationMethod` attribute is used to define the authentication method. This is a multivalued attribute.

serviceCredentialLevel

Specify credential level to be used by a service. Multiple values can be specified in a space-separated list. The default value for all services is NULL. The supported credential levels are: `anonymous` or `proxy`. At present, no service uses this attribute. This is a multivalued attribute.

serviceSearchDescriptor

Override the default base DN for LDAP searches for a given service. The format of the descriptors also allow overriding the default search scope and search filter for each service.

The syntax of `serviceSearchDescriptor` is defined in the profile IETF draft. The default value for all services is NULL. This is a multivalued attribute. In the example,

```
serviceSearchDescriptor=passwd:ou=people,dc=a1,dc=acme,dc=com?one
```

the LDAP client would do a one level search in `ou=people,dc=a1,dc=acme,dc=com` rather than `ou=people,defaultSearchBase` for the `passwd` service.

Options The following options are supported:

`-a attrName=attrValue`

Specify `attrName` and its value. See SYNOPSIS for a complete list of possible attribute names and values.

`-D bindDN`

Specifies an entry that has read permission for the requested database.

`-j passwdFile`

Specify a file containing the password for the bind DN or the password for the SSL client's key database. To protect the password, use this option in scripts and place the password in a secure file. This option is mutually exclusive of the `-w` option.

`-q`

Quiet mode. No output is generated.

`-v`

Verbose output.

`-w bindPassword`

Password to be used for authenticating the bind DN. If this parameter is missing, the command will prompt for a password. NULL passwords are not supported in LDAP.

When you use `-w bindPassword` to specify the password to be used for authentication, the password is visible to other users of the system by means of the `ps` command, in script files, or in shell history.

If you supply “-” (hyphen) as a password, the command will prompt for a password.

`-y passwdFile`

Specify a file containing the password for the proxy DN. To protect the password, use this option in scripts and place the password in a secure file. This option is mutually exclusive of the `-a proxyPassword` option.

`-z adminrPasswdFile`

Specify a file containing the password for the `adminDN`. To protect the password, use this option in scripts and place the password in a secure file. This option is mutually exclusive of the `-a adminPassword` option.

Operands The following operand is supported:

LDAP_server

An address or a name for the LDAP server from which the profile will be loaded. The current naming service specified in the `nswitch.conf` file is used. Once the profile is loaded, the `preferredServerList` and `defaultServerList` specified in the profile are used.

Examples **EXAMPLE 1** Setting Up a Client By Using the Default Profile Stored on a Specified LDAP Server

The following example shows how to set up a client using the default profile stored on the specified LDAP server. This command will only be successful if either the credential level in the profile is set to anonymous or the authentication method is set to none.

```
example# ldapclient init 172.16.100.1
```

EXAMPLE 2 Setting Up a Client By Using the simple Profile Stored on a Specified LDAP Server

The following example shows how to set up a client using the simple profile stored on the specified LDAP server. The domainname is set to `xyz.mycompany.com` and the `proxyPassword` is `secret`.

```
example# ldapclient init -a profileName=simple \
-a domainName=xyz.mycompany.com \
-a proxyDN=cn=proxyagent,ou=profile,dc=xyz,dc=mycompany,dc=com \
-a proxyPassword=secret '['fe80::a00:20ff:fea3:388']':386
```

EXAMPLE 3 Setting Up a Client Using Only One Server

The following example shows how to set up a client using only one server. The authentication method is set to none, and the search base is `dc=mycompany,dc=com`.

```
example# ldapclient manual -a authenticationMethod=none \
-a defaultSearchBase=dc=mycompany,dc=com \
-a defaultServerList=172.16.100.1
```

EXAMPLE 4 Setting Up a Client Using Only One Server That Does Not Follow Referrals

The following example shows how to set up a client using only one server. The credential level is set to proxy. The authentication method of is `sasl/CRAM-MD5`, with the option not to follow referrals. The domain name is `xyz.mycompany.com`, and the LDAP server is running on port number 386 at IP address `172.16.100.1`.

```
example# ldapclient manual \
-a credentialLevel=proxy \
-a authenticationMethod=sasl/CRAM-MD5 \
-a proxyPassword=secret \
-a proxyDN=cn=proxyagent,ou=profile,dc=xyz,dc=mycompany,dc=com \
-a defaultSearchBase=dc=xyz,dc=mycompany,dc=com \
-a domainName=xyz.mycompany.com \
-a followReferrals=false \
```

EXAMPLE 4 Setting Up a Client Using Only One Server That Does Not Follow Referrals (Continued)

```
-a defaultServerList=172.16.100.1:386
```

EXAMPLE 5 Using genprofile to Set Only the defaultSearchBase and the Server Addresses

The following example shows how to use the genprofile command to set the defaultSearchBase and the server addresses.

```
example# ldapclient genprofile -a profileName=myprofile \  
-a defaultSearchBase=dc=eng,dc=sun,dc=com \  
-a "defaultServerList=172.16.100.1 172.16.234.15:386" \  
> myprofile.ldif
```

EXAMPLE 6 Creating a Profile on IPv6 servers

The following example creates a profile on IPv6 servers

```
example# ldapclient genprofile -a profileName=eng \  
-a credentialLevel=proxy \  
-a authenticationMethod=sasl/DIGEST-MD5 \  
-a defaultSearchBase=dc=eng,dc=acme,dc=com \  
-a "serviceSearchDescriptor=passwd:ou=people,dc=a1,dc=acme,dc=com?one"\  
-a preferredServerList= '['fe80::a00:20ff:fea3:388']' \  
-a "defaultServerList=['fec0::111:a00:20ff:fea3:edcf']' \  
  '['fec0::111:a00:20ff:feb5:e41']'" > eng.ldif
```

EXAMPLE 7 Creating a Profile That Overrides Every Default Value

The following example shows a profile that overrides every default value.

```
example# ldapclient genprofile -a profileName=eng \  
-a credentialLevel=proxy -a authenticationMethod=sasl/DIGEST-MD5 \  
-a bindTimeLimit=20 \  
-a defaultSearchBase=dc=eng,dc=acme,dc=com \  
-a "serviceSearchDescriptor=passwd:ou=people,dc=a1,dc=acme,dc=com?one"\  
-a serviceAuthenticationMethod=pam_ldap:tls:simple \  
-a defaultSearchScope=sub \  
-a attributeMap=passwd:uid=employeeNumber \  
-a objectclassMap=passwd:posixAccount=unixAccount \  
-a followReferrals=false -a profileTTL=6000 \  
-a preferredServerList=172.16.100.30 -a searchTimeLimit=30 \  
-a "defaultServerList=172.16.200.1 172.16.100.1 192.168.5.6" > eng.ldif
```

Exit Status The following exit values are returned:

- 0 The command successfully executed.
- 1 An error occurred. An error message is output.
- 2 proxyDN and proxyPassword attributes are required, but they are not provided.

Files /var/ldap/ldap_client_cred
 /var/ldap/ldap_client_file
 Contain the LDAP configuration of the client. These files are not to be modified manually. Their content is not guaranteed to be human readable. Use `ldapclient` to update them.

/etc/defaultdomain
 System default domain name, matching the domain name of the data in the LDAP servers. See [defaultdomain\(4\)](#).

/etc/nsswitch.conf
 Configuration file for the name-service switch. See [nsswitch.conf\(4\)](#).

/etc/nsswitch.ldap
 Sample configuration file for the name-service switch configured with LDAP and files.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|--------------------|
| Availability | system/network/nis |
| Interface Stability | Committed |

See Also [chkey\(1\)](#), [ldap\(1\)](#), [ldapadd\(1\)](#), [ldapdelete\(1\)](#), [ldaplist\(1\)](#), [ldapmodify\(1\)](#), [ldapmodrdn\(1\)](#), [ldapsearch\(1\)](#), [idsconfig\(1M\)](#), [ldapaddent\(1M\)](#), [ldap_cachemgr\(1M\)](#), [suninstall\(1M\)](#), [defaultdomain\(4\)](#), [nsswitch.conf\(4\)](#), [resolv.conf\(4\)](#), [attributes\(5\)](#)

Caution Currently StartTLS is not supported by `libldap.so.5`, therefore the port number provided refers to the port used during a TLS open, rather than the port used as part of a StartTLS sequence. To avoid timeout delays, mixed use of TLS and non-TLS authentication mechanisms is not recommended.

For example:

```
-h foo:1000 -a authenticationMethod=tls:simple
```

...or:

```
defaultServerList= foo:1000
authenticationMethod= tls:simple
```

The preceding refers to a raw TLS open on host `foo` port 1000, not an open, StartTLS sequence on an unsecured port 1000. If port 1000 is unsecured the connection will not be made.

As a second example, the following will incur a significant timeout delay while attempting the connection to `foo:636` with an unsecured bind.

```
defaultServerList= foo:636 foo:389
authenticationMethod= simple
```

Name ldmad – Logical Domains Agents daemon

Synopsis /usr/lib/ldoms/ldmad

Description The ldmad daemon is part of the framework that enables Logical Domain agents to run on a Logical Domain. A Logical Domain agent is a component that interacts with the control domain to provide features or information.

ldmad is responsible for running agents on a Logical Domain. ldmad must be enabled to ensure the proper functionality of all features provided by the domain manager on the control domain. The daemon is started at boot time and has no configuration options.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWldomu |
| Interface Stability | Unstable |

See Also [svcs\(1\)](#), [svcadm\(1M\)](#), [syslog\(3C\)](#), [syslog.conf\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Logical Domains 1.2 Administration Guide

Errors ldmad uses [syslog\(3C\)](#) to report status and error messages. Error messages are logged with the LOG_ERR and LOG_NOTICE priorities. Informational messages are logged with the LOG_INFO priority. The default entries in the /etc/syslog.conf file specify that all ldmad error messages are written to the /var/adm/messages log.

Notes The ldmad service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/ldoms/agents:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Name link, unlink – link and unlink files and directories

Synopsis /usr/sbin/link *existing-file new-file*
 /usr/xpg4/bin/link *existing-file new-file*
 /usr/sbin/unlink *file*

Description The `link` and `unlink` commands link and unlink files and directories. Only super-users can use these commands on directories.

Use `link` to create a new file that points to an existing file. The *existing-file* and *new-file* operands specify the existing file and newly-created files. See OPERANDS.

`link` and `unlink` directly invoke the `link(2)` and `unlink(2)` system calls, performing exactly what they are told to do and abandoning all error checking. This differs from the `ln(1)` command. See `ln(1)`.

While linked files and directories can be removed using `unlink`, it is safer to use `rm(1)` and `rmdir(1)` instead. See `rm(1)` and `rmdir(1)`.

/usr/xpg4/bin/link If the existing file being hard linked is itself a symbolic link, then the newly created file (*new-file*) will be a hard link to the file referenced by the symbolic link, not to the symbolic link object itself (*existing-file*).

Operands The following operands are supported:

existing-file Specifies the name of the existing file to be linked.
file Specifies the name of the file to be unlinked.
new-file Specifies the name of newly created (linked) file.

Environment Variables See `environ(5)` for descriptions of the following environment variables that affect the execution of `link`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

Attributes See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

/usr/xpg4/bin/link

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|---------------------------------|
| Availability | SUNWxcu4 |
| Interface Stability | Committed |
| Standard | See <code>standards(5)</code> . |

See Also [ln\(1\)](#), [rm\(1\)](#), [link\(2\)](#), [unlink\(2\)](#), [attributes\(5\)](#), [environ\(5\)](#), [standards\(5\)](#)

Name listdgrp – lists members of a device group

Synopsis /usr/bin/listdgrp *dgroup*...

Description listdgrp displays the members of the device groups specified by the *dgroup* list.

Examples EXAMPLE 1 An example of listdgrp.

The following example lists the devices that belong to group partitions:

```
example% listdgrp partitions
        root
        swap
        usr
```

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 Command was syntax incorrect, an invalid option used, or an internal error occurred.
- 2 A device group table could not be opened for reading.
- 3 A device group *dgroup* could not be found in the device group table.

Files /etc/dgroup.tab Device group table.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [putdgrp\(1M\)](#), [attributes\(5\)](#)

Name listen – network listener daemon

Synopsis /usr/lib/saf/listen [-m *devstem*] *net_spec*

Description The `listen` process “listens” to a network for service requests, accepts requests when they arrive, and invokes servers in response to those service requests. The network listener process may be used with any connection-oriented network (more precisely, with any connection-oriented transport provider) that conforms to the Transport Layer Interface (TLI) Specification.

The listener internally generates a pathname for the minor device for each connection; it is this pathname that is used in the `utmpx` entry for a service, if one is created. By default, this pathname is the concatenation of the prefix `/dev/netspec` with the decimal representation of the minor device number. In either case, the representation of the minor device number will be at least two digits (for example, 05 or 27), or longer when it is necessary to accommodate minor device numbers larger than 99.

Server Invocation When a connection indication is received, the listener creates a new transport endpoint and accepts the connection on that endpoint. Before giving the file descriptor for this new connection to the server, any designated STREAMS modules are pushed and the configuration script is executed, (if one exists). This file descriptor is appropriate for use with either TLI (see `t_sync(3NSL)`) or the sockets interface library.

By default, a new instance of the server is invoked for each connection. When the server is invoked, file descriptor 0 refers to the transport endpoint, and is open for reading and writing. File descriptors 1 and 2 are copies of file descriptor 0; no other file descriptors are open. The service is invoked with the user and group IDs of the user name under which the service was registered with the listener, and with the current directory set to the HOME directory of that user.

Alternatively, a service may be registered so that the listener will pass connections to a standing server process through a FIFO or a named stream, instead of invoking the server anew for each connection. In this case, the connection is passed in the form of a file descriptor that refers to the new transport endpoint. Before the file descriptor is sent to the server, the listener interprets any configuration script registered for that service using `doconfig(3NSL)`, although `doconfig` is invoked with both the `NORUN` and `NOASSIGN` flags. The server receives the file descriptor for the connection in a `strrecvfd` structure using an `I_RECVFD ioctl(2)`.

For more details about the listener and its administration, see `nlsadmin(1M)`.

Options `-mdevstem` The listener will use *devstem* as the prefix for the pathname.

Files `/etc/saf/pmtag/*`

Attributes See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [nlsadmin\(1M\)](#), [pmadm\(1M\)](#), [sac\(1M\)](#), [sacadm\(1M\)](#), [ioctl\(2\)](#), [doconfig\(3NSL\)](#), [nlsgetcall\(3NSL\)](#), [nlsprovider\(3NSL\)](#), [t_sync\(3NSL\)](#), [attributes\(5\)](#), [streamio\(7I\)](#)

System Administration Guide: Basic Administration

Notes When passing a connection to a standing server, the user and group IDs contained in the `strrecvfd` structure will be those for the listener (that is, they will both be 0); the user name under which the service was registered with the listener is not reflected in these IDs.

When operating multiple instances of the listener on a single transport provider, there is a potential race condition in the binding of addresses during initialization of the listeners, if any of their services have dynamically assigned addresses. This condition would appear as an inability of the listener to bind a static-address service to its otherwise valid address, and would result from a dynamic-address service having been bound to that address by a different instance of the listener.

Name llc2_loop – loopback diagnostics to test the driver, adapter and network.

Synopsis /usr/lib/llc2/llc2_loop2 [-v] *ppa*
 /usr/lib/llc2/llc2_loop3 *ppa sap frames*
 /usr/lib/llc2/llc2_loop3 *ppa type frames*
 /usr/lib/llc2/llc2_loop4 [-v] *ppa*

Description

loop2 The loop2 test sends a NULL XID frame to the broadcast (all 1's) destination MAC address. The source SAP (Service Access Point) value used is 0x04 (SNA's SAP). Therefore, if SNA is running on the system, the loop2 test will fail. The destination SAP value is the NULL SAP (0x00). This test finds out who is listening and can receive frames sent out from a node. The verbose (-v) option displays the MAC address of responding nodes. All possible responders may not be displayed, since the loop2 test only waits for responses for 2 seconds, but during this time 50-200 nodes may be displayed. The most likely error is:

Unexpected DLPI primitive *x*, expected *y*.

where $x = 5$ and $y = 6$. From /usr/include/sys/dlpi.h, the expected return value from one of the DLPI primitives is 6 (DL_OK_ACK), but instead a 5 (DL_ERROR_ACK) was received. This can occur for two reasons:

- The loop2 command was issued to a non-existent PPA (Physical Point of Attachment).
- The SAP (0x04) is already in use (for example, the SNA subsystem is up).

loop3 The loop3 test sends 1,495 byte Unnumbered Information (UI) frames to the NULL (all 0's) destination MAC address. This should be used along with data capture either on the local node or another node on the same LAN to verify the transmission of data. The *ppa* argument specifies the adapter on which to run the test. The *ppa* is the relative physical position of the adapter and may be ascertained by viewing the adapter configuration (see [llc2_config\(1\)](#)). For Token Ring or Ethernet, specify an even *sap* value from 2 through 254, or, for Ethernet only, any *type* value from 1519 (0x05ef) through 65535 (0xffff). It is advised to pick a value that is easily recognized when the data capture output is viewed. *frames* is the decimal number of 1,495 bytes packets to transmit. The test will only display a message if a failure occurs.

loop4 The loop4 test sends a TEST frame (no information field) to the broadcast (all 1's) destination MAC address. The source SAP value used is 0x04 (SNA's SAP). Therefore, if SNA is running on the system, the loop4 test will fail. The destination SAP value is the NULL SAP (0x00). This test finds out who is listening and can receive frames sent out from a node. The verbose (-v) option displays the MAC address of responding nodes. All possible responders may not be displayed since the loop4 test only waits for responses for 2 seconds, but during this time 50-200 nodes may be displayed. The loop4 test displays information similar to the following example if other nodes are listening and respond (verbose mode):

-Attaching
 -Binding

```
-Sending TEST
-Responders
  1-0000c0c12449
  2-08000e142990
  3-08000e142a51
  4-0000c0450044
  5-0000c0199e46
-Unbinding
-Detaching
5 nodes responding
```

The errors displayed are the same as for `loop2`.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWllc |

See Also [llc2_config\(1\)](#), [llc2\(4\)](#), [attributes\(5\)](#), [llc2\(7D\)](#)

Notes For information about how to start the service, see [llc2\(7D\)](#)

Name lms – allow applications to access the Intel Active Management Technology

Synopsis lms

Description The Local Manageability Service, lms, allows applications to access the Intel Active Management Technology (Intel AMT) ME (Management Engine) using the local HECI interface. LMS is dependent on the HECI driver.

To use lms, ensure that the Intel AMT Manageability Interface driver is installed and connected to the ME.

lms is intended to be run as a daemon. Messages from the service are sent to the sys log. LMS messages are marked with a source of "LMS".

For an example of how to enable the LMS service using SMF, see EXAMPLES.

Examples EXAMPLE 1 Enabling the LMS service using SMF

The following example enables the LMS service using SMF:

```
svcadm enable network/lms
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------------------|
| Architecture | x86 |
| Availability | system/management/intel-amt |
| Interface Stability | Volatile |

See Also [attributes\(5\)](#), [smf\(5\)](#)

Name localeadm – query and configure locales

Synopsis localeadm [-lcst] [-q *locale* | *region*] [-h] [-d *device*]...
 localeadm -r *locale* | *region* [-t] [-v] [-m] [-R *root_path*]
 localeadm -a *locale* | *region* [-t] [-v] [-m] [-d *device*]...
 [-R *root_path*]
 localeadm -f *locale* | *region* [-t] [-v] [-m] [-d *device*]...
 [-R *root_path*]
 localeadm -s
 localeadm -h
 localeadm -C

Description The localeadm utility queries and configures Solaris locales through a command line interface.

In query (-q) or list (-l) modes, localeadm displays information about locale packages that are installed on the system or that reside on a particular device or directory.

To make it easier for users to pick out locales, the output from localeadm consists of a list of country or region names rather than a list of packages. Users can use the output to determine which locales or regions to add or remove.

When the user specifies a locale or region to add or remove using the name given by the output of the list mode, localeadm calculates which locale packages need to be changed and add or remove them. localeadm uses pkgadd(1M) or pkgrm(1M) to add or remove packages.

If the locales changed were Asian locales, then extra processes such as input method server daemons might need to be started before the new locales work properly. Once the locales are installed, the user is prompted to either reboot the machine or manually start the daemons. The user is also given a list of daemons which need to be started.

All locales are part of a set geographic region. A locale is an indivisible part of a region. You cannot have a locale which doesn't exist in a region, or a region without locales. If you choose to add or remove a particular locale, all of the locales in the region to which it belongs will be added or removed. Likewise, if you query a locale, localeadm checks the system for the region of which the local is part.

Options The following options are supported:

-a *locale* | *region* Add the packages for locale (*locale*) or geographic region *region* to the system.

Specify *locale* or *region* as the short name displayed by the -l option. For example, the -l option outputs Australasia (aua), therefore, the argument for -a is aua.

This option requires the `-d` option with arguments. If necessary packages are already installed, `localeadm` does not overwrite them. It simply skips such packages.

If you use the `-a` and `-m` options with a locale that has already been added without desktop translated message packages, it adds the desktop translated message packages for that locale to the system.

Only superusers or others who have been assigned package administration access through role-based access control can use this option. See [rbac\(5\)](#) for information on adding and removing packages. See [smc\(1M\)](#) for information on setting up and adding users to a package manager role.

- c Display the locale name with codeset in [locale\(1\)](#) format.

- Use this option in conjunction with the `-l` option to display the locale name with codeset in the format shown by the [locale\(1\)](#) command. For example, it displays `fr_FR.ISO8859-1` as opposed to `french`.
- C Enable user to recreate the `Locale_config` file based on the images available to them. This attempts to ensure that any inaccuracies (more likely for non-GA versions) in the bundled configuration file are addressed.

- d *device* Install or list locales from packages located in *device*. Specify *device* as a full path name to a directory containing Solaris packages or the path to the top directory of a complete Solaris image. You can also specify *device* as a device alias such as `/cdrom/cdrom0`, a device nickname as defined by [eject\(1\)](#), or an alternative device nickname such as `cdrom`, `dvd` or `dvdrom`. If the packages are to be installed from a series of CDROM images, then multiple images can be specified in a comma separated list. The same device or nickname can be repeated to indicate multiple loadings of different media at the same device.

- f Check the pkgs modified by a previous add or remove operation to ensure all pkgs were added or removed properly. If a pkg was incorrectly added due to a `pkgadd` or `pkgrm` failure, the pkg is backed out and reinstalled.

- Only superusers or others who have been assigned package administration access through role-based access control can use this option. See [rbac\(5\)](#) for information on adding and removing packages. See [smc\(1M\)](#) for information on setting up and adding users to a package manager role.

- h** Print a short help message. The help message lists all the flags and their usage.
- l** List all the locales that are installed on the system or available on an install media. The list is sorted by geographic region.
- When you specify the **-d** option with **-l**, `localedm` lists all of the locales or regions available on the device pointed to by the **-d** option arguments.
- When you do not specify the **-d** option, `localedm -l` lists all of the locales or regions installed on the current system.
- When you specify the **-t** option with **-l**, `localedm` lists all of the locales or regions that could possibly be added to the system.
- m** Deselect translated message packages.
- By default, with the **-a** option, `localedm` adds the translated desktop message packages for the locale or region specified in the **-a** option argument. If you use the **-a** option with the **-m** option, the desktop translated message packages for the locale or region will not be added, thus effectively disabling the desktop translated messages support for that locale or region. If used with the **-r** option, `localedm` will remove only the translated desktop message packages for the locale or region specified in the **-r** option argument.
- If you use the **-m** option with a locale that has already been added without the translated desktop message packages it adds the translated desktop message packages for that locale to the system.
- q locale | region** Query the system to see if the locale (*locale*) or geographic region *region* are already installed. The expected input for a locale or region name is the name displayed by the **-l** option.
- r locale | region** Remove the packages for locale (*locale*) or geographic region (*region*) from the system.
- Specify *locale* or *region* as the short name displayed by the **-l** option. For example, the **-l** option outputs Australasia (aia), therefore, the argument for **-a** is aia.
- Only superusers or others who have been assigned package administration access through role-based access control can use this option. See [rbac\(5\)](#) for information on adding and removing packages. See [smc\(1M\)](#) for information on setting up and adding users to a package manager role.

- R *root_path*** Define the full path name of a directory to use as the root path. All files, including package system information files, are relocated to a directory tree starting in the specified *root_path*. You can specify *root_path* when you install to a client from a server.
- Note** – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).
- s** Display only the geographic regions of specific locales or regions.
- Use this option in conjunction with the -l option to display listed regions or locales.
- t** Test mode.
- Use this option with -a, -f or -r to list all operations to be done. It will not actually add or remove packages.
- Use the this option with -l to list all of the locales or regions that could possibly be added to the system.
- v** Print out messages produced during a pkgadd or pkgrm command.
- This option works on loca`leadm` add and remove commands. It does not work on individual pkgadd or pkgrm commands. It displays additional information, but only as part of the larger program.

Examples **EXAMPLE 1** Listing All of the Locales and Codesets

The following example lists all of the geographic regions installed on the machine. All locales in the regions are listed by their codesets:

```
example% localeadm -lc
```

EXAMPLE 2 Listing the Regions Available on a Solaris CD or DVD

The following example command checks the `Solaris_10/Product` directory of the CD or DVD mounted on `/cdrom/cdrom0`. It also lists the names of the regions that can be installed from packages in that directory. The -s option displays the region names without any locales.

```
example% localeadm -ls -d /cdrom/cdrom0
```

EXAMPLE 3 Querying for a Locale

The following example queries whether the Central European region called `ceu` on the current machine.

```
example% localeadm -q ceu
```

EXAMPLE 4 Removing Western European Locales

The following example removes all packages associated with the Western Europe region from the system, except for those packages needed by other regions.

```
example% localeadm -r weu
```

EXAMPLE 5 Adding Russian Locales

The following example installs the Eastern Europe region, of which Russian locale is a part, from packages located in `/net/sparc_images/export/pkg`s.

```
example# localeadm -a ru_RU -d /net/sparc_images/export/pkg
```

EXAMPLE 6 Adding the Traditional Chinese Locale

The following example adds the Traditional Chinese region to the system. This differs from the previous example in that Traditional Chinese is installed as a geographic region rather than just a locale. This is the case for all Asian languages, for example, `zh_TW`, `zh_CN`, `zh_HK`, `hi_IN`, `th_TH`, `ko_KR`, `ja`.

```
# localeadm -a zh_TW -d /net/sparc_images/export/pkg
```

Exit Status The following exit values are returned when you invoke `localeadmin` without the `-q` (query) option:

- 0 Successful completion.
- 1 An error occurred.

The following exit values are returned when you invoke `localeadmin` with the `-q` (query) option:

- 0 Successful search. The locale or region was found.
- 1 Unsuccessful search. The locale or region was not found.
- 2 An error occurred.

Files `/var/sadm/install/logs/localeadmin_install.date`
`/var/sadm/install/logs/localeadmin_uninstall.date`
Log files for installation and removal operations.

date is specified in `YYYY_MM_DD` format. If a particular day has multiple installs, *date* has a period (`.`) followed by a number appended to it, for example, `2003_10_20.1`, `2003_10_20.2`.

`/tmp/locales.list`

File that contains the output of the `-l` option.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWladm |
| Interface Stability | Committed |

See Also [eject\(1\)](#), [locale\(1\)](#), [pkgadd\(1M\)](#), [pkgrm\(1M\)](#), [smc\(1M\)](#), [attributes\(5\)](#), [rbac\(5\)](#)

International Language Environments Guide

Name `localectr` – customize and build new locales

Synopsis `/usr/bin/localectr`

```
/usr/bin/localectr -l locale1,locale2... [-d destination_path]
    [-c compiler_path] [-r 0 | 1 | 2] [-i pkginfo_template]
    [-p pkgname_prefix]

/usr/bin/localectr -h

/usr/bin/localectr -q

/usr/bin/localectr -V
```

Description The `localectr` utility allows new locales to be customized and built. The output of `localectr` is an installable package containing the compiled shared object binary which contains the locale data information as well as a number of other supporting files that are required to have a fully working locale on the system.

Once generated, the package can be added to the system by using the [pkgadd\(1M\)](#) command and removed with [pkgrm\(1M\)](#).

Depending on your default system login, you might have to reset your user environment after you add a locale. If `dtlogin(1X)` (for the CDE user environment) is the default system login, you need to restart `dtlogin`. No action is required if `gdm(1)` (for the Gnome user environment) is the default login.

There are two interfaces to `localectr`, command line (CLI) and graphical user interface (GUI). To customize the locale data, you must use the GUI. To create locales with standard locale data according to Unicode's Common Locale Data Repository (CLDR), the CLI is sufficient.

With the CLI it is also possible to generate several locales in a single step, with a separate package being generated for each locale. With the GUI, a single locale is processed at a time.

To launch the GUI, run the `localectr` command with no options. To run from the CLI, use the appropriate options as described below.

`localectr` uses the [localedef\(1\)](#) utility to build the locale data binary shared object. Therefore, access to a C compiler is required in order to run `localectr` successfully, as this is also required by `localedef`.

`localectr` is mainly concerned with locale data. However, in order to create a fully working locale on the system with `localectr`, many features, such as fonts, translations and input methods, are also required. Depending on what locales are already installed on the system, the relevant features might or might not be present on the system. If they are not present, then [localedm\(1M\)](#) should be used to add the relevant packages before adding packages created by `localectr`. `localectr` bundles locale data for the latest set of locales available in Unicode's CLDR. A user can also create a locale not available in CLDR by supplying her own data in the `localectr` GUI.

Options The following options are supported:

- c *compiler_path*
Specify the path to the C compiler that is used to compile the locale data into a shared object binary. Not required if the compiler is already in the user's PATH.
- d *destination_path*
Specify the path to the directory where the created package is to be stored.
- h
Displays the usage message.
- i *template_file*
The full path to user defined `pkginfo(4)` template file.
- l *locale1,locale2...*
Specify a comma-separated list of locale(s) to generate. Locale names are in the form: *locale.codeset@variant*, where *codeset* and *variant* are optional. The default and only allowed *codeset* is UTF-8. The default *variant* is `localectr`.
- p
The package name prefix
- q
Queries `localectr` for a complete list of locales for which locale data is defined in `localectr`. When `localectr` is run from the CLI, the locale(s) specified with the `-l` option must be on this list in order for an installable locale package to be generated.
- r
Specify the range of Unicode characters for which locale data rules in the LC_CTYPE and LC_COLLATE categories are to be generated. There are three valid options:
 - 0
Locale data rules are restricted to the exemplar or to commonly used characters of the locale in question.
 - 1
Locale data rules are restricted to the Unicode plane 0 characters, whose codepoints fall in the range `u0000-uFFFF`.
 - 2
Locale data rules are generated for all codepoints defined in the latest version of Unicode that is supported by the system on which `localectr` is being run.
- V
Shows the version of this software.

Examples EXAMPLE 1 Launching the GUI

The following example launches the `localectr` GUI.

```
example% localectr
```

EXAMPLE 2 Generating Locale for Afrikaans (South Africa) with Default Locale Data

The following example generates a package in the specified destination directory, which can be used to install the Afrikaans (af_ZA.UTF-8) locale on the system. The package name is composed of a prefix followed by the hyphen separated ISO-639 language code, the ISO-3166 country code, the locale encoding and an optional user-defined tag. The resulting package can then be added to the system using [pkgadd\(1M\)](#).

```
example% localectr -l af_ZA -d /tmp
```

EXAMPLE 3 Generating Several South Africa Locales with Full Unicode Range of Characters

The following example generates an installable package for each of the specified locales.

```
example% localectr -l af_ZA,en_ZA,xh_ZA,zu_ZA -d /tmp -r 2
```

EXAMPLE 4 Generating the Irish Locale with a User-Specified Tag

The following example will generate a locale whose full name is ga_IE.UTF-8@mycompanyname.

```
example% localectr -l ga_IE@mycompanyname -d /tmp
```

Exit Status The following exit codes are returned:

0
Successful completion

>0
An error occurred.

Files /usr/bin/localectr
Wrapper script that launches locale creator.

/usr/lib/localectr
Jar files, scripts, and locale data repository needed to run the application.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

International Language Environments Guide

Name locator – location indicator control

Synopsis /usr/sbin/locator [-f | -n]

Description The locator command sets or queries the state of the system locator if such a device exists.

Without options, the locator command reports the current state of the system.

The privileges required to use this command are hardware dependent. Typically, only the super user can get or set a locator.

Options The following options are supported:

-f Turns the locator off.

-n Turns the locator on.

Examples EXAMPLE 1 Using the locator Command on a Platform Which Has a System Locator LED

When issued on a platform which has a system locator LED, the following command turns the locator on:

```
# locator -n
# locator
The 'system' locator is on
```

EXAMPLE 2 Using the locator Command on a Platform Which Does Not Have a System Locator LED

When issued on a platform which does not have a system locator LED, the following command attempts to turn the locator on. The command returns an error message.

```
# locator -n
'system' locator not found
```

Exit Status The following exit values are returned:

0 Successful completion.

1 Invalid command line input.

2 The requested operation failed.

Name lockd – network lock daemon

Synopsis /usr/lib/nfs/lockd [-g *graceperiod*] [-l *listen_min_backlog*]
[-t *timeout*] [*nthreads*]

Description The lockd utility is part of the NFS lock manager, which supports record locking operations on NFS files. See [fcntl\(2\)](#) and [lockf\(3C\)](#). The lock manager provides the following two functions:

- It forwards [fcntl\(2\)](#) locking requests for NFS mounted file systems to the lock manager on the NFS server.
- It generates local file locking operations in response to requests forwarded from lock managers running on NFS client machines.

State information kept by the lock manager about these locking requests can be lost if the lockd is killed or the operating system is rebooted. Some of this information can be recovered as follows. When the server lock manager restarts, it waits for a grace period for all client-site lock managers to submit reclaim requests. Client-site lock managers, on the other hand, are notified by the status monitor daemon, [statd\(1M\)](#), of the restart and promptly resubmit previously granted lock requests. If the lock daemon fails to secure a previously granted lock at the server site, then it sends SIGLOST to a process.

Administrators can make changes to the startup parameters for lockd by logging in as root and using the [sharectl\(1M\)](#) command.

SMF Management The lockd service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/nfs/nlockmgr
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

If it is disabled, it will be enabled by [mount_nfs\(1M\)](#), [share_nfs\(1M\)](#), and [automountd\(1M\)](#) unless its `application/auto_enable` property is set to `false`.

The [sharectl\(1M\)](#) command is used to manipulate the startup SMF parameters for lockd. Currently supported parameters are as follows:

`lockd_listen_backlog=num`

Set connection queue length for lockd over a connection-oriented transport. The default and minimum value is 32. Equivalent to `-l` option.

`lockd_servers=num`

Maximum number of concurrent lockd requests. The default is 20. Equivalent to the `nthreads` operand.

`lockd_retransmit_timeout=num`

Retransmit timeout, in seconds, before lockd retries. The default is 5. Equivalent to `-t` option.

`grace_period=num`

Grace period, in seconds, that all clients (both NLM and NFSv4) have to reclaim locks after a server reboot. This parameter also controls the NFSv4 lease interval. The default is 90. Equivalent to `-g` option.

See EXAMPLES, below.

Options The following options are supported:

`-g graceperiod`

Deprecated in favor of `grace_period`. Specify the number of seconds that all clients (both NLM and NFSv4) have to reclaim locks after the server reboots. It also controls the NFSv4 lease interval. This option is equivalent to the `grace_period` property described above.

`-l listen_min_backlog`

Specify the listener backlog (`listen_min_backlog`). `listen_min_backlog` is the number connect requests that are queued and waiting to be processed before new connect requests start to get dropped. Equivalent of the `lockd_listen_backlog` property described above.

`-t timeout`

Specify the number of seconds to wait before retransmitting a lock request to the remote server. The default value is 5 seconds. Equivalent of the `lockd_retransmit_timeout` property described above.

Operands `nthreads`

Specify the maximum number of concurrent threads that the server can handle. This concurrency is achieved by up to `nthreads` threads created as needed in the kernel. `nthreads` should be based on the load expected on this server. If `nthreads` is not specified, the maximum number of concurrent threads will default to 20. Equivalent of the `lockd_servers` property described above.

Examples EXAMPLE 1 Setting a lockd Property

The following command sets `lockd_listen_backlog` to a new value:

```
# sharectl set -p lockd_listen_backlog=40 nfs
```

The `lockd_listen_backlog` and other lockd properties are described under NOTES, below.

EXAMPLE 2 Getting a lockd Property Value

The following command retrieves the value of the `lockd_listen_backlog` property.

```
% sharectl get -p lockd_listen_backlog nfs
lockd_listen_backlog=40
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|------------------------|
| Availability | system/file-system/nfs |

See Also [svcs\(1\)](#), [automountd\(1M\)](#), [clear_locks\(1M\)](#), [mount_nfs\(1M\)](#), [share\(1M\)](#), [share_nfs\(1M\)](#), [sharectl\(1M\)](#), [statd\(1M\)](#), [svcadm\(1M\)](#), [fcntl\(2\)](#), [lockf\(3C\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Notes The lockd daemon might not exist in a future release of Solaris.

Name lockfs – change or report file system locks

Synopsis /usr/sbin/lockfs [-adefhnuw] [-c *string*] [*file-system*]. . .

Description lockfs is used to change and report the status of file system locks. lockfs reports the lock status and unlocks the file systems that were improperly left locked.

Using lockfs to lock a file system is discouraged because this requires extensive knowledge of SunOS internals to be used effectively and correctly.

When invoked with no arguments, lockfs lists the UFS file systems that are locked. If *file-system* is not specified, and -a is specified, lockfs is run on all mounted, UFS type file systems.

Options The options are mutually exclusive: wndheuf. If you do specify more than one of these options on a lockfs command line, the utility does not protest and invokes only the last option specified. In particular, you cannot specify a flush (-f) and a lock (for example, -w) on the same command line. However, all locking operations implicitly perform a flush, so the -f is superfluous when specifying a lock.

You must be super-user to use any of the following options, with the exception of -a, -f and -v.

The following options are supported.

-a

Apply command to all mounted, UFS type file systems. *file-system* is ignored when -a is specified.

-c *string*

Accept a string that is passed as the comment field. The -c only takes affect when the lock is being set using the -d, -h, -n, -u, or -w options.

-d

Delete-lock (dlock) the specified *file-system*. dlock suspends access that could remove directory entries.

-e

Error-lock (elock) the specified *file-system*. elock blocks all local access to the locked file system and returns EWOULDBLOCK on all remote access. File systems are elocked by UFS on detection of internal inconsistency. They may only be unlocked after successful repair by fsck, which is usually done automatically (see [mount_ufs\(1M\)](#)). elocked file systems can be unmounted.

-f

Force a synchronous flush of all data that is dirty at the time fsflush is run to its backing store for the named file system (or for all file systems.)

It is a more reliable method than using [sync\(1M\)](#) because it does not return until all possible data has been pushed. In the case of UFS filesystems with logging enabled, the log is also rolled before returning. Additional data can be modified by the time `fsflush` exits, so using one of the locking options is more likely to be of general use.

- h
Hard-lock (`hlock`) the specified *file-system*. `hlock` returns an error on every access to the locked file system, and cannot be unlocked. `hlocked` file systems can be unmounted.
- n
Name-lock (`nlock`) the specified *file-system*. `nlock` suspends accesses that could change or remove existing directories entries.
- u
Unlock (`unlock`) the specified *file-system*. `unlock` awakens suspended accesses.
- v
Enable verbose output.
- w
Write-lock (`wlock`) the specified *file-system*. `wlock` suspends writes that would modify the file system. Access times are not kept while a file system is write-locked.

Operands The following operands are supported.

file-system

A list of path names separated by whitespace. Note that *file-system* can be a directory rather than the specific name of a file system, such as `/` or `/usr`. For example, if you specify `/export/home` as an argument to a `lockfs` command and `/export/home` is mounted on the root (`/`) file system, the `lockfs` command will take effect on the root file system.

Usage See [largefile\(5\)](#) for the description of the behavior of `lockfs` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples **EXAMPLE 1** Using `lockfs -a`

In the following examples, *filesystem* is the pathname of the mounted-on directory (mount point). Locktype is one of “write,” “name,” “delete,” “hard,” or “unlock”. When enclosed in parenthesis, the lock is being set. Comment is a string set by the process that last issued a lock command.

The following example shows the `lockfs` output when only the `-a` option is specified.

```
example# /usr/sbin/lockfs -a
```

| Filesystem | Locktype | Comment |
|------------|----------|---------|
| / | unlock | |

EXAMPLE 1 Using lockfs -a (Continued)

```
/var                unlock
```

```
example#
```

EXAMPLE 2 Using lockfs -w

The following example shows the lockfs output when the -w option is used to write lock the /var file system and the comment string is set using the -c option. The -a option is then specified on a separate command line.

```
example# /usr/sbin/lockfs -w -c "lockfs: write lock example" /var
example# /usr/sbin/lockfs -a
```

| Filesystem | Locktype | Comment |
|------------|----------|----------------------------|
| / | unlock | |
| /var | write | lockfs: write lock example |

```
example#
```

EXAMPLE 3 Using lockfs -u

The following example shows the lockfs output when the -u option is used to unlock the /var file system and the comment string is set using the -c option.

```
example# /usr/sbin/lockfs -uc "lockfs: unlock example" /var
example# /usr/sbin/lockfs /var
```

| Filesystem | Locktype | Comment |
|------------|----------|------------------------|
| /var | unlock | lockfs: unlock example |

```
example#
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

System Administration Guide: Basic Administration

Diagnostics *file system*: Not owner

You must be root to use this command.

file system :Deadlock condition detected/avoided

A file is enabled for accounting or swapping, on *file system*.

file system: Device busy

Another process is setting the lock on *file system*.

Name lockstat – report kernel lock and profiling statistics

Synopsis lockstat [-ACEHI] [-e *event_list*] [-i *rate*]
 [-b | -t | -h | -s *depth*] [-n *nrecords*]
 [-l *lock* [, *size*]] [-d *duration*]
 [-f *function* [, *size*]] [-T] [-ckgWRpP] [-D *count*]
 [-o *filename*] [-x *opt* [=val]] *command* [*args*]

Description The lockstat utility gathers and displays kernel locking and profiling statistics. lockstat allows you to specify which events to watch (for example, spin on adaptive mutex, block on read access to rwlock due to waiting writers, and so forth) how much data to gather for each event, and how to display the data. By default, lockstat monitors all lock contention events, gathers frequency and timing data about those events, and displays the data in decreasing frequency order, so that the most common events appear first.

lockstat gathers data until the specified command completes. For example, to gather statistics for a fixed-time interval, use `sleep(1)` as the command, as follows:

```
example# lockstat sleep 5
```

When the -I option is specified, lockstat establishes a per-processor high-level periodic interrupt source to gather profiling data. The interrupt handler simply generates a lockstat event whose caller is the interrupted PC (program counter). The profiling event is just like any other lockstat event, so all of the normal lockstat options are applicable.

lockstat relies on DTrace to modify the running kernel's text to intercept events of interest. This imposes a small but measurable overhead on all system activity, so access to lockstat is restricted to super-user by default. The system administrator can permit other users to use lockstat by granting them additional DTrace privileges. Refer to the *Solaris Dynamic Tracing Guide* for more information about DTrace security features.

Options The following options are supported:

Event Selection If no event selection options are specified, the default is -C.

-A
 Watch all lock events. -A is equivalent to -CH.

-C
 Watch contention events.

-E
 Watch error events.

-e *event_list*
 Only watch the specified events. *event list* is a comma-separated list of events or ranges of events such as 1,4-7,35. Run lockstat with no arguments to get a brief description of all events.

-
- H
Watch hold events.
 - I
Watch profiling interrupt events.
 - i *rate*
Interrupt rate (per second) for -I. The default is 97 Hz, so that profiling doesn't run in lockstep with the clock interrupt (which runs at 100 Hz).
 - Data Gathering -x *arg[=val]*
Enable or modify a DTrace runtime option or D compiler option. The list of options is found in the *Solaris Dynamic Tracing Guide*. Boolean options are enabled by specifying their name. Options with values are set by separating the option name and value with an equals sign (=).
 - Data Gathering (Mutually Exclusive) -b
Basic statistics: lock, caller, number of events.
 - h
Histogram: Timing plus time-distribution histograms.
 - s *depth*
Stack trace: Histogram plus stack traces up to *depth* frames deep.
 - t
Timing: Basic plus timing for all events [default].
 - Data Filtering -d *duration*
Only watch events longer than *duration*.
 - f *func[,size]*
Only watch events generated by *func*, which can be specified as a symbolic name or hex address. *size* defaults to the ELF symbol size if available, or 1 if not.
 - l *lock[,size]*
Only watch *lock*, which can be specified as a symbolic name or hex address. *size* defaults to the ELF symbol size or 1 if the symbol size is not available.
 - n *nrecords*
Maximum number of data records.
 - T
Trace (rather than sample) events [off by default].
 - Data Reporting -c
Coalesce lock data for lock arrays (for example, `pse_mutex[]`).
 - D *count*
Only display the top *count* events of each type.

- g Show total events generated by function. For example, if `foo()` calls `bar()` in a loop, the work done by `bar()` counts as work generated by `foo()` (along with any work done by `foo()` itself). The `-g` option works by counting the total number of stack frames in which each function appears. This implies two things: (1) the data reported by `-g` can be misleading if the stack traces are not deep enough, and (2) functions that are called recursively might show greater than 100% activity. In light of issue (1), the default data gathering mode when using `-g` is `-s 50`.
- k Coalesce PCs within functions.
- o *filename* Direct output to *filename*.
- P Sort data by (*count * time*) product.
- p Parsable output format.
- R Display rates (events per second) rather than counts.
- W Whichever: distinguish events only by caller, not by lock.
- w Wherever: distinguish events only by lock, not by caller.

Display Formats The following headers appear over various columns of data.

- Count or ops/s Number of times this event occurred, or the rate (times per second) if `-R` was specified.
- indv Percentage of all events represented by this individual event.
- genr Percentage of all events generated by this function.
- cuml Cumulative percentage; a running total of the individuals.
- rcnt Average reference count. This will always be 1 for exclusive locks (mutexes, spin locks, rwlocks held as writer) but can be greater than 1 for shared locks (rwlocks held as reader).
- nsec Average duration of the events in nanoseconds, as appropriate for the event. For the profiling event, duration means interrupt latency.

Lock

Address of the lock; displayed symbolically if possible.

CPU+PIL

CPU plus processor interrupt level (PIL). For example, if CPU 4 is interrupted while at PIL 6, this will be reported as `cpu[4]+6`.

Caller

Address of the caller; displayed symbolically if possible.

Examples EXAMPLE 1 Measuring Kernel Lock Contention

example# **lockstat sleep 5**

Adaptive mutex spin: 2210 events in 5.055 seconds (437 events/sec)

EXAMPLE 4 Basic Kernel Profiling

For basic profiling, we don't care whether the profiling interrupt sampled `foo()+0x4c` or `foo()+0x78`; we care only that it sampled somewhere in `foo()`, so we use `-k`. The CPU and PIL aren't relevant to basic profiling because we are measuring the system as a whole, not a particular CPU or interrupt level, so we use `-W`.

```
example# lockstat -kIW -D 20 ./polltest
```

```
Profiling interrupt: 82 events in 0.424 seconds (194
events/sec)
```

```

EXAMPLE 5 Generated-load Profiling

In the example above, 5% of the samples were in `poll()`. This tells us how much time was spent inside `poll()` itself, but tells us nothing about how much work was *generated* by `poll()`; that is, how much time we spent in functions called by `poll()`. To determine that, we use the `-g` option. The example below shows that although `polltest` spends only 5% of its time in `poll()` itself, `poll()`-induced work accounts for 34% of the load.

Note that the functions that generate the profiling interrupt (`lockstat_intr()`, `cyclic_fire()`, and so forth) appear in every stack trace, and therefore are considered to have generated 100% of the load. This illustrates an important point: the generated load percentages do *not* add up to 100% because they are not independent. If 72% of all stack traces contain both `foo()` and `bar()`, then both `foo()` and `bar()` are 72% load generators.

```
example# lockstat -kgIW -D 20 ./polltest
```

```
Profiling interrupt: 80 events in 0.412 seconds (194 events/sec)
```

Solaris Dynamic Tracing Guide

Notes The profiling support provided by `lockstat -I` replaces the old (and undocumented) `/usr/bin/kgmon` and `/dev/profile`.

Tail-call elimination can affect call sites. For example, if `foo()+0x50` calls `bar()` and the last thing `bar()` does is call `mutex_exit()`, the compiler can arrange for `bar()` to branch to `mutex_exit()` with a return address of `foo()+0x58`. Thus, the `mutex_exit()` in `bar()` will appear as though it occurred at `foo()+0x58`.

The PC in the stack frame in which an interrupt occurs can be bogus because, between function calls, the compiler is free to use the return address register for local storage.

When using the `-I` and `-s` options together, the interrupted PC will usually not appear anywhere in the stack since the interrupt handler is entered asynchronously, not by a function call from that PC.

The `lockstat` technology is provided on an as-is basis. The format and content of `lockstat` output reflect the current Solaris kernel implementation and are therefore subject to change in future releases.

Name lofiadm – administer files available as block devices through lofi

Synopsis `/usr/sbin/lofiadm -a file [device]`
`/usr/sbin/lofiadm -c crypto_algorithm -a file [device]`
`/usr/sbin/lofiadm -c crypto_algorithm -k raw_key_file -a file [device]`

`/usr/sbin/lofiadm -d file | device`
`/usr/sbin/lofiadm -U file`
`/usr/sbin/lofiadm [file | device]`

Description lofiadm administers lofi, the loopback file driver. lofi allows a file to be associated with a block device. That file can then be accessed through the block device. This is useful when the file contains an image of some filesystem (such as a floppy or CD-ROM image), because the block device can then be used with the normal system utilities for mounting, checking or repairing file systems. See [fsck\(1M\)](#) and [mount\(1M\)](#).

Use lofiadm to add a file as a loopback device, remove such an association, or display information about the current associations.

The number of potential lofi devices is limited by the zone.max-lofi rctl, which can be set by means of [zonecfg\(1M\)](#) in the global zone. See [resource_controls\(5\)](#) for a description of zone.max-lofi.

Encryption and compression options are mutually exclusive on the command line. Further, an encrypted file cannot be compressed later, nor can a compressed file be encrypted later.

In the global zone, lofiadm can be used on both the global zone devices and all devices owned by other non-global zones on the system.

Options The following options are supported:

`-a file [device]`
Add file as a block device.

If device is not specified, an available device is picked.

If device is specified, lofiadm attempts to assign it to file. device must be available or lofiadm will fail. The ability to specify a device is provided for use in scripts that wish to reestablish a particular set of associations.

`-C {gzip | gzip-N | lzma}`

Compress the file with the specified compression algorithm.

The `gzip` compression algorithm uses the same compression as the open-source `gzip` command. You can specify the `gzip` level by using the value `gzip-N` where `N` is 6 (fast) or 9 (best compression ratio). Currently, `gzip`, without a number, is equivalent to `gzip-6` (which is also the default for the `gzip` command).

`lzma` stands for the LZMA (Lempel-Ziv-Markov) compression algorithm.

Note that you cannot write to a compressed file, nor can you mount a compressed file read/write.

`-d file | device`

Remove an association by `file` or `device` name, if the associated block device is not busy, and deallocates the block device.

`-s segment_size`

The segment size to use to divide the file being compressed. `segment_size` can be an integer multiple of 512.

`-U file`

Uncompress a compressed file.

The following options are used when the file is encrypted:

`-c crypto_algorithm`

Select the encryption algorithm. The algorithm must be specified when encryption is enabled because the algorithm is not stored in the disk image.

If none of `-e`, `-k`, or `-T` is specified, `lofiadm` prompts for a passphrase, with a minimum length of eight characters, to be entered. The passphrase is used to derive a symmetric encryption key using PKCS#5 PBKD2.

`-k raw_key_file | wrapped_key_file`

Path to raw or wrapped symmetric encryption key. If a PKCS#11 object is also given with the `-T` option, then the key is wrapped by that object. If `-T` is not specified, the key is used raw.

`-T token_key`

The key in a PKCS#11 token to use for the encryption or for unwrapping the key file.

If `-k` is also specified, `-T` identifies the unwrapping key, which must be an RSA private key.

`-e`

Generate an ephemeral symmetric encryption key.

Operands The following operands are supported:

crypto_algorithm

One of: aes-128-cbc, aes-192-cbc, aes-256-cbc, des3-cbc, blowfish-cbc.

device

Display the file name associated with the block device *device*.

Without arguments, print a list of the current associations. Filenames must be valid absolute pathnames.

When a file is added, it is opened for reading or writing by root. Any restrictions apply (such as restricted root access over NFS). The file is held open until the association is removed. It is not actually accessed until the block device is used, so it will never be written to if the block device is only opened read-only.

Note that the filename might appear as a question mark (?) if it is not possible to resolve the path in the current context (for example, if it is an NFS path in a non-global zone).

file

Display the block device associated with *file*.

raw_key_file

Path to a file of the appropriate length, in bits, to use as a raw symmetric encryption key.

token_key

PKCS#11 token object in the format:

token_name:manufacturer_id:serial_number:key_label

All but the key label are optional and can be empty. For example, to specify a token object with only its key label MylofiKey, use:

```
-T :::MylofiKey
```

wrapped_key_file

Path to file containing a symmetric encryption key wrapped by the RSA private key specified by -T.

Examples **EXAMPLE 1** Mounting an Existing CD-ROM Image

You should ensure that Solaris understands the image before creating the CD. `lofi` allows you to mount the image and see if it works.

This example mounts an existing CD-ROM image (`sparc.iso`), of the Red Hat 6.0 CD which was downloaded from the Internet. It was created with the `mkisofs` utility from the Internet.

Use `lofiadm` to attach a block device to it:

```
# lofiadm -a /home/mike_s/RH6.0/sparc.iso  
/dev/lofi/1
```

EXAMPLE 1 Mounting an Existing CD-ROM Image (Continued)

lofiadm picks the device and prints the device name to the standard output. You can run lofiadm again by issuing the following command:

```
# lofiadm
Block Device      File                                Options
/dev/lofi/1      /home/mike_s/RH6.0/sparc.iso      -
```

Or, you can give it one name and ask for the other, by issuing the following command:

```
# lofiadm /dev/lofi/1
/home/mike_s/RH6.0/sparc.iso
```

Use the mount command to mount the image:

```
# mount -F hsfs -o ro /dev/lofi/1 /mnt
```

Check to ensure that Solaris understands the image:

```
# df -k /mnt
Filesystem          kbytes   used   avail capacity  Mounted on
/dev/lofi/1         512418  512418     0   100%    /mnt
# ls /mnt
./          RedHat/    doc/       ls-lR      rr_moved/
../         TRANS.TBL dosutils/  ls-lR.gz   sbin@
.buildlog  bin@       etc@       misc/      tmp/
COPYING    boot/     images/    mnt/       usr@
README     boot.cat* kernels/   modules/
RPM-PGP-KEY dev@      lib@       proc/
```

Solaris can mount the CD-ROM image, and understand the filenames. The image was created properly, and you can now create the CD-ROM with confidence.

As a final step, unmount and detach the images:

```
# umount /mnt
# lofiadm -d /dev/lofi/1
# lofiadm
Block Device      File                                Options
```

EXAMPLE 2 Mounting a Floppy Image

This is similar to the first example.

Using lofi to help you mount files that contain floppy images is helpful if a floppy disk contains a file that you need, but the machine which you are on does not have a floppy drive. It is also helpful if you do not want to take the time to use the dd command to copy the image to a floppy.

This is an example of getting to MDB floppy for Solaris on an x86 platform:

EXAMPLE 2 Mounting a Floppy Image *(Continued)*

```
# lofiadm -a /export/s28/MDB_s28x_wos/latest/boot.3
/dev/lofi/1
# mount -F pcfs /dev/lofi/1 /mnt
# ls /mnt
./          COMMENT.BAT* RC.D/          SOLARIS.MAP*
../         IDENT*        REPLACE.BAT*  X/
APPEND.BAT* MAKEDIR.BAT* SOLARIS/
# umount /mnt
# lofiadm -d /export/s28/MDB_s28x_wos/latest/boot.3
```

EXAMPLE 3 Making a UFS Filesystem on a File

Making a UFS filesystem on a file can be useful, particularly if a test suite requires a scratch filesystem. It can be painful (or annoying) to have to repartition a disk just for the test suite, but you do not have to. You can `newfs` a file with `lofi`

Create the file:

```
# mkfile 35m /export/home/test
```

Attach it to a block device. You also get the character device that `newfs` requires, so `newfs` that:

```
# lofiadm -a /export/home/test
/dev/lofi/1
# newfs /dev/rlofi/1
newfs: construct a new file system /dev/rlofi/1: (y/n)? y
/dev/rlofi/1: 71638 sectors in 119 cylinders of 1 tracks, 602 sectors
              35.0MB in 8 cyl groups (16 c/g, 4.70MB/g, 2240 i/g)
super-block backups (for fsck -F ufs -o b=#) at:
 32, 9664, 19296, 28928, 38560, 48192, 57824, 67456,
```

Note that `ufs` might not be able to use the entire file. Mount and use the filesystem:

```
# mount /dev/lofi/1 /mnt
# df -k /mnt
Filesystem          kbytes    used  avail capacity  Mounted on
/dev/lofi/1          33455      9  30101     1%    /mnt
# ls /mnt
./          ../          lost+found/
# umount /mnt
# lofiadm -d /dev/lofi/1
```

EXAMPLE 4 Creating a PC (FAT) File System on a Unix File

The following series of commands creates a FAT file system on a Unix file. The file is associated with a block device created by `lofiadm`.

```
# mkfile 10M /export/test/testfs
# lofiadm -a /export/test/testfs
```

EXAMPLE 4 Creating a PC (FAT) File System on a Unix File (Continued)

```

/dev/lofi/1
Note use of rlofi, not lofi, in following command.
# mkfs -F pcfs -o nofdisk,size=20480 /dev/rlofi/1
Construct a new FAT file system on /dev/rlofi/1: (y/n)? y
# mount -F pcfs /dev/lofi/1 /mnt
# cd /mnt
# df -k .
Filesystem          kbytes   used   avail capacity  Mounted on
/dev/lofi/1         10142     0    10142     0%    /mnt

```

EXAMPLE 5 Compressing an Existing CD-ROM Image

The following example illustrates compressing an existing CD-ROM image (`solaris.iso`), verifying that the image is compressed, and then uncompressing it.

```
# lofiadm -C gzip /export/home/solaris.iso
```

Use `lofiadm` to attach a block device to it:

```
# lofiadm -a /export/home/solaris.iso
/dev/lofi/1
```

Check if the mapped image is compressed:

```
# lofiadm
Block Device      File                                Options
/dev/lofi/1       /export/home/solaris.iso           Compressed(gzip)
/dev/lofi/2       /export/home/regular.iso           -
```

Unmap the compressed image and uncompress it:

```
# lofiadm -d /dev/lofi/1
# lofiadm -U /export/home/solaris.iso
```

EXAMPLE 6 Creating an Encrypted UFS File System on a File

This example is similar to the example of making a UFS filesystem on a file, above.

Create the file:

```
# mkfile 35m /export/home/test
```

Attach the file to a block device and specify that the file image is encrypted. As a result of this command, you obtain the character device, which is subsequently used by `newfs`:

```
# lofiadm -c aes-256-cbc -a /export/home/secrets
Enter passphrase: My-M0th3r;l0v3s_m3+4lw4ys!      (not echoed)
Re-enter passphrase: My-M0th3r;l0v3s_m3+4lw4ys!   (not echoed)
/dev/lofi/1
```

EXAMPLE 6 Creating an Encrypted UFS File System on a File *(Continued)*

```
# newfs /dev/rlofi/1
newfs: construct a new file system /dev/rlofi/1: (y/n)? y
/dev/rlofi/1: 71638 sectors in 119 cylinders of 1 tracks, 602 sectors
           35.0MB in 8 cyl groups (16 c/g, 4.70MB/g, 2240 i/g)
super-block backups (for fsck -F ufs -o b=#) at:
32, 9664, 19296, 28928, 38560, 48192, 57824, 67456,
```

The mapped file system shows that encryption is enabled:

```
# lofiadm
Block Device  File                      Options
/dev/lofi/1   /export/home/secrets      Encrypted
```

Mount and use the filesystem:

```
# mount /dev/lofi/1 /mnt
# cp moms_secret*_recipe /mnt
# ls /mnt
./          moms_secret_cookie_recipe  moms_secret_soup_recipe
../         moms_secret_fudge_recipe   moms_secret_stuffing_recipe
lost+found/ moms_secret_meatloaf_recipe moms_secret_waffle_recipe
# umount /mnt
# lofiadm -d /dev/lofi/1
```

Subsequent attempts to map the filesystem with the wrong key or the wrong encryption algorithm will fail:

```
# lofiadm -c blowfish-cbc -a /export/home/secrets
Enter passphrase: mommy                (not echoed)
Re-enter passphrase: mommy             (not echoed)
lofiadm: could not map file /root/lofi: Invalid argument
# lofiadm
Block Device  File                      Options
#
```

Attempts to map the filesystem without encryption will succeed, however attempts to mount and use the filesystem will fail:

```
# lofiadm -a /export/home/secrets
/dev/lofi/1
# lofiadm
Block Device  File                      Options
/dev/lofi/1   /export/home/secrets      -
# mount /dev/lofi/1 /mnt
mount: /dev/lofi/1 is not this fstype
#
```

Environment Variables See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `lofiadm`: `LC_CTYPE`, `LC_MESSAGES` and `NLSPATH`.

Exit Status The following exit values are returned:

- 0
Successful completion.
- >0
An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [fsck\(1M\)](#), [mount\(1M\)](#), [mount_ufs\(1M\)](#), [newfs\(1M\)](#), [zonecfg\(1M\)](#), [attributes\(5\)](#), [resource_controls\(5\)](#), [lofi\(7D\)](#), [lofs\(7FS\)](#)

Notes Just as you would not directly access a disk device that has mounted file systems, you should not access a file associated with a block device except through the `lofi` file driver. It might also be appropriate to ensure that the file has appropriate permissions to prevent such access.

The abilities of `lofiadm`, and who can use them, are controlled by the permissions of `/dev/lofictl`. Read-access allows query operations, such as listing all the associations. Write-access is required to do any state-changing operations, like adding an association. As shipped, `/dev/lofictl` is owned by `root`, in group `sys`, and mode `0644`, so all users can do query operations but only `root` can change anything. The administrator can give users write-access, allowing them to add or delete associations, but that is very likely a security hole and should probably only be given to a trusted group.

When mounting a filesystem image, take care to use appropriate mount options. In particular, the `nosuid` mount option might be appropriate for UFS images whose origin is unknown. Also, some options might not be useful or appropriate, like `logging` or `forcedirectio` for UFS. For compatibility purposes, a raw device is also exported along with the block device. For example, [newfs\(1M\)](#) requires one.

The output of `lofiadm` (without arguments) might change in future releases.

Name logadm – manage endlessly growing log files

Synopsis logadm

logadm [-options] logname...

Description logadm is a general log rotation tool that is suitable for running from [cron\(1M\)](#).

Without arguments, logadm reads the /etc/logadm.conf file, and for every entry found in that file checks the corresponding log file to see if it should be rotated. Typically this check is done each morning by an entry in the root's crontab.

If the *logname* argument is specified, logadm renames the corresponding log file by adding a suffix so that the most recent log file ends with .0 (that is, *logfile.0*), the next most recent ends with .1 (that is, *logfile.1*), and so forth. By default, ten versions of old log files are kept (that is, *logfile.0* through *logfile.9*). At the point when what would be the eleventh file is logged, logadm automatically deletes the oldest version to keep the count of files at ten.

logadm takes a number of *options*. You can specify these options on the command line or in the /etc/logadm.conf file. The logadm command searches /etc/logadm.conf for lines of the form *logname options*

logname

Identifies an entry in /etc/logadm.conf. This can be a name or the pathname of the log file. If you specify a log file, rather than a name, for this field, it must be a fully qualified pathname.

options

Identifies command line options exactly as they would be entered on the command line. This allows commonly used log rotation policies to be stored in the /etc/logadm.conf file. See EXAMPLES.

If *options* are specified both in /etc/logadm.conf and on the command line, those in the /etc/logadm.conf file are applied first. Therefore, the command line options override those in /etc/logadm.conf.

Log file names specified in /etc/logadm.conf may contain filename substitution characters such as * and ?, that are supported by [csh\(1\)](#).

Two options control when a log file is rotated. They are: -s size -p period.

When using more than one of these options at a time, there is an implied *and* between them. This means that all conditions must be met before the log is rotated.

If neither of these two options are specified, the default conditions for rotating a log file are: -s 1b -p 1w, which means the log file is only rotated if the size is non-zero and if at least 1 week has passed since the last time it was rotated.

By specifying `-p never` as a rotation condition, any other rotation conditions are ignored and `logadm` moves on to the expiration of old log files. By specifying `-p now` as a rotation condition, a log rotation is forced.

Unless specified by the `-o`, `-g`, or `-m` options, `logadm` replaces the log file (after renaming it) by creating an empty file whose owner, group ID, and permissions match the original file.

Three options control when old log files are expired: `-A age` `-C count` `-S size`. These options expire the oldest log files until a particular condition or conditions are met. For example, the combination `-C 5` and the `-S 10m` options expires old log files until there are no more than 5 of the *and* their combined disk usage is no more than 10 megabytes. If none of these options are specified, the default expiration is `-C 10` which keeps ten old log files. If no files are to be expired, use `-C 0` to prevent expiration by default.

`logadm` stores timestamps in the file `/var/logadm/timestamps`. For users of previous versions of `logadm`, the utility automatically moves timestamps from `/etc/logadm.conf`, their previous repository, to `/var/logadm/timestamps`.

Options The following options are supported:

`-a post_command`

Execute the *post_command* after renaming the log file. *post_command* is passed to `sh -c`.

Specify *post_command* as a valid shell command. Use quotes to protect spaces or shell metacharacters in *post_command*.

This option can be used to restart a daemon that is writing to the file. When rotating multiple logs with one `logadm` command, *post_command* is executed only once after all the logs are rotated, not once per rotated log.

`-A age`

Delete any versions that have not been modified for the amount of time specified by *age*.

Specify *age* as a number followed by an `h` (hours), `d` (days), `w`(weeks), `m` (months), or `y` (years).

`-b pre_command`

Execute *pre_command* before renaming the log file. *pre_command* is passed to `sh -c`.

Specify *pre_command* as a valid shell command. Use quotes to protect spaces or shell metacharacters in the *pre_command*.

This option can be used to stop a daemon that is writing to the file. When rotating multiple logs with one `logadm` command, *pre_command* is executed only once before all the logs are rotated, not once per rotated log.

`-c`

Rotate the log file by copying it and truncating the original logfile to zero length, rather than renaming the file.

-C *count*

Delete the oldest versions until there are not more than *count* files left.

If no expire options (-A, -C, or -S) are specified, -C 10 is the default. To prevent the default expire rule from being added automatically, specify -C 0.

-e *mail_addr*

Send error messages by email to *mail_addr*.

As logadm is typically run from [cron\(1M\)](#), error messages are captured by cron and mailed to the owner of the crontab.

This option is useful if you want the mail regarding error messages to go to another address instead. If no errors are encountered, no mail message is generated.

-E *cmd*

Execute *cmd* to expire the file, rather than deleting the old log file to expire it.

cmd is passed it to `sh -c`. The file is considered expired after *cmd* completes. If the old log file is not removed or renamed by the *cmd*, logadm considers it for expiration the next time that it runs on the specified log file. If present, the keyword `$file` is expanded in the specified *cmd* to the name of the file being expired.

This option is useful for tasks such as mailing old log files to administrators, or copying old log files to long term storage.

-f *conf_file*

Use *conf_file* instead of `/etc/logadm.conf`.

This option allows non-root users to keep their own logadm configuration files.

-F *timestamp_file*

Use *timestamp_file* instead of `/var/logadm/timestamps` to store logadm timestamps.

-g *group*

Create a new empty file with the ID specified by *group*, instead of preserving the group ID of the log file.

Specify *group* by name or by numeric group ID, as accepted by [chgrp\(1\)](#).

This option requires the ability to change file group ownership using the [chgrp\(1\)](#) command.

-h

Print a help message that describes logadm's options.

-l

Use local time rather than the Coordinated Universal Time (UTC) when naming rotated log files (see the discussion of percent sequences in the templates supplied with the -t option).

-m *mode*

Create a new empty file with the mode specified by *mode*, instead of preserving the mode of the log file.

Specify *mode* in any form that is accepted by the [chmod\(1\)](#) command.

-M *cmd*

Use *cmd* to rename the log file. If the keyword *\$file* is specified, it is expanded to the name of the log file. Similarly, the keyword *\$nfile* is expanded to the new name of the log file.

The *\$nfile* keyword is only available with commands provided with the **-M** option. After the command completes, the log file is replaced by the rotate file. The default *cmd* is `"/bin/mv $file$nfile"`.

-n

Print the actions that the `logadm` command will perform without actually performing them.

This option is useful for checking arguments before making any changes to the system.

It is important to remember, however, that since log rotating actions are only printed with this option, `logadm` might not find files that need expiring, but if run without the **-n** `logadm` might create a file that needs expiring by performing the log rotating actions. Therefore, if you see no files being expired with the **-n** option, files still might be expired without it.

-N

Prevent an error message if the specified logfile does not exist. Normally, `logadm` produces an error message if the log file is not found. With **-N**, if the log file doesn't exist `logadm` moves on to the expire rules (if any) and then to the next log file (if any), without creating the empty replacement log file.

-o *owner*

Create the new empty file with *owner*, instead of preserving the owner of the log file.

Specify *owner* in any form that is accepted by the [chown\(1\)](#) command.

-p *period*

Rotate a log file after the specified time period (*period*).

Specify *period* as a number followed by *d* for days, *h* for hours, *w* for weeks, *m* for months (30 days) or *y* for years. There are also two special values for period: `now` and `never`. `-p now` forces log rotation. `-p never` forces no log rotation.

-P *timestamp*

Used by `logadm` to record the last time the log was rotated in `/var/logadm/timestamps`.

This option uses *timestamp* to determine if the log rotation period has passed. The format of *timestamp* matches the format generated by [ctime\(3C\)](#), with quotes around it to protect embedded spaces. *timestamp* is always recorded in the Coordinated Universal Time (UTC) timezone.

-r
Remove any entries corresponding to the specified *logname* from the `/etc/logadm.conf`.

-R *cmd*
Run the *cmd* when an old log file is created by a log rotation. If the keyword `$file` is embedded in the specified command, it is expanded to the name of the old log file just created by log rotation.

This option is useful for processing log file contents after rotating the log. *cmd* is executed by passing it to `sh -c`. When rotating multiple logs with one `logadm` command, the command supplied with `-R` is executed once every time a log is rotated. This is useful for post-processing a log file (that is, sorting it, removing uninteresting lines, etc.). The `-a` option is a better choice for restarting daemons after log rotation.

-s *size*
Rotate the log file only if its size is greater than or equal to *size*.

Specify *size* as a number followed by the letter `b` for bytes, `k` for kilobytes, `m` for megabytes, or `g` for gigabytes.

-S *size*
Delete the oldest versions until the total disk space used by the old log files is less than the specified size.

Specify *size* as a number followed by the letter `b` for bytes, `k` for kilobytes, `m` for megabytes, or `g` for gigabytes.

-t *template*
Specify the template to use when renaming log files.

template can be a simple name, such as `/var/adm/oldfile`, or it can contain special keywords which are expanded by `logadm` and are in the form `$word`. Allowed sequences are:

\$basename
The log file name, without the directory name

\$dirname
The directory of the file to be rotated

\$domain
Expands to the output of `domainname`

\$file
The full path name of the file to be rotated

\$isa
Expands to the output of `uname -p`

\$machine
Expands to the output of `uname -m`

\$n
The version number, 0 is most recent, 1 is next most recent, and so forth

\$N
The same as *\$n*, but starts at 1 instead of zero

\$nodename
Expands to the output of `uname -n`

\$platform
Expands to the output of `uname -i`

\$release
Expands to the output of `uname -r`

\$secs
The number of seconds since 00:00:00 UTC, January 1, 1970

\$zonename
Expands to the output of `zonename(1)`.

To actually have the dollar sign character in the file name, use `$$`. Any percent sequences allowed by `strftime(3C)` are also allowed, for example, `%d` expands to the day of the month. To actually have a percent sign character in the file name, use `%%`. Both dollar-sign keywords and percent sequences can appear anywhere in the template. If the template results in a pathname with non-existent directories, they are created as necessary when rotating the log file.

If no `-t` option is specified, the default template is `$file.$n`. Actual *rotation* of log files, where each version is shifted up until it expires is done using the `$n` keyword. If the template does not contain the `$n` keyword, the log file is simply renamed to the new name and then the expire rules, if any, are applied.

`-T pattern`
Normally `logadm` looks for a list of old log files by turning the template (specified with the `-t` option) into a pattern and finding existing files whose names match that pattern. The `-T` option causes the given pattern to be used instead.

This option is useful if another program fiddles with the old log file names, like a `cron` job to compress them over time. The pattern is in the form of a pathname with special characters such as `*` and `?` as supported by `cs(1)` filename substitution.

`-v`
Print information about the actions being executed in verbose mode.

`-V`
Validate the configuration file.

This option validates that an entry for the specified *logname* exists in the `/etc/logadm.conf` file and is syntactically correct. If *logname* is not specified, all entries in

the configuration file are validated. If a *logname* argument is specified, the command validates the syntax of that entry. If the entry is found, it is printed and the exit value of the command is true. Otherwise the exit value is false.

-w *entryname*

Write an entry into the config file (that is, `/etc/logadm.conf`) that corresponds to the current command line arguments. If an entry already existed for the specified *entryname*, it is removed first. This is the preferred method for updating `/etc/logadm.conf`, because it prevents syntax errors. The *entryname* is an argument to an invocation of `logadm`. *entryname* might be chosen as something easy to remember or it can be the pathname of the log file. If a pathname, rather than a name is used, it must be a fully qualified pathname.

If no log file name is provided on a `logadm` command line, the entry name is assumed to be the same as the log file name. For example, the following two lines achieve the same thing, keeping two copies of rotated log files:

```
% logadm -C2 -w mylog /my/really/long/log/file/name
% logadm -C2 -w /my/really/long/log/file/name
```

-z *count*

Compress old log files after all other commands have been executed. *count* of the most recent log files are left uncompressed, therefore making the *count* most recent files easier to peruse. Use *count* of zero to compress all old logs.

The compression is done with `gzip(1)` and the resulting log file has the suffix of `.gz`.

Operands The following operands are supported:

logname

Identifies the name of the entry in `/etc/logadm.conf`. If the log file name is specified in the *logname* field, it is assumed that *logname* is the same as the actual log file name.

Examples **EXAMPLE 1** Rotating a File and Keeping Previous Versions

The following example rotates the `/var/adm/exacct/proc` file, keeping ten previous versions in `/var/adm/exacct/proc.0` through `/var/adm/exacct/proc.9`.

Tell `logadm` to copy the file and truncate it.

```
% logadm -c /var/adm/exacct/proc
```

EXAMPLE 2 Rotating syslog

The following example rotates `syslog` and keeps eight log files. Old log files are put in the directory `/var/oldlogs` instead of `/var/log`:

```
% logadm -C8 -t'/var/oldlogs/syslog.$n' /var/log/syslog
```

EXAMPLE 3 Rotating /var/adm/sulog and Expiring Based on Age

The following entry in the /etc/logadm.conf file rotates the /var/adm/sulog file and expires any copies older than 30 days.

```
/var/adm/sulog -A 30d
```

EXAMPLE 4 Rotating Files and Expiring Based on Disk Usage

The following entry in the /etc/logadm.conf file rotates the /var/adm/sulog file and expires old log files when more than 100 megabytes are used by the sum of all the rotated log files.

```
/var/adm/sulog -S 100m
```

EXAMPLE 5 Creating an Entry that Stores the Logfile Name

This example creates an entry storing the log file name and the fact that we want to keep 20 copies in /etc/logadm.conf, but the -p never means the entry is ignored by the normal logadm run from root's crontab every morning.

```
% logadm -w locallog /usr/local/logfile -C20 -p never
```

Use the following entry on the command line to override the -p never option:

```
% logadm -p now locallog
```

EXAMPLE 6 Rotating the apache Error and Access Logs

The following example rotates the apache error and access logs monthly to filenames based on current year and month. It keeps the 24 most recent copies and tells apache to restart after renaming the logs.

This command is run once, and since the -w option is specified, an entry is made in /etc/logadm.conf so the apache logs are rotated from now on.

```
% logadm -w apache -p 1m -C 24\  
-t '/var/apache/old-logs/$basename.%Y-%m\'\  
-a '/usr/apache/bin/apachectl graceful\'\  
'/var/apache/logs/*{access,error}_log'
```

This example also illustrates that the entry name supplied with the -w option doesn't have to match the log file name. In this example, the entry name is apache and once the line has been run, the entry in /etc/logadm.conf can be forced to run by executing the following command:

```
% logadm -p now apache
```

Because the expression matching the apache log file names was enclosed in quotes, the expression is stored in /etc/logadm.conf, rather than the list of files that it expands to. This means that each time logadm runs from cron it expands that expression and checks all the log files in the resulting list to see if they need rotating.

EXAMPLE 6 Rotating the apache Error and Access Logs (Continued)

The following command is an example without the quotes around the log name expression. The shell expands the last argument into a list of log files that exist at the time the command is entered, and writes an entry to `/etc/logadm.conf` that rotates the files.

```
logadm -w apache /var/apache/logs/*_log
```

Files `/etc/logadm.conf`
configuration file for `logadm` command

`/var/logadm/timestamps`
repository for logging timestamps

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | Committed |

See Also [chgrp\(1\)](#), [chmod\(1\)](#), [chown\(1\)](#), [csh\(1\)](#), [gzip\(1\)](#), [cron\(1M\)](#), [ctime\(3C\)](#), [strftime\(3C\)](#), [logadm.conf\(4\)](#), [attributes\(5\)](#)

Notes When `logadm` applies expire conditions (supplied by the `-A`, `-C`, and `-S` options), it deletes files, the oldest first, until the conditions are satisfied. If the template used for naming the old logs contained `$n` or `$N`, `logadm` picks the highest value of `$n` or `$N` found in the old log file names first. If the template used is something else, `logadm` uses the modification time to determine which files to expire first. This may not be the expected behavior if an old log file has been modified since it was rotated.

Depending on log file sizes and number of log files, log file rotations can be very time-consuming.

By default, `logadm` works in GMT. Therefore, all entries written to the `/etc/logadm.conf` file (see [logadm.conf\(4\)](#)) will have a GMT timestamp. Users can use the `-l` option to set `logadm` to local time.

The `-f` and `-F` options can specify the same file, in which case `logadm` reverts to the same behavior as in prior releases. That is, timestamps are written to the configuration file.

Name logins – list user and system login information

Synopsis /usr/bin/logins [-admopstux] [-g *group...*]
[-l *login_name...*]

Description This command displays information on user and system logins known to the system. Contents of the output is controlled by the command options and can include the following: user or system login, user id number, passwd account field value (user name or other information), primary group name, primary group id, multiple group names, multiple group ids, home directory, login shell, and four password aging parameters. The default information is the following: login id, user id, primary group name, primary group id and the account field value. Output is sorted by user id, system logins, followed by user logins.

Options Options may be used together. If so, any login that matches any criteria are displayed.

The following options are supported:

- a Add two password expiration fields to the display. The fields show how many days a password can remain unused before it automatically becomes inactive, and the date that the password expires.
- d Selects logins with duplicate uids.
- g *group* Selects all users belonging to group, sorted by login. Multiple groups can be specified as a comma-separated list. When the -l and -g options are combined, a user is only listed once, even if the user belongs to more than one of the selected groups.
- l *login_name...* Selects the requested login. Multiple logins can be specified as a comma-separated list. Depending on the nameservice lookup types set in /etc/nsswitch.conf, the information can come from the /etc/passwd and /etc/shadow files and other nameservices. When the -l and -g options are combined, a user is only listed once, even if the user belongs to more than one of the selected groups.
- m Displays multiple group membership information.
- o Formats output into one line of colon-separated fields.
- p Selects logins with no passwords.
- s Selects all system logins.
- t Sorts output by login instead of by uid.
- u Selects all user logins.
- x Prints an extended set of information about each selected user. The extended information includes home directory, login shell and password aging information, each displayed on a separate line. The password information currently consists of password status:

- NP Account has no password
- LK Account is locked for UNIX authentication
- NL Account is a no login account
- PS Account probably has a valid password
- UN Account password status is unknown. That is, it is not a recognizable hashed password or any of the above entries. See [crypt\(3C\)](#) for valid password hashes.

If the login is passworded, status is followed by the date the password was last changed, the number of days required between changes, and the number of days allowed before a change is required. The password aging information shows the time interval that the user receives a password expiration warning message (when logging on) before the password expires.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

Name lpadmin – configure the LP print service

Synopsis `lpadmin -p printer {options}`
`lpadmin -x dest`
`lpadmin -d [dest]`
`lpadmin -S print-wheel -T [-A alert-type] [-W minutes]`
`[-Q requests]`

Description `lpadmin` configures the LP print service by defining printers and devices. It is used to add and change printers, to remove printers from service, to set or change the system default destination, to define alerts for printer faults, and to mount print wheels.

Options The `lpadmin` command has options for:

- Adding or changing a printer
- Removing a printer destination
- Setting or changing the system default destination
- Setting an alert for a print wheel

The options for each of the above categories are specified in the following subsections.

Several options support the use of lists. A list might contain, for example, user names, printers, printer forms, or content types. A list of multiple items can have the form of either comma-separated names or have the entire list enclosed by double quotes with a space between each name. For example, both lists below are acceptable:

```
one,two,three
"one two three"
```

Adding or Changing a Printer The first form of the `lpadmin` command (`lpadmin -p printer {options}`) configures a new printer or changes the configuration of an existing printer. It also starts the print scheduler.

When creating a new printer, one of three options (`-v`, `-U`, or `-s`) must be supplied. In addition, only one of the following can be supplied: `-e`, `-i`, or `-m`; if none of these three options is supplied, the model standard is used. The `-h` and `-l` options are mutually exclusive. Printer and class names must be no longer than 14 characters and must consist entirely of the characters A-Z, a-z, 0-9, dash (-) and underscore (_). If `-s` is specified, the following options are invalid: `-A`, `-e`, `-F`, `-h`, `-i`, `-l`, `-M`, `-m`, `-o`, `-U`, `-v`, and `-W`.

The following options can appear in any order.

`-A alert-type [-W minutes]`

The `-A` option is used to define an alert that informs the administrator when a printer fault is detected, and periodically thereafter, until the printer fault is cleared by the administrator. The *alert-types* are:

`mail` Send the alert message using mail (see [mail\(1\)](#)) to the administrator.

| | |
|----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>write</code> | Write the message to the terminal on which the administrator is logged in. If the administrator is logged in on several terminals, one is chosen arbitrarily. |
| <code>quiet</code> | Do not send messages for the current condition. An administrator can use this option to temporarily stop receiving further messages about a known problem. Once the fault has been cleared and printing resumes, messages are sent again when another fault occurs with the printer. |
| <code>showfault</code> | Attempt to execute a fault handler on each system that has a print job in the queue. The fault handler is <code>/etc/lp/alerts/printer</code> . It is invoked with three parameters: <i>printer_name</i> , <i>date</i> , <i>file_name</i> . The <i>file_name</i> is the name of a file containing the fault message. |
| <code>none</code> | Do not send messages; any existing alert definition for the printer is removed. No alert is sent when the printer faults until a different alert-type (except <code>quiet</code>) is used. |
| <code>shell-command</code> | Run the <i>shell-command</i> each time the alert needs to be sent. The shell command should expect the message in standard input. If there are blank spaces embedded in the command, enclose the command in quotes. Notice that the <code>mail</code> and <code>write</code> values for this option are equivalent to the values <code>mail user-name</code> and <code>write user-name</code> respectively, where <i>user-name</i> is the current name for the administrator. This is the login name of the person submitting this command unless he or she has used the <code>su</code> command to change to another user ID. If the <code>su</code> command has been used to change the user ID, then the <i>user-name</i> for the new ID is used. |
| <code>list</code> | Display the type of the alert for the printer fault. No change is made to the alert. |

When a fault occurs, the printing subsystem displays a message indicating that printing for a specified printer has stopped and the reason for the stoppage. The message also indicates that printing will restart in a few minutes and that you can enter an `enable` command if you want to restart sooner than that.

Following a fault that occurs in the middle of a print job, the job is reprinted from the beginning. An exception to this occurs when you enter a command, such as the one shown below, that changes the page list to be printed.

```
% lp -i request-id -P ...
```

For a given print request, the presence of multiple reasons for failure indicate multiple attempts at printing.

The LP print service can detect printer faults only through an adequate fast filter and only when the standard interface program or a suitable customized interface program is used. Furthermore, the level of recovery after a fault depends on the capabilities of the filter.

If, instead of a single printer, the keyword `all` is displayed in an alert, the alert applies to all printers.

If the `-W` option is not used to arrange fault alerting for *printer*, the default procedure is to mail one message to the administrator of *printer* per fault. This is equivalent to specifying `-W once` or `-W 0`. If *minutes* is a number greater than zero, an alert is sent at intervals specified by *minutes*.

`-c class`

Insert *printer* into the specified *class*. *class* is created if it does not already exist. This option requires the `-U dial-info` or `-v device` options.

`-D comment`

Save this *comment* for display whenever a user asks for a full description of *printer* (see [lpstat\(1\)](#)). The LP print service does not interpret this comment.

`-e printer`

Copy the interface program of an existing *printer* to be the interface program for *printer*. (Options `-i` and `-m` must not be specified with this option.)

`-f allow:form-list`

`-f deny:form-list`

Allow or deny the forms in *form-list* to be printed on *printer*. By default no forms are allowed on a new printer.

For each printer, the LP print service keeps two lists of forms: an “allow-list” of forms that can be used with the printer, and a “deny-list” of forms that cannot be used with the printer. With the `-f allow` option, the forms listed are added to the allow-list and removed from the deny-list. With the `-f deny` option, the forms listed are added to the deny-list and removed from the allow-list.

If the allow-list is not empty, only the forms in the list can be used on the printer, regardless of the contents of the deny-list. If the allow-list is empty, but the deny-list is not, the forms in the deny-list cannot be used with the printer. All forms can be excluded from a printer by specifying `-f deny:all`. All forms can be used on a printer (provided the printer can handle all the characteristics of each form) by specifying `-f allow:all`.

The LP print service uses this information as a set of guidelines for determining where a form can be mounted. Administrators, however, are not restricted from mounting a form on any printer. If mounting a form on a particular printer is in disagreement with the information in the allow-list or deny-list, the administrator is warned but the mount is accepted. Nonetheless, if a user attempts to issue a print or change request for a form and printer combination that is in disagreement with the information, the request is accepted

only if the form is currently mounted on the printer. If the form is later unmounted before the request can print, the request is canceled and the user is notified by mail.

If the administrator tries to specify a form as acceptable for use on a printer that does not have the capabilities needed by the form, the command is rejected.

Notice the other use of `-f`, with the `-M` option, below.

The `-T` option must be invoked first with `lpadmin` to identify the printer type before the `-f` option can be used.

`-F` *fault-recovery*

This option specifies the recovery to be used for any print request that is stopped because of a printer fault, according to the value of *fault-recovery*:

- `continue` Continue printing on the top of the page where printing stopped. This requires a filter to wait for the fault to clear before automatically continuing.
- `beginning` Start printing the request again from the beginning.
- `wait` Disable printing on *printer* and wait for the administrator or a user to enable printing again.

During the wait, the administrator or the user who submitted the stopped print request can issue a change request that specifies where printing should resume. (See the `-i` option of the `lp` command.) If no change request is made before printing is enabled, printing resumes at the top of the page where stopped, if the filter allows; otherwise, the request is printed from the beginning.

`-h`

Indicate that the device associated with the printer is hardwired. If neither of the mutually exclusive options, `-h` and `-l`, is specified, `-h` is assumed.

`-i` *interface*

Establish a new interface program for *printer*. *interface* is the pathname of the new program. (The `-e` and `-m` options must not be specified with this option.)

`-I` *content-type-list*

Allow *printer* to handle print requests with the content types listed in a *content-type-list*.

The type `simple` is recognized as the default content type for files in the UNIX system. A `simple` type of file is a data stream containing only printable ASCII characters and the following control characters:

| Control Char | Octal Value | Meaning |
|--------------|-------------|----------------------------|
| BACKSPACE | 10 | Move back one char, except |

| Control Char | Octal Value | Meaning |
|-----------------------|-------------|--------------------------------------|
| | | at beginning of line |
| TAB | 11 | Move to next tab stop |
| LINEFEED
(newline) | 12 | Move to beginning of
next line |
| FORMFEED | 14 | Move to beginning of
next page |
| RETURN | 15 | Move to beginning of
current line |

To prevent the print service from considering `simple` a valid type for the printer, specify either an explicit value (such as the printer type) in the *content-type-list*, or an empty list. If you do want `simple` included along with other types, you must include `simple` in the *content-type-list*.

In addition to content types defined by the print administrator, the type `PostScript` is recognized and supported by the Solaris print subsystem. This includes filters to support `PostScript` as the printer content type.

The type `any` is recognized as a special content type for files. When declared as the input type for a printer, it signals the print sub-system not to do any filtering on the file before sending it to the printer.

Except for `simple` and `any`, each *content-type* name is determined by the administrator. If the printer type is specified by the `-T` option, then the printer type is implicitly considered to be also a valid content type.

`-t`

Indicate that the device associated with *printer* is a login terminal. The LP scheduler (`lpsched`) disables all login terminals automatically each time it is started. (The `-h` option must not be specified with this option.)

`-m model`

Select *model* interface program, provided with the LP print service, for the printer. (Options `-e` and `-i` must not be specified with this option.)

`-M -f form-name [-a [-o filebreak]] [-t tray-number]`

Mount the form *form-name* on *printer*. Print requests that need the pre-printed form *form-name* is printed on *printer*. If more than one printer has the form mounted and the user has specified any (with the `-d` option of the `lp` command) as the printer destination, then the print request is printed on the one printer that also meets the other needs of the request.

The page length and width, and character and line pitches needed by the form are compared with those allowed for the printer, by checking the capabilities in the `terminfo` database for the type of printer. If the form requires attributes that are not available with the printer, the administrator is warned but the mount is accepted. If the form lists a print wheel as mandatory, but the print wheel mounted on the printer is different, the administrator is also warned but the mount is accepted.

If the `-a` option is given, an alignment pattern is printed, preceded by the same initialization of the physical printer that precedes a normal print request, with one exception: no banner page is printed. Printing is assumed to start at the top of the first page of the form. After the pattern is printed, the administrator can adjust the mounted form in the printer and press return for another alignment pattern (no initialization this time), and can continue printing as many alignment patterns as desired. The administrator can quit the printing of alignment patterns by typing `q`.

If the `-o filebreak` option is given, a formfeed is inserted between each copy of the alignment pattern. By default, the alignment pattern is assumed to correctly fill a form, so no formfeed is added.

If the `-t tray-number` option is specified, printer tray *tray-number* is used.

A form is "unmounted" either by mounting a new form in its place or by using the `-f none` option. By default, a new printer has no form mounted.

Notice the other use of `-f` without the `-M` option above.

`-M -S print-wheel`

Mount the *print-wheel* on *printer*. Print requests that need the *print-wheel* are printed on *printer*. If more than one printer has *print-wheel* mounted and the user has specified any (with the `-d` option of the `lp` command) as the printer destination, then the print request is printed on the one printer that also meets the other needs of the request.

If the *print-wheel* is not listed as acceptable for the printer, the administrator is warned but the mount is accepted. If the printer does not take print wheels, the command is rejected.

A print wheel is "unmounted" either by mounting a new print wheel in its place or by using the option `-S none`. By default, a new printer has no print wheel mounted.

Notice the other uses of the `-S` option without the `-M` option described below.

`-n ppdfilename`

Specify a PPD file for creating and modifying printer queues. *ppdfilename* is the full path and file name to the PPD file. Used in conjunction with the `-p`, `-d`, `-x`, or `-S` options.

`-o option`

The `-o` option defines default printer configuration values given to an interface program. The default can be explicitly overwritten for individual requests by the user (see `lp(1)`), or taken from a preprinted form description (see `lpforms(1M)` and `lp(1)`).

There are several options which are predefined by the system. In addition, any number of key-value pairs can be defined. See the section “Predefined Options Used with the -o Option”, below.

-P *paper-name*

Specify a paper type list that the printer supports.

-r *class*

Remove *printer* from the specified *class*. If *printer* is the last member of *class*, then *class* is removed.

-S *list*

Allow either the print wheels or aliases for character sets named in *list* to be used on the printer.

If the printer is a type that takes print wheels, then *list* is a comma or space separated list of print wheel names. These are the only print wheels considered mountable on the printer. (You can always force a different print wheel to be mounted.) Until the option is used to specify a list, no print wheels are considered mountable on the printer, and print requests that ask for a particular print wheel with this printer are rejected.

If the printer is a type that has selectable character sets, then *list* is a list of character set name “mappings” or aliases. Each “mapping” is of the form *known-name=alias*. The *known-name* is a character set number preceded by *cs* (such as *cs3* for character set three) or a character set name from the `terminfo` database entry *csnm*. See [terminfo\(4\)](#). If this option is not used to specify a list, only the names already known from the `terminfo` database or numbers with a prefix of *cs* is acceptable for the printer. If *list* is the word *none*, any existing print wheel lists or character set aliases are removed.

Notice the other uses of the -S with the -M option described above.

The -T option must be invoked first with `lpadmin` to identify the printer type before the -S option can be used.

-s *system-name*

The -s option can be used for both remote or local printers. For remote printers:

-s *system-name*[!*printer-name*] (UUCP format)

-s *printer-name@system-name* (RCMD format)

Make a remote printer (one that must be accessed through another system) accessible to users on your system. *system-name* is the name of the remote system on which the remote printer is located it. *printer-name* is the name used on the remote system for that printer. For example, if you

-s *scheme://end-point* (URI format)

want to access *printer1* on *system1* and you want it called *printer2* on your system:

```
-p printer2 -s system1!printer1
```

```
-p printer2 -s printer1@system1
```

Make a remote printer (one that must be accessed through another system) accessible to users on your system.

The supported schemes include `lpd` and `ipp`. Specify URI's using the `lpd` format as follows:

```
lpd://server/printers/queue[#Solaris]
```

URI's using the `ipp` format are defined by the remote print server.

They are generally of the format:

```
ipp://server/printers/queue
```

In either case, *server* specifies the hostname or IP address of the remote print server, *queue* specifies the name of the print queue on the remote print server, and the optional `#Solaris` specifies that the remote print server is a Solaris server when `lpd` URI format is being used.

For example:

```
-p printer -s lpd://server/printers/queue#Solaris
```

```
-p printer -s ipp://server/printers/queue
```

For local printers:

-s "localhost" Use `localhost` for the *system-name* to be used by the print service. In an environment where the nodename is variable, print queues are invalidated when the nodename changes. Using `localhost` as the *system-name* allows print queues to be maintained across changing nodenames. The *system-name*, as used by the print service, is only set to `localhost` when explicitly set with this option; by default, `lpadmin` sets *system-name* to *nodename*. For example, if you want to configure a new printer on the local system, and want it called *printer3*:

```
-p printer3 -s localhost -v device
```

This option should never be used when creating name service maps.

-T *printer-type-list*

Identify the printer as being of one or more *printer-types*. Each *printer-type* is used to extract data from the `terminfo` database; this information is used to initialize the printer before printing each user's request. Some filters might also use a *printer-type* to convert content for the printer. If this option is not used, the default *printer-type* is unknown. No information is extracted from `terminfo` so each user request is printed without first initializing the printer. Also, this option must be used if the following are to work: `-o cpi`, `-o lpi`, `-o width`, and `-o length` options of the `lpadmin` and `lp` commands, and the `-S` and `-f` options of the `lpadmin` command.

If the *printer-type-list* contains more than one type, then the *content-type-list* of the `-I` option must either be specified as `simple`, as empty (`-I ""`), or not specified at all.

-t *number-of-trays*

Specify the number of trays when creating the printer.

-u allow: *login-ID-list*

-u deny: *login-ID-list*

Allow or deny the users in *login-ID-list* access to the printer. By default all users are allowed on a new printer. The *login-ID-list* argument can include any or all of the following constructs:

| | |
|--------------------------------------|----------------------------------------|
| <i>login-ID</i> | a user on any system |
| <i>system-name!</i> <i>login-ID</i> | a user on system <i>system-name</i> |
| <i>system-name!</i> <code>all</code> | all users on system <i>system-name</i> |
| <code>all!</code> <i>login-ID</i> | a user on all systems |
| <code>all</code> | all users on all systems |

For each printer, the LP print service keeps two lists of users: an “allow-list” of people allowed to use the printer, and a “deny-list” of people denied access to the printer. With the `-u allow` option, the users listed are added to the allow-list and removed from the deny-list. With the `-u deny` option, the users listed are added to the deny-list and removed from the allow-list.

If the allow-list is not empty, only the users in the list can use the printer, regardless of the contents of the deny-list. If the allow-list is empty, but the deny-list is not, the users in the deny-list cannot use the printer. All users can be denied access to the printer by specifying `-u deny:all`. All users can use the printer by specifying `-u allow:all`.

The `-U` option allows your print service to access a remote printer. (It does not enable your print service to access a remote printer service.) Specifically, `-U` assigns the “dialing” information *dial-info* to the printer. *dial-info* is used with the `dial` routine to call the printer. Any network connection supported by the Basic Networking Utilities works.

dial-info can be either a phone number for a modem connection, or a system name for other kinds of connections. Or, if `-U direct` is given, no dialing takes place, because the name `direct` is reserved for a printer that is directly connected. If a system name is given, it is used to search for connection details from the file `/etc/uucp/Systems` or related files. The Basic Networking Utilities are required to support this option. By default, `-U direct` is assumed.

-v device

Associate a *device* with *printer*. *device* is the path name of a file that is writable by `lp`. Notice that the same *device* can be associated with more than one printer.

-v scheme://end-point

Associate a network attached device with printer.

scheme is the method or protocol used to access the network attached device and *end-point* is the information necessary to contact that network attached device. Use of this device format requires the use of the `uri` interface script and can only be used with the `smb` scheme at this time.

For example:

```
# lpadmin -p queue -v smb://smb-service/printer -m uri
```

See the `/usr/sfw/man/man1m/smbpool.1m` man page for details.

Removing a Printer
Destination

The `-x dest` option removes the destination *dest* (a printer or a class), from the LP print service. If *dest* is a printer and is the only member of a class, then the class is deleted, too. If *dest* is `all`, all printers and classes are removed. If there are no remaining local printers and the scheduler is still running, the scheduler is shut down.

No other *options* are allowed with `-x`.

Setting/Changing the
System Default
Destination

The `-d [dest]` option makes *dest* (an existing printer or class) the new system default destination. If *dest* is not supplied, then there is no system default destination. No other *options* are allowed with `-d`.

Setting an Alert for a
Print Wheel

`-S print-wheel [-A alert-type] [-W minutes] [-Q requests] -T`

The `-S print-wheel` option is used with the `-A alert-type` option to define an alert to mount the print wheel when there are jobs queued for it. If this command is not used to arrange alerting for a print wheel, no alert is sent for the print wheel. Notice the other use of `-A`, with the `-p` option, above.

The *alert-types* are:

| | |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>mail</code> | Send the alert message using the <code>mail</code> command to the administrator. |
| <code>write</code> | Write the message, using the <code>write</code> command, to the terminal on which the administrator is logged in. If the administrator is logged in on several terminals, one is arbitrarily chosen. |

| | |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>quiet</code> | Do not send messages for the current condition. An administrator can use this option to temporarily stop receiving further messages about a known problem. Once the <i>print-wheel</i> has been mounted and subsequently unmounted, messages are sent again when the number of print requests reaches the threshold specified by the <code>-Q</code> option. |
| <code>none</code> | Do not send messages until the <code>-A</code> option is given again with a different <i>alert-type</i> (other than <code>quiet</code>). |
| <i>shell-command</i> | Run the <i>shell-command</i> each time the alert needs to be sent. The shell command should expect the message in standard input. If there are blanks embedded in the command, enclose the command in quotes. Notice that the <code>mail</code> and <code>write</code> values for this option are equivalent to the values <code>mail user-name</code> and <code>write user-name</code> respectively, where <i>user-name</i> is the current name for the administrator. This is the login name of the person submitting this command unless he or she has used the <code>su</code> command to change to another user ID. If the <code>su</code> command has been used to change the user ID, then the <i>user-name</i> for the new ID is used. |
| <code>list</code> | Display the type of the alert for the print wheel on standard output. No change is made to the alert. |

The message sent appears as follows:

```
The print wheel print-wheel needs to be mounted
on the printer(s):
printer(integer1requests) integer2 print requests
await this print wheel.
```

The printers listed are those that the administrator had earlier specified were candidates for this print wheel. The number *integer1* listed next to each printer is the number of requests eligible for the printer. The number *integer2* shown after the printer list is the total number of requests awaiting the print wheel. It is less than the sum of the other numbers if some requests can be handled by more than one printer.

If the *print-wheel* is `all`, the alerting defined in this command applies to all print wheels already defined to have an alert.

If the `-W` option is not given, the default procedure is that only one message is sent per need to mount the print wheel. Not specifying the `-W` option is equivalent to specifying `-W once` or `-W 0`. If *minutes* is a number greater than zero, an alert is sent at intervals specified by *minutes*.

If the `-Q` option is also given, the alert is sent when a certain number (specified by the argument *requests*) of print requests that need the print wheel are waiting. If the `-Q` option is not given, or *requests* is 1 or any (which are both the default), a message is sent as soon as

anyone submits a print request for the print wheel when it is not mounted.

Predefined Options Used with the -o Option A number of options, described below, are predefined for use with `-o`. These options are used for adjusting printer capabilities, adjusting printer port characteristics, configuring network printers, and controlling the use of banner. The `-o` also supports an arbitrary *keyword=value* format, which is referred to below as an undefined option.

Adjusting Printer Capabilities The `length`, `width`, `cpi`, and `lpi` parameters can be used in conjunction with the `-o` option to adjust printer capabilities. The format of the parameters and their values is as follows:

```
length=scaled-decimal-number
width=scaled-decimal-number
cpi=scaled-decimal-number
lpi=scaled-decimal-number
```

The term *scaled-decimal-number* refers to a non-negative number used to indicate a unit of size. The type of unit is shown by a “trailing” letter attached to the number. Three types of *scaled-decimal-numbers* can be used with the LP print service: numbers that show sizes in centimeters (marked with a trailing `c`); numbers that show sizes in inches (marked with a trailing `i`); and numbers that show sizes in units appropriate to use (without a trailing letter), that is, lines, characters, lines per inch, or characters per inch.

The option values must agree with the capabilities of the type of physical printer, as defined in the terminfo database for the printer type. If they do not, the command is rejected.

The defaults are defined in the `terminfo` entry for the specified printer type. The defaults can be reset by:

```
lpadmin -p printername -o length=
lpadmin -p printername -o width=
lpadmin -p printername -o cpi=
lpadmin -p printername -o lpi=
```

Adjusting Printer Port Characteristics You use the `stty` keyword in conjunction with the `o` option to adjust printer port characteristics. The general form of the `stty` portion of the command is:

```
stty="stty-option-list"
```

The *stty-option-list* is not checked for allowed values, but is passed directly to the `stty` program by the standard interface program. Any error messages produced by `stty` when a request is processed (by the standard interface program) are mailed to the user submitting the request.

The default for `stty` is:

```
stty="9600 cs8 -cstopb -parenb ixon
      -ixany opost -olcuc onlcr
      -ocrnl -onocr
      -onlret -ofill nl0 cr0 tab0 bs0 vt0 ff0"
```

The default can be reset by:

```
lpadmin -p printername -o stty=
```

Configuring Network Printers

The `dest`, `protocol`, `bsdctrl`, and `timeout` parameters are used in conjunction with the `-o` option to configure network printers. The format of these keywords and their assigned values is as follows:

```
dest=string protocol=string bsdctrl=string \
timeout=non-negative-integer-seconds
```

These four options are provided to support network printing. Each option is passed directly to the interface program; any checking for allowed values is done there.

The value of `dest` is the name of the destination for the network printer; the semantics for value `dest` are dependent on the printer and the configuration. There is no default.

The value of option `protocol` sets the over-the-wire protocol to the printer. The default for option `protocol` is `bsd`. The value of option `bsdctrl` sets the print order of control and data files (BSD protocol only); the default for this option is `control file first`. The value of option `timeout` sets the seed value for backoff time when the printer is busy. The default value for the `timeout` option is 10 seconds. The defaults can be reset by:

```
lpadmin -p printername -o protocol=
lpadmin -p printername -o bsdctrl=
lpadmin -p printername -o timeout=
```

Controlling the Use of the Banner Page

Use the following commands to control the use of the banner page:

```
lpadmin -p printer -o nobanner
lpadmin -p printer -o banner
lpadmin -p printer -o banner=always
lpadmin -p printer -o banner=never
lpadmin -p printer -o banner=optional
```

The first and fifth commands (`-o nobanner` and `-o banner=optional`) are equivalent. The default is to print the banner page, unless a user specifies `-o nobanner` on an `lp` command line.

The second and third commands (`-o banner` and `-o banner=always`) are equivalent. Both cause a banner page to be printed always, even if a user specifies `lp -o nobanner`. The root user can override this command.

The fourth command (`-o banner=never`) causes a banner page never to be printed, even if a user specifies `lp -o banner`. The root user can override this command.

Undefined Options

The `-o` option supports the use of arbitrary, user-defined options with the following format:

key=value

Each *key=value* is passed directly to the interface program. Any checking for allowed values is done in the interface program.

Any default values for a given *key=value* option are defined in the interface program. If a default is provided, it can be reset by typing the key without any value:

```
lpadmin -p printername -o key=
```

```
lpadmin -p printer -o foo | nofoo    Sets boolean values foo=true | foo=false.
```

Examples In the following examples, *prtr* can be any name up to 14 characters and can be the same name as the [ping\(1M\)](#) name.

EXAMPLE 1 Configuring an HP Postscript Printer with a Jet Direct Network Interface

The following example configures an HP postscript printer with a jet direct network interface:

```
example# lpadmin -p prtr -v /dev/null -m netstandard \
-o dest=ping_name_of_prtr:9100 -o protocol=tcp -T PS -I \
  postscript
example# enable prtr
example# accept prtr
```

EXAMPLE 2 Configuring a Standard Postscript Network Printer

The following example configures a standard postscript network printer:

```
example# lpadmin -p prtr -v /dev/null -m netstandard \
-o dest=ping_name_of_prtr -T PS -I postscript
example# enable prtr
example# accept prtr
```

Exit Status The following exit values are returned:

0 Successful completion.
non-zero An error occurred.

System Administration Guide: Basic Administration

Notes When using lpadmin to provide access to a remote printer, remote configuration data is stored in `/etc/printers.conf`. This data includes a `bsdaddr` and a `printer-uri-supported` attribute. The data in this file can be shared through the use of a network name service or replicated across multiple systems. If the data is shared, it is important to make sure that the `bsdaddr` and `printer-uri-supported` contain hostname information that is correctly resolved on all hosts sharing this data. Also, the `printer-uri-supported` is the preferred means of accessing remote print service. The `bsdaddr` is supplied for backward compatibility with Solaris 2.6-10 systems.

Name lpfilter – administer filters used with the LP print service

Synopsis /usr/sbin/lpfilter -f *filter-name*
 {- | -i | -l | -x | -F *pathname*}

Description The `lpfilter` command is used to add, change, delete, or list a filter used with the LP print service. These filters convert the content of a file to have a content type acceptable to a printer.

Options Arguments consist of the -f *filter-name* option and exactly one of the arguments appearing within braces ({ }) in the SYNOPSIS.

- Adds or changes a filter as specified from standard input. The format of the input is specified below. If -f all is specified with the – option, the specified change is made to all existing filters. This is not useful.
- f *filter-name* Specifies the *filter-name* of the filter to be added, changed, reset, deleted, or listed. The filter name all is a special filter name defined below. The -f option is required.
- F *pathname* Adds or changes a filter as specified by the contents of the file *pathname*. The format of the file's contents is specified below. If -f all is specified with the -F option, the specified change is made to all existing filters. This is not useful.
- i Resets a filter to its default settings. Using -f all with the -i option restores all filters for which predefined settings are available to their original settings.
- l Lists a filter description. Using -f all with the -l option produces a list of all filters.
- x Deletes a filter. Using -f all with the -x option results in all filters being deleted.

Usage

Adding or Changing a Filter The filter named in the -f option is added to the filter table. If the filter already exists, its description is changed to reflect the new information in the input.

When – is specified, standard input supplies the filter description. When -F is specified, the file *pathname* supplies the filter description. One of these two options must be specified to add or change a filter.

When an existing filter is changed with the -F or – option, lines in the filter description that are not specified in the new information are not changed. When a new filter is added with this command, unspecified lines receive default values. See below.

Filters are used to convert the content of a request from its initial type into a type acceptable to a printer. For a given print request, the LP print service knows the following:

- The content type of the request (specified by `lp -T` or determined implicitly).
- The name of the printer (specified by `lp -d`).
- The printer type (specified by `lpadmin -T`).
The printer type is intended to be a printer model, but some people specify it with a content type even though `lpadmin -I` is intended for this purpose.
- The content types acceptable to the printer (specified by `lpadmin -I`).
The values specified by the `lpadmin -T` are treated as if they were specified by the `-I` option as well.
- The modes of printing asked for by the originator of the request (specified by various options to `lp`).

The system uses the above information to construct a list of one or more filters that converts the document's content type into a content type acceptable to the printer and consumes all `lp` arguments that invoke filters (`-y` and `-P`).

The contents of the file (specified by the `-F` option) and the input stream from standard input (specified by `-`) must consist of a series of lines, such that each line conforms to the syntax specified by one of the seven lines below. All lists are comma or space separated. Each item contains a description.

Input types: *content-type-list*
 Output types: *content-type-list*
 Printer types: *printer-type-list*
 Printers: *printer-list*
 Filter type: *filter-type*
 Command: *shell-command*
 Options: *template-list*

- | | |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Input types | This gives the content types that can be accepted by the filter. The default is any. The document content type must be a member of this list for the initial filter in the sequence. |
| Output types | This gives the content types that the filter can produce from any of the input (content) types. The default is any. The intersection of the output types of this list and the content types acceptable to the printer (from <code>lpadmin -I</code> and <code>lpadmin -T</code>) must be non-null for the last filter in the sequence. For adjacent filters in the sequence, the intersection of output types of one and the input types of the next must be non-null. |
| Printer types | This gives the printer types for which this printer can be used. The LP print service will restrict the use of the filter to these printer types (from <code>lpadmin -T</code>). The default is any. |

| | |
|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Printers | This gives the names of the printers for which the filter can be used. The LP print service will restrict the use of the filter to just the printers named. The default is any. |
| Filter type | This marks the filter as a <code>slow</code> filter or a <code>fast</code> filter. Slow filters are generally those that take a long time to convert their input (that is, minutes or hours). They are run before the job is scheduled for a printer, to keep the printers from being tied up while the filter is running. If a listed printer is on a remote system, the filter type for it must have the value <code>slow</code> . That is, if a client defines a filter, it must be a slow filter. Fast filters are generally those that convert their input quickly (that is, faster than the printer can process the data), or those that must be connected to the printer when run. Fast filters will be given to the interface program to run while connected to the physical printer. |
| Command | This specifies which program to run to invoke the filter. The full program pathname as well as fixed options must be included in the <i>shell-command</i> ; additional options are constructed, based on the characteristics of each print request and on the <code>Options</code> field. A command must be given for each filter. The command must accept a data stream as standard input and produce the converted data stream on its standard output. This allows filter pipelines to be constructed to convert data not handled by a single filter. |
| Options | This is a comma-separated list of templates used by the LP print service to construct options to the filter from the characteristics of each print request listed in the table later. The <code>-y</code> and <code>-P</code> arguments to the <code>lp</code> command cause a filter sequence to be built even if there is no need for a conversion of content types. |

In general, each template is of the following form:

keyword pattern = replacement

The *keyword* names the characteristic that the template attempts to map into a filter-specific option; each valid *keyword* is listed in the table below.

A *pattern* is one of the following: a literal pattern of one of the forms listed in the table, a single asterisk (*), or a regular expression. If *pattern* matches the value of the characteristic, the template fits and is used to generate a filter-specific option. The *replacement* is what will be used as the option.

Regular expressions are the same as those found on the [regexp\(5\)](#) manual page. This includes the `\(...\)` and `\n` constructions, which can be used to extract portions of the *pattern* for copying into the *replacement*, and the `&`, which can be used to copy the entire *pattern* into the *replacement*.

The *replacement* can also contain a *; it too, is replaced with the entire *pattern*, just like the & of [regexp\(5\)](#).

The keywords are:

| lp Option | Characteristic | keyword | Possible <i>patterns</i> |
|----------------|------------------------------|--------------------|----------------------------------------|
| -T | Content type
(input) | INPUT | content-type |
| Not applicable | Content type
(output) | OUTPUT | content-type |
| not applicable | Printer type | TERM | printer-type |
| -d | Printer name | PRINTER | <i>printer-name</i> |
| -f, -o cpi= | Character pitch | CPI | integer |
| -f, -o lpi= | Line pitch | LPI | integer |
| -f, -o length= | Page length | LENGTH | integer |
| -f, -o width= | Page width | WIDTH | integer |
| -P | Pages to print | PAGES | page-list |
| -S | Character set
Print wheel | CHARSET
CHARSET | character-set-name
print-wheel-name |
| -f | Form name | FORM | form-name |
| -y | Modes | MODES | mode |
| -n | Number of
copies | COPIES | <i>integer</i> |

Resetting a Filter to Defaults If the filter named is one originally delivered with the LP print service, the `-i` option restores the original filter description.

Deleting a Filter The `-x` option is used to delete the filter specified in `filter-name` from the LP filter table.

Listing a Filter Description The `-l` option is used to list the description of the filter named in `filter-name`. If the command is successful, the following message is sent to standard output:

Input types: *content-type-list*
 Output types: *content-type-list*
 Printer types: *printer-type-list*

Printers: *printer-list*
Filter type: *filter-type*
Command: *shell-command*
Options: *template-list*

If the command fails, an error message is sent to standard error.

Large File Behavior See [largefile\(5\)](#) for the description of the behavior of `lpfilter` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples **EXAMPLE 1** Printing with the landscape option

For example, the template

```
MODES landscape = -l
```

shows that if a print request is submitted with the `-y landscape` option, the filter will be given the option `-l`.

EXAMPLE 2 Selecting the printer type

As another example, the template

```
TERM * = -T *
```

shows that the filter will be given the option `-T printer-type` for whichever *printer-type* is associated with a print request using the filter.

EXAMPLE 3 Using the keywords table

Consider the template

```
MODES prwidth=\(.*\) = -w\1
```

Suppose a user gives the command

```
lp -y prwidth=10
```

From the table above, the LP print service determines that the `-y` option is handled by a `MODES` template. The `MODES` template here works because the pattern `prwidth=)` matches the `prwidth=10` given by the user. The replacement `-w1` causes the LP print service to generate the filter option `-w10`. If necessary, the LP print service will construct a filter pipeline by concatenating several filters to handle the user's file and all the print options. See [sh\(1\)](#) for a description of a pipeline. If the print service constructs a filter pipeline, the `INPUT` and `OUTPUT` values used for each filter in the pipeline are the types of input and output for that filter, not for the entire pipeline.

Exit Status The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | print/lp |

See Also [lp\(1\)](#), [sh\(1\)](#), [lpadmin\(1M\)](#), [attributes\(5\)](#), [largefile\(5\)](#), [regex\(5\)](#)

System Administration Guide: Basic Administration

Notes If the `lp` command specifies more than one document, the filtering chain is determined by the first document. Other documents may have a different format, but they will print correctly only if the filter chain is able to handle their format.

Name lpforms – administer forms used with the LP print service

Synopsis lpforms -f *form-name* *option*

```
lpforms -f form-name -A alert-type [-P paper-name [-d]]
        [-Q requests] [-W minutes]
```

Description The lpforms command administers the use of preprinted forms, such as company letterhead paper, with the LP print service. A form is specified by its *form-name*. Users may specify a form when submitting a print request (see lp(1)). The argument *all* can be used instead of *form-name* with either of the command lines shown above. The first command line allows the administrator to add, change, and delete forms, to list the attributes of an existing form, and to allow and deny users access to particular forms. The second command line is used to establish the method by which the administrator is alerted that the form *form-name* must be mounted on a printer.

Options The following options are supported:

-f *form-name* Specify a form.

The first form of lpforms requires that one of the following *options* (-, -l, -F, -x) must be used:

-F *pathname* To add or change form *form-name*, as specified by the information in *pathname*.

- To add or change form *form-name*, as specified by the information from standard input.

-l To list the attributes of form *form-name*.

-x To delete form *form-name* (this option must be used separately; it may not be used with any other option).

The second form of the lpforms command requires the -A *alert-type* option. The other options are optional.

-A *alert-type* Defines an alert to mount the form when there are queued jobs which need it.

-P *paper-name* [-d] Specify the paper name when creating the form. If -d is specified, this paper is the default.

-Q *requests* An alert will be sent when a certain number of print requests that need the form are waiting.

-W *minutes* An alert will be sent at intervals specified by minutes.

Usage

Adding or Changing a Form The `-F pathname` option is used to add a new form, *form-name*, to the LP print service, or to change the attributes of an existing form. The form description is taken from *pathname* if the `-F` option is given, or from the standard input if the `-` option is used. One of these two options must be used to define or change a form.

pathname is the path name of a file that contains all or any subset of the following information about the form.

Page length: *scaled-decimal-number1*
 Page width: *scaled-decimal-number2*
 Number of pages: *integer*
 Line pitch: *scaled-decimal-number3*
 Character pitch: *scaled-decimal-number4*
 Character set choice: *character-set/print-wheel* [mandatory]
 Ribbon color: *ribbon-color*
 Comment:
comment
 Alignment pattern: [*content-type*]
content

The term “scaled-decimal-number” refers to a non-negative number used to indicate a unit of size. The type of unit is shown by a “trailing” letter attached to the number. Three types of scaled decimal numbers can be used with the LP print service: numbers that show sizes in centimeters (marked with a trailing *c*); numbers that show sizes in inches (marked with a trailing *i*); and numbers that show sizes in units appropriate to use (without a trailing letter); lines, characters, lines per inch, or characters per inch.

Except for the last two lines, the above lines may appear in any order. The `Comment :` and *comment* items must appear in consecutive order but may appear before the other items, and the `Alignment pattern :` and the *content* items must appear in consecutive order at the end of the file. Also, the *comment* item may not contain a line that begins with any of the key phrases above, unless the key phrase is preceded with a `>` sign. Any leading `>` sign found in the *comment* will be removed when the comment is displayed. There is no case distinction among the key phrases.

When this command is issued, the form specified by *form-name* is added to the list of forms. If the form already exists, its description is changed to reflect the new information. Once added, a form is available for use in a print request, except where access to the form has been restricted, as described under the `-u` option. A form may also be allowed to be used on certain printers only.

A description of each form attribute is below:

| | |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Page length and Page Width | Before printing the content of a print request needing this form, the generic interface program provided with the LP print service will initialize the physical printer to handle pages <i>scaled-decimal-number1</i> long, and |
|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| | |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | <p><i>scaled-decimal-number2</i> wide using the printer type as a key into the <code>terminfo(4)</code> database. The page length and page width will also be passed, if possible, to each filter used in a request needing this form.</p> |
| Number of pages | <p>Each time the alignment pattern is printed, the LP print service will attempt to truncate the <i>content</i> to a single form by, if possible, passing to each filter the page subset of <i>1-integer</i>.</p> |
| Line pitch and Character pitch | <p>Before printing the content of a print request needing this form, the interface program provided with the LP print service will initialize the physical printer to handle these pitches, using the printer type as a key into the <code>terminfo(4)</code> database. Also, the pitches will be passed, if possible, to each filter used in a request needing this form. <i>scaled-decimal-number3</i> is in lines-per-centimeter if a <i>c</i> is appended, and lines-per-inch otherwise; similarly, <i>scaled-decimal-number4</i> is in characters-per-centimeter if a <i>c</i> is appended, and characters-per-inch otherwise. The character pitch can also be given as <i>elite</i> (12 characters-per-inch), <i>pica</i> (10 characters-per-inch), or <i>compressed</i> (as many characters-per-inch as possible).</p> |
| Character set choice | <p>When the LP print service alerts an administrator to mount this form, it will also mention that the print wheel <i>print-wheel</i> should be used on those printers that take print wheels. If printing with this form is to be done on a printer that has selectable or loadable character sets instead of print wheels, the interface programs provided with the LP print service will automatically select or load the correct character set. If <i>mandatory</i> is appended, a user is not allowed to select a different character set for use with the form; otherwise, the character set or print wheel named is a suggestion and a default only.</p> |
| Ribbon color | <p>When the LP print service alerts an administrator to mount this form, it will also mention that the color of the ribbon should be <i>ribbon-color</i>.</p> |
| Comment | <p>The LP print service will display the <i>comment</i> unaltered when a user asks about this form (see <code>lpstat(1)</code>).</p> |

Alignment pattern When mounting this form, an administrator can ask for the *content* to be printed repeatedly, as an aid in correctly positioning the preprinted form. The optional *content-type* defines the type of printer for which *content* had been generated. If *content-type* is not given, *simple* is assumed. Note that the *content* is stored as given, and will be readable only by the user `lp`.

When an existing form is changed with this command, items missing in the new information are left as they were. When a new form is added with this command, missing items will get the following defaults:

```
Page Length: 66
Page Width: 80
Number of Pages: 1
Line Pitch: 6
Character Pitch: 10
Character Set Choice: any
Ribbon Color: any
```

- Deleting a Form** LP print service" The `-x` option is used to delete the form *form-name* from the LP print service.
- Listing Form Attributes** The `-l` option is used to list the attributes of the existing form *form-name*. The attributes listed are those described under *Adding and Changing a Form*, above. Because of the potentially sensitive nature of the alignment pattern, only the administrator can examine the form with this command. Other people may use the `lpstat(1)` command to examine the non-sensitive part of the form description.
- Allowing and Denying Access to a Form** The `-u` option, followed by the argument `allow:login-ID-list` or `-u deny:login-ID-list` lets you determine which users will be allowed to specify a particular form with a print request. This option can be used with the `-F` or `-` option, each of which is described above under *Adding or Changing a Form*.
- The *login-ID-list* argument may include any or all of the following constructs:
- | | |
|--------------------------------------|----------------------------------------|
| <i>login-ID</i> | A user on any system |
| <i>system_name!</i> <i>login-ID</i> | A user on system <i>system_name</i> |
| <i>system_name!</i> <code>all</code> | All users on system <i>system_name</i> |
| <code>all!<i>login-ID</i></code> | A user on all systems |
| <code>all</code> | All users on all systems |
- The LP print service keeps two lists of users for each form: an "allow-list" of people allowed to use the form, and a "deny-list" of people that may not use the form. With the `-u allow` option,

the users listed are added to the allow-list and removed from the deny-list. With the `-u deny` option, the users listed are added to the deny-list and removed from the allow-list. (Both forms of the `-u` option can be run together with the `-F` or the `-` option.)

If the allow-list is not empty, only the users in the list are allowed access to the form, regardless of the content of the deny-list. If the allow-list is empty but the deny-list is not, the users in the deny-list may not use the form, (but all others may use it). All users can be denied access to a form by specifying `-f deny:all`. All users can be allowed access to a form by specifying `-f allow:all`. (This is the default.)

Setting an Alert to Mount a Form

The `-f form-name` option is used with the `-A alert-type` option to define an alert to mount the form when there are queued jobs which need it. If this option is not used to arrange alerting for a form, no alert will be sent for that form.

The method by which the alert is sent depends on the value of the *alert-type* argument specified with the `-A` option. The *alert-types* are:

| | |
|----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>mail</code> | Send the alert message using the <code>mail</code> command to the administrator. |
| <code>write</code> | Write the message, using the <code>write</code> command, to the terminal on which the administrator is logged in. If the administrator is logged in on several terminals, one is arbitrarily chosen. |
| <code>quiet</code> | Do not send messages for the current condition. An administrator can use this option to temporarily stop receiving further messages about a known problem. Once the form <i>form-name</i> has been mounted and subsequently unmounted, messages will again be sent when the number of print requests reaches the threshold specified by the <code>-Q</code> option. |
| <code>showfault</code> | Attempt to execute a form alert handler on each system that has a print job for that form in the queue. The fault handler is <code>/etc/lp/alerts/form</code> . It is invoked with three parameters: <i>form_name</i> , <i>date</i> , <i>file_name</i> . <i>file_name</i> is the name of a file containing the form alert message. |
| <code>none</code> | Do not send messages until the <code>-A</code> option is given again with a different <i>alert-type</i> (other than <code>quiet</code>). |
| <code>shell-command</code> | Run the <i>shell-command</i> each time the alert needs to be sent. The shell command should expect the message in standard input. If there are blank spaces embedded in the command, enclose the command in quotes. Note that the <code>mail</code> and <code>write</code> values for this option are equivalent to the values <code>mail login-ID</code> and <code>write login-ID</code> respectively, where <i>login-ID</i> is the current name for the administrator. This will be the login name of the person submitting this command unless he or she has used the <code>su</code> command to change to another login-ID. If the <code>su</code> command has been used to change the user ID, then the <i>user-name</i> for the new ID is used. |

`list` Display the type of the alert for the form on standard output. No change is made to the alert.

The message sent appears as follows:

```
The form form-name needs to be mounted
on the printer(s):printer (integer1 requests).
integer2 print requests await this form.
Use the ribbon-color ribbon.
Use the print-wheel print wheel, if appropriate.
```

The printers listed are those that the administrator has specified as candidates for this form. The number *integer1* listed next to each printer is the number of requests eligible for the printer. The number *integer2* shown after the list of printers is the total number of requests awaiting the form. It will be less than the sum of the other numbers if some requests can be handled by more than one printer. The *ribbon-color* and *print-wheel* are those specified in the form description. The last line in the message is always sent, even if none of the printers listed use print wheels, because the administrator may choose to mount the form on a printer that does use a print wheel.

Where any color ribbon or any print wheel can be used, the statements above will read:

```
Use any ribbon.
Use any print-wheel.
```

If *form-name* is any, the *alert-type* defined in this command applies to any form for which an alert has not yet been defined. If *form-name* is `all`, the *alert-type* defined in this command applies to all forms.

If the `-W minutes` option is not given, the default procedure is that only one message will be sent per need to mount the form. Not specifying the `-W` option is equivalent to specifying `-W once` or `-W 0`. If *minutes* is a number greater than 0, an alert will be sent at intervals specified by *minutes*.

If the `-Q requests` option is also given, the alert will be sent when a certain number (specified by the argument *requests*) of print requests that need the form are waiting. If the `-Q` option is not given, or the value of *requests* is 1 or any (which are both the default), a message is sent as soon as anyone submits a print request for the form when it is not mounted.

Listing the Current Alert The `-f` option, followed by the `-A` option and the argument `list` is used to list the *alert-type* that has been defined for the specified form *form-name*. No change is made to the alert. If *form-name* is recognized by the LP print service, one of the following lines is sent to the standard output, depending on the type of alert for the form.

- When *requests* requests are queued: alert with *shell-command* every *minutes* minutes
- When *requests* requests are queued: write to *user-name* every *minutes* minutes

- When *requests* requests are queued: mail to *user-name* every *minutes* minutes
- No alert

The phrase every *minutes* minutes is replaced with once if *minutes* (*-Wminutes*) is 0.

Terminating an Active Alert The *-A quiet* option is used to stop messages for the current condition. An administrator can use this option to temporarily stop receiving further messages about a known problem. Once the form has been mounted and then unmounted, messages will again be sent when the number of print requests reaches the threshold *requests*.

Removing an Alert Definition No messages will be sent after the *-A none* option is used until the *-A* option is given again with a different *alert-type*. This can be used to permanently stop further messages from being sent as any existing alert definition for the form will be removed.

Large File Behavior See [largefile\(5\)](#) for the description of the behavior of `lpforms` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Exit Status The following exit values are returned:

- 0 Successful completion.
- non-zero An error occurred.

Files `/etc/lp/alerts/form` Fault handler for `lpform`.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | print/lp |

See Also [lp\(1\)](#), [lpstat\(1\)](#), [lpadmin\(1M\)](#), [terminfo\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

System Administration Guide: Basic Administration

Name lpget – get printing configuration

Synopsis lpget [-k *key*] [*destination...* | *list*]

Description The lpget utility reads printing configuration information from the configuration databases in \$HOME/.printers, /etc/printers.conf, printers.conf.byname, and printers.org_dir printer. This information, called a *configuration report*, is displayed to the standard output. See [printers\(4\)](#) and [printers.conf\(4\)](#) for information about the printer configuration databases.

lpget displays a configuration report for all keys for the specified destination or destinations by default. Use the -k option to display a configuration report for specific keys. Use the list operand to display a configuration report for all configured destinations.

Options The following option is supported:

-k *key* Displays a configuration report for *key*. See [printers.conf\(4\)](#) for information about specifying *key*.

Operands The following operands are supported:

destination Displays a configuration report for *destination*. Destination can be either a printer of a class of printers. See [lpadmin\(1M\)](#). Specify *destination* using atomic or POSIX-style (*server:destination*) names. See [printers.conf\(4\)](#) for information regarding the naming conventions for atomic names and [standards\(5\)](#) for information concerning POSIX.

list Displays a configuration report for all configured destinations.

Examples **EXAMPLE 1** Displaying a Configuration Report for the *bsdaddr* Key

The following example displays a configuration report for the *bsdaddr* key for printer *catalpa*.

```
example% lpget -k bsdaddr catalpa
```

EXAMPLE 2 A Configuration Report for all Keys for all Configured Destinations

The following example displays a configuration report for all keys for all configured destinations.

```
example% lpget list
```

Exit Status The following exit values are returned:

0 Successful completion.
non-zero An error occurred.

Files /etc/printers.conf System printer configuration database.
 \$HOME/.printers User-configurable printer database.
 printers.conf.byname NIS version of /etc/printers.conf.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|--------------------------------|
| Availability | print/lp/print-client-commands |
| Interface Stability | Committed |

See Also [ldap\(1\)](#), [lp\(1\)](#), [lpc\(1B\)](#), [lpq\(1B\)](#), [lpr\(1B\)](#), [lpstat\(1\)](#), [lpadmin\(1M\)](#), [lpset\(1M\)](#), [printers\(4\)](#), [printers.conf\(4\)](#), [attributes\(5\)](#), [standards\(5\)](#)

System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)

Notes Be mindful of the following if the LDAP database is used as the name service. If the [ldapclient\(1M\)](#) server is a replica LDAP server, LDAP printer database updates may not appear immediately, as the replica server may not have been updated by the master server and can be out of sync. For example, a printer that you deleted by using [lpset\(1M\)](#) may still appear in the printer list you display with `lpget` until the replica is updated from the master. Replica servers vary as to how often they are updated from the master. Refer to the *System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)* for more information on LDAP replication.

- Name** lpmove – move print requests
- Synopsis** lpmove [*request-ID*] *destination*
lpmove *source destination*
- Description** The lpmove command moves print requests queued by [lp\(1\)](#) or [lpr\(1B\)](#) between destinations. The first form of lpmove moves specific print requests (*request-ID*) to a specific *destination*. The second form of the lpmove command moves all print requests from one destination (*destination1*) to another (*destination2*). This form of lpmove also rejects new print requests for *destination1*.
- lpmove moves individual requests or entire queues only within an instance of a print service, not between a local and a remote queues or local queues on different instances of a print service. Requests can only be moved if the print service or protocol supports it. The LP print server and IPP print protocol both support moving requests between queues. The BSD print protocol does not.
- When moving requests, lpmove does not check the acceptance status of the destination to which the print requests are being moved (see [accept\(1M\)](#)). lpmove does not move requests that have options (for example, content type or requiring a special form) that cannot be handled by the new destination.
- Operands** The following operands are supported:
- request-ID* The specific print request to be moved. Specify *request-ID* as the identifier associated with a print request as reported by [lpstat\(1\)](#). See [lpstat\(1\)](#).
- destination* The name of the printer or class of printers (see [lpadmin\(1M\)](#)) to which lpmove moves a *specified* print request. Specify *destination* using atomic, URI-style (*scheme://endpoint*), POSIX-style (*server: destination*) syntax.
- source* The name of the destination from which lpmove moves *all* print requests. Specify *destination* using atomic, URI-style (*scheme://endpoint*), POSIX-style (*server: destination*) syntax.
- See [printers.conf\(4\)](#) for information regarding the naming conventions for atomic names and [standards\(5\)](#) for information regarding POSIX.
- Exit Status** The following exit values are returned:
- 0 Successful completion.
- non-zero An error occurred.
- Files**
- | | |
|--------------------|---------------------------------------|
| /etc/printers.conf | System printer configuration database |
| \$HOME/.printers | User-configurable printer database |
| ou=printers | LDAP version of /etc/printers.conf |

printers.conf.byname NIS version of /etc/printers.conf

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWlp-cmds |
| Interface Stability | Obsolete |

See Also [lp\(1\)](#), [lpr\(1B\)](#), [lpstat\(1\)](#), [accept\(1M\)](#), [lpadmin\(1M\)](#), [lpsched\(1M\)](#), [printers.conf\(4\)](#), [attributes\(5\)](#), [standards\(5\)](#)

System Administration Guide: Printing

Notes When IPP is in use, the user is prompted for a passphrase if the remote print service is configured to require authentication.

Name lpsched – start the LP print service

Synopsis lpsched [-f *num_filters*] [-n *num_notifiers*] [-p *fd_limit*]
[-r *reserved_fds*]

Description The lpsched command starts or restarts the LP print service.

The lpshut command stops the LP print service. Printers that are restarted using lpsched reprint (in their entirety) print requests that were stopped by lpshut. See [lpshut\(1M\)](#).

It is recommended that you start and stop the LP print service using [svcadm\(1M\)](#). See NOTES.

Options The following options are supported:

- f *num_filters* Specifies the number of concurrent slow filters that may be run on a print server. A default value of 1 is used if none is specified. Depending on server configuration, a value of 1 may cause printers to remain idle while there are jobs queued to them.
- n *num_notifiers* Specifies the number of concurrent notification processes that can run on a print server. A default value of 1 is used when none is specified.
- p *fd_limit* Specifies the file descriptor resource limit for the lpsched process. A default value of 4096 is used if none is specified. On extremely large and active print servers, it may be necessary to increase this value.
- r *reserved_fds* Specifies the number of file descriptors that the scheduler reserves for internal communications under heavy load. A default value of 2 is used when none is specified. It should not be necessary to modify this value unless instructed to do so when troubleshooting problems under high load.

Exit Status The following exit values are returned:

- 0 Successful completion.
- non-zero An error occurred.

Files /var/spool/lp/* LP print queue.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | print/lp |

See Also [lp\(1\)](#), [svcs\(1\)](#), [lpstat\(1\)](#), [lpadmin\(1M\)](#), [lpmove\(1M\)](#), [lpshut\(1M\)](#), [svcadm\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#)

System Administration Guide: Basic Administration

Notes The `lpsched` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/application/print/server
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Name lpset – set printing configuration in /etc/printers.conf or other supported databases

Synopsis lpset [-n system | fnsldap] [-x]
 [[-D binddn] [-w passwd] [-h ldapost]]
 [-a key=value] [-d key] destination

Description The lpset utility sets printing configuration information in the system configuration databases. Use lpset to create and update printing configuration in /etc/printers.conf. See [nsswitch.conf\(4\)](#) and [printers.conf\(4\)](#).

Only a superuser or a member of Group 14 may execute lpset.

Options The following options are supported:

- n system|ldap Create or update the configuration information for the *destination* entry in /etc/printers.conf or LDAP printer contexts. *system* specifies that the information is created or updated in /etc/printers.conf. *ldap* specifies that the information is written to an LDAP server. See [Notes](#).

If -n is not specified, *system* is the default.
- x Remove all configuration for the *destination* entry from the database specified by the -n option.
- a key=value Configure the specified *key=value* pair for the *destination*. See [printers.conf\(4\)](#) for information regarding the specification of *key=value* pairs.
- d key Delete the configuration option specified by *key* for the *destination* entry. See [printers.conf\(4\)](#) for information regarding the specification of *key* and *key=value* pairs.
- D binddn Use the distinguished name (DN) *binddn* to bind to the LDAP directory server.
- w passwd Use *passwd* as the password for authentication to the LDAP directory server.
- h ldapost Specify an alternate host on which the LDAP server is running. This option is only used when *ldap* is specified as the naming service. If this option is not specified, the default is the current host system.

Operands The following operand is supported:

- destination* Specifies the entry in /etc/printers.conf, printers.org_dir, or LDAP, in which to create or modify information. *destination* names a printer of class of printers. See [lpadmin\(1M\)](#). Each entry in *printers.conf* describes one destination. Specify *destination* using atomic names. POSIX-style destination names are not acceptable. See [printers.conf\(4\)](#) for information regarding the naming conventions for atomic names and [standards\(5\)](#) for information

regarding POSIX.

Examples EXAMPLE 1 Removing All Existing Printing Configuration Information

The following example removes all existing printing configuration information for destination dogs from `/etc/printers.conf`:

```
example% lpset -x dogs
```

EXAMPLE 2 Setting a key=value Pair

The following example sets the user-equivalence=true key=value pair for destination tabloid in the NIS context:

```
example% lpset -n nis -a user-equivalence=true tabloid
```

EXAMPLE 3 Setting a key=value Pair in LDAP

```
example% lpset -n ldap -h ldap1.xyz.com -D "cn=Directory Manager" \
-w passwd -a key1=value1 printer1
```

Exit Status The following exit values are returned:

0 Successful completion.
non-zero An error occurred.

Files `/etc/printers.conf` System configuration database.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|--------------------------------|
| Availability | print/lp/print-client-commands |
| Interface Stability | Committed |

See Also [ldap\(1\)](#), [lp\(1\)](#), [lpc\(1B\)](#), [lpq\(1B\)](#), [lpr\(1B\)](#), [lpstat\(1\)](#), [ldapclient\(1M\)](#), [lpadmin\(1M\)](#), [lpget\(1M\)](#), [nsswitch.conf\(4\)](#), [printers\(4\)](#), [printers.conf\(4\)](#), [attributes\(5\)](#), [standards\(5\)](#)

System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)

Notes If the `ldap` database is used, the printer administrator should be mindful of the following when updating printer information.

1. Because the domain information for the printer being updated is extracted from the [ldapclient\(1M\)](#) configuration, the LDAP server being updated must host the same domain that is used by the current [ldapclient\(1M\)](#) server.

2. If the LDAP server being updated is a replica LDAP server, the updates will be referred to the master LDAP server and completed there. The updates might be out of sync and not appear immediately, as the replica server may not have been updated by the master server. For example, a printer that you deleted by using `lpset` may still appear in the printer list you display with `lpget` until the replica is updated from the master. Replica servers vary as to how often they are updated from the master. See *System Administration Guide: Printing* for information on LDAP server replication.
3. Although users can use the LDAP command line utilities `ldapadd(1)` and `ldapmodify(1)` to update printer entries in the directory, the preferred method is to use `lpset`. Otherwise, if the `ldapadd` and `ldapmodify` utilities are used, the administrator must ensure that the `printer-name` attribute value is unique within the `ou=printers` container on the LDAP server. If the value is not unique, the result of modifications done using `lpset` or the Solaris Print Manager, `printmgr(1M)` may be unpredictable.

Name lpshut – stop the LP print service

Synopsis lpshut

Description The lpshut command stops the LP print service.

Printers that are printing when lpshut is invoked stop printing. Start or restart printers using [lpsched\(1M\)](#).

Exit Status The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

Files /var/spool/lp/* LP print queue.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWpsu |

See Also [lp\(1\)](#), [lpstat\(1\)](#), [lpadmin\(1M\)](#), [lpmove\(1M\)](#), [lpsched\(1M\)](#), [attributes\(5\)](#)

System Administration Guide: Basic Administration

Name lpsystem – register remote systems with the print service

Description The lpsystem command is obsolete, and could be removed at any time. The print system no longer uses the information generated by lpsystem. See [lpadmin\(1M\)](#), [lpusers\(1M\)](#) or [printers.conf\(4\)](#) for equivalent functionality.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|--------------------------------|
| Availability | print/lp/print-client-commands |
| Interface Stability | Obsolete* |

* This command could be removed at any time.

See Also [lpadmin\(1M\)](#), [lpusers\(1M\)](#), [printers.conf\(4\)](#), [attributes\(5\)](#)

Name lpusers – set printing queue priorities

Synopsis lpusers -d *priority-level*
 lpusers -q *priority-level* -u *login-ID-list*
 lpusers -u *login-ID-list*
 lpusers -q *priority-level*
 lpusers -l

Description The lpusers command sets limits to the queue priority level that can be assigned to jobs submitted by users of the LP print service.

The first form of the command (with -d) sets the system-wide priority default to *priority-level*, where *priority-level* is a value of 0 to 39, with 0 being the highest priority. If a user does not specify a priority level with a print request (see lp(1)), the default priority level is used. Initially, the default priority level is 20.

The second form of the command (with -q and -u) sets the default highest *priority-level* (0-39) that the users in *login-ID-list* can request when submitting a print request. The *login-ID-list* argument may include any or all of the following constructs:

| | |
|-------------------------------------|-----------------------------------------|
| <i>login-ID</i> | A user on any system |
| <i>system_name!</i> <i>login-ID</i> | A user on the system <i>system_name</i> |
| <i>system_name!</i> all | All users on system <i>system_name</i> |
| all! <i>login-ID</i> | A user on all systems |
| all | All users on all systems |

Users that have been given a limit cannot submit a print request with a higher priority level than the one assigned, nor can they change a request that has already been submitted to have a higher priority. Any print requests submitted with priority levels higher than allowed will be given the highest priority allowed.

The third form of the command (with -u) removes any explicit priority level for the specified users.

The fourth form of the command (with -q) sets the default highest priority level for all users not explicitly covered by the use of the second form of this command.

The last form of the command (with -l) lists the default priority level and the priority limits assigned to users.

Options The following options are supported:

-d *priority-level* Set the system-wide priority default to *priority-level*.

- l List the default priority level and the priority limits assigned to users.
- q *priority-level* Set the default highest priority level for all users not explicitly covered.
- q *priority-level* -u *login-ID-list* Set the default highest *priority-level* that the users in *login-ID-list* can request when submitting a print request.
- u *login-ID-list* Remove any explicit priority level for the specified users.

Exit Status The following exit values are returned:

- 0 Successful completion.
- non-zero An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | print/lp |

See Also [lp\(1\)](#), [attributes\(5\)](#)

Name lu – FMLI-based interface to Live Upgrade functions

Synopsis /usr/sbin/lu

Description Sun no longer recommends use of the `lu` command. The `lu` command displays a character user interface (CUI). The underlying command sequence for the CUI--typically `lucreate`, `luupgrade`, and `luactivate--` is straightforward to use. The **SEE ALSO** section below highlights the full Solaris Live Upgrade command set.

The `lu` program is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `lu` program is a Forms and Menu Language Interpreter-based user interface. `lu` enables you to create and upgrade boot environments (BEs) and perform other administrative tasks on BEs. The `lu` program performs a subset of the functions provided by the Live Upgrade command-line utilities.

Users of `lu` should be aware of the following:

- `lu` is a deprecated interface. It will be replaced in the future and should not be depended on for critical functionality.
- All new Live Upgrade features are being implemented in the Live Upgrade command-line utilities. No new features are being made available in `lu`.
- The `lu` command is not internationalized. It will not be internationalized in a future release.

`lu` should be used for learning or experimenting only. For any production use or to use the full capabilities of Live Upgrade, use the Live Upgrade command-line utilities.

Invocation of the `lu` command requires root privileges.

The `lu` command accepts no arguments. After invoking `lu`, you receive a display with the following options:

- | | |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Activate | Activate a boot environment. This option designates that the system boot from the specified BE upon next reboot. This option is equivalent to the command-line <code>luactivate(1M)</code> utility. |
| Cancel | Cancel a copy job. Live Upgrade allows you to schedule the copy, upgrade, and flash functions (all described below) at a later time. The cancel function enables you to cancel a scheduled job. This function is equivalent to the command-line <code>lucancel(1M)</code> utility. |
| Compare | Compare the contents of BEs. Enables you to obtain a detailed comparison of two BEs. Equivalent to the command-line <code>lucompare(1M)</code> utility. |

| | |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Copy | Start/schedule a copy. Copies the contents of one BE to another. Equivalent of the command-line <code>lumake(1M)</code> utility. At any time, you can have only one Live Upgrade operation scheduled. |
| Create | Create a boot environment. Implements a subset of the functions performed by the command-line <code>lucreate(1M)</code> utility. |
| Current | Display the name of the current boot environment. Equivalent of the command-line <code>lucurr(1M)</code> utility. |
| Delete | Delete a boot environment. Equivalent of the command-line <code>ludelete(1M)</code> utility. |
| List | List the file systems of a boot environment. Equivalent of the command-line <code>lufslist(1M)</code> utility. |
| Rename | Change the name of a boot environment. Equivalent of the command-line <code>lurename(1M)</code> utility. |
| Status | List the status of all boot environments. Equivalent of the command-line <code>lustatus(1M)</code> utility. |
| Upgrade | Upgrade a boot environment or upgrade the OS on an inactive BE. This option enables you to upgrade to a new operating system or install new packages or patches on a specified BE. Implements a subset of the functions performed by the command-line <code>luupgrade(1M)</code> utility. Note that if you are performing an upgrade that requires more than one CD, you must use the <code>-i</code> option of <code>luupgrade</code> . |
| Flash | Flash a boot environment. This option enables you to install an operating system on a BE from a flash archive. You can perform the same function with <code>luupgrade(1M)</code> . |
| Help | Displays help information. There are also context-specific help screens for many of the options. |
| Exit | Exit <code>lu</code> . |
| Navigation | You navigate through <code>lu</code> 's various screens using arrow keys and function keys (usually F2 through F9 on the keyboard of a Sun desktop system). Available key functions are displayed at the base of the <code>lu</code> screen. You can use Ctrl-F, plus a number key, to duplicate a function key. For example, press Ctrl-F and the number key 2 to duplicate the F2 key.

In a screen for a given option, you can press Esc to obtain context-specific help. |
| Display Issues | When viewing the FMLI interface remotely, such as over a <code>tip</code> line, you might need to set the <code>TERM</code> environment variable to <code>VT220</code> . When using the FMLI interface in a CDE environment use <code>dtterm</code> , rather than <code>xterm</code> , as the value of the <code>TERM</code> variable. |

The `lu` command supports only single-byte environments.

Common Functions Most of the options listed above offer the following functions. These functions are accessible through function keys indicated at the base of the screen.

Choice Available to you whenever you have a field that can be filled in. Pressing the Choice function key gives you a popup screen displaying a list of alternatives. For example, for options involving copying or upgrading BEs, you receive a list of available BEs. You can then use arrow and function keys to make a selection from this popup. The choice function is useful because it prevents you from selecting an invalid alternative. In our example, it prevents you from choosing a BE that is not available for a copy or upgrade operation. Such non-availability might occur when a BE is in the midst of an upgrade.

Cancel Cancel an operation.

Save Proceed with an operation.

Other Functions The “Create” option, described above, offers the following functions:

Split Split a file system. For example, you can split a `/` file system into `/`, `/usr`, and `/var`. To split a file system, you must have disk slices available on which to mount the separated file system(s). If you do not, `lu` invokes the [format\(1M\)](#) utility, in which you can use the `partition` option to create a new disk slice.

Merge Join one or more file systems with its (or their) parent file system. For example, using a source BE that has separate `/`, `/usr`, and `/var` file systems, you can merge these file systems under `/` on a target BE.

Solaris Installation Guide

Warnings The `lu` command is a deprecated interface. See DESCRIPTION.

Name luactivate – activate a boot environment

Synopsis /usr/sbin/luactivate [-l *error_log*] [-o *outfile*] [-s]
[*BE_name*] [-X]

Description The `luactivate` command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `luactivate` command, with no arguments, displays the name of the boot environment (BE) that will be active upon the next reboot of the system. When an argument (a BE) is specified, `luactivate` activates the specified BE.

`luactivate` activates a BE by making the BE's root partition bootable. On an x86 machine, this might require that you take steps following the completion of `luactivate`. If so, `luactivate` displays the correct steps to take.

To successfully activate a BE, that BE must meet the following conditions:

- The BE must have a status of “complete,” as reported by `lustatus(1M)`.
- If the BE is not the current BE, you cannot have mounted the partitions of that BE (using `lumount(1M)` or `mount(1M)`).
- The BE you want to activate cannot be involved in an `lucompare(1M)` operation.

After activating a specified BE, `luactivate` displays the steps to be taken for fallback in case of any problem on the next reboot. Make note of these instructions and follow them exactly, if necessary.

Note – Before booting a new BE, you must run `luactivate` to specify that BE as active. `luactivate` performs a number of tasks, described below, that ensure correct operation of the BE. In some cases, a BE is not bootable until after you have run the command.

The `luactivate` command performs the following tasks:

- The first time you boot from a newly created BE, Live Upgrade software synchronizes this BE with the BE that was last active. (This is not necessarily the BE that was the source for the newly created BE.) *Synchronize* here means that certain system files and directories are copied from the last-active BE to the BE being booted. (See `sync(4)`.) Live Upgrade software does not perform this synchronization after a BE's initial boot, unless you use the `-s` option, described below.
- If `luactivate` detects conflicts between files that are subject to synchronization, it issues a warning and does not perform the synchronization for those files. Activation can complete successfully, in spite of such a conflict. A conflict can occur if you upgrade one BE or another to a new operating system version or if you modify system files (for example, `/etc/passwd`) on one of the BEs.

- `luactivate` checks to see whether upgrade problems occurred. For example, packages required for the correct operation of the operating system might be missing. This package check is done for the global zone as well as all non-global zones inside of the BE. The command can issue a warning or, if a BE is incomplete, can refuse activation.
- `luactivate` determines whether the bootstrap program requires updating and takes steps to update if necessary. If a bootstrap program changed from one operating release to another, an incorrect bootstrap program might render an upgraded BE unbootable. See [installboot\(1M\)](#).
- `luactivate` modifies the root partition ID on a Solaris x86 disk to enable multiple BEs to reside on a single disk. In this configuration, if you do not run `luactivate`, booting of the BE will fail. See [fmthard\(1M\)](#) and [dkio\(7I\)](#).

The `luactivate` command requires root or equivalent privileges.

Options The `luactivate` command has the following options:

- l *error_log* Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.
- o *outfile* All command output is sent to *outfile*, in addition to where it is sent in your current environment.
- s Causes synchronization to occur (see DESCRIPTION) even if next boot of a specified BE is not the first boot of that BE. Use this option with great caution, because you might not be aware or in control of changes that might have occurred in the last-active BE.

If using `-s`, take special care when booting to an earlier release of Solaris than what is installed on the last-active BE. For example, consider that the last-active BE contains Solaris 9 and you want to activate a BE that contains Solaris 2.6. If you forced synchronization with the `-s` option, the BE containing Solaris 2.6 might be synchronized with files that, while compatible with Solaris 9, might not work under Solaris 2.6.

- X Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.<num>`, where `<num>` is the version number of the DTD file.

Operands *BE_name* Name of the BE to be activated.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Files /etc/lutab list of BEs on the system
 /usr/share/lib/xml/dtd/lu_cli.dtd.<num> Live Upgrade DTD (see -X option)

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWlu |

See Also [lucancel\(1M\)](#), [lucompare\(1M\)](#), [lucreate\(1M\)](#), [lucurr\(1M\)](#), [ludelete\(1M\)](#), [ludesc\(1M\)](#), [lufslis\(1M\)](#), [lumake\(1M\)](#), [lumount\(1M\)](#), [lurename\(1M\)](#), [lustatus\(1M\)](#), [luupgrade\(1M\)](#), [lutab\(4\)](#), [attributes\(5\)](#), [live_upgrade\(5\)](#), [zones\(5\)](#)

Notes After entering `init 6`, if an activated BE fails to boot, consult `/var/svc/log/rc6.log` on the current BE for possible obstacles.

Name lucancel – cancel a scheduled Live Upgrade copy/create procedure

Synopsis `/usr/sbin/lucancel [-l error_log] [-o outfile] [-X]`

Description The `lucancel` command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `lucancel` command cancels a boot environment (BE) creation or upgrade that was scheduled in the FMLI-based interface, `lu(1M)`, or the repopulation of a BE, scheduled with `lumake(1M)`. Note that Sun recommends against the use of the `lu` command.

`lucancel` does not cancel a job that is active (that is, is in the process of creation or repopulation).

The `lucancel` command requires root privileges.

Options The `lucancel` command has the following options:

- l *error_log* Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.
- o *outfile* All command output is sent to *outfile*, in addition to where it is sent in your current environment.
- X Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.<num>`, where `<num>` is the version number of the DTD file.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Files `/etc/lutab` list of BEs on the system

Attributes See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------|----------------|
| Availability | SUNWlu |

See Also `luactivate(1M)`, `lucompare(1M)`, `lucreate(1M)`, `lucurr(1M)`, `ludelete(1M)`, `ludesc(1M)`, `lufslis(1M)`, `lumake(1M)`, `lumount(1M)`, `lurename(1M)`, `lustatus(1M)`, `luupgrade(1M)`, `lutab(4)`, `attributes(5)`, `live_upgrade(5)`

Name lucompare – compare boot environments

Synopsis /usr/sbin/lucompare [-i *infile* | -t] [-o *outfile*] *BE_name*
[-X]

/usr/sbin/lucompare [-C *file* [-o *outfile*]] [-X]

Description The `lucompare` command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `lucompare` command compares the contents of the current boot environment (BE) with the contents of another BE. With the `-C` option, `lucompare` compares file statistics so that you can determine which files have changed on a BE since a specified time, such as the creation time of a BE. A specified BE must be inactive and in the complete state, as reported by the `lustatus(1M)` command. Also, a BE cannot have a copy job scheduled, which is also reported by `lustatus(1M)`. A specified BE cannot have any partitions mounted with `lumount(1M)` or `mount(1M)`.

For each file system defined for a specified BE, `lucompare` compares all files with the files with the same pathnames in the current BE. The files present in the active BE, but not in the specified BE, and vice-versa, are reported. You also have the option to specify a list of files to be compared.

If you specify the `-C` option, instead of doing an absolute comparison of the current BE with a target BE, `lucompare` compares the files in a specified BE with the list of files recorded in a file. When a BE is created, `lucreate(1M)` creates a file named `<BE_name>` in `/etc/lu/compare`. You can use the `-C` option to compare the files in a specified BE to this snapshot in `/etc/lu/compare` or you can compare the BE to a file previously created with the `-o` option. Comparing a BE to its own snapshot in `/etc/lu/compare` enables you to determine which files have changed on the BE since its creation.

By default, the output of `lucompare` is written to stdout. With the `-C` option, you must use the `-o` option to specify an output file. The output for `lucompare` is a list of files that differ in permissions, owner, group, or sum, along with the reason for difference. The output format is shown below:

```
> active BE
< BE_name
reason
> file_name:owner:group:number_of_links:mode:type: size
or major_minor number:checksum
< file_name:owner:group:number_of_links:mode:type: size
or major_minor number:checksum
```

The above fields are obtained from the `stat(2)` structure of the file.

The `type` field can be one of the following:

SYMLINK symbolic link

| | |
|--------|-------------------|
| FIFO | FIFO file |
| CHRSPC | character special |
| BLKSPC | block special |
| DIR | directory |
| REGFIL | regular file |
| UNKNOW | unknown file type |

lucompare computes checksums only if the file on the specified BE matches its counterpart on the active BE in all of the fields described above. If the checksums differ, lucompare appends the differing checksums to the entries for the compared files.

The lucompare command requires root privileges.

Options The lucompare command has the following options:

- C *file* Compare file statistics of BE with those recorded in *file*. *file* can be the snapshot created at BE creation time, /etc/lu/compare/:<BE_name>, or a file previously created with the -o option. You must use the -o option with this option.
- i *infile* Compare files listed in *infile*. The files to be compared should be an absolute filename. If the entry in the file is a directory, then comparison is recursive with respect to the directory. Mutually exclusive of -t.
- o *outfile* Send output of differences to *outfile*. You must use this option if you use -C.
- t Compare only nonbinary files. This is achieved by performing a [file\(1\)](#) command on each file in the tree walk and only comparing text files. Mutually exclusive of -i.
- X Enable XML output. Characteristics of XML are defined in DTD, in /usr/share/lib/xml/dtd/lu_cli.dtd. <num>, where <num> is the version number of the DTD file.

Operands *BE_name* Name of the BE to which the active BE will be compared. You cannot specify a BE that is involved in another Live Upgrade operation, or specify a BE for which you have mounted partitions (using [lumount\(1M\)](#) or [mount\(1M\)](#)).

Examples **EXAMPLE 1** Checking Differences Since BE Creation

The following command lists the differences in the BE s8u5 between its creation time and the present.

```
# lucompare -C /etc/lu/compare/:s8u5 -o /var/tmp/compare.out s8u5
```

EXAMPLE 1 Checking Differences Since BE Creation (Continued)

Note that `/etc/lu/compare/:s8u5` is the file created by `lucreate` upon creation of a BE. The list of differences is sent to `/var/tmp/compare.out`.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Files `/etc/lutab` list of BEs on the system
`/usr/share/lib/xml/dtd/lu_cli.dtd.<num>` Live Upgrade DTD (see `-X` option)

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWlu |

See Also [luactivate\(1M\)](#), [lucancel\(1M\)](#), [lucreate\(1M\)](#), [lucurr\(1M\)](#), [ludelete\(1M\)](#), [ludesc\(1M\)](#), [lufslst\(1M\)](#), [lumake\(1M\)](#), [lumount\(1M\)](#), [lurename\(1M\)](#), [lustatus\(1M\)](#), [luupgrade\(1M\)](#), [lutab\(4\)](#), [attributes\(5\)](#), [live_upgrade\(5\)](#)

Notes The `lucompare` command makes no attempt to reconcile any differences it detects between BEs.

Name lucreate – create a new boot environment

Synopsis /usr/sbin/lucreate [-A *BE_description*] [-c *BE_name*]
 [-C (*boot_device* | -)] -n *BE_name*
 [-f *exclude_list_file*] [-I] [-l *error_log*]
 [-o *outfile*] [-s (- | *source_BE_name*)]
 [[-M *slice_list_file* [-M]...]
 [-m *mount_point:device* [, *volume*]:*fs_options*[:*zonename*] [-m...]] |
 [-p *zfs_root_pool*]
 [-x *exclude* [-x]...] [-X] [-y *include* [-y]...]
 [-Y *include_list_file*] [-z *filter_list*]

Description The lucreate command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature and its associated terminology.

The lucreate command offers a set of command line options that enable you to perform the following functions:

- Create a new boot environment (BE), based on the current BE.
- Create a new BE, based on a BE other than the current BE.
- Join or separate the file systems of a BE onto a new BE. For example, join `/var` and `/opt` under `/`, or separate these directories to be mounted under different disk slices.
- Specify separate file systems belonging to a particular zone inside of the new BE. (See [zones\(5\)](#).)
- Create the file systems for a BE, but leave those file systems unpopulated.

If lucreate is invoked without the `-m`, `-M`, or `-p` options (described below), it brings up an FMLI-based interface that provides curses-based screens for Live Upgrade administration. Note that the FMLI-based interface does not support all of the Live Upgrade features supported by the command-line version of lucreate. Also, Sun is not committed to ongoing development of the FMLI-based interface.

With the `-p` option, lucreate supports the creation of BEs on ZFS file systems. The source BE can be a UFS root file system on a disk slice or a ZFS file system in an existing ZFS storage pool. lucreate provides a convenient means of migrating a BE from a UFS root file system to a ZFS root file system. You cannot create a BE on a UFS file system from a source BE on a ZFS file system.

The creation of a BE includes selecting the disk or device slices for all the mount points of the BE. Slices can be physical disks or logical devices, such as Solaris Volume Manager volumes. You can also change the mount points of the BE using the SPLIT and MERGE functions of the FMLI-based configuration screen.

Upon successful creation of a BE, you can use `lustatus(1M)` to view the state of that BE and `lufslist(1M)` to view the BE's file systems. You can use `luupgrade(1M)` to upgrade the OS on that BE and `luactivate(1M)` to make a BE active, that is, designate it as the BE to boot from at the next reboot of the system.

Note – Before booting a new BE, you must run `luactivate` to specify that BE as active. `luactivate` performs a number of tasks that ensure correct operation of the BE. In some cases, a BE is not bootable until after you have run the command. See `luactivate(1M)` for a list of the operations performed by that command.

The `lucreate` command makes a distinction between the file systems that contain the OS—`/`, `/usr`, `/var`, and `/opt`—and those that do not, such as `/export`, `/home`, and other, user-defined file systems. The file systems in the first category cannot be shared between the source BE and the BE being created; they are always copied from the source BE to the target BE. By contrast, the user-defined file systems are shared by default. For Live Upgrade purposes, the file systems that contain the OS are referred to as non-shareable (or *critical*) file systems; other file systems are referred to as shareable. A non-shareable file system listed in the source BE's `vfstab` is copied to a new BE. For a shareable file system, if you specify a destination slice, the file system is copied. If you do not, the file system is shared.

When migrating from a UFS-based BE to a ZFS-based BE, you cannot migrate shared UFS file systems to ZFS. Also, when the source and destination BEs are both ZFS-based, you cannot copy shared file systems. Such file systems can only be shared.

The `lucreate` command copies all non-global zones from the current BE to the BE being created. For non-global zones residing in a non-shared file system, the new BE gets a copy of the zone in its non-shared file system. For non-global zones residing in a shared file system, `lucreate` makes a copy of the zone for the new BE in that shared file system and uses a different zonpath (see `zoneadm(1M)`) for the zone. The zonpath used is of the form `zonpath-newBE`. This prevents BEs from sharing the same non-global zone in the shared file system. When the new BE gets booted, the zone in the shared file system belonging to the new BE has its zonpath renamed to `zonpath` and the zone in the shared file system belonging to the original BE has its zonpath renamed to `zonpath-origBE`.

If a zone exists in a non-shared file system, the zone is automatically copied when the UFS root file system is migrated to a ZFS root file system. If a zone exists in a shared UFS file system, to migrate to a ZFS root file system, you must first upgrade the zone, as in previous Solaris releases. A zone in a non-shared file system within a ZFS BE is cloned when upgrading to a ZFS BE within the same ZFS pool.

The `lucreate` command supports a limited subset of Solaris Volume Manager functions. In particular, using `lucreate` with the `-m` option, you can:

- Create a mirror.
- Detach existing SVM concatenations from mirrors. Similarly, you can attach existing Solaris Volume Manager concatenations to mirrors. These can be mirrors that were created in Solaris Volume Manager or those created by `lucreate`.

- Create a single-slice concatenation and attach a single disk slice to it.
- Detach a single disk slice from a single-slice concatenation.
- Attach multiple single-slice concatenations to a mirror. `lucreate` can attach as many of these concatenations as are allowed by Solaris Volume Manager.

`lucreate` does not allow you to attach multiple disk slices or multiple storage devices to a concatenation. Similarly, it does not allow you to detach multiple slices or devices from a concatenation.

If you use Solaris Volume Manager volumes for boot environments, it is recommended that you use `lucreate` rather than Solaris Volume Manager commands to manipulate these volumes. The Solaris Volume Manager software has no knowledge of boot environments, whereas the `lucreate` command contains checks that prevent you from inadvertently destroying a boot environment by, for example, overwriting or deleting a Solaris Volume Manager volume.

If you have already used Solaris Volume Manager software to create complex Solaris Volume Manager volumes (for example, RAID-5 volumes), Live Upgrade will support the use of these. However, to create and manipulate these complex objects, you must use Solaris Volume Manager software. As described above, the use of Solaris Volume Manager software, rather than the `lucreate` command, entails the risk of destroying a boot environment. If you do use Solaris Volume Manager software, use `lufslist(1M)` to determine which devices are in use for boot environments.

Except for a special use of the `-s` option, described below, you must have a source BE for the creation of a new BE. By default, it is the current BE. You can use the `-s` option to specify a BE other than the current BE.

When creating a new BE on a UFS file system, `lucreate` enables you to exclude and include certain files from the source BE. You perform this inclusion or exclusion with the `-f`, `-x`, `-y`, `-Y`, and `-z` options, described below. See the subsection on combining these options, following `OPTIONS`, below.

By default, all swap partitions on a UFS-based source BE are shared with a UFS-based target BE. For UFS-based target BEs, you can use the `-m` option (see below) to specify an additional or new set of swap partitions on the source BE for sharing with the target. When a UFS-based source BE is copied to a ZFS target BE, `lucreate` creates in the new BE a swap area and a dump device on separate ZFS volumes. When both the source and target BEs are ZFS-based and are in the same pool, both BEs use the same swap volume. If source and target are in different pools, a new swap volume is created in the pool of the target BE.

The `lucreate` command allows you to assign a description to a BE. A description is an optional attribute of a BE that can be of any format or length. It might be, for example, a text string or binary data. After you create a BE, you can change a BE description with the `ludesc(1M)` utility.

The `lucreate` command requires root privileges or that you assume the Primary Administrator role.

Options The `lucreate` command has the options listed below. Note that a BE name must not exceed 30 characters in length and must consist only of alphanumeric characters and other ASCII characters that are not special to the Unix shell. See the “Quoting” section of [sh\(1\)](#). The BE name can contain only single-byte, 8-bit characters; it cannot contain whitespace characters.

Omission of `-m`, `-M`, and `-p` options (described below) in an `lucreate` command line invokes the FMLI-based interface, which allows you to select disk or device slices for a UFS-based BE.

-A `BE_description`

Assigns the `BE_description` to a BE. `BE_description` can be a text string or other characters that can be entered on a Unix command line. See [ludes\(1M\)](#) for additional information on BE descriptions.

-c `BE_name`

Assigns the name `BE_name` to the current BE. This option is not required and can be used only when the first BE is created. For the first time you run `lucreate`, for a UFS-based BE, if you omit `-c`, `lucreate` supplies a default name according to the following rules:

1. If the physical boot device can be determined, the base name of that device is used to name the new boot environment. For example, if the physical boot device is `/dev/dsk/c0t0d0s0`, `lucreate` names the new boot environment `c0t0d0s0`.
2. If the physical boot device cannot be determined, the operating system name (from `uname -s`) and operating system release level (from `uname -r`) are combined to produce the name of the new boot environment. For example, if `uname -s` returns `SunOS` and `uname -r` returns `5.9`, then `lucreate` assigns the name `SunOS5.9` to the new boot environment.
3. If `lucreate` can determine neither boot device nor operating system name, it assigns the name `current` to the new boot environment.

For a ZFS-based BE, the default BE name is the base name of the root file system.

If you use the `-c` option after the first boot environment is created, the option is ignored if the name specified is the same as the current boot environment name. If the name is different, `lucreate` displays an error message and exits.

-C (`boot_device` | -)

Provided for occasions when `lucreate` cannot figure out which physical storage device is your boot device. This might occur, for example, when you have a mirrored root device on the source BE on an x86 machine. The `-C` specifies the physical boot device from which the source BE is booted. Without this option, `lucreate` attempts to determine the physical device from which a BE boots. If the device on which the root file system is located is not a physical disk (for example, if root is on a Solaris Volume Manager volume) and `lucreate` is able to make a reasonable guess as to the physical device, you receive the query:

Is the physical device *devname* the boot device for the logical device *devname*?

If you respond *y*, the command proceeds.

If you specify *-C boot_device*, *lucreate* skips the search for a physical device and uses the device you specify. The *-* (hyphen) with the *-C* option tells *lucreate* to proceed with whatever it determines is the boot device. If the command cannot find the device, you are prompted to enter it.

If you omit *-C* or specify *-C boot_device* and *lucreate* cannot find a boot device, you receive an error message.

Use of the *-C -* form is a safe choice, because *lucreate* either finds the correct boot device or gives you the opportunity to specify that device in response to a subsequent query.

-f exclude_list_file

Use the contents of *exclude_list_file* to exclude specific files (including directories) from the newly created BE. *exclude_list_file* contains a list of files and directories, one per line. If a line item is a file, only that file is excluded; if a directory, that directory and all files beneath that directory, including subdirectories, are excluded.

This option is not supported when the source BE is on a ZFS file system.

-I

Ignore integrity check. Prior to creating a new BE, *lucreate* performs an integrity check, to prevent you from excluding important system files from the BE. Use this option to override this integrity check. The trade-off in use of this option is faster BE creation (with *-I*) versus the risk of a BE that does not function as you expect.

-l error_log

Error messages and other status messages are sent to *error_log*, in addition to where they are sent in your current environment.

-m mount_point:device[,volume]:fs_option[:zonename]

[*-m mount_point:device:fs_option[:zonename]*] ...

Specifies the [vfstab\(4\)](#) information for a new UFS-based BE. The file systems specified as arguments to *-m* can be on the same disk or can be spread across multiple disks.

The *-m* option is not supported for BEs based on ZFS file systems. This option also does not support EFI-labeled disks.

mount_point can be any valid mount point or *-* (hyphen), indicating a swap partition. The *device* field can be one of the following:

- The name of a disk slice, of the form */dev/dsk/cnumtnumdnumsnm*.
- The name of a Solaris Volume Manager volume, of the form */dev/md/dsk/dnum*.
- The name of a Solaris Volume Manager disk set, of the form */dev/md/setname/dsk/dnum*.

- The name of a Veritas volume, of the form `/dev/vx/dsk/dgname/volname`.
- The keyword `merged`, indicating that the file system at the specified mount point is to be merged with its parent.
- The keyword `shared`, indicating that all of the swap partitions in the source BE are to be shared with the new BE.

The `-m` option enables you to attach a physical disk device to a Solaris Volume Manager single-slice concatenation or attach a Solaris Volume Manager volume to a mirror. Both operations are accomplished with the `attach` keyword, described below. With this option, you have the choice of specifying a concatenation or mirror or allowing `lucreate` to select one for you. To specify a concatenation or mirror, append a comma and the name of the Solaris Volume Manager logical device to the device name to which the logical device is being attached. If you omit this specification, `lucreate` selects a concatenation or mirror from a list of free devices. See EXAMPLES.

The `fs_option` field can be one or more of the keywords listed below. The first two keywords specify types of file systems. The remaining keywords specify actions to be taken on a file system. When you specify multiple keywords, separate these with a comma.

| | |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ufs</code> | Create the file system as a UFS volume. |
| <code>vxf</code> | Create the file system as a Veritas device. |
| <code>preserve</code> | Preserve the file system contents of the specified physical storage device. Use of this keyword presumes that the device's file system and its contents are appropriate for the specified mount point. For a given mount point, you can use <code>preserve</code> with only one device. This keyword enables you to bypass the default steps of creating a new file system on the specified storage device, then copying the file system contents from the source BE to the specified device. When you use <code>preserve</code> , <code>lucreate</code> checks that the storage device's contents is suitable for a specified file system. This check is limited and cannot guarantee suitability. |
| <code>mirror</code> | Create a mirror on the specified storage device. The specified storage device must be a correctly named (for example, <code>/dev/md/dsk/d10</code>) logical device that can serve as a mirror. In subsequent <code>-m</code> options, you must specify <code>attach</code> (see below) to attach at least one physical device to the new mirror. |
| <code>attach</code> | Attach a physical storage device, contained by a volume, to the mirror or single-slice concatenation associated with a specified mount point. When using <code>attach</code> , if you want to attach a disk to a specific mirror or concatenation, you append a comma and the name of that logical device to the device name. If you omit the comma and the concatenation name, <code>lucreate</code> selects a free mirror or single-slice concatenation as the container volume for the storage device. See EXAMPLES. |

lucreate allows you to create only concatenations that contain a single physical drive and allows you to attach up to four such concatenations to a mirror.

detach Detach a physical storage device from the mirror or concatenation associated with a specified mount point.

The optional *zonename* field specifies the name of an installed non-global zone. It is used to specify a separate file system that belongs to the particular zone, named *zonename*, that exists in the new BE being created.

At minimum, you must specify one disk or device slice, for root. You can do this with *-m*, *-M* (described below), or in the FMLI-based interface. You must specify an *-m* argument for each file system you want to create on a new BE. For example, if you have three file systems on a source BE (say, */*, */usr*, and */var*) and want these three entities as separate file systems on a new BE, you must specify three *-m* arguments. If you were to specify only one, in our example, */*, */usr*, and */var* would be merged on the new BE into a single file system, under */*.

When using the *-m* option to specify swap partition(s), you can designate device(s) currently used for swap on any BE and any unused devices. Regarding swap assignments, you have the following choices:

- Omit any specification of swap devices, in which case all swap devices associated with the source BE will be used by the new BE.
- Specify one or more swap devices, in which case the new BE will use only the specified swap devices and not automatically share the swap devices associated with the source BE.
- Specify one or more swap devices and use the syntax *-m - : shared : swap*, in which case the new BE will use the specified swap devices and will share swap devices with the source BE.

See EXAMPLES, below.

-M slice_list

List of *-m* options, collected in the file *slice_list*. Specify these arguments in the format specified for *-m*. Comment lines, beginning with a hash mark (*#*), are ignored. The *-M* option is useful where you have a long list of file systems for a BE. Note that you can combine *-m* and *-M* options. For example, you can store swap partitions in *slice_list* and specify */* and */usr* slices with *-m*.

The *-M* option is not supported for BEs based on ZFS file systems.

The *-m* and *-M* options support the listing of multiple slices for a given mount point. In processing these slices, lucreate skips any unavailable slices and selects the first available slice. See EXAMPLES.

-n *BE_name*

The name of the BE to be created. *BE_name* must be unique on a given system.

-o *outfile*

All command output is sent to *outfile*, in addition to where it is sent in your current environment.

-p *zfs_root_pool*

Specifies the ZFS pool in which a new BE will reside.

This option can be omitted if the source and target BEs are within the same pool.

The -p option does not support the splitting and merging of file systems in a target BE that is supported by the -m option.

-s (- | *BE_name*)

Source for the creation of the new BE. This option enables you to use a BE other than the current BE as the source for creation of a new BE.

If you specify a hyphen (-) as an argument to -s, `lucreate` creates the new BE, but does not populate it. This variation of the -s option is intended for the subsequent installation of a flash archive on the unpopulated BE using `luupgrade(1M)`. See `flar(1M)`.

-x *exclude*

Exclude the file or directory *exclude* from the newly created BE. If *exclude* is a directory, `lucreate` excludes that directory and all files beneath that directory, including subdirectories.

This option is not supported when the source BE is on a ZFS file system.

-X

Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.<num>`, where `<num>` is the version number of the DTD file.

-y *include*

Include the file or directory *include* in the newly created BE. If *include* is a directory, `lucreate` includes that directory and all files beneath that directory, including subdirectories.

This option is not supported when the source BE is on a ZFS file system.

-Y *include_list_file*

Use the contents of *include_list_file* to include specific files (including directories) from the newly created BE. *include_list_file* contains a list of files and directories, one per line. If a line item is a file, only that file is included; if a directory, that directory and all files beneath that directory, including subdirectories, are included.

This option is not supported when the source BE is on a ZFS file system.

`-z filter_list_file`

`filter_list_file` contains a list of items, files and directories, one per line. Each item is preceded by either a `+`, indicating the item is to be included in the new BE, or `-`, indicating the item is to be excluded from the new BE.

This option is not supported when the source BE is on a ZFS file system.

Combining File Inclusion and Exclusion Options

When a source BE is on a UFS file system, the `lucreate` command allows you to include or exclude specific files and directories when creating a new BE. You can include files and directories with:

- the `-y include` option
- the `-Y include_list_file` option
- items with a leading `+` in the file used with the `-z filter_list` option

You can exclude files and directories with:

- the `-x exclude` option
- the `-f exclude_list_file` option
- items with a leading `-` in the file used with the `-z filter_list` option

If the parent directory of an excluded item is included with include options (for example, `-y include`), then only the specific file or directory specified by `exclude` is excluded. Conversely, if the parent directory of an included file is specified for exclusion, then only the file `include` is included. For example, if you specify:

```
-x /a -y /a/b
```

all of `/a` except for `/a/b` is excluded. If you specify:

```
-y /a -x /a/b
```

all of `/a` except for `/a/b` is included.

Examples The `lucreate` command produces copious output. In the following examples, this output is not reproduced, except where it is needed for clarity.

EXAMPLE 1 Creating a New Boot Environment for the First Time

The following command sequence creates a new boot environment on a machine on which a BE has never been created. All non-shareable (critical) file systems are mounted under `/`.

```
# lucreate -c first_disk -m /:/dev/dsk/c0t4d0s0:ufs -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

The following command, like the preceding, creates a new boot environment on a machine on which a BE has never been created. However, the following command differs in two respects: the `-c` option is omitted and the `/usr` file system is mounted on its own disk slice, separate from `/`.

EXAMPLE 1 Creating a New Boot Environment for the First Time (Continued)

```
# lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
-n second_disk
lucreate: Please wait while your system configuration is determined.
many lines of output
lucreate: Creation of Boot Environment c0t4d0s0 successful.
```

In the absence of the `-c` option, `lucreate` assigns the name `c0t4d0s0`, the base name of the root device, to the new boot environment.

The same command is entered, with the addition of `-c`:

```
# lucreate -c first_disk -m /:/dev/dsk/c0t4d0s0:ufs \
-m /usr:/dev/dsk/c0t4d0s1:ufs -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

Following creation of a BE, you use [luupgrade\(1M\)](#) to upgrade the OS on the new BE and [luactivate\(1M\)](#) to make that BE the BE you will boot from upon the next reboot of your machine. Note that the swap partition and all shareable file systems for `first_disk` will be available to (shared with) `second_disk`.

```
# luupgrade -u -n second_disk \
-s /net/installmachine/export/solarisX/OS_image
many lines of output
luupgrade: Upgrade of Boot Environment <second_disk> successful.

# luactivate second_disk
```

See [luupgrade\(1M\)](#) and [luactivate\(1M\)](#) for descriptions of those commands.

EXAMPLE 2 Creating a BE Using a Source Other than the Current BE

The following command uses the `-s` option to specify a source BE other than the current BE.

```
# lucreate -s third_disk -m /:/dev/dsk/c0t4d0s0:ufs \
-m /usr:/dev/dsk/c0t4d0s1:ufs -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

EXAMPLE 3 Migrating a BE from a UFS Root File System to a ZFS Root File System

The following command creates a BE of a ZFS root file system from a UFS root file system. The current BE, `c1t0d0s0`, containing a UFS root file system, is identified by the `-c` option. The new BE, `zfsBE`, is identified by the `-n` option. A ZFS storage pool must exist before the `lucreate` operation and must be created with slices rather than whole disks to be upgradeable and bootable.

```
# zpool create rpool mirror c1t0d0s0 c2t0d0s0
# lucreate -c c1t0d0s0 -n zfsBE -p rpool
```

EXAMPLE 3 Migrating a BE from a UFS Root File System to a ZFS Root File System *(Continued)*

Note that if the current BE also resides on the ZFS pool `rpool`, the `-p` option could be omitted. For example:

```
# lucreate -n zfsBE
```

EXAMPLE 4 Creating a BE from a Flash Archive

Performing this task involves use of `lucreate` with the `-s` option and `luupgrade`.

```
# lucreate -s -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
-n second_disk
brief messages
lucreate: Creation of Boot Environment <second_disk> successful.
```

With the `-s` option, the `lucreate` command completes its work within seconds. At this point, you can use `luupgrade` to install the flash archive:

```
# luupgrade -f -n second_disk \
-s /net/installmachine/export/solarisX/OS_image \
-J "archive_location http://example.com/myflash.flar"
```

See [luupgrade\(1M\)](#) for a description of that command.

EXAMPLE 5 Sharing and Adding Swap Partitions

In the simplest case, if you do not specify any swap partitions in an `lucreate` command, all swap partitions in the source BE are shared with the new BE. For example, assume that the current BE uses `/dev/dsk/c0t4d0s7` as its swap partition. You enter the command:

```
# lucreate -n second_disk -m /:/dev/dsk/c0t4d0s0:ufs
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

Upon conclusion of the preceding command, the partition `/dev/dsk/c0t4d0s7` will be used by the BE `second_disk` when that BE is activated and booted.

If you want a new BE to use a different swap partition from that used by the source BE, enter one or more `-m` options to specify a new partition or new partitions. Assume, once again, that the current BE uses `/dev/dsk/c0t4d0s7` as its swap partition. You enter the command:

```
# lucreate -m /:/dev/dsk/c0t0d0s0:ufs -m -:/dev/dsk/c0t4d0s1:swap \
-m -:/dev/dsk/c0t4d0s2:swap -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.
```

Upon activation and boot, the new BE `second_disk` will use `/dev/dsk/c0t4d0s1` and `/dev/dsk/c0t4d0s2` and will not use `/dev/dsk/c0t4d0s7`, the swap partition used by the source BE.

EXAMPLE 5 Sharing and Adding Swap Partitions (Continued)

Assume you want the new BE `second_disk` to share the source BE's swap partition *and* have an additional swap partition. You enter:

```
# lucreate -m /:/dev/dsk/c0t0d0s0:ufs -m -:/dev/dsk/c0t4d0s1:swap \  
-m -:/dev/dsk/c0t4d0s7:swap -n second_disk
```

many lines of output

```
lucreate: Creation of Boot Environment <second_disk> successful.
```

Upon activation and boot, the new BE `second_disk` will use for swapping `/dev/dsk/c0t4d0s7`, shared with the source BE, and, in addition, `/dev/dsk/c0t4d0s1`.

EXAMPLE 6 Using Swap Partitions on Multiple Disks

The command below creates a BE on a second disk and specifies swap partitions on both the first and second disks.

```
# lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m -:/dev/dsk/c0t4d0s1:swap \  
-m -:/dev/dsk/c0t0d0s1:swap -n second_disk
```

many lines of output

```
lucreate: Creation of Boot Environment <second_disk> successful.
```

Following completion of the preceding command, the BE `second_disk` will use both `/dev/dsk/c0t0d0s1` and `/dev/dsk/c0t4d0s1` as swap partitions. These swap assignments take effect only after booting from `second_disk`. If you have a long list of swap partitions, it is useful to use the `-M` option, as shown below.

EXAMPLE 7 Using a Combination of `-m` and `-M` Options

In this example, a list of swap partitions is collected in the file `/etc/lu/swapslices`. The location and name of this file is user-defined. The contents of `/etc/lu/swapslices`:

```
-:/dev/dsk/c0t3d0s2:swap  
-:/dev/dsk/c0t3d0s2:swap  
-:/dev/dsk/c0t4d0s2:swap  
-:/dev/dsk/c0t5d0s2:swap  
-:/dev/dsk/c1t3d0s2:swap  
-:/dev/dsk/c1t4d0s2:swap  
-:/dev/dsk/c1t5d0s2:swap
```

This file is specified in the following command:

```
# lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \  
-M /etc/lu/swapslices -n second_disk
```

many lines of output

```
lucreate: Creation of Boot Environment <second_disk> successful.
```

The BE `second_disk` will swap onto the partitions specified in `/etc/lu/swapslices`.

EXAMPLE 8 Copying Versus Sharing

The following command copies the user file system /home (in addition to the non-shareable file systems / and /usr) from the current BE to the new BE:

```
# lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
-m /home:/dev/dsk/c0t4d0s4:ufs -n second_disk
```

The following command differs from the preceding in that the -m option specifying a destination for /home is omitted. The result of this is that /home will be shared between the current BE and the BE second_disk.

```
# lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
-n second_disk
```

EXAMPLE 9 Using Solaris Volume Manager Volumes

The command shown below does the following:

1. Creates the mirror d10 and establishes this mirror as the receptacle for the root file system.
2. Attaches c0t0d0s0 and c0t1d0s0 to single-slice concatenations d1 and d2, respectively. Note that the specification of these volumes is optional.
3. Attaches the concatenations associated with c0t0d0s0 and c0t1d0s0 to mirror d10.
4. Copies the current BE's root file system to mirror d10, overwriting any d10 contents.

```
# lucreate -m /:/dev/md/dsk/d10:ufs,mirror \
-m /:/dev/md/dsk/d1:attach \
-m /:/dev/dsk/c0t1d0s0,d2:attach -n newBE
```

The following command differs from the preceding only in that concatenations for the physical storage devices are not specified. In this example, lucreate chooses concatenation names from a list of free names and attaches these volumes to the mirror specified in the first -m option.

```
# lucreate -m /:/dev/md/dsk/d10:ufs,mirror \
-m /:/dev/dsk/c0t0d0s0:attach \
-m /:/dev/dsk/c0t1d0s0:attach -n newBE
```

The following command differs from the preceding commands in that one of the physical disks is detached from a mirror before being attached to the mirror you create. Also, the contents of one of the physical disks is preserved. The command does the following:

1. Creates the mirror d10 and establishes this mirror as the receptacle for the root file system.
2. Detaches c0t0d0s0 from the mirror to which it is currently attached.
3. Attaches c0t0d0s0 and c0t1d0s0 to concatenations d1 and d2, respectively. Note that the specification of these concatenations is optional.
4. Preserves the contents of c0t0d0s0, which presumes that c0t0d0s0 contains a valid copy of the current BE's root file system.

EXAMPLE 9 Using Solaris Volume Manager Volumes (Continued)

5. Attaches the concatenations associated with `c0t0d0s0` and `c0t1d0s0` (d1 and d2) to mirror d10.

```
# lucreate -m /:/dev/md/dsk/d10:ufs,mirror \
-m /:/dev/dsk/c0t0d0s0,d1:detach,attach,preserve \
-m /:/dev/dsk/c0t1d0s0,d2:attach -n newBE
```

The following command is a follow-on to the first command in this set of examples. This command detaches a concatenation (containing `c0t0d0s0`) from one mirror (d10, in the first command) and attaches it to another (d20), preserving its contents.

```
# lucreate -m /:/dev/md/dsk/d20:ufs,mirror \
-m /:/dev/dsk/c0t0d0s0:detach,attach,preserve -n nextBE
```

The following command creates two mirrors, placing the `/` file system of the new BE on one mirror and the `/opt` file system on the other.

```
# lucreate -m /:/dev/md/dsk/d10:ufs,mirror \
-m /:/dev/dsk/c0t0d0s0,d1:attach \
-m /:/dev/dsk/c1t0d0s0,d2:attach \
-m /opt:/dev/md/dsk/d11:ufs,mirror \
-m /opt:/dev/dsk/c2t0d0s1,d3:attach \
-m /opt:/dev/dsk/c3t1d0s1,d4:attach -n anotherBE
```

EXAMPLE 10 Invoking FMLI-based Interface

This example is included for historical purposes as the `lu` interface is now obsolete.

The command below, by omitting `-m` or `-M` options, invokes `lu`, the FMLI-based interface for Live Upgrade operations.

```
# lucreate -n second_disk
```

The preceding command uses the current BE as the source for the target BE `second_disk`. In the FMLI interface, you can specify the target disk slices for `second_disk`. The following command is a variation on the preceding:

```
# lucreate -n second_disk -s third_disk
```

In the preceding command, a source for the target BE is specified. As before, the FMLI interface comes up, enabling you to specify target disk slices for the new BE.

EXAMPLE 11 Merging File Systems

The command below merges the `/usr/opt` file system into the `/usr` file system. First, here are the disk slices in the BE `first_disk`, expressed in the format used for arguments to the `-m` option:

EXAMPLE 11 Merging File Systems (Continued)

```

/:/dev/dsk/c0t4d0s0:ufs
/usr:/dev/dsk/c0t4d0s1:ufs
/usr/opt:/dev/dsk/c0t4d0s3:ufs

```

The following command creates a BE `second_disk` and performs the merge operation, merging `/usr/opt` with its parent, `/usr`.

```

# lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
-m /usr/opt:merged:ufs -n second_disk

```

EXAMPLE 12 Splitting a File System

Assume a source BE with `/`, `/usr`, and `/var` all mounted on the same disk slice. The following command creates a BE `second_disk` that has `/`, `/usr`, and `/var` all mounted on different disk slices.

```

# lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /usr:/dev/dsk/c0t4d0s1:ufs \
/var:/dev/dsk/c0t4d0s3:ufs -n second_disk

```

This separation of a file system's (such as root's) components onto different disk slices is referred to as splitting a file system.

EXAMPLE 13 Specifying Alternative Slices

The following command uses multiple `-m` options as alternative disk slices for the new BE `second_disk`.

```

# lucreate -m /:/dev/dsk/c0t4d0s0:ufs -m /:/dev/dsk/c0t4d0s1:ufs \
-m /:/dev/dsk/c0t4d0s5:ufs -n second_disk
many lines of output
lucreate: Creation of Boot Environment <second_disk> successful.

```

The preceding command specifies three possible disk slices, `s0`, `s1`, and `s5` for the `/` file system. `lucreate` selects the first one of these slices that is not being used by another BE. Note that the `-s` option is omitted, meaning that the current BE is the source BE for the creation of the new BE.

EXAMPLE 14 Specifying Separate File Systems for Non-Global Zones

The following command specifies a separate file system belonging to the zone, `zone1`, within the new BE, `second_disk`.

```

# lucreate -n second_disk -m /:/dev/dsk/c0d0s3:ufs \
-m /export/home:/dev/dsk/c0d0s5:ufs:zone1

```

The zone named `zone1`, inside the new BE, has a separate disk slice allocated for its `/export/home` file system.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Files /etc/lutab list of BEs on the system
 /usr/share/lib/xml/dtd/lu_cli.dtd.<num> Live Upgrade DTD (see -X option)

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWlu |

See Also [luactivate\(1M\)](#), [lucancel\(1M\)](#), [lucompare\(1M\)](#), [lucurr\(1M\)](#), [ludelete\(1M\)](#), [ludesc\(1M\)](#), [lufslst\(1M\)](#), [lumake\(1M\)](#), [lumount\(1M\)](#), [lurename\(1M\)](#), [lustatus\(1M\)](#), [luupgrade\(1M\)](#), [zfs\(1M\)](#), [zpool\(1M\)](#), [zoneadm\(1M\)](#), [lutab\(4\)](#), [attributes\(5\)](#), [live_upgrade\(5\)](#), [zones\(5\)](#)

Notes As is true for any Solaris operating system upgrade (and not a feature of Live Upgrade), when splitting a directory into multiple mount points, hard links are not maintained across file systems. For example, if /usr/test1/buglist is hard linked to /usr/test2/buglist, and /usr/test1 and /usr/test2 are split into separate file systems, the link between the files will no longer exist. If lucreate encounters a hard link across file systems, the command issues a warning message and creates a symbolic link to replace the lost hard link.

lucreate cannot prevent you from making invalid configurations with respect to non-shareable file systems. For example, you could enter an lucreate command that would create separate file systems for / and /kernel—an invalid division of /. The resulting BE would be unbootable. When creating file systems for a boot environment, the rules are identical to the rules for creating file systems for the Solaris operating environment.

Mindful of the principle described in the preceding paragraph, consider the following:

- In a source BE, you must have valid vfstab entries for every file system you want to copy to or share with a new BE.
- You cannot create a new BE on a disk with overlapping partitions (that is, partitions that share the same physical disk space). The lucreate command that specifies such a disk might complete, but the resulting BE would be unbootable.

Note – As stated in the description of the -m option, if you use Solaris Volume Manager volumes for boot environments, use lucreate rather than Solaris Volume Manager commands to manipulate these volumes. The Solaris Volume Manager software has no knowledge of boot environments; the lucreate command contains checks that prevent you from inadvertently destroying a boot environment by, for example, overwriting or deleting a Solaris Volume Manager volume.

For versions of the Solaris operating system prior to Solaris 10, Live Upgrade supports the release it is distributed on and up to three marketing releases back. For example, if you obtained Live Upgrade with Solaris 9 (including a Solaris 9 upgrade), that version of Live Upgrade supports Solaris versions 2.6, Solaris 7, and Solaris 8, in addition to Solaris 9. No version of Live Upgrade supports a Solaris version prior to Solaris 2.6.

Starting with version 10 of the Solaris operating system, Live Upgrade supports the release it is distributed on and up to two marketing releases back. For example, if you obtained Live Upgrade with Solaris 10 (including a Solaris 10 upgrade), that version of Live Upgrade supports Solaris 8 and Solaris 9, in addition to Solaris 10. For instructions on adding Live Upgrade packages for the release you want to install, see *Solaris 10 5/08 Installation Guide: Solaris Live Upgrade and Upgrade Planning*.

Correct operation of Solaris Live Upgrade requires that a limited set of patch revisions be installed for a given OS version. Before installing or running Live Upgrade, you are required to install the limited set of patch revisions. Make sure you have the most recently updated patch list by consulting <http://sunsolve.sun.com>. Search for the infodoc 72099 on the SunSolve web site.

Name lucurr – display the name of the active boot environment

Synopsis /usr/sbin/lucurr [-l *error_log*] [-m *mount_point*]
[-o *outfile*] [-X]

Description The lucurr command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See [live_upgrade\(5\)](#) for a description of the Live Upgrade feature.

The lucurr command displays the name of the currently running boot environment (BE). If no BEs are configured on the system, lucurr displays the message "No Boot Environments are defined". Note that lucurr reports only the name of the current BE, not the BE that will be active upon the next reboot. Use [lustatus\(1M\)](#) or [luactivate\(1M\)](#) for this information.

The lucurr command requires root privileges.

Options The lucurr command has the following options:

- l *error_log* Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.
- m *mount_point* Returns the name of the BE that owns *mount_point*, where *mount_point* is the mount point of a BE's root file system. This can be a mount point of the current BE or the mount point of a BE other than the current BE. If the latter, the file system of the BE must have been mounted with [lumount\(1M\)](#) or [mount\(1M\)](#) before entering this option.
- o *outfile* All command output is sent to *outfile*, in addition to where it is sent in your current environment.
- X Enable XML output. Characteristics of XML are defined in DTD, in [/usr/share/lib/xml/dtd/lu_cli.dtd.<num>](#), where [<num>](#) is the version number of the DTD file.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Files /etc/lutab list of BEs on the system
/usr/share/lib/xml/dtd/lu_cli.dtd.<num> Live Upgrade DTD (see -X option)

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWlu |

See Also [luactivate\(1M\)](#), [lucancel\(1M\)](#), [lucompare\(1M\)](#), [lucreate\(1M\)](#), [ludelete\(1M\)](#), [ludesc\(1M\)](#), [lufslis\(1M\)](#), [lumake\(1M\)](#), [lumount\(1M\)](#), [lurename\(1M\)](#), [lustatus\(1M\)](#), [luupgrade\(1M\)](#), [lutab\(4\)](#), [attributes\(5\)](#), [live_upgrade\(5\)](#)

Name ludelete – delete a boot environment

Synopsis /usr/sbin/ludelete [-l *error_log*] [-o *outfile*] *BE_name* [-X]

Description The ludelete command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See [live_upgrade\(5\)](#) for a description of the Live Upgrade feature.

The ludelete command deletes all records associated with a boot environment (BE) on all defined complete BEs. A complete BE is one that is not participating in an [lucreate\(1M\)](#), [luupgrade\(1M\)](#), or [lucompare\(1M\)](#) operation. Use [lustatus\(1M\)](#) to determine a BE's status. You can delete neither the current BE, nor the BE that will become current upon the next reboot.

ludelete does not alter any files on the BE being deleted.

The ludelete command requires root privileges.

Options The ludelete command has the following options:

- l *error_log* Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.
- o *outfile* All command output is sent to *outfile*, in addition to where it is sent in your current environment.
- X Enable XML output. Characteristics of XML are defined in DTD, in */usr/share/lib/xml/dtd/lu_cli.dtd.<num>*, where *<num>* is the version number of the DTD file.

Operands *BE_name* Name of the BE to be deleted.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Files /etc/lutab list of BEs on the system
 /usr/share/lib/xml/dtd/lu_cli.dtd.<num> Live Upgrade DTD (see -X option)

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWlu |

See Also [lu\(1M\)](#), [luactivate\(1M\)](#), [lucancel\(1M\)](#), [lucompare\(1M\)](#), [lucreate\(1M\)](#), [lucurr\(1M\)](#), [ludesc\(1M\)](#), [lufslist\(1M\)](#), [lumake\(1M\)](#), [lumount\(1M\)](#), [lurename\(1M\)](#), [lustatus\(1M\)](#), [luupgrade\(1M\)](#), [lutab\(4\)](#), [attributes\(5\)](#), [live_upgrade\(5\)](#)

Name ludesc – display or set boot environment description

Synopsis /usr/sbin/ludesc {-A *BE_description*} | {-f *filename* | -}
 [-l *error_log*] [-o *outfile*] [-X]
 /usr/sbin/ludesc -n *BE_name* [-f *filename* | -]
 [-l *error_log*] [-o *outfile*] [-X]
 /usr/sbin/ludesc -n *BE_name* [-l *error_log*] [-o *outfile*]
 [-X] *BE_description*

Description The ludesc command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See [live_upgrade\(5\)](#) for a description of the Live Upgrade feature.

The ludesc command allows you to manipulate boot environment (BE) descriptions. A BE description is an optional attribute of a BE. It can be text or binary data. For example, it might be a string such as “S9 beta test BE” or it might be a file that contains 8-bit multi-byte characters. The ludesc command in general and the options to manipulate binary-format descriptions in particular are suitable for use in programs.

You create a BE description using ludesc or [lucreate\(1M\)](#). Only ludesc allows you to change a BE description or add a description following BE creation.

While a BE description is associated with a BE name, it is not interchangeable with that name. No Live Upgrade command allows you to specify a BE description instead of a BE name when performing an operation on a BE.

A shell might restrict what you enter for a BE description (in both ludesc and [lucreate\(1M\)](#)). In entering a description, use the following guidelines:

- Always enclose a description in single quotes ('), unless the description includes a single quote.
- If your description includes a single quote, enclose the description in double quotes (“). You then must use an escape sequence (usually a backslash [\]) to enter a character that is special to the shell. See [sh\(1\)](#) for a list of special characters and a description of the escape sequence mechanism.

Descriptions that include many special characters might be more conveniently inserted in a file (-f option) than entered on a command line (-A option).

When ludesc outputs a BE description, it does so exactly as the description was entered. Because of this feature, a description that is a text string does not have a concluding newline, which means the system prompt immediately follows the last character of the description.

The ludesc command requires root privileges.

Options The `ludesc` command has the following options:

- `-A BE_description` Displays the BE name associated with *BE_description*.
- `-f {filename | -}` Specify the BE description contained in *filename* or read from `stdin`. When used without `-n`, displays the BE name associated with the specified BE description. Used with `-n`, changes the description for the specified BE to the description specified with `-f`.
- `-l error_log` Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.
- `-n BE_name` With no other arguments, displays the BE description for the specified BE. With the `-f` option or the *BE_description* operand, changes the description for the specified BE to that specified with `-f` or *BE_description*.
- `-o outfile` All command output is sent to *outfile*, in addition to where it is sent in your current environment.
- `-X` Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.<num>`, where `<num>` is the version number of the DTD file.

Operands *BE_description* Used only with the `-n` option. *BE_description* replaces the current BE description for the specified BE.

Examples The following are examples of the use of `ludesc`.

EXAMPLE 1 Basic Use

The first command, below, assigns a description to a BE. The second command returns the name of the BE associated with the specified description. The last command returns the description associated with a specified BE.

```
# ludesc -n first_disk 'Test disk'
Setting description for boot environment <first_disk>.
Propagating the change of BE description to all BEs.

# ludesc -A 'Test disk'
first_disk
#

# ludesc -n first_disk
Test disk#
```

As seen above and noted in the DESCRIPTION, `ludesc` does not append a newline to the display of BE description that is a text string.

EXAMPLE 2 Using Binary Files

The following commands are analogs of the preceding examples, substituting a binary file—here, a file containing a description in Russian, using the Cyrillic alphabet—for a text string. In the third command, note the use of a file to capture output. Sending output of a binary file to the console can produce erratic results.

```
# ludesc -n first_disk -f arrayBE.ru
Setting description for boot environment <first_disk>.
Propagating the change of BE description to all BEs.

# ludesc -f arrayBE.ru
first_disk

# ludesc -n first_disk > /tmp/arrayBE.out
```

Exit Status The following exit values are returned:

0 Successful completion.
>0 An error occurred.

Files /etc/lutab list of BEs on the system
/usr/share/lib/xml/dtd/lu_cli.dtd.<num> Live Upgrade DTD (see -X option)

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWlu |

See Also [luactivate\(1M\)](#), [lucancel\(1M\)](#), [lucompare\(1M\)](#), [lucreate\(1M\)](#), [ludelete\(1M\)](#), [lufsls\(1M\)](#), [lumake\(1M\)](#), [lumount\(1M\)](#), [lurename\(1M\)](#), [lustatus\(1M\)](#), [luupgrade\(1M\)](#), [lutab\(4\)](#), [attributes\(5\)](#), [live_upgrade\(5\)](#)

Name lufslst – list configuration of a boot environment

Synopsis /usr/sbin/lufslst [-l *error_log*] [-o *outfile*] *BE_name* [-X]

Description The `lufslst` command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `lufslst` command lists the configuration of a boot environment (BE). The output contains the disk slice (file system), file system type, and file system size for each BE mount point. The output also notes any separate file systems that belong to a non-global zone inside the BE being displayed.

The following is an example of `lufslst` output, which shows a separate filesystem for the zone, `zone1`, within the BE being displayed.

```
# lufslst BE_name
Filesystem                fstype      size(Mb) Mounted on
-----
/dev/dsk/c0t0d0s1         swap        512.11  -
/dev/dsk/c0t4d0s3         ufs         3738.29  /
/dev/dsk/c0t4d0s4         ufs         510.24  /opt

                zone zone1 within boot environment BE_name
/dev/dsk/c0t4d0s7         ufs         7000.48  /export
```

File system type can be `ufs`, `swap`, or `vxfs`, for a Veritas file system. Under the `Filesystem` heading can be a disk slice or a logical device, such as a disk metadvice used by volume management software.

The `lufslst` command requires root privileges or the Primary Administrator role.

Options The `lufslst` command has the following options:

- l *error_log* Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.
- o *outfile* All command output is sent to *outfile*, in addition to where it is sent in your current environment.
- X Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.<num>`, where `<num>` is the version number of the DTD file.

Operands *BE_name* Name of the BE for which file systems are to be reported. You cannot specify a BE that is involved in another Live Upgrade operation.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Files /etc/lutab list of BEs on the system
 /usr/share/lib/xml/dtd/lu_cli.dtd.<num> Live Upgrade DTD (see -X option)

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWlu |

See Also [luactivate\(1M\)](#), [lucancel\(1M\)](#), [lucompare\(1M\)](#), [lucreate\(1M\)](#), [lucurr\(1M\)](#), [ludelete\(1M\)](#), [ludesc\(1M\)](#), [lumake\(1M\)](#), [lumount\(1M\)](#), [lurename\(1M\)](#), [lustatus\(1M\)](#), [luupgrade\(1M\)](#), [lutab\(4\)](#), [attributes\(5\)](#), [live_upgrade\(5\)](#), [zones\(5\)](#)

Name lumake – populate a boot environment

Synopsis /usr/sbin/lumake [-l *error_log*] [-o *outfile*] [-s *source_BE*] -n *BE_name*
[-X]

/usr/sbin/lumake [-l *error_log*] -t *time* [-o *outfile*]
[-s *source_BE*] -n *BE_name* [-m *email_address*] [-X]

Description The lumake command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See [live_upgrade\(5\)](#) for a description of the Live Upgrade feature.

The lumake command populates (that is, copies files to) the file systems of a specified boot environment (BE) by copying files from the corresponding file systems of the active or a source (-s) BE. Any existing data on the target BE are destroyed. All file systems on the target BE are re-created.

The target BE must already exist. Use [lucreate\(1M\)](#) to create a new BE.

The lumake command requires root privileges.

Options The lumake command has the following options:

- n *BE_name* Name of the BE to be populated.
- s *source_BE* The optional name of a source BE. If you omit this option, lumake uses the current BE as the source. A BE must have the status "complete" before you can copy from it. Use [lustatus\(1M\)](#) to determine a BE's status.
- l *error_log* Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.
- o *outfile* All command output is sent to *outfile*, in addition to where it is sent in your current environment.
- t *time* Setup a batch job to populate the specified BE at a specified time. The time is given in the format specified by the [at\(1\)](#) man page. At any time, you can have only one Live Upgrade operation scheduled. You can use [lucancel\(1M\)](#) to cancel a scheduled lumake operation.
- m *email_address* Allows you to email lumake output to a specified address upon command completion. There is no checking of *email_address*. Use this option in conjunction with -t, to obtain notification of batch command completion. If you use -m with options other than -t, no email is sent.
- X Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.<num>`, where `<num>` is the version number of the DTD file.

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Files /etc/lutab list of BEs on the system
 /usr/share/lib/xml/dtd/lu_cli.dtd.<num> Live Upgrade DTD (see -X option)

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWlu |

See Also [luactivate\(1M\)](#), [lucancel\(1M\)](#), [lucompare\(1M\)](#), [lucreate\(1M\)](#), [lucurr\(1M\)](#), [ludelete\(1M\)](#), [ludesc\(1M\)](#), [lufsls\(1M\)](#), [lumount\(1M\)](#), [lurename\(1M\)](#), [lustatus\(1M\)](#), [luupgrade\(1M\)](#), [lutab\(4\)](#), [attributes\(5\)](#), [live_upgrade\(5\)](#)

Name lumount, luumount – mount or unmount all file systems in a boot environment

Synopsis /usr/sbin/lumount [-l *error_log*] [-o *outfile*] *BE_name*
 [*mount_point*] [-X]
 /usr/sbin/luumount
 /usr/sbin/luumount [-f]
 { [-n] *BE_name* | [-m] *mount_point* | *block_device* }
 [-l *error_log*] [-o *outfile*] [-X]

Description The lumount and luumount commands are part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See live_upgrade(5) for a description of the Live Upgrade feature.

The lumount and luumount commands enable you to mount or unmount all of the file systems in a boot environment (BE). This allows you to inspect or modify the files in a BE while that BE is not active. By default, lumount mounts the file systems on a mount point of the form / .alt .*BE_name*, where *BE_name* is the name of the BE whose file systems are being mounted. See NOTES.

lumount and luumount also mount or unmount all installed non-global zones within the BE. For each running, mounted, or ready non-global zone in the current BE, lumount mounts all file systems in the mounted BE that belong to the non-global zone, at the specified mount point in the non-global zone. This provides the non-global zone administrator access to the corresponding file systems that exist in the mounted BE.

When invoked with no arguments, lumount returns the name(s) of the mounted BEs on a system.

The lumount and luumount commands require root privileges or the Primary Administrator role.

Options The lumount and luumount commands have the following options:

- f For luumount only, forcibly unmount a BE's file systems after attempting (and failing) an unforced unmount. This option is analogous to the [mount\(1M\) -f](#) option.
- l *error_log* Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.
- m *mount_point* luumount unmounts the file systems of the BE that owns *mount_point*. See description of *mount_point* under OPERANDS, below. The use of -m is optional when specifying a mount point for luumount.
- n *BE_name* Name of the BE whose file systems will be unmounted. See description of *BE_name* under OPERANDS, below. The use of -n is optional when specifying a BE name for luumount.

- o *outfile* All command output is sent to *outfile*, in addition to where it is sent in your current environment.
- X Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.<num>`, where *<num>* is the version number of the DTD file.

For `lumount`, if you supply an argument and specify neither `-m` nor `-n`, the command determines whether your argument is a BE name, a mount point, or a block device. If it is one of these three and the argument is associated with a BE that has mounted file systems, `lumount` unmounts the file systems of that BE. Otherwise, `lumount` returns an error.

| | | |
|-----------------|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Operands | <i>BE_name</i> | Name of the BE whose file systems will be mounted or unmounted. This is a BE on the current system other than the active BE. Note that, for successful completion of an <code>lumount</code> or <code>luumount</code> command, the status of a BE must be complete, as reported by <code>lustatus(1M)</code> . Also, none of the BE's disk slices can be mounted (through use of <code>mount(1M)</code>). |
| | <i>mount_point</i> | For <code>lumount</code> , a mount point to use instead of the default <code>/.alt.BE_name</code> . If <i>mount_point</i> does not exist, <code>lumount</code> creates it. For <code>luumount</code> , the BE associated with <i>mount_point</i> will have its file systems unmounted. Note that default mount points are automatically deleted upon unmounting with <code>lumount</code> . Mount points that you specify are not deleted. |
| | <i>block_device</i> | For <code>luumount</code> only, <i>block_device</i> is the root slice of a BE, such as <code>/dev/dsk/c0t4d0s0</code> . <code>luumount</code> unmounts the file systems of the BE associated with <i>block_device</i> . |

Examples **EXAMPLE 1** Specifying a Mount Point

The following command creates the mount point `/test` and mounts the file systems of the BE `second_disk` on `/test`.

```
# lumount second_disk /test
/test
```

You can then `cd` to `/test` to view the file systems of `second_disk`. If you did not specify `/test` as a mount point, `lumount` would create a default mount point named `/.alt.second_disk`.

If you have installed non-global zones on your system, this command will also mount all non-global zones in `second_disk` inside their corresponding non-global zones in the currently running system at the mount point `/test` (or `/.alt.second_disk` if a mount point was not specified).

EXAMPLE 2 Unmounting File Systems

The following command unmounts the file systems of the BE `second_disk`. In this example, we `cd` to `/` to ensure we are not in any of the file systems in `second_disk`.

EXAMPLE 2 Unmounting File Systems (Continued)

```
# cd /
# luumount second_disk
#
```

If `/dev/dsk/c0t4d0s0` were the root slice for `second_disk`, you could enter the following command to match the effect of the preceding command.

```
# cd /
# luumount /dev/dsk/c0t4d0s0
#
```

Exit Status The following exit values are returned:

```
0      Successful completion.
>0    An error occurred.
```

Files `/etc/lutab` list of BEs on the system
`/usr/share/lib/xml/dtd/lu_cli.dtd.<num>` Live Upgrade DTD (see `-X` option)

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWlu |

See Also [luactivate\(1M\)](#), [lucancel\(1M\)](#), [lucompare\(1M\)](#), [lucreate\(1M\)](#), [lucurr\(1M\)](#), [ludelete\(1M\)](#), [ludesc\(1M\)](#), [lufslst\(1M\)](#), [lumake\(1M\)](#), [lurename\(1M\)](#), [lustatus\(1M\)](#), [luupgrade\(1M\)](#), [lutab\(4\)](#), [attributes\(5\)](#), [live_upgrade\(5\)](#), [zones\(5\)](#)

Notes If a BE name contains slashes (`/`), `lumount` replaces those slashes with colons in a default mount point name. For example:

```
# lumount 'first/disk'
/.alt.first:disk
```

Name lurename – change the name of a boot environment

Synopsis /usr/sbin/lurename -e *BE_name* -n *new_name* [-l *error_log*]
[-o *outfile*] [-X]

Description The lurename command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See [live_upgrade\(5\)](#) for a description of the Live Upgrade feature.

The lurename command renames the boot environment (BE) *BE_name* to *new_name*.

The string *new_name* must not exceed 30 characters in length and must consist only of alphanumeric characters and other ASCII characters that are not special to the Unix shell. See the “Quoting” section of [sh\(1\)](#). The BE name can contain only single-byte, 8-bit characters. It cannot contain whitespace characters. Also, *new_name* must be unique on the system.

A BE must have the status “complete” before you rename it. Use [lustatus\(1M\)](#) to determine a BE's status. Also, you cannot rename a BE that has file systems mounted with [lumount\(1M\)](#) or [mount\(1M\)](#).

Renaming a BE is often useful when you upgrade the BE from one Solaris release to another. For example, following an operating system upgrade, you might rename the BE `solaris7` to `solaris8`.

The lurename command requires root privileges.

Options The lurename command has the options listed below.

- e *BE_name* Name of the BE whose name you want to change.
- l *error_log* Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.
- n *new_name* New name of the BE. *new_name* must be unique on a given system.
- o *outfile* All command output is sent to *outfile*, in addition to where it is sent in your current environment.
- X Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.<num>`, where `<num>` is the version number of the DTD file.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Files /etc/lutab list of BEs on the system
/usr/share/lib/xml/dtd/lu_cli.dtd.<num> Live Upgrade DTD (see -X option)

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWlu |

See Also [luactivate\(1M\)](#), [lucancel\(1M\)](#), [lucompare\(1M\)](#), [lucreate\(1M\)](#), [lucurr\(1M\)](#), [ludelete\(1M\)](#), [ludesc\(1M\)](#), [lufsls\(1M\)](#), [lumake\(1M\)](#), [lumount\(1M\)](#), [lustatus\(1M\)](#), [luupgrade\(1M\)](#), [lutab\(4\)](#), [attributes\(5\)](#), [live_upgrade\(5\)](#)

Name lustatus – display status of boot environments

Synopsis /usr/sbin/lustatus [-l *error_log*] [-o *outfile*] [*BE_name*]
[-X]

Description The `lustatus` command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See `live_upgrade(5)` for a description of the Live Upgrade feature.

The `lustatus` command displays the status information of the boot environment (BE) *BE_name*. If no BE is specified, the status information for all BEs on the system is displayed.

The headings in the `lustatus` information display are described as follows:

| | |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Boot Environment Name | Name of the BE. |
| Is Complete | Indicates whether a BE is able to be booted. Any current activity or failure in an <code>lucreate(1M)</code> or <code>luupgrade(1M)</code> operation causes a BE to be incomplete. For example, if there is a copy operation proceeding on or scheduled for a BE, that BE is considered incomplete. |
| Active Now | Indicates whether the BE is currently active. The “active” BE is the one currently booted. |
| Active On Reboot | Indicates whether the BE becomes active upon next reboot of the system. |
| Can Delete | Indicates that no copy, compare, or upgrade operations are being performed on a BE. Also, none of that BE's file systems are currently mounted. With all of these conditions in place, the BE can be deleted. |
| Copy Status | Indicates whether the creation or repopulation of a BE is scheduled or active (that is, in progress). A status of ACTIVE, COMPARING (from <code>lucompare(1M)</code>), UPGRADING, or SCHEDULED prevents you performing Live Upgrade copy, rename, or upgrade operations. |

The following is an example `lustatus` display:

| Boot Environment Name | Is Complete | Active Now | Active On Reboot | Can Delete | Copy Status |
|-----------------------|-------------|------------|------------------|------------|-------------|
| disk_a_S7 | yes | yes | yes | no | - |
| disk_b_S7db | yes | no | no | no | UPGRADING |
| disk_b_S8 | no | no | no | no | - |
| S9testbed | yes | no | no | yes | - |

Note that you could not perform copy, rename, or upgrade operations on `disk_b_S8`, because it is not complete, nor on `disk_b_S7db`, because a Live Upgrade operation is pending.

The `lustatus` command requires root privileges.

Options The `lustatus` command has the following options:

- `-l error_log` Error and status messages are sent to `error_log`, in addition to where they are sent in your current environment.
- `-o outfile` All command output is sent to `outfile`, in addition to where it is sent in your current environment.
- `-X` Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.<num>`, where `<num>` is the version number of the DTD file.

Operands `BE_name` Name of the BE for which to obtain status. If `BE_name` is omitted, `lustatus` displays status for all BEs in the system.

Exit Status The following exit values are returned:

- `0` Successful completion.
- `>0` An error occurred.

Files `/etc/lutab` list of BEs on the system
`/usr/share/lib/xml/dtd/lu_cli.dtd.<num>` Live Upgrade DTD (see `-X` option)

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWlu |

See Also [luactivate\(1M\)](#), [lucancel\(1M\)](#), [lucompare\(1M\)](#), [lucreate\(1M\)](#), [lucurr\(1M\)](#), [ludesc\(1M\)](#), [ludelete\(1M\)](#), [lufsls\(1M\)](#), [lumake\(1M\)](#), [lumount\(1M\)](#), [lurename\(1M\)](#), [luupgrade\(1M\)](#), [lutab\(4\)](#), [attributes\(5\)](#), [live_upgrade\(5\)](#)

Name luupgrade – installs, upgrades, and performs other functions on software on a boot environment

Synopsis /usr/sbin/luupgrade [-iIufpPtTcC] [options]

Description The luupgrade command is part of a suite of commands that make up the Live Upgrade feature of the Solaris operating environment. See [live_upgrade\(5\)](#) for a description of the Live Upgrade feature.

The luupgrade command enables you to install software on a specified boot environment (BE). Specifically, luupgrade performs the following functions:

- Upgrades an operating system image on a BE (-u option). The source for the image can be any valid Solaris installation medium, including a Solaris Flash archive.
- Extract a Solaris Flash archive onto a BE (-f option). (See [flar\(1M\)](#).)
- Add a package to (-p) or remove a package from (-P) a BE.
- Add a patch to (-t) or remove a patch from (-T) a BE.
- Check (-C) or obtain information about (-I) packages.
- Check an operating system installation medium (-c).

Before using luupgrade, you must have created a BE, using the [lucreate\(1M\)](#) command. You can upgrade only BEs other than the current BE.

The functions described in the preceding list each has its own set of options, which are described separately for each function.

Note that, for successful completion of an luupgrade operation, the status of a BE must be complete, as reported by [lustatus\(1M\)](#). Also, the BE must not have any mounted disk slices, mounted either with [lumount\(1M\)](#) or [mount\(1M\)](#).

luupgrade allows you to install an operating system image from a different marketing release of the Solaris operating system from the release running on the machine from which you invoke luupgrade. This feature has the following conditions:

- You can install Live Upgrade packages (SUNWluu, SUNWlur, and SUNWlucfg) from a given release of the Solaris operating system on a machine running a previous release. You can install these packages on a machine running a version of Solaris that is up to three releases prior to the release of the Live Upgrade packages. Live Upgrade is not supported on Solaris releases prior to Solaris 2.6. Thus, you can, for example, install Solaris 2.9 packages on Solaris 2.8, 2.7, and 2.6 machines.
- You can upgrade to a release of the Solaris operating system that is the same as the release of the Live Upgrade packages installed on a machine. This feature allows you to upgrade to Solaris upgrade releases within a marketing release. For example, if have the Solaris 9 FCS Live Upgrade packages installed on a machine, you can use luupgrade to upgrade a BE to the Solaris 9 update 3 release of the Solaris operating system.

See the *Solaris Installation Guide* for instructions on installing Live Upgrade packages.

The `luupgrade` command requires root privileges.

Options that Apply to All Uses

The following options are available for all uses of `luupgrade`:

- l *error_log* Error and status messages are sent to *error_log*, in addition to where they are sent in your current environment.
- o *outfile* All command output is sent to *outfile*, in addition to where it is sent in your current environment.
- N Dry-run mode. Enables you to determine whether your command arguments are correctly formed. Does not apply to the -c (check medium) function.
- X Enable XML output. Characteristics of XML are defined in DTD, in `/usr/share/lib/xml/dtd/lu_cli.dtd.<num>`, where `<num>` is the version number of the DTD file.

Upgrading an Operating System Image

The `luupgrade` command uses -u to upgrade an operating system image. The syntax is as follows:

```
luupgrade -u -n BE_name [ -l error_log ] [ -o outfile ] [-N]
-s os_image_path [ -j profile_path [-D] ]
```

The first option, -u, indicates the function to perform—to install an OS image. The remaining options for this use of `luupgrade`, shown above, are described as follows:

- n *BE_name* Name of the BE to receive an OS upgrade.
- s *os_image_path* Path name of a directory containing an OS image. This can be a directory on an installation medium such as a DVD or CD, or can be an NFS or UFS directory.
- j *profile_path* Path to a JumpStart profile. See the section "JumpStart Profile Keywords," below, for a list of valid keywords for use in a profile invoked by `luupgrade`. See [pfinstall\(1M\)](#) and the Solaris installation documentation for information on the JumpStart software.
- D Tests the profile values provided with -j against the disk configuration of the specified BE. The upgrade is not performed. The effect of this option is a dry run to test your profile. `luupgrade` creates log files, specified in its output, which allow you to examine the command's results.

Before upgrading a boot environment, do the following:

- Run `analyze_patches`.
- Install Live Upgrade packages for the operating system version to which you are upgrading.

The `analyze_patches` command is available in the `/Misc` directory on the Solaris software DVD (formerly the Solaris installation CD). This command determines which patches would be removed as a result of the upgrade. Then, following the upgrade, you can reinstall the list of patches provided by `analyze_patches`.

The Live Upgrade packages, `SUNWluu`, `SUNWlur`, and `SUNWlucfg`, are available on the Solaris software DVD (or CD, depending on the Solaris version). Before running `luupgrade` with the `-u` option, ensure that you have installed the packages from the version of Solaris to which you want to upgrade.

Note that if you are upgrading from a medium with multiple components, such as from multiple DVDs, use `luupgrade` with the `-i` option, as described in the section below, to install software from the second and any following media.

Continuing an Upgrade
by Running an Installer
Program

The `luupgrade` command uses `-i` to run an installer program. As discussed below, its primary use is following an invocation of `luupgrade` with the `-u` option. The syntax for `-i` is as follows:

```
luupgrade -i -n BE_name [ -l error_log ] [ -o outfile ] [ -N ]
-s installation_medium [ -O "installer_options" ]
```

The first option, `-i`, indicates the function to perform—to run an installer program on the installation medium specified with `-s`. The remaining options for this use of `luupgrade`, shown above, are described as follows:

- `-n BE_name` Name of the BE on which software is to be installed.
- `-O "installer_options"` Options passed directly to the Solaris installer program. See [installer\(1M\)](#) for descriptions of the installer options.
- `-s installation_medium` Path name of an installation medium. This can be a DVD, CD, or an NFS or UFS directory.

With the `-i` option, `luupgrade` looks for an installation program on the specified medium and runs that program.

The primary use of the `-i` option is to upgrade an operating system image from a multiple-component medium, such as multiple DVDs. In this use, an `luupgrade` command with the `-i` option follows an invocation of `luupgrade` with `-u`. See `EXAMPLES`. The `-u` option is described above.

Installing from a Solaris
Flash Archive

The `luupgrade` command uses `-f` to install an operating system from a Solaris Flash archive. Note that installing an archive overwrites all files on the target BE. The syntax is as follows:

```
luupgrade -f -n BE_name [ -l error_log ] [ -o outfile ] [ -N ] [-D]
-s os_image_path ( -a archive | -j profile_path | -J "profile" )
```

The first option, `-f`, indicates the function to perform—to install an OS from a Solaris Flash archive. The remaining options for this use of `luupgrade`, shown above, are described as follows:

- `-n BE_name` Name of the BE to receive an OS installation.
- `-D` Tests the profile values provided with `-j` or `-J` against the disk configuration of the specified BE. The upgrade is not performed. The effect of this option is a dry run to test your profile. `luupgrade` creates log files, specified in its output, which allow you to examine the command's results.
- `-s os_image_path` Path name of a directory containing an OS image. This can be a directory on an installation medium, such as a DVD or CD, or can be an NFS or UFS directory.
- `-a archive` Path to the Solaris Flash archive when the archive is available on the local file system. You must specify one of `-a`, `-j`, or `-J`.
- `-j profile_path` Path to a JumpStart profile that is configured for a Solaris Flash installation. See the section "JumpStart Profile Keywords," below, for a list of valid keywords for use in a profile invoked by `luupgrade`. See [pfinstall\(1M\)](#) and the Solaris installation documentation for information on the JumpStart software. You must specify one of `-a`, `-j`, or `-J`.
- `-J "profile"` Entry from a JumpStart profile that is configured for a Solaris Flash installation. The only valid keyword for this option is `archive_location`. See [pfinstall\(1M\)](#) and the Solaris installation documentation for information on the JumpStart software. You must specify one of `-a`, `-j`, or `-J`.

Note that the version of the OS image specified with `-s` must be identical to the version of the OS contained in the Solaris Flash archive specified with the `-a`, `-j`, or `-J` options.

Adding or Removing Packages The `luupgrade` command uses `-p` to add a package and `-P` to remove a package. The syntax is as follows:

For adding packages:

```
luupgrade -p -n BE_name [ -l error_log ] [ -o outfile ] [ -N ]
-s packages_path [ -O "pkgadd_options" ] [ -a admin ]
[ pkginst [ pkginst... ] ]
```

For removing packages:

```
luupgrade -P -n BE_name [ -l error_log ] [ -o outfile ] [ -N ]
[ -O "pkgrm_options" ] [ pkginst [ pkginst... ] ]
```

The first option, `-p`, to add packages, or `-P` to remove packages, indicates the function to perform. The remaining options for this use of `luupgrade`, shown above, are described as follows:

| | |
|-----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-n BE_name</code> | Name of the BE to which packages will be added or from which packages will be removed. |
| <code>-s packages_path</code> | (For adding packages only.) Path name of a directory containing packages to add. You can substitute <code>-d</code> for <code>-s</code> . The <code>-d</code> support is for pkgadd(1M) compatibility. |
| <code>-d packages_path</code> | Identical to <code>-s</code> . Use of <code>-s</code> is recommended. |
| <code>-O "pkgadd_options" or "pkgrm_options"</code> | Options passed directly to <code>pkgadd</code> (for <code>-p</code>) or <code>pkgrm</code> (for <code>-P</code>). See pkgadd(1M) and pkgrm(1M) for descriptions of the options for those commands. |
| <code>-a admin</code> | (For adding packages only.) Path to an admin file. Identical to the <code>pkgadd -a</code> option. Use of the <code>-a</code> option here is identical to <code>-O "-a admin"</code> |
| <code>pkginst [pkginst...]</code> | Zero or more packages to add or remove. For adding packages, the default is to add all of the packages specified with the <code>-s</code> option, above. Separate multiple package names with spaces. |

It is critically important that any packages you add be compliant with the SVR4 Advanced Packaging Guidelines. See WARNINGS, below.

Adding or Removing Patches The `luupgrade` command uses `-t` to add a patch and `-T` to remove a patch. The syntax is as follows:

For adding patches:

```
luupgrade -t -n BE_name [ -l error_log ][ -o outfile ] [ -N ]
-s patch_path [ -O "patchadd_options" ] [ patch_name [ patch_name... ] ]
```

For removing patches:

```
luupgrade -T -n BE_name [ -l error_log ][ -o outfile ] [ -N ]
[ -O "patchrm_options" ] [ patch_name [ patch_name... ] ]
```

The first option, `-t`, to add patches, or `-T` to remove patches, indicates the function to perform. The remaining options for this use of `luupgrade`, shown above, are described as follows:

| | |
|-----------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-n <i>BE_name</i></code> | Name of the BE to which patches will be added or from which patches will be removed. |
| <code>-s <i>patch_path</i></code> | (For adding patches only.) Path name of a directory containing patches to add or path name of a <code>patch_order</code> file. |
| <code>-O "<i>patchadd_options</i>" or "<i>patchrm_options</i>"</code> | Options passed directly to <code>patchadd</code> (for <code>-p</code>) or <code>patchrm</code> (for <code>-P</code>). |
| <code><i>patch_name</i> [<i>patch_name</i>...]</code> | Zero or more patches to add or remove. For adding patches, the default is to add all of the patches specified with the <code>-s</code> option, above. Separate multiple patch names with spaces. |

It is critically important that any patches you add be compliant with the SVR4 Advanced Packaging Guidelines. See WARNINGS, below.

Checking or Returning Information on Packages

Use the `-C` to perform a [pkgchk\(1M\)](#) on all or the specified packages on a BE. Use the `-I` option to perform a [pkginfo\(1\)](#).

For performing a `pkgchk`:

```
luupgrade -C -n BE_name [ -l error_log ] [ -o outfile ] [ -N ]
[ -O "pkgchk_options" ] [ pkginst [ pkginst... ] ]
```

For performing a `pkginfo`:

```
luupgrade -I -n BE_name [ -l error_log ] [ -o outfile ] [ -N ]
[ -O "pkginfo_options" ] [ pkginst [ pkginst... ] ]
```

The first option, `-C`, for `pkgchk`, or `-I`, for `pkginfo`, indicates the function to perform. The remaining options for this use of `luupgrade`, shown above, are described as follows:

| | |
|---------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-n <i>BE_name</i></code> | Name of the BE on which packages will be checked or on whose packages information will be returned. |
| <code>-O "<i>pkgchk_options</i>" or "<i>pkginfo_options</i>"</code> | Options passed directly to <code>pkgchk</code> (for <code>-C</code>) or <code>pkginfo</code> (for <code>-I</code>). See pkgchk(1M) or pkginfo(1) for a description of these options. |
| <code><i>pkginst</i> [<i>pkginst</i>...]</code> | Zero or more packages to check or for which to have information returned. If you omit package names, <code>luupgrade</code> returns information on all of the packages on the BE. Separate multiple package names with spaces. |

Checking an OS Installation Medium With the `-c` option, `luupgrade` allows you to check that a local or remote medium, such as a DVD or CD, is a valid installation medium. The `-c` option returns useful information about the specified medium. The syntax for this use of `luupgrade` is as follows:

```
luupgrade -c [ -l error_log ] [ -o outfile ] -s path_to_medium
```

The first option, `-c`, indicates the function to perform—to check on an installation medium. The `-s` option, shown above, is described as follows:

`-s path_to_medium` Path name to an installation medium such as a DVD or CD.

JumpStart Profile Keywords This section specifies the Solaris JumpStart keywords that can be used in a profile with `luupgrade`, using the `-j` option in conjunction with the `-u` (upgrade) or `-f` (flash) options. For `-u`, there are no required keywords. For `-f`, you must specify a value for `install_type`: `flash_install` for a full flash archive or `flash_update` for a differential flash archive. Also for the `-f` option with the `-j` option, you must specify the `-a` (archive location) option or specify the `archive_location` keyword in your profile.

The `archive_location` keyword is the only valid argument for the `-J` option.

The following optional keywords are sometimes used in profiles used with the `-u` and `-f` options:

| | |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>cluster</code> | Designates the software group to add to the system. |
| <code>geo</code> | Designates the regional locale or locales that you want to install on or add to a system. See the <i>Solaris Installation Guide</i> for a list of possible values. |
| <code>isa_bits</code> | Specifies whether 64-bit or 32-bit packages are to be installed. Valid values are 64 and 32. |
| <code>locale</code> | Designates the locale packages you want to install on or add to a system. See the <i>Solaris Installation Guide</i> for a list of possible values. |
| <code>package</code> | Specifies a package to be added to or deleted from a system. |

The following keywords must not be used in a profile used with `luupgrade`:

- `boot_device`
- `dontuse`
- `fdisk`
- `filesys`
- `layout_constraint`
- `noreboot`
- `partitioning`
- `root_device`
- `usedisk`

See the *Solaris Installation Guide* for descriptions of all JumpStart profile keywords and instructions for creating a JumpStart profile.

Examples EXAMPLE 1 Removing, then Adding Packages

The following example removes from then adds a set of packages to a boot environment.

```
# luupgrade -P -n second_disk SUNWabc SUNWdef SUNWghi
```

Now, to add the same packages:

```
# luupgrade -p -n second_disk -s /net/installmachine/export/packages \
SUNWabc SUNWdef SUNWghi
```

The following command adds the `-O` option to the preceding command. This option passes arguments directly to `pkgadd`.

```
# luupgrade -p -n second_disk -s /net/installmachine/export/packages \
-O "-r /net/testmachine/export/responses" SUNWabc SUNWdef SUNWghi
```

See [pkgadd\(1M\)](#) for a description of the options for that command.

EXAMPLE 2 Upgrading to a New OS from a Combined Image

The following example upgrades the operating environment on a boot environment. The source image is stored as a combined image on a remote disk or on a DVD.

```
# luupgrade -u -n second_disk \
-s /net/installmachine/export/solarisX/OS_image
```

Following the command above you could enter the command below to activate the upgraded BE.

```
# luactivate second_disk
```

Then, upon the next reboot, `second_disk` would become the current boot environment. See [luactivate\(1M\)](#).

EXAMPLE 3 Upgrading to a New OS from Multiple CDs

The following example is a variation on the preceding. The OS upgrade resides on two CDs. To begin the upgrade on a SPARC machine, you enter:

```
# luupgrade -u -n second_disk -s /cdrom/cdrom0/s0
```

On x86 machines, replace the `s0` in the argument to `-s` with `s2`.

When the installer is finished with the contents of the first CD, insert the next CD in the drive and enter the following:

EXAMPLE 3 Upgrading to a New OS from Multiple CDs (Continued)

```
# luupgrade -i -n second_disk -s /cdrom/cdrom0 \
-0 "-nodisplay -noconsole"
```

Note the use of `-i` rather than `-u` in the preceding. Were there additional CDs, you would enter the same command as the one immediately above. The `-0` options, above, are passed to [installer\(1M\)](#). If you omit these options, a graphical interface is invoked following the insertion and reading of the second CD. See [installer\(1M\)](#) for a description of the `-0` options.

Note that a multiple-CD upgrade is not complete until you have entered and completed `luupgrade` commands for all of the CDs in a set. Following installation of packages from a CD, you might receive a message such as:

```
WARNING: <num> packages must be installed on boot environment <disk_device>.
```

Such a message indicates the requirement that you install packages from one or more additional CDs, as in the example above. If you do not complete package installation, you will not be able to use `luactivate` to activate (designate for booting) the upgraded BE.

EXAMPLE 4 Upgrading Using a JumpStart Profile

The following example command uses the `-D` option to test the profile `/home2/profiles/test.profile`.

```
# luupgrade -u -n second_disk \
-s /net/installmachine/export/solarisX/OS_image \
-j /home2/profiles/test.profile -D
```

Assuming the results of this command were acceptable, you could omit the `-D` in the preceding command to perform the upgrade.

EXAMPLE 5 Installing a New OS from a Solaris Flash Archive

The following example installs the operating environment on a boot environment, using a Solaris Flash archive. The file pointed to by `-J` is a JumpStart profile that specifies a flash installation.

```
# luupgrade -f -n second_disk \
-s /net/installmachine/export/solarisX/OS_image \
-J "archive_location http://example.com/myflash.flar"
```

The following command differs from the preceding only in that `-j` replaces `-J`. You could append the `-D` option to either of these commands to test the profile prior to actually performing the flash installation.

```
# luupgrade -f -n second_disk \
-s /net/installmachine/export/solarisX/OS_image \
```

EXAMPLE 5 Installing a New OS from a Solaris Flash Archive (Continued)

```
-j /net/example/flash_archives/flash_gordon
```

Either of the preceding commands works for a full or differential flash installation. Whether a flash installation is differential or full is determined by the value of the `install_type` keyword in the profile. See “JumpStart Profile Keywords,” above.

EXAMPLE 6 Obtaining Information on Packages

The following example runs a `pkgchk` on the packages `SUNWluu`, `SUNWlur`, and `SUNWlucfg`, passing to `pkgchk` the `-v` option.

```
# luupgrade -C -n second_disk -O "-v" SUNWluu SUNWlur SUNWlucfg
```

The following command runs `pkginfo` on the same set of packages:

```
# luupgrade -I -n second_disk -O "-v" SUNWluu SUNWlur SUNWlucfg
```

For both commands, if the package names were omitted, `luupgrade` returns package information on all of the packages in the specified BE. See [pkgchk\(1M\)](#) and [pkginfo\(1\)](#) for a description of the options for those commands.

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Files `/etc/lutab` list of BEs on the system
`/usr/share/lib/xml/dtd/lu_cli.dtd.<num>` Live Upgrade DTD (see `-X` option in “Options that Apply to All Uses,” above)

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWlu |

See Also [installer\(1M\)](#), [luactivate\(1M\)](#), [lucancel\(1M\)](#), [lucompare\(1M\)](#), [lucreate\(1M\)](#), [lucurr\(1M\)](#), [ludelete\(1M\)](#), [ludesc\(1M\)](#), [lufslst\(1M\)](#), [lumake\(1M\)](#), [lumount\(1M\)](#), [lurename\(1M\)](#), [lustatus\(1M\)](#), [lutab\(4\)](#), [attributes\(5\)](#), [live_upgrade\(5\)](#), [zones\(5\)](#)

Warnings For adding packages or patches (`-p`, `-P`, `-t`, or `-T`), `luupgrade` requires packages or patches that comply with the SVR4 Advanced Packaging Guidelines and the guidelines spelled out in Appendix C of the . This means that the package or patch is compliant with the [pkgadd\(1M\)](#) `-R` option, described in the man page for that utility. While nearly all Sun packages and patches conform to these guidelines, Sun cannot guarantee the conformance of packages and

patches from third-party vendors. Some older Sun packages and patches might not be -R compliant. If you encounter such a package or patch, please report it to Sun. A non-conformant package can cause the package- or patch-addition software in luupgrade to fail or, worse, alter the current BE.

Notes For versions of the Solaris operating system prior to Solaris 10, Live Upgrade supports the release it is distributed on and up to three marketing releases back. For example, if you obtained Live Upgrade with Solaris 9 (including a Solaris 9 upgrade), that version of Live Upgrade supports Solaris versions 2.6, Solaris 7, and Solaris 8, in addition to Solaris 9. No version of Live Upgrade supports a Solaris version prior to Solaris 2.6.

Starting with version 10 of the Solaris operating system, Live Upgrade supports the release it is distributed on and up to two marketing releases back. For example, if you obtained Live Upgrade with Solaris 10 (including a Solaris 10 upgrade), that version of Live Upgrade supports Solaris 8 and Solaris 9, in addition to Solaris 10. For instructions on adding Live Upgrade packages for the release you want to install, see *Solaris 10 5/08 Installation Guide: Solaris Live Upgrade and Upgrade Planning*.

Correct operation of Solaris Live Upgrade requires that a limited set of patch revisions be installed for a given OS version. Before installing or running Live Upgrade, you are required to install the limited set of patch revisions. Make sure you have the most recently updated patch list by consulting <http://sunsolve.sun.com>. Search for the infodoc 72099 on the SunSolve web site.

Name luxadm – administer Sun Fire 880 storage subsystem and FC_AL devices

Synopsis luxadm [*options*]. . . *subcommand* [*options*]. . . *enclosure*
 [,*dev*] | *pathname*. . .

Description The luxadm program is an administrative command that manages the SENA, Sun Fire 880 internal storage subsystem, and individual Fiber Channel Arbitrated Loop (FC_AL) devices. luxadm performs a variety of control and query tasks depending on the command line arguments and options used.

The command line must contain a subcommand. The command line may also contain options, usually at least one enclosure name or pathname, and other parameters depending on the subcommand. You need specify only as many characters as are required to uniquely identify a subcommand.

Specify the device that a subcommand interacts with by entering a pathname. For the SENA subsystem, a disk device or enclosure services controller may instead be specified by entering the World Wide Name (WWN) for the device or a port to the device. The device may also be specified by entering the name of the SENA enclosure, and an optional identifier for the particular device in the enclosure. The individual FC_AL devices may be specified by entering the WWN for the device or a port to the device.

Pathname Specify the device or controller by either a complete physical pathname or a complete logical pathname.

For SENA, a typical physical pathname for a device is:

```
/devices/sbus@1f,0/SUNW,socal@1,0/sf@0,0/ssd@w2200002037000f96,  
0:a,raw
```

For all SENA IBs (Interface Boards) and Sun Fire 880 SES device controllers on the system, a logical link to the physical paths is kept in the directory /dev/es. An example of a logical link is /dev/es/ses0.

The WWN may be used in place of the pathname to select an FC_AL device, SENA subsystem IB, or Sun Fire 880 internal storage subsystem. The WWN is a unique 16 hexadecimal digit value that specifies either the port used to access the device or the device itself. A typical WWN value is:

```
2200002037000f96
```

See NOTES for more information on the WWN formats.

For a disk in a Sun Fire 880 internal storage subsystem, a typical physical pathname is:

```
/devices/pci@8,600000/SUNW,q1c@2/fp@0,0/ssd@w2100002037a6303c,0:a
```

and a typical logical pathname is:

```
/dev/rdisk/c2t8d0s2
```

For individual FC_AL devices, a typical physical pathname is:

```
/devices/sbus@3.0/SUNW,socal@d,10000/sf@0,0/ssd@w2200002037049fc3,0:a,raw
```

and a typical logical pathname is:

```
/dev/rdisk/c1t0d0s2
```

Enclosure For SENA, a device may be identified by its enclosure name and slotname:

```
box_name [ , fslot_number ]
```

```
box_name [ , rslot_number ]
```

box_name is the name of the SENA enclosure, as specified by the `enclosure_name` subcommand. When used without the optional `slot_number` parameter, the *box_name* identifies the SENA subsystem IB.

f or *r* specifies the front or rear slots in the SENA enclosure.

slot_number specifies the slot number of the device in the SENA enclosure, 0-6 or 0-10.

For a Sun Fire 880 internal storage subsystem, a device may also be identified by its enclosure name and slot name. However, there is only one set of disks:

```
box_name [ , slot_number ]
```

box_name is the name of the Sun Fire 880 enclosure, as specified by the `enclosure_name` subcommand. When used without the optional `slot_number` parameter, *box_name* identifies the Sun Fire 880 internal storage subsystem enclosure services device. Use *s* to specify the disk slot number in the Sun Fire 880 internal storage subsystem, 0 - 11.

See [disks\(1M\)](#) and [devlinks\(1M\)](#) for additional information on logical names for disks and subsystems.

Options The following options are supported by all subcommands:

- e Expert mode. This option is not recommended for the novice user.
- v Verbose mode.

Options that are specific to particular subcommands are described with the subcommand in the USAGE section.

Operands The following operands are supported:

enclosure

The *box_name* of the SENA or Sun Fire 880 internal storage subsystem.

fibre_channel_HBA_port

The path to the host controller port. A typical path is:

```
/devices/pci@8,600000/pci@1/SUNW,qlc@4/fp@0,0:devctl
```

pathname

The logical or physical path of a SENA IB, Sun Fire 880 internal storage subsystem, or disk device. *pathname* can also be the WWN of a SENA IB, SENA disk, or individual FC_AL device.

Usage

```
Subcommands  display enclosure[,dev]... | pathname...
              display -p pathname...
              display -r enclosure[,dev]... | pathname...
              display -v enclosure[,dev]... | pathname...
              Displays enclosure or device specific data.
```

Subsystem data consists of enclosure environmental sense information and status for all subsystem devices, including disks.

Disk data consists of inquiry, capacity, and configuration information.

- p Displays performance information for the device or subsystem specified by *pathname*. This option only applies to subsystems that accumulate performance information.
- r Displays error information for the FC_AL device specified by the *pathname*, or, if the path is a SENA, for all devices on the loop. The -r option only applies to SENA subsystems and individual FC_AL devices.
- v Displays in verbose mode, including mode sense data.

```
download [ -s ] [ -f filename_path ] enclosure... .
```

Download the prom image pointed to the SENA subsystem Interface Board unit or the Sun Fire 880 internal storage subsystem specified by the enclosure or *pathname*.

When the SENA's download is complete, the SENA will be reset and the downloaded code executed. If no filename is specified, the default prom image will be used. The default prom image for the SENA is in the directory `usr/lib/locale/C/LC_MESSAGES` and is named `ibfirmware`

When the Sun Fire 880 internal storage subsystem's download is complete, the subsystem resets and the downloaded code begins execution. The default firmware image for the Sun Fire 880 internal storage subsystem is in:

```
/usr/platform/SUNW,Sun-Fire-880/lib/images/int_fcbpl_fw.
```

- s Save. The -s option is used to save the downloaded firmware in the FEPRM. If -s is not specified, the downloaded firmware will not be saved across power cycles.

The -s option does not apply to the Sun Fire 880 internal storage subsystem as it always stores downloaded firmware in the flash memory.

When using the `-s` option, the `download` subcommand modifies the FEPROM on the subsystem and should be used with *caution*.

`enclosure_name new_name enclosure | pathname`

Change the enclosure name of the enclosure or enclosures specified by the enclosure or pathname. The new name (*new_name*) must be 16 or less characters. Only alphabetic or numeric characters are acceptable. This subcommand applies only to the SENA and the Sun Fire 880 internal storage subsystem.

`failover primary | secondary pathname`

Select which Sun Storage T3 storage array partner group controller accesses a given logical volume. If `primary` is specified, the logical volume is accessed through the primary controller. If `secondary` is specified, the logical volume is accessed through the secondary controller specified by *pathname*.

`fcal_s_download [-f fcode-file]`

Download the fcode contained in the file *fcode-file* into *all* the FC100/S Sbus Cards. This command is interactive and expects user confirmation before downloading the fcode.

Use `fcal_s_download` *only* in single-user mode. Using `fcal_s_download` to update a host adapter while there is I/O activity through that adapter *will* cause the adapter to reset. Newly updated FCode will not be executed or visible until a system reboot.

`-f fcode-file` When invoked without the `-f` option, the current version of the fcode in each FC100/S Sbus card is printed.

`fcode_download -p`

`fcode_download -d dir-name`

Locate the installed FC/S, FC100/S, FC100/P, or FC100/2P host bus adapter cards and download the FCode files in *dir-name* to the appropriate cards. The command determines the correct card for each type of file, and is interactive. User confirmation is required before downloading the FCode to each device.

Use `fcode_download` to load FCode only in single-user mode. Using `fcode_download` to update a host adapter while there is I/O activity through that adapter causes the adapter to reset. Newly updated FCode will not be executed or visible until a system reboot.

`-d dir-name` Download the FCode files contained in the directory *dir-name* to the appropriate adapter cards.

`-p` Prints the current version of FCode loaded on each card. No download is performed.

`inquiry enclosure[,dev] ... | pathname ...`

Display the inquiry information for the selected device specified by the enclosure or pathname.

`insert_device [enclosure,dev ...]`

Assist the user in the hot insertion of a new device or a chain of new devices. Refer to NOTES for limitations on hotplug operations. This subcommand applies only to the SENA, Sun Fire 880 internal storage subsystem, and individual FC_AL drives. For the SENA, if more than one enclosure has been specified, concurrent hot insertions on multiple busses can be performed. With no arguments to the subcommand, entire enclosures or individual FC_AL drives can be inserted. For the SENA or the Sun Fire 880 internal storage subsystem, this subcommand guides the user interactively through the hot insertion steps of a new device or chain of devices. If a list of disks was entered it will ask the user to verify the list of devices to be inserted is correct, at which point the user can continue or quit. It then interactively asks the user to insert the disk(s) or enclosure(s) and then creates and displays the logical pathnames for the devices.

`led enclosure,dev ... | pathname ...`

Display the current state of the LED associated with the disk specified by the enclosure or pathname. This subcommand only applies to subsystems that support this functionality.

`led_blink enclosure,dev ... | pathname ...`

Requests the subsystem to start blinking the LED associated with the disk specified by the enclosure or pathname. This subcommand only applies to subsystems that support this functionality.

`led_off enclosure,dev ... | pathname ...`

Requests the subsystem to disable (turn off) the LED associated with the disk specified by the enclosure or pathname. On a SENA subsystem, this may or may not cause the LED to turn off or stop blinking depending on the state of the SENA subsystem. Refer to the SENA Array Installation and Service Manual (p/n 802-7573). This subcommand only applies to subsystems that support this functionality.

`led_on pathname ...`

Requests the subsystem to enable (turn on) the LED associated with the disk specified by the pathname. This subcommand only applies to subsystems that support this functionality.

`power_off [-F] enclosure[,dev] ... | pathname ...`

When a SENA is addressed, this subcommand causes the SENA subsystem to go into the power-save mode. The SENA drives are not available when in the power-save mode. When a drive in a SENA is addressed the drive is set to the drive off/unmated state. In the drive off/unmated state, the drive is spun down (stopped) and in bypass mode. This command does not apply to the Sun Fire 880 internal storage subsystem.

-F The force option only applies to the SENA. Instructs luxadm to attempt to power off one or more devices even if those devices are being used by this host (and are, therefore, busy).

Warning: Powering off a device which has data that is currently being used will cause unpredictable results. Users should attempt to power off the device normally (without -F) first, only resorting to this option when sure of the consequences of

overriding normal checks.

`power_on enclosure[, dev] . .`

Causes the SENA subsystem to go out of the power-save mode, when this subcommand is addressed to a SENA.. When this subcommand is addressed to a drive the drive is set to its normal start-up state. This command does not apply to the Sun Fire 880 internal storage subsystem.

`probe [-p]`

Finds and displays information about all attached SENA subsystems, Sun Fire 880 internal storage subsystems, and individual FC_AL devices, including the logical pathname, the WWNs, and enclosure names. This subcommand warns the user if it finds different SENAs with the same enclosure names.

`-p` Includes the physical pathname in the display.

`qlgc_s_download [-f fcode-file]`

Download the FCode contained in the file *fcode-file* into all the FC100/P, FC100/2P PCI host adapter cards. This command is interactive and expects user confirmation before downloading the FCode to each device. Only use `qlgc_s_download` in single-user mode. Using `qlgc_s_download` to update a host adapter while there is I/O activity through that adapter will cause the adapter to reset. Newly updated FCode will not be executed or visible until a system reboot.

`-f fcode-file` When invoked without the `-f` option, the current version of the FCode in each FC100/P, FC100/2P PCI card is printed.

`release pathname`

Release a reservation held on the specified disk. The pathname should be the physical or logical pathname for the disk.

This subcommand is included for historical and diagnostic purposes only.

`remove_device [-F] enclosure[, dev] . . . | pathname . . .`

Assists the user in hot removing a device or a chain of devices. This subcommand can also be used to remove entire enclosures. This subcommand applies to the SENA, Sun Fire 880 internal storage subsystem, and individual FC_AL drives. Refer to NOTES for limitations on hotplug operations. For the SENA, Sun Fire 880 internal storage subsystem, and individual FC_AL devices, this subcommand guides the user through the hot removal of a device or devices. During execution it will ask the user to verify the list of devices to be removed is correct, at which point the user can continue or quit. It then prepares the disk(s) or enclosure(s) for removal and interactively asks the user to remove the disk(s) or enclosure(s).

For Multi-Hosted disk, the steps taken are:

- Issue the `luxadm remove_device` command on the first host. When prompted to continue, wait.

- Issue the `luxadm remove_device` command on the secondary hosts. When prompted to continue, wait.
 - Continue with the `remove_device` command on the first host. Remove the device when prompted to do so.
 - Complete the `luxadm remove_device` command on the additional hosts.
- F Instructs `luxadm` to attempt to hot plug one or more devices even if those devices are being used by this host (and are, therefore, *busy* or *reserved*), to *force* the hotplugging operation.

Warning: Removal of a device which has data that is currently being used will cause unpredictable results. Users should attempt to hotplug normally (without -F) first, only resorting to this option when sure of the consequences of overriding normal hotplugging checks.

`reserve pathname` Reserve the specified disk for exclusive use by the issuing host. The pathname used should be the physical or logical pathname for the disk.

This subcommand is included for historical and diagnostic purposes only.

`set_boot_dev [-y] pathname` Set the boot-device variable in the system PROM to the physical device name specified by *pathname*, which can be a block special device or the pathname of the directory on which the boot file system is mounted. The command normally runs interactively requesting confirmation for setting the default boot-device in the PROM. The -y option can be used to run it non-interactively, in which case no confirmation is requested or required.

`start pathname` Spin up the specified disk(s) in a SENA.

`stop pathname...` Spin down the specified disks in a SENA.

SENA, Sun Fire 880
Internal Storage
Subsystem, and
Individual FC_AL Drive
Expert Mode
Subcommands

The following subcommands are for expert use only, and are applicable only to the SENA, Sun Fire 880 internal storage subsystem, and fiber channel loops. They should only be used by users that are knowledgeable about the SENA subsystem and fiber channel loops.

If you specify a disk to an expert subcommand that operates on a bus, the subcommand operates on the bus to which the specified disk is attached.

`-e bypass [-ab] enclosure,dev`

`-e bypass -f enclosure`

Request the enclosure services controller to set the LRC (Loop Redundancy Circuit) to the bypassed state for the port and device specified.

| | | |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | | This subcommand supports the following options: |
| | -a | Bypass port a of the device specified. |
| | -b | Bypass port b of the device specified. |
| -e dump_map | <i>fibre_channel_HBA_port</i> | Display WWN data for a target device or host bus adapter on the specified fibre channel port. If there are no target devices on the specified port, an error is returned. |
| -e enable | [-ab] <i>enclosure,dev</i> | |
| -e enable | -f <i>enclosure</i> | Request the enclosure services controller to set the LRC (Loop Redundancy Circuit) to the enabled state for the port and device specified. |
| | | This subcommand supports the following options: |
| | -a | Enable port a of the device specified. |
| | -b | Enable port b of the device specified. |
| -e forcelip | <i>enclosure[,dev] ... pathname ...</i> | Force the link to reinitialize, using the Loop Initialization Primitive (LIP) sequence. The enclosure or pathname can specify any device on the loop. Use the pathname to specify a specific path for multiple loop configurations. |
| | | This is an expert only command and should be used with caution. It will reset all ports on the loop. |
| -e rdls | <i>enclosure[,dev] ... pathname ...</i> | Read and display the link error status information for all available devices on the loop that contains the device specified by the enclosure or pathname. |
| Other Expert Mode Subcommands | See NOTES for limitations of these subcommands. They should only be used by users that are knowledgeable about the systems they are managing. | |

These commands do not apply to the Sun Fire 880 internal storage subsystem.

| | |
|----------------------------------|----------------------------------------------------|
| -e bus_getstate <i>pathname</i> | Get and display the state of the specified bus. |
| -e bus_quiesce <i>pathname</i> | Quiesce the specified bus. |
| -e bus_reset <i>pathname</i> | Reset the specified bus only. |
| -e bus_resetall <i>pathname</i> | Reset the specified bus and all devices. |
| -e bus_unquiesce <i>pathname</i> | Unquiesce the specified bus. the specified device. |
| -e dev_getstate <i>pathname</i> | Get and display the state of the specified device. |
| -e dev_reset <i>pathname</i> | Reset the specified device. |
| -e offline <i>pathname</i> | Take the specified device offline. |
| -e online <i>pathname</i> | Put the specified device online. |

Examples EXAMPLE 1 Displaying the SENAs and Individual FC_AL Devices on a System

The following example finds and displays all of the SENAs and individual FC_AL devices on a system:

```
example% luxadm probe
```

EXAMPLE 2 Displaying a SENA or Sun Fire 880 Internal Storage Subsystem

The following example displays a SENA or Sun Fire 880 internal storage subsystem:

```
example% luxadm display /dev/es/ses0
```

EXAMPLE 3 Displaying Two Subsystems

The following example displays two subsystems using the enclosure names:

```
example% luxadm display BOB system1
```

EXAMPLE 4 Displaying Information about the First Disk

The following example displays information about the first disk in the front of the enclosure named BOB. Use *f* to specify the front disks. Use *r* to specify the rear disks.

```
example% luxadm display BOB,f0
```

EXAMPLE 5 Displaying Information on a Sun Fire 880 Internal Storage Subsystem

The Sun Fire 880 internal storage subsystem has only one set of disks. In this case, use *s* to specify the slot:

```
example% luxadm display BOB,s0
```

EXAMPLE 6 Displaying Information about a SENA disk, an Enclosure, or an Individual FC_AL Drive

The following example displays information about a SENA disk, an enclosure, or an individual FC_AL drive with the port WWN of 2200002037001246:

```
example% luxadm display 2200002037001246
```

EXAMPLE 7 Using Unique Characters to Issue a Subcommand

The following example uses only as many characters as are required to uniquely identify a subcommand:

```
example% luxadm disp BOB
```

EXAMPLE 8 Displaying Error Information

The following example displays error information about the loop that the enclosure BOB is on:

```
example% luxadm display -r BOB
```

EXAMPLE 9 Downloading New Firmware into the Interface Board

The following example downloads new firmware into the Interface Board in the enclosure named BOB (using the default path for the file to download):

```
example% luxadm download -s BOB
```

EXAMPLE 10 Displaying Information from the SCSI Inquiry Command

The following example displays information from the SCSI inquiry command from all individual disks on the system, using only as many characters as necessary to uniquely identify the inquiry subcommand:

```
example% luxadm inq /dev/rdisk/c?t?d?s2
```

EXAMPLE 11 Hotplugging

The following example hotplugs a new drive into the first slot in the front of the enclosure named BOB:

```
example% luxadm insert_device BOB,f0
```

The following example hotplugs a new drive into the first slot in the Sun Fire 880 internal storage subsystem named SF880-1:

```
example% luxadm insert_device SF880-1,s0
```

EXAMPLE 12 Running an Expert Subcommand

The following example runs an expert subcommand. The subcommand forces a loop initialization on the loop that the enclosure BOB is on:

```
example% luxadm -e forcelp BOB
```

EXAMPLE 13 Using the Expert Mode Hot Plugging Subcommands

An example of using the expert mode hot plugging subcommands to hot remove a disk follows. See NOTES for hot plugging limitations.

The first step reserves the SCSI device so that it can't be accessed by way of its second SCSI bus:

```
example# luxadm reserve /dev/rdisk/c1t8d0s2
```

EXAMPLE 14 Taking the Disk to be Removed Offline

The next two steps take the disk to be removed offline then quiesce the bus:

```
example# luxadm -e offline /dev/rdisk/c1t8d0s2
example# luxadm -e bus_quiesce /dev/rdisk/c1t8d0s2
```

EXAMPLE 15 Unquiescing the Bus

The user then removes the disk and continues by unquiescing the bus, putting the disk back online, then unreserving it:

```
example# luxadm -e bus_unquiesce /dev/rdisk/c1t8d0s2
example# luxadm -e online /dev/rdisk/c1t8d0s2
example# luxadm release /dev/rdisk/c1t8d0s2
```

Environment Variables See [environ\(5\)](#) for a description of the LANG environment variable that affects the execution of luxadm.

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.

Files `usr/lib/firmware/fc_s/fc_s_fcode`
`usr/lib/locale/C/LC_MESSAGES/ibfirmware`

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| usr/sbin | ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------|----------------|-----------------------|
| | Availability | system/storage/luxadm |

See Also [devlinks\(1M\)](#), [disks\(1M\)](#), [attributes\(5\)](#), [environ\(5\)](#), [ses\(7D\)](#)

SENA Array Installation and Service Manual (p/n 802-7573).

RAID Manager 6.1 Installation and Support Guide Answerbook

RAID Manager 6.1 User's Guide Answerbook

Notes See the *SENA Array Installation and Service Manual* for additional information on the SENA. Refer to *Tutorial for SCSI use of IEEE Company_ID*, R. Snively, for additional information regarding the IEEE extended WWN. See SEE ALSO. Currently, only some device drivers support hot plugging. If hot plugging is attempted on a disk or bus where it is not supported, an error message of the form:

```
luxadm: can't acquire "PATHNAME": No such file or directory
```

will be displayed.

You must be careful not to quiesce a bus that contains the root or the /usr filesystems or any swap data. If you do quiesce such a bus a deadlock can result, requiring a system reboot.

Name m64config, SUNWm64_config – configure the M64 Graphics Accelerator

Synopsis /usr/sbin/m64config [-defaults] [-depth 8 | 24 | 32]
[-dev *device-filename*] [-file machine | system]
[-prconf] [-propt]
[-res *video-mode* [now | try] [noconfirm | nocheck]]

/usr/sbin/m64config [-prconf] [-propt]

/usr/sbin/m64config [-help] [-res ?]

Description m64config configures the M64 Graphics Accelerator and some of the X11 window system defaults for M64.

The first form of `m64config` stores the specified options in the `OWconfig` file. These options will be used to initialize the M64 device the next time the window system is run on that device. Updating options in the `OWconfig` file provides persistence of these options across window system sessions and system reboots.

The second and third forms which invoke only the `-prconf`, `-propt`, `-help`, and `-res ?` options do not update the `OWconfig` file. Additionally, for the third form all other options are ignored.

Options may be specified for only one M64 device at a time. Specifying options for multiple M64 devices requires multiple invocations of `m64config`.

Only M64-specific options can be specified through `m64config`. The normal window system options for specifying default depth, default visual class and so forth are still specified as device modifiers on the `openwin` command line. See the *Open Windows Desktop Reference Manual* for details.

The user can also specify the `OWconfig` file that is to be updated. By default, the machine-specific file in the `/etc/openwin` directory tree is updated. The `-file` option can be used to specify an alternate file to use. For example, the system-global `OWconfig` file in the `/usr/openwin` directory tree can be updated instead.

Both of these standard `OWconfig` files can only be written by root. Consequently, the `m64config` program, which is owned by the root user, always runs with `setuid root` permission.

Options `-defaults`
Resets all option values to their default values.

`-depth 8 | 24 | 32`
Sets the depth (bits per pixel) on the device. Possible values are 8, 24, or 32 (where 32 uses 24 bits per pixel). Log out of the current window system session and log back in for the change to take effect. 24 or 32 enables TrueColor graphics in the window system, at the expense of screen resolution.

The 32 setting enables simultaneous 8- and 24-bit color windows on m64 devices that support it. With setting 32, `-propt` shows depth 32 and `-prconf` shows depth 24. To check window depth, use the `xwininfo` utility. The `xwininfo` utility is usually shipped in the package containing frame buffer software (such as `SUNWxwpl1t`).

The maximum resolution that is available with 24 bits per pixel depends on the amount of memory installed on the PGX card. For 2-MB PGX cards, the maximum available resolution is 800x600. For 4-MB cards, it is 1152x900. For 8-MB cards, it is 1920x1080. If there is not enough memory for the specified combination of resolution and depth, `m64config` displays an error message and exits.

`-dev device-filename`

Specifies the M64 special file. If not specified, `m64config` will try `/dev/fbs/m640` through `/dev/fbs/m648` until one is found.

`-file machine| system`

Specifies which OWconfig file to update. If `machine`, the machine-specific OWconfig file in the `/etc/openwin` directory tree is used. If `system`, the global OWconfig file in the `/usr/openwin` directory tree is used. If the file does not exist, it is created. This option has no effect unless other options are specified. The default is *machine*.

`-help`

Prints a list of the `m64config` command line options, along with a brief explanation of each.

`-prconf`

Prints the M64 hardware configuration. The following is a typical display using the `-prconf` option:

```

--- Hardware Configuration for /dev/fbs/m640 ---
ASIC: version 0x41004754
DAC: version 0x0
PROM: version 0x0
Card possible resolutions: 640x480x60, 800x600x75, 1024x768x60
    1024x768x70, 1024x768x75, 1280x1024x75, 1280x1024x76
    1280x1024x60, 1152x900x66, 1152x900x76, 1280x1024x67
    960x680x112S, 960x680x108S, 640x480x60i, 768x575x50i
    1280x800x76, 1440x900x76, 1600x1000x66, 1600x1000x76
    vga, svga, 1152, 1280, stereo, ntsc, pal
Monitor possible resolutions: 720x400x70, 720x400x85, 640x480x60
    640x480x67, 640x480x72, 640x480x75, 800x600x56, 800x600x60
    800x600x72, 800x600x75, 832x624x75, 1024x768x85, 1024x768x60
    1024x768x70, 1024x768x75, 1280x1024x75, 1280x1024x76,
    1152x900x66, 1152x900x76, 1280x1024x67, 960x680x112S
    vga, svga, 1152, 1280, stereo
Possible depths: 8, 24
Current resolution setting: 1280x1024x76
Current depth: 8

```

-propt

Prints the current values of all M64 options in the OWconfig file specified by the `-file` option for the device specified by the `-dev` option. Prints the values of options as they will be in the OWconfig file after the call to `m64config` completes. The following is a typical display using the `-propt` option:

```
--- OpenWindows Configuration for /dev/fbs/m640 ---
OWconfig: machine
Video Mode: not set
Depth: 8
```

-res *video-mode* [now | try [noconfirm | nocheck]]

Specifies the video mode used to drive the monitor connected to the specified M64 device. Video modes are built-in. *video-mode* has the format of *widthxheightxrate*. *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh. As a convenience, `-res` also accepts formats with `@` preceding the refresh rate instead of `x`. For example, `1280x1024@76`.

A list of valid video modes is obtained by issuing the following command: `m64config -res '??'`. Note that the `?` must be quoted. Not all resolutions are supported by both the video board and by the monitor. `m64config` will not permit you to set a resolution the board does not support, and will request confirmation before setting a resolution the monitor does not support.

Symbolic names

For convenience, some video modes have symbolic names defined for them. Instead of the form *widthxheightxrate*, one of these names may be supplied as the argument to `-res`. The meaning of the symbolic name `none` is that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.

| Name | Corresponding Video Mode |
|------|---------------------------------------------|
| svga | 1024x768x60 |
| 1152 | 1152x900x76 |
| 1280 | 1280x1024x76 |
| none | (video mode currently programmed in device) |

The `-res` option also accepts additional sub-options immediately following the video mode specification. Any or all of these may be present.

nocheck If present, the normal error checking based on the monitor sense code will be suspended. The video mode specified by the user will be accepted regardless of whether it is appropriate for the currently attached monitor.

This option is useful if a different monitor is to be connected to the M64 device. *Use of this option implies noconfirm as well.*

noconfirm Using the `-res` option, the user could potentially put the system into an unusable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this, the default behavior of `m64config` is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. The `noconfirm` option instructs `m64config` to bypass this confirmation and to program the requested video mode anyway. This option is useful when `m64config` is being run from a shell script.

now If present, not only will the video mode be updated in the OWconfig file, but the M64 device will be immediately programmed to display this video mode. (This is useful for changing the video mode before starting the window system).

It is inadvisable to use this sub-option with `m64config` while the configured device is being used (for example, while running the window system); unpredictable results may occur. To run `m64config` with the `now` sub-option, first bring the window system down. If the `now` sub-option is used within a window system session, the video mode will be changed immediately, but the width and height of the affected screen won't change until the window system is exited and reentered again. Consequently, this usage is strongly discouraged.

try If present, the specified video mode will be programmed on a trial basis. The user will be asked to confirm the video mode by typing `y` within 10 seconds. Or the user may terminate the trial before 10 seconds are up by typing any character. Any character other than `'y'` or carriage return is considered a no and the previous video mode will be restored and `m64config` will not change the video mode in the OWconfig file (other options specified will still take effect). If a carriage return is typed, the user is prompted for a yes or no answer on whether to keep the new video mode.

This sub-option should not be used with `m64config` while the configured device is being used (for example, while running the window system) as unpredictable results may occur. To run `m64config` with the `try` sub-option, the window system should be brought down first.

Defaults For a given invocation of `m64config` command line if an option does not appear on the command line, the corresponding OWconfig option is not updated; it retains its previous value.

When the window system is run, if an M64 option has never been specified by `m64config`, a default value is used. The option defaults are as follows:

| Option | Default |
|--------|---------------|
| -dev | /dev/fbs/m640 |
| -file | machine |
| -res | none |

The default for the -res option of none means that when the window system is run the screen resolution will be the video mode that is currently programmed in the device.

This provides compatibility for users who are used to specifying the device resolution through the PROM. On some devices (for example, GX) this is the only way of specifying the video mode. This means that the PROM ultimately determines the default M64 video mode.

Examples EXAMPLE 1 Switching the Monitor Type

The following example switches the monitor type to the maximum resolution of 1280 x 1024 at 76 Hz:

```
example% /usr/sbin/m64config -res 1280x1024x76
```

OpenWindows Desktop Reference Manual

Name mail.local – store mail in a mailbox

Synopsis /usr/lib/mail.local [-f *sender*] [-d] *recipient*

Description mail.local reads the standard input up to an end-of-file and appends it to each user's mail file (mailbox). This program is intended to be used by [sendmail\(1M\)](#) as a mail delivery agent for local mail. It is not a user interface agent.

Messages are appended to the user's mail file in the /var/mail directory. The user must be a valid user name.

Each delivered mail message in the mailbox is preceded by a "Unix From line" with the following format:

```
From sender_address time_stamp
```

The *sender_address* is extracted from the SMTP envelope address (the envelope address is specified with the -f option).

A trailing blank line is also added to the end of each message.

The mail files are locked with a .lock file while mail is appended.

The mail files are created with mode 660, owner is set to *recipient*, and group is set to mail. If the "biff" service is returned by [getservbyname\(3SOCKET\)](#), the biff server is notified of delivered mail. This program also computes the Content-Length: header which will be used by the mailbox reader to mark the message boundary.

Options The following options are supported:

- f *sender* Specifies the "envelope from address" of the message. This flag is technically optional, but should be used.
- d Specifies the recipient of the message. This flag is also optional and is supported here for backward compatibility. That is, mail.local *recipient* is the same as mail.local -d *recipient*.
- l Turn on LMTP mode.
- r *from* Specify the sender's name (for backward compatibility).
- 7 Do not advertise 8BITMIME support in LMTP mode.
- b Return a permanent error instead of a temporary error if a mailbox exceeds quota.

Operands The following operand is supported:

recipient The recipient of the mail message.

Environment Variables TZ Used to set the appropriate time zone on the timestamp.

Exit Status The following exit values are returned:

0 Successful operation.

>0 An error occurred.

Files /tmp/local.XXXXXX temporary files

/tmp/lochd.XXXXXX temporary files

/var/mail/user_name user's mail file

REFERENCE

System Administration Commands - Part 2

Name makedbm – make a dbm file, or get a text file from a dbm file

Synopsis makedbm [-b] [-l] [-s] [-E] [-i *yp_input_file*]
 [-o *yp_output_name*] [-d *yp_domain_name*]
 [-m *yp_master_name*] [-S *delimiter*]
 [-D *number_of_delimiters*] *infile outfile*
 makedbm [-u *dbmfilename*]

Description The makedbm utility takes the *infile* and converts it to a pair of files in ndbm format (see [ndbm\(3C\)](#)), namely *outfile.pag* and *outfile.dir*. Each line of the input file is converted to a single dbm record. All characters up to the first TAB or SPACE form the key, and the rest of the line is the data. If a line ends with ‘\’ (backslash), the data for that record is continued on to the next line. makedbm does not treat ‘#’ (pound-sign) as a special character.

Because makedbm is mainly used in generating dbm files for the NIS name service, it generates a special entry with the key *yp_last_modified*, which is the date of *infile* (or the current time, if *infile* is ‘-’). The entries that have keys with the prefix *yp_* are interpreted by NIS server utilities.

Options The following options are supported:

- b Insert the YP_INTERDOMAIN into the output. This key causes [ypserv\(1M\)](#) to use DNS for host name and address lookups for hosts not found in the maps.
- d *yp_domain_name* Create a special entry with the key *yp_domain_name*.
- D *number_of_delimiters* Specify *number_of_delimiters* to skip before forming the key.
- E Delimiters are escaped.
- i *yp_input_file* Create a special entry with the key *yp_input_file*.
- l Lower case. Convert the keys of the given map to lower case, so that, for example, host name matches succeed independent of upper or lower case distinctions.
- m *yp_master_name* Create a special entry with the key *yp_master_name*. If no master host name is specified, *yp_master_name* is set to the local host name.
- o *yp_output_name* Create a special entry with the key *yp_output_name*.
- s Secure map. Accept connections from secure NIS networks only.
- S *delimiter* Specify the *delimiter* to use instead of the default delimiter for forming the key.
- u *dbmfilename* Undo a dbm file. Prints out the file in text format, one entry per line, with a single space separating keys from values.

Operands The following operands are supported:

infile Input file for makedbm. If *infile* is '-' (dash), the standard input is read.

outfile One of two output files in ndbm format: *outfile.pag* and *outfile.dir*.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

Name makemap – create database maps for sendmail

Synopsis makemap [-N] [-d] [-f] [-o] [-r] [-s] [-v] [-C *file*]
[-c *cache*size] [-D *comment*char] [-e] [-l] [-t *delim*]
[-u] *mantype mapname*

Description makemap creates the database maps used by the keyed map lookups in [sendmail\(1M\)](#). makemap reads from the standard input and outputs to the specified *mapname*.

In all cases, makemap reads lines from the standard input consisting of two words separated by whitespace. The first is the database key, the second is the value. The value may contain *%n* strings to indicated parameter substitution. Literal percents should be doubled (%%). Blank lines and lines beginning with # are ignored.

makemap handles three different database formats. Database format is selected using the *maptype* parameter. See OPERANDS.

Options The following options are supported:

- c *cache*size Use the specified hash and B-Tree cache size (*cache*size).
- C *file* Use the specified sendmail configuration file (*file*) for looking up the TrustedUser option.
- d Allow duplicate keys in the map. This is only allowed on B-Tree format maps. If two identical keys are read, both be inserted into the map.
- D *comment*char Use the specified character to indicate a comment (which is ignored) instead of the default of '#'.
- e Allow empty value (right hand side).
- f Normally, all upper case letters in the key are folded to lower case. This flag disables that behavior. This is intended to mesh with the -f flag in the K line in `sendmail.cf`. The value is never case folded.
- l List supported map types.
- N Include the null byte that terminates strings in the map. This must match the -N flag in the K line in `sendmail.cf`
- o Append to an old file. This allows you to augment an existing file.
- r Allow replacement of existing keys. Normally makemap complains if you repeat a key, and does not do the insert.
- s Ignore safety checks on maps being created. This includes checking for hard or symbolic links in world writable directories.
- t *delim* Use the specified delimiter (*delim*) instead of whitespace.

- u Dump (unmap) the content of the database to standard output. Note that, if the -t option is also provided, the specified delimiter is used when the content is dumped instead of whitespace.
- v Verbosely print what it is doing.

Operands The following operands are supported:

- mapname* File name of the database map being created.
- maptype* Specifies the database format. The following *maptype* parameters are available:
 - dbm Specifies DBM format maps.
 - bt tree Specifies B-Tree format maps.
 - hash Specifies hash format maps.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

Name makeuuid – generate Universal Unique Identifiers

Synopsis makeuuid [-e *ether*] [-n *count*] [-R *root*]

Description The `makeuuid` command generates UUIDs (Universal Unique Identifiers) conforming to the OSF DCE specification for UUIDs. The specification states:

"A UUID is an identifier that is unique across both space and time, with respect to the space of all UUIDs. A UUID can be used for multiple purposes, from tagging objects with an extremely short lifetime, to reliably identifying very persistent objects across a network.

"The generation of UUIDs does not require a registration authority for each single identifier. Instead, it requires a unique value over space for each UUID generator. This spatially unique value is [normally] specified as an IEEE 802 address, which is usually already applied to network-connected systems."

The `makeuuid` command generates one or more UUIDs on the standard output.

Options The `makeuuid` command supports the following options:

-e *ether* Supplies an alternate address to be used in the generation of the UUIDs. Normally, the system's Ethernet address is acquired and used during the generation of a UUID. However, this requires root privileges to open and read the network devices. If this is not possible, you must supply an alternate Ethernet address.

-n *count* Generate multiple UUIDs. This option generates the specified number of UUIDs, one per line. Using this form is more efficient than, and functionally equivalent to, calling the `makeuuid` command multiple times. This can be used, for example, when a large number of UUIDs need to be generated for a given application.

-R *root* Use *root* as the root filesystem path when updating the shared state file (see FILES). The shared state file must be writable by the user running `makeuuid`, otherwise no UUIDs will be generated and the command will return in failure.

Note – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).

Usage Normally, you run the `makeuuid` command with root privileges, as the Ethernet address and state files can be easily accessed and updated. If this is not possible, you must use the `-R` and `-e` options to specify an alternate root and Ethernet address to use when calculating the UUIDs.

Examples **EXAMPLE 1** Generating Multiple UUIDs

The following command generates 3000 UUIDs:

```
example# makeuuid -n 3000
```

EXAMPLE 2 Invoking Without Root Privileges

If you cannot obtain root privileges, you must specify an alternate Ethernet address and state file location:

```
example% makeuuid -e 11:22:33:44:55:66 -R /export/root/example2
```

See the caveat on the use of the `-R` option in the description of that option, above.

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 Out of memory.
- 1 Invalid Ethernet address given or access denied.

Files `/var/sadm/system/uuid_state` UUID state file. Use of time values is one way that UUID generators, such as `makeuuid`, guarantee uniqueness. A state file is a mechanism that allows `makeuuid` to "remember" the last time value it used so it can increment that value for use in a new UUID. See the Internet Draft "UUIDs and GUIDs," dated February 4, 1998, for details on the state file mechanism.

Name masfcnv – SNMP configuration migration script

Synopsis /usr/lib/sma_snmp/masfcnv [-cimnrs] [-l *agentmaster*]
[-p *enabledisableerror*] [-t *noneadd*]
[-u *agentmastererror*] [-y *agentmastererror*]

masfcnv [-V]

masfcnv [-?]

Description The `masfcnv` script is used to assist the system administrator in migrating an existing set of configuration files for the Sun SNMP Management Agent for Sun Fire and Netra Systems (MASF) to the Systems Management Agent (SMA).

The script accepts as input the currently installed set of MASF and SMA configuration files and outputs a new set of SMA configuration files. Existing SMA configuration files are backed up by appending `.bak` to the filename. The administrator can choose to output the new configuration to standard output, instead of replacing the current configuration, by specifying the `-n` option.

The migration script must be run as the superuser. Failure to do so causes the script to exit with an error message. Before running the script you should ensure that both the SMA and MASF agents are not running. If the agents are running they will be shut down by the script.

The migration script installs a new startup script for the MASF agent in `/etc/init.d`, as well as a backup of the old script. During migration, MASF will be configured as an AgentX subagent of SMA. All migration settings will be migrated to the SMA configuration file.

The migration script aborts if any unrecognized directives are found in either the MASF configuration files or the SMA configuration files. This can be overridden with the `-i` option. If this option is selected, the behavior is to retain unrecognized directives that were present in the SMA configuration, but remove those present in the MASF configuration.

The migration script then proceeds to migrate access control and trap configuration. As a side effect of running the migration script, the following directives might be expanded by the script into multiple directives with an equivalent interpretation:

- `rwcommunity`
- `rocommunity`
- `rwuser`
- `rouser`
- `trapcommunity`
- `trapsink`
- `trap2sink`
- `informsink`

- Access Control Migration Access control directives are expanded into the equivalent `com2sec`, `group`, `access` and `view` directives. Existing group names are renamed by prepending a prefix to avoid conflict with any which may already be defined in SMA.
- When migrating SNMPv1 or v2c access control, a conflict can occur if both MASF and SMA configuration files have defined access permissions for the same community and source address. The default behavior is to abort with a message, unless a use of the `-y` option specifies otherwise. If `-y agent` is specified then the MASF configuration takes precedence. If `-y master` is specified then the SMA configuration is retained.
- When migrating USM configuration (SNMPv3), a conflict can occur if both SMA and MASF configurations define a user with the same `securityName`. If this occurs, the behavior of the script is determined by the `-u` option. If `-u agent` is specified, the configuration of the user defined in the MASF configuration files is the one that is retained. Otherwise, if the `-u master` option is specified, the use defined in the SMA configuration files is retained.
- By default, the migration script attempts to migrate USM users from MASF to SMA. The script determines whether there are any SNMPv3 users present in the SMA configuration and whether the default `engineID` has been overridden in the SMA configuration files. If neither of these conditions obtain, then the any `usmUser` statements containing localized authentication keys can be migrated to SMA, along with the MASF `engineID`. This results in the `engineID` of the SMA master agent changing.
- If the script determines that there are existing SNMPv3 users or a manually configured `engineID` present in the SMA configuration, only those users defined in `createUser` statements are transferred. Those users that were defined in `usmUser` statements are transferred but will have their passwords reset to a random value. You should notify your users of their new password or reset the password yourself by editing the newly-generated configuration file.
- Trap/Inform Migration The migration script performs a check to determine whether a trap destination defined for MASF is already specified in an existing SMA `trapsink`, `trap2sink` or `informsink` directive. If this is the case, then the directive in the MASF configuration will be discarded to avoid duplicate traps/informs being received.
- `trapsink`, `trap2sink` and `informsink` directives specified in the existing SMA configuration are considered valid destinations for MASF traps/informs and will receive them from the MASF subagent after migration.
- If the `-t none` option was specified on the command line, the migration script carries over any remaining MASF trap/inform directives without modification.
- If the `-t add` option was specified (the default), the migration script expands any `trapsink`, `trap2sink`, or `informsink` directives to use the `TARGET-MIB` and `NOTIFICATION-MIB`. The `TARGET-MIB` specifies targets using IP addresses, so it might be desirable to use the `-t none` option if, for example, the network allocates IP addresses to hostnames dynamically by means of DHCP.

The expanded directives defines filters specific to the MASF agent so that traps from other subagents will not be received by migrated trap destinations. Existing filters present in the SMA configuration are, by default, not modified and might or might not receive MASF traps, depending upon the filters that were originally defined for them.

If the `-l` option is specified, any filters already defined in the `TARGET-MIB` and the `NOTIFICATION-MIB` for SMA are extended to include traps from MASF. In the event that a trap destination is already configured in the `TARGET-MIB` with the same target address and community as an existing MASF trap/inform sink, a conflict will arise.

If `-l agent` was specified and a conflict arises, the migration script uses the target SNMP parameters (that is, the SNMP version and choice of trap/inform) defined by the MASF `trap/informsink` directive to send traps to this destination. Otherwise, if the `-l master` option was specified, the conflict will be resolved using the target SNMP parameters specified in the SMA configuration.

Miscellaneous If the migration script encounters in the MASF configuration file any of the directives listed below and the directives are either not present or differ from the SMA configuration, the script will log a warning message.

- `syslocation`
- `syscontact`
- `sysname`
- `sysseervices`
- `agentgroup`
- `agentuser`
- `authtrapeenable`

Options The following options are supported:

- `-?`
- `--help` Displays usage information.
- `-c`
- `--no-community` Do not transfer v1/v2c communities.
- `-i`
- `--ignore-unrecognized-directives` Continue processing if unrecognized directives are present.
- `-l agent | master`
- `--master-trap-target=agent | master` If `agent` is specified, the existing SMA trap targets will be configured to receive traps that were previously sent to destinations for the Sun Fire SNMP agent. If `master` is specified, the targets will be configured to receive Sun Fire SNMP traps, but existing SNMP target parameters will be used.

| | |
|--------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-m</code> | |
| <code>--no-usmuser</code> | Do not transfer usm (v3) users. |
| <code>-n</code> | |
| <code>--dry-run</code> | Run the migration without modifying any files. If an error arises, continue processing. This can be used to determine the likely migration issues. |
| <code>-p enable disable error</code> | |
| <code>--use-agent-port=enable disable error</code> | Indicates whether the port originally used by the Sun Fire SNMP agent should be used by the SMA agent after migration (if the two agents are using different ports). If <code>enable</code> is specified, then the port used by the Sun Fire SNMP agent will also be used by the SMA agent after migration. If <code>disable</code> is specified, the ports used by SMA will not be updated by the migration tool. If the <code>error</code> option is specified and the SMA agent is not already using the same ports as those used by the original Sun Fire SNMP agent, an error is reported and the migration process is terminated. If no option is specified the default behavior is equivalent to the <code>error</code> flag. |
| <code>-r</code> | |
| <code>--no-trap</code> | Do not transfer trap destinations. |
| <code>-s</code> | |
| <code>--skip-user</code> | If a user is found in the MASF configuration file that cannot be created in the new configuration because of a change in the engine ID, then output a message indicating that the user could not be migrated (needs to be manually recreated) and continue processing. If this option is not present, the migration tool will consider such a situation as an error and abort. |
| <code>-t none add</code> | |
| <code>--trap-filter=none add</code> | If <code>none</code> is specified then the script will copy trap directives directly. The administrator might need to manually update the |

-u agent | master | error
--select-user=agent | master | error

configuration file to ensure traps are only delivered to their intended destinations. If add is specified, trap filters will be constructed so that traps originating from the original Sun Fire SNMP agent are delivered only to the destinations that originally received them. The default behavior is add.

Specifies that if a user with the same name is found in both configuration files that the conflict is to be resolved using the specified configuration file as input. Selecting a user from a particular file will also cause the group declaration for that user to be taken from the same file. If agent is specified then the user will be taken from the configuration file for the Sun Fire SNMP Agent. If master is specified, the user will be taken from the SMA configuration. Otherwise, if error is given, the script will terminate. If this option is not present, the default behavior is equivalent to the error flag.

-V
--version
-y agent | master | error
--select-community=agent | master | error

Display the version of this script.

Specifies that if a community with the same name is found in both configuration files that the conflict is to be resolved using the specified configuration file as input. If agent is specified then the community will be taken from the configuration file for the Sun Fire SNMP Agent. If master is specified, the community will be taken from the SMA configuration. Otherwise, if error is given, the script will terminate. If this option is not present, the default behavior is equivalent to the error flag.

Examples EXAMPLE 1 Simplest Case

The command shown below is appropriate for a simple migration. The migration fails if there are any potential conflicts.

```
# masfcnv
```

EXAMPLE 2 Migrating Such That MASF Settings Override

To migrate the MASF configuration such that it will always succeed, that MASF settings will override in the event of a conflict with SMA, and that access will still be provided on the original MASF port, enter:

```
# masfcnv -is -l agent -p enable -u agent -y agent
```

EXAMPLE 3 Dry Run, Retaining SMA Settings

To attempt a dry run and migrate the configuration such that any conflicts will be resolved by retaining existing SMA settings, enter:

```
masfcnv -l master -u master -y master
```

Exit Status 0 Success.
non-zero A problem occurred during migration.

Files /etc/sma/snmp/snmpd.conf
/var/sma_snmp/snmpd.conf SMA configuration files
/etc/opt/SUNWmasf/conf/snmpd.conf
/var/opt/SUNWmasf/snmpd.dat MASF configuration files
/tmp/sma_migration.log masfcnv log file

Notes The former path to this utility, /usr/sfw/lib, is now a link to /usr/lib.

Name mdlogd – Solaris Volume Manager daemon

Synopsis mdlogd

Description mdlogd implements a simple daemon that watches the system console looking for messages written by the Solaris Volume Manger. When a Solaris Volume Manager message is detected, mdlogd sends a generic SNMP trap.

To enable traps, you must configure mdlogd into the SNMP framework. See *Solaris Volume Manager Administration Guide*.

Usage mdlogd implements the following SNMP MIB:

```
SOLARIS-VOLUME-MGR-MIB DEFINITIONS ::= BEGIN
    IMPORTS
        enterprises FROM RFC1155-SMI
        DisplayString FROM SNMPv2-TC;

    -- Sun Private MIB for Solaris Volume Manager

    sun          OBJECT IDENTIFIER ::= { enterprises 42 }
    sunSVM       OBJECT IDENTIFIER ::= { sun 104 }

    -- this is actually just the string from /dev/log that
    -- matches the md: regular expressions.
    -- This is an interim SNMP trap generator to provide
    -- information until a more complete version is available.

    -- this definition is a formalization of the old
    -- Solaris DiskSuite mdlogd trap mib.

    svmOldTrapString OBJECT-TYPE
        SYNTAX DisplayString (SIZE (0..255))
        ACCESS read-only
        STATUS mandatory
        DESCRIPTION
            "This is the matched string that
            was obtained from /dev/log."
    ::= { sunSVM 1 }

    -- SVM Compatibility ( error trap )

    svmNotice    TrapTRAP-TYPE

Solaris Volume Manager Administration Guide

Name mdmonitord – daemon to monitor metadevices

Synopsis /usr/sbin/mdmonitord [-t *time_interval*]

Description The mdmonitord utility is part of Solaris Volume Manager. It monitors and checks RAID1 (mirrors), RAID5 and hot spares.

There are two methods for checking:

- At fixed time intervals.
- When a RAID-1 (mirror), RAID-5, or hot spare fails. A failure generates an error event which triggers a check of these metadevices.

Options The following options are supported:

- t Time interval in seconds. The default value is 0, which causes probes to occur only upon an error. If you want to run mdmonitord at a regular interval, a value of 1800 (seconds, every half hour) is recommended as a starting point.

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | storage/svm |

See Also [svcs\(1\)](#), [metaclear\(1M\)](#), [metadb\(1M\)](#), [metaddetach\(1M\)](#), [metahs\(1M\)](#), [metainit\(1M\)](#), [metaoffline\(1M\)](#), [metaonline\(1M\)](#), [metaparam\(1M\)](#), [metarecover\(1M\)](#), [metarename\(1M\)](#), [metareplace\(1M\)](#), [metaroot\(1M\)](#), [metaset\(1M\)](#), [metassist\(1M\)](#), [metastat\(1M\)](#), [metasync\(1M\)](#), [metattach\(1M\)](#), [svcadm\(1M\)](#), [md.tab\(4\)](#), [md.cf\(4\)](#), [mddb.cf\(4\)](#), [md.tab\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#), [md\(7D\)](#)

Solaris Volume Manager Administration Guide

Notes Since frequent probes can affect performance, it is recommended that the intervals between probes be limited.

The mdmonitord service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/mdmonitor
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Name mdnsd – Multicast DNS daemon

Synopsis mdnsd [-debug]

Description mdnsd is the daemon program for Multicast DNS and DNS Service Discovery.

The mdnsd daemon listens on UDP port 5353 for Multicast DNS Query packets. When it receives a query for which it knows an answer, mdnsd issues the appropriate Multicast DNS Reply packet.

The mdnsd daemon also performs Multicast DNS Queries on behalf of client processes, and maintains a cache of the replies.

The mdnsd daemon has no user-specifiable command-line argument, and users should not run mdnsd manually. The mdnsd daemon should be managed by the Solaris Management Facility (SMF) and should be administered by the [svcadm\(1M\)](#) command using the following fault management resource identifier (FMRI):

```
svc:/network/dns/multicast:default
```

To examine mdnsd's internal state for debugging and diagnostic purposes, send it a SIGUSR1 signal, and it will then log a snapshot summary of its internal state using the [syslog\(3C\)](#) facility. mdnsd uses the syslog facility code daemon and info priority level.

Options The mdnsd daemon recognizes the following option:

-debug Debug mode. The mdnsd daemon sends output to the standard error, and does not run in the background. This option is only intended for debugging the daemon.

CONFIGURATION Multicast DNS can be used to look up host names and host addresses by specifying mdns as a source for hosts and ipnodes in the name service switch configuration file [nsswitch.conf\(4\)](#). The configuration options for host name and host address queries using Multicast DNS are stored in the SMF repository. This configuration can be modified by the [svccfg\(1M\)](#) command using the following fault management resource identifier (FMRI):

```
svc:/network/dns/multicast:default
```

The configuration options for host name and host address queries using Multicast DNS are stored in a property group named “nss_mdns_config”. The properties that make up the configuration options are as follows:

search A list of search domains for host name look up. By default, no search domains are included in the configuration. The search list is currently limited to six domains.

valid A list of valid domains checked before Multicast DNS is used to look up the host name or host address for a domain. Domains specified in the search list are always included in the valid list. The valid domain list is currently limited to ten domains.

Please note the above configuration options are Volatile and may change in a future release.

Files /usr/lib/inet/mdnsd

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|--------------------------|
| Availability | service/network/dns/mdns |
| Interface Stability | Volatile |

For information on DNS Service Discovery, see <http://www.dns-sd.org/>

- Name** medstat – check the status of mediator hosts for a given diskset
- Synopsis** /usr/sbin/medstat [-q] -s *setname*
- Description** If a specified diskset has been configured for mediators, medstat attempts to contact these hosts to see if they are accessible and returns the results of the communication.
- Options**
- q This optional argument disables the printing of informative text. When used with -q, medstat still prints error messages and returns a result code.
 - s *setname* Specifies the name of a diskset on which medstat will work.
- Examples** **EXAMPLE 1** Checking diskset
- This example checks the mediator hosts for the selected diskset.
- ```
medstat -s relo-red
```
- The name of the diskset is relo-red. The medstat command prints the status for each mediator host. Additionally, if the mediator quorum is met, either through a “golden” mediator host or because half+1 of the mediator hosts respond, the exit code is 0. If the quorum is not met, then the exit code is 1. If no mediator hosts have been configured for the named diskset, the exit code is 2. The status field will contain one of the following values: Unreachable, Bad, Fatal, or Ok, where Unreachable indicates an RPC/communication problem, Bad indicates an error in the mediator data, Fatal indicates any other error condition, and Ok indicates no error conditions.
- Files** /etc/lvm/mddb Contains the mediator data for a host that has been selected as a mediator host.
- Exit Status** The following exit values are returned:
- 0 Successful completion.
  - >0 An error occurred.
- Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmdu
Interface Stability	Committed

**See Also** [metaclear\(1M\)](#), [metadb\(1M\)](#), [metadetach\(1M\)](#), [metahs\(1M\)](#), [metainit\(1M\)](#), [metaoffline\(1M\)](#), [metaonline\(1M\)](#), [metaparam\(1M\)](#), [metareplace\(1M\)](#), [metaroot\(1M\)](#), [metaset\(1M\)](#), [metastat\(1M\)](#), [metasync\(1M\)](#), [metattach\(1M\)](#), [md.cf\(4\)](#), [md.tab\(4\)](#), [mddb.cf\(4\)](#), [mddb\(4\)](#), [mediator\(7D\)](#)

Sun Cluster documentation, *Solaris Volume Manager Administration Guide*

**Notes** This command is designed for use in the high availability product.

**Name** metaclear – delete active metadevices and hot spare pools

**Synopsis** /usr/sbin/metaclear -h  
 /usr/sbin/metaclear [-s *setname*] -a [-f]  
 /usr/sbin/metaclear *component*  
 /usr/sbin/metaclear [-s *setname*] [-f] *metadevice... hot\_spare\_pool...*  
 /usr/sbin/metaclear [-s *setname*] -r [-f] *metadevice... hot\_spare\_pool...*  
 /usr/sbin/metaclear [-s *setname*] -p *component*  
 /usr/sbin/metaclear [-s *setname*] -p *metadevice*

**Description** The `metaclear` command deletes the specified metadevice or `hot_spare_pool`, or purges all soft partitions from the designated component. Once a metadevice or hot spare pool is deleted, it must be re-created using `metainit` before it can be used again.

Any metadevice currently in use (open) cannot be deleted.

**Options** Root privileges are required for all of the following options except `-h`.

- a Deletes all metadevices and configured hot spare pools in the set named by `-s`, or the local set by default.
- f Deletes (forcibly) a metadevice that contains a subcomponent in an error state.
- h Displays usage message.
- p Deletes (purges) all soft partitions from the specified metadevice or component.
- r Recursively deletes specified metadevices and hot spare pools, but does not delete metadevices on which others depend.
- s *setname* Specifies the name of the diskset on which `metaclear` will work. Using the `-s` option causes the command to perform its administrative function within the specified diskset. Without this option, the command performs its function on local metadevices and/or hot spare pools.

**Operands** *metadevice ...* Specifies the name(s) of the metadevice(s) to be deleted.

*component* Specifies the `c*d*t*s*` name(s) of the components containing soft partitions to be deleted.

*hot\_spare\_pool ...* Specifies the name(s) of the hot spare pools to be deleted. Names for hot spare pools can be any legal file name that is composed of alphanumeric characters, a dash (“-”), an underscore (“\_”), or a period (“.”). Names must begin with a letter. The words “all” and “none” are reserved and cannot be used.

**Examples** EXAMPLE 1 Deleting Various Devices

The following example deletes a metadvice named `d10`.

```
metaclear /dev/md/dsk/d10
```

The following example deletes all local metadvice and hot spare pools on the system.

```
metaclear -a
```

The following example deletes a mirror, `mymirror`, with a submirror in an error state.

```
metaclear -f mymirror
```

The following example deletes a hot spare pool, `hsp001`.

```
metaclear hsp001
```

The following example deletes a soft partition, `d23`.

```
metaclear d23
```

The following example purges all soft partitions on the slice `c2t3d5s2` if those partitions are not being used by other metadvice or are not open.

```
metaclear -p c2t3d5s2
```

The following example purges soft partitions from a metadvice.

```
metaclear -p d2
d3: Soft Partition is cleared
d4: Soft Partition is cleared
d5: Soft Partition is cleared
```

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

*Solaris Volume Manager Administration Guide*

**Name** metadb – create and delete replicas of the metadvice state database

**Synopsis** /sbin/metadb -h  
/sbin/metadb [-s *setname*]  
/sbin/metadb [-s *setname*] -a [-f] [-k *system-file*] mddbnn  
/sbin/metadb [-s *setname*] -a [-f] [-k *system-file*]  
[-c *number*] [-l *length*] *slice*...  
/sbin/metadb [-s *setname*] -d [-f] [-k *system-file*] mddbnn  
/sbin/metadb [-s *setname*] -d [-f] [-k *system-file*] *slice*...  
/sbin/metadb [-s *setname*] -i  
/sbin/metadb [-s *setname*] -p [-k *system-file*]  
[*mddb.cf-file*]

**Description** The metadb command creates and deletes replicas of the metadvice state database. State database replicas can be created on dedicated slices, or on slices that will later become part of a simple metadvice (concatenation or stripe) or RAID5 metadvice. Do not place state database replicas on fabric-attached storage, SANs, or other storage that is not directly attached to the system and available at the same point in the boot process as traditional SCSI or IDE drives. See NOTES.

The metadvice state database contains the configuration of all metadevices and hot spare pools in the system. Additionally, the metadvice state database keeps track of the current state of metadevices and hot spare pools, and their components. Solaris Volume Manager automatically updates the metadvice state database when a configuration or state change occurs. A submirror failure is an example of a state change. Creating a new metadvice is an example of a configuration change.

The metadvice state database is actually a collection of multiple, replicated database copies. Each copy, referred to as a replica, is subject to strict consistency checking to ensure correctness.

Replicated databases have an inherent problem in determining which database has valid and correct data. To solve this problem, Volume Manager uses a *majority consensus algorithm*. This algorithm requires that a majority of the database replicas be available before any of them are declared valid. This algorithm strongly encourages the presence of at least three initial replicas, which you create. A consensus can then be reached as long as at least two of the three replicas are available. If there is only one replica and the system crashes, it is possible that all metadvice configuration data can be lost.

The majority consensus algorithm is conservative in the sense that it will fail if a majority consensus cannot be reached, even if one replica actually does contain the most up-to-date data. This approach guarantees that stale data will not be accidentally used, regardless of the failure scenario. The majority consensus algorithm accounts for the following: the system will

stay running with exactly half or more replicas; the system will panic when less than half the replicas are available; the system will not reboot without one more than half the total replicas.

When used with no options, the `metadb` command gives a short form of the status of the metadvice state database. Use `metadb -i` for an explanation of the flags field in the output.

The initial state database is created using the `metadb` command with both the `-a` and `-f` options, followed by the slice where the replica is to reside. The `-a` option specifies that a replica (in this case, the initial) state database should be created. The `-f` option forces the creation to occur, even though a state database does not exist. (The `-a` and `-f` options should be used together only when no state databases exist.)

Additional replicas beyond those initially created can be added to the system. They contain the same information as the existing replicas, and help to prevent the loss of the configuration information. Loss of the configuration makes operation of the metadvice impossible. To create additional replicas, use the `metadb -a` command, followed by the name of the new slice(s) where the replicas will reside. All replicas that are located on the same slice must be created at the same time.

To delete all replicas that are located on the same slice, the `metadb -d` command is used, followed by the slice name.

When used with the `-i` option, `metadb` displays the status of the metadvice state databases. The status can change if a hardware failure occurs or when state databases have been added or deleted.

To fix a replica in an error state, delete the replica and add it back again.

The metadvice state database (`mddb`) also contains a list of the replica locations for this set (local or shared diskset).

The local set `mddb` can also contain host and drive information for each of the shared disksets of which this node is a member. Other than the diskset host and drive information stored in the local set `mddb`, the local and shared diskset `mddb`s are functionality identical.

The `mddb`s are written to during the `resync` of a mirror or during a component failure or configuration change. A configuration change or failure can also occur on a single replica (removal of a `mddb` or a failed disk) and this causes the other replicas to be updated with this failure information.

**Options** Root privileges are required for all of the following options except `-h` and `-i`.

The following options can be used with the `metadb` command. Not all the options are compatible on the same command line. Refer to the SYNOPSIS to see the supported use of the options.

- a  
Attach a new database device. The `/kernel/drv/md.conf` file is automatically updated with the new information and the `/etc/lvm/mddb.cf` file is updated as well. An alternate way to create replicas is by defining them in the `/etc/lvm/md.tab` file and specifying the assigned name at the command line in the form, `mddbnn`, where *nn* is a two-digit number given to the replica definitions. Refer to the [md.tab\(4\)](#) man page for instructions on setting up replicas in that file.
- c *number*  
Specifies the number of replicas to be placed on each device. The default number of replicas is 1.
- d  
Deletes all replicas that are located on the specified *slice*. The `/kernel/drv/md.conf` file is automatically updated with the new information and the `/etc/lvm/mddb.cf` file is updated as well.
- f  
The `-f` option is used to create the initial state database. It is also used to force the deletion of replicas below the minimum of one. (The `-a` and `-f` options should be used together only when no state databases exist.)
- h  
Displays a usage message.
- i  
Inquire about the status of the replicas. The output of the `-i` option includes characters in front of the device name that represent the status of the state database. Explanations of the characters are displayed following the replica status and are as follows:
  - d  
replica does not have an associated device ID.
  - o  
replica active prior to last `mddb` configuration change
  - u  
replica is up to date
  - l  
locator for this replica was read successfully
  - c  
replica's location was in `/etc/lvm/mddb.cf`
  - p  
replica's location was patched in kernel
  - m  
replica is master, this is replica selected as input

- 
- r  
replica does not have device relocation information
  - t  
tagged data is associated with the replica
  - W  
replica has device write errors
  - a  
replica is active, commits are occurring to this
  - M  
replica had problem with master blocks
  - D  
replica had problem with data blocks
  - F  
replica had format problems
  - S  
replica is too small to hold current database
  - R  
replica had device read errors
  - B  
tagged data associated with the replica is not valid
- k *system-file***  
Specifies the name of the kernel file where the replica information should be written. The default *system-file* is `/kernel/drv/md.conf`. This option is for use with the local diskset only.
- l *length***  
Specifies the size of each replica. The default *length* is 8192 blocks, which should be appropriate for most configurations. “Replica” sizes of less than 128 blocks are not recommended.
- p**  
Specifies updating the system file (`md.conf`) in the current working directory with entries from the `/etc/lvm/mddb.cf` file. This option is normally used to update a newly built system before it is booted for the first time. If the system has been built on a system other than the one where it will run, the location of the `mddb.cf` on the local machine can be passed as an argument. The system file to be updated can be changed using the `-k` option. This option is for use with the local diskset only.

**-s setname**

Specifies the name of the diskset on which the `metadb` command will work. Using the `-s` option will cause the command to perform its administrative function within the specified diskset. Without this option, the command will perform its function on local database replicas.

**slice**

Specifies the logical name of the physical slice (partition), such as `/dev/dsk/c0t0d0s3`.

**Examples** EXAMPLE 1 Creating Initial State Database Replicas

The following example creates the initial state database replicas on a new system.

```
metadb -a -f c0t0d0s7 c0t1d0s3 c1t0d0s7 c1t1d0s3
```

The `-a` and `-f` options force the creation of the initial database and replicas. You could then create metadevices with these same slices, making efficient use of the system.

## EXAMPLE 2 Adding Two Replicas on Two New Disks

This example shows how to add two replicas on two new disks that have been connected to a system currently running Volume Manager.

```
metadb -a c0t2d0s3 c1t1d0s3
```

## EXAMPLE 3 Deleting Two Replicas

This example shows how to delete two replicas from the system. Assume that replicas have been set up on `/dev/dsk/c0t2d0s3` and `/dev/dsk/c1t1d0s3`.

```
metadb -d c0t2d0s3 c1t1d0s3
```

Although you can delete all replicas, you should never do so while metadevices still exist. Removing all replicas causes existing metadevices to become inoperable.

**Files** `/etc/lvm/mddb.cf`

Contains the location of each copy of the metadevice state database.

`/etc/lvm/md.tab`

Workspace file for metadevice database configuration.

`/kernel/drv/md.conf`

Contains database replica information for all metadevices on a system. Also contains Solaris Volume Manager configuration information.

**Exit Status** The following exit values are returned:

0  
successful completion

>0  
an error occurred

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm
Interface Stability	Committed

**See Also** [mdmonitord\(1M\)](#), [metaclear\(1M\)](#), [metadetach\(1M\)](#), [metahs\(1M\)](#), [metainit\(1M\)](#), [metaoffline\(1M\)](#), [metaonline\(1M\)](#), [metaparam\(1M\)](#), [metarecover\(1M\)](#), [metarename\(1M\)](#), [metareplace\(1M\)](#), [metaroot\(1M\)](#), [metaset\(1M\)](#), [metassist\(1M\)](#), [metastat\(1M\)](#), [metasync\(1M\)](#), [metattach\(1M\)](#), [md.tab\(4\)](#), [md.cf\(4\)](#), [mddb.cf\(4\)](#), [md.tab\(4\)](#), [attributes\(5\)](#), [md\(7D\)](#)

*Solaris Volume Manager Administration Guide*

**Notes** Replicas cannot be stored on fabric-attached storage, SANs, or other storage that is not directly attached to the system. Replicas must be on storage that is available at the same point in the boot process as traditional SCSI or IDE drives. A replica can be stored on a:

- Dedicated local disk partition
- Local partition that will be part of a volume
- Local partition that will be part of a UFS logging device

**Name** metadevadm – update metadvice information

**Synopsis** /usr/sbin/metadevadm [-h] [-n] [ [-l]-r] [-s *setname*]  
[-u *disk\_specifier*] [-v]

**Description** The `metadevadm` command facilitates the administration of device ID entries in Solaris Volume Manager. Use this command when the pathname stored in the metadvice state database no longer correctly addresses the device or when a disk drive has had its device ID changed.

This command requires root privileges.

**Options** The following options are supported.

- h Provide a help display.
- l Specify that `metadevadm` log to `syslog(3C)`. `metadevadm` logs to the DAEMON facility at the ERR level by default. See `syslog.conf(4)` for additional information on changing logging levels.  
  
Use this option anytime. It is most useful in startup scripts and less useful interactively.
- n Emulate the effect of a command, without making any changes to the system.
- r Recompute the pathname and disk specifier (including slice) associated with all devices in the metadvice state database if the device supports device IDs. If a device does not support device IDs or the device is not available, then no action is taken for that device.  
  
Use this option when the disk has been moved or readdressed.  
  
This option is run automatically at boot time to detect device ID changes and update the state database.
- s *setname* Specify the name of the disk set on which `metadevadm` works. This option causes the command to perform its administrative function within the specified disk set. Without this option, the command performs its function on devices in the local disk set.
- u *disk\_specifier* Obtain the device ID associated with the *disk\_specifier* (for example, `c1t2d0`) of a device and update the metadvice state database. If the device ID has not changed this option does nothing. Use this option when a disk drive has had its device ID changed during a firmware upgrade or due to changing the controller of a storage subsystem.
- v Execute in verbose mode. This option has no effect when used with `-u`. Verbose is the default.

**Examples** EXAMPLE 1 Updating Device ID of Disk

The following example updates the device c2t3d0:

```
metadevadm -u c2t3d0
Updating SLVM device relocation information for c2t3d0.
Old device reloc information: id19280192391293123012012010012012091398
New device reloc information: id19380192391293123012012010012012091398
```

The following example is a variation of the preceding, using the full pathname.

```
metadevadm -u /dev/dsk/c2t3d0
```

The following example uses the -n option, which means that the command is emulated, but does not take effect. Note that when the -v option is used with -u, -v has no effect (verbose is the default).

```
metadevadm -u -v -n c2t3d0
Updating SLVM device relocation information for c2t3d0.
Old device reloc information: id19280192391293123012012010012012091398
New device reloc information: id19380192391293123012012010012012091398
```

## EXAMPLE 2 Recomputing Pathnames

In the following example, all device names are valid.

```
metadevadm -r
Disk movement detected.
Updating device names in SLVM.
```

In the following example, once again device names are valid.

```
metadevadm -r -v
Disk movement detected.
Updating device names in SLVM.
c0t0d0s0 changed to c0t0d1s0 from device relocation information
id12098123lknklsdjaasdkfjadfjakds
```

In the following example, metadevadm detects an invalid device name.

```
metadevadm -r
Invalid device relocation information detected in SLVM.
Please check status of following disk(s):
c3t0d0
```

**Return Values** The following exit values are returned:

- 0 Command was successful.
- 1 metadevadm encountered an error condition.

- An invalid device ID was detected when using the `-r` option. This is for use in the `rc2.d` script. See `init.d(4)`.

 /usr/sbin/metahs [-s *setname*] -r *hot\_spare\_pool component-old*  
 /usr/sbin/metahs [-s *setname*] -r *all component-old component-new*  
 /usr/sbin/metahs [-s *setname*] -i [*hot\_spare\_pool*]. . .

**Description** The metahs command manages existing hot spares and hot spare pools. It is used to add, delete, enable, and replace components (slices) in hot spare pools. Like the `metainit` command, the metahs command can also create an initial hot spare pool. The metahs command does not replace a component of a metadvice. This function is performed by the `metareplace` command.

Hot spares are always in one of three states: available, in-use, or broken. Available hot spares are running and ready to accept data, but are not currently being written to or read from. In-use hot spares are currently being written to and read from. Broken hot spares are out of service and should be repaired. The status of hot spares is displayed when metahs is invoked with the `-i` option.

Solaris Volume Manager supports storage devices and logical volumes, including hot spares, greater than 1 terabyte (TB) when Solaris 10 is running a 64-bit kernel.

If a system with large volumes or hot spares is rebooted under a 32-bit Solaris 10 kernel, the large volumes are visible through `metastat` output, but they cannot be accessed, modified or deleted, and no new large volumes can be created. Any volumes or file systems on a large volume in this situation are also unavailable. If a system with large volumes is rebooted under a version of Solaris prior to Solaris 10, Solaris Volume Manager will not start. All large volumes must be removed before Solaris Volume Manager runs under another version of the Solaris Operating Environment.

**Options** Root privileges are required for any of the following options except `-i`.

The following options are supported:

-a <i>all component</i>	Add <i>component</i> to all hot spare pools. <i>all</i> is not case sensitive.
-a <i>hot_spare_pool [component]</i>	Add the <i>component</i> to the specified <i>hot_spare_pool</i> . <i>hot_spare_pool</i> is created if it does not already exist.

<code>-d all component</code>	Delete <i>component</i> from all the hot spare pools. The <i>component</i> cannot be deleted if it is in the in-use state.
<code>-d hot_spare_pool [component]</code>	Delete <i>hot_spare_pool</i> , if the <i>hot_spare_pool</i> is both empty and not referenced by a metadvice. If <i>component</i> is specified, it is deleted from the <i>hot_spare_pool</i> . Hot spares in the in-use state cannot be deleted.
<code>-e component</code>	Enable <i>component</i> to be available for use as a hot spare. The <i>component</i> can be enabled if it is in the broken state and has been repaired.
<code>-i [hot_spare_pool . . .]</code>	Display the status of the specified <i>hot_spare_pool</i> or for all hot spare pools if one is not specified.
<code>-r all component-old component-new</code>	Replace <i>component-old</i> with <i>component-new</i> in all hot spare pools which have the component associated. Components cannot be replaced from any hot spare pool if the old hot spare is in the in-use state.
<code>-r hot_spare_pool component-old component-new</code>	Replace <i>component-old</i> with <i>component-new</i> in the specified <i>hot_spare_pool</i> . Components cannot be replaced from a hot spare pool if the old hot spare is in the in-use state.
<code>-s setname</code>	Specify the name of the diskset on which metahs works. Using the <code>-s</code> option causes the command to perform its administrative function within the specified diskset. Without this option, the command performs its function on local hot spare pools.

**Operands** The following operands are supported:

<i>component</i>	The logical name for the physical slice (partition) on a disk drive, such as <code>/dev/dsk/c0t0d0s2</code> .
<i>hot_spare_pool</i>	Names for hot spare pools can be any legal file name that is composed of alphanumeric characters, a dash (“-”), an underscore (“_”), or a period

(“.“). Names must begin with a letter. The words “all” and “none” are reserved and cannot be used.

**Examples** **EXAMPLE 1** Adding a Hot Spare to a Hot Spare Pool

The following example adds a hot spare `/dev/dsk/c0t0d0s7` to a hot spare pool `mirror1_pool`:

```
metahs -a mirror1_pool c0t0d0s7
```

When the hot spare is added to the pool, the existing order of the hot spares already in the pool is preserved. The new hot spare is added at the end of the list of hot spares in the hot spare pool specified.

**EXAMPLE 2** Adding a Hot Spare to All Currently Defined Pools

This example adds a hot spare to the hot spare pools that are currently defined:

```
metahs -a all c0t0d0s7
```

The keyword `all` in this example specifies adding the hot spare, `/dev/dsk/c0t0d0s7`, to all the hot spare pools.

**EXAMPLE 3** Deleting a Hot Spare

This example deletes a hot spare, `/dev/dsk/c0t0d0s7`, from a hot spare pool, `hsp003`:

```
metahs -d hsp003 c0t0d0s7
```

When you delete a hot spare, the position of the remaining hot spares in the pool changes to reflect the new order. For instance, if in this example `/dev/dsk/c0t0d0s7` were the second of three hot spares, after deletion the third hot spare would move to the second position.

**EXAMPLE 4** Replacing a Hot Spare

This example replaces a hot spare that was previously defined:

```
metahs -r hsp001 c0t1d0s0 c0t3d0s0
```

In this example, the hot spare `/dev/dsk/c0t1d0s0` is replaced by `/dev/dsk/c0t3d0s0`. The order of the hot spares does not change.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm
Interface Stability	Committed

*Solaris Volume Manager Administration Guide*

**Warnings** Do not create large (>1 TB) volumes if you expect to run the Solaris Operating Environment with a 32-bit kernel or if you expect to use a version of the Solaris Operating Environment prior to Solaris 10.

**Name** metaimport – imports disk sets into existing Solaris Volume Manager configurations

**Synopsis** metaimport -s *setname* [-n] [-f] [-v] [*disks*]...  
 metaimport -r [-v] [*disks*]...  
 metaimport -V  
 metaimport -?

**Description** The metaimport command allows the importing of disk sets, including replicated disk sets, into an existing Solaris Volume Manager configuration. Replicated disk sets are disk sets created using remote replication software.

The default Solaris Volume Manager configuration specifies a maximum number of disk sets that can be configured. The metaimport command fails if importing the disk set would result in exceeding the number of disk sets configured on the system. To increase the number of disk sets allowed on a system, see the *Solaris Volume Manager Administration Guide*.

Use [metaset\(1M\)](#) or [metastat\(1M\)](#) to view the configuration of the imported set.

You must run metaimport as root.

metaimport requires a functional Solaris Volume Manager configuration before it runs.

**Options** The following options are supported:

- f Force the import, even if a quorum of replicas from the imported disk set is not available. This option could result in corrupt configurations and should only be used when metaimport fails with the “Insufficient quorum detected; exiting” error. If only a partial disk set is available, this option might be necessary to successfully import. Some or all data could be corrupted or unavailable when importing a partial set or a set lacking a replica quorum.
- n Does not actually perform the operation, but shows the output or errors that would have resulted from the operation, had it been run.
- r Report on the non-configured disk sets found on the system. If no disk device or LUN is specified, metaimport reports on all non-configured disk sets attached to the system. When the name of one disk is specified, metaimport reports on the disk set (or virtual LUN) containing the specified disk. If two or more disks are specified, metaimport reports on the set (or sets, if they belong to different disk sets) containing the specified disks. If two or more disks are specified, metaimport reports on the set (or sets, if they belong to different disk sets) containing the specified disks.

This option can be used in conjunction with the -v option to give verbose output on each disk set reported.

- s *setname* Specify the disk set name to use when importing. The imported disk set will be called *setname*, without regard to the name it may have had on a different system.
- v Verbose. Provides detailed information about the metadb replica location and status. It also provides detailed information about the disk set configuration and status similar to the “metastat -c” output.
- V Version information.
- ? Display a help message.

### Examples **EXAMPLE 1** Importing a Disk Set

The following example creates a disk set called `blue` and identifies `c1t5d0` as a disk containing a state database replica from the disk set being imported.

```
metainport -s blue c1t5d0
```

### **EXAMPLE 2** Reporting Disk Sets to Import

The following example scans all disks and LUNs attached to the system and configured as part of the system. It scans for disks that could be part of a disk set to be imported. Components that are already part of the Solaris Volume Manager configuration are ignored.

This use of `metainport` provides suggested forms of the `metainport` command to use to actually import the disk sets that have been found. You can specify a component on the command line to reduce the scope of the scan and generate results more quickly.

```
metainport -r
```

- Exit Status**
- 0 Successful completion.
  - >0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm
Interface Stability	Committed

**See Also** [mdmonitord\(1M\)](#), [metaclear\(1M\)](#), [metadb\(1M\)](#), [metadetach\(1M\)](#), [metahs\(1M\)](#), [metainit\(1M\)](#), [metaoffline\(1M\)](#), [metaonline\(1M\)](#), [metaparam\(1M\)](#), [metarecover\(1M\)](#), [metareplace\(1M\)](#), [metaroot\(1M\)](#), [metaset\(1M\)](#), [metastat\(1M\)](#), [metasync\(1M\)](#), [metattach\(1M\)](#), [md.tab\(4\)](#), [md.cf\(4\)](#), [mddb.cf\(4\)](#), [attributes\(5\)](#)

*Solaris Volume Manager Administration Guide*

**Name** metainit – configure metadevices

**Synopsis** /sbin/metainit -h

/sbin/metainit [*generic options*] *concat/stripe numstripes width component...* [-i *interlace*]

/sbin/metainit [*width component...* [-i *interlace*]] [-h *hot\_spare\_pool*]

/sbin/metainit [*generic options*] *mirror* -m *submirror* [*read\_options*] [*write\_options*] [*pass\_num*]

/sbin/metainit [*generic options*] *RAID* -r *component...* [-i *interlace*] [-h *hot\_spare\_pool*] [-k] [-o *original\_column\_count*]

/sbin/metainit [*generic options*] *hot\_spare\_pool* [*hot spare...*]

/sbin/metainit [*generic options*] *metadevice-name*

/sbin/metainit [*generic options*] -a

/sbin/metainit [*generic options*] *softpart* -p [-e] *component* [-A *alignment*] *size*

/sbin/metainit -r

**Description** The metainit command configures metadevices and hot spares according to the information specified on the command line. Alternatively, you can run metainit so that it uses configuration entries you specify in the /etc/lvm/md.tab file (see [md.tab\(4\)](#)). All metadevices must be set up by the metainit command before they can be used.

Solaris Volume Manager supports storage devices and logical volumes greater than 1 terabyte (TB) when a system runs a 64-bit Solaris kernel. Support for large volumes is automatic. If a device greater than 1 TB is created, Solaris Volume Manager configures it appropriately and without user intervention.

If a system with large volumes is rebooted under a 32-bit Solaris kernel, the large volumes are visible through `metastat` output. Large volumes cannot be accessed, modified or deleted, and no new large volumes can be created. Any volumes or file systems on a large volume in this situation are unavailable. If a system with large volumes is rebooted under a version of Solaris prior to the Solaris 9 4/03 release, Solaris Volume Manager does not start. You must remove all large volumes before Solaris Volume Manager runs under an earlier version of the Solaris Operating System.

If you edit the /etc/lvm/md.tab file to configure metadevices, specify one complete configuration entry per line. You then run the metainit command with either the -a option, to activate all metadevices you entered in the /etc/lvm/md.tab file, or with the metadevice name corresponding to a specific configuration entry.

`metainit` does not maintain the state of the volumes that would have been created when `metainit` is run with both the `-a` and `-n` flags. Any volumes in `md.tab` that have dependencies on other volumes in `md.tab` are reported as errors when `metainit -a -n` is run, although the operations might succeed when `metainit -a` is run. See [md.tab\(4\)](#).

Solaris Volume Manager never updates the `/etc/lvm/md.tab` file. Complete configuration information is stored in the metadvice state database, not `md.tab`. The only way information appears in `md.tab` is through editing it by hand.

When setting up a disk mirror, the *first* step is to use `metainit` create a one-on-one concatenation for the root slice. See [EXAMPLES](#).

**Options** The following options are supported:

Generic Options Root privileges are required for all of the following options except `-h`.

The following generic options are supported:

`-f`

Forces the `metainit` command to continue even if one of the slices contains a mounted file system or is being used as swap, or if the stripe being created is smaller in size than the underlying soft partition. This option is required when configuring mirrors on root (`/`), swap, and `/usr`.

`-h`

Displays usage message.

`-n`

Checks the syntax of your command line or `md.tab` entry without actually setting up the metadvice. If used with `-a`, all devices are checked but not initialized.

`-r`

Only used in a shell script at boot time. Sets up all metadvice that were configured before the system crashed or was shut down. The information about previously configured metadvice is stored in the metadvice state database (see [metadb\(1M\)](#)).

`-s setname`

Specifies the name of the diskset on which `metainit` works. Without the `-s` option, the `metainit` command operates on your local metadvice and/or hotspares.

Concat/Stripe Options The following concat/stripe options are supported:

*concat/stripe*

Specifies the metadvice name of the concatenation, stripe, or concatenation of stripes being defined.

*numstripes*

Specifies the number of individual stripes in the metadvice. For a simple stripe, *numstripes* is always 1. For a concatenation, *numstripes* is equal to the number of slices. For a concatenation of stripes, *numstripes* varies according to the number of stripes.

*width*

Specifies the number of slices that make up a stripe. When *width* is greater than 1, the slices are striped.

*component*

The logical name for the physical slice (partition) on a disk drive, such as `/dev/dsk/c0t0d0s0`. For RAID level 5 metadevices, a minimum of three slices is necessary to enable striping of the parity information across slices.

*-i interlace*

Specifies the interlace size. This value tells Solaris Volume Manager how much data to place on a slice of a striped or RAID level 5 metadevice before moving on to the next slice. *interlace* is a specified value, followed by either 'k' for kilobytes, 'm' for megabytes, or 'b' for blocks. The characters can be either uppercase or lowercase. The *interlace* specified cannot be less than 16 blocks, or greater than 100 megabytes. If *interlace* is not specified, it defaults to 512 kilobytes.

*-h hot\_spare\_pool*

Specifies the *hot\_spare\_pool* to be associated with the metadevice. If you use the command line, the hot spare pool must have been previously created by the `metainit` command before it can be associated with a metadevice. Use `/-h hspnnn` when the concat/striping being created is to be used as a submirror.

Names for hot spare pools can be any legal file name that is composed of alphanumeric characters, a dash ("-"), an underscore ("\_"), or a period ("."). Names must begin with a letter. The words "all" and "none" are reserved and cannot be used.

Mirror Options The following mirror options are supported:

*mirror -m submirror*

Specifies the metadevice name of the mirror. The `-m` indicates that the configuration is a mirror. *submirror* is a metadevice (stripe or concatenation) that makes up the initial one-way mirror. Solaris Volume Manager supports a maximum of four-way mirroring. When defining mirrors, first create the mirror with the `metainit` command as a one-way mirror. Then attach subsequent submirrors using the `metattach` command. This method ensures that Solaris Volume Manager properly syncs the mirrors. (The second and any subsequent submirrors are first created using the `metainit` command.)

*read\_options*

The following read options for mirrors are supported:

*-g*

Enables the geometric read option, which results in faster performance on sequential reads.

*-r*

Directs all reads to the first submirror. This should only be used when the devices comprising the first submirror are substantially faster than those of the second mirror. This flag cannot be used with the `-g` flag.

If neither the `-g` nor `-r` flags are specified, reads are made in a round-robin order from all submirrors in the mirror. This enables load balancing across the submirrors.

#### *write\_options*

The following write options for mirrors are supported:

`-S`

Performs serial writes to mirrors. The first submirror write completes before the second is started. This can be useful if hardware is susceptible to partial sector failures. If `-S` is not specified, writes are replicated and dispatched to all mirrors simultaneously.

#### *pass\_num*

A number in the range 0-9 at the end of an entry defining a mirror that determines the order in which that mirror is resynced during a reboot. The default is 1. Smaller pass numbers are resynced first. Equal pass numbers are run concurrently. If 0 is used, the resync is skipped. 0 should be used only for mirrors mounted as read-only, or as swap.

RAID Level 5 Options The following RAID level 5 options are available:

#### *RAID -r*

Specifies the name of the RAID level 5 metadvice. The `-r` specifies that the configuration is RAID level 5.

`-k`

For RAID level 5 metadvice, informs the driver that it is not to initialize (zero the disk blocks) due to existing data. Only use this option to recreate a previously created RAID level 5 device.

Use the `-k` option with extreme caution. This option sets the disk blocks to the OK state. If any errors exist on disk blocks within the metadvice, Solaris Volume Manager might begin fabricating data. Instead of using the `-k` option, you might want to initialize the device and restore data from tape.

#### `-o` *original\_column\_count*

For RAID level 5 metadvice, used with the `-k` option to define the number of original slices in the event the originally defined metadvice was grown. This is necessary since the parity segments are not striped across concatenated devices.

Use the `-o` option with extreme caution. This option sets the disk blocks to the OK state. If any errors exist on disk blocks within the metadvice, Solaris Volume Manager might begin fabricating data. Instead of using the `-o` option, you might want to initialize the device and restore data from tape.

Soft Partition Options The following soft partition options are supported:

#### *softpart -p [-e] component [-A alignment] size*

The *softpart* argument specifies the name of the soft partition. The `-p` specifies that the configuration is a soft partition.

The `-e` specifies that the entire disk specified by *component* as `c*t*d*` should be repartitioned and reserved for soft partitions. The specified component is repartitioned such that slice 7 reserves space for system (state database replica) usage and slice 0 contains all remaining space on the disk. Slice 7 is a minimum of 4MB, but can be larger, depending on the disk geometry. The newly created soft partition is placed on slice 0 of the device.

The *component* argument specifies the disk (`c*t*d*`), slice (`c*t*d*s*`), or meta device (`d*`) from which to create the soft partition. The *size* argument determines the space to use for the soft partition and can be specified in `K` or `k` for kilobytes, `M` or `m` for megabytes, `G` or `g` for gigabytes, `T` or `t` for terabyte (one terabyte is the maximum size), and `B` or `b` for blocks (sectors). All values represent powers of 2, and upper and lower case options are equivalent. Only integer values are permitted.

The `-A` alignment option sets the value of the soft partition extent alignment. This option used when it is important specify a starting offset for the soft partition. It preserves the data alignment between the metadvice address space and the address space of the underlying physical device. For example, a hardware device that does checksumming should not have its I/O requests divided by Solaris Volume Manager. In this case, use a value from the hardware configuration as the value for the alignment. When you use this option in conjunction with a software I/O load, the alignment value corresponds to the I/O load of the application. This prevents I/O from being divided unnecessarily and affecting performance.

The literal `all`, used instead of specifying size, specifies that the soft partition should occupy all available space on the device.

Hot Spare Pool Options The following hot spare pool options are supported:

*hot\_spare\_pool* [ *hotspare...* ]

When used as arguments to the `metainit` command, *hot\_spare\_pool* defines the name for a hot spare pool, and *hotspare...* is the logical name for the physical slice(s) for availability in that pool. Names for hot spare pools can be any legal file name that is composed of alphanumeric characters, a dash (“-”), an underscore (“\_”), or a period (“.”). Names must begin with a letter. The words “all” and “none” are reserved and cannot be used.

md.tab File Options The following `md.tab` file options are supported:

*metadvice-name*

When the `metainit` command is run with a *metadvice-name* as its only argument, it searches the `/etc/lvm/md.tab` file to find that name and its corresponding entry. The order in which entries appear in the `md.tab` file is unimportant. For example, consider the following `md.tab` entry:

```
d0 2 1 c1t0d0s0 1 c2t1d0s0
```

When you run the command `metainit d0`, it configures metadvice `d0` based on the configuration information found in the `md.tab` file.

-a

Activates all metadevices defined in the `md.tab` file.

`metainit` does not maintain the state of the volumes that would have been created when `metainit` is run with both the `-a` and `-n` flags. If a device `d0` is created in the first line of the `md.tab` file, and a later line in `md.tab` assumes the existence of `d0`, the later line fails when `metainit -an` runs (even if it would succeed with `metainit -a`).

### Examples **EXAMPLE 1** Creating a One-on-One Concatenation

The following command creates a one-on-one concatenation for the root slice. This is the first step you take when setting up a mirror for the root slice (and any other slice that cannot be unmounted). The `-f` option is required to create a volume with an existing file system, such as `root(/)`.

```
metainit -f dl 1 1 c0t0d0s0
```

The preceding command makes `d1` a one-on-one concatenation, using the root slice. You can then enter:

```
metainit d0 -m d1
```

...to make a one-way mirror of the root slice.

### **EXAMPLE 2** Concatenation

All drives in the following examples have the same size of 525 Mbytes.

This example shows a metadvice, `/dev/md/dsk/d7`, consisting of a concatenation of four slices.

```
metainit d7 4 1 c0t1d0s0 1 c0t2d0s0 1 c0t3d0s0 1 /dev/dsk/c0t4d0s0
```

The number 4 indicates there are four individual stripes in the concatenation. Each stripe is made of one slice, hence the number 1 appears in front of each slice. The first disk sector in all of these devices contains a disk label. To preserve the labels on devices `/dev/dsk/c0t2d0s0`, `/dev/dsk/c0t3d0s0`, and `/dev/dsk/c0t4d0s0`, the metadisk driver must skip at least the first sector of those disks when mapping accesses across the concatenation boundaries. Because skipping only the first sector would create an irregular disk geometry, the entire first cylinder of these disks is skipped. This allows higher level file system software to optimize block allocations correctly.

### **EXAMPLE 3** Stripe

This example shows a metadvice, `/dev/md/dsk/d15`, consisting of two slices.

```
metainit d15 1 2 c0t1d0s0 c0t2d0s0 -i 32k
```

The number 1 indicates that one stripe is being created. Because the stripe is made of two slices, the number 2 follows next. The optional `-i` followed by `32k` specifies the interlace size as 32 Kbytes. If the interlace size were not specified, the stripe would use the default value of 16

**EXAMPLE 3** Stripe (Continued)

Kbytes.

**EXAMPLE 4** Concatenation of Stripes

This example shows a metadvice, `/dev/md/dsk/d75`, consisting of a concatenation of two stripes of three disks.

```
metainit d75 2 3 c0t1d0s0 c0t2d0s0 \
 c0t3d0s0 -i 16k \
 3 c1t1d0s0 c1t2d0s0 c1t3d0s0 -i 32k
```

On the first line, the `-i` followed by `16k` specifies that the stripe interlace size is 16 Kbytes. The second set specifies the stripe interlace size as 32 Kbytes. If the second set did not specify 32 Kbytes, the set would use the default interlace value of 16 Kbytes. The blocks of each set of three disks are interlaced across three disks.

**EXAMPLE 5** Mirroring

This example shows a two-way mirror, `/dev/md/dsk/d50`, consisting of two submirrors. This mirror does not contain any existing data.

```
metainit d51 1 1 c0t1d0s0
metainit d52 1 1 c0t2d0s0
metainit d50 -m d51
metattach d50 d52
```

In this example, two submirrors, `d51` and `d52`, are created with the `metainit` command. These two submirrors are simple concatenations. Next, a one-way mirror, `d50`, is created using the `-m` option with `d51`. The second submirror is attached later using the `metattach` command. When creating a mirror, any combination of stripes and concatenations can be used. The default read and write options in this example are a round-robin read algorithm and parallel writes to all submirrors.

**EXAMPLE 6** Creating a metadvice in a diskset

This example shows a metadvice, `/dev/md/dsk/d75`, consisting of a concatenation of two stripes within a diskset called `set1`.

```
metainit -s set1 d75 2 3 c2t1d0s0 c2t2d0s0 \
 c2t3d0s0 -i 32k
metainit -s set1 d51 1 1 c2t1d0s0
metainit -s set1 d52 1 1 c3t1d0s0
metainit -s set1 d50 -m d51
metattach -s set1 d50 d52
```

In this example, a diskset is created using the `metaset` command. Metadevices are then created within the diskset using the `metainit` command. The two submirrors, `d51` and `d52`, are simple concatenations. Next, a one-way mirror, `d50`, is created using the `-m` option with

**EXAMPLE 6** Creating a metadvice in a diskset (Continued)

d51. The second submirror is attached later using the `metattach` command. When creating a mirror, any combination of stripes and concatenations can be used. The default read and write options in this example are a round-robin read algorithm and parallel writes to all submirrors.

**EXAMPLE 7** RAID Level 5

This example shows a RAID level 5 device, `d80`, consisting of three slices:

```
metainit d80 -r c1t0d0s0 c1t1d0s0 c1t3d0s0 -i 20k
```

In this example, a RAID level 5 metadvice is defined using the `-r` option with an interlace size of 20 Kbytes. The data and parity segments are striped across the slices, `c1t0d0s0`, `c1t2d0s0`, and `c1t3d0s0`.

**EXAMPLE 8** Soft Partition

The following example shows a soft partition device, `d1`, built on metadvice `d100` and 100 Mbytes (indicated by `100M`) in size:

```
metainit d1 -p d100 100M
```

The preceding command creates a 100 Mbyte soft partition on the `d100` metadvice. This metadvice could be a RAID level 5, stripe, concatenation, or mirror.

**EXAMPLE 9** Soft Partition on Full Disk

The following example shows a soft partition device, `d1`, built on disk `c3t4d0`:

```
metainit d1 -p -e c3t4d0 9G
```

In this example, the disk is repartitioned and a soft partition is defined to occupy all 9 Gbytes of disk `c3t4d0s0`.

**EXAMPLE 10** Soft Partition Taking All Available Space

The following example shows a soft partition device, `d1`, built on disk `c3t4d0`:

```
metainit d1 -p -e c3t4d0 all
```

In this example, the disk is repartitioned and a soft partition is defined to occupy all available disk space on slice `c3t4d0s0`.

**EXAMPLE 11** Hot Spare

This example shows a two-way mirror, `/dev/md/dsk/d10`, and a hot spare pool with three hot spare components. The mirror does not contain any existing data.

```
metainit hsp001 c2t2d0s0 c3t2d0s0 c1t2d0s0
metainit d41 1 1 c1t0d0s0 -h hsp001
metainit d42 1 1 c3t0d0s0 -h hsp001
```

**EXAMPLE 11** Hot Spare (Continued)

```
metainit d40 -m d41
metattach d40 d42
```

In this example, a hot spare pool, `hsp001`, is created with three slices from three different disks used as hot spares. Next, two submirrors are created, `d41` and `d42`. These are simple concatenations. The `metainit` command uses the `-h` option to associate the hot spare pool `hsp001` with each submirror. A one-way mirror is then defined using the `-m` option. The second submirror is attached using the `metattach` command.

**EXAMPLE 12** Setting the Value of the Soft Partition Extent Alignment

This example shows how to set the alignment of the soft partition to 1 megabyte.

```
metainit -s red d13 -p clt3d0s4 -A 1m 4m
```

In this example the soft partition, `d13`, is created with an extent alignment of 1 megabyte. The `metainit` command uses the `-A` option with an alignment of `1m` to define the soft partition extent alignment.

**Files** `/etc/lvm/md.tab`

Contains list of metadvice and hot spare configurations for batch-like creation.

**Warnings** This section contains information on different types of warnings.

**Devices and Volumes Greater Than 1 TB** Do not create large (>1 TB) volumes if you expect to run the Solaris Operating Environment with a 32-bit kernel or if you expect to use a version of the Solaris Operating Environment prior to Solaris 10.

**Multi-Way Mirror** Do not use the `metainit` command to create a multi-way mirror. Rather, create a one-way mirror with `metainit` then attach additional submirrors with `metattach`. When the `metattach` command is not used, no resync operations occur and data could become corrupted.

If you use `metainit` to create a mirror with multiple submirrors, the following message is displayed:

```
WARNING: This form of metainit is not recommended.
The submirrors may not have the same data.
Please see ERRORS in metainit(1M) for additional information.
```

**Truncation of Soft Partitions** When creating stripes on top of soft partitions it is possible for the size of the new stripe to be less than the size of the underlying soft partition. If this occurs, `metainit` fails with an error indicating the actions required to overcome the failure.

If you use the `-f` option to override this behavior, the following message is displayed:

```
WARNING: This form of metainit is not recommended.
The stripe is truncating the size of the underlying device.
Please see ERRORS in metainit(1M) for additional information.
```

**Write-On-Write Problem** When mirroring data in Solaris Volume Manager, transfers from memory to the disks do not all occur at exactly the same time for all sides of the mirror. If the contents of buffers are changed while the data is in-flight to the disk (called write-on-write), then different data can end up being stored on each side of a mirror.

This problem can be addressed by making a private copy of the data for mirror writes, however, doing this copy is expensive. Another approach is to detect when memory has been modified across a write by looking at the dirty-bit associated with the memory page. Solaris Volume Manager uses this dirty-bit technique when it can. Unfortunately, this technique does not work for raw I/O or direct I/O. By default, Solaris Volume Manager is tuned for performance with the liability that mirrored data might be out of sync if an application does a “write-on-write” to buffers associated with raw I/O or direct I/O. Without mirroring, you were not guaranteed what data would actually end up on media, but multiple reads would return the same data. With mirroring, multiple reads can return different data. The following line can be added to `/etc/system` to cause a stable copy of the buffers to be used for all raw I/O and direct I/O write operations.

```
set md_mirror:md_mirror_wow_flg=0x20
```

Setting this flag degrades performance.

**Exit Status** The following exit values are returned:

- 0  
Successful completion.
- >0  
An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

*Solaris Volume Manager Administration Guide*

**Limitations** Recursive mirroring is not allowed; that is, a mirror cannot appear in the definition of another mirror.

Recursive logging is not allowed; that is, a trans metadvice cannot appear in the definition of another metadvice.

Stripes, concatenations, and RAID level 5 metadvice must consist of slices only.

Mirroring of RAID level 5 metadvice is not allowed.

Soft partitions can be built on raw devices, or on stripes, RAID level 5, or mirrors.

RAID level 5 or stripe metadvice can be built directly on soft partitions.

**Notes** Trans metadvice have been replaced by UFS logging. Existing trans devices are *not* logging--they pass data directly through to the underlying device. See [mount\\_ufs\(1M\)](#) for more information about UFS logging.

**Name** metaoffline, metaonline – place submirrors offline and online

**Synopsis** /usr/sbin/metaoffline -h  
/usr/sbin/metaoffline [-s *setname*] [-f] *mirror submirror*  
/usr/sbin/metaonline -h  
/usr/sbin/metaonline [-s *setname*] *mirror submirror*

**Description** The `metaoffline` command prevents Solaris Volume Manager from reading and writing to the submirror that has been taken offline. While the submirror is offline, all writes to the mirror will be kept track of (by region) and will be written when the submirror is brought back online. The `metaoffline` command can also be used to perform online backups: one submirror is taken offline and backed up while the mirror remains accessible. (However, if this is a two-way mirror, data redundancy is lost while one submirror is offline.) The `metaoffline` command differs from the `metadetach` command because it does not sever the logical association between the submirror and the mirror. To completely remove a submirror from a mirror, use the `metadetach` command.

A submirror that has been taken offline will only remain offline until the `metaonline` command is invoked or the system is rebooted.

When the `metaonline` command is used, reading from and writing to the submirror resumes. A resync is automatically invoked to resync the regions written while the submirror was offline. Writes are directed to the submirror during resync. Reads, however, will come from a different submirror. Once the resync operation completes, reads and writes are performed on that submirror. The `metaonline` command is only effective on a submirror of a mirror that has been taken offline.

The `metaoffline` and `metaonline` commands can not be used on RAID 1 volumes in application-based recovery (ABR) mode.

A submirror that has been taken offline with the `metaoffline` command can only be mounted as read-only.

**Options** Root privileges are required for all of the following options except `-h`.

- `-f` Forces offlining of submirrors that have slices requiring maintenance.
- `-h` Displays usage message.
- `-s setname` Specifies the name of the diskset on which `metaoffline` and `metaonline` will work. Using the `-s` option will cause the command to perform its administrative function within the specified diskset. Without this option, the command will perform its function on local metadevices.
- `mirror` Specifies the metadvice name of the mirror from which the submirror will be either taken offline or put online.

*submirror* Specifies the metadvice name of the submirror to be either taken offline or put online.

**Examples** EXAMPLE 1 Taking a Submirror Offline

This example takes one submirror, `mymirror_sub1`, offline from mirror `mymirror`.

```
metaoffline mymirror mymirror_sub1
```

**Exit Status** The following exit values are returned:

0 Successful completion.

>0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm
Interface Stability	Committed

**See Also** [mdmonitord\(1M\)](#), [metaclear\(1M\)](#), [metadb\(1M\)](#), [metadetach\(1M\)](#), [metahs\(1M\)](#), [metainit\(1M\)](#), [metaparam\(1M\)](#), [metarecover\(1M\)](#), [metarename\(1M\)](#), [metareplace\(1M\)](#), [metaroot\(1M\)](#), [metaset\(1M\)](#), [metassist\(1M\)](#), [metastat\(1M\)](#), [metasync\(1M\)](#), [metattach\(1M\)](#), [md.tab\(4\)](#), [md.cf\(4\)](#), [mddb.cf\(4\)](#), [md.tab\(4\)](#), [attributes\(5\)](#), [md\(7D\)](#)

*Solaris Volume Manager Administration Guide*

**Notes** The `metaonline` and `metaoffline` commands are not applicable to mirrors in application-based recovery (ABR) mode.

**Name** metaparam – modify parameters of metadevices

**Synopsis** /usr/sbin/metaparam -h  
/usr/sbin/metaparam [-s *setname*]  
          [*concat/stripe* or *RAID5 options*] *concat/stripe* RAID  
/usr/sbin/metaparam [-s *setname*] [*mirror options*] *mirror*

**Description** The metaparam command is used to display or modify current parameters of metadevices.

If just the metadvice is specified as an argument to the metaparam command, the current settings are displayed.

The metaparam command enables most metadvice (volume) parameters to be changed. Only the interlace value cannot be changed by metaparam, because it is established when the metadvice is created and cannot be changed thereafter.

**Options** Root privileges are required for all of the options.

The following options are supported:

-h

Displays usage message.

-s *setname*

Specify the name of the diskset on which metaparam works. Using the -s option causes the command to perform its administrative function within the specified diskset. Without this option, the command performs its function on local metadevices.

**Concat/STRIPE Or  
Raid5 Options** -h*hot\_spare\_pool* | none

Specifies the hot spare pool to be used by a metadvice. If none is specified, the metadvice is disassociated with the hot spare pool assigned to it. If the metadvice is currently using a hot spare, then metaparam cannot replace the hot spare pool.

*concat/stripe* | *RAID*

Specifies the metadvice name of the concatenation, stripe, or concatenation of stripes, or of the RAID5 metadvice.

**Mirror Options** -r *roundrobin* | *geometric* | *first*

Modifies the read option for a mirror. The -r option must be followed by either *roundrobin*, *geometric*, or *first*. *roundrobin*, which is the default action under the *metainit* command, specifies reading the disks in a round-robin (load balancing) method. *geometric* allows for faster performance on sequential reads. *first* specifies reading only from the first submirror.

-w *parallel* | *serial*

Modifies the write option for a mirror. The -w option must be followed by either *parallel* or *serial*. *parallel*, the default action under the *metainit* command, specifies that all writes are parallel. *serial* specifies that all writes are serial.

`-p pass_number`

A number from 0-to-9 that specifies the order in which a mirror is resynced during reboot. The default is 1. Smaller pass numbers are resynced first. Equal pass numbers are run concurrently. If 0 is used, the mirror resync is skipped. 0 should only be used for mirrors mounted as read-only, or as swap.

`mirror`

Specifies the metadvice name of the mirror.

**Examples** EXAMPLE 1 Associating Hot Spare Pool with RAID5 Metadvice

This example associates a hot spare pool, `user_pool`, with a RAID5 metadvice, `user_raid`.

```
metaparam -h user_pool user_raid
```

EXAMPLE 2 Changing Read Option to Geometric

This example changes the read option on a mirror `d50` from the default of `roundrobin` to `geometric`.

```
metaparam -r geometric d50
```

**Exit Status** The following exit values are returned:

0

Successful completion.

>0

An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm
Interface Stability	Committed

**See Also** [mdmonitord\(1M\)](#), [metaclear\(1M\)](#), [metadb\(1M\)](#), [metadetach\(1M\)](#), [metahs\(1M\)](#), [metainit\(1M\)](#), [metaoffline\(1M\)](#), [metaonline\(1M\)](#), [metarecover\(1M\)](#), [metarename\(1M\)](#), [metareplace\(1M\)](#), [metaroot\(1M\)](#), [metaset\(1M\)](#), [metassist\(1M\)](#), [metastat\(1M\)](#), [metasync\(1M\)](#), [metattach\(1M\)](#), [md.tab\(4\)](#), [md.cf\(4\)](#), [mddb.cf\(4\)](#), [md.tab\(4\)](#), [attributes\(5\)](#), [md\(7D\)](#)

*Solaris Volume Manager Administration Guide*

**Name** metarecover – recover soft partition information

**Synopsis** /sbin/metarecover [-n] [-v] [-s *setname*] *component* -p  
/sbin/metarecover [-n] [-v] [-s *setname*] *component* -p {-d}  
/sbin/metarecover [-n] [-v] [-s *setname*] *component* -p {-m}

**Description** The `metarecover` command scans a specified component to look for soft partition configuration information and to regenerate the configuration.

**Options** The following options are supported:

- d Recover soft partitions in the metadvice state database from the extent headers on the device. Options -d and -m are mutually exclusive.
- m Regenerate the extent headers and reapplies them to the underlying device based on the soft partitions listed in the metadvice state database. Options -d and -m are mutually exclusive.
- n Do not actually perform the operation. Show the output or errors that would have resulted from the operation, had it been run.
- p Regenerate soft partitions based on the metadvice state database or extent headers on the underlying device. If neither -d nor -m are specified, this option compares the soft partition information in the metadvice state database to the extent headers.
- s *setname* Specify the name of the diskset on which `metarecover` works. Using the `s` option causes the command to perform its function within the specified diskset. Without the `-s` option, the `metarecover` command operates on the metadevices and/or hot spare pools in the local diskset.  
  
This option is required to recover former `sps` from a diskset component or `raw-device`. *setname* must be identical to the former *setname* in which the `sps` were created. The set numbers, however, seem irrelevant.
- v Verbose mode, displaying the changes being made.

**Operands** The following operand is supported:

*component* Specifies the `c*t*d*s*` number of the disk or slice containing the partitions, or the device name (for example, `d10`) of the metadvice containing the partitions.

*component* can be a slice name, component name, `/dev/dsk` path, or `/dev/rdisk` path.

**Examples** EXAMPLE 1 Updating Metadevice State Database Based on Disk Extent Headers

A disk containing soft partitions is moved from one system to another. The system administrator would like to use the existing soft partitions. `metarecover` updates the metadevice state database based on the extent headers on the disk.

```
metarecover -v c0t3d0s2 -p -d
```

## EXAMPLE 2 Updating Metadevice State Database Based on Incomplete Soft Partition Creation

A system crashes in the middle of creating a new soft partition. The soft partition is in the creating state and the driver does not let that device be opened. `metarecover` rewrites the extent headers for the partially created soft partition and mark it as Okay.

```
metarecover -v c0t3d0s2 -p -m
```

## EXAMPLE 3 Updating Extent Headers Based on Metadevice State Database

Someone accidentally overwrote a portion of a disk leaving extent headers destroyed. `metarecover` rewrites the extent headers to ensure a valid soft partition configuration, though user data is not recovered.

```
metarecover -v d5 -m
```

The following example implements the same command using a descriptive name.

```
metarecover -v myvolume -m
```

## EXAMPLE 4 Validating Soft Partition Configuration

To validate the existing soft partition configuration, use `metarecover` with only the `-p` flag.

```
metarecover c0t3d0s2 -p
```

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

*Solaris Volume Manager Administration Guide*

**Name** metarename – rename metadevice or switch layered metadevice names

**Synopsis** /usr/sbin/metarename [-s *setname*] *metadevice1* *metadevice2*  
 /usr/sbin/metarename [-s *setname*] [-f] -x *metadevice1* *metadevice2*  
 /usr/sbin/metarename -h

**Description** There are two ways to use `metarename`, one with and one without the `-x` option. The first method (without `-x`) renames an existing metadevice to a new name. This makes managing the metadevice namespace easier. The metadevice being renamed cannot be mounted or open, nor can the new name already exist. For example, to rename a metadevice that contains a mounted file system, you would first need to unmount the file system.

With the second way to use `metarename`, using the `-x` option, `metarename` switches (exchanges) the names of an existing layered metadevice and one of its subdevices. In Solaris Volume Manager terms, a layered metadevice can be either a mirror or a trans metadevice. The `-x` option enables you to switch the metadevice names of a mirror and one of its submirrors, or a trans metadevice and its master device.

`metarename -x` makes it easier to mirror or unmirror an existing stripe or concatenation, and to remove a trans device.

When used to mirror an existing stripe or concatenation, you must stop access to the device. For example, if the device contains a mounted file system, you must first unmount the file system before doing the rename.

You can also use the `metarename -x` command to untrans a trans metadevice from an existing device. This applies only to the master device. You cannot remove a logging device with `metarename`. Before you can rename a trans device, you must detach the logging device. Then you must stop access to the trans metadevice itself.

You cannot rename or switch metadevices that are in an error state or that have subcomponents in an error state, or metadevices actively using a hot spare replacement.

You can only switch metadevices that have a direct child/parent relationship. You could not, for example, directly exchange a stripe in a mirror that is a master device with the trans metadevice.

You must use the `-f` flag when switching members of a trans metadevice.

Only metadevices can be switched, not slices.

**Options** The following options are supported:

-f Force the switching of trans metadevice members.  
 -h Display a help message.

- `-s setname` Specifies the name of the diskset on which `metarename` will work. Using the `-s` option will cause the command to perform its administrative function within the specified diskset. Without this option, the command will perform its function on the local metadevices.
- `-x` Exchange the metadvice names *metadvice1* and *metadvice2*.
- metadvice1* Specifies the metadvice to be renamed or switched.
- metadvice2* Specifies the target metadvice name for the rename or switch operation.

**Examples** EXAMPLE 1 Renaming a Metadvice

This example renames a metadvice named `d10` to `account_records`. Note that `account_records` must not exist for the rename to succeed.

```
metarename d10 account_records
```

## EXAMPLE 2 Creating a Two-Way Mirror

This example creates a two-way mirror from an existing stripe named `d1` with a mounted file system, `/home2`.

```
metainit d2 1 1 c13d0s1
metainit -f d20 -m d1
umount /home2
metarename -x d20 d1
metattach d1 d2
mount /home2
```

First, a second concatenation `d2`, is created. (`d1` already exists.) The `metainit` command creates a one-way mirror, `d20`, from `d1`. Next, you unmount the file system and switch `d1` for `d20`, making `d1` the top-level device (mirror). You attach the second submirror, `d2`, to create a two-way mirror. Lastly, you remount the file system.

## EXAMPLE 3 Mounting a Mirrored File System on Stripe

This example takes an existing mirror named `d1` with a mounted file system, and ends up with the file system mounted on a stripe `d1`.

```
umount /fs2
metarename -x d1 d20
metadetach d20 d1
metaclear -r d20
mount /fs2
```

First, you unmount the file system, then switch the mirror `d1` and its submirror `d20`. This makes the mirror into `d20`. Next, you detach `d1` from `d20`, then delete the mirror `d20` and its other submirror. You then remount the file system.

**EXAMPLE 4** Deleting a Trans Metadevice

This example deletes a trans metadevice named `d10` while its mount point is `/myhome`. The master device, which is a stripe, is named `d2`. The logging device, also a stripe, is named `d5`.

```
umount /myhome
metadetach d10
metarename -f -x d10 d2
metaclear d2
metaclear d5
fsck /dev/md/dsk/d10
mount /myhome
```

You unmount the file system first, then detach the trans metadevice's logging device. The trans metadevice is switched with the master device, making the trans metadevice `d2` and the underlying stripe `d10`. You clear the trans metadevice `d2` and the logging device `d5`. `d10` must be `fsck'd`, and then the file system is remounted.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm
Interface Stability	Committed

**See Also** [mdmonitord\(1M\)](#), [metaclear\(1M\)](#), [metadb\(1M\)](#), [metadetach\(1M\)](#), [metahs\(1M\)](#), [metainit\(1M\)](#), [metaoffline\(1M\)](#), [metaonline\(1M\)](#), [metaparam\(1M\)](#), [metarecover\(1M\)](#), [metareplace\(1M\)](#), [metaroot\(1M\)](#), [metaset\(1M\)](#), [metassist\(1M\)](#), [metastat\(1M\)](#), [metasync\(1M\)](#), [metattach\(1M\)](#), [md.tab\(4\)](#), [md.cf\(4\)](#), [mddb.cf\(4\)](#), [md.tab\(4\)](#), [attributes\(5\)](#), [md\(7D\)](#)

*Solaris Volume Manager Administration Guide*

**Limitations** Renaming and exchanging metadevice names can only be used for metadevices. A physical slice cannot be renamed to a metadevice, nor can a metadevice be exchanged with a physical slice name.

Metadevice names are strings of the pattern `d<xyz>` where `xyz` is a value between 0 and 8192. You cannot use logical names for metadevices.

**Notes** Trans metadvicees have been replaced by UFS logging. Existing trans devices are *not* logging--they pass data directly through to the underlying device. See [mount\\_ufs\(1M\)](#) for more information about UFS logging.

**Name** metareplace – enable or replace components of submirrors or RAID5 metadevices

**Synopsis** /usr/sbin/metareplace -h  
 /usr/sbin/metareplace [-s *setname*] -e *mirror component*  
 /usr/sbin/metareplace [-s *setname*] *mirror component-old component-new*  
 /usr/sbin/metareplace [-s *setname*] -e *RAID component*  
 /usr/sbin/metareplace [-s *setname*] [-f] *RAID component-old component-new*

**Description** The `metareplace` command is used to enable or replace components (slices) within a submirror or a RAID5 metadvice.

When you replace a component, the `metareplace` command automatically starts resyncing the new component with the rest of the metadvice. When the resync completes, the replaced component becomes readable and writable. If the failed component has been hot spare replaced, the hot spare is placed in the available state and made available for other hot spare replacements.

Note that the new component must be large enough to replace the old component.

A component may be in one of several states. The `Last Erred` and the `Maintenance` states require action. Always replace components in the `Maintenance` state first, followed by a resync and validation of data. After components requiring maintenance are fixed, validated, and resynced, components in the `Last Erred` state should be replaced. To avoid data loss, it is always best to back up all data before replacing `Last Erred` devices.

**Options** Root privileges are required for all of the following options except `-h`.

- e Transitions the state of *component* to the available state and resyncs the failed component. If the failed component has been hot spare replaced, the hot spare is placed in the available state and made available for other hot spare replacements. This command is useful when a component fails due to human error (for example, accidentally turning off a disk), or because the component was physically replaced. In this case, the replacement component must be partitioned to match the disk being replaced before running the `metareplace` command.
- f Forces the replacement of an errored component of a metadvice in which multiple components are in error. The component determined by the `metastat display` to be in the “Maintenance” state must be replaced first. This option may cause data to be fabricated since multiple components are in error.
- h Display help message.
- s *setname* Specifies the name of the diskset on which `metareplace` will work. Using the `-s` option will cause the command to perform its administrative

function within the specified diskset. Without this option, the command will perform its function on local metadevices.

<i>mirror</i>	The metadvice name of the mirror.
<i>component</i>	The logical name for the physical slice (partition) on a disk drive, such as <code>/dev/dsk/c0t0d0s2</code> .
<i>component-old</i>	The physical slice that is being replaced.
<i>component-new</i>	The physical slice that is replacing <i>component-old</i> .
<i>RAID</i>	The metadvice name of the RAID5 device.

### Examples

**EXAMPLE 1** Recovering from Error Condition in RAID5 Metadvice

This example shows how to recover when a single component in a RAID5 metadvice is errored.

```
metareplace d10 c3t0d0s2 c5t0d0s2
```

In this example, a RAID5 metadvice `d10` has an errored component, `c3t0d0s2`, replaced by a new component, `c5t0d0s2`.

**EXAMPLE 2** Use of `-e` After Physical Disk Replacement

This example shows the use of the `-e` option after a physical disk in a submirror (a submirror of mirror `mymirror1`, in this case) has been replaced.

```
metareplace -e mymirror1 c1t4d0s2
```

Note: The replacement disk must be partitioned to match the disk it is replacing before running the `metareplace` command.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

*Solaris Volume Manager Administration Guide*

**Name** metaroot – setup system files for root (/) metadvice

**Synopsis** /usr/sbin/metaroot -h

```
/usr/sbin/metaroot [-n] [-k system-name] [-v vfstab-name]
[-c mddb.cf-name] [-m md.conf-name] [-R root-path] device
```

**Description** The metaroot command edits the /etc/vfstab and /etc/system files so that the system may be booted with the root file system (/) on an appropriate metadvice. The only metadevices that support the root file system are a stripe with only a single slice or a mirror on a single-slice stripe.

If necessary, the metaroot command can reset a system that has been configured to boot the root file system (/) on a metadvice so that it uses a physical slice.

**Options** Root privileges are required for all of the following options except -h.

The following options are supported:

-c *mddb.cf-name* Use *mddb.cf-name* instead of the default /etc/lvm/mddb.cf file as a source of metadvice database locations.

-h Display a usage message.

-k *system-name* Edit a user-supplied *system-name* instead of the default /etc/system system configuration information file.

-m *md.conf-name* Edit the configuration file specified by *md.conf-name* rather than the default, /kernel/drv/md.conf.

-n Print what would be done without actually doing it.

-R *root-path* When metaroot modifies system files, it accesses them in their relative location under *root-path*.

The -R option cannot be used in combination with the -c, -k, -m, or -v options.

**Note** – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).

-v *vfstab-name* Edit *vfstab-name* instead of the default /etc/vfstab table of file system defaults.

**Operands** The following operands are supported:

*device* Specifies either the metadvice or the conventional disk device (slice) used for the root file system (/).

**Examples** EXAMPLE 1 Specifying Root File System on Metadevice

The following command edits `/etc/system` and `/etc/vfstab` to specify that the root file system is now on metadevice `d0`.

```
metaroot d0
```

The following example shows the same command using a descriptive name for the metadevice.

```
metaroot newrootfilesystem
```

## EXAMPLE 2 Specifying Root File System on SCSI Disk

The following command edits `/etc/system` and `/etc/vfstab` to specify that the root file system is now on the SCSI disk device `/dev/dsk/c0t3d0s0`.

```
metaroot /dev/dsk/c0t3d0s0
```

<b>Files</b>	<code>/etc/system</code>	System configuration information file. See <a href="#">system(4)</a> .
	<code>/etc/vfstab</code>	File system defaults.
	<code>/etc/lvm/mddb.cf</code>	Metadevice state database locations.
	<code>/kernel/drv/md.conf</code>	Configuration file for the metadevice driver, <code>md</code> .

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

/usr/sbin/metaset -s *setname* -r  
/usr/sbin/metaset -s *setname* -w  
/usr/sbin/metaset -s *setname* -t [-f] [-u *tagnumber*] [y]  
/usr/sbin/metaset -s *setname* -b  
/usr/sbin/metaset -s *setname* -P  
/usr/sbin/metaset -s *setname* -q  
/usr/sbin/metaset -s *setname* -o [-h *hostname*]  
/usr/sbin/metaset [-s *setname*]  
/usr/sbin/metaset [-s *setname*] -a | -d  
    [ [m] *mediator\_host\_list*]

**Description** The metaset command administers sets of disks in named disk sets. Named disk sets include any disk set that is not in the local set. While disk sets enable a high-availability configuration, Solaris Volume Manager itself does not actually provide a high-availability environment.

A single-owner disk set configuration manages storage on a SAN or fabric-attached storage, or provides namespace control and state database replica management for a specified set of disks.

In a shared disk set configuration, multiple hosts are physically connected to the same set of disks. When one host fails, another host has exclusive access to the disks. Each host can control a shared disk set, but only one host can control it at a time.

When you add a new disk to any disk set, Solaris Volume Manager checks the disk format. If necessary, it repartitions the disk to ensure that the disk has an appropriately configured reserved slice 7 (or slice 6 on an EFI labelled device) with adequate space for a state database replica. The precise size of slice 7 (or slice 6 on an EFI labelled device) depends on the disk geometry. For traditional disk sets, the slice is no less than 4 Mbytes, and probably closer to 6 Mbytes, depending on where the cylinder boundaries lie. For multi-owner disk sets, the slice is

a minimum of 256 Mbytes. The minimal size for slice 7 might change in the future. This change is based on a variety of factors, including the size of the state database replica and information to be stored in the state database replica.

For use in disk sets, disks must have a dedicated slice (six or seven) that meets specific criteria:

- The slice must start at sector 0
- The slice must include enough space for disk label
- The state database replicas cannot be mounted
- The slice does not overlap with any other slices, including slice 2

If the existing partition table does not meet these criteria, or if the `-L` flag is specified, Solaris Volume Manager repartitions the disk. A small portion of each drive is reserved in slice 7 (or slice 6 on an EFI labelled device) for use by Solaris Volume Manager. The remainder of the space on each drive is placed into slice 0. Any existing data on the disks is lost by repartitioning.

After you add a drive to a disk set, it can be repartitioned as necessary, with the exception that slice 7 (or slice 6 on an EFI labelled device) is not altered in any way.

After a disk set is created and metadevices are set up within the set, the metadvice name is in the following form:

```
/dev/md/setname{dsk,rdsk}/dnumber
```

where *setname* is the name of the disk set, and *number* is the number of the metadvice (0-127).

If you have disk sets that you upgraded from Solstice DiskSuite software, the default state database replica size on those sets is 1034 blocks, not the 8192 block size from Solaris Volume Manager. Also, slice 7 on the disks that were added under Solstice DiskSuite are correspondingly smaller than slice 7 on disks that were added under Solaris Volume Manager.

If disks you add to a disk set have acceptable slice 7s (that start at cylinder 0 and that have sufficient space for the state database replica), they are not reformatted.

Hot spare pools within local disk sets use standard Solaris Volume Manager naming conventions. Hot spare pools with shared disk sets use the following convention:

```
setname/hot_spare_pool
```

where *setname* is the name of the disk set, and *hot\_spare\_pool* is the name of the hot spare pool associated with the disk set.

Multi-node  
Environment

To create and work with a disk set in a multi—node environment, `root` must be a member of Group 14 on all hosts, or the `.rhosts` file must contain an entry for all other host names. This is not required in a SunCluster 3.x environment.

**Tagged data** Tagged data occurs when there are different versions of a disk set's replicas. This tagged data consists of the set owner's nodename, the hardware serial number of the owner and the time it was written out to the available replicas. The system administrator can use this information to determine which replica contains the correct data.

When a disk set is configured with an even number of storage enclosures and has replicas balanced across them evenly, it is possible that up to half of the replicas can be lost (for example, through a power failure of half of the storage enclosures). After the enclosure that went down is rebooted, half of the replicas are not recognized by SVM. When the set is retaken, the `metaset` command returns an error of "stale databases", and all of the metadevices are in a read-only state.

Some of the replicas that are not recognized need to be deleted. The action of deleting the replicas also causes updates to the replicas that are not being deleted. In a dual hosted disk set environment, the second node can access the deleted replicas instead of the existing replicas when it takes the set. This leads to the possibility of getting the wrong replica record on a disk set take. An error message is displayed, and user intervention is required.

Use the `-q` to query the disk set and the `-t`, `-u`, and `-y`, options to select the tag and take the disk set. See `OPTIONS`.

**Mediator Configuration** SVM provides support for a low-end HA solution consisting of two hosts that share only two strings of drives. The hosts in this type of configuration, referred to as *mediators* or mediator hosts, run a special daemon, `rpc.metamedd(1M)`. The mediator hosts take on additional responsibilities to ensure that data is available in the case of host or drive failures.

A mediator configuration can survive the failure of a single host or a single string of drives, without administrative intervention. If both a host and a string of drives fail (multiple failures), the integrity of the data cannot be guaranteed. At this point, administrative intervention is required to make the data accessible. See [mediator\(7D\)](#) for further details.

Use the `-m` option to add or delete a mediator host. See `OPTIONS`.

**Options** The following options are supported:

`-a drivename`

Add drives or hosts to the named set. For a drive to be accepted into a set, the drive must not be in use within another metadevice or disk set, mounted on, or swapped on. When the drive is accepted into the set, it is repartitioned and the metadevice state database replica (for the set) can be placed on it. However, if a slice 7 (or slice 6 on an EFI labelled device), starts at cylinder 0, and is large enough to hold a state database replica, then the disk is not repartitioned. Also, a drive is not accepted if it cannot be found on all hosts specified as part of the set. This means that if a host within the specified set is unreachable due to network problems, or is administratively down, the add fails.

Specify a drive name in the form `cnumt numdnum`. Do not specify a slice number (`snum`). For drives in a Sun Cluster, you must specify a complete pathname for each drive. Such a name has the form:

`/dev/did/[r]dsk/dnum`

`-a | -d | -m mediator_host_list`

Add (-a) or delete (-d) mediator hosts to the specified disk set. A *mediator\_host\_list* is the [nodename\(4\)](#) of the mediator host to be added and (for adding) up to two other aliases for the mediator host. The nodename and aliases for each mediator host are separated only by commas. Up to three mediator hosts can be specified for the named disk set. Specify only the nodename of that host as the argument to -m to delete a mediator host.

In a single metaset command you can add or delete up to three mediator hosts. See EXAMPLES.

`-A {enable | disable}`

Specify auto-take status for a disk set. If auto-take is enabled for a set, the disk set is automatically taken at boot, and file systems on volumes within the disk set can be mounted through `/etc/vfstab` entries. Only a single host can be associated with an auto-take set, so attempts to add a second host to an auto-take set or attempts to configure a disk set with multiple hosts as auto-take fails with an error message. Disabling auto-take status for a specific disk set causes the disk set to revert to normal behavior. That is, the disk set is potentially shared (non-concurrently) among hosts, and unavailable for mounting through `/etc/vfstab`.

`-b`

Insure that the replicas are distributed according to the replica layout algorithm. This can be invoked at any time, and does nothing if the replicas are correctly distributed. In cases where the user has used the `metadb` command to manually remove or add replicas, this command can be used to insure that the distribution of replicas matches the replica layout algorithm.

`-C {take | release | purge}`

Do not interact with the Cluster Framework when used in a Sun Cluster 3 environment. In effect, this means do not modify the Cluster Configuration Repository. These options should only be used to fix a broken disk set configuration.

`take`

Take ownership of the disk set but do not inform the Cluster Framework that the disk set is available. This option is not for use with a multi-owner disk set.

`release`

Release ownership of the disk set without informing the Cluster Framework. This option should only be used if the disk set ownership was taken with the corresponding -C take option. This option is not for use with a multi-owner disk set.

`purge`

Remove the disk set without informing the Cluster Framework that the disk set has been purged. This option should only be used when the disk set is not accessible and requires rebuilding.

**-d *drivename***

Delete drives or hosts from the named disk set. For a drive to be deleted, it must not be in use within the set. The last host cannot be deleted unless all of the drives within the set are deleted. Deleting the last host in a disk set destroys the disk set.

Specify a drive name in the form *cnumt numdnum*. Do not specify a slice number (*snum*). For drives in a Sun Cluster, you must specify a complete pathname for each drive. Such a name has the form:

```
/dev/did/[r]dsk/dnum
```

This option fails on a multi-owner disk set if attempting to withdraw the master node while other nodes are in the set.

**-f**

Force one of three actions to occur: takes ownership of a disk set when used with **-t**; deletes the last disk drive from the disk set; or deletes the last host from the disk set. Deleting the last drive or host from a disk set requires the **-d** option.

When used to forcibly take ownership of the disk set, this causes the disk set to be grabbed whether or not another host owns the set. All of the disks within the set are taken over (reserved) and fail fast is enabled, causing the other host to panic if it had disk set ownership. The metadvice state database is read in by the host performing the take, and the shared metadvice contained in the set are accessible.

You can use this option to delete the last drive in the disk set, because this drive would implicitly contain the last state database replica.

You can use **-f** option to delete hosts from a set. When specified with a partial list of hosts, it can be used for one-host administration. One-host administration could be useful when a host is known to be non-functional, thus avoiding timeouts and failed commands. When specified with a complete list of hosts, the set is completely deleted. It is generally specified with a complete list of hosts to clean up after one-host administration has been performed.

**-h *hostname...***

Specify one or more host names to be added to or deleted from a disk set. Adding the first host creates the set. The last host cannot be deleted unless all of the drives within the set have been deleted. The host name is not accepted if all of the drives within the set cannot be found on the specified host. The host name is the same name found in `/etc/nodename`.

**-j**

Join a host to the owner list for a multi-owner disk set. The concepts of take and release, used with traditional disk sets, do not apply to multi-owner sets, because multiple owners are allowed.

As a host boots and is brought online, it must go through three configuration levels to be able to use a multi-owner disk set:

1. It must be included in the cluster nodelist, which happens automatically in a cluster or single-node situation.

2. It must be added to the multi-owner disk set with the `-a -h` options documented elsewhere in this man page
3. It must join the set. When the host is first added to the set, it is automatically joined.

On manual restarts, the administrator must manually issue

```
metaset -s multinodesetname -j
```

to join the host to the owner list. After the cluster reconfiguration, when the host reenters the cluster, the node is automatically joined to the set. The `metaset -j` command joins the host to all multi-owner sets that the host has been added to. In a single node situation, joining the node to the disk set starts any necessary resynchronizations.

**-L**

When adding a disk to a disk set, force the disk to be repartitioned using the standard Solaris Volume Manager algorithm. See DESCRIPTION.

**-l *length***

Set the size (in blocks) for the metadvice state database replica. The length can only be set when adding a new drive; it cannot be changed on an existing drive. The default (and maximum) size is 8192 blocks, which should be appropriate for most configurations. Replica sizes of less than 128 blocks are not recommended.

**-M**

Specify that the disk set to be created or modified is a multi-owner disk set that supports multiple concurrent owners.

This option is required when creating a multi-owner disk set. Its use is optional on all other operations on a multi-owner disk set and has no effect. Existing disk sets cannot be converted to multi-owner sets.

**-o**

Return an exit status of 0 if the local host or the host specified with the `-h` option is the owner of the disk set.

**-P**

Purge the named disk set from the node on which the `metaset` command is run. The disk set must not be owned by the node that runs this command. If the node does own the disk set, the command fails.

If you need to delete a disk set but cannot take ownership of the set, use the `-P` option.

**-q**

Displays an enumerated list of tags pertaining to “tagged data” that can be encountered during a take of the ownership of a disk set.

This option is not for use with a multi-owner disk set.

-r

Release ownership of a disk set. All of the disks within the set are released. The metadevices set up within the set are no longer accessible.

This option is not for use with a multi-owner disk set.

-s *setname*

Specify the name of a disk set on which `metaset` works. If no *setname* is specified, all disk sets are returned.

-t

Take ownership of a disk set safely. If `metaset` finds that another host owns the set, this host is not be allowed to take ownership of the set. If the set is not owned by any other host, all the disks within the set are owned by the host on which `metaset` was executed. The metadvice state database is read in, and the shared metadevices contained in the set become accessible. The `-t` option takes a disk set that has stale databases. When the databases are stale, `metaset` exits with code 66, and prints a message. At that point, the only operations permitted are the addition and deletion of replicas. Once the addition or deletion of the replicas has been completed, the disk set should be released and retaken to gain full access to the data.

This option is not for use with a multi-owner disk set.

-u *tagnumber*

Once a tag has been selected, a subsequent take with `-u tagnumber` can be executed to select the data associated with the given *tagnumber*.

w

Withdraws a host from the owner list for a multi-owner disk set. The concepts of take and release, used with traditional disk sets, do not apply to multi-owner sets, because multiple owners are allowed.

Instead of releasing a set, a host can issue

```
metaset -s multinodesetname -w
```

to withdraw from the owner list. A host automatically withdraws on a reboot, but can be manually withdrawn if it should not be able to use the set, but should be able to rejoin at a later time. A host that withdrew due to a reboot can still appear joined from other hosts in the set until a reconfiguration cycle occurs.

`metaset -w` withdraws from ownership of all multi-owner sets of which the host is a member. This option fails if you attempt to withdraw the master node while other nodes are in the disk set owner list. This option cancels all resyncs running on the node. A cluster reconfiguration process that is removing a node from the cluster membership list effectively withdraws the host from the ownership list.

-y

Execute a subsequent take. If the take operation encounters “tagged data,” the take operation exits with code 2. You can then run the `metaset` command with the `-q` option to see an enumerated list of tags.

### Examples EXAMPLE 1 Defining a Disk Set

This example defines a disk set.

```
metaset -s re1o-red -a -h red blue
```

The name of the disk set is `re1o-red`. The names of the first and second hosts added to the set are `red` and `blue`, respectively. (The hostname is found in `/etc/nodename`.) Adding the first host creates the disk set. A disk set can be created with just one host, with the second added later. The last host cannot be deleted until all of the drives within the set have been deleted.

### EXAMPLE 2 Adding Drives to a Disk Set

This example adds drives to a disk set.

```
metaset -s re1o-red -a c2t0d0 c2t1d0 c2t2d0 c2t3d0 c2t4d0 c2t5d0
```

The name of the previously created disk set is `re1o-red`. The names of the drives are `c2t0d0`, `c2t1d0`, `c2t2d0`, `c2t3d0`, `c2t4d0`, and `c2t5d0`. There is no slice identifier (“`sx`”) at the end of the drive names.

### EXAMPLE 3 Adding Multiple Mediator Hosts

The following command adds three mediator hosts to the specified disk set.

```
metaset -s mydiskset -a -m myhost1,alias1 myhost2,alias2 myhost3,alias3
```

### EXAMPLE 4 Purging a Disk Set from the Node

The following command purges the disk set `re1o-red` from the node:

```
metaset -s re1o-red -P
```

### EXAMPLE 5 Querying a Disk Set for Tagged Data

The following command queries the disk set `re1o-red` for a list of the tagged data:

```
metaset -s re1o-red -q
```

This command produces the following results:

```
The following tag(s) were found:
 1 - vha-1000c - Fri Sep 20 17:20:08 2002
 2 - vha-1000c - Mon Sep 23 11:01:27 2002
```

**EXAMPLE 6** Selecting a tag and taking a Disk set

The following command selects a tag and takes the disk set `relo-red`:

```
metaset -s relo-red -t -u 2
```

**EXAMPLE 7** Defining a Multi-Owner Disk Set

The following command defines a multi-owner disk set:

```
metaset -s blue -M -a -h hahost1 hahost2
```

The name of the disk set is `blue`. The names of the first and second hosts added to the set are `hahost1` and `hahost2`, respectively. The hostname is found in `/etc/nodename`. Adding the first host creates the multi-owner disk set. A disk set can be created with just one host, with additional hosts added later. The last host cannot be deleted until all of the drives within the set have been deleted.

**Files** `/etc/lvm/md.tab`  
Contains list of metadvice configurations.

**Exit Status** The following exit values are returned:

`0`  
Successful completion.

`>0`  
An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

*Solaris Volume Manager Administration Guide*

**Notes** Disk set administration, including the addition and deletion of hosts and drives, requires all hosts in the set to be accessible from the network.

**Name** metassist – automated volume creation utility to support Solaris Volume Manager

**Synopsis** metassist -V  
 metassist -?  
 metassist create [-v n] [-c] -F *config\_file*  
 metassist create [-v n] [-c | -d] -F *request\_file*  
 metassist create [-v n] [-c | -d] [-f] [-n *name*]  
     [-p *datapaths*] [-r *redundancy*]  
     [-a *available* [,*available*,...]]  
     [-u *unavailable* [,*unavailable*,...]] -s *setname* -S *size*  
 metassist create -?

**Description** The `metassist` command provides assistance, through automation, with common Solaris Volume Manager tasks.

**SUBCOMMANDS** The following subcommands are supported:

**create** The `create` subcommand creates one or more Solaris Volume Manager volumes. You can specify this request on the command line or in a file specified on the command line.

If you create a volume using the command line, you can specify the characteristics of the volume in terms of the desired quality of service it will provide - its size, the number of redundant copies of the data it contains, the number of data paths by which it is accessible, and whether faulty components are replaced automatically. The diskset in which the volume will reside and the volume's size must be specified on the command line in this form of the command.

If you create a volume using a request in a file, you can specify the characteristics of the volume in terms of the quality of service they provide, as on the command line. Alternatively, the file can specify the types and component parts of the volume, (for example, mirrors, stripes, concatenations, and their component slices). The file may also specify volumes partly in terms of their types and partly in terms of their component parts, and may specify the characteristics of more than one volume. All volumes specified in a file must reside in the same diskset, whose name must be specified in the file.

If you specify the `-c` or `-d` option on the command line, the command runs without creating an actual volume or volumes. Instead, it outputs either a Bourne shell command script (`-c` option) or a volume configuration (`-d` option). The command script, when run, creates the specified volume or volumes. The volume configuration specifies the volume or volumes in complete detail, naming all their components.

The input file given on the command line can take one of the following forms:

- a volume request, which specifies a request for a volume with explicit attributes and components, or matching a given quality of service
- a volume configuration, produced by a previous execution of the command

**Options** The following option is mandatory if you specify a volume request or volume configuration in a file:

*-F config\_file | request\_file* Specify the volume request or volume configuration file to process. If *config\_file* or *request\_file* is -, it is read from standard input.

The *-d* option cannot be specified when *inputfile* is a volume configuration file.

The following options are mandatory if you specify a volume request on the command line:

*-s set* Specify the disk set to use when creating volumes. All the volumes and hot spare pools are created in this disk set. If necessary, disks are moved into the diskset for use in the volumes and hot spare pools. If the diskset doesn't exist the command creates it. This option is required. *metassist* works entirely within a named disk set. Use of the local, or unnamed disk set, is not allowed.

*-S size* Specify the size of the volume to be created. The size argument consists of a numeric value (a decimal can be specified) followed by KB, MB, GB, or TB, indicating kilobytes, megabytes, gigabytes, or terabytes, respectively. Case is ignored when interpreting this option. This option is required.

The following options are optional command line parameters:

*-a device1, device2, . . .* Explicitly specify the devices that can be used in the creation of this volume. Named devices may be controllers or disks. Only used when specifying a volume on the command line.

*-c* Output the command script that would implement the specified or generated volume configuration. The command script is not run, and processing stops at this stage.

*-d* Output the volume configuration that satisfies the specified or generated volume request. No command script is generated or executed, and processing stops at this stage.

*-f* Specify whether the volume should support automatic component replacement after a fault. If this option is specified, a mirror is created and its submirrors are associated with a hot spare.

*-n name* Specify the name of the new volume. See [metainit\(1M\)](#) for naming guidelines.

-p <i>n</i>	Specify the number of required paths to the storage volume. The value of <i>n</i> cannot be greater than the number of different physical paths and logical paths to attached storage. Only used when specifying a volume on the command line.
-r <i>n</i>	Specify the redundancy level (0-4) of the data. The default is 0. Only used when specifying a volume on the command line. If redundancy is 0, a stripe is created. If redundancy is 1 or greater, a mirror with this number of submirrors is created. In this case, the volume can suffer a disk failure on <i>n</i> - 1 copies without data loss. With the use of hot spares (see the -f option), a volume can suffer a disk failure on <i>n</i> + <i>hsp</i> s - 1 volumes without data loss, assuming non-concurrent failures.
-u <i>device1, device2, . . .</i>	Explicitly specify devices to exclude in the creation of this volume. Named devices can be controllers or disks. You can use this option alone, or to exclude some of the devices listed as available with the -a option, Only used when specifying a volume on the command line.
-v <i>value</i>	Specify the level of verbosity. Values from 0 to 2 are available, with higher numbers specifying more verbose output when the command is run. -v 0 indicates silent output, except for errors or other critical messages. The default level is 1.
-V	Display program version information.
-?	Display help information. This option can follow a subcommand for subcommand-specific help.

### Examples EXAMPLE 1 Creating a Mirror

The following example creates a two-way, 36Gb mirror on available devices from controller 1 and controller 2. It places the volume in diskset `mirrorset`.

```
metassist create -r 2 -a c1,c2 -s mirrorset -S 36GB
```

### EXAMPLE 2 Creating a Mirror with Additional Fault Tolerance

The following example creates a two-way, 36Gb mirror on available devices from controller 1 and controller 2. It provides additional fault tolerance in the form of a hot spare. It places the volume in diskset `mirrorset`.

```
metassist create -f -r 2 -a c1,c2 -s mirrorset -S 36GB
```

**EXAMPLE 3** Creating a Three-way Mirror and Excluding Devices

The following example creates a three-way, 180Gb mirror from storage devices on controller 1 or controller 2. It excludes the disks `c1t2d0` and `c2t2d1` from the volume. It places the volume in diskset `mirrorset`.

```
metassist create -r 3 -a c1,c2 -u c1t2d0, c2t2d1 \
 -s mirrorset -S 180GB
```

**EXAMPLE 4** Determining and Implementing a Configuration

The following example determines and implements a configuration satisfying the request specified in a request file:

```
metassist create -F request.xml
```

**EXAMPLE 5** Determining a Configuration and Saving It in a volume-config File

The following example determines a configuration which satisfies the given request. It saves the configuration in a volume-config file without implementing it:

```
metassist create -d -F request.xml > volume-config
```

**EXAMPLE 6** Determining a Configuration and Saving It in a Shell Script

The following example determines a configuration which satisfies the given request. It saves the configuration in a shell script without implementing it:

```
metassist create -c -F request.xml > setupvols.sh
```

**EXAMPLE 7** Implementing the Given volume-config

The following example implements the given volume-config:

```
metassist create -F config.xml
```

**EXAMPLE 8** Converting the Given volume-config to a Shell Script

The following example converts the given volume-config to a shell script that you can run later:

```
metassist create -c -F config.xml > setupvols.sh
```

**Exit Status** The following exit values are returned:

0 Successful completion.

>0 An error occurred.

**Files** /usr/share/lib/xml/dtd/volume-request.dtd  
/usr/share/lib/xml/dtd/volume-defaults.dtd  
/usr/share/lib/xml/dtd/volume-config.dtd

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm
Interface Stability	Committed

**See Also** [mdmonitord\(1M\)](#), [metaclear\(1M\)](#), [metadb\(1M\)](#), [metadetach\(1M\)](#), [metahs\(1M\)](#), [metainit\(1M\)](#), [metaoffline\(1M\)](#), [metaonline\(1M\)](#), [metaparam\(1M\)](#), [metarecover\(1M\)](#), [metarename\(1M\)](#), [metareplace\(1M\)](#), [metaroot\(1M\)](#), [metaset\(1M\)](#), [metastat\(1M\)](#), [metasync\(1M\)](#), [metattach\(1M\)](#), [md.tab\(4\)](#), [md.cf\(4\)](#), [mddb.cf\(4\)](#), [md.tab\(4\)](#), [volume-config\(4\)](#), [volume-request\(4\)](#), [attributes\(5\)](#), [md\(7D\)](#)

**Notes** The quality of service arguments are mutually exclusive with the `-F inputfile` argument.

When specifying a request file or quality of service arguments on the command line, the `/etc/default/metassist.xml` file is read for global and per-disk set defaults.

Characteristics of this file are specified in the DTD, in `/usr/share/lib/xml/dtd/volume-defaults.dtd`.

Characteristics of the XML request file are specified in the DTD, in `/usr/share/lib/xml/dtd/volume-request.dtd`.

Characteristics of the XML configuration file are specified in the DTD, in `/usr/share/lib/xml/dtd/volume-config.dtd`.

This command must be run as root.

This command requires a functional Solaris Volume Manager configuration before it runs.

**Name** metastat – display status for metadevice or hot spare pool

**Synopsis** /usr/sbin/metastat -h

```
/usr/sbin/metastat [-a] [-B] [-D] [-c] [-i] [-p] [-q]
 [-s setname] [-t] [metadevice...] [hot_spare_pool...]
```

```
/usr/sbin/metastat [-a] [-B] [-D] [-c] [-i] [-p] [-q]
 [-s setname] component...
```

**Description** The `metastat` command displays the current status for each metadevice (including stripes, concatenations, concatenations of stripes, mirrors, RAID5, soft partitions, and trans devices) or hot spare pool, or of specified metadevices, components, or hot spare pools.

It is helpful to run the `metastat` command after using the `metattach` command to view the status of the metadevice.

`metastat` displays the state of each Solaris Volume Manager RAID-1 volume on the system. The possible states include:

Okay	The device reports no errors.
Needs maintenance	A problem has been detected. This requires that the system administrator replace the failed physical device. Volumes displaying Needs maintenance have incurred no data loss, although additional failures could risk data loss. Take action as quickly as possible.
Last erred	A problem has been detected. Data loss is a possibility. This might occur if a component of a submirror fails and is not replaced by a hot spare, therefore going into Needs maintenance state. If the corresponding component also fails, it would go into Last erred state and, as there is no remaining valid data source, data loss could be a possibility.
Unavailable	A device cannot be accessed, but has not incurred errors. This might occur if a physical device has been removed with Solaris Dynamic Reconfiguration (DR) features, thus leaving the Solaris Volume Manager volume unavailable. It could also occur if an array or disk is powered off at system initialization, or if a >1TB volume is present when the system is booted in 32-bit mode.

After the storage has been made available, run the `metastat` command with the `-i` option to update the status of the metadevices. This clears the unavailable state for accessible devices.

See the *Solaris Volume Manager Administration Guide* for instructions on replacing disks and handling volumes in Needs maintenance or Last erred states.

**Options** The following options are supported:

- a Display all disk sets. Only metadevices in disk sets that are owned by the current host are displayed.
- B Display the current status of all of the 64-bit metadevices and hot spares.
- c Display concise output.  
  
There is one line of output for each metadvice. The output shows the basic structure and the error status, if any, for each metadvice.  
  
The -c output format is distinct from the -p output format. The -p option does not display metadvice status and is not intended as human-readable output.
- D Display the current status of all of the descriptive name metadevices and hotspares.
- h Display usage message.
- i Check the status of RAID-1 (mirror) volumes, RAID-5 volumes, and hot spares. The inquiry checks each metadvice for accessibility, starting at the top level metadvice. When problems are discovered, the metadvice state databases are updated as if an error had occurred.
- p Display the list of active metadevices and hot spare pools in the same format as `md.tab`. See `md.tab(4)`.  
  
The -p output is designed for snapshotting the configuration for later recovery or setup.
- q Display the status for metadevices without the device relocation information.
- s *setname* Specify the name of the disk set on which `metastat` works. Using the -s option causes the command to perform its administrative function within the specified disk set. Without this option, the command performs its function on metadevices and hot spare pools in the local disk set.
- t Display the current status and timestamp for the specified metadevices and hot spare pools. The timestamp provides the date and time of the last state change.

**Operands** The following operands are supported:

- component* Display the status of the component hosting a soft partition, including extents, starting blocks, and block count.
- hot\_spare\_pool* Display the status of the specified hot spare pool(s).

*metadevice*      Display the status of the specified metadevice(s). If a trans metadevice is specified, the status of the master and log devices is also displayed. Trans metadevices have been replaced by UFS logging. See NOTES.

**Examples**    **EXAMPLE 1**    Output Showing Mirror with Two Submirrors

The following example shows the partial output of the `metastat` command after creating a mirror, `opt_mirror`, consisting of two submirrors, `opt_sub1` and `opt_sub2`.

```
metastat opt_mirror
opt_mirror: Mirror
 Submirror 0: opt_sub1
 State: Okay
 Submirror 1: opt_sub2
 State: Resyncing
 Resync in progress: 15 % done
 Pass: 1
 Read option: roundrobin (default)
 Write option: parallel (default)
 Size: 2006130 blocks
 .
 .
 .
```

**EXAMPLE 2**    Soft Partition on Mirror with Submirror

The following example shows the partial output of the `metastat` command after creating a soft partition, `d3`, on concat `d2`, which is built on a soft partition.

```
metastat
d2: Concat/Stripe
 Size: 204800 blocks
 Stripe 0:
 Device Start Block Dbase State Hot Spare
 d0 0 No Okay
d0: Soft Partition
 Component: c0t3d0s0
 Status: Okay
 Size: 204800 blocks
 Extent Start Block Block count
 0 129 204800
d3: Soft Partition
 Component: d2
 Status: Okay
 Size: 202752 blocks
 Extent Start Block Block count
 0 129 202752
```

**EXAMPLE 3** Trans Metadevice

The following example shows the output of the `metastat` command after creating a trans metadevice.

```
metastat
d2: Concat/Stripe
 Size: 204800 blocks
 Stripe 0:
 Device Start Block Dbase State Hot Spare
 d0 0 No Okay
d0: Soft Partition
 Component: c0t3d0s0
 Status: Okay
 Size: 204800 blocks
 Extent Start Block Block count
 0 129 204800
d3: Soft Partition
 Component: d2
 Status: Okay
 Size: 202752 blocks
 Extent Start Block Block count
 0 129 202752
```

**EXAMPLE 4** Multi-owner disk set

The following example shows the output of the `metastat` command with a multi-owner disk set and application-based mirror resynchronization option. Application-based resynchronization is set automatically if needed.

```
metastat -s oban
oban/d100: Mirror
 Submirror 0: oban/d10
 State: Okay
 Submirror 1: oban/d11
 State: Okay
 Pass: 1
 Read option: roundrobin (default)
 Write option: parallel (default)
 Resync option: application based
 Owner: None
 Size: 1027216 blocks (501 MB)
oban/d10: Submirror of oban/d100
 State: Okay
 Size: 1027216 blocks (501 MB)
 Stripe 0:
```

**EXAMPLE 4** Multi-owner diskset (Continued)

```

Device Start Block Dbase State Reloc Hot Spare
c1t3d0s0 0 No Okay

oban/d11: Submirror of oban/d100
State: Okay
Size: 1027216 blocks (501 MB)
Stripe 0:
Device Start Block Dbase State Reloc Hot Spare
c1t4d0s0 0 No Okay

```

**Warnings** `metastat` displays states as of the time the command is entered. It is unwise to use the output of the `metastat -p` command to create a `md.tab(4)` file for a number of reasons:

- The output of `metastat -p` might show hot spares being used.
- It might show mirrors with multiple submirrors. See [metainit\(1M\)](#) for instructions for creating multi-way mirrors using `metainit` and `metattach`.
- A slice may go into an error state after `metastat -p` is issued.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm
Interface Stability	Committed

**See Also** [mdmonitord\(1M\)](#), [metaclear\(1M\)](#), [metadb\(1M\)](#), [metadetach\(1M\)](#), [metahs\(1M\)](#), [metainit\(1M\)](#), [metaoffline\(1M\)](#), [metaonline\(1M\)](#), [metaparam\(1M\)](#), [metarecover\(1M\)](#), [metarename\(1M\)](#), [metareplace\(1M\)](#), [metaroot\(1M\)](#), [metaset\(1M\)](#), [metassist\(1M\)](#), [metasync\(1M\)](#), [metattach\(1M\)](#), [md.tab\(4\)](#), [md.cf\(4\)](#), [mddb.cf\(4\)](#), [md.tab\(4\)](#), [attributes\(5\)](#), [md\(7D\)](#)

*Solaris Volume Manager Administration Guide*

**Notes** Trans metadevices have been replaced by UFS logging. Existing trans devices are *not* logging--they pass data directly through to the underlying device. See [mount\\_ufs\(1M\)](#) for more information about UFS logging.

**Name** metasync – handle metadvice resync during reboot

**Synopsis** /usr/sbin/metasync -h  
 /usr/sbin/metasync [-s *setname*] [*buffer\_size*] *metadvice*  
 /usr/sbin/metasync [-s *setname*] -r [*buffer\_size*]  
 /usr/sbin/metasync -p *metadvice*  
 /usr/sbin/metasync -c *metadvice*

**Description** The `metasync` command starts a resync operation on the specified *metadvice*. All components that need to be resynced are resynced. If the system crashes during a RAID5 initialization, or during a RAID5 resync, either an initialization or resync restarts when the system reboots.

Applications are free to access a metadvice at the same time that it is being resynced by `metasync`. Also, `metasync` performs the copy operations from inside the kernel, which makes the utility more efficient.

Use the `-r` option in boot scripts to resync all possible submirrors.

**Options** The following options are supported:

- c *metadvice* Cancels the resync that is in progress on the specified metadvice. The resync will be stopped at its current point and can be resumed by running the “`metasync metadvice`” command. This option only applies to RAID1 volumes.
- h Displays usage message.
- p *metadvice* Regenerates parity information for RAID5 metadvicees.
- s *setname* Specifies the name of the diskset on which `metasync` will work. Using the `-s` option will cause the command to perform its administrative function within the specified diskset. Without this option, the command will perform its function on local metadvicees.
- r Specifies that the `metasync` command handle special resync requirements during a system reboot. `metasync -r` should only be invoked from the `svc:/system/mdmonitor` service. The `metasync` command only resyncs those metadvicees that need to be resynced. `metasync` schedules all the mirror resyncs according to their pass numbers.

To override the default `buffer_size` value used by the `svc:/system/mdmonitor` service, you can edit `/etc/system` to specify:

```
set md_mirror:md_resync_bufsz = 2048
```

so that resyncs occur as quickly as possible.

**Operands** *buffer\_size* Specifies the size (number of 512-byte disk blocks) of the internal copy buffer for the mirror resync. The size defaults to 1024 512-byte disk blocks. It can be no more than 2048 blocks. For best performance (quickest completion of the resync), 2048 blocks is the recommended size.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm

**See Also** [mdmonitord\(1M\)](#), [metaclear\(1M\)](#), [metadb\(1M\)](#), [metadetach\(1M\)](#), [metahs\(1M\)](#), [metainit\(1M\)](#), [metaoffline\(1M\)](#), [metaonline\(1M\)](#), [metaparam\(1M\)](#), [metarecover\(1M\)](#), [metarename\(1M\)](#), [metareplace\(1M\)](#), [metaroot\(1M\)](#), [metaset\(1M\)](#), [metassist\(1M\)](#), [metastat\(1M\)](#), [metattach\(1M\)](#), [md.tab\(4\)](#), [md.cf\(4\)](#), [mddb.cf\(4\)](#), [md.tab\(4\)](#), [attributes\(5\)](#), [md\(7D\)](#)

*Solaris Volume Manager Administration Guide*

**Notes** The `metasync` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/mdmonitor
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

**Name** metattach, metadetach – attach or detach a metadevice

**Synopsis** /usr/sbin/metattach [-h]

/usr/sbin/metattach [-s *setname*] *mirror* [*metadevice*]

/usr/sbin/metattach [-s *setname*] [-i *interlace*] *concat/strip* *component...*

/usr/sbin/metattach [-s *setname*] *RAID* *component...*

/usr/sbin/metattach [-s *setname*] [-A *alignment*] *softpart* *size* | *all*

/usr/sbin/metadetach [-s *setname*] [-f] *mirror* *submirror*

/usr/sbin/metadetach [-s *setname*] [-f] *trans*

**Description** metattach adds submirrors to a mirror, grows metadevices, or grows soft partitions. Growing metadevices can be done without interrupting service. To grow the size of a mirror or trans, the slices must be added to the submirrors or to the master devices.

Solaris Volume Manager supports storage devices and logical volumes greater than 1 terabyte (TB) when a system runs a 64-bit Solaris kernel. Support for large volumes is automatic. If a device greater than 1 TB is created, Solaris Volume Manager configures it appropriately and without user intervention.

If a system with large volumes is rebooted under a 32-bit Solaris kernel, the large volumes are visible through `metastat` output. Large volumes cannot be accessed, modified or deleted, and no new large volumes can be created. Any volumes or file systems on a large volume in this situation are also unavailable. If a system with large volumes is rebooted under a version of Solaris prior to the Solaris 9 4/03 release, Solaris Volume Manager does not start. You must remove all large volumes before Solaris Volume Manager runs under an earlier version of the Solaris Operating System.

Solaris Volume Manager supports one-to-four-way mirrors. You can only attach a metadevice to a mirror if there are three or fewer submirrors beneath the mirror. Once a new metadevice is attached to a mirror, `metattach` automatically starts a resync operation to the new submirror.

`metadetach` detaches submirrors from mirrors and logging devices from trans metadevices.

When a submirror is detached from a mirror, it is no longer part of the mirror, thus reads and writes to and from that metadevice by way of the mirror are no longer performed through the mirror. Detaching the only existing submirror is not allowed. Detaching a submirror that has slices reported as needing maintenance (by `metastat`) is not allowed unless the `-f` (force) flag is used.

`metadetach` also detaches the logging device from a trans. This step is necessary before you can clear the trans volume. Trans metadevices have been replaced by UFS logging. Existing trans devices are not logging. They pass data directly through to the underlying device. See [mount\\_ufs\(1M\)](#) for more information about UFS logging.

Detaching the logging device from a busy trans device is not allowed unless the `-f` (force) flag is used. Even so, the logging device is not actually detached until the trans is idle. The trans is in the *Detaching* state (`metastat`) until the logging device is detached.

**Options** Root privileges are required for all of the following options except `-h`.

The following options are supported:

- `-A alignment` Set the value of the soft partition extent alignment. Use this option when it is important specify a starting offset for the soft partition. It preserves the data alignment between the metadevice address space and the address space of the underlying physical device.

For example, a hardware device that does checksumming should not have its I/O requests divided by Solaris Volume Manager. In this case, use a value from the hardware configuration as the value for the alignment. When using this option in conjunction with a software I/O load, the alignment value corresponds to the I/O load of the application. This prevents I/O from being divided unnecessarily and affecting performance.
- `-f` Force the detaching of metadevices that have components that need maintenance or are busy. You can use this option only when a mirror is in a maintenance state that can be fixed with `metareplace(1M)`. If the mirror is in a maintenance state that can only be fixed with `metasync(1M)` (as shown by the output of `metastat(1M)`), `metadetach -f` has no effect, because the mirrors must be resynchronized before one of them can be detached.
- `-h` Display a usage message.
- `-i interlace` Specify the interlace value for stripes, where `size` is a specified value followed by either `k` for kilobytes, `m` for megabytes, or `b` for blocks. The units can be either uppercase or lowercase. If `size` is not specified, the size defaults to the interlace size of the last stripe of the metadevice. When an interlace size change is made on a stripe, it is carried forward on all stripes that follow.
- `-s setname` Specify the name of the diskset on which the `metattach` command or the `metadetach` command works.. Using the `-s` option causes the command to perform its administrative function within the specified diskset. Without this option, the command performs its function on local metadevices.

**Operands** The following operands are supported:

- `component` The logical name for the physical slice (partition) on a disk drive, such as `/dev/dsk/c0t0d0s2`, being added to the concatenation, stripe, concatenation of stripes, or RAID5 metadevice.
- `concat/stripe` The metadevice name of the concatenation, stripe, or concatenation of stripes.

<i>log</i>	The metadvice name of the logging device to be attached to the trans metadvice.
<i>metadvice</i>	The metadvice name to be attached to the mirror as a submirror. This metadvice must have been previously created by the <code>metainit</code> command.
<i>mirror</i>	The name of the mirror.
<i>RAID</i>	The metadvice name of the RAID5 metadvice.
<i>size</i>   <i>all</i>	The amount of space to add to the soft partition in K or k for kilobytes, M or m for megabytes, G or g for gigabytes, T or t for terabytes, and B or b for blocks (sectors). All values represent powers of 2, and upper and lower case options are equivalent. Only integer values are permitted. The literal <code>all</code> specifies that the soft partition should grow to occupy all available space on the underlying volume.
<i>softpart</i>	The metadvice name of the existing soft partition.
<i>submirror</i>	The metadvice name of the submirror to be detached from the mirror.
<i>trans</i>	The metadvice name of the trans metadvice (not the master or logging device).

#### Examples EXAMPLE 1 Concatenating a New Slice to a Metadvice

This example concatenates a single new slice to an existing metadvice, `Volume.1`. Afterwards, you would use the `growfs(1M)` command to expand the file system.

```
metattach Volume.1 /dev/dsk/c0t1d0s2
```

#### EXAMPLE 2 Detaching Logging Device from Trans Metadvice

This example detaches the logging device from a trans metadvice `d9`. Notice that you do not have to specify the logging device itself, as there can only be one.

```
metadetach d9
```

#### EXAMPLE 3 Expanding a RAID5 Metadvice

This example expands a RAID5 metadvice, `d45`, by attaching another slice.

```
metattach d45 /dev/dsk/c3t0d0s2
```

When you add additional slices to a RAID5 metadvice, the additional space is devoted to data. No new parity blocks are allocated. The data on the added slices is, however, included in the overall parity calculations, so it is protected against single-device failure.

#### EXAMPLE 4 Expanding a Soft Partition

The following example expands a soft partition, `d42`, attaching all space available on the underlying device.

**EXAMPLE 4** Expanding a Soft Partition *(Continued)*

```
metattach d42 all
```

When you add additional space to a soft partition, the additional space is taken from any available space on the slice and might not be contiguous with the existing soft partition.

**EXAMPLE 5** Adding Space to Two-Way Mirror

This example adds space to a two-way mirror by adding a slice to each submirror. Afterwards, you would use the [growfs\(1M\)](#) command to expand the file system.

```
metattach d9 /dev/dsk/c0t2d0s5
metattach d10 /dev/dsk/c0t3d0s5
```

This example tells the mirror to grow to the size of the underlying devices

```
metattach d11
```

This example increases the size of the UFS on the device so the space can be used.

```
growfs -M /export /dev/md/rdisk/d11
```

**EXAMPLE 6** Detaching a Submirror from a Mirror

This example detaches a submirror, d2, from a mirror, d4.

```
metadetach d4 d2
```

**EXAMPLE 7** Adding Four Slices to Metadevice

This example adds four slices to an existing metadevice, d9. Afterwards, you would use the [growfs\(1M\)](#) command to expand the file system.

```
metattach d9 /dev/dsk/c0t1d0s2 /dev/dsk/c0t2d0s2 \\
/dev/dsk/c0t3d0s2 /dev/dsk/c0t4d0s2
```

**EXAMPLE 8** Setting the Value of the Soft Partition Extent Alignment

This example shows how to set the alignment of the soft partition to 1mb when the soft partition is expanded.

```
metattach -s red -A 2m d13 1m
```

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm
Interface Stability	Committed

**See Also** [mdmonitord\(1M\)](#), [metaclear\(1M\)](#), [metadb\(1M\)](#), [metahs\(1M\)](#), [metainit\(1M\)](#), [metaoffline\(1M\)](#), [metaonline\(1M\)](#), [metaparam\(1M\)](#), [metarecover\(1M\)](#), [metarename\(1M\)](#), [metareplace\(1M\)](#), [metaroot\(1M\)](#), [metaset\(1M\)](#), [metassist\(1M\)](#), [metastat\(1M\)](#), [metasync\(1M\)](#), [md.tab\(4\)](#), [md.cf\(4\)](#), [mddb.cf\(4\)](#), [md.tab\(4\)](#), [attributes\(5\)](#), [md\(7D\)](#)

*Solaris Volume Manager Administration Guide*

**Warnings** This section provides information regarding warnings for devices greater than 1 TB and for multi-way mirrors.

**Devices and Volumes Greater Than 1 TB** Do not create large (>1 TB) volumes if you expect to run the Solaris Operating System with a 32-bit kernel or if you expect to use a version of the Solaris Operating System prior to Solaris 9 4/03.

**Multi-Way Mirrors** When a submirror is detached from its mirror, the data on the metadvice might not be the same as the data that existed on the mirror prior to running `metadetach`. In particular, if the `-f` option was needed, the metadvice and mirror probably do not contain the same data.

**Notes** Trans metadvicees have been replaced by UFS logging. Existing trans devices are *not* logging. They pass data directly through to the underlying device. See [mount\\_ufs\(1M\)](#) for more information about UFS logging.

**Name** mib2mof – generate MOF file(s) from input SNMP MIB file(s)

**Synopsis** /usr/sadm/bin/mib2mof [-n] [-d *directory*] [-q] [-c] [-a]  
[-h] *files*

**Description** The mib2mof utility reads input Management Information Base (MIB) files and produces one or more Managed Object Format (MOF) files. MOF files contain a Common Information Model (CIM) class declaration that represents the MIB for the Solaris Simple Network Management Protocol (SNMP) provider. The SNMP provider allows Web-Based Enterprise Management (WBEM) applications to access SNMP device information.

SNMP scalar variables map to properties in the CIM class. Qualifiers on each property convey the following MIB information for each scalar variable:

- syntax
- read/write access
- OID (Object Identifier)
- description (optional)
- index (if the variable is within a group [sequence] that defines a row)

The syntax of an SNMP scalar variable is represented in a CIM class by the property's CIM datatype. All properties are marked with write access (true or false).

The following table shows how a Solaris SNMP datatype in a MIB maps to a Web-Based Enterprise Management (WBEM) CIM datatype and then to an SNMP datatype used by the WBEM SNMP API:

SNMP SMI Datatype	SNMP Ver.	CIM Datatype	SNMP API Object type
INTEGER	v1	sint32	SnmpInt
OCTET STRING	v1	string	SnmpString
OBJECT IDENTIFIER	v1	string	SnmpOid
IpAddress	v1	string	SnmpIpAddress
Counter	v1	uint32	SnmpCounter
Gauge	v1	uint32	SnmpGauge
TimeTicks	v1	uint32	SnmpTimeticks
Opaque	v1	sint8[]	SnmpOpaque
DisplayString - see OCTET STRING	v1		
NetworkAddress - see IpAddress	v1		
Counter32 - see Counter	v2		
Counter64	v2	uint64	SnmpCounter64
Integer32	v2	sint32	SnmpInt
Gauge32 - see Gauge	v2		
Unsigned32	v2	uint32	SnmpGauge
TruthValue	v2	sint32	SnmpInt
BITS - see OCTET STRING	v2		

The mib2mof utility includes its required `Solaris_SNMPmib_core.txt` file (containing core MIB definitions), installed in `/usr/sadm/mof`. The mib2mof utility looks first for mib core file in local directory. If this file is not found in the local directory, mib2mof looks in `/usr/sadm/mof`.

A MOF file is generated for each SNMP group and table row sequence (that is, the columns in one row) found in the supplied MIBs. (This does not include the core MIB definitions contained in the `Solaris_SNMPmib_core.txt` file.)

There is no MOF file or property for an SNMP table - all table access is through the rows and columns of the table, and the SNMP variable for the table is marked as inaccessible in the MIB.

The MOF file created contains a CIM class that represents an SNMP group or row and a CIM class to represent a CIM association. The output file name (and CIM class) is of the format `<SNMP_><MIB name><Group name>.mof`.

**Options** The following options are supported:

- a Generate MOF files for all of the input MIB files. If -a is not given, a MOF file is generated only for the last file of the input list.
- c Do not use the default `Solaris_SNMPmib_core.txt` definitions file shipped with the Solaris SNMP Provider for WBEM. If this option is specified, you must specify another `MIB_CORE` definitions file as one of the input files.
- d *directory* Generate output MOF files in the specified directory.
- h Show how to invoke `mib2mof` and list its arguments.
- n Parse the input MIB files without generating any output.
- q Include the `DESCRIPTION` clause of `SNMP OBJECT - TYPE` as a qualifier in the generated MOF file.

**Operands** The following operands are supported:

*files* List of SNMP MIB files to be converted.

**Exit Status** The `mib2mof` utility terminates with exit status 0.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWwbco

**See Also** [init.wbem\(1M\)](#), [mofcomp\(1M\)](#), [wbemadmin\(1M\)](#), [attributes\(5\)](#)

**Name** mibiisa – Sun SNMP Agent

**Synopsis** mibiisa [-ar] [-c *config-dir*] [-d *debug-level*] [-p *port*]  
[-t *cache-timer*]

**Description** The `mibiisa` utility is an RFC 1157-compliant SNMP agent. It supports MIB-II as defined in *RFC 1213*, with Sun extensions under Sun's enterprise number. The MIB (Management Information Base) is both readable and writable. The `mibiisa` utility supports all SNMP protocol operations including GET-REQUEST, GETNEXT-REQUEST, SET-REQUEST, GET-REPLY, and TRAP.

The SMA (Systems Management Agent) is the default SNMP agent in Solaris. MIB-II subagent `mibiisa` does not run by default. To enable `mibiisa`, rename the configuration file from `/etc/snmp/conf/mibiisa.rsrc` to `/etc/snmp/conf/mibiisa.rsrc`. SMA has the capability to handle any MIB-II requests.

The `mibiisa` utility supports the `coldStart`, `linkUp`, `linkDown`, and authentication traps. The authentication trap may be disabled by a command-line switch, which itself may be overridden by a management station writing to a MIB variable in the standard SNMP MIB group.

The `mibiisa` utility supports four distinct views of the MIB. The view used for any request is determined by the community string contained in that request.

To enhance security, `mibiisa` supports an option to block all writes to the MIB. You can also limit the set of management stations from which the agent will accept requests in the configuration file used when starting the `mibiisa`. See the [Security](#) section for more information.

Unless overridden, `mibiisa` uses UDP port 161, the standard SNMP port. The `mibiisa` utility issues traps through the same port on which it receives SNMP requests.

The `mibiisa` utility must run with super-user privileges and is typically started at system startup via `/etc/rc3.d`. `mibiisa` may not be started using `inetd(1M)`. When started, `mibiisa` detaches itself from the keyboard, disables all signals except SIGKILL, SIGILL, SIGUSR1, and SIGUSR2, and places itself in the background.

**Options** The following options are supported by `mibiisa`:

- a Disable the generation of authentication traps. However, an SNMP manager may write a value into `snmpEnableAuthenTraps` to enable or disable authentication traps.
- c *config-dir* Specify a directory where it expects `snmpd.conf` file, on startup. The default directory is `/etc/snmp/conf`.
- d *debug-level* Debug. A value of 0 disables all debug and is the default. Levels 1 through 3 represent increasing levels of debug output. When `mibiisa` receives the

signal SIGUSR1, it resets the debug-level to 0. When `mibiisa` receives the signal SIGUSR2, it increments the debug-level by one.

Debug output is sent to the standard output in effect at the time `mibiisa` is started. No matter what debug level is in effect, certain significant events are logged in the system log.

- `-p port` Define an alternative UDP port on which `mibiisa` listens for incoming requests. The default is UDP port 161.
- `-r` Place the MIB into read-only mode.
- `-t cache-timer` By default, information fetched from the kernel is considered to be valid for 45 seconds from the time it is retrieved. This cache lifetime may be altered with this parameter. You cannot set `cache-timer` to any value less than 1.

**Configuration File** The `snmpd.conf` file is used for configuration information. Each entry in the file consists of a keyword followed by a parameter string. The keyword must begin in the first position. Parameters are separated from the keyword and from one another by white space. Case in keywords is ignored. Each entry must be contained on a single line. All text following (and including) a pound sign (#) is ignored. Keywords currently supported are:

<code>sysdescr</code>	The value to be used to answer queries for <code>sysDescr</code> .
<code>syscontact</code>	The value to be used to answer queries for <code>sysContact</code> .
<code>syslocation</code>	The value to be used to answer queries for <code>sysLocation</code> .
<code>trap</code>	The parameter names one or more hosts to receive traps. Only five hosts may be listed.
<code>system-group-read-community</code>	The community name to get read access to the system group and Sun's extended system group.
<code>system-group-write-community</code>	The community name to get write access to the system group and Sun's extended system group.
<code>read-community</code>	The community name to get read access to the entire MIB.
<code>write-community</code>	The community name to get write access to the entire MIB (implies read access).
<code>trap-community</code>	The community name to be used in traps.
<code>kernel-file</code>	The name of the file to use for kernel symbols.
<code>managers</code>	The names of hosts that may send SNMP queries. Only five hosts may be listed on any one line. This keyword may be repeated for a total of 32 hosts.

`newdevice` The additional devices which are not built in SNMPD. The format is as follows: `newdevice type speed name` where `newdevice` is the keyword, `type` is an integer which has to match your schema file, `speed` is the new device's speed, and `name` is this new device's name.

An example `snmpd.conf` file is shown below:

```
sysdescr Sun SNMP Agent, Sun Fire 4800, Company
 Property Number 123456
syscontact Cliff Claven
sysLocation Room 1515, building 1
#
system-group-read-community public
system-group-write-community private
#
read-community all_public
write-community all_private
#
trap localhost
trap-community SNMP-trap
#
#kernel-file /vmunix
#
managers lvs golden
managers swap
```

**Installation** The `mibiisa` utility and its configuration file, `snmpd.conf`, may be placed in any directory. However for Solaris 2.4 and subsequent releases, use `/usr/lib/snmp` for `mibiisa` itself and `/etc/snmp/conf` for the configuration file. You can modify the configuration file as appropriate. If you make any changes to `snmpd.conf` file keyword values, you must kill and restart `mibiisa` for the changes to take effect.

Your `/etc/services` file (or NIS equivalent) should contain the following entries:

---

<code>snmp</code>	<code>161/udp</code>		<code># Simple Network Mgmt Protocol</code>
<code>snmp-trap</code>	<code>162/udp</code>	<code>snmptrap</code>	<code># SNMP trap (event) messages</code>

---

The following is an example for Solaris 2.x and releases compatible with Solaris 2.x, such as Solaris 9:

```
#
Start the SNMP agent
#
```

```

if [-f /etc/snmp/conf/snmpd.conf -a -x
 /usr/lib/snmp/mibiisa];
then
/opt/SUNWconn/snm/agents/snmpd
echo 'Starting SNMP-agent.'
```

**Security** SNMP, as presently defined, offers relatively little security. The `mibiisa` utility accepts requests from other machines, which can have the effect of disabling the network capabilities of your computer. To limit the risk, the configuration file lets you specify a list of up to 32 manager stations from which `mibiisa` will accept requests. If you do not specify any such manager stations, `mibiisa` accepts requests from anywhere.

The `mibiisa` utility also allows you to mark the MIB as “read-only” by using the `-r` option.

`mibiisa` supports four different community strings. These strings, however, are visible in the configuration file and within the SNMP packets as they flow on the network.

The configuration file should be owned by, and readable only by super-user. In other words the mode should be:

```

-rw----- 1 root 2090 Oct 17 15:04 /etc/snmp/conf/snmpd.conf
```

Managers can be restricted based on the community strings. This can be configured by creating an optional secondary configuration file `/etc/snmp/conf/mibiisa.acl`. To enable such a restriction, add the security line in the `/etc/snmp/conf/mibiisa.rsrc` file.

An example `mibiisa.acl` file is as follows:

```

acl = {
 {
 communities = public
 access = read-only
 managers = xyz
 }
 {
 communities = private
 access = read-write
 managers = abc,pqrs
 }
}
```

An example `mibiisa.rsrc` file is as follows:

```

resource =
{
 {
 registration_file = "/etc/snmp/conf/mibiisa.reg"
 security = "/etc/snmp/conf/mibiisa.acl"
 policy = "spawn"
 type = "legacy"
```

```

 command = "/usr/lib/snmp/mibiisa -r -p $PORT"
 }
}

```

**Mib** This section discusses some of the differences between the `mibiisa` MIB and the standard MIB-II (as defined in RFC 1213).

The following variables are read-only in the `mibiisa` MIB:

```

sysName
atIfIndex
ipDefaultTTL

```

These variables are read-write in the standard MIB-II.

The `mibiisa` MIB Address Translation tables support limited write access: only `atPhysAddress` may be written, either to change the physical address of an existing entry or to delete an entire ARP table entry.

The `mibiisa` MIB IP Net to Media table supports limited write access: only `ipNetToMediaPhysAddress` and `ipNetToMediaType` may be written, either to change the physical address of an existing entry or to delete an entire ARP table entry.

The following variables are read-write in the `mibiisa` MIB; however, these variables have fixed values. Any new values “set” to them are accepted, but have no effect:

```

ipRoutIfIndex
ipRouteMetric1
ipRouteMetric2
ipRouteMetric3
ipRouteMetric4
ipRouteMetric5
ipRouteType
ipRouteAge
ipRouteMask
ipRouteMetric5

```

The following `mibiisa` MIB variable reflects the actual state of the related table entry. “Sets” are accepted but have no effect:

```

tcpConnState

```

The following `mibiisa` MIB variables are readable, but return a fixed value:

---

<code>icmpInDestUnreachs</code>	Returns 1
<code>icmpInTimeExcds</code>	Returns 1
<code>icmpInParmProbs</code>	Returns 1
<code>icmpInSrcQuenchs</code>	Returns 1

---

---

icmpInRedirects	Returns 1
icmpInEchos	Returns 1
icmpInEchoReps	Returns 1
icmpInTimestamps	Returns 1
icmpInTimestampReps	Returns 1
icmpInAddrMasks	Returns 1
icmpInAddrMaskReps	Returns 1
icmpOutDestUnreachs	Returns 1
icmpOutTimeExcds	Returns 1
icmpOutParmProbs	Returns 1
icmpOutSrcQuenchs	Returns 1
icmpOutRedirects	Returns 1
icmpOutEchos	Returns 1
icmpOutEchoReps	Returns 1
icmpOutTimestamps	Returns 1
icmpOutTimestampReps	Returns 1
icmpOutAddrMasks	Returns 1
icmpOutAddrMaskReps	Returns 1
ifInUnknownProtos	Returns 0
ipAdEntBcastAddr	Returns 1
ipAdEntReasmMaxSiz	Returns 65535
ipRouteMetric1	Returns -1
ipRouteMetric2	Returns -1
ipRouteMetric3	Returns -1
ipRouteMetric4	Returns -1
ipRouteAge	Returns 0
ipRouteMetric5	Returns -1
ipNetToMediaType	Returns (3) dynamic
ipRoutingDiscards	Returns 0

---

The following variables return a fixed value of 0 for drivers not conforming to the GLD framework (see [gld\(7D\)](#)), including the old LAN drivers on SPARC machines:

---

<code>ifInOctets</code>	Returns 0
<code>ifInNUcastPkts</code>	Returns 0
<code>ifInDiscards</code>	Returns 0
<code>ifOutOctets</code>	Returns 0
<code>ifOutNUcastPkts</code>	Returns 0
<code>ifOutDiscards</code>	Returns 0

---

**Schema Attributes** The following describes the attributes in the group and table definitions in the `/var/snmp/mib/sun.mib` file.

**system** The `system` group reports statistics about a particular system (for example, a workstation or a printer).

`sysDescr` – A textual description of the entity. This value should include the full name and version identification of the system's hardware type, software operating-system, and networking software. This value must only contain printable ASCII characters. (string[255])

`sysObjectID` – The vendor's authoritative identification of the network management subsystem contained in the entity. This value is allocated within the SMI enterprises subtree (1.3.6.1.4.1) and provides an easy and unambiguous means for determining what type of equipment is being managed. For example, if vendor “Flintstones, Inc.” was assigned the subtree 1.3.6.1.4.1.4242, it could assign the identifier 1.3.6.1.4.1.4242.1.1 to its “Fred Router.” (objectid)

`sysUpTime` – Time (in hundredths of a second) since the network management portion of the system was last reinitialized. (timeticks)

`sysContact` – The textual identification of the contact person for this managed node, together with information on how to contact this person. (string[255])

`sysName` – An administratively-assigned name for this managed node. By convention, this is the node's fully-qualified domain name. (string[255])

`sysLocation` – The physical location of this node (for example, “telephone closet, 3rd floor” (string[255]))

`sysServices` – A value indicating the set of services that this entity primarily offers. (int) The value is a sum. This sum initially takes the value zero. Then, for each layer L in the range 1 through 7 for which this node performs transactions, 2 raised to (L - 1) is added to the sum. For example, a node that performs primarily routing functions would have a value of 4

$(2^{**}(3-1))$ ). In contrast, a node that is a host offering application services would have a value of 72 ( $2^{**}(4-1) + 2^{**}(7-1)$ ). Note that in the context of the Internet suite of protocols, values should be calculated accordingly:

Layer	Functionality
1	physical (such as repeaters)
2	datalink/subnetwork (such as bridges)
3	internet (such as IP gateways)
4	end-to-end (such as IP hosts)
7	applications (such as mail relays)

For systems including OSI protocols, Layers 5 and 6 may also be counted.

**interfaces** The `interfaces` group reports the number of interfaces handled by the agent.

`ifNumber` – The number of network interfaces, regardless of their current state, present on this system. (int)

`ifTable` The `ifTable` is a table of interface entries. The number of entries is given by the value of `ifNumber`.

`ifIndex` – A unique value for each interface. Its value ranges between 1 and the value of `ifNumber`. The value for each interface must remain constant at least from one reinitialization of the entity's network management system to the next reinitialization. (int)

`ifDescr` – A textual string containing information about the interface. This string should include the name of the manufacturer, the product name, and the version of the hardware interface. (string[255])

`ifType` – The type of interface, distinguished according to the physical/link protocol(s) immediately below the network layer in the protocol stack. (enum)

`ifMtu` – The size of the largest datagram that can be sent/received on the interface, specified in octets. For interfaces used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface. (int)

`ifSpeed` – An estimate of the interface's current bandwidth in bits-per-second. For interfaces that do not vary in bandwidth, or for those where no accurate estimation can be made, this object should contain the nominal bandwidth. (gauge)

`ifPhysAddress` – The interface's address at the protocol layer immediately below the network layer in the protocol stack. For interfaces without such an address (for example, a serial line), this object should contain an octet string of zero length. (octet[128])

`ifAdminStatus` – The desired state of the interface. The `testing(3)` state indicates that no operational packets can be passed. (enum)

`ifOperStatus` – The current operational state of the interface. The `testing(3)` state indicates that no operational packets can be passed. (enum)

`ifLastChange` – The value of `sysUpTime` at the time the interface entered its current operational state. If the current state was entered prior to the last reinitialization of the local network management subsystem, then this object contains a zero value. (timeticks)

`ifInOctets` – The total number of octets received on the interface, including framing characters. (counter) Returns a fixed value of 0.

`ifInUcastPkts` – The number of subnetwork-unicast packets delivered to a higher-layer protocol. (counter)

`ifInNUcastPkts` – The number of non-unicast (that is, subnetwork-broadcast or subnetwork-multicast) packets delivered to a higher-layer protocol. (counter) Returns a fixed value of 0.

`ifInDiscards` – The number of inbound packets chosen to be discarded, even though no errors had been detected to prevent their being deliverable to a higher-layer protocol. One possible reason for discarding such a packet could be to free up buffer space. (counter) Returns a fixed value of 0.

`ifInErrors` – The number of inbound packets that contained errors preventing them from being deliverable to a higher-layer protocol. (counter)

`ifInUnknownProtos` – The number of packets received via the interface that were discarded because of an unknown or unsupported protocol. (counter) Returns a fixed value of 0.

`ifOutOctets` – The total number of octets transmitted out of the interface, including framing characters. (counter) Returns a fixed value of 0.

`ifOutUcastPkts` – The total number of packets that higher-level protocols requested be transmitted to a subnetwork-unicast address, including those that were discarded or not sent. (counter)

`ifOutNUcastPkts` – The total number of packets that higher-level protocols requested be transmitted to a non-unicast (that is, a subnetwork-broadcast or subnetwork-multicast) address, including those that were discarded or not sent. (counter) Returns a fixed value of 0.

`ifOutDiscards` – The number of outbound packets that were chosen to be discarded even though no errors had been detected to prevent their being transmitted. One possible reason for discarding such a packet could be to free up buffer space. (counter) Returns a fixed value of 0.

`ifOutErrors` – The number of outbound packets that could not be transmitted because of errors. (counter)

`ifOutQLen` – The length of the output packet queue (in packets). (gauge)

`ifSpecific` – A reference to MIB definitions specific to the particular media being used to realize the interface. For example, if the interface is realized by an Ethernet, then the value of this object refers to a document defining objects specific to Ethernet. If this information is not present, its value should be set to the OBJECT IDENTIFIER { 0 0 }, which is a syntactically valid object identifier. Any conformant implementation of ASN.1 and BER must be able to generate and recognize this value. (objectid)

`atTable` `atTable` Address Translation tables contain the `NetworkAddress` to physical address equivalences. Some interfaces do not use translation tables for determining address equivalences (for example, DDN-X.25 has an algorithmic method). If all interfaces are of this type, then the Address Translation table is empty, that is, has zero entries.

`atIfIndex` – The interface on which this entry's equivalence is effective. The interface identified by a particular value of this index is the same interface as identified by the same value of `ifIndex`. (int)

`atPhysAddress` – The media-dependent physical address. (octet[128]) Setting this object to a null string (one of zero length) has the effect of invalidating the corresponding entry in the `atTable` object. That is, it effectively dissociates the interface identified with said entry from the mapping identified with said entry. It is an implementation-specific matter as to whether the agent removes an invalidated entry from the table. Accordingly, management stations must be prepared to receive tabular information from agents that corresponds to entries not currently in use. Proper interpretation of such entries requires examination of the relevant `atPhysAddress` object.

`atNetAddress` – The `NetworkAddress` (that is, the IP address) corresponding to the media-dependent physical address. (netaddress)

`ip` The `ip` group reports statistics about the Internet Protocol (IP) group.

`ipForwarding` – The indication of whether this entity is acting as an IP gateway in respect to the forwarding of datagrams received by, but not addressed to, this entity. IP gateways forward datagrams. IP hosts do not— except those source-routed via the host. (enum)

Note that for some managed nodes, this object may take on only a subset of the values possible. Accordingly, it is appropriate for an agent to return a “badValue” response if a management station attempts to change this object to an inappropriate value.

`ipDefaultTTL` – The default value inserted into the Time-To-Live field of the IP header of datagrams originated at this entity, whenever a TTL value is not supplied by the transport layer protocol. (int)

`ipInReceives` – The total number of input datagrams received from interfaces, including those received in error. (counter)

`ipInHdrErrors` – The number of input datagrams discarded due to errors in their IP headers, including bad checksums, version number mismatch, other format errors, time-to-live exceeded, errors discovered in processing their IP options, and so on. (counter)

`ipInAddrErrors` – The number of input datagrams discarded because the IP address in their IP header's destination field was not a valid address to be received at this entity. This count includes invalid addresses (for example, 0.0.0.0) and addresses of unsupported Classes (for example, Class E). For entities that are not IP Gateways and therefore do not forward datagrams, this counter includes datagrams discarded because the destination address was not a local address. (counter)

`ipForwDatagrams` – The number of input datagrams for which this entity was not their final IP destination, as a result of which an attempt was made to find a route to forward them to that final destination. In entities that do not act as IP Gateways, this counter will include only those packets that were Source-Routed via this entity, and the Source-Route option processing was successful. (counter)

`ipInUnknownProtos` – The number of locally-addressed datagrams received successfully but discarded because of an unknown or unsupported protocol. (counter)

`ipInDiscards` – The number of input IP datagrams for which no problems were encountered to prevent their continued processing, but which were discarded, for example, for lack of buffer space. Note that this counter does not include any datagrams discarded while awaiting reassembly. (counter)

`ipInDelivers` – The total number of input datagrams successfully delivered to IP user-protocols (including ICMP). (counter)

`ipOutRequests` – The total number of IP datagrams that local IP user-protocols (including ICMP) supplied to IP in requests for transmission. Note that this counter does not include any datagrams counted in `ipForwDatagrams`. (counter)

`ipOutDiscards` – The number of output IP datagrams for which no problem was encountered to prevent their transmission to their destination, but which were discarded (for example, for lack of buffer space). Note that this counter would include datagrams counted in `ipForwDatagrams` if any such packets met this (discretionary) discard criterion. (counter)

`ipOutNoRoutes` – The number of IP datagrams discarded because no route could be found to transmit them to their destination. Note that this counter includes any packets counted in `ipForwDatagrams` which meet this “no-route” criterion. Note that this includes any datagrams that a host cannot route because all its default gateways are down. (counter)

`ipReasmTimeout` – The maximum number of seconds that received fragments are held while they are awaiting reassembly at this entity. (int)

`ipReasmReqds` – The number of IP fragments received that needed to be reassembled at this entity. (counter)

`ipReasmOKs` – The number of IP datagrams successfully reassembled. (counter)

`ipReasmFails` – The number of failures detected by the IP reassembly algorithm, for whatever reason: timed out, errors, and the like. Note that this is not necessarily a count of discarded IP fragments since some algorithms (notably the algorithm in RFC 815) can lose track of the number of fragments by combining them as they are received. (counter)

`ipFragOKs` – The number of IP datagrams that have been successfully fragmented at this entity. (counter)

`ipFragFails` – The number of IP datagrams that have been discarded because they needed to be fragmented at this entity but could not be, for example, because their “Don’t Fragment” flag was set. (counter)

`ipFragCreates` – The number of IP datagram fragments that have been generated as a result of fragmentation at this entity. (counter)

`ipRoutingDiscards` – The number of routing entries that were chosen to be discarded even though they were valid. One possible reason for discarding such an entry could be to free-up buffer space for other routing entries. (counter) Returns a fixed value of 0.

`ipAddrTable` `ipAddrTable` is a table of addressing information relevant to this entity’s IP addresses.

`ipAdEntAddr` – The IP address to which this entry’s addressing information pertains. (netaddress)

`ipAdEntIfIndex` – The index value that uniquely identifies the interface to which this entry is applicable. The interface identified by a particular value of this index is the same interface as identified by the same value of `ifIndex`. (int)

`ipAdEntNetMask` – The subnet mask associated with the IP address of this entry. The value of the mask is an IP address with all the network bits set to 1, and all the hosts bits set to 0. (netaddress)

`ipAdEntBcastAddr` – The value of the least-significant bit in the IP broadcast address used for sending datagrams on the (logical) interface associated with the IP address of this entry. For example, when the Internet standard all-ones broadcast address is used, the value will be 1. This value applies to both the subnet and network broadcasts addresses used by the entity on this (logical) interface. (int) Returns a fixed value of 1.

`ipAdEntReasmMaxSize` – The size of the largest IP datagram that this entity can reassemble from incoming IP fragmented datagrams received on this interface. (int) Returns a fixed value of 65535.

`ipRouteTable` `ipRouteTable` is this entity’s IP Routing table.

`ipRouteDest` – The destination IP address of this route. An entry with a value of 0.0.0.0 is considered a default route. Multiple routes to a single destination can appear in the table, but

access to such multiple entries is dependent on the table- access mechanisms defined by the network management protocol in use. (netaddress)

`ipRouteIfIndex` – The index value that uniquely identifies the local interface through which the next hop of this route should be reached. The interface identified by a particular value of this index is the same interface as identified by the same value of `ifIndex`. (int)

`ipRouteMetric1` – The primary routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route's `ipRouteProto` value. If this metric is not used, its value should be set to `-1`. (int) Returns a fixed value of `-1`.

`ipRouteMetric2` – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route's `ipRouteProto` value. If this metric is not used, its value should be set to `-1`. (int) Returns a fixed value of `-1`.

`ipRouteMetric3` – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route's `ipRouteProto` value. If this metric is not used, its value should be set to `-1`. (int) Returns a fixed value of `-1`.

`ipRouteMetric4` – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route's `ipRouteProto` value. If this metric is not used, its value should be set to `-1`. (int) Returns a fixed value of `-1`.

`ipRouteNextHop` – The IP address of the next hop of this route. (In the case of a route bound to an interface that is realized via a broadcast media, the value of this field is the agent's IP address on that interface.) (netaddress)

`ipRouteType` – The type of route. Note that the values `direct` (3) and `indirect` (4) refer to the notion of direct and indirect routing in the IP architecture. (enum)

Setting this object to the value `invalid` (2) has the effect of invalidating the corresponding entry in the `ipRouteTable` object. That is, it effectively dissociates the destination identified with said entry from the route identified with said entry. It is an implementation-specific matter as to whether the agent removes an invalidated entry from the table. Accordingly, management stations must be prepared to receive tabular information from agents that corresponds to entries not currently in use. Proper interpretation of such entries requires examination of the relevant `ipRouteType` object.

`ipRouteProto` – The routing mechanism through which this route was learned. Inclusion of values for gateway routing protocols is not intended to imply that hosts should support those protocols. (enum)

`ipRouteAge` – The number of seconds since this route was last updated or otherwise determined to be correct. Note that no semantics of “too old” can be implied except through knowledge of the routing protocol by which the route was learned. (int) Returns a fixed value of 0.

**ipRouteMask** – Indicate the mask to be logical-ANDed with the destination address before being compared to the value in the **ipRouteDest** field. For those systems that do not support arbitrary subnet masks, an agent constructs the value of the **ipRouteMask** by determining whether the value of the correspondent **ipRouteDest** field belongs to a class-A, B, or C network, and then using one of:

Mask	Network
255.0.0.0	class-A
255.255.0.0	class-B
255.255.255.0	class-C

If the value of the **ipRouteDest** is 0.0.0.0 (a default route), then the mask value is also 0.0.0.0. It should be noted that all IP routing subsystems implicitly use this mechanism. (netaddress)

**ipRouteMetric5** – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route's **ipRouteProto** value. If this metric is not used, its value should be set to -1. (int) Returns a fixed value of -1.

**ipRouteInfo** – A reference to MIB definitions specific to the particular routing protocol responsible for this route, as determined by the value specified in the route's **ipRouteProto** value. If this information is not present, its value should be set to the OBJECT IDENTIFIER { 0 0 }, which is a syntactically valid object identifier. Any conformant implementation of ASN.1 and BER must be able to generate and recognize this value. (objectid)

**ipNetToMediaTable** The **ipNetToMediaTable** is the IP Address Translation table used for mapping from IP addresses to physical addresses.

**ipNetToMediaIfIndex** – The interface on which this entry's equivalence is effective. The interface identified by a particular value of this index is the same interface as identified by the same value of **ifIndex**. (int)

**ipNetToMediaPhysAddress** – The media-dependent physical address. (octet[128])

**ipNetToMediaNetAddress** – The **IpAddress** corresponding to the media- dependent physical address. (netaddress)

**ipNetToMediaType** – The type of mapping. (enum) Returns a fixed value of (3)dynamic. Setting this object to the value **invalid(2)** has the effect of invalidating the corresponding entry in the **ipNetToMediaTable**. That is, it effectively dissociates the interface identified with said entry from the mapping identified with said entry. It is an implementation-specific matter as to whether the agent removes an invalidated entry from the table. Accordingly, management stations must be prepared to receive tabular information from agents that corresponds to entries not currently in use. Proper interpretation of such entries requires examination of the relevant **ipNetToMediaType** object.

`icmp` The `icmp` group reports statistics about the ICMP group.

`icmpInMsgs` – The total number of ICMP messages that the entity received. Note that this counter includes all those counted by `icmpInErrors`. (counter)

`icmpInErrors` – The number of ICMP messages that the entity received but determined as having ICMP-specific errors (bad ICMP checksums, bad length, and the like.). (counter)

`icmpInDestUnreachs` – The number of ICMP Destination Unreachable messages received. (counter)

`icmpInTimeExcds` – The number of ICMP Time Exceeded messages received. (counter)

`icmpInParmProbs` – The number of ICMP Parameter Problem messages received. (counter)

`icmpInSrcQuenchs` – The number of ICMP Source Quench messages received. (counter)

`icmpInRedirects` – The number of ICMP Redirect messages received. (counter)

`icmpInEchos` – The number of ICMP Echo (request) messages received. (counter)

`icmpInEchoReps` – The number of ICMP Echo Reply messages received. (counter)

`icmpInTimestamps` – The number of ICMP Timestamp (request) messages received. (counter)

`icmpInTimestampReps` – The number of ICMP Timestamp Reply messages received. (counter)

`icmpInAddrMasks` – The number of ICMP Address Mask Request messages received. (counter)

`icmpInAddrMaskReps` – The number of ICMP Address Mask Reply messages received. (counter)

`icmpOutMsgs` – The total number of ICMP messages that this entity attempted to send. Note that this counter includes all those counted by `icmpOutErrors`. (counter)

`icmpOutErrors` – The number of ICMP messages that this entity did not send due to problems discovered within ICMP, such as a lack of buffers. This value should not include errors discovered outside the ICMP layer, such as the inability of IP to route the resultant datagram. In some implementations there may be no types of errors that contribute to this counter's value. (counter)

`icmpOutDestUnreachs` – The number of ICMP Destination Unreachable messages sent. (counter)

`icmpOutTimeExcds` – The number of ICMP Time Exceeded messages sent. (counter)

`icmpOutParmProbs` – The number of ICMP Parameter Problem messages sent. (counter)

- `icmpOutSrcQuenchs` – The number of ICMP Source Quench messages sent. (counter)
- `icmpOutRedirects` – The number of ICMP Redirect messages sent. For a host, this object will always be zero, since hosts do not send redirects. (counter)
- `icmpOutEchos` – The number of ICMP Echo (request) messages sent. (counter)
- `icmpOutEchoReps` – The number of ICMP Echo Reply messages sent. (counter)
- `icmpOutTimestamps` – The number of ICMP Timestamp (request) messages sent. (counter)
- `icmpOutTimestampReps` – The number of ICMP Timestamp Reply messages sent. (counter)
- `icmpOutAddrMasks` – The number of ICMP Address Mask Request messages sent. (counter)
- `icmpOutAddrMaskReps` – The number of ICMP Address Mask Reply messages sent. (counter)
- `tcp` The `tcp` group reports statistics about the TCP group.
- `tcpRtoAlgorithm` – The algorithm used to determine the timeout value used for retransmitting unacknowledged octets. (enum)
- `tcpRtoMin` – The minimum value permitted by a TCP implementation for the retransmission timeout, measured in milliseconds. More refined semantics for objects of this type depend upon the algorithm used to determine the retransmission timeout. In particular, when the timeout algorithm is `rsre(3)`, an object of this type has the semantics of the `LBOUND` quantity described in RFC 793. (int)
- `tcpRtoMax` – The maximum value permitted by a TCP implementation for the retransmission timeout, measured in milliseconds. More refined semantics for objects of this type depend upon the algorithm used to determine the retransmission timeout. In particular, when the timeout algorithm is `rsre(3)`, an object of this type has the semantics of the `UBOUND` quantity described in RFC 793. (int)
- `tcpMaxConn` – The limit on the total number of TCP connections that the entity can support. In entities where the maximum number of connections is dynamic, this object should contain the value `-1`. (int)
- `tcpActiveOpens` – The number of times that TCP connections have made a direct transition to the `SYN-SENT` state from the `CLOSED` state. (counter)
- `tcpPassiveOpens` – The number of times that TCP connections have made a direct transition to the `SYN-RCVD` state from the `LISTEN` state. (counter)
- `tcpAttemptFails` – The number of times that TCP connections have made a direct transition to the `CLOSED` state from either the `SYN-SENT` state or the `SYN-RCVD` state, plus the number of times TCP connections have made a direct transition to the `LISTEN` state from the `SYN-RCVD` state. (counter)

`tcpEstabResets` – The number of times TCP connections have made a direct transition to the CLOSED state from either the ESTABLISHED state or the CLOSE-WAIT state. (counter)

`tcpCurrEstab` – The number of TCP connections for which the current state is either ESTABLISHED or CLOSE-WAIT. (gauge)

`tcpInSegs` – The total number of segments received, including those received in error. This count includes segments received on currently established connections. (counter)

`tcpOutSegs` – The total number of segments sent, including those on current connections but excluding those containing only retransmitted octets. (counter)

`tcpRetransSegs` – The total number of segments retransmitted - that is, the number of TCP segments transmitted containing one or more previously transmitted octets. (counter)

`tcpInErrs` – The total number of segments received in error (for example, bad TCP checksums). (counter)

`tcpOutRsts` – The number of TCP segments sent containing the RST flag. (counter)

`tcpConnTable` The `tcpConnTable` is a table containing TCP connection-specific information.

`tcpConnState` – The state of this TCP connection. (enum)

The only value that may be set by a management station is `deleteTCB(12)`. Accordingly, it is appropriate for an agent to return a “badValue” response if a management station attempts to set this object to any other value.

If a management station sets this object to the value `deleteTCB(12)`, then this has the effect of deleting the TCB (as defined in RFC 793) of the corresponding connection on the managed node. This results in immediate termination of the connection.

As an implementation-specific option, an RST segment may be sent from the managed node to the other TCP endpoint. (Note, however, that RST segments are not sent reliably.)

`tcpConnLocalAddress` – The local IP address for this TCP connection. For a connection in the listen state that is willing to accept connections for any IP interface associated with the node, the value 0.0.0.0 is used. (netaddress)

`tcpConnLocalPort` – The local port number for this TCP connection. (int)

`tcpConnRemAddress` – The remote IP address for this TCP connection. (netaddress)

`tcpConnRemPort` – The remote port number for this TCP connection. (int)

`udp` The `udp` group reports statistics about the UDP group.

`udpInDatagrams` – The total number of UDP datagrams delivered to UDP users. (counter)  
Returns a fixed value of 0.

`udpNoPorts` – The total number of received UDP datagrams for which there was no application at the destination port. (counter) Returns a fixed value of 0.

`udpInErrors` – The number of received UDP datagrams that could not be delivered for reasons other than the lack of an application at the destination port. (counter)

`udpOutDatagrams` – The total number of UDP datagrams sent from this entity. (counter) Returns a fixed value of 0.

`udpTable` The `udpTable` is a table containing UDP listener information.

`udpLocalAddress` – The local IP address for this UDP listener. For a UDP listener that is willing to accept datagrams for any IP interface associated with the node, the value 0.0.0.0 is used. (netaddress)

`udpLocalPort` – The local port number for this UDP listener. (int)

`snmp` The `snmp` group reports statistics about the SNMP group.

`snmpInPkts` – The total number of Messages delivered to the SNMP entity from the transport service. (counter)

`snmpOutPkts` – The total number of SNMP Messages passed from the SNMP protocol entity to the transport service. (counter)

`snmpInBadVersions` – The total number of SNMP Messages delivered to the SNMP protocol entity that were for an unsupported SNMP version. (counter)

`snmpInBadCommunityNames` – The total number of SNMP Messages delivered to the SNMP protocol entity that used a SNMP community name not known to said entity. (counter)

`snmpInBadCommunityUses` – The total number of SNMP Messages delivered to the SNMP protocol entity, which represented an SNMP operation not allowed by the SNMP community named in the Message. (counter)

`snmpInASNParseErrs` – The total number of ASN.1 or BER errors encountered by the SNMP protocol entity when decoding received SNMP Messages. (counter)

`snmpInTooBigs` – The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “tooBig.” (counter)

`snmpInNoSuchNames` – The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “noSuchName.” (counter)

`snmpInBadValues` – The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “badValue.” (counter)

`snmpInReadOnLys` – The total number valid SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “readOnly.” It should be noted that it is a protocol error to generate an SNMP PDU that contains the value “readOnly” in the error-status field. This object is provided as a means of detecting incorrect implementations of the SNMP. (counter)

`snmpInGenErrs` – The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is “genErr.” (counter)

`snmpInTotalReqVars` – The total number of MIB objects successfully retrieved by the SNMP protocol entity as the result of receiving valid SNMP Get-Request and Get-Next PDUs. (counter)

`snmpInTotalSetVars` – The total number of MIB objects successfully altered by the SNMP protocol entity as the result of receiving valid SNMP Set-Request PDUs. (counter)

`snmpInGetRequests` – The total number of SNMP Get-Request PDUs accepted and processed by the SNMP protocol entity. (counter)

`snmpInGetNexts` – The total number of SNMP Get-Next PDUs accepted and processed by the SNMP protocol entity. (counter)

`snmpInSetRequests` – The total number of SNMP Set-Request PDUs accepted and processed by the SNMP protocol entity. (counter)

`snmpInGetResponses` – The total number of SNMP Get-Response PDUs accepted and processed by the SNMP protocol entity. (counter)

`snmpInTraps` – The total number of SNMP Trap PDUs accepted and processed by the SNMP protocol entity. (counter)

`snmpOutTooBig` – The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status field is “tooBig.” (counter)

`snmpOutNoSuchNames` – The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status is “noSuchName.” (counter)

`snmpOutBadValues` – The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status field is “badValue.” (counter)

`snmpOutGenErrs` – The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status field is “genErr.” (counter)

`snmpOutGetRequests` – The total number of SNMP Get-Request PDUs which have been generated by the SNMP protocol entity. (counter)

`snmpOutGetNexts` – The total number of SNMP Get-Next PDUs generated by the SNMP protocol entity. (counter)

`snmpOutSetRequests` – The total number of SNMP Set-Request PDUs generated by the SNMP protocol entity. (counter)

`snmpOutGetResponses` – The total number of SNMP Get-Response PDUs generated by the SNMP protocol entity. (counter)

`snmpOutTraps` – The total number of SNMP Trap PDUs generated by the SNMP protocol entity. (counter)

`snmpEnableAuthenTraps` – Indicates whether the SNMP agent process is permitted to generate authentication-failure traps. The value of this object overrides any configuration information. As such, it provides a means whereby all authentication-failure traps may be disabled. (enum)

Note that this object must be stored in non-volatile memory, so that it remains constant between reinitializations of the network management system.

The following are Sun-specific group and table definitions.

`sunSystem` The `sunSystem` group reports general system information.

`agentDescr` – The SNMP agent's description of itself. (string[255])

`hostID` – The unique Sun hardware identifier. The value returned is four byte binary string. (octet[4])

`motd` – The first line of `/etc/motd`. (string[255])

`unixTime` – The UNIX system time. Measured in seconds since January 1, 1970 GMT. (counter)

`sunProcessTable` The `sunProcessTable` table reports UNIX process table information.

`psProcessID` – The process identifier for this process. (int)

`psParentProcessID` – The process identifier of this process's parent. (int)

`psProcessSize` – The combined size of the data and stack segments (in kilobytes.) (int)

`psProcessCpuTime` – The CPU time (including both user and system time) consumed so far. (int)

`psProcessState` – The run-state of the process. (octet[4])

---

R	Runnable
T	Stopped
P	In page wait

---

---

D	Non-interruptable wait
S	Sleeping (less than 20 seconds)
I	Idle (more than 20 seconds)
Z	Zombie

---

psProcessWaitChannel – Reason process is waiting. (octet[16])

psProcessTTY – Terminal, if any, controlling this process. (octet[16])

psProcessUserName – Name of the user associated with this process. (octet[16])

psProcessUserID – Numeric form of the name of the user associated with this process. (int)

psProcessName – Command name used to invoke this process. (octet[64])

psProcessStatus – Setting this variable will cause a signal of the set value to be sent to the process. (int)

sunHostPerf The sunHostPerf group reports hostperf information.

rsUserProcessTime – Total number of timeticks used by user processes since the last system boot. (counter)

rsNiceModeTime – Total number of timeticks used by “nice” mode since the last system boot. (counter)

rsSystemProcessTime – Total number of timeticks used by system processes since the last system boot. (counter)

rsIdleModeTime – Total number of timeticks in idle mode since the last system boot. (counter)

rsDiskXfer1 – Total number of disk transfers since the last boot for the first of four configured disks. (counter)

rsDiskXfer2 – Total number of disk transfers since the last boot for the second of four configured disks. (counter)

rsDiskXfer3 – Total number of disk transfers since the last boot for the third of four configured disks. (counter)

rsDiskXfer4 – Total number of disk transfers since the last boot for the fourth of four configured disks. (counter)

rsVPagesIn – Number of pages read in from disk. (counter)

rsVPagesOut – Number of pages written to disk. (counter)

rsVSwapIn – Number of pages swapped in. (counter)

rsVSwapOut – Number of pages swapped out. (counter)

rsVIntr – Number of device interrupts. (counter)

rsIfInPackets – Number of input packets. (counter)

rsIfOutPackets – Number of output packets. (counter)

rsIfInErrors – Number of input errors. (counter)

rsIfOutErrors – Number of output errors. (counter)

rsIfCollisions – Number of output collisions. (counter)

**Files**

/etc/snmp/conf/snmpd.conf	configuration information
/etc/snmp/conf/mibiisa.acl	access control file
/var/snmp/mib/sun.mib	standard SNMP MIBII file

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/snmp/mibiisa
Interface Stability	Obsolete

**See Also** [inetd\(1M\)](#), [select\(3C\)](#), [recvfrom\(3SOCKET\)](#), [sendto\(3SOCKET\)](#), [attributes\(5\)](#), [gld\(7D\)](#)

<b>Diagnostics</b>	cannot dispatch request	The proxy cannot dispatch the request. The rest of the message indicates the cause of the failure.
	select(3C) failed	A <a href="#">select(3C)</a> call failed. The rest of the message indicates the cause of the failure.
	sendto(3SOCKET) failed	A <a href="#">sendto(3SOCKET)</a> call failed. The rest of the message indicates the cause of the failure.
	recvfrom(3SOCKET) failed	A <a href="#">recvfrom(3SOCKET)</a> call failed. The rest of the message indicates the cause of the failure.
	no response from system	The SNMP agent on the target system does not respond to SNMP requests. This error might indicate that the

	SNMP agent is not running on the target system, the target system is down, or the network containing the target system is unreachable.
response too big	The agent could not fit the results of an operation into a single SNMP message. Split large groups or tables into smaller entities.
missing attribute	An attribute is missing from the requested group.
bad attribute type	An object attribute type received from the SNMP agent that does not match the attribute type specified by the proxy agent schema. The rest of the message indicates the expected type and received type.
cannot get sysUpTime	The proxy agent cannot get the variable <i>sysUpTime</i> from the SNMP agent.
sysUpTime type bad	The variable <i>sysUpTime</i> received from the SNMP agent has the wrong data type.
unknown SNMP error	An unknown SNMP error was received.
bad variable value	The requested specified an incorrect syntax or value for a set operation.
variable is read only	The SNMP agent did not perform the set request because a variable to set may not be written.
general error	A general error was received.
cannot make request PDU	An error occurred building a request PDU.
cannot make request varbind list	An error occurred building a request variable binding list.
cannot parse response PDU	An error occurred parsing a response PDU.

request ID - response ID mismatch	The response ID does not match the request ID.
string contains non-displayable characters	A displayable string contains non-displayable characters.
cannot open schema file	An error occurred opening the proxy agent schema file.
cannot parse schema file	The proxy agent couldn't parse the proxy agent schema file.
cannot open host file	An error occurred opening the file associated with the <i>na.snmp.hostfile</i> keyword in <code>/etc/snmp/conf/snmpd.conf</code>
cannot parse host file	The proxy agent was unable to parse the file associated with the <i>na.snmp.hostfile</i> keyword in <code>/etc/snmp/conf/snmp.conf</code> .
attribute unavailable for set operations	The set could not be completed because the attribute was not available for set operations.

**Bugs** The `mibiisa` utility returns the wrong interface speed for the SBUS FDDI interface (for example, "bf0").

The `mibiisa` utility does not return a MAC address for the SBUS FDDI interface (for example, "bf0").

Process names retrieved from `mibiisa` contain a leading blank space.

When you change attribute values in the system group with an SNMP set request, the change is effective only as long as `mibiisa` is running. `mibiisa` does not save the changes to `/etc/snmp/conf/snmpd.conf`.

**Name** mkbootmedia – create bootable Solaris ISO image

**Synopsis** `/usr/bin/mkbootmedia -v [-l label] media-root iso`

**Description** The `mkbootmedia` utility takes *media-root* (the root of an on-disk Solaris install media) as input and creates a bootable Solaris ISO image in the file *iso*, using `mkisofs(8)`. The file can then be burned onto a CD/DVD with utilities such as `cdwrw(1)` or `cdrecord(1)`. (Neither `mkisofs(8)` nor `cdrecord(1)` are SunOS man pages.)

**Caution** – The directory tree *media-root* must contain the file `boot/grub/stage2_eltorito`, which will be written to the media boot sectors. This file will be modified with some boot information, thus it must be writable. If necessary, first save a copy prior to running this utility.

**Options** The following options are supported:

`-l label`

Sets *label* as the label/volume name of the ISO image.

`-v`

Verbose. Multiple `-v` options increase verbosity.

**Operands** The following operands are supported:

*media-root*

Top-level directory of an on-disk Solaris install media.

*iso*

Name of the output file which will contain the resulting ISO image.

**Examples** EXAMPLE 1 Creating an ISO Image and Burning a CD/DVD

The following commands create an ISO image from the content of `s10u1` and burn the image to a CD/DVD.

```
/usr/bin/mkbootmedia s10u1 s10u1.iso
/usr/bin/cdrw -i s10u1.iso
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

**See Also** [cdwrw\(1\)](#), [attributes\(5\)](#)

`mkisofs(8)`, (`/usr/share/man/man8/mkisofs.8`), in the `SUNWfsman` package (not a SunOS man page)

**Name** mkdevalloc – Make device\_allocate entries

**Synopsis** /usr/sbin/mkdevalloc

**Description** The `mkdevalloc` command writes to standard out a set of `device_allocate(4)` entries describing the system's frame buffer, audio and removable media devices.

The `mkdevalloc` command is used by the `init.d(4)` scripts to create or update the `/etc/security/device_allocate` file.

Entries are generated based on the device special files found in `/dev`. For the different categories of devices, the `mkdevalloc` command checks for the following files under `/dev`:

```
audio /dev/audio, /dev/audioctl, /dev/sound/...
tape /dev/rst*, /dev/nrst*, /dev/rmt/...
floppy /dev/diskette, /dev/fd*, /dev/rdiskette, /dev/rfd*
removable disk /dev/sr*, /dev/nsr*, /dev/dsk/c0t?d0s?, /dev/rdisk/c0t?d0s?
frame buffer /dev/fb
```

All entries set the `device-minimum` and `device-maximum` fields to the hex representations of `ADMIN_LOW` and `ADMIN_HIGH`, respectively. The `device-authorization` field is set to `solaris.device.allocate`, except for the `framebuffer` entry, where it is set to `*`. The `device-name`, `device-type` and `device-clean` fields are set to the following values:

	device-name	device-type	device-clean
audio	audio	audio	audio_clean_wrapper
tape	mag_tape_0,1,...	st	st_clean
floppy	floppy_0,1,...	fd	disk_clean
removable disk	cdrom_0,1,...	sr	disk_clean
frame buffer	framebuffer	fb	/bin/true

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs
Interface Stability	Obsolete

**See Also** [allocate\(1\)](#), [attributes\(5\)](#)

**Notes** `mkdevalloc` might not be supported in a future release of the Solaris operating system.

**Name** mkdevmaps – make device\_maps entries

**Synopsis** /usr/sbin/mkdevmaps

**Description** The mkdevmaps command writes to standard out a set of [device\\_maps\(4\)](#) entries describing the system's frame buffer, audio, and removable media devices.

The mkdevmaps command is used by the [init.d\(4\)](#) scripts to create or update the /etc/security/device\_maps file.

Entries are generated based on the device special files found in /dev. For the different categories of devices, the mkdevmaps command checks for the following files under /dev:

```
audio /dev/audio, /dev/audioctl, /dev/sound/...
tape /dev/rst*, /dev/nrst*, /dev/rmt/...
floppy /dev/diskette, /dev/fd*, /dev/rdiskette, /dev/rfd*
removable disk /dev/dsk/c0t?d0s?, /dev/rdisk/c0t?d0s?
frame buffer /dev/fb
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs
Interface Stability	Obsolete

**See Also** [allocate\(1\)](#), [attributes\(5\)](#)

**Notes** mkdevmaps might not be supported in a future release of the Solaris operating system.

**Name** mkfifo – make FIFO special file

**Synopsis** /usr/bin/mkfifo [-m *mode*] *path*...

ksh93 mkfifo [ *options* ] *file*...

## Description

/usr/bin/mkfifo The `mkfifo` utility creates the FIFO special files named by its argument list. The arguments are taken sequentially, in the order specified; and each FIFO special file is either created completely or, in the case of an error or signal, not created at all.

If errors are encountered in creating one of the special files, `mkfifo` writes a diagnostic message to the standard error and continues with the remaining arguments, if any.

The `mkfifo` utility calls the library routine `mkfifo(3C)`, with the *path* argument is passed as the *path* argument from the command line, and *mode* is set to the equivalent of `a=rw`, modified by the current value of the file mode creation mask `umask(1)`.

ksh93 The `mkfifo` utility creates one or more FIFOs. By default, the mode of the created FIFO is `a=rw` minus the bits set in `umask(1)`.

## Options

/usr/bin/ksh93 The following option is supported for /usr/bin/mkfifo:

`-m mode` Set the file permission bits of the newly-created FIFO to the specified *mode* value. The *mode* option-argument will be the same as the *mode* operand defined for the `chmod(1)` command. In *<symbolicmode>* strings, the *op* characters + and – will be interpreted relative to an assumed initial mode of `a=rw`.

ksh93 The following option is supported for ksh93:

`-m mode`  
`--mode=mode` Set the mode of the created FIFO to *mode*. The *mode* option-argument is a symbolic or octal mode as in `chmod(1)`. Relative modes assume an initial mode of `a=rw`.

**Operands** The following operand is supported:

*file* A path name of the FIFO special file to be created.

**Usage** See `largefile(5)` for the description of the behavior of `mkfifo` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**Environment Variables** See `environ(5)` for descriptions of the following environment variables that affect the execution of `mkfifo`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**Exit Status** The following exit values are returned:

- 0 All the specified FIFO special files were created successfully.
- >0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/extended-system-utilities
Interface Stability	Committed
Standard	See <a href="#">standards(5)</a> .

**See Also** [chmod\(1\)](#), [umask\(1\)](#), [mkfifo\(3C\)](#), [attributes\(5\)](#), [environ\(5\)](#), [largefile\(5\)](#), [standards\(5\)](#)

**Name** `mkfile` – create a file

**Synopsis** `mkfile [-nv] size [g | k | b | m] filename...`

**Description** `mkfile` creates one or more files that are suitable for use as NFS-mounted swap areas, or as local swap areas. When a root user executes `mkfile()`, the sticky bit is set and the file is padded with zeros by default. When non-root users execute `mkfile()`, they must manually set the sticky bit using `chmod(1)`. The default `size` is in bytes, but it can be flagged as gigabytes, kilobytes, blocks, or megabytes, with the `g`, `k`, `b`, or `m` suffixes, respectively.

**Options** `-n` Create an empty *filename*. The *size* is noted, but disk blocks are not allocated until data is written to them. Files created with this option cannot be swapped over local UFS mounts.

`-v` Verbose. Report the names and sizes of created files.

**Exit Status** The following exit values are returned:

`0` Success.

`>0` An error occurred.

**Usage** See [largefile\(5\)](#) for the description of the behavior of `mkfile` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs
Interface Stability	Committed

**See Also** [chmod\(1\)](#), [swap\(1M\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

**Name** mkfs – construct a file system

**Synopsis** mkfs [-F *FSType*] [*generic\_options*]  
 [-o *FSType-specific\_options*] *raw\_device\_file*  
 [*operands*]

**Description** The `mkfs` utility constructs a file system on the *raw\_device\_file* by calling the specific `mkfs` module indicated by `-F FSType`.

Note: ufs file systems are normally created with the `newfs(1M)` command.

*generic\_options* are independent of file system type. *FSType-specific\_options* is a comma-separated list of *keyword=value* pairs (with no intervening spaces), which are *FSType*-specific. *raw\_device\_file* specifies the disk partition on which to write the file system. It is required and must be the first argument following the *specific\_options* (if any). *operands* are *FSType*-specific. See the *FSType*-specific manual page of `mkfs` (for example, `mkfs_ufs(1M)`) for a detailed description.

**Options** The following are the generic options for `mkfs`:

- F Specify the *FSType* to be constructed. If `-F` is not specified, the *FSType* is determined from `/etc/vfstab` by matching the *raw\_device\_file* with a `vfstab` entry, or by consulting the `/etc/default/fs` file.
- V Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided and adding to them information derived from `/etc/vfstab` or `/etc/default/fs`. This option may be used to verify and validate the command line.
- m Return the command line which was used to create the file system. The file system must already exist. This option provides a means of determining the command used in constructing the file system.
- o Specify *FSType*-specific options. See the manual page for the `mkfs` module specific to the file system type.

**Usage** See `largefile(5)` for the description of the behavior of `mkfs` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**Files** `/etc/default/fs` Default file system type. Default values can be set for the following flags in `/etc/default/fs`. For example: `LOCAL=ufs`

`LOCAL` The default partition for a command if no *FSType* is specified.

`/etc/vfstab` List of default parameters for each file system

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [mkfs\\_ufs\(1M\)](#), [newfs\(1M\)](#), [vfstab\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

Manual pages for the *FSType*-specific modules of `mkfs`.

**Notes** This command might not be supported for all *FSTypes*.

You can use `lofiadm` to create a file that appears to a `mkfs` command as a raw device. You can then use a `mkfs` command to create a file system on that device. See [lofiadm\(1M\)](#) for examples of creating a UFS and a PC (FAT) file system (using [mkfs\\_ufs\(1M\)](#) and [mkfs\\_pcfs\(1M\)](#)) on a device created by `lofiadm`.

**Name** mkfs\_pcfs – construct a FAT file system

**Synopsis** `mkfs -F pcfs [generic_options] [-o FSType_specific_options]  
raw_device_file`

**Description** The `pcfs`-specific module of `mkfs` constructs a File Allocation Table (FAT) on removable media (diskette, JAZ disk, ZIP disk, PCMCIA card), a hard disk, or a file (see NOTES). FATs are the standard MS-DOS and Windows file system format. Note that you can use [fdformat\(1\)](#) to construct a FAT file system only on a diskette or PCMCIA card.

`mkfs` for `pcfs` determines an appropriate FAT size for the medium, then it installs an initial boot sector and an empty FAT. A sector size of 512 bytes is used. `mkfs` for `pcfs` can also install the initial file in the file system (see the `pcfs`-specific `-o i` option). This first file can optionally be marked as read-only, system, and/or hidden.

If you want to construct a FAT with `mkfs` for `pcfs` on a medium that is not formatted, you must first perform a low-level format on the medium with [fdformat\(1\)](#) or [format\(1M\)](#). Non-diskette media must also be partitioned with the [fdisk\(1M\)](#) utility. Note that all existing data on the diskette or disk partition, if any, is destroyed when a new FAT is constructed.

*generic\_options* are supported by the generic `mkfs` command. See [mkfs\(1M\)](#) for a description of these options.

*raw\_device\_file* indicates the device on which to write unless the `-o N` option has been specified, or if the `-V` or `-m` generic options are passed from the generic `mkfs` module.

**Options** See [mkfs\(1M\)](#) for the list of supported generic options.

The following options are supported:

`-o FSType_specific_options`

Specify `pcfs` file system-specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored.

`b=label`

Label the media with volume label. The volume label is restricted to 11 uppercase characters.

`B=filename`

Install *filename* as the boot loader in the file system's boot sector. If you don't specify a boot loader, an MS-DOS boot loader is installed. The MS-DOS boot loader requires specific MS-DOS system files to make the diskette bootable. See NOTES for more information.

`fat=n`

The size of a FAT entry. Currently, 12, 16, and 32 are valid values. The default is 12 for diskettes, 16 for larger media.

**h**

Mark the first file installed as a hidden file. The `-i` option must also be specified.

**hidden=*n***

Set the number of hidden sectors to *n*. This is the number of sectors on the physical disk preceding the start of the volume (which is the boot sector itself). This defaults to 0 for diskettes or a computed value (based on the `fdisk` table) for disks. This option may be used only in conjunction with the `nofdisk` option.

**i=*filename***

Install *filename* as the initial file in the new file system. The initial file's contents are guaranteed to occupy consecutive clusters at the start of the files area. When creating bootable media, a boot program should be specified as the initial file.

**nofdisk**

Do not attempt to find an `fdisk` table on the medium. Instead rely on the `size` option for determining the partition size. By default, the created FAT is 16 bits and begins at the first sector of the device. This origination sector can be modified with the `hidden` option (`-h`).

**nsect=*n***

The number of sectors per track on the disk. If not specified, the value is determined by using a `dkio(7I)` ioctl to get the disk geometry, or (for diskette) from the results of an `FDIOGCHAR` ioctl.

**ntrack=*n***

The number of tracks per cylinder on the disk. If not specified, the value is determined by using a `dkio(7I)` ioctl to get the disk geometry, or (for diskette) from the results of an `FDIOGCHAR` ioctl.

**N**

No execution mode. Print normal output, but do not actually write the file system to the medium. This is most useful when used in conjunction with the `verbose` option.

**r**

Mark the first file installed as read-only. The `-i` option must also be specified.

**reserve=*n***

Set the number of reserved sectors to *n*. This is the number of sectors in the volume, preceding the start of the first FAT, including the boot sector. The value should always be at least 1, and the default value is exactly 1.

**s**

Mark the first file installed as a system file. The `-i` option must also be specified.

**size=*n***

The number of sectors in the file system. If not specified, the value is determined from the size of the partition given in the `fdisk` table or (for diskette) by way of computation using the `FDIOGCHAR` ioctl.

`spc=n`

The size of the allocation unit for space within the file system, expressed as a number of sectors. The default value depends on the FAT entry size and the size of the file system.

`v`

Verbose output. Describe, in detail, operations being performed.

**Files** *raw\_device\_file*

The device on which to build the FAT. The device name for a diskette must be specified as `/dev/rdiskette0` for the first diskette drive, or `/dev/rdiskette1` for a second diskette drive. For non-diskette media, a disk device name must be qualified with a suffix to indicate the proper partition. For example, in the name `/dev/rdisk/c0t0d0p0:c`, the `:c` suffix indicates that the first partition on the disk should receive the new FAT.

For a file, *raw\_device\_file* is the block device name returned by [lofiadm\(1M\)](#).

**Examples** The media in these examples must be formatted before running `mkfs` for `pcfs`. See DESCRIPTION for more details.

**EXAMPLE 1** Creating a FAT File System on a Diskette

The following command creates a FAT file system on a diskette:

```
mkfs -F pcfs /dev/rdiskette
```

**EXAMPLE 2** Creating a FAT File System on a Disk

The following command creates a FAT file system on the second fdisk partition of a disk attached to an x86 based system:

```
mkfs -F pcfs /dev/rdisk/c0d0p0:d
```

**EXAMPLE 3** Creating a FAT File System on a ZIP Disk

The following command creates a FAT file system on a ZIP disk located on a SPARC based system:

```
mkfs -F pcfs /dev/rdisk/c0t4d0s2:c
```

**EXAMPLE 4** Creating a FAT File System on a JAZ Disk

The following command creates a FAT file system on a JAZ disk located on a SPARC based system and overrides the sectors/track and tracks/cylinder values obtained from the device's controller:

```
mkfs -F pcfs -o nsect=32,ntrack=64 /dev/rdisk/c0t3d0s2:c
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/extended-system-utilities
Interface Stability	Committed

**See Also** [fdformat\(1\)](#), [fdisk\(1M\)](#), [format\(1M\)](#), [lofiadm\(1M\)](#), [mkfs\(1M\)](#), [attributes\(5\)](#), [fd\(7D\)](#), [dkio\(7I\)](#), [fdio\(7I\)](#)

**Notes** The default MS-DOS boot loader, which is installed by default if `-o B` is not specified, requires specific MS-DOS system files to make the diskette bootable. These MS-DOS files are not installed when you format a diskette with `mkfs` for `pcfs`, which makes a diskette formatted this way not bootable. Trying to boot from it on an x86 based system will result in the following message:

```
Non-System disk or disk error
Replace and strike any key when ready
```

You must format a diskette with the DOS `format` command to install the specific MS-DOS system files required by the default boot loader.

You can use `lofiadm` to create a file that appears to a `mkfs` command (for example, `mkfs_pcfs` or `mkfs_ufs`) as a raw device. You can then use a `mkfs` command to create a file system on that device. See [lofiadm\(1M\)](#) for examples of creating a UFS and a PC (FAT) file system on a device created by `lofiadm`.

**Name** mkfs\_udfs – construct a udfs file system

**Synopsis** `mkfs -F udfs [generic_options] [-o specific_options] raw_device_file [size]`

**Description** This is the universal disk format file system (udfs) -specific module of the `mkfs` command. `mkfs` constructs a udfs file system with a root directory.

**Options** See `mkfs(1M)` for the list of supported *generic\_options*.

The following options are supported:

`-o specific_options` Specify a udfs-specific option. Specify udfs file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored.

The following *specific\_options* are available:

`N` Print the file system parameters without actually creating the file system.

`label=string` Specify the label to be written into the volume header structures. Specify *string* as the name of the label. If *string* is not specified, a default *string* is generated in the form of `*NoLabel*`.

**Operands** The following operands are supported:

`raw_device_file` Specify the disk partition on which to write.

`size` Specify the number of 512-byte blocks in the file system.

**Attributes** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/udfs

**See Also** `fscck(1M)`, `mkfs(1M)`, `attributes(5)`

**Diagnostics** not currently a valid file system

The specified device does not contain a valid udfs file system.

Invalid size: larger than the partition size

Number of blocks given as parameter to create the file system is larger than the size of the device specified.

`is mounted` can't `mkfs`

Device is in use, cannot create file system when the device is in use.

preposterous size

Negative size parameter provided is invalid.

sector size must be between 512, 8192 bytes

Sector size given is not in the valid range.

Volume integrity sequence descriptors too long

File set descriptor too long.

Not enough space to create volume integrity sequence or file set descriptor.

mkfs: argument out of range

One of the arguments is out of range.

mkfs: bad numeric arg

One of the arguments is potentially a bad numeric.

**Notes** You can use `lofiadm` to create a file that appears to a `mkfs` command (for example, `mkfs_pcfs` or `mkfs_ufs`) as a raw device. You can then use a `mkfs` command to create a file system on that device. See [lofiadm\(1M\)](#) for examples of creating a UFS and a PC (FAT) file system on a device created by `lofiadm`.

**Name** mkfs\_ufs – construct a UFS file system

**Synopsis** `mkfs -F ufs [generic_options] [-o FSType_specific_options] raw_device_file [size]`

**Description** The UFS-specific module of `mkfs` builds a UFS file system with a root directory and a `lost+found` directory (see [fsck\(1M\)](#)).

The UFS-specific `mkfs` is rarely run directly. Use the [newfs\(1M\)](#) command instead.

`raw_device_file` indicates the disk partition on which to create the new file system. If the `-o N`, `-V`, or `-m` options are specified, the `raw_device_file` is not actually modified. `size` specifies the number of disk sectors in the file system, where a disk sector is usually 512 bytes. This argument must follow the `raw_device_file` argument and is required (even with `-o N`), unless the `-V` or `-m` generic options are specified.

`generic_options` are supported by the generic `mkfs` command. See [mkfs\(1M\)](#) for a description of these options.

**Options** The following generic options are supported:

- `-m` Print the command line that was used to create the existing file system.
- `-V` Print the current `mkfs` command line.

**Options** The following UFS-specific options are supported:

- `-o` Use one or more of the following values separated by commas (with no intervening spaces) to specify UFS-specific options:
 

<code>apc=<i>n</i></code>	The number of alternate sectors per cylinder to reserve for bad block replacement for SCSI devices only. The default is 0.  This option is not applicable for disks with EFI labels and is ignored.
<code>bsize=<i>n</i></code>	The logical block size of the file system in bytes, either 4096 or 8192. The default is 8192. The sun4u architecture does not support the 4096 block size.
<code>calcbinsb</code>	Sends to stdout a binary (machine-readable) version of the superblock that would be used to create a file system with the specified configuration parameters.
<code>calcsb</code>	Sends to stdout a human-readable version of the superblock that would be used to create a file system with the specified configuration parameters.
<code>cgsiz=<i>n</i></code>	The number of cylinders per cylinder group, ranging from 16 to 256. The default is calculated by dividing the number of sectors in the file system by the number of sectors in a gigabyte. Then, the result is multiplied by 32. The default value is always between 16 and 256.

	The per-cylinder-group meta data must fit in a space no larger than what is available in one logical file system block. If too large a <code>cgsiz</code> is requested, it is changed by the minimum amount necessary.
<code>fragsize=n</code>	<p>The smallest amount of disk space in bytes that can be allocated to a file. <code>fragsize</code> must be a power of 2 divisor of <code>bsize</code>, where:</p> <p><math>bsize / fragsize</math> is 1, 2, 4, or 8.</p> <p>This means that if the logical block size is 4096, legal values for <code>fragsize</code> are 512, 1024, 2048, and 4096. When the logical block size is 8192, legal values are 1024, 2048, 4096, and 8192. The default value is 1024.</p> <p>For file systems greater than 1 terabyte or for file systems created with the <code>mtb=y</code> option, <code>fragsize</code> is forced to match block size (<code>bsize</code>).</p>
<code>free=n</code>	<p>The minimum percentage of free space to maintain in the file system between 0% and 99%, inclusively. This space is off-limits to users. Once the file system is filled to this threshold, only the superuser can continue writing to the file system.</p> <p>The default is <math>((64 \text{ Mbytes/partition size}) * 100)</math>, rounded down to the nearest integer and limited between 1% and 10%, inclusively.</p> <p>This parameter can be subsequently changed using the <a href="#">tunefs(1M)</a> command.</p>
<code>gap=n</code>	Rotational delay. This option is obsolete in the Solaris 10 release. The value is always set to 0, regardless of the input value.
<code>maxcontig=n</code>	<p>The maximum number of logical blocks, belonging to one file, that are allocated contiguously. The default is calculated as follows:</p> <p><math>maxcontig = \text{disk drive maximum transfer size} / \text{disk block size}</math></p> <p>If the disk drive's maximum transfer size cannot be determined, the default value for <code>maxcontig</code> is calculated from kernel parameters as follows:</p> <p>If <code>maxphys</code> is less than <code>ufs_maxmaxphys</code>, which is typically 1 Mbyte, then <code>maxcontig</code> is set to <code>maxphys</code>. Otherwise, <code>maxcontig</code> is set to <code>ufs_maxmaxphys</code>.</p> <p>You can set <code>maxcontig</code> to any positive integer value.</p> <p>The actual value will be the lesser of what has been specified and what the hardware supports.</p>

---

	You can subsequently change this parameter by using <a href="#">tunefs(1M)</a> .
<code>mtb=y</code>	Set the parameters of the file system to allow eventual growth to over a terabyte in total file system size. This option sets <i>fragsize</i> to be the same as <i>bsize</i> , and sets <i>nbpi</i> to 1 Mbyte, unless the <code>-i</code> option is used to make it even larger. If you explicitly set the <i>fragsize</i> or <i>nbpi</i> parameters to values that are incompatible with this option, the user-supplied value of <i>fragsize</i> or <i>nbpi</i> is ignored.
<code>N</code>	Print out the file system parameters that would be used to create the file system without actually creating the file system.
<code>nbpi=n</code>	The number of bytes per inode, which specifies the density of inodes in the file system. The number is divided into the total size of the file system to determine the number of inodes to create.  This value should reflect the expected average size of files in the file system. If fewer inodes are desired, a larger number should be used. To create more inodes, a smaller number should be given. The default is 2048.  The number of inodes can increase if the file system is expanded with the <code>growfs</code> command.
<code>nrpos=n</code>	The number of different rotational positions in which to divide a cylinder group. The default is 8.
	This option is not applicable for disks with EFI labels and is ignored.
<code>nsect=n</code>	The number of sectors per track on the disk. The default is 32.
<code>ntrack=n</code>	The number of tracks per cylinder on the disk. The default is 16.
	This option is not applicable for disks with EFI labels and is ignored.
<code>opt=s   t</code>	The file system can either be instructed to try to minimize the <i>time</i> spent allocating blocks, or to try to minimize the <i>space</i> fragmentation on the disk. The default is <i>time</i> .  This parameter can be subsequently changed with the <a href="#">tunefs(1M)</a> command.
<code>rps=n</code>	The rotational speed of the disk, in revolutions per second. The default is 60.  Note that you specify <i>rps</i> for <code>mkfs</code> and <i>rpm</i> for <code>newfs</code> .  This option is not applicable for disks with EFI labels and is ignored.

Alternatively, parameters can be entered as a list of space-separated values (without keywords) whose meaning is positional. In this case, the `-o` option is omitted and the list follows the size operand. This is the way `newfs` passes the parameters to `mkfs`.

**Operands** The following operands are supported:

*raw\_device\_file* The disk partition on which to write.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [fsck\(1M\)](#), [mkfs\(1M\)](#), [newfs\(1M\)](#), [tunefs\(1M\)](#), [dir\\_ufs\(4\)](#), [attributes\(5\)](#), [ufs\(7FS\)](#)

**Diagnostics** The following error message typically occurs with very high density disks. On such disks, the file system structure cannot encode the proper disk layout information. However, such disks have enough onboard intelligence to make up for any layout deficiencies, so there is no actual impact on performance. The warning that performance might be impaired can be safely ignored.

```
Warning: insufficient space in super block for
rotational layout tables with nsect sblock.fs_nsect
and ntrak sblock.fs_ntrak. (File system performance may be impaired.)
```

The following error message occurs when the disk geometry results in a situation where the last truncated cylinder group cannot contain the correct number of data blocks. Some disk space is wasted.

```
Warning: inode blocks/cyl group (grp) >= data blocks (num) in last cylinder
```

If there is only one cylinder group and if the above condition holds true, `mkfs` fails with the following error:

```
File system creation failed. There is only one cylinder group and that is
not even big enough to hold the inodes.
```

The following error message occurs when the best calculated file system layout is unable to include the last few sectors in the last cylinder group. This is due to the interaction between how much space is used for various pieces of meta data and the total blocks available in a cylinder group. Modifying `nbpi` and `cpg` might reduce this number, but it is rarely worth the effort.

```
Warning: num sector(s) in last cylinder group unallocated
```

**Notes** You can use `lofiadm` to create a file that appears to the `mkfs` command (for example, `mkfs_pcfs` or `mkfs_ufs`) as a raw device. You can then use the `mkfs` command to create a file system on that device. See [lofiadm\(1M\)](#) for examples of creating a UFS and a PC (FAT) file system on a device created by `lofiadm`.

Both the block and character devices, such as devices in `/dev/dsk` and `/dev/rdisk`, must be available prior to running the `mkfs` command.

**Name** mknod – make a special file

**Synopsis** mknod *name* b *major* *minor*  
 mknod *name* c *major* *minor*  
 mknod *name* p

**Description** mknod makes a directory entry for a special file.

**Options** The following options are supported:

- b Create a block-type special file.
- c Create a character-type special file.
- p Create a FIFO (named pipe).

**Operands** The following operands are supported:

- major* The *major* device number.
- minor* The *minor* device number; can be either decimal or octal. The assignment of major device numbers is specific to each system. You must be the super-user to use this form of the command.
- name* A special file to be created.

**Usage** See [largefile\(5\)](#) for the description of the behavior of mknod when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [ftp\(1\)](#), [in.ftpd\(1M\)](#), [mknod\(2\)](#), [symlink\(2\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

**Notes** If [mknod\(2\)](#) is used to create a device, the major and minor device numbers are always interpreted by the kernel running on that machine.

With the advent of physical device naming, it would be preferable to create a symbolic link to the physical name of the device (in the `/devices` subtree) rather than using mknod.

**Name** mkntfs – create an NTFS file system

**Synopsis** `mkntfs [options] device [number_of_sectors]`

```
mkntfs [-C] [-c cluster-size] [-F] [-f] [-H heads] [-h] [-I]
 [-L volume-label] [-l] [-n] [-p part-start-sect] [-Q] [-q]
 [-S sectors-per-track] [-s sector-size] [-T] [-V] [-v]
 [-z mft-zone-multiplier] [--debug] device [number-of-sectors]
```

**Description** The `mkntfs` utility is used to create an NTFS file system on a device, usually a disk partition, or file. The *device* operand is the special file corresponding to the device; for example, `/dev/dsk/c0d0p0`. The *number-of-sectors* operand is the number of blocks on the device. If omitted, `mkntfs` automatically figures the file system size.

**Options** Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, `-fv` is the equivalent of `-f -v`. A full-name option can be abbreviated to a unique prefix of its name.

Options are divided among basic, advanced, output, and help options, as listed below.

**Basic Options** `-C, --enable-compression`

Enable compression on the volume.

`-f, --fast` or `-q, --quick`

Perform quick (fast) format. This option skips both zeroing of the volume and bad sector checking.

`-L, --label string`

Set the volume label for the filesystem to *string*.

`-n, --no-action`

Causes `mkntfs` to not actually create a file system, but display what it would do if it were to create a file system. All formatting steps are carried out except the actual writing to the device.

**Advanced Options** `-c, --cluster-size bytes`

Specify the size of clusters in bytes. Valid cluster size values are powers of two, with at least 256, and at most 65536, bytes per cluster. If omitted, `mkntfs` uses 4096 bytes as the default cluster size.

Note that the default cluster size is set to be at least equal to the sector size, as a cluster cannot be smaller than a sector. Also, note that values greater than 4096 have the side effect that compression is disabled on the volume. This is due to limitations in the NTFS compression algorithm used by Windows.

`-F, --force`

Force `mkntfs` to run, even if the specified device is not a block special device, or appears to be mounted.

- H, --heads *num***  
Specify the number of heads. The maximum is 65535 (0xffff). If omitted, `mkntfs` attempts to determine the number of heads automatically. If that fails a default of 0 is used. Note that specifying *num* is required for Windows to be able to boot from the created volume.
- I, --no-indexing**  
Disable content indexing on the volume. This option is only meaningful on Windows 2000 and later. Windows NT 4.0 and earlier ignore this, as they do not implement content indexing.
- p, --partition-start *sector***  
Specify the partition start sector. The maximum is 4294967295 ( $2^{32-1}$ ). If omitted, `mkntfs` attempts to determine *sector* automatically. If that fails, a default of 0 is used. Note that specifying *sector* is required for Windows to be able to boot from the created volume.
- S, --sectors-per-track *num***  
Specify the number of sectors per track. The maximum is 65535 (0xffff). If omitted, `mkntfs` attempts to determine the number of sectors-per-track automatically and if that fails a default of 0 is used. Note that sectors-per-track is required for Windows to be able to boot from the created volume.
- s, --sector-size *bytes***  
Specify the size of sectors in bytes. Valid sector size values are 256, 512, 1024, 2048, and 4096. If omitted, `mkntfs` attempts to determine the sector-size automatically. If that fails, a default of 512 bytes per sector is used.
- T, --zero-time**  
Fake the time to be 00:00:00 UTC, Jan 1, 1970, instead of the current system time. This can be useful for debugging purposes.
- z, --mft-zone-multiplier *num***  
Set the master file table (MFT) zone multiplier, which determines the size of the MFT zone to use on the volume. The MFT zone is the area at the beginning of the volume reserved for the MFT, which stores the on-disk inodes (MFT records). It is noteworthy that small files are stored entirely within the inode; thus, if you expect to use the volume for storing large numbers of very small files, it is useful to set the zone multiplier to a higher value. Although the MFT zone is resized on the fly as required during operation of the NTFS driver, choosing an optimal value reduces fragmentation. Valid values are 1, 2, 3, and 4. The values have the following meaning:

MFT zone multiplier	MFT zone size (% of volume size)
1	12.5% (default)
2	25.0%
3	37.5%
4	50.0%

- Output Options**
- `--debug`  
Includes the verbose output from the `-v` option, as well as additional output useful for debugging `mkntfs`.
  - `-q, --quiet`  
Verbose execution. Errors are written to `stderr`, no output to `stdout` occurs at all. Useful if `mkntfs` is run in a script.
  - `-v, --verbose`  
Verbose execution.
- Help Options**
- `-h, --help`  
Show a list of options with a brief description of each one.
  - `-l, --license`  
Display the `mkntfs` licensing information and exit.
  - `-V, --version`  
Display the `mkntfs` version number and exit.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/ntfsprogs
Interface Stability	Uncommitted

**See Also** [ntfsprogs\(1M\)](#), [ntfsresize\(1M\)](#), [ntfsundelete\(1M\)](#), [attributes\(5\)](#)

<http://www.linux-ntfs.org/>

**Authors** `mkntfs` was written by Anton Altaparmakov, Richard Russon, Erik Sornes and Szabolcs Szakacsits.

**Name** mkpwdict – maintain password-strength checking database

**Synopsis** /usr/sbin/mkpwdict [-s *dict1*,... ,*dictN*]  
 [-d *destination-path*]

**Description** The mkpwdict command adds words to the dictionary-lookup database used by [pam\\_authok\\_check\(5\)](#) and [passwd\(1\)](#).

Files containing words to be added to the database can be specified on the command-line using the -s flag. These source files should have a single word per line, much like /usr/share/lib/dict/words.

If -s is omitted, mkpwdict will use the value of DICTIONLIST specified in /etc/default/passwd (see [passwd\(1\)](#)).

The database is created in the directory specified by the -d option. If this option is omitted, mkpwdict uses the value of DICTIONDBDIR specified in /etc/default/passwd (see [passwd\(1\)](#)). The default location is /var/passwd.

**Options** The following options are supported:

- s Specifies a comma-separated list of files containing words to be added to the dictionary-lookup database.
- d Specifies the target location of the dictionary-database.

**Files** /etc/default/passwd See [passwd\(1\)](#).  
 /var/passwd default destination directory

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

**Name** modinfo – display information about loaded kernel modules

**Synopsis** /usr/sbin/modinfo [-c] [-w] [-i *module-id*]

**Description** The modinfo utility displays information about the loaded modules. The format of the information is as follows:

```
Id Loadaddr Size Info Rev Module Name
```

where *Id* is the module ID, *Loadaddr* is the starting text address in hexadecimal, *Size* is the size of text, data, and bss in hexadecimal bytes, *Info* is module specific information, *Rev* is the revision of the loadable modules system, and *Module Name* is the filename and description of the module.

The module specific information is the block and character major numbers for drivers, the system call number for system calls, and unspecified for other module types.

**Options** The following options are supported:

- c                    Display the number of instances of the module loaded and the module's current state.
- i *module-id*      Display information about this module only.
- w                    Do not truncate module information at 80 characters.

**Examples** EXAMPLE 1 Displaying the Status of a Module

The following example displays the status of module 2:

```
example% modinfo -i 2
Id Loadaddr Size Info Rev Module Name
2 ff08e000 1734 - 1 swappgeneric (root and swap configuration)
```

EXAMPLE 2 Displaying the Status of Kernel Modules

The following example displays the status of some kernel modules:

```
example% modinfo
Id Loadaddr Size Info Rev Module Name
2 ff08e000 1734 - 1 swappgeneric
4 ff07a000 3bc0 - 1 specfs (filesystem for specfs)
6 ff07dbc0 2918 - 1 TS (time sharing sched class)
7 ff0804d8 49c - 1 TS_DPTBL (Time sharing dispatch table)
8 ff04a000 24a30 2 1 ufs (filesystem for ufs)
9 ff080978 c640 226 1 rpcmod (RPC syscall)
9 ff080978 c640 - 1 rpcmod (rpc interface str mod)
10 ff08cfb8 2031c - 1 ip (IP Streams module)
10 ff08cfb8 2031c 2 1 ip (IP Streams device)
```

**EXAMPLE 3** Using the -c Option

Using the `modinfo` command with the `-c` option displays the number of instances of the module loaded and the module's current state.

```
example% modinfo -c
Id Loadcnt Module Name State
1 0 krtld UNLOADED/UNINSTALLED
2 0 genunix UNLOADED/UNINSTALLED
3 0 platmod UNLOADED/UNINSTALLED
4 0 SUNW,UltraSPARC-IIi UNLOADED/UNINSTALLED
5 0 cl_bootstrap UNLOADED/UNINSTALLED
6 1 specfs LOADED/INSTALLED
7 1 swappgeneric UNLOADED/UNINSTALLED
8 1 TS LOADED/INSTALLED
9 1 TS_DPTBL LOADED/INSTALLED
10 1 ufs LOADED/INSTALLED
11 1 fssnap_if LOADED/INSTALLED
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs
Interface Stability	Committed

**See Also** [modload\(1M\)](#), [modunload\(1M\)](#), [attributes\(5\)](#)

**Name** modload – load a kernel module

**Synopsis** modload [-p] [-e *exec\_file*] *filename*

**Description** The modload command loads the loadable module *filename* into the running system.

*filename* is an object file produced by `ld -r`. If *filename* is an absolute pathname then the file specified by that absolute path is loaded. If *filename* does not begin with a slash (/), then the path to load *filename* is relative to the current directory unless the `-p` option is specified.

The kernel's `modpath` variable can be set using the `/etc/system` file. The default value of the kernel's `modpath` variable is set to the path where the operating system was loaded. Typically this is `/kernel /usr/kernel`.

For example, the following command looks for `./drv/foo`:

```
example# modLoad drv/foo
```

The following command looks for `/kernel/drv/foo` and then `/usr/kernel/drv/foo`:

```
example# modLoad -p drv/foo
```

**Options** The following options are supported:

`-e exec_file` Specify the name of a shell script or executable image file that is executed after the module is successfully loaded. The first argument passed is the module ID (in decimal). The other argument is module specific. The module specific information is: the block and character major numbers for drivers, the system call number for system calls, or, for other module types, the index into the appropriate kernel table. See [modinfo\(1M\)](#)

`-p` Use the kernel's internal `modpath` variable as the search path for the module.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [ld\(1\)](#), [add\\_drv\(1M\)](#), [kernel\(1M\)](#), [modinfo\(1M\)](#), [modunload\(1M\)](#), [system\(4\)](#), [attributes\(5\)](#), [modldrv\(9S\)](#), [modlinkage\(9S\)](#), [modlstrmod\(9S\)](#), [module\\_info\(9S\)](#)

*Writing Device Drivers*

**Notes** Use [add\\_drv\(1M\)](#) to add device drivers, not `modLoad`. See *Writing Device Drivers* for procedures on adding device drivers.

**Name** modunload – unload a module

**Synopsis** modunload -i *module\_id* [-e *exec\_file*]

**Description** modunload unloads a loadable module from the running system. The *module\_id* is the ID of the module as shown by [modinfo\(1M\)](#). If ID is 0, all modules that were autoloaded which are unloadable, are unloaded. Modules loaded by [modload\(1M\)](#) are not affected.

**Options** The following options are supported:

-e *exec\_file* Specify the name of a shell script or executable image file to be executed before the module is unloaded. The first argument passed is the module id (in decimal). There are two additional arguments that are module specific. For loadable drivers, the second argument is the driver major number. For loadable system calls, the second argument is the system call number. For loadable exec classes, the second argument is the index into the execsw table. For loadable filesystems, the second argument is the index into the vfstsw table. For loadable streams modules, the second argument is the index into the fmodsw table. For loadable scheduling classes, the second argument is the index into the class array. Minus one is passed for an argument that does not apply.

-i *module\_id* Specify the module to be unloaded.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [modinfo\(1M\)](#), [modload\(1M\)](#), [update\\_drv\(1M\)](#), [attributes\(5\)](#)

**Notes** The modunload command is often used on driver modules to force the system to reread the associated driver configuration file. While this works in the current Solaris release, it is not the supported way to reread the configuration file and is not guaranteed to work in future releases. The supported way for rereading driver configuration file is through the [update\\_drv\(1M\)](#) command.

**Name** mofcomp – compile MOF files into CIM classes

**Synopsis** /usr/sadm/bin/mofcomp [-c *cimom\_hostname* ] [-h]  
[-j *filename*] [-n *namespace*] [-o *dirname*]  
[-p *password* ] [-CIQ] [-u *username*] [-v ] [-version]  
[-x] *file*

**Description** The `mofcomp` utility is executed during installation to compile managed object format (MOF) files that describe the Common Information Model (CIM) and Solaris Schemas into the CIM Object Manager Repository, a central storage area for management data. The CIM Schema is a collection of class definitions used to represent managed objects that occur in every management environment. The Solaris Schema is a collection of class definitions that extend the CIM Schema and represent managed objects in a typical Solaris operating environment.

The `mofcomp` utility must be run as root or as a user with write access to the namespace in which you are compiling.

MOF is a language for defining CIM classes and instances. MOF files are ASCII text files that use the MOF language to describe CIM objects. A CIM object is a computer representation or model of a managed resource, such as a printer, disk drive, or CPU.

Many sites store information about managed resources in MOF files. Because MOF can be converted to Java, Java applications that can run on any system with a Java Virtual Machine can interpret and exchange this information. You can also use the `mofcomp` utility to compile MOF files at any time after installation.

**Options** The following options are supported:

- c *cimom\_hostname* Specify a remote system running the CIM Object Manager.
- C Run the compiler set with the class option, which updates a class if it exists, and returns an error if the class does not exist. If you do not specify this option, the compiler adds a CIM class to the connected namespace, and returns an error if the class already exists.
- h List the arguments to the `mofcomp` utility.
- I Run the compiler set with the instance option, which updates an instance if it exists, and returns an error if the instance does not exist. If you do not specify this option, the compiler adds a CIM instance to the connected namespace, and returns an error if the instance already exists.
- j *filename* Generate Java Beans and Java Interfaces to manage the CIM instances related to the CIM classes in the MOF being compiled.

The contents of *filename* are:

```
PACKAGE=Java package name
IMPORTS=import1:...:importN
```

<EXCEPTIONS=*exception1*:...:*exceptionN*

PACKAGE is a valid Java package name to include in all generated Java source. IMPORTS is an optional colon separated list of valid Java classes to be imported in all generated Java source. EXCEPTIONS is an optional colon separated list of valid Java exceptions to be thrown by the methods in all generated Java source.

- n *namespace* Requests that the compiler load the MOF file into the namespace specified as *namespace*. The default namespace (`root\cimv2`) is used unless this switch is used or a `#pragma namespace ("namespace")` statement appears in the MOF file. If both the -n *namespace* switch and the `#pragma namespace` construct are used, all namespaces are created, but the objects are created only in the `#pragma` namespaces.
- o *dirname* Run compiler in standalone mode, without the CIM Object Manager. Specify *dirname* as the directory in which the compiler output is to be stored. In this mode, the CIM Object Manager need not be running.
- p *password* Specify a password for connecting to the CIM Object Manager. Use this option for compilations that require privileged access to the CIM Object Manager. If you specify both -p and -u, you must type the password on the command line, which can pose a security risk. A more secure way to specify a password is to specify -u but not -p, so that the compiler will prompt for the password.
- Q Run the compiler set with the qualifier types option, which updates a qualifier type if it exists, and returns an error if the qualifier type does not exist. If you do not specify this option, the compiler adds a CIM qualifier type to the connected namespace, and returns an error if the qualifier type already exists.
- u *username* Specify user name for connecting to the CIM Object Manager. Use this option for compilations that require privileged access to the CIM Object Manager. If you specify both -p and -u, you must type the password on the command line, which can pose a security risk. A more secure way to specify a password is to specify -u but not -p, so that the compiler will prompt for the password.
- v Run the compiler in verbose mode, which displays compiler messages.
- version Display the version of the MOF compiler.
- x Generate XML documents for the CIM classes defined in the input MOF file.

**Operands** The following operands are supported:

*file* The pathname of the file to be compiled.

**Exit Status** The `mofcomp` utility exits with 0 upon success and a positive integer upon failure.

**Files** MOF files are installed in `/usr/sadm/mof`.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWwbco

**See Also** [init.wbem\(1M\)](#), [mofreg\(1M\)](#), [wbemadmin\(1M\)](#), [wbemlogviewer\(1M\)](#), [attributes\(5\)](#), [wbem\(5\)](#)

- Name** mofreg – register MOF classes with WBEM services
- Synopsis** `/usr/sadm/bin/mofreg -r tag file`  
`/usr/sadm/bin/mofreg -s`  
`/usr/sadm/bin/mofreg -u tag [file]`
- Description** The `mofreg` command is used by package and patch install scripts, or by any applications that wish to register managed object format (MOF) classes with Sun The Web-Based Enterprise Management (WBEM) services.
- The WBEM services daemon (Common Information Model or CIM object manager) processes at start up the files that are specified by `mofreg` commands. Files are processed in the order that the individual `mofreg` commands are executed.
- As an alternative to using the `mofreg` command, MOFs can be registered or unregistered by manipulating directories in `/var/sadm/wbem/logr`. Instead of running the `mofreg -r tag file` version fo the command you can create a directory named `tag` under `/var/sadm/wbem/logr/preReg` and copy `file` to the `tag` directory.
- Similarly, instead of running the `mofreg -u tag [file]` command, you can create a directory named `tag` under `/var/sadm/wbem/logr/preUnreg` and copy the optional `file` to the `tag` directory.
- The entries are processed in increasing order of last modification time of the `tag` directories. If you issue `mofreg` commands in rapid succession, the timestamps might be the same. If you have a situation where the timestamp order is critical, you can place appropriate sleeps between the successive registration or unregistration operations. As with the `mofreg` command, processing is done at next restart or by using the `-s` option.
- This alternative mechanism is typically used in package install scripts which do not have access to `/usr`, and therefore do not have access to the `mofreg` command. This case arises when packages are installed for diskless clients.

**Options** The following options are supported:

`-r tag file` The `file` argument is the actual MOF registration file. Its form is identical to the MOF syntax as defined by the Distributed Management Task Force (DMTF). The only difference is the addition of the following 3 new pseudo-pragmas, which are variations of the namespace pragma. The name of file cannot end in `.unreg`.

```
#pragma namespace("__create")
#pragma namespace("__delete")
#pragma namespace("__modify")
```

These three pragmas are used specify if the elements following the pragmas should be created, deleted, or modified by the CIM object manager. The `__delete` pragma can currently only be applied for a `mofreg -u` command.

The *tag* argument is a unique string that specifies the identity of the registry action. This tag can be set to the package name or the patch number if the `mofreg` script is being invoked through packages/patches, though any tag can be specified.

Errors and warnings that are encountered when the CIM object manager handles the `mofreg` script are logged. Processing of the `mofreg` script stops at the first error. Specific warnings include:

Element already defined - the element already exists and cannot be created.

Element not found - the element does not exist and cannot be modified.

The error conditions are:

Key modification - A class cannot be modified if its keys are being changed.

Other mod compilation errors.

- s Forces the CIM object manager to immediately process outstanding registry requests, instead of at the next restart. This currently requires Java.
- u *tag* [*file*] Undoes the operations performed during `mof` registry.

The *tag* argument must correspond to the value set during the original `mofreg` invocation. If no `mofreg` was done with the original *tag*, the command does not succeed.

If required, an *unreg* file can be specified. If no *unreg* file is specified, the CIM object manager automatically undoes the actions of the registry. Any class created by the registry process is removed and any classes modified by the registry revert to the old state.

The `mofreg` command does not take care of cases where packages and patches make conflicting changes to classes. This should be taken care of by the standard patch and package conflict resolution.

**Exit Status** The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred. The reason for error is displayed.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

**Name** monitor – SPARC system PROM monitor

**Synopsis** STOP–A

BREAK

initial system power-on

exit from a client program, e.g., the Operating System

**Description** The CPU board of a workstation contains one or more EPROMs or EEPROMs. The program which executes from the PROMs is referred to as “the monitor”. Among other things, the monitor performs system initialization at power-on and provides a user interface.

**Monitor Prompt** The monitor of earlier workstations was known as the SunMON monitor and displayed the > for its prompt. See the SunMON MONITOR USAGE section for further details.

Existing workstations use a monitor which is known as the OpenBoot monitor. The OpenBoot monitor typically displays ok as its prompt, but it may also display the > prompt under certain circumstances.

If the 'auto-boot?' NVRAM parameter is set to 'false' when the workstation is powered on, the system does not attempt to boot and the monitor issues its prompt. If 'auto-boot' is set to 'true', the system initiates the boot sequence. The boot sequence can be aborted by simultaneously pressing two keys on the system's keyboard: L1 and A (on older keyboards), or Stop and A (on newer keyboards). Either a lower case a or an upper case A works for the keyboard abort sequence. If a console has been attached by way of one of the system's serial ports then the abort sequence can be accomplished by sending a BREAK. See [tip\(1\)](#).

When the NVRAM 'security-mode' parameter has been turned on, or when the value of the 'sunmon-compat?' parameter is true, then the OpenBoot monitor displays the message: Type b (boot), c (continue), or n (new command mode)

and the > prompt appears.

**Openboot Prom Usage** Some of the more useful commands that can be issued from OpenBoot's ok prompt are described here. Refer to the [OpenBoot 2.x Command Reference Manual](#) book for a complete list of commands.

**Help** Help for various functional areas of the OpenBoot monitor can be obtained by typing help. The help listing provides a number of other key words which can then be used in the help command to provide further details.

**NVRAM Parameters** Each workstation contains one or more NVRAM devices which contains unique system ID information, as well as a set of user-configurable parameters. The NVRAM parameters allow the user a certain level of flexibility in configuring the system to act in a given manner under a specific set of circumstances.

See [eeprom\(1M\)](#) for a description of the parameters and information regarding setting the parameters from the OS level.

The following commands can be used at the OpenBoot monitor to access the NVRAM parameters.

<code>printenv</code>	Used to list the NVRAM parameters, along with their default values and current values.
<code>setenv <i>pn pv</i></code>	Used to set or modify a parameter. The <i>pn</i> represents the parameter name, and <i>pv</i> represents the parameter value.
<code>set-default <i>pn</i></code>	Used to set an individual parameter back to its default value.
<code>set-defaults</code>	Used to reset all parameters to their default values. (Note that 'set-defaults' only affects parameters that have assigned default values.)

Security Parameters Newer OpenBoot monitors contain user interfaces that support the storage and listing of keys for later use by client programs.

<code>list-security-keys</code>	Lists the names of keys currently stored on a machine.
<code>set-security-key <i>keyname</i> [ <i>keydata</i> ]</code>	Stores key data <i>keydata</i> in a key named <i>keyname</i> . Actual key data can be up to 32 bytes in length. The maximum length of <i>keyname</i> is 64 bytes, which allows for the hex-formatted ASCII used to present the key data. If <i>keydata</i> is not present, <i>keyname</i> and its corresponding data is deleted.

Hardware Checks and Diagnostics The following commands are available for testing or checking the system's hardware. If the 'diag-switch?' NVRAM parameter is set to true when the system is powered on, then a Power-On Self Test (POST) diagnostic is run, if present, sending its results messages to the system's serial port A. Not all of the commands shown are available on all workstations.

<code>test-all</code>	Run the diagnostic tests on each device which has provided a self-test.
<code>test floppy</code>	Run diagnostics on the system's floppy device.
<code>test /memory</code>	Run the main memory tests. If the NVRAM parameter 'diag-switch?' is set to true, then all of main memory is tested. If the parameter is false then only the amount of memory specified in the 'selftest-#megs' NVRAM parameter is tested.
<code>test net</code>	Test the network connection for the on-board network controller.
<code>watch-net</code>	Monitor the network attached to the on-board net controller.
<code>watch-net-all</code>	Monitor the network attached to the on-board net controller, as well as the network controllers installed in SBus slots.
<code>watch-clock</code>	Test the system's clock function.

System Information The following commands are available for displaying information about the system. Not all commands are available on all workstations.

banner	Display the power-on banner.
.enet-addr	Display the system's Ethernet address.
.idprom	Display the formatted contents of the IDPROM.
module-info	Display information about the system's processor(s).
probe-scsi	Identify the devices attached to the on-board SCSI controller.
probe-scsi-all	Identify the devices attached to the on-board SCSI controller as well as those devices which are attached to SBus SCSI controllers.
show-disks	Display a list of the device paths for installed SCSI disk controllers.
show-displays	Display a list of the device paths for installed display devices.
show-nets	Display a list of the device paths for installed Ethernet controllers.
show-sbus	Display list of installed SBus devices.
show-tapes	Display a list of the device paths for installed SCSI tape controllers.
show-ttys	Display a list of the device paths for tty devices.
.traps	Display a list of the SPARC trap types.
.version	Display the version and date of the OpenBoot PROM.

Emergency Commands These commands must be typed from the keyboard, they do not work from a console which is attached by way of the serial ports. With the exception of the Stop-A command, these commands are issued by pressing and holding down the indicated keys on the keyboard immediately after the system has been powered on. The keys must be held down until the monitor has checked their status. The Stop-A command can be issued at any time after the console display begins, and the keys do not need to be held down once they've been pressed. The Stop-D, Stop-F and Stop-N commands are not allowed when one of the security modes has been set. Not all commands are available on all workstations.

Stop (L1)	Bypass the Power-On Self Test (POST). This is only effective if the system has been placed into the diagnostic mode.
Stop-A (L1-A)	Abort the current operation and return to the monitor's default prompt.
Stop-D (L1-D)	Set the system's 'diag-switch?' NVRAM parameter to 'true', which places the system in diagnostic mode. POST diagnostics, if present, are run, and the messages are displayed by way of the system's serial port A.
Stop-F (L1-F)	Enter the OpenBoot monitor before the monitor has probed the system for devices. Issue the 'fexit' command to continue with system initialization.

Stop-N (L1-N) Causes the NVRAM parameters to be reset to their default values. Note that not all parameters have default values.

Line Editor Commands The following commands can be used while the monitor is displaying the ok prompt. Not all of these editing commands are available on all workstations.

CTRL-A Place the cursor at the start of line.

CTRL-B Move the cursor backward one character.

ESC-B Move the cursor backward one word.

CTRL-D Erase the character that the cursor is currently highlighting.

ESC-D Erase the portion of word from the cursor's present position to the end of the word.

CTRL-E Place the cursor at the end of line.

CTRL-F Move the cursor forward one character.

ESC-F Move the cursor forward one word.

CTRL-H Erase the character preceding the cursor (also use Delete or Back Space)

ESC-H Erase the portion of the word which precedes the cursor (use also CTRL-W)

CTRL-K Erase from the cursor's present position to the end of the line.

CTRL-L Show the command history list.

CTRL-N Recall the next command from the command history list

CTRL-P Recall a previous command from the command history list.

CTRL-Q Quote the next character (used to type a control character).

CTRL-R Retype the current line.

CTRL-U Erase from the cursor's present position to the beginning of the line.

CTRL-Y Insert the contents of the memory buffer into the line, in front (to the left) of the cursor.

nvrarc The nvrarc is an area of the system's NVRAM where users may store Forth programs. The programs which are stored in the nvrarc are executed each time the system is reset, provided that the 'use-nvrarc?' NVRAM parameter has been set to 'true'. Refer to the [OpenBoot 2.x Command Reference Manual](#) book for information on how to edit and use the nvrarc.

Restricted Monitor The command 'old-mode' is used to move OpenBoot into a restricted monitor mode, causing the > prompt to be displayed. Only three commands are allowed while in the restricted monitor; the 'go' command (to resume a program which was interrupted with the

Stop-A command), the 'n' command (to return to the normal OpenBoot monitor), and boot commands. The restricted monitor's boot commands approximate the older SunMON monitor's boot command syntax. If a 'security-mode' has been turned on then the restricted monitor becomes the default monitor environment. The restricted monitor may also become the default environment if the 'sunmon-compat?' NVRAM parameter is set to true. Not all workstations have the 'sunmon-compat?' parameter.

### SunMON Prom Usage

The following commands are available systems with older SunMON-based PROM:

+|-

Increment or decrement the current address and display the contents of the new location.

^C *source destination n*

(caret-C) Copy, byte-by-byte, a block of length *n* from the source address to the *destination* address.

^I *program*

(caret-I) Display the compilation date and location of *program*.

^T *virtual\_address*

(caret-T) Display the physical address to which *virtual\_address* is mapped.

b [ ! ] [ *device* [ ( *c, u, p* ) ] ] [ *pathname* ] [ *arguments\_list* ]

b[?]

Reset appropriate parts of the system and bootstrap a program. A '!' (preceding the *device* argument) prevents the system reset from occurring. Programs can be loaded from various devices (such as a disk, tape, or Ethernet). 'b' with no arguments causes a default boot, either from a disk, or from an Ethernet controller. 'b?' displays all boot devices and their *devices*.

*device*

one of

le Lance Ethernet

ie Intel Ethernet

sd SCSI disk, CDROM

st SCSI 1/4" or 1/2" tape

fd Diskette

id IPI disk

mt Tape Master 9-track 1/2" tape

xd Xylogics 7053 disk

xt Xylogics 1/2" tape

xy Xylogics 440/450 disk

- 
- c* A controller number (0 if only one controller),
- u* A unit number (0 if only one driver), and
- p* A partition.
- pathname* A pathname for a program such as /stand/diag.
- arguments\_list* A list of up to seven arguments to pass to the program being booted.
- c [*virtual\_address*]  
Resume execution of a program. When given, *virtual\_address* is the address at which execution resumes. The default is the current PC. Registers are restored to the values shown by the d, and r commands.
- d [*window\_number*]  
Display (dump) the state of the processor. The processor state is observable only after:
- An unexpected trap was encountered.
  - A user program dropped into the monitor (by calling *abortent*).
  - The user manually entered the monitor by typing L1-A or BREAK.
- The display consists of the following:
- The special registers: PSR, PC, nPC, TBR, WIM, and Y
  - Eight global registers
  - 24 window registers (8 *in*, 8 *local*, and 8 *out*), corresponding to one of the 7 available windows. If a Floating-Point Unit is on board, its status register along with 32 floating-point registers are also shown.
- window\_number* Display the indicated *window\_number*, which can be any value between 0 and 6, inclusive. If no window is specified and the PSR's current window pointer contains a valid window number, registers from the window that was active just prior to entry into the monitor are displayed. Otherwise, registers from window 0 are displayed.
- e [*virtual\_address*] [*action*] . . .  
Open the 16-bit word at *virtual\_address* (default zero). The address is interpreted in the address space defined by the s command. See the a command for a description of *action*.
- f *virtual\_address1* *virtual\_address2* *pattern* [*size* ]  
Fill the bytes, words, or long words from *virtual\_address1* (lower) to *virtual\_address2* (higher) with the constant, *pattern*. The *size* argument can take one of the following values:
- b byte format (the default)
  - w word format
  - l long word format

For example, the following command fills the address block from 0x1000 to 0x2000 with the word pattern, 0xABCD:

```
f 1000 2000 ABCD W
```

**g** [*vector*] [*argument*]

**g** [*virtual\_address*] [*argument*]

Goto (jump to) a predetermined or default routine (first form), or to a user-specified routine (second form). The value of *argument* is passed to the routine. If the *vector* or *virtual\_address* argument is omitted, the value in the PC is used as the address to jump to.

To set up a predetermined routine to jump to, a user program must, prior to executing the monitor's **g** command, set the variable `*romp->v_vector_cmd` to be equal to the virtual address of the desired routine. Predetermined routines need not necessarily return control to the monitor.

The default routine, defined by the monitor, prints the user-supplied *vector* according to the format supplied in *argument*. This format can be one of:

%x    hexadecimal

%d    decimal

**g0**

Force a panic and produce a crash dump when the monitor is running as a result of the system being interrupted,

**g4**

(Sun-4 systems only) Force a kernel stack trace when the monitor is running as a result of the system being interrupted,

**h**

Display the help menu for monitor commands and their descriptions. To return to the monitor's basic command level, press ESCAPE or q before pressing RETURN.

**i** [*cache\_data\_offset*] [*action*] . . .

Modify cache data RAM command. Display and/or modify one or more of the cache data addresses. See the **a** command for a description of *action*.

**j** [*cache\_tag\_offset*] [*action*] . . .

Modify cache tag RAM command. Display and/or modify the contents of one or more of the cache tag addresses. See the **a** command for a description of *action*.

**k** [*reset\_level*]

Reset the system, where *reset\_level* is:

0    Reset VMEbus, interrupt registers, video monitor (Sun-4 systems). This is the default.

1    Software reset.

- 2 Power-on reset. Resets and clears the memory. Runs the EPROM-based diagnostic self test, which can take several minutes, depending upon how much memory is being tested.

kb

Display the system banner.

l [*virtual\_address*] [*action*] . . .

Open the long word (32 bit) at memory address *virtual\_address* (default zero). The address is interpreted in the address space defined by the *s* command (below). See the *a* command for a description of *action*.

m [*virtual\_address*] [*action*] . . .

Open the segment map entry that maps *virtual\_address* (default zero). The address is interpreted in the address space defined by the *s* command. See the *a* command for a description of *action*.

ne

ni

Disable, enable, or invalidate the cache, respectively.

o [*virtual\_address*] [*action*] . . .

Open the byte location specified by *virtual\_address* (default zero). The address is interpreted in the address space defined by the *s* command. See the *a* command for a description of *action*.

p [*virtual\_address*] [*action*] . . .

Open the page map entry that maps *virtual\_address* (default zero) in the address space defined by the *s* command. See the *a* command for a description of *action*.

q [*eprom\_offset*] [*action*] . . .

Open the EEPROM *eprom\_offset* (default zero) in the EEPROM address space. All addresses are referenced from the beginning or base of the EEPROM in physical address space, and a limit check is performed to insure that no address beyond the EEPROM physical space is accessed. This command is used to display or modify configuration parameters, such as: the amount of memory to test during self test, whether to display a standard or custom banner, if a serial port (A or B) is to be the system console, etc. See the *a* command for a description of *action*.

r [*register\_number*]

r [*register\_type*]

r [*w window\_number*]

Display and/or modify one or more of the IU or FPU registers. A hexadecimal *register\_number* can be one of:

0x00–0x0f    window(0,i0)–window(0,i7), window(0,i0)–window(0,i7)

0x16–0x1f    window(1,i0)–window(1,i7), window(1,i0)–window(1,i7)

0x20–0x2f	window(2,i0)–window(2,i7), window(2,i0)—window(2,i7)
0x30–0x3f	window(3,i0)–window(3,i7), window(3,i0)—window(3,i7)
0x40–0x4f	window(4,i0)–window(4,i7), window(4,i0)—window(4,i7)
0x50–0x5f	window(5,i0)–window(5,i7), window(5,i0)—window(5,i7)
0x60–0x6f	window(6,i0)–window(6,i7), window(6,i0)—window(6,i7)
0x70–0x77	g0, g1, g2, g3, g4, g5, g6, g7
0x78–0x7d	PSR, PC, nPC, WIM, TBR, Y.
0x7e–0x9e	FSR, f0–f31

Register numbers can only be displayed after an unexpected trap, a user program has entered the monitor using the *abortent* function, or the user has entered the monitor by manually typing L1–A or BREAK.

If a *register\_type* is given, the first register of the indicated type is displayed. *register\_type* can be one of:

- f floating-point
- g global
- s special

If *w* and a *window\_number* (0–6) are given, the first *in*-register within the indicated window is displayed. If *window\_number* is omitted, the window that was active just prior to entering the monitor is used. If the PSR's current window pointer is invalid, window 0 is used.

s [*asi*])

Set or display the Address Space Identifier. With no argument, s displays the current Address Space Identifier. The *asi* value can be one of:

- 0x2 control space
- 0x3 segment table
- 0x4 Page table
- 0x8 user instruction
- 0x9 supervisor instruction
- 0xa user data
- 0xb supervisor data
- 0xc flush segment

0xd flush page

0xe flush context

0xf cache data

u [ echo ]

u [ port ] [ options ] [ baud\_rate ]

u [ u ] [ virtual\_address ]

With no arguments, display the current I/O device characteristics including: current input device, current output device, baud rates for serial ports A and B, an input-to-output echo indicator, and virtual addresses of mapped UART devices. With arguments, set or configure the current I/O device. With the u argument (uu. . .), set the I/O device to be the *virtual\_address* of a UART device currently mapped.

echo Can be either e to enable input to be echoed to the output device, or ne, to indicate that input is not echoed.

*port* Assign the indicated *port* to be the current I/O device. *port* can be one of:

- a serial port A
- b serial port B
- k the workstation keyboard
- s the workstation screen

*baud\_rate* Any legal baud rate.

*options* can be any combination of:

- i input
- o output
- u UART
- e echo input to output
- ne do not echo input
- r reset indicated serial port (a and b ports only)

If either a or b is supplied, and no *options* are given, the serial port is assigned for both input and output. If k is supplied with no options, it is assigned for input only. If s is supplied with no options, it is assigned for output only.

v *virtual\_address1* *virtual\_address2* [size]

Display the contents of *virtual\_address1* (lower) *virtual\_address2* (higher) in the format specified by size:

b byte format (the default)

- w word format
- l long word format

Enter return to pause for viewing; enter another return character to resume the display. To terminate the display at any time, press the space bar.

For example, the following command displays the contents of virtual address space from address 0x1000 to 0x2000 in word format:

```
v 1000 2000 W
```

w [*virtual\_address*] [*argument*]

Set the execution vector to a predetermined or default routine. Pass *virtual\_address* and *argument* to that routine.

To set up a predetermined routine to jump to, a user program must, prior to executing the monitor's w command, set the variable \*romp->v\_vector\_cmd to be equal to the virtual address of the desired routine. Predetermined routines need not necessarily return control to the monitor.

The default routine, defined by the monitor, prints the user-supplied *vector* according to the format supplied in *argument*. This format can be one of:

- %x hexadecimal
- %d decimal

x

Display a menu of extended tests. These diagnostics permit additional testing of such things as the I/O port connectors, video memory, workstation memory and keyboard, and boot device paths.

y c *context\_number*

y p|s *context\_number virtual\_address*

Flush the indicated context, context page, or context segment.

c flush context *context\_number*

p flush the page beginning at *virtual\_address* within context *context\_number*

s flush the segment beginning at *virtual\_address* within context *context\_number*

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

*OpenBoot 2.x Command Reference Manual*

**Name** mount, umount – mount or unmount file systems and remote resources

**Synopsis** mount [-p | -v]

```
mount [-F FSType] [generic_options] [-o specific_options]
 [-O] special | mount_point
```

```
mount [-F FSType] [generic_options] [-o specific_options]
 [-O] special mount_point
```

```
mount -a [-F FSType] [-V] [current_options]
 [-o specific_options] [mount_point]...
```

```
umount [-f] [-V] [-o specific_options] special | mount_point
```

```
umount -a [-f] [-V] [-o specific_options] [mount_point]...
```

**Description** mount attaches a file system to the file system hierarchy at the *mount\_point*, which is the pathname of a directory. If *mount\_point* has any contents prior to the mount operation, these are hidden until the file system is unmounted.

umount unmounts a currently mounted file system, which may be specified either as a *mount\_point* or as *special*, the device on which the file system resides.

The table of currently mounted file systems can be found by examining the mounted file system information file. This is provided by a file system that is usually mounted on `/etc/mnttab`. The mounted file system information is described in [mnttab\(4\)](#). Mounting a file system adds an entry to the mount table; a umount removes an entry from the table.

When invoked with both the *special* and *mount\_point* arguments and the `-F` option, mount validates all arguments except for *special* and invokes the appropriate *FSType*-specific mount module. If invoked with no arguments, mount lists all the mounted file systems recorded in the mount table, `/etc/mnttab`. If invoked with a partial argument list (with only one of *special* or *mount\_point*, or with both *special* or *mount\_point* specified but not *FSType*), mount will search `/etc/vfstab` for an entry that will supply the missing arguments. If no entry is found, and the *special* argument starts with `/`, the default local file system type specified in `/etc/default/fs` will be used. Otherwise the default remote file system type will be used. The default remote file system type is determined by the first entry in the `/etc/dfs/fstypes` file. After filling in missing arguments, mount will invoke the *FSType*-specific mount module.

For file system types that support it, a file can be mounted directly as a file system by specifying the full path to the file as the *special* argument. In such a case, the `nosuid` option is enforced. If specific file system support for such loopback file mounts is not present, you can still use [lofiadm\(1M\)](#) to mount a file system image. In this case, no special options are enforced.

Only a user with sufficient privilege (at least `PRIV_SYS_MOUNT`) can mount or unmount file systems using mount and umount. However, any user can use mount to list mounted file systems and resources.

**Options** -F *FSType*

Used to specify the *FSType* on which to operate. The *FSType* must be specified or must be determinable from `/etc/vfstab`, or by consulting `/etc/default/fs` or `/etc/dfs/fstypes`.

**-a** [*mount\_points*. . .]

Perform mount or umount operations in parallel, when possible.

If mount points are not specified, mount will mount all file systems whose `/etc/vfstab` “mount at boot” field is yes. If mount points are specified, then `/etc/vfstab` “mount at boot” field will be ignored.

If mount points are specified, umount will only umount those mount points. If none is specified, then umount will attempt to unmount all file systems in `/etc/mnttab`, with the exception of certain system required file systems: `/`, `/usr`, `/var`, `/var/adm`, `/var/run`, `/proc`, `/dev/fd` and `/tmp`.

**-f**

Forcibly unmount a file system.

Without this option, umount does not allow a file system to be unmounted if a file on the file system is busy. Using this option can cause data loss for open files; programs which access files after the file system has been unmounted will get an error (EIO).

**-p**

Print the list of mounted file systems in the `/etc/vfstab` format. Must be the only option specified. See BUGS.

**-v**

Print the list of mounted file systems in verbose format. Must be the only option specified.

**-V**

Echo the complete command line, but do not execute the command. umount generates a command line by using the options and arguments provided by the user and adding to them information derived from `/etc/mnttab`. This option should be used to verify and validate the command line.

*generic\_options*

Options that are commonly supported by most *FSType*-specific command modules. The following options are available:

**-m**

Mount the file system without making an entry in `/etc/mnttab`.

**-g**

Globally mount the file system. On a clustered system, this globally mounts the file system on all nodes of the cluster. On a non-clustered system this has no effect.

-o

Specify *FSType*-specific options in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the *FSType*-specific module of the command. (See [mount\\_ufs\(1M\)](#).) When you use -o with a file system that has an entry in `/etc/vfstab`, any mount options entered for that file system in `/etc/vfstab` are ignored.

The following options are supported:

`devices` | `nodevices`

Allow or disallow the opening of device-special files. The default is `devices`.

If you use `nosuid` in conjunction with `devices`, the behavior is equivalent to that of `nosuid`.

`exec` | `noexec`

Allow or disallow executing programs in the file system. Allow or disallow [mmap\(2\)](#) with `PROT_EXEC` for files within the file system. The default is `exec`.

`loop`

Ignored for compatibility.

`nbmand` | `nonbmand`

Allow or disallow non-blocking mandatory locking semantics on this file system. Non-blocking mandatory locking is disallowed by default.

If the file system is mounted with the `nbmand` option, then applications can use the [fcntl\(2\)](#) interface to place non-blocking mandatory locks on files and the system enforces those semantics. If you enable this option, it can cause standards conformant applications to see unexpected errors.

To avoid the possibility of obtaining mandatory locks on system files, do not use the `nbmand` option with the following file systems:

```
/
/usr
/etc
/var
/proc
/dev
/devices
/system/contract
/system/object
/etc/mnttab
/etc/dfs/sharetab
```

Do not use the `remount` option to change the `nbmand` disposition of the file system. The `nbmand` option is mutually exclusive of the `global` option. See `-g`.

ro | rw

Specify read-only or read-write. The default is rw.

setuid | nosetuid

Allow or disallow setuid or setgid execution. The default is setuid.

If you specify setuid in conjunction with nosuid, the behavior is the same as nosuid.

nosuid is equivalent to nosetuid and nodevices. When suid or nosuid is combined with setuid or nosetuid and devices or nodevices, the most restrictive options take effect.

This option is highly recommended whenever the file system is shared by way of NFS with the root= option. Without it, NFS clients could add setuid programs to the server or create devices that could open security holes.

suid | nosuid

Allow or disallow setuid or setgid execution. The default is suid. This option also allows or disallows opening any device-special entries that appear within the filesystem.

nosuid is equivalent to nosetuid and nodevices. When suid or nosuid is combined with setuid or nosetuid and devices or nodevices, the most restrictive options take effect.

This option is highly recommended whenever the file system is shared using NFS with the root=*option*, because, without it, NFS clients could add setuid programs to the server, or create devices that could open security holes.

rstchown | norstchown

Allow or disallow restricted chown. If the file system is mounted with rstchown, the owner of the file is prevented from changing the owner ID of the file. If the file system is mounted with norstchown, the user can permit ownership changes for files they own. Only the super-user or a user with appropriate privilege can arbitrarily change owner IDs.

-O

Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error “device busy”.

-r

Mount the file system read-only.

### Examples EXAMPLE 1 Mounting and Unmounting a DVD Image Directly

The following commands mount and unmount a DVD image.

EXAMPLE 1 Mounting and Unmounting a DVD Image Directly (Continued)

```
mount -F hsfs /images/solaris.iso /mnt/solaris-image
umount /mnt/solaris-image
```

**Usage** See [largefile\(5\)](#) for the description of the behavior of mount and umount when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**Files** /etc/mnttab

Table of mounted file systems.

/etc/default/fs

Default local file system type. Default values can be set for the following flags in /etc/default/fs. For example: LOCAL=ufs

LOCAL:

The default partition for a command if no *FSType* is specified.

/etc/vfstab

List of default parameters for each file system.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTETYPE	ATTRIBUTEVALUE
Availability	SUNWcs

**See Also** [lofiadm\(1M\)](#), [mount\\_hsfs\(1M\)](#), [mount\\_nfs\(1M\)](#), [mount\\_pcfs\(1M\)](#), [mount\\_smbfs\(1M\)](#), [mount\\_tmpfs\(1M\)](#), [mount\\_udfs\(1M\)](#), [mount\\_ufs\(1M\)](#), [mountall\(1M\)](#), [umountall\(1M\)](#), [fcntl\(2\)](#), [mmap\(2\)](#), [mnttab\(4\)](#), [vfstab\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#), [privileges\(5\)](#), [lofs\(7FS\)](#), [pcfs\(7FS\)](#)

**Notes** If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

**Bugs** The mount -p output is incorrect for cachefs.

**Name** mountall, umountall – mount, unmount multiple file systems

**Synopsis** mountall [-F *FSType*] [-l | -r] [*file\_system\_table*]  
 umountall [-k] [-s] [-F *FSType*] [-l | -r] [-n] [-Z]  
 umountall [-k] [-s] [-h *host*] [-n] [-Z]

**Description** mountall is used to mount file systems specified in a file system table. The file system table must be in [vfstab\(4\)](#) format. If no *file\_system\_table* is specified, /etc/vfstab is used. If – is specified as *file\_system\_table*, mountall reads the file system table from the standard input. mountall mounts only those file systems with the mount at boot field set to yes in the *file\_system\_table*.

For each file system in the file system table, the following logic is executed: if there exists a file /usr/lib/fs/*FSType*/fsckall, where *FSType* is the type of the file system, save that file system in a list to be passed later, and all at once, as arguments to the /usr/lib/fs/*FSType*/fsckall script. The /usr/lib/fs/*FSType*/fsckall script checks all of the file systems in its argument list to determine whether they can be safely mounted. If no /usr/lib/fs/*FSType*/fsckall script exists for the *FSType* of the file system, the file system is individually checked using [fsck\(1M\)](#). If the file system does not appear mountable, it is fixed using fsck before the mount is attempted. File systems with a – entry in the fsckdev field are mounted without first being checked.

umountall causes all mounted file systems in the current zone except root, /usr, /var, /var/adm, /var/run, /proc, and /dev/fd to be unmounted. If the *FSType* is specified, mountall and umountall limit their actions to the *FSType* specified. There is no guarantee that umountall unmounts *busy* file systems, even if the -k option is specified.

**Options** The following options are supported:

- F Specify the *FSType* of the file system to be mounted or unmounted.
- h *host* Unmount all file systems listed in /etc/mnttab that are remote-mounted from *host*.
- k Use the fuser -k *mount-point* command. See the [fuser\(1M\)](#) for details. The -k option sends the SIGKILL signal to each process using the file. As this option spawns kills for each process, the kill messages might not show up immediately. There is no guarantee that umountall unmounts *busy* file systems, even if the -k option is specified.
- l Limit the action to local file systems.
- n List the actions that would be performed for the specified options, but do not actually execute these actions. Repeating the command without the -n option executes the listed actions, assuming that the /etc/mnttab file has not changed in the interval prior to repeating the command.
- r Limit the action to remote file system types.

- s Do not perform the umount operation in parallel.
- Z Apply the action(s) only to the file systems mounted in non-global zones. By default, `umountall` unmounts only file systems mounted in the current zone. Option -Z is ignored if used in a non-global zone.

**Files** `/etc/mnttab`  
Mounted file system table

`/etc/vfstab`  
Table of file system defaults

`/usr/lib/fs/FSType/fsckall`  
Script called by `mountall` to perform the file system check of all file systems of type *FSType*

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs
Interface Stability	Committed
Output Stability	Uncommitted

**See Also** [fsck\(1M\)](#), [fuser\(1M\)](#), [mount\(1M\)](#), [mnttab\(4\)](#), [vfstab\(4\)](#), [attributes\(5\)](#)

**Diagnostics** No messages are printed if the file systems are mountable and clean.

Error and warning messages come from [fsck\(1M\)](#) and [mount\(1M\)](#).

**Notes** At this time, NFS is the only remote file system supported by the -l, -r, and -h options.

**Name** mount\_cachefs – mount CacheFS file systems

**Synopsis** mount -F cachefs [*generic\_options*] -o backfstype=*file\_system\_type*  
 [*specific\_options*]  
 [-O] *special mount\_point*

**Description** The CacheFS-specific version of the mount command mounts a cached file system; if necessary, it NFS-mounts its back file system. It also provides a number of CacheFS-specific options for controlling the caching process. For more information regarding back file systems, refer to the *System Administration Guide: Basic Administration*.

mount\_cachefs cannot be used with replicated NFS mounts. mount\_cachefs creates a pass through when used with an NFS version 4 mount. No caching is performed.

**Options** To mount a CacheFS file system, use the generic mount command with the -F option followed by the argument cachefs.

See [mount\(1M\)](#) for a list of supported *generic\_options*.

-o *specific\_options* Specify CacheFS file system specific options in a comma-separated list with no intervening spaces.

acdirmax=*n* Specifies that cached attributes are held for no more than *n* seconds after directory update. After *n* seconds, all directory information is purged from the cache. The default value is 30 seconds.

acdirmin=*n* Specifies that cached attributes are held for at least *n* seconds after directory update. After *n* seconds, CacheFS checks to see if the directory modification time on the back file system has changed. If it has, all information about the directory is purged from the cache and new data is retrieved from the back file system. The default value is 30 seconds.

acregmax=*n* Specifies that cached attributes are held for no more than *n* seconds after file modification. After *n* seconds, all file information is purged from the cache. The default value is 30 seconds.

<code>acregmin=<i>n</i></code>	Specifies that cached attributes are held for at least <i>n</i> seconds after file modification. After <i>n</i> seconds, CacheFS checks to see if the file modification time on the back file system has changed. If it has, all information about the file is purged from the cache and new data is retrieved from the back file system. The default value is 30 seconds.
<code>actimeo=<i>n</i></code>	Sets <code>acregmin</code> , <code>acregmax</code> , <code>acdirmin</code> , and <code>acdirmax</code> to <i>n</i> .
<code>backfstype=<i>file_system_type</i></code>	The file system type of the back file system (can be <code>nfs</code> or <code>hsfs</code> ).
<code>backpath=<i>path</i></code>	Specifies where the back file system is already mounted. If this argument is not supplied, CacheFS determines a mount point for the back file system. The back file system must be read-only.
<code>cachedir=<i>directory</i></code>	The name of the cache directory.
<code>cacheid=<i>ID</i></code>	<i>ID</i> is a string specifying a particular instance of a cache. If you do not specify a cache ID, CacheFS will construct one.
<code>demandconst</code>	Verifies cache consistency only when explicitly requested, rather than the periodic checking that is done by default. A consistency check is requested by using the <code>-s</code> option of the <code>cfsadmin(1M)</code> command. This option is useful for back file systems that change infrequently, for example, <code>/usr/openwin</code> . <code>demandconst</code> and <code>noconst</code> are mutually exclusive.
<code>local-access</code>	Causes the front file system to interpret the mode bits used for access checking instead of having the back file system verify access

	permissions. Do not use this argument with secure NFS.
<code>noconst</code>	Disables cache consistency checking. By default, periodic consistency checking is enabled. Specify <code>noconst</code> only when you know that the back file system will not be modified. Trying to perform cache consistency check using <code>cfsadmin -s</code> will result in error. <code>demandconst</code> and <code>noconst</code> are mutually exclusive.
<code>write-around   non-shared</code>	Write modes for CacheFS. The <code>write-around</code> mode (the default) handles writes the same as NFS does; that is, writes are made to the back file system, and the affected file is purged from the cache. You can use the <code>non-shared</code> mode when you are sure that no one else will be writing to the cached file system. In this mode, all writes are made to both the front and the back file system, and the file remains in the cache.
<code>-O</code>	Overlay mount. Allows the filesystem to be mounted over an existing mount point, making the underlying filesystem inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, mount will fail with the error: <code>mount -F cachefs: mount failed Device busy.</code>

### Examples EXAMPLE 1 CacheFS-mounting a File System

The following example CacheFS-mounts the file system `server1:/user2`, which is already NFS-mounted on `/usr/abc` as `/xyz`.

```
example# mount -F cachefs -o backfstype=nfs,backpath=/usr/abc,
 cachedir=/cache1 server1:/user2 /xyz
```

The lines similar to the following appear in the `/etc/mnttab` file after the mount command is executed:

```
server1:/user2 /usr/abc nfs
/usr/abc /cache1/xyz cachefs backfstype=nfs
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [cfsadmin\(1M\)](#), [fsck\\_cachefs\(1M\)](#), [mount\(1M\)](#), [attributes\(5\)](#) *System Administration Guide: Basic Administration*

**Bugs** The output for the *generic\_option -p* output is incorrect for cachefs.

**Name** mountd – server for NFS mount requests and NFS access checks

**Synopsis** /usr/lib/nfs/mountd [-v] [-r]

**Description** mountd is an RPC server that answers requests for NFS access information and file system mount requests. It reads the file /etc/dfs/sharetab to determine which file systems are available for mounting by which remote machines. See [sharetab\(4\)](#). nfsd running on the local server will contact mountd the first time an NFS client tries to access the file system to determine whether the client should get read-write, read-only, or no access. This access can be dependent on the security mode used in the remotd procedure call from the client. See [share\\_nfs\(1M\)](#).

The command also provides information as to what file systems are mounted by which clients. This information can be printed using the [showmount\(1M\)](#) command.

The mountd daemon is automatically invoked by [share\(1M\)](#).

Only super user can run the mountd daemon.

**SMF Management** Since mountd must be running for nfsd to function properly, mountd is automatically started by the svc:/network/nfs/server service.

Startup SMF parameters for mountd can be manipulated using the [sharectl\(1M\)](#) command. The currently supported parameters are:

`client_versmin=num`

`client_versmax=num`

The NFS client uses only NFS versions in the range specified by these variables. Valid values or versions are: 2, 3, and 4. By default, these variables are unspecified (commented out) and the client's default minimum is Version 2. The default maximum is version 4. You can override this range on a per-mount basis by using the `-o vers=` option to [mount\\_nfs\(1M\)](#).

**Options** The options shown below are supported for NVSv2/v3 clients. They are not supported for Solaris NFSv4 clients.

-r Reject mount requests from clients. Clients that have file systems mounted will not be affected.

-v Run the command in verbose mode. Each time mountd determines what access a client should get, it will log the result to the console, as well as how it got that result.

**Files** /etc/dfs/sharetab shared file system table

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/file-system/nfs

**See Also** [mount\\_nfs\(1M\)](#), [nfsd\(1M\)](#), [share\(1M\)](#), [share\\_nfs\(1M\)](#), [sharectl\(1M\)](#), [showmount\(1M\)](#), [sharetab\(4\)](#), [attributes\(5\)](#)

**Notes** Some routines that compare hostnames use case-sensitive string comparisons; some do not. If an incoming request fails, verify that the case of the hostname in the file to be parsed matches the case of the hostname called for, and attempt the request again.

**Name** mount\_hfs – mount hfs file systems

**Synopsis** `mount -F hfs [generic_options]`  
`[-o FSType-specific_options] [-O ] special | mount_point`

`mount -F hfs [generic_options]`  
`[-o FSType-specific_options] [-O] special mount_point`

**Description** `mount` attaches an ISO 9660 filesystem (the High Sierra file system, `hfs`, is a draft predecessor to ISO 9660, so the name reflects the filesystem's history) to the file system hierarchy at the `mount_point`, which is the pathname of a directory. If `mount_point` has any contents prior to the mount operation, these are hidden until the file system is unmounted.

If `mount` is invoked with `special` or `mount_point` as the only arguments, `mount` will search `/etc/vfstab` to fill in the missing arguments, including the `FSType-specific_options`; see [mount\(1M\)](#) for more details.

The `hfs` file system supports direct mounting of files containing the file system as well as block devices. See [mount\(1M\)](#) and [lofiadm\(1M\)](#).

A file system conforming to ISO 9660 can contain extensions that allow it to overcome limitations of the original ISO 9660:1988 (version 1) standard. The following types of extensions are supported by `hfs`:

#### Rock Ridge extensions

This is the preferred type of extension as it allows file attributes, name length, and types equivalent to those on other UNIX-style filesystems. Example of supported features are device special files, POSIX permissions, symbolic links, and filenames of up to 255 bytes in length. Rock Ridge extensions also remove the ISO9660:1988 restriction on maximum nesting depth for directories (eight levels). `hfs` automatically detects the presence of Rock Ridge extensions and uses them, unless `mount` options are specified to disable the use of Rock Ridge or to use a different extension.

#### ISO9660:1999 (version 2) extensions

The first version of ISO9660, released in 1988, supported only uppercase ASCII filenames of no more than 31 characters in length. ISO9660 version 2, released in 1999, provides an extension that allows filenames of at least 207 bytes that can use UTF-8 characters and removes the limitation on the nesting depth for directories. Unlike Rock Ridge, it does not provide support for UNIX-style file types and file attributes. `hfs` automatically detects this extension and will use it for filename lookup if no Rock Ridge extensions are found on the media.

#### Joliet extensions

The Joliet extension was devised by Microsoft to allow Unicode (UCS-2) long filenames with CDROM-based media. It allows filename lengths of up to 110 Unicode characters and does not support UNIX-style file types and attributes. `hfs` falls back to using Joliet if such an extension is present and neither Rock Ridge nor ISO9660 version 2 extensions are found.

If filenames are longer than the 64 UCS-2 characters officially allowed by Microsoft (that is, 110 Unicode characters), they can translate to up to 330 UTF-8 octets. Filenames that translate to more than 255 UTF-8 octets will be truncated.

**Options** *generic\_options*

See [mount\(1M\)](#) for the list of supported options.

-o

Specify `hfs` file system specific options. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available:

`global` | `noglobal`

If `global` is specified and supported on the file system, and the system in question is part of a cluster, the file system will be globally visible on all nodes of the cluster. If `noglobal` is specified, the mount will not be globally visible. The default behavior is `noglobal`.

`ro`

Mount the file system read-only. This option is required.

`rr` | `nrr`

Enable (`rr`) or disable (`nrr`) the use of Rock Ridge. `rr` is the default and need not be specified. If you use `nrr` and Rock Ridge extensions are present in the file system, ignore them and search for other available extensions or fall back to plain ISO9660.

`vers2` | `novers2`

Enable or disable the use of ISO9660 version 2 extensions. If `vers2` is specified and ISO9660 version 2 extensions are available, `hfs` will use ISO9660 version 2 even if the file system contains the preferred Rock Ridge extensions as well. If `novers2` is specified, it will fall back to using either Joliet extensions or plain ISO9660 even if ISO9660 version 2 extensions are available.

`joliet` | `nojoliet`

Enable or disable the use of Joliet extensions. If `joliet` is specified and Joliet extensions are available, `hfs` will use them even if the file system contains the preferred Rock Ridge and/or ISO9660 version 2 extensions. If `nojoliet` is specified, it will fall back to using plain ISO9660.

`notraildot`

File names on High Sierra file systems consist of a proper name and an extension separated by a '.' (dot) character. By default, the separating dot is always considered part of the file's name for all file access operations, even if there is no extension present. Specifying `notraildot` makes it optional to specify the trailing dot to access a file whose name lacks an extension.

*Exceptions:* This option is effective only on file systems for which Rock Ridge, ISO9660 version 2 or Joliet extensions are not active, either because they are not present on the CD-ROM, or they have been deliberately disabled via the `nrr`, `novers2` and `nojoliet` option. If either extension is active, `hfs` quietly ignores this option.

**nomaplcse**

File names on High Sierra/ISO9660 CD-ROMs with no extensions present should be uppercase characters only. By default, `hfs` maps file names read from a non-Rock Ridge disk to all lowercase characters. `nomaplcse` turns off this mapping. The exceptions for `notraildot` discussed above apply to `nomaplcse`.

**-O**

Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a preexisting mount point without setting this flag, the mount will fail, producing the error: `device busy`.

**Examples** EXAMPLE 1 Mounting and Unmounting a DVD Image Directly

The following commands mount and unmount a DVD image.

```
mount -F hfs /images/solaris.iso /mnt/solaris-image
umount /mnt/solaris-image
```

**Files** `/etc/mnttab`  
table of mounted file systems

`/etc/vfstab`  
list of default parameters for each file system

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [lofiadm\(1M\)](#), [mount\(1M\)](#), [mountall\(1M\)](#), [mount\(2\)](#), [mnttab\(4\)](#), [vfstab\(4\)](#), [attributes\(5\)](#)

**Notes** If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

**Name** mount\_nfs – mount remote NFS resources

**Synopsis** mount [-F nfs] [*generic\_options*] [-o *specific\_options*] [-O] *resource*  
 mount [-F nfs] [*generic\_options*] [-o *specific\_options*] [-O] *mount\_point*  
 mount [-F nfs] [*generic\_options*] [-o *specific\_options*]  
 [-O] *resource mount\_point*

**Description** The mount utility attaches a named *resource* to the file system hierarchy at the pathname location *mount\_point*, which must already exist. If *mount\_point* has any contents prior to the mount operation, the contents remain hidden until the *resource* is once again unmounted.

mount\_nfs starts the [lockd\(1M\)](#) and [statd\(1M\)](#) daemons if they are not already running.

If the resource is listed in the /etc/vfstab file, the command line can specify either *resource* or *mount\_point*, and mount consults /etc/vfstab for more information. If the -F option is omitted, mount takes the file system type from /etc/vfstab.

If the resource is not listed in the /etc/vfstab file, then the command line must specify both the *resource* and the *mount\_point*.

*host* can be an IPv4 or IPv6 address string. As IPv6 addresses already contain colons, enclose *host* in a pair of square brackets when specifying an IPv6 address string. Otherwise the first occurrence of a colon can be interpreted as the separator between the host name and path, for example, [1080::8:800:200C:417A]:tmp/file. See [inet\(7P\)](#) and [inet6\(7P\)](#).

*host:pathname*

Where *host* is the name of the NFS server host, and *pathname* is the path name of the directory on the server being mounted. The path name is interpreted according to the server's path name parsing rules and is not necessarily slash-separated, though on most servers, this is the case.

*nfs://host[:port]/pathname*

This is an NFS URL and follows the standard convention for NFS URLs as described in *NFS URL Scheme*, RFC 2224. See the discussion of URL's and the public option under NFS FILE SYSTEMS for a more detailed discussion.

*host:pathname nfs://host[:port]/pathname*

*host:pathname* is a comma-separated list of *host:pathname*.

See the discussion of replicated file systems and failover under NFS FILE SYSTEMS for a more detailed discussion.

*hostlist pathname*

*hostlist* is a comma-separated list of hosts.

See the discussion of replicated file systems and failover under NFS FILE SYSTEMS for a more detailed discussion.

The `mount` command maintains a table of mounted file systems in `/etc/mnttab`, described in [mnttab\(4\)](#).

`mount_nfs` supports both NFSv3 and NFSv4 mounts. The default NFS version is NFSv4.

SMF Management The NFS client service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/nfs/client:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

**Options** See [mount\(1M\)](#) for the list of supported *generic\_options*. See [share\\_nfs\(1M\)](#) for a description of server options.

*-o specific\_options*

Set file system specific options according to a comma-separated list with no intervening spaces.

`acdirmax=n`

Hold cached attributes for no more than *n* seconds after directory update. The default value is 60.

`acdirmin=n`

Hold cached attributes for at least *n* seconds after directory update. The default value is 30.

`acregmax=n`

Hold cached attributes for no more than *n* seconds after file modification. The default value is 60.

`acregmin=n`

Hold cached attributes for at least *n* seconds after file modification. The default value is 3.

`actimeo=n`

Set *min* and *max* times for regular files and directories to *n* seconds. See “File Attributes,” below, for a description of the effect of setting this option to 0.

See “Specifying Values for Attribute Cache Duration Options,” below, for a description of how `acdirmax`, `acdirmin`, `acregmax`, `acregmin`, and `actimeo` are parsed on a `mount` command line.

`bg | fg`

If the first attempt fails, retry in the background, or, in the foreground. The default is `fg`.

**forcedirectio | noforcedirectio**

If **forcedirectio** is specified, then for the duration of the mount, forced direct I/O is used. If the filesystem is mounted using **forcedirectio**, data is transferred directly between client and server, with no buffering on the client. If the filesystem is mounted using **noforcedirectio**, data is buffered on the client. **forcedirectio** is a performance option that is of benefit only in large sequential data transfers. The default behavior is **noforcedirectio**.

**grpuid**

By default, the GID associated with a newly created file obeys the System V semantics; that is, the GID is set to the effective GID of the calling process. This behavior can be overridden on a per-directory basis by setting the set-GID bit of the parent directory; in this case, the GID of a newly created file is set to the GID of the parent directory (see [open\(2\)](#) and [mkdir\(2\)](#)). Files created on file systems that are mounted with the **grpuid** option obeys BSD semantics independent of whether the set-GID bit of the parent directory is set; that is, the GID is unconditionally inherited from that of the parent directory.

**hard | soft**

Continue to retry requests until the server responds (**hard**) or give up and return an error (**soft**). The default value is **hard**. Note that NFSv4 clients do not support soft mounts.

**intr | nointr**

Allow (do not allow) keyboard interrupts to kill a process that is hung while waiting for a response on a hard-mounted file system. The default is **intr**, which makes it possible for clients to interrupt applications that can be waiting for a remote mount.

**llock**

Use local locking (no lock manager). Note that this is a private interface.

**noac**

Suppress data and attribute caching. The data caching that is suppressed is the write-behind. The local page cache is still maintained, but data copied into it is immediately written to the server.

**nocto**

Do not perform the normal close-to-open consistency. When a file is closed, all modified data associated with the file is flushed to the server and not held on the client. When a file is opened the client sends a request to the server to validate the client's local caches. This behavior ensures a file's consistency across multiple NFS clients. When **nocto** is in effect, the client does not perform the flush on close and the request for validation, allowing the possibility of differences among copies of the same file as stored on multiple clients.

This option can be used where it can be guaranteed that accesses to a specified file system are made from only one client and only that client. Under such a condition, the effect of **nocto** can be a slight performance gain.

**port=*n***

The server IP port number. The default is `NFS_PORT`. If the `port` option is specified, and if the resource includes one or more NFS URLs, and if any of the URLs include a port number, then the port number in the option and in the URL must be the same.

**posix**

Request POSIX.1 semantics for the file system. Requires a mount Version 2 [mountd\(1M\)](#) on the server. See [standards\(5\)](#) for information regarding POSIX.

**proto=*netid* | rdma**

By default, the transport protocol that the NFS mount uses is the first available RDMA transport supported both by the client and the server. If no RDMA transport is found, then it attempts to use a TCP transport or, failing that, a UDP transport, as ordered in the `/etc/netconfig` file. If it does not find a connection oriented transport, it uses the first available connectionless transport.

Use this option to override the default behavior.

`proto` is set to the value of `netid` or `rdma`. `netid` is the value of the `network_id` field entry in the `/etc/netconfig` file.

The UDP protocol is not supported for NFS Version 4. If you specify a UDP protocol with the `proto` option, NFS version 4 is not used.

**public**

The `public` option forces the use of the public file handle when connecting to the NFS server. The resource specified might not have an NFS URL. See the discussion of URLs and the `public` option under NFS FILE SYSTEMS for a more detailed discussion.

**quota | noquota**

Enable or prevent [quota\(1M\)](#) to check whether the user is over quota on this file system; if the file system has quotas enabled on the server, quotas are still checked for operations on this file system.

**remount**

Remounts a read-only file system as read-write (using the `rw` option). This option cannot be used with other `-o` options, and this option works only on currently mounted read-only file systems.

**retrans=*n***

Set the number of NFS retransmissions to *n*. The default value is 5. For connection-oriented transports, this option has no effect because it is assumed that the transport performs retransmissions on behalf of NFS.

**retry=*n***

The number of times to retry the mount operation. The default for the `mount` command is `10000`.

The default for the automounter is 0, in other words, do not retry. You might find it useful to increase this value on heavily loaded servers, where automounter traffic is dropped, causing unnecessary server not responding errors.

**rsize=*n***

Set the read buffer size to a maximum of *n* bytes. The default value is 1048576 when using connection-orientated transports with Version 3 or Version 4 of the NFS protocol, and 32768 when using connection-less transports. The default can be negotiated down if the server prefers a smaller transfer size. “Read” operations may not necessarily use the maximum buffer size. When using Version 2, the default value is 32768 for all transports.

**sec=*mode***

Set the security *mode* for NFS transactions. If *sec=* is not specified, then the default action is to use AUTH\_SYS over NFS Version 2 mounts, use a user-configured default auth over NFS version 3 mounts, or to negotiate a mode over Version 4 mounts.

The preferred mode for NFS Version 3 mounts is the default mode specified in `/etc/nfssec.conf` (see [nfssec.conf\(4\)](#)) on the client. If there is no default configured in this file or if the server does not export using the client's default mode, then the client picks the first mode that it supports in the array of modes returned by the server. These alternatives are limited to the security flavors listed in `/etc/nfssec.conf`.

NFS Version 4 mounts negotiate a security mode when the server returns an array of security modes. The client attempts the mount with each security mode, in order, until one is successful.

Only one mode can be specified with the *sec=* option. See [nfssec\(5\)](#) for the available *mode* options.

**secure**

This option has been deprecated in favor of the *sec=dh* option.

**timeo=*n***

Set the NFS timeout to *n* tenths of a second. The default value is 11 tenths of a second for connectionless transports, and 600 tenths of a second for connection-oriented transports. This value is ignored for connectionless transports. Such transports might implement their own timeouts, which are outside the control of NFS.

**vers=*NFS version number***

By default, the version of NFS protocol used between the client and the server is the highest one available on both systems. The default maximum for the client is Version 4. This can be changed by setting `client_versmax` to a valid version number (2, 3, or 4). Use the [sharetl\(1M\)](#) command to manipulate the `client_versmax` property. If the NFS server does not support the client's default maximum, the next lowest version attempted until a matching version is found.

`wsize=n`

Set the write buffer size to a maximum of *n* bytes. The default value is 1048576 when using connection-orientated transports with Version 3 or Version 4 of the NFS protocol, and 32768 when using connection-less transports. The default can be negotiated down if the server prefers a smaller transfer size. “Write” operations may not necessarily use the maximum buffer size. When using Version 2, the default value is 32768 for all transports.

`xattr | noxattr`

Allow or disallow the creation and manipulation of extended attributes. The default is `xattr`. See `fsattr(5)` for a description of extended attributes.

`-O`

Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount fails, producing the error “device busy.”

### Nfs File Systems Background versus Foreground

File systems mounted with the `bg` option indicate that mount is to retry in the background if the server's mount daemon (`mountd(1M)`) does not respond. `mount` retries the request up to the count specified in the `retry=n` option. (Note that the default value for `retry` differs between `mount` and `automount`. See the description of `retry`, above.) Once the file system is mounted, each NFS request made in the kernel waits `timeo=n` tenths of a second for a response. If no response arrives, the time-out is multiplied by 2 and the request is retransmitted. When the number of retransmissions has reached the number specified in the `retrans=n` option, a file system mounted with the `soft` option returns an error on the request; one mounted with the `hard` option prints a warning message and continues to retry the request.

### Hard versus Soft

File systems that are mounted read-write or that contain executable files should always be mounted with the `hard` option. Applications using `soft` mounted file systems can incur unexpected I/O errors, file corruption, and unexpected program core dumps. The `soft` option is not recommended.

### Authenticated requests

The server can require authenticated NFS requests from the client. `sec=dh` authentication might be required. See `nfssec(5)`.

### URLs and the public option

If the `public` option is specified, or if the `resource` includes an NFS URL, `mount` attempts to connect to the server using the public file handle lookup protocol. See *WebNFS Client Specification*, RFC 2054. If the server supports the public file handle, the attempt is successful; `mount` does not need to contact the server's `rpcbind(1M)` and the `mountd(1M)` daemons to get the port number of the mount server and the initial file handle of `pathname`, respectively. If the NFS client and server are separated by a firewall that allows all outbound connections through specific ports, such as `NFS_PORT`, then this enables NFS operations

through the firewall. The public option and the NFS URL can be specified independently or together. They interact as specified in the following matrix:

	Resource Style	
	<i>host:pathname</i>	NFS URL
public option	Force public file handle and fail mount if not supported.	Force public file handle and fail mount if not supported.
	Use Native paths.	Use Canonical paths.
default	Use MOUNT protocol.	Try public file handle with Canonical paths. Fall back to MOUNT protocol if not supported.

A Native path is a path name that is interpreted according to conventions used on the native operating system of the NFS server. A Canonical path is a path name that is interpreted according to the URL rules. See *Uniform Resource Locators (URL)*, RFC 1738. See [Examples](#) for uses of Native and Canonical paths.

#### Replicated file systems and failover

*resource* can list multiple read-only file systems to be used to provide data. These file systems should contain equivalent directory structures and identical files. It is also recommended that they be created by a utility such as *rdist(1)*. The file systems can be specified either with a comma-separated list of *host:/pathname* entries and/or NFS URL entries, or with a comma-separated list of hosts, if all file system names are the same. If multiple file systems are named and the first server in the list is down, failover uses the next alternate server to access files. If the read-only option is not chosen, replication is disabled. File access, for NFS Versions 2 and 3, is blocked on the original if NFS locks are active for that file.

**File Attributes** To improve NFS read performance, files and file attributes are cached. File modification times get updated whenever a write occurs. However, file access times can be temporarily out-of-date until the cache gets refreshed.

The attribute cache retains file attributes on the client. Attributes for a file are assigned a time to be flushed. If the file is modified before the flush time, then the flush time is extended by the time since the last modification (under the assumption that files that changed recently are likely to change soon). There is a minimum and maximum flush time extension for regular files and for directories. Setting `actimeo=n` sets flush time to *n* seconds for both regular files and directories.

Setting `actimeo=0` disables attribute caching on the client. This means that every reference to attributes is satisfied directly from the server though file data is still cached. While this

guarantees that the client always has the latest file attributes from the server, it has an adverse effect on performance through additional latency, network load, and server load.

Setting the `noac` option also disables attribute caching, but has the further effect of disabling client write caching. While this guarantees that data written by an application is written directly to a server, where it can be viewed immediately by other clients, it has a significant adverse effect on client write performance. Data written into memory-mapped file pages (`mmap(2)`) are not written directly to this server.

#### Specifying Values for Attribute Cache Duration Options

The attribute cache duration options are `acdirmax`, `acdirmin`, `acregmax`, `acregmin`, and `actimeo`, as described under `OPTIONS`. A value specified for `actimeo` sets the values of all attribute cache duration options except for any of these options specified following `actimeo` on a `mount` command line. For example, consider the following command:

```
example# mount -o acdirmax=10,actimeo=1000 server:/path /localpath
```

Because `actimeo` is the last duration option in the command line, its value (`1000`) becomes the setting for all of the duration options, including `acdirmax`. Now consider:

```
example# mount -o actimeo=1000,acdirmax=10 server:/path /localpath
```

Because the `acdirmax` option follows `actimeo` on the command line, it is assigned the value specified (`10`). The remaining duration options are set to the value of `actimeo` (`1000`).

#### Examples EXAMPLE 1 Mounting an NFS File System

To mount an NFS file system:

```
example# mount serv:/usr/src /usr/src
```

#### EXAMPLE 2 Mounting An NFS File System Read-Only With No suid Privileges

To mount an NFS file system read-only with no suid privileges:

```
example# mount -r -o nosuid serv:/usr/src /usr/src
```

#### EXAMPLE 3 Mounting An NFS File System Over Version 2, with the UDP Transport

To mount an NFS file system over Version 2, with the UDP transport:

```
example# mount -o vers=2,proto=udp serv:/usr/src /usr/src
```

#### EXAMPLE 4 Mounting an NFS File System Using An NFS URL

To mount an NFS file system using an NFS URL (a canonical path):

```
example# mount nfs://serv/usr/man /usr/man
```

#### EXAMPLE 5 Mounting An NFS File System Forcing Use Of The Public File Handle

To mount an NFS file system and force the use of the public file handle and an NFS URL (a canonical path) that has a non 7-bit ASCII escape sequence:

```
example# mount -o public nfs://serv/usr/%A0abc /mnt/test
```

**EXAMPLE 6** Mounting an NFS File System Using a Native Path

To mount an NFS file system using a native path (where the server uses colons (“:”) as the component separator) and the public file handle:

```
example# mount -o public serv:C:doc:new /usr/doc
```

**EXAMPLE 7** Mounting a Replicated Set of NFS File Systems with the Same Pathnames

To mount a replicated set of NFS file systems with the same pathnames:

```
example# mount serv-a,serv-b,serv-c:/usr/man /usr/man
```

**EXAMPLE 8** Mounting a Replicated Set of NFS File Systems with Different Pathnames

To mount a replicated set of NFS file systems with different pathnames:

```
example# mount serv-x:/usr/man,serv-y:/var/man,nfs://serv-z/man /usr/man
```

**Files** /etc/mnttab  
table of mounted file systems

/etc/dfs/fstypes  
default distributed file system type

/etc/vfstab  
table of automatically mounted resources

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/nfs

**See Also** [rdist\(1\)](#), [lockd\(1M\)](#), [mountall\(1M\)](#), [mountd\(1M\)](#), [nfsd\(1M\)](#), [quota\(1M\)](#), [sharectl\(1M\)](#), [statd\(1M\)](#), [mkdir\(2\)](#), [mmap\(2\)](#), [mount\(2\)](#), [open\(2\)](#), [umount\(2\)](#), [mnttab\(4\)](#), [nfssec.conf\(4\)](#), [attributes\(5\)](#), [fsattr\(5\)](#), [nfssec\(5\)](#), [standards\(5\)](#), [inet\(7P\)](#), [inet6\(7P\)](#), [lofs\(7FS\)](#)

Callaghan, Brent, *WebNFS Client Specification*, RFC 2054, October 1996.

Callaghan, Brent, *NFS URL Scheme*, RFC 2224, October 1997.

Berners-Lee, Masinter & McCahill, *Uniform Resource Locators (URL)*, RFC 1738, December 1994.

**Notes** An NFS server should not attempt to mount its own file systems. See [lofs\(7FS\)](#).

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on *the directory to which the symbolic link refers*, rather than being mounted on top of the symbolic link itself.

SunOS 4.x used the `bi od` maintenance procedure to perform parallel read-ahead and write-behind on NFS clients. SunOS 5.x made `bi od` obsolete with multi-threaded processing, which transparently performs parallel read-ahead and write-behind.

Since the root (`/`) file system is mounted read-only by the kernel during the boot process, only the `remount` option (and options that can be used in conjunction with `remount`) affect the root (`/`) entry in the `/etc/vfstab` file.

`mount_cachefs` cannot be used with replicated NFS mounts or any NFS Version 4 mount.

**Name** mount\_pcfs – mount pcfs file systems

**Synopsis** mount -F pcfs [*generic\_options*]  
 [-o *FSType-specific\_options*] *special* | *mount\_point*  
 mount -F pcfs [*generic\_options*]  
 [-o *FSType-specific\_options*] *special* *mount\_point*

**Description** mount attaches an MS-DOS file system (pcfs) to the file system hierarchy at the *mount\_point*, which is the pathname of a directory. If *mount\_point* has any contents prior to the mount operation, these are hidden until the file system is unmounted.

The pcfs file system supports direct mounting of files containing the file system as well as block devices. See [mount\(1M\)](#) and [lofiadm\(1M\)](#).

If mount is invoked with *special* or *mount\_point* as the only arguments, mount will search /etc/vfstab to fill in the missing arguments, including the *FSType-specific\_options*; see [mount\(1M\)](#) for more details.

The *special* argument can be one of two special device file types:

- A floppy disk, such as /dev/diskette0 or /dev/diskette1.
- A DOS logical drive on a hard disk expressed as *device-name:logical-drive*, where *device-name* specifies the special block device-file for the whole disk and *logical-drive* is either a drive letter (c through z) or a drive number (1 through 24). Examples are /dev/dsk/c0t0d0p0:c and /dev/dsk/c0t0d0p0:1.

The *special* device file type must have a formatted MS-DOS file system with either a 12-bit, 16-bit, or 32-bit File Allocation Table.

**Options** *generic\_options*  
 See [mount\(1M\)](#) for the list of supported options.

-o

Specify pcfs file system-specific options. The following options are supported:

clamptime | noclamptime

File timestamps in pcfs cover a range between January 1st 1980 and December 31st 2127. This is not equal to the range of `time_t` on Unix for either 32-bit or 64-bit applications. In particular, 32-bit applications fail with EOVERFLOW errors on the [stat\(2\)](#) system call when timestamps beyond the range of 32-bit `time_t` are encountered. In order to prevent such spurious failures, pcfs by default clamps timestamps to the common subset of possible pcfs timestamps and the range available to 32-bit applications in Unix. The `clamptime` mount option therefore is active by default. If you want access to the full range of possible timestamps on pcfs, mount the file system with the `noclamptime` mount option. Note that if `noclamptime` is used, only 64-bit applications will have access to timestamps beyond January 19th 2038, 03:14:06 UTC; 32-bit applications will encounter EOVERFLOW errors.

`foldcase | nofoldcase`

Force uppercase characters in filenames to lowercase when reading them from the filesystem. This is for compatibility with the previous behavior of `pcfs`. The default is `nofoldcase`.

`hidden | nohidden`

Allow or disallow listing of files with hidden or system bits set. Option `hidden` is the default. When `nohidden` is effect, hidden and system files are neither visible nor accessible. Note that PCFS in previous releases of the Solaris operating system used the `nohidden` option as the default.

`atime | noatime`

Enable or disable write access timestamps on DOS-formatted media. Default for fixed disks is `atime`, while for removable media `noatime` is used. The latter default is so that writes to flash-based media (“memory sticks”) can be minimized, to prolong lifetime.

`timezone=timezone`

Timestamps on DOS-formatted media are recorded in the local time of the recording system. This can cause confusion when accessing removable media in which the recording and receiving system use different time zones. Use this option to force media timestamps to be interpreted for a specific time zone. The `mount_pcfs` command converts the given time zone name into a numerical offset that is passed to the `pcfs` kernel module, using the same rules as described in [environ\(5\)](#) for the TZ environment variable. By default, the `timezone` value is taken from the TZ environment variable.

**Files** `/etc/mnttab`  
table of mounted file systems

`/etc/vfstab`  
list of default parameters for each file system

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/extended-system-utilities

**See Also** [lofiadm\(1M\)](#), [mount\(1M\)](#), [mountall\(1M\)](#), [mount\(2\)](#), [stat\(2\)](#), [time\(2\)](#), [mnttab\(4\)](#), [vfstab\(4\)](#), [attributes\(5\)](#), [environ\(5\)](#), [pcfs\(7FS\)](#)

**Notes** If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

**Name** mount\_smbfs, umount\_smbfs – mount and unmount a shared resource from an SMB file server

**Synopsis** /sbin/mount [-F smbfs] [*generic-options*] [-o *name=value*] [-O] *resource*  
 /sbin/mount [-F smbfs] [*generic-options*] [-o *name=value*] [-O] *mount-point*  
 /sbin/mount [-F smbfs] [*generic-options*] [-o *name=value*]  
     [-O] *resource mount-point*  
 /sbin/umount [-F smbfs] [*generic-options*] *mount-point*

**Description** The mount utility attaches a named resource, *resource*, to the file system hierarchy at the path name location, *mount-point*, which must already exist.

If *mount-point* has any contents prior to the mount operation, those contents remain hidden until the resource is unmounted. An authorized user with the SYS\_MOUNT privilege can perform a mount operation. Also, a user can perform SMBFS mount operations on a directory the user owns.

If the resource is listed in the /etc/vfstab file, you can specify either *resource* or *mount-point* as the mount command will consult the /etc/vfstab file for more information. If the -F option is omitted, mount takes the file system type from the entry in the /etc/vfstab file.

If the resource is not listed in the /etc/vfstab file, the command line must specify both *resource* and *mount-point*.

The umount utility detaches a mounted file system from the file system hierarchy. An authorized user with the SYS\_MOUNT privilege can perform a umount operation. Also, a user can perform SMBFS unmount operations on a directory the user owns.

The network/smb/client service must be enabled to successfully mount an SMB share. This service is enabled, by default.

To enable the service, enter the following [svcadm\(1M\)](#) command:

```
svcadm enable network/smb/client
```

**Operands** The mount command supports the following operands:

*resource* // [*workgroup*;] [*user*[:*password*]@] *server/share*

The name of the resource to be mounted. In addition to its name, you can specify the following information about the resource:

- *password* is the password associated with *user*. If *password* is not specified, the mount first attempts to use the password stored by the smbutil login command (if any). If that password fails to authenticate, the mount\_smbfs prompts you for a password.
- *server* is the DNS or NetBIOS name of the remote computer.
- *share* is the resource name on the remote server.

- *user* is the remote user name. If *user* is omitted, the logged in user ID is used.
- *workgroup* is the name of the workgroup or the Windows domain in which the user name is defined.

If the resource includes a workgroup, you must escape the semicolon that appears after the workgroup name to prevent it from being interpreted by the command shell. For instance, surround the entire resource name with double quotes: `mount -F smbfs "//SALES;george@RSERVER" /mnt.`

#### *mount-point*

The path to the location where the file system is to be mounted or unmounted. The mount command maintains a table of mounted file systems in the `/etc/mnttab` file. See the [mnttab\(4\)](#) man page.

**Options** See the [mount\(1M\)](#) man page for the list of supported *generic-options*.

`-o name=value` or

`-o name`

Sets the file system-specific properties. You can specify more than one name-value pair as a list of comma-separated pairs. No spaces are permitted in the list. The properties are as follows:

`acdirmax=n`

Hold cached attributes for no more than *n* seconds after directory update. The default value is 60.

`acdirmin=n`

Hold cached attributes for at least *n* seconds after directory update. The default value is 30.

`acregmax=n`

Hold cached attributes for no more than *n* seconds after file modification. The default value is 60.

`acregmin=n`

Hold cached attributes for at least *n* seconds after file modification. The default value is 3.

`actimeo=n`

Set minimum and maximum times for regular files and directories to *n* seconds. See “File Attributes,” below, for a description of the effect of setting this option to 0.

See “Specifying Values for Attribute Cache Duration Options,” below, for a description of how `acdirmax`, `acdirmin`, `acregmax`, `acregmin`, and `actimeo` are parsed on a mount command line.

**dirperms=octaltriplet**

Specifies the permissions to be assigned to directories. The value must be specified as an octal triplet, such as 755. The default value for the directory mode is taken from the `fileperms` setting, with execute permission added where `fileperms` has read permission.

Note that these permissions have no relation to the rights granted by the SMB server.

**fileperms=octaltriplet**

Specifies the permissions to be assigned to files. The value must be specified as an octal triplet, such as 644. The default value is 700.

Note that these permissions have no relation to the rights granted by the SMB server.

**gid=groupid**

Assigns the specified group ID to files. The default value is the group ID of the directory where the volume is mounted.

**intr|nointr**

Enable (or disable) cancellation of `smbfs(7FS)` I/O operations when the user interrupts the calling thread (for example, by hitting Ctrl-C while an operation is underway). The default is `intr` (interruption enabled), so cancellation is normally allowed.

**noac**

Suppress attribute caching. Local `stat(2)` calls always request attributes from the SMB server.

**noprompt**

Suppresses the prompting for a password when mounting a share. This property enables you to permit anonymous access to a share. Anonymous access does not require a password.

The mount operation fails if a password is required, the `noprompt` property is set, and no password is stored by the `smbutil login` command.

**retry\_count=number**

Specifies the number of SMBFS retries to attempt before the connection is marked as broken. By default, 4 attempts are made.

The `retry_count` property value set by the `mount` command overrides the global value set in SMF or the value set in your `.nsmbrc` file.

**timeout=seconds**

Specifies the SMB request timeout. By default, the timeout is 15 seconds.

The `timeout` property value set by the `mount` command overrides the global value set in SMF or the value set in your `.nsmbrc` file.

`uid=userid`

Assigns the specified user ID files. The default value is the owner ID of the directory where the volume is mounted.

`xattr|noxattr`

Enable (or disable) Solaris Extended Attributes in this mount point. This option defaults to `xattr` (enabled Extended Attributes), but note: if the SMB server does not support SMB “named streams”, `smbfs(7FS)` forces this option to `noxattr`. When a mount has the `noxattr` option, attempts to use Solaris Extended attributes fail with `EINVAL`.

`-O`

Overlays mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount fails, producing the error “device busy.”

**File Attributes** To improve `smbfs` performance, file attributes are cached. File modification times get updated whenever any local modifications occur. However, file access times can be temporarily out-of-date until the cache gets refreshed.

The attribute cache retains file attributes on the client. Attributes for a file are assigned a time to be flushed. If the file is modified before the flush time, then the flush time is extended by the time since the last modification (under the assumption that files that changed recently are likely to change soon). There is a minimum and maximum flush time extension for regular files and for directories. Setting `actimeo=n` sets flush time to  $n$  seconds for both regular files and directories.

Setting `actimeo=n` disables attribute caching on the client. This means that every reference to attributes is satisfied directly from the server. While this guarantees that the client always has the latest file attributes from the server, it has an adverse effect on performance through additional latency, network load, and server load.

Setting the `noac` option also disables attribute caching. When `smbfs` is enhanced to support write caching, this option will have the further effect of disabling that write caching.

### Specifying Values for Attribute Cache Duration Options

The attribute cache duration options are `acdirmax`, `acdirmin`, `acregmax`, `acregmin`, and `actimeo`, as described under `OPTIONS`, above. A value specified for `actimeo` sets the values of all attribute cache duration options except for any of these options specified following `actimeo` on a mount command line. For example, consider the following command:

```
mount -F smbfs -o acdirmax=10,actimeo=1000 \
//server/share /mountpoint
```

Because `actimeo` is the last duration option in the command line, its value (1000) becomes the setting for all of the duration options, including `acdirmax`. Now consider:

```
mount -F smbfs -o actimeo=1000,acdirmax=10 \
//server/share /mountpoint
```

Because the `actimeo` option follows `actimeo` on the command line, it is assigned the value specified (10). The remaining duration options are set to the value of `actimeo` (1000).

### Examples **EXAMPLE 1** Mounting an SMBFS Share

The following example shows how to mount the `/tmp` share from the `nano` server in the `SALES` workgroup on the local `/mnt` mount point. You must supply the password for the `root` user to successfully perform the mount operation.

```
mount -F smbfs "//SALES;root@nano.sfbay/tmp" /mnt
Password:
```

### **EXAMPLE 2** Verifying That an SMBFS File System Is Mounted

The following example shows how to mount the `/tmp` share from the `nano` server on the local `/mnt` mount point. You must supply the password for the `root` user to successfully perform the mount operation.

```
mount -F smbfs //root@nano.sfbay/tmp /mnt
Password:
```

You can verify that the share is mounted in the following ways:

- View the file system entry in the `/etc/mnttab` file.

```
grep root /etc/mnttab
//root@nano.sfbay/tmp /mnt smbfs dev=4900000 1177097833
```

- View the output of the `mount` command.

```
mount | grep root
/mnt on //root@nano.sfbay/tmp read/write/setuid/devices/dev=4900000 on
Fri Apr 20 13:37:13 2007
```

- View the output of the `df /mnt` command.

```
df /mnt
/mnt (//root@nano.sfbay/tmp): 3635872 blocks -1 files
```

Obtain information about the mounted share by viewing the output of the `df -k /mnt` command.

```
df -k /mnt
Filesystem kbytes used avail capacity Mounted on
//root@nano.sfbay/tmp
 1882384 64448 1817936 4% /mnt
```

### **EXAMPLE 3** Unmounting an SMB Share

This example assumes that an SMB share has been mounted on the `/mnt` mount point. The following command line unmounts the share from the mount point.

```
umount /mnt
```

- Files** /etc/mnttab  
Table of mounted file systems.
- /etc/dfs/fstypes  
Default distributed file system type.
- /etc/vfstab  
Table of automatically mounted resources.
- \$HOME/.nsmbrc  
User-settable mount point configuration file to store the description for each connection.

**Attributes** See the [attributes\(5\)](#) man page for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsmbfscu
Interface Stability	Committed

**See Also** [smbutil\(1\)](#), [mount\(1M\)](#), [mountall\(1M\)](#), [svcadm\(1M\)](#), [acl\(2\)](#), [fcntl\(2\)](#), [link\(2\)](#), [mknod\(2\)](#), [mount\(2\)](#), [stat\(2\)](#), [symlink\(2\)](#), [umount\(2\)](#), [mnttab\(4\)](#), [nsmbrc\(4\)](#), [vfstab\(4\)](#), [attributes\(5\)](#), [pcfs\(7FS\)](#), [smbfs\(7FS\)](#)

**Authors** This manual page contains material originally authored by Boris Popov, bpATbutya.kz, bpATFreeBSD.org.

**Notes** The Solaris SMB client always attempts to use `gethostbyname()` to resolve host names. If the host name cannot be resolved, the SMB client uses NetBIOS name resolution (NBNS). By default, the Solaris SMB client permits the use of NBNS to enable Solaris SMB clients in Windows environments to work without additional configuration.

Since NBNS has been exploited in the past, you might want to disable it. To disable NBNS, set the `nbns-enabled` service management facility property to `false`. By default, `nbns-enabled` is set to `true`.

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than being mounted on top of the symbolic link itself.

**Name** mount\_tmpfs – mount tmpfs file systems

**Synopsis** mount [-F tmpfs] [-o *specific\_options*] [-O] *special mount\_point*

**Description** tmpfs is a memory based file system which uses kernel resources relating to the VM system and page cache as a file system.

mount attaches a tmpfs file system to the file system hierarchy at the pathname location *mount\_point*, which must already exist. If *mount\_point* has any contents prior to the mount operation, these remain hidden until the file system is once again unmounted. The attributes (mode, owner, and group) of the root of the tmpfs filesystem are inherited from the underlying *mount\_point*, provided that those attributes are determinable. If not, the root's attributes are set to their default values.

The *special* argument is usually specified as swap but is in fact disregarded and assumed to be the virtual memory resources within the system.

**Options** -o *specific\_options* Specify tmpfs file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available:

size=*sz* The *sz* argument controls the size of this particular tmpfs file system. If the argument is has a 'k' suffix, the number will be interpreted as a number of kilobytes. An 'm' suffix will be interpreted as a number of megabytes. No suffix is interpreted as bytes. In all cases, the actual size of the file system is the number of bytes specified, rounded up to the physical pagesize of the system.

xattr | noxattr Allow or disallow the creation and manipulation of extended attributes. The default is xattr. See [fsattr\(5\)](#) for a description of extended attributes.

-O Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error `device busy`.

**Files** /etc/mnttab Table of mounted file systems

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [mount\(1M\)](#), [mkdir\(2\)](#), [mount\(2\)](#), [open\(2\)](#), [umount\(2\)](#), [mnttab\(4\)](#), [attributes\(5\)](#), [fsattr\(5\)](#), [tmpfs\(7FS\)](#)

**Notes** If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

**Name** mount\_udfs – mount a udfs file system

**Synopsis** mount -F udfs [*generic\_options*] [-o *specific\_options*]  
          [-O] *special mount\_point*

mount -F udfs [*generic\_options*] [-o *specific\_options*]  
          [-O] *special* | *mount\_point*

**Description** The mount utility attaches a udfs file system to the file system hierarchy at the *mount\_point*, which is the pathname of a directory. If *mount\_point* has any contents prior to the mount operation, these are hidden until the file system is unmounted.

If mount is invoked with either *special* or *mount\_point* as the only arguments, mount searches /etc/vfstab to fill in the missing arguments, including the *specific\_options*. See [mount\(1M\)](#).

The udfs file system supports direct mounting of files containing the file system as well as block devices. See [mount\(1M\)](#) and [lofiadm\(1M\)](#).

If *special* and *mount\_point* are specified without any *specific\_options*, the default is rw.

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

**Options** See [mount\(1M\)](#) for the list of supported *generic\_options*.

The following options are supported:

-o *specific\_options*

Specify udfs file system specific options in a comma-separated list with no intervening spaces. The following *specific\_options* are available:

m

Mount the file system without making an entry in /etc/mnttab.

remount

Remount the file system as read-write. The option is used in conjunction with the rw option.

A file system mounted read-only can be remounted as read-write. This option fails if the file system is not currently mounted.

-O

Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount fails, producing the error device busy.

**Files** /etc/mnttab  
Table of mounted file systems

/etc/vfstab  
List of default parameters for each file system

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/udfs

**See Also** [fsck\(1M\)](#), [fsck\\_udfs\(1M\)](#), [lofiadm\(1M\)](#), [mount\(1M\)](#), [mountall\(1M\)](#), [mount\(2\)](#), [mnttab\(4\)](#), [vfstab\(4\)](#), [attributes\(5\)](#)

**Diagnostics** not super user  
The command is run by a non-root user. Run as root.

no such device  
The device name specified does not exist.

not a directory  
The specified mount point is not a directory.

is not an udfs file system  
The device specified does not contain a udf 1.50 file system or the udfs file system module is not available.

is already mounted  
The specified device is already in use.

not a block device  
The device specified is not a block device. Use block device to mount.

write-protected  
The device is read-only.

is corrupted. needs checking  
The file system is in an inconsistent state. Run `fsck`.

**Notes** Copy-protected files can be stored on DVD-ROM media using Universal Disk Format (UDF). Reading these copy-protected files is not possible as this involves an authentication process. Unless an authentication process between the host and the drive is completed, reading these copy-protected files after mounting and before the authentication process, returns an error.

**Name** mount\_ufs – mount ufs file systems

**Synopsis** mount -F ufs [*generic\_options*] [-o *specific\_options*]  
 [-O] *special* | *mount\_point*

mount -F ufs [*generic\_options*] [-o *specific\_options*]  
 [-O] *special* *mount\_point*

**Description** The mount utility attaches a ufs file system to the file system hierarchy at the *mount\_point*, which is the pathname of a directory. If *mount\_point* has any contents prior to the mount operation, these are hidden until the file system is unmounted.

The ufs file system supports direct mounting of files containing the file system as well as block devices. See [mount\(1M\)](#) and [lofiadm\(1M\)](#).

If mount is invoked with *special* or *mount\_point* as the only arguments, mount will search /etc/vfstab to fill in the missing arguments, including the *specific\_options*. See [mount\(1M\)](#).

If *special* and *mount\_point* are specified without any *specific\_options*, the default is rw.

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

**Options** See [mount\(1M\)](#) for the list of supported *generic\_options*.

The following options are supported:

-o *specific\_options*

Specify ufs file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available:

dfratime | nodfratime

By default, writing access time updates to the disk may be deferred (dfratime) for the file system until the disk is accessed for a reason other than updating access times. nodfratime disables this behavior.

If power management is enabled on the system, do not set nodfratime unless noatime is also set. If you set nodfratime without setting noatime, the disk is spun up every time a file within a file system on the disk is accessed - even if the file is not modified.

forcedirectio | noforcedirectio

If forcedirectio is specified and supported by the file system, then for the duration of the mount, forced direct I/O will be used. If the filesystem is mounted using forcedirectio, data is transferred directly between user address space and the disk. If the filesystem is mounted using noforcedirectio, data is buffered in kernel address space when data is transferred between user address space and the disk. forcedirectio is a performance option that is of benefit only in large sequential data transfers. The default behavior is noforcedirectio.

`global | noglobal`

If `global` is specified and supported on the file system, and the system in question is part of a cluster, the file system will be globally visible on all nodes of the cluster. If `noglobal` is specified, the mount will not be globally visible. The default behavior is `noglobal`.

`intr | nointr`

Allow (do not allow) keyboard interrupts to kill a process that is waiting for an operation on a locked file system. The default is `intr`.

`largefiles | nolargefiles`

If `nolargefiles` is specified and supported by the file system, then for the duration of the mount it is guaranteed that all regular files in the file system have a size that will fit in the smallest object of type `off_t` supported by the system performing the mount. The mount will fail if there are any files in the file system not meeting this criterion. If `largefiles` is specified, there is no such guarantee. The default behavior is `largefiles`.

If `nolargefiles` is specified, `mount` will fail for `ufs` if the file system to be mounted has contained a large file (a file whose size is greater than or equal to 2 Gbyte) since the last invocation of `fsck` on the file system. The large file need not be present in the file system at the time of the mount for the mount to fail; it could have been created previously and destroyed. Invoking `fsck` (see `fsck_ufs(1M)`) on the file system will reset the file system state if no large files are present. After invoking `fsck`, a successful mount of the file system with `nolargefiles` specified indicates the absence of large files in the file system; an unsuccessful mount attempt indicates the presence of at least one large file.

`logging | nologging`

If `logging` is specified, then logging is enabled for the duration of the mounted file system. Logging is the process of storing transactions (changes that make up a complete UFS operation) in a log before the transactions are applied to the file system. Once a transaction is stored, the transaction can be applied to the file system later. This prevents file systems from becoming inconsistent, therefore reducing the possibility that `fsck` might run. And, if `fsck` is bypassed, logging generally reduces the time required to reboot a system.

The default behavior is `logging` for all UFS file systems.

The log is allocated from free blocks in the file system, and is sized approximately 1 Mbyte per 1 Gbyte of file system, up to a maximum of 256 Mbytes. The log size may be larger (up to a maximum of 512 Mbytes) dependent upon the number of cylinder groups present in the file system.

Logging is enabled on any UFS file system, including root (`/`), except under the following conditions:

- When logging is specifically disabled.
- If there is insufficient file system space for the log. In this case, the following message is displayed and file system is still mounted:

```
mount /dev/dsk/c0t4d0s0 /mnt
/mnt: No space left on device
Could not enable logging for /mnt on /dev/dsk/c0t4d0s0.
```

The log created by UFS logging is continually flushed as it fills up. The log is totally flushed when the file system is unmounted or as a result of the `lockfs -f` command.

**m**

Mount the file system without making an entry in `/etc/mnttab`.

**noatime**

By default, the file system is mounted with normal access time (`atime`) recording. If `noatime` is specified, the file system will ignore access time updates on files, except when they coincide with updates to the `ctime` or `mtime`. See [stat\(2\)](#). This option reduces disk activity on file systems where access times are unimportant (for example, a Usenet news spool).

`noatime` turns off access time recording regardless of `df ratime` or `nodf ratime`.

The POSIX standard requires that access times be marked on files. `-noatime` ignores them unless the file is also modified.

**nosec**

By default, Access Control Lists (ACLs) are supported on a mounted UFS file system. Use this option to disallow the setting or any modification of an ACL on a file within a mounted UFS file system. See [getfacl\(1\)](#) for background on ACLs.

**onerror = *action***

This option specifies the action that UFS should take to recover from an internal inconsistency on a file system. Specify *action* as `panic`, `lock`, or `umount`. These values cause a forced system shutdown, a file system lock to be applied to the file system, or the file system to be forcibly unmounted, respectively. The default is `panic`.

**quota**

Quotas are turned on for the file system.

**remount**

Remounts a file system with a new set of options. All options not explicitly set with `remount` revert to their default values.

**rw**

Read-write with quotas turned on. Equivalent to `rw`, `quota`.

**xattr | noxattr**

Allow or disallow the creation and manipulation of extended attributes. The default is `xattr`. See [fsattr\(5\)](#) for a description of extended attributes.

**-O**

Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount

point without setting this flag, the mount will fail, producing the error “device busy”.

**Examples** EXAMPLE 1 Turning Off (and On) Logging

The following command turns off logging on an already mounted file system. The subsequent command restores logging.

```
mount -F ufs -o remount,nologging /export
(absence of message indicates success)
mount -F ufs -o remount,logging /export
```

In the preceding commands, the `-F ufs` option is not necessary.

**Files** `/etc/mnttab`  
table of mounted file systems

`/etc/vfstab`  
list of default parameters for each file system

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [getfacl\(1\)](#), [fsck\(1M\)](#), [fsck\\_ufs\(1M\)](#), [lofiadm\(1M\)](#), [mount\(1M\)](#), [mountall\(1M\)](#), [fcntl\(2\)](#), [mount\(2\)](#), [stat\(2\)](#), [mnttab\(4\)](#), [vfstab\(4\)](#), [attributes\(5\)](#), [fsattr\(5\)](#), [largefile\(5\)](#)

**Notes** Since the root (`/`) file system is mounted read-only by the kernel during the boot process, only the `remount` option (and options that can be used in conjunction with `remount`) affect the root (`/`) entry in the `/etc/vfstab` file.

**Name** mpathadm – multipath discovery and administration

**Synopsis** mpathadm *subcommand direct-object [options] [operand]*

**Description** The mpathadm command enables multipathing discovery and management. The mpathadm command is implemented as a set of subcommands, many with their own options, that are described in the section for that subcommand. Options not associated with a particular subcommand are described under OPTIONS. The mpathadm subcommands operate on a *direct-object*. These are described in this section for each subcommand. The *direct-objects*, *initiator-port*, *target-port*, and *logical-unit* in the subcommands are consistent with SCSI standard definitions.

The mpathadm command supports the following subcommands, which are described in detail in subsections that follow.

list	Display a list of discovered instances for a given object.
show	Display information about a given object instance.
modify	Modify properties of an object.
enable	Enable an object.
disable	Disable an object.
failover	Cause target port group failover for a logical-unit.
override	Set a path to be used over other paths on a logical-unit.

The mpathadm subcommands operate on a *direct-object*. These are described in this section for each subcommand.

**list Subcommand** The syntax for the list subcommand is:

```
mpathadm list direct-object [operands...]
```

The list subcommand displays data for following direct-objects:

*mpath-support* [*mpath-support-name, ...*]

List the multipathing support that can be administered by this CLI. This presents itself in the form of a library name registered through the MPAPI framework. If no *mpath-support* name *mpath-support-name* is specified, all registered multipathing support libraries will be displayed.

*initiator-port* [*initiator-port-name, ...*]

List the initiator ports that are discovered on this system. If no *initiator-port-name* is specified, all discovered initiator ports are displayed.

{*logical-unit* | *lu*} [*options*] [*logical-unit-name, ...*]

List the information on multipath logical units. If no *logical-unit-name* is specified, all discovered logical-units will be displayed.

Options for `list logical-unit` are as follows:

- n, --name *name* Return the logical unit name that is associated with the given name string. This name can be extracted from the output of the `mpathadm show lu` command.
- t, --target-port *target-port-name* Return the list of logical units names that are associated with the given *target-port-name*.

`show` Subcommand The syntax for the `show` subcommand is:

```
mpathadm show direct-object [operands...]
```

The `show` subcommand displays detailed information for following the direct-objects:

```
mpath-support [mpath-support-name, ...]
```

Show the detailed information on the given *mpath-support-name* if the name exists. If the given *mpath-support-name* supports only a limited set of device products, the list of device products will be listed as part of the output.

```
initiator-port initiator-port-name[,initiator-port-name, ...]
```

Show the detailed information for the given *initiator-port-name*.

```
{logical-unit | lu} [logical-unit-name, ...]
```

Display the detailed information on multipath logical unit(s), including path and target port group information. Note that the name property in the logical unit information represents the identifier for this LUN, derived from the hardware, and used by this system. If the name is derived from SCSI Inquiry Vital Product Data (VPD) page 83h, the name type property represents an associated identifier type defined by the SCSI standards.

`modify` Subcommand The syntax for the `modify` subcommand is:

```
mpathadm modify direct-object [options] [operands...]
```

The `modify` subcommand modifies characteristics of the following direct-objects:

- mpath-support* [*options*] *mpath-support-name, ...* Configuration management of an *mpath-support*. Options to modify *mpath-support* are as follows:
  - `Set auto failback` `applicable` only when *mpath-support* provides auto failback support.
  - `Set auto probing` `applicable` only when *mpath-support* provides auto probing support.
  - `Change the default load balance type`. The loadbalance type is one of the

`{logical-unit | lu} [options] logical-unit-name, ...`

supported types listed in the `show mpath - support` output.

Configuration management of a logical unit. Options to modify `logical-unit` are as follows:

`Set auto-failback` Applicable only when `mpath - support` provides auto failback support

`Set auto-probing` Applicable only when `mpath - support` provides auto probing support.

`Set load-balance-type` Applicable only when load balance configuration is supported at the logical unit level.

`enable` Subcommand The syntax for the `enable` subcommand is:

```
mpathadm disable [options]
```

The `enable` subcommand supports the following direct-objects to be enabled:

```
path -i initiator-port-name -t target-port-name
-l logical-unit-name
```

The path that consists of the specified initiator port, target port, and logical unit will be enabled.

`disable` Subcommand The syntax for the `disable` subcommand is:

```
mpathadm disable [options]
```

The `disable` subcommand supports the following direct-objects to be disabled:

```
path -i initiator-port-name -t target-port-name
-l logical-unit-name
```

The path that consists of the specified initiator port, target port, and logical unit will be disabled.

`failover` Subcommand The syntax for the `failover` subcommand is:

```
mpathadm failover direct-object [operand]
```

The `failover` subcommand supports failover for the following direct-objects:

```
{logical-unit | lu} logical-unit-name
```

The target port group will failover when the given logical-unit is asymmetric and supports explicit

state change. The currently active target port group will be changed to the standby state and the standby target port group will be active.

**override Subcommand** The syntax for the `override` subcommand is:

```
mpathadm override [options]
```

The `override` subcommand controls whether or not the following direct-objects override another:

```
path { -i initiator-port-name -t target-port-name | -c }
-l logical-unit-name
```

Cause a path that consists of the specified initiator port, target port, and logical unit to override other paths on the logical unit. Once a path overrides other paths, the `mpath-support` uses only that path regardless of any other path selection configuration. The `-c` option cancels the setting. The path that consists of the specified initiator port, target port, and logical unit will be disabled.

Options for `override path` are as follows:

<code>-i, --initiator-port <i>initiator-port-name</i></code>	Represent the initiator port element of a path. Options <code>-t</code> and <code>-l</code> must also be included.
<code>-t, --target-port <i>target-port-name</i></code>	Represent the target port element of a path. Options <code>-i</code> and <code>-l</code> must also be included.
<code>-l, --logical-unit <i>logical-unit</i></code>	Represent the logical unit element of a path. Options <code>-i</code> and <code>-t</code> must also be included.
<code>-c, --cancel</code>	Cancels overriding setting for the given logical unit. Option <code>-l</code> must also be included.

**Options** The following options are supported:

<code>-V, --version</code>	Display the version information.
<code>-, --help</code>	Display context help. Can be used following an <code>mpathadm</code> command with no arguments, following a subcommand, or following a subcommand direct-object combination. Responds with help information appropriate for your entry. For example, if you enter:

```
mpathadm add mpath-support-help
```

... `mpathadm` responds with a display of the options available for that combination of subcommand and direct-object.

**Examples** EXAMPLE 1 Obtaining a List of Multipathing Support

The following command uses the `list` subcommand to list all currently registered `mpath-support` libraries.

```
mpathadm list mpath-support
mpath-support: libmpscsi_vhci.so
```

## EXAMPLE 2 Displaying the Properties of a Particular Multipathing Support

The following command uses the `show` subcommand to display the properties for a currently registered `mpath-support` library.

```
mpathadm show mpath-support libmpscsi_vhci.so
mpath-support: libmpscsi_vhci.so
Vendor: Sun Microsystems
Driver Name: scsi_vhci
Default Load Balance: round-robin
Supported Load Balance Types:
 round-robin
 logical-block
Allows To Activate Target Port Group Access: yes
Allows Path Override: no
Supported Auto Failback Config: 1
Auto Failback: on
Failback Polling Rate (current/max): 0/0
Supported Auto Probing Config: 0
Auto Probing: NA
Probing Polling Rate (current/max): NA/NA
Supported Devices:
Vendor: SUN
Product: T300
Revision:
Supported Load Balance Types:
 round-robin
Vendor: SUN
Product: T4
Revision:
Supported Load Balance Types:
 round-robin
```

EXAMPLE 3 Obtaining a List of Initiator Ports Discovered Through the `mpath-support` Libraries

The following command uses the `list initiator-port` subcommand to display a list of initiator ports discovered by the currently registered `mpath-support` libraries.

```
mpathadm list initiator-port
Initiator-Port: iqn.1986-03.com.sun:01:080020b7ac2b.437a3b3e,4000002a0000
Initiator-Port: 2000000173018713
Initiator-Port: 2000000173818713
```

**EXAMPLE 4** Displaying the Properties of a Particular Initiator Port

The following command uses the `show initiator-port` subcommand to display the properties of a particular initiator port discovered using the `list initiator-port` subcommand in an example above.

```
mpathadm show initiator-port 2000000173018713
initiator-port: 2000000173018713
 Transport Type: Fibre Channel
 OS device File: devices/pci@1f,4000/pci@2/SUNW,qlca@5/fp@0,0:fc
```

**EXAMPLE 5** Displaying the Properties of a Particular Logical Unit

The following command uses the `show logical-unit` subcommand to display the properties of the logical unit with the specified name.

```
mpathadm show lu /dev/rdisk/c4t60003BA27D2120004204AC2B000DAB00d0s2
Logical Unit: /dev/rdisk/c4t60003BA27D2120004204AC2B000DAB00d0s2
 mpath-support libmpscsi_vhci.so
 Vendor: SUN
 Product: T4
 Revision: 0301
 Name Type: SCSI Inquiry VPD Page 83 type 3
 Name: 60003ba27d2120004204ac2b000dab00
 Asymmetric: yes
 Current Load Balance: round-robin
 Logical Unit Group ID: NA
 Aauto Failback: on
 Auto Probing: NA
```

## Paths:

```
Initiator Port Name: 2000000173818713
Target Port Name: 20030003ba27d212
Override Path: NA
Path State: OK
Disabled: no
```

```
Initiator Port Name: 2000000173018713
Target Port Name: 20030003ba27d095
Override Path: NA
Path State: OK
Disabled: no
```

## Target Port Group:

```
ID: 2
Explicit Failover: yes
Access State: standby
Target Ports:
 Name: 20030003ba27d212
```

**EXAMPLE 5** Displaying the Properties of a Particular Logical Unit *(Continued)*

```

Relative ID: 0

ID: 5
Explicit Failover: yes
Access State: active
Target Ports
 Name: 20030003ba27d095
 Relative ID: 0

```

**EXAMPLE 6** Enabling a Path

The following command uses the `enable path` subcommand to enable the path with the specified initiator port, target port, and logical unit.

```
mpathadm enable path -i 2000000173018713 -t 20030003ba27d095 \
-l /dev/rdisk/c4t60003BA27D2120004204AC2B000DAB00d0s2
```

**EXAMPLE 7** Modifying mpath-support To Turn On autofailback

```
mpathadm modify mpath-support -a on libmpscsi_vhci.so
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/library/storage/libmpapi
	system/library/storage/libmpapi ( <a href="#">exec_attr(4)</a> entry)
Interface Stability	Committed

**See Also** [stmsboot\(1M\)](#), [libMPAPI\(3LIB\)](#), [exec\\_attr\(4\)](#), [attributes\(5\)](#)

**Name** mpstat – report per-processor or per-processor-set statistics

**Synopsis** /usr/bin/mpstat [-aq] [-p | -P *set*] [-T u | d] [*interval* [*count*]]

**Description** The `mpstat` command reports processor statistics in tabular form. Each row of the table represents the activity of one processor. The first table summarizes all activity since boot. Each subsequent table summarizes activity for the preceding interval. All values are rates listed as events per second unless otherwise noted.

During execution of the kernel status command, the state of the kernel can change. If relevant, a state change message is included in the `mpstat` output, in one of the following forms:

```
<<processor 3 moved from pset: -1 to: 1>>
<<pset destroyed: 1>>
<<pset created: 1>>
<<processors added: 1, 3>>
<<processors removed: 1, 3>>
```

The `mpstat` command reports the following information:

**CPU or SET** Without the `-a` option, `mpstat` reports CPU statistics for a processor ID. With the `-a` option, `mpstat` reports SET statistics for a processor set ID.

<code>minf</code>	minor faults
<code>mjf</code>	major faults
<code>xcal</code>	inter-processor cross-calls
<code>intr</code>	interrupts
<code>ithr</code>	interrupts as threads (not counting clock interrupt)
<code>csw</code>	context switches
<code>icsw</code>	involuntary context switches
<code>migr</code>	thread migrations (to another processor)
<code>smtx</code>	spins on mutexes (lock not acquired on first try)
<code>srw</code>	spins on readers/writer locks (lock not acquired on first try)
<code>syscl</code>	system calls
<code>usr</code>	percent user time
<code>sys</code>	percent system time
<code>wt</code>	the I/O wait time is no longer calculated as a percentage of CPU time, and this statistic will always return zero.
<code>idl</code>	percent idle time

`size`            number of processors in the requested processor set  
`set`             processor set membership of each CPU

**Options** The following options are supported:

`-a`            Aggregate output by processor set. Sort the output by set. The default output is sorted by CPU number.  
`-p`            Report processor set membership of each CPU. Sort the output by set. The default output is sorted by CPU number.  
`-P set`        Display only those processors in the specified *set*.  
`-q`            Suppress messages related to state changes.  
`-T u | d`      Specify *u* for a printed representation of the internal representation of time. See [time\(2\)](#). Specify *d* for standard date format. See [date\(1\)](#).  
*interval*     Report once each *interval* seconds.  
*count*        Only print *count* reports.

**Examples** **EXAMPLE 1** Using `mpstat` to Generate User and System Operation Statistics

The following command generates processor statistics over a five-second interval in two reports. The command shows the processor set membership of each CPU. The default output is sorted by CPU number, aggregated by *processor set*, for user (*usr*) and system (*sys*) operations.

```
example% mpstat -ap 5 2
```

```
SET minf mjf xcal intr ithr csw icsw migr smtx srw syscl usr sys wt idl size
 0 6 0 355 291 190 22 0 0 0 0 43 0 2 0 43 1
 1 24 17 534 207 200 70 1 0 2 0 600 4 1 0 84 2
 2 19 7 353 325 318 44 0 0 5 0 345 1 1 0 94 3
 3 36 2 149 237 236 14 0 0 4 0 97 0 0 0 98 2
SET minf mjf xcal intr ithr csw icsw migr smtx srw syscl usr sys wt idl size
 0 1 0 720 405 304 55 0 0 18 0 12 0 15 0 81 1
 1 0 69 1955 230 200 313 33 4 41 9 7086 34 10 0 19 2
 2 0 46 685 314 300 203 11 0 54 1 5287 36 6 0 28 3
 3 0 0 14 386 384 0 0 0 0 0 0 0 0 100 2
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	See below.

Invocation is evolving. Human readable output is unstable.

**See Also** [sar\(1\)](#), [date\(1\)](#), [iostat\(1M\)](#), [sar\(1M\)](#), [vmstat\(1M\)](#), [time\(2\)](#), [attributes\(5\)](#)

**Notes** The sum of CPU utilization might vary slightly from 100 due to rounding errors in the production of a percentage figure.

The total time used for CPU processing is the sum of `usr` and `sys` output values, reported for user and system operations. The `idl` value reports the time that the CPU is idle for any reason other than pending disk I/O operations.

Run the `iostat` command with the `-x` option to report I/O service times in `svc_t` output. The `iostat` utility also reports the same `wt`, `user` (`us`), and `system` (`sy`) statistics. See [iostat\(1M\)](#) for more information.

When executing in a zone and if the pools facility is active, `mpstat(1M)` will only provide information for those processors which are a member of the processor set of the pool to which the zone is bound.

**Name** msgid – generate message IDs

**Synopsis** /usr/sbin/msgid

**Description** The msgid utility generates message IDs.

A message ID is a numeric identifier that uniquely identifies a message. Although the probability of two distinct messages having the same ID is high, this can be greatly reduced with the appropriate priority or facility.level designator (see [syslogd\(1M\)](#)). Specifically, the message ID is a hash signature on the message's unexpanded format string, generated by `STRLOG_MAKE_MSGID()` as defined in `<sys/strlog.h>`.

[syslogd\(1M\)](#) is a simple filter that takes strings as input and produces those same strings, preceded by their message IDs, as output. Every message logged by `syslogd(1M)` includes the message ID. The message ID is intended to serve as a small, language-independent identifier.

**Examples** **EXAMPLE 1** Using the msgid command to generate a message ID

The following example uses the msgid command to generate a message ID for the echo command.

```
example# echo hello | msgid205790 hello
```

**EXAMPLE 2** Using the msgid command to generate a message catalog

The following example uses the msgid command to enumerate all of the messages in the binary ufs, to generate a message catalog.

```
example# strings /kernel/fs/ufs | msgid
```

```
137713 free:
 freeing free frag, dev:0x%lx, blk:%ld, cg:%d, ino:%lu, fs:%s
567420 iallocg: block not in mapfs = %s
845546 alloc: %s: file system full
...
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [syslogd\(1M\)](#), [attributes\(5\)](#), [log\(7D\)](#)

**Name** mvmkdir – move a directory

**Synopsis** /usr/sbin/mvmkdir *dirname name*

**Description** mvmkdir moves directories within a file system. *dirname* must be a directory. If *name* does not exist, it will be created as a directory. If *name* does exist, and is a directory, *dirname* will be created as *name/dirname*. *dirname* and *name* may not be on the same path; that is, one may not be subordinate to the other. For example:

```
example% mvmkdir x/y x/z
```

is legal, but

```
example% mvmkdir x/y x/y/z
```

is not.

**Operands** *dirname* The name of the directory that is to be moved to another directory in the filesystem.

*name* The name of the directory into which *dirname* is to be moved. If *name* does not exist, it will be created. It may not be on the same path as *dirname*.

**Usage** See [largefile\(5\)](#) for the description of the behavior of mvmkdir when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**Exit Status** 0 Successful operation.

>0 Operation failed.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [mkdir\(1\)](#), [mv\(1\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

**Name** named, in.named – Internet domain name server

**Synopsis** named [-fgsVv] [-c *config-file*] [-d *debug-level*] [-m *flag*]  
[-n *#cpus*] [-p *port*] [-S *#max-socks*] [-t *directory*]  
[-u *user*] [-x *cache-file*] [-4 | -6]

**Description** The named utility is a Domain Name System (DNS) server, part of the BIND 9 distribution from ISC. For more information on the DNS, see RFCs 1033, 1034, and 1035.

When invoked without arguments, named reads the default configuration file `/etc/named.conf`, reads any initial data, and listens for queries.

`in.named` is a link to `named`.

**Options** The following options are supported:

-4

Use only IPv4 transport. By default, both IPv4 and IPv6 transports can be used. Options -4 and -6 are mutually exclusive.

-6

Use only IPv6 transport. By default, both IPv4 and IPv6 transports can be used. Options -4 and -6 are mutually exclusive.

-c *config-file*

Use *config-file* as the configuration file instead of the default `/etc/named.conf`. To ensure that reloading the configuration file continues to work after the server has changed its working directory due to a possible *directory* option in the configuration file, *config-file* should be an absolute pathname.

-d *debug-level*

Set the daemon's debug level to *debug-level*. Debugging traces from named become more verbose as the debug level increases.

-f

Run the server in the foreground (that is, do not run as a daemon).

-g

Run the server in the foreground and force all logging to `stderr`.

-m *flag*

Turn on memory usage debugging flags. Possible flags are `usage`, `trace`, and `record`, `size`, and `mctx`. These correspond to the `ISC_MEM_DEBUGXXXX` flags described in `<isc/mem.h>`.

-n *#cpus*

Create *#cpus* worker threads to take advantage of multiple CPUs. If not specified, named will try to determine the number of CPUs present and create one thread per CPU. If it is unable to determine the number of CPUs, a single worker thread will be created.

-p *port*

Listen for queries on port *port*. If not specified, the default is port 53.

**-S #max-socks**

Allow named to use up to #max-socks sockets.

This option should be unnecessary for the vast majority of users. The use of this option could even be harmful, because the specified value might exceed the limitation of the underlying system API. It therefore should be set only when the default configuration causes exhaustion of file descriptors and the operational environment is known to support the specified number of sockets. Note also that the actual maximum number is normally a little smaller than the specified value because named reserves some file descriptors for its internal use.

**-s**

Write memory usage statistics to *stdout* on exit.

This option is mainly of interest to BIND 9 developers and might be removed or changed in a future release.

**-t directory**

Change the root directory using [chroot\(2\)](#) to *directory* after processing the command line arguments, but before reading the configuration file.

This option should be used in conjunction with the -u option, as chrooting a process running as root does not enhance security on most systems; the way `chroot()` is defined allows a process with root privileges to escape a chroot jail.

**-u user**

Set the real user ID using [setuid\(2\)](#) to *user* after completing privileged operations, such as creating sockets that listen on privileged ports.

**-V**

Report the version number and build options, and exit.

**-v**

Report the version number and exit.

**-x cache-file**

Load data from *cache-file* into the cache of the default view.

Do not use this option. It is of interest only to BIND 9 developers and might be removed or changed in a future release.

**Extended Description**

This section describes additional attributes of named.

**SMF Properties**

When starting named from the service management facility, [smf\(5\)](#), named configuration is read from the service configuration repository. Use [svccprop\(1\)](#) to list the properties and [svccfg\(1M\)](#) to make changes.

The following application configuration properties are available to administrators:

**options/server**

Specifies the server executable to be used instead of the default server, `/usr/sbin/named`.

**options/configuration\_file**

Specifies the configuration file to be used instead of the default, `/etc/named.conf`. A directory option might be specified in the configuration file. To ensure that reloading the configuration file continues to work in such a situation, *configuration\_file* should be specified as an absolute pathname. This pathname should not include the *chroot\_dir* pathname. This property is the equivalent of the `-c` option.

**options/ip\_interfaces**

Specifies over which IP transport, IPv4 or IPv6, BIND will transmit. Possible values are IPv4 or IPv6. Any other setting assumes `all`, the default. This property is the equivalent of command line option `-4` or `-6`

**options/listen\_on\_port**

Specifies the default UDP and TCP port to be used for listening to DNS requests. This property is the equivalent of the command line option `-p port`.

**options/debug\_level**

Specifies the default debug level. The default is 0, which means no debugging. The higher the number the more verbose debug information becomes. Equivalent of the command line option `-d debug_level`.

**options/threads**

Specifies the number of CPU worker threads to create. The default of 0 causes named to try and determine the number of CPUs present and create one thread per CPU. Equivalent of command line option `-n #cpus`.

**options/chroot\_dir**

Specifies the directory to be used as the root directory after processing SMF properties and the command line arguments but before reading the configuration file. Use this property when using a [chroot\(2\)](#) environment. Synonymous to command line option `-t pathname`.

When using [chroot\(2\)](#), named is unable to disable itself when receiving [rndc\(1M\)](#) `stop` or `halt` commands. Instead, you must use the [svcadm\(1M\)](#) `disable` command.

In the event of a configuration error originating in one of the above SMF application options, named displays a message providing information about the error and the parameters that need correcting. The process then exits with exit code `SMF_EXIT_ERR_CONFIG`.

At startup, in the event of an error other than a configuration error, named exits with exit code `SMF_EXIT_ERR_FATAL`. Both of this code and `SMF_EXIT_ERR_CONFIG` cause the start method, [smf\\_method\(5\)](#), to place the service in the maintenance state, which can be observed with the [svcs\(1\)](#) command `svcs -x`.

In addition to the properties listed above, the following property can be used to invoke named as a user other than root:

**start/user**

Specifies the identity of the user that is invoking named. See `smf_method(5)` and `chroot(2)`. Note that the user must have `solaris.smf.manage.bind` authorization. Without this role the named will be unable to manage its SMF FMRI and named will automatically be restarted by the SMF after an `rndc(1M)` stop or halt command. See EXAMPLES for a sequence of commands that establishes the correct authorization.

**SIGNALS** In routine operation, signals should not be used to control the nameserver; `rndc(1M)` should be used instead.

**SIGHUP**

Force a reload of the server.

**SIGINT, SIGTERM**

Shut down the server.

The result of sending any other signals to the server is undefined.

**Configuration** The named configuration file is too complex to describe in detail here. A list of configuration options is provided in the `named.conf` man page shipped with the BIND 9 distribution. A complete description is provided in the *BIND 9 Administrator Reference Manual*.

**Examples** EXAMPLE 1 Configuring named to Transmit Only over IPv4 Networks

The following command sequence configures named such that it will transmit only over IPv4 networks.

```
svccfg -s svc:network/dns/server:default setprop \
> options/ip_interfaces=IPv4
svcadm refresh svc:network/dns/server:default
#
```

## EXAMPLE 2 Listing Current Configuration File and Setting an Alternative File

The following sequence of commands lists the current named configuration file and sets an alternative file.

```
svccprop -p options/configuration_file dns/server:default
/etc/named.conf
svccfg -s dns/server:default setprop \
> options/configuration_file=/var/named/named.conf
svcadm refresh dns/server:default
svccprop -p options/configuration_file dns/server:default
/var/named/named.conf
```

## EXAMPLE 3 Establishing Appropriate Authorization for named

To have named start with the `solaris.smf.manage.bind` authorization, perform the steps shown below.

Add the user `dnsadmin` to the `solaris.smf.manage.bind` role:

**EXAMPLE 3** Establishing Appropriate Authorization for named (Continued)

```
usermod -A solaris.smf.manage.bind dnsadmin
Observe effect of command:
tail -1 /etc/user_attr
dnsadmin:::type=normal;auths=solaris.smf.manage.bind
```

Modify the service properties:

```
svccfg
svc:> select svc:/network/dns/server:default
svc:/network/dns/server:default> setprop start/user = dnsadmin
svc:/network/dns/server:default> setprop start/group = dnsadmin
svc:/network/dns/server:default> exit
svcadm refresh svc:/network/dns/server:default
svcadm restart svc:/network/dns/server:default
```

Because only root has write access to create the default process-ID file, `/var/run/named/named.pid`, named must be configured to use an alternative path for the user `dnsadmin`. Here is an example of how to accomplish this:

```
mkdir /var/named/tmp
chown dnsadmin /var/named/tmp
```

Shown below is what you must add to `named.conf` to make use of the directory created above.

```
head /etc/named.conf
options {
 directory "/var/named";
 pid-file "/var/named/tmp/named.pid";
};
```

**Files** `/etc/named.conf`  
default configuration file

`/var/run/named/named.pid`  
default process-ID file

The `named.conf` man page shipped with the BIND 9 distribution

**Name** named-checkconf – named configuration file syntax checking tool

**Synopsis** named-checkconf [-h]vz] [-t *directory*] *filename*

**Description** The named-checkconf utility checks the syntax, but not the semantics, of a specified configuration file.

**Options** The following options are supported:

-h

Display the usage summary and exit.

-j

When loading a zonefile, read the journal if it exists.

-t *directory*

Change the root directory to *directory* so that include directives in the configuration file are processed as if run by a named configuration whose root directory has been similarly changed.

-v

Print the version of the named-checkconf program and exit.

-z

Perform a test load of the master zones found in named.conf.

**Operands** The following operands are supported:

*filename*

The name of the configuration file to be checked. If not specified, it defaults to /etc/named.conf.

**Exit Status** 0

No errors were detected.

1

An error was detected.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/dns/bind
Interface Stability	Volatile

**See Also** [named\(1M\)](#), [named-checkzone\(1M\)](#), [attributes\(5\)](#)

See the BIND 9 *Administrator's Reference Manual*. As of the date of publication of this man page, this document is available at <https://www.isc.org/software/bind/documentation>.

**Name** named-checkzone, named-compilezone – zone file validity checking or converting tool

**Synopsis** named-checkzone [-Ddhjqv] [-c *class*] [-F *format*] [-f *format*]  
 [-i *mode*] [-k *mode*] [-M *mode*] [-m *mode*] [-n *mode*]  
 [-o *filename*] [-S *mode*] [-s *style*] [-t *directory*]  
 [-W *mode*] [-w *directory*] *zonename filename*

named-compilezone [-Ddjqv] [-C *mode*] [-c *class*] [-F *format*]  
 [-f *format*] [-i *mode*] [-k *mode*] [-m *mode*] [-n *mode*]  
 [-o *filename*] [-s *style*] [-t *directory*]  
 [-W *mode*] [-w *directory*] *zonename filename*

**Description** The named-checkzone utility checks the syntax and integrity of a zone file. It performs the same checks as [named\(1M\)](#) does when loading a zone. The named-checkzone utility is useful for checking zone files before configuring them into a name server.

named-compilezone is similar to named-checkzone, differing in that it always dumps the zone contents to a specified file in a specified format. Additionally, it applies stricter check levels by default, since the dump output will be used as an actual zone file loaded by [named\(1M\)](#). Unless manually specified otherwise, the check levels must be at least as strict as those specified in the named configuration file.

**Options** For either or both utilities, the following options are supported:

-c *class*

Specify the class of the zone. If not specified, “IN” is assumed.

-D

Dump zone file in canonical format.

-d

Enable debugging.

-F *format*

Specify the format of the output file specified. Possible formats are text (default) and raw. For named-checkzone, this does not cause any effects unless it dumps the zone contents.

-f *format*

Specify the format of the zone file. Possible formats are text (default) and raw.

-h

Display usage message for named-checkzone.

-i *mode*

Perform post-load zone integrity checks. Possible modes are full (default), full-sibling, local, local-sibling, and none.

Mode full checks that MX records refer to the A or AAAA record (both in-zone and out-of-zone hostnames). Mode local checks only MX records that refer to in-zone hostnames.

Mode `full` checks that SRV records refer to the A or AAAA record (both in-zone and out-of-zone hostnames). Mode `local` checks only SRV records that refer to in-zone hostnames.

Mode `full` checks that delegation NS records refer to A or AAAA record (both in-zone and out-of-zone hostnames). It also checks that glue address records in the zone match those advertised by the child. Mode `local` checks only NS records that refer to in-zone hostnames or check that some required glue exists, that is, when the nameserver is in a child zone.

Mode `full-sibling` and `local-sibling` disable sibling glue checks, but are otherwise the same as `full` and `local`, respectively.

Mode `none` disables the checks.

**-k** *mode*

Perform “check-name” checks with the specified failure mode. Possible modes are `fail` (default for `named-compilezone`), `warn` (default for `named-checkzone`) and `ignore`.

**-j**

Read the journal, if it exists, when loading the zone file.

**-M** *mode*

Check if an MX record refers to a CNAME. Possible modes are `fail`, `warn` (default) and `ignore`.

**-m** *mode*

Specify whether MX records should be checked to see if they are addresses. Possible modes are `fail`, `warn` (default) and `ignore`.

**-n** *mode*

Specify whether NS records should be checked to see if they are addresses. Possible modes are `fail` (default for `named-compilezone`), `warn` (default for `named-checkzone`) and `ignore`.

**-o** *filename*

Write zone output to *filename*. If *filename* is `-` (a hyphen), then write to standard out. The hyphen mandatory for `named-compilezone`

**-q**

Run in quiet mode, reporting only the exit status.

**-S** *mode*

Check if a SRV record refers to a CNAME. Possible modes are `fail`, `warn` (default) and `ignore`.

**-s** *style*

Specify the style of the dumped zone file. Possible styles are `full` (default) and `relative`. The `full` format is most suitable for processing automatically by a separate script. The `relative` format is more human-readable and is thus suitable for editing by hand. For

`named-checkzone` this option does not cause any effects unless it dumps the zone contents. It also has no effect if the output format is not text.

`-t directory`

`chroot` to `directory` so that include directives in the configuration file are processed as if run by a similarly `chrooted` `named`.

`-v`

Print the version of the `named-checkzone` program and exit.

`-W mode`

Specify whether to check for non-terminal wildcards. Non-terminal wildcards are almost always the result of a failure to understand the wildcard matching algorithm (RFC 1034). Possible modes are `warn` (default) and `ignore`.

`-w directory`

`chdir` to `directory` so that relative filenames in master file `$INCLUDE` directives work. This is similar to the `directory` clause in `named.conf`.

**Operands** The following operands are supported:

*filename*

The name of the zone file.

*zonename*

The domain name of the zone being checked.

**Exit Status** 0

No errors were detected.

1

An error was detected.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/dns/bind
Interface Stability	Volatile

**See Also** [named\(1M\)](#), [named-checkconf\(1M\)](#), [attributes\(5\)](#)

*RFC 1035*

See the *BIND 9 Administrator's Reference Manual*. As of the date of publication of this man page, this document is available at <https://www.isc.org/software/bind/documentation>.

**Name** ncaconfd – Solaris Network Cache and Accelerator (NCA) configuration daemon

**Synopsis** /usr/lib/inet/ncaconfd [-al ] *interface1* [*interface2* ...]

**Description** Use the ncaconfd utility to set up NCA on a system. At boot time, the ncakmod initialization script reads in [nca.if\(4\)](#) to determine on which interface(s) NCA should run. ncaconfd then sets up the interface.

ncaconfd also operates as a daemon if the nca\_active key is set to enabled in [ncakmod.conf\(4\)](#) file. In this case, ncaconfd will continue as a daemon after all the NCA interfaces have been set up, listening for routing changes. The changes are then passed to NCA to control which interface NCA should use to make active outgoing TCP connections.

**Options** The following options are supported:

- a Enable active connections.
- l Enable logging.

**Files** /etc/nca/ncakmod.conf

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/http-cache-accelerator
Interface Stability	Committed

**See Also** [nca\(1\)](#), [ncakmod\(1\)](#), [nca.if\(4\)](#), [ncakmod.conf\(4\)](#), [attributes\(5\)](#)

- Name** ncheck – generate a list of path names versus i-numbers
- Synopsis** ncheck [-F *FSType*] [-V] [*generic\_options*]  
[-o *FSType-specific\_options*] [*special*] . . .
- Description** ncheck with no options generates a path-name versus i-number list of all files on *special*. If *special* is not specified on the command line the list is generated for all *specials* in */etc/vfstab* which have a numeric *fsckpass*. *special* is the raw device on which the file system exists.
- Options**
- F Specify the *FSType* on which to operate. The *FSType* should either be specified here or be determinable from */etc/vfstab* by finding an entry in the table that has a numeric *fsckpass* field and an *fsckdev* that matches *special*.
  - V Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from */etc/vfstab*. This option may be used to verify and validate the command line.
- generic\_options* Options that are commonly supported by most *FSType*-specific command modules. The following options are available:
- i *i-list* Limit the report to the files on the *i-list* that follows. The *i-list* must be separated by commas with no intervening spaces.
  - a Print the names “.” and “. .” which are ordinarily suppressed.
  - s Report only special files and files with set-user-ID mode. This option may be used to detect violations of security policy.
- o Specify *FSType-specific\_options* in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the *FSType*-specific module of the command.
- Usage** See [largefile\(5\)](#) for the description of the behavior of ncheck when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).
- Files** */etc/vfstab* list of default parameters for each file system
- Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [vfstab\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#) Manual pages for the *FSType*-specific modules of ncheck

**Notes** This command may not be supported for all *FSTypes*.

**Name** ncheck\_ufs – generate pathnames versus i-numbers for ufs file systems

**Synopsis** ncheck -F ufs [*generic\_options*] [-o m] [*special*]...

**Description** ncheck -F ufs generates a pathname versus i-number list of files for the ufs file system residing on *special*. Names of directory files are followed by `./.`

**Options** See [ncheck\(1M\)](#) for the list of *generic\_options* supported.

-o Specify ufs file system specific options. The available option is:

m Print mode information.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTETYPE	ATTRIBUTEVALUE
Availability	SUNWcs

**See Also** [ff\(1M\)](#), [ncheck\(1M\)](#), [attributes\(5\)](#)

**Diagnostics** When the file system structure is improper, `??` denotes the “parent” of a parentless file and a pathname beginning with `./.` denotes a loop.

**Name** ndd – get and set driver configuration parameters

**Synopsis** ndd [-set] *driver parameter* [*value*]

**Description** ndd gets and sets selected configuration parameters in some kernel drivers. Currently, ndd only supports the drivers that implement the TCP/IP Internet protocol family. Each driver chooses which parameters to make visible using ndd. Since these parameters are usually tightly coupled to the implementation, they are likely to change from release to release. Some parameters may be read-only.

**Note** – It is strongly encouraged that you use [ipadm\(1M\)](#), rather than ndd, to modify or retrieve TCP/IP Internet protocols. The current ndd command will be made obsolete in a future release, replaced by [ipadm\(1M\)](#). Please see NOTES for more information.

If the ndd -set option is omitted, ndd queries the named *driver*, retrieves the value associated with the specified *parameter*, and prints it. If the -set option is given, ndd passes *value*, which must be specified, down to the named *driver* which assigns it to the named *parameter*.

By convention, drivers that support ndd also support a special read-only *parameter* named “?” which can be used to list the parameters supported by the driver.

**Examples** EXAMPLE 1 Getting Parameters Supported By The TCP Driver

To see which parameters are supported by the TCP driver, use the following command:

```
example% ndd /dev/tcp \?
```

The parameter name “?” may need to be escaped with a backslash to prevent its being interpreted as a shell meta character.

The following command sets the value of the parameter *ip\_forwarding* in the dual stack IP driver to zero. This disables IPv4 packet forwarding.

```
example% ndd -set /dev/ip ip_forwarding 0
```

Similarly, in order to disable IPv6 packet forwarding, the value of parameter *ip6\_forwarding*

```
example% ndd -set /dev/ip ip6_forwarding 0
```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [nca\(1\)](#), [dladm\(1M\)](#), [ipadm\(1M\)](#), [ioctl\(2\)](#), [attributes\(5\)](#), [arp\(7P\)](#), [ip\(7P\)](#), [ip6\(7P\)](#), [tcp\(7P\)](#), [udp\(7P\)](#)

**Notes** The parameters supported by each driver may change from release to release. Like programs that read `/dev/kmem`, user programs or shell scripts that execute `nnd` should be prepared for parameter names to change.

The `ioctl()` command that `nnd` uses to communicate with drivers is likely to change in a future release. User programs should avoid making dependencies on it.

The use of `nnd` to administer Layer 2 (Data Link layer) drivers is strongly discouraged as this capability is to be obsoleted in a future release, replaced by `dladm(1M)`. Please refer to the driver-specific man page in section 7D of the SunOS man pages.

The use of `nnd` to administer the drivers that implement the TCP/IP Internet protocol family (IP/TCP/SCTP/UDP/ICMP) is strongly discouraged as this capability is to be obsoleted in a future release, replaced by `ipadm`. Please see `ipadm(1M)` for instructions for modifying and retrieving supported protocol properties.

The meanings of many `nnd` parameters make sense only if you understand how the driver is implemented.

If a TCP driver sends a report that is truncated, it could be because that driver uses `nnd` for transporting the report. `nnd` imposes a 64K limit on such reports.

**Name** ndmpadm – administer Network Data Management Protocol activities

**Synopsis** `/usr/sbin/ndmpadm [-? ] subcommand [options] [direct-object]`

**Description** The `ndmpadm` command can be used to query the `ndmpd(1M)` daemon to get the status of active sessions, terminate a session, query backup devices, and set or get the current NDMP (Network Data Management Protocol) service variables and properties. `ndmpadm` is implemented as a set of subcommands, many with their own direct object, which are described in the section for a given subcommand. Certain subcommands support options, which are described along with the subcommand.

The `ndmpadm` command supports the following subcommands:

`disable`

Disable the specified authentication password handling.

`enable`

Enable the specified authentication password handling.

`get`

Get the value of an NDMP configuration property.

`kill-sessions`

Terminate an active session.

`set`

Set the value of an NDMP configuration property.

`show-devices`

Get a list of tape devices connected to the server.

`show-sessions`

Display the details of active NDMP sessions.

**Options** The following option is supported:

`-?` Display a list of all subcommands and options.

**Sub-commands** The `ndmpadm` command supports the subcommands described below.

**disable Subcommand** The syntax for the `disable` subcommand is:

```
ndmpadm disable -a auth-type
```

This subcommand disables the authentication type specified by *auth-type* for an NDMP client's remote access. Valid values for *auth-type* are `cram-md5` or `cleartext`.

**enable Subcommand** The syntax for the `enable` subcommand is:

```
ndmpadm enable -a auth-type -u username
```

This subcommand prompts for the user's password twice for confirmation and activates the specified authentication type with the given username and password for NDMP client access. Valid values for *auth-type* are `cram-md5` or `cleartext`.

**get Subcommand** The syntax for the `get` subcommand is:

```
ndmpadm get [-p] [property] [[-p] property=value]...
```

The property names are the same as used for the `set` subcommand and are described below. If you do not specify a property, the `get` subcommand returns all configuration properties.

**kill-sessions Subcommand** The `kill-sessions` subcommand allows you to terminate the session number *ID*.

The syntax for the `kill-sessions` subcommand is:

```
ndmpadm kill-sessions ID
```

**set Subcommand** The syntax for the `set` subcommand is:

```
ndmpadm set [-p] property=value [[-p] property=value]...
```

The properties you can set with the `set` subcommand are described in the [ndmp\(4\)](#) man page.

**show-devices Subcommand** The syntax for the `show-devices` subcommand is:

```
ndmpadm show-devices
```

This subcommand lists the name, vendor, serial number, and other information about the current tape drive and libraries connected to the system.

**show-sessions Subcommand** The `show-sessions` subcommand displays details of a session. The syntax for the `show-sessions` subcommand is:

```
ndmpadm show-sessions [-i tape,scsi,data,mover] [ID]
```

The `show-sessions` subcommand supports the following arguments:

`-i tape,scsi,data,mover`

Identify a type of interface about which to obtain data. If no interface is specified, `show-sessions` displays information for all types of interfaces.

*ID*

Identifies a particular session about which to display data. If no *ID* is specified, `show-sessions` displays data for all sessions.

**Examples** **EXAMPLE 1** Obtaining the Status of All NDMP Connections

The following command obtains status on all connections.

```
ndmpadm show-devices
```

**EXAMPLE 2** Obtaining the Status of Certain Types of Connections

The following command obtains status on tape and SCSI interfaces.

```
ndmpadm show-sessions -i scsi,tape
```

**EXAMPLE 3** Limiting Protocol Version

The following command limits the use of the NDMP protocol to version 3.

```
ndmpadm set -p version=3
```

**EXAMPLE 4** Obtaining Current Version Number

The following command obtains the version number of the currently running NDMP.

```
ndmpadm get -p version
```

**EXAMPLE 5** Disconnecting a Specific Session

The command shown below disconnects session 5. The session number was previously obtained from an `ndmpadm show-sessions` command.

```
ndmpadm kill-session 5
```

**EXAMPLE 6** Obtaining the Values for All NDMP Properties

The following command obtains the values for all NDMP properties.

```
ndmpadm get
```

**EXAMPLE 7** Enabling CRAM-MD5 Authentication

The following command enables CRAM-MD5 authentication.

```
ndmpadm enable -a cram-md5 -u admin
```

```
Enter new password:*****
```

```
Re-enter password:*****
```

**EXAMPLE 8** Disabling Clear Text Password Authentication

The following command disables clear text password authentication.

```
ndmpadm disable -a cleartext
```

- Exit Status**
- 0 Successful completion.
  - 1 An error occurred, such as the `ndmpd` daemon is not running, that prevented `ndmpadm` from contacting the demon.
  - 2 Invalid command-line options were specified.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/storage/ndmp, SUNWndmpr
Interface Stability	Committed

**See Also** [dump\(1\)](#), [tar\(1\)](#), [ndmpd\(1M\)](#), [ndmpstat\(1M\)](#), [svccfg\(1M\)](#), [syslogd\(1M\)](#), [ndmp\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

**Notes** The [ndmpd\(1M\)](#) daemon is managed by the service management facility ([smf\(5\)](#)), under the service identifier:

```
svc:/system/ndmpd
```

Administrative actions on this service, such as setting and getting a property can be alternatively performed using [svccfg\(1M\)](#). For example to enable Direct Access Recovery (DAR) mode:

```
svccfg -s svc:/system/ndmpd
svc:/system/ndmpd> setprop ndmpd/dar-support = yes
```

...and to get the list of properties:

```
svccfg -s svc:/system/ndmpd
svc:/system/ndmpd> listprop
```

**Name** ndmpd – Network Data Management Protocol daemon

**Synopsis** /usr/lib/ndmp/ndmpd [-d]

**Description** The ndmpd daemon handles client Network Data Management Protocol (NDMP) requests. NDMP is an open, enterprise-wide, network-based data management protocol used for backup and recovery. The ndmpd daemon enables users to manage data backup and recovery using Data Management Application (DMA) clients. The NDMP protocol is used to coordinate data movement and control between a DMA and an NDMP server or between two NDMP servers.

By default, ndmpd is disabled.

**Options** The following option is supported:

-d  
Debugging mode; log file will be created.

**Exit Status**

- 0 Successful completion.
- 1 An error occurred that prevented the ndmpd daemon from initializing, such as failure to fork a process, mutex initialization.
- 2 Invalid command-line options were specified.

**Files** /usr/lib/ndmp/ndmpd  
Network data management protocol server binary.

/var/ndmp/ndmp.log  
Network data management protocol log messages file. This file is deleted upon reboot.

/var/ndmp/dumpdates  
A text file that stores information about the date and the level of dump backups.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/storage/ndmp, SUNWndmpr
Interface Stability	Committed

**See Also** [svcs\(1\)](#), [ndmpadm\(1M\)](#), [svcadm\(1M\)](#), [svccfg\(1M\)](#), [syslogd\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#)

**Notes** The ndmpd daemon is managed by the service management facility ([smf\(5\)](#)), under the service identifier:

```
svc:/system/ndmp:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

**Name** ndmpstat – show NDMP backup progress statistics

**Synopsis** ndmpstat [*tapes*] [*interval* [*count*]]

**Description** The `ndmpstat` utility reports Network Data Management Protocol (NDMP) statistics, among which are NDMP worker threads, disk IO, tape IO, files operation, performance, and backup activity.

`ndmpstat` reports the aggregate statistics for all tapes and disks. In order to obtain statistics for specific tape devices, the tape device name should be passed as argument to the utility.

When invoked, `ndmpstat` begins its display with a one-line summary of the NDMP daemon activity since the NDMP service was invoked.

**Display Fields** The fields in `ndmpstat` output are described as follows:

`wthr`

Report the number of worker threads in each of the four following states:

`r`

the number of worker threads running

`w`

the number of blocked worker threads that are waiting for resources such as I/O and paging

`b`

the number of backup operations currently running

`r`

the number of restore operations currently running

`file`

Report on usage of filesystem.

`rd`

the number of files being read

`wr`

the number of files being written

`disk`

Report the number of disk operations per interval.

`rd`

the number of disk blocks being read

`wr`

the number of disk blocks being written

**tape**

Report the number of tape operations per interval. There are slots for up to four tapes, labeled with a single number. The number indicates the name of the device under `/dev/rmt`.

**rd**

the number of tape blocks being read

**wr**

the number of tape blocks being written

**bytes**

Report the number of bytes transferred. This is the aggregate value of both tape and disk devices. The number is in kilobytes.

**rd**

the number of kilobytes being read

**wr**

the number of kilobytes being written

**perf**

Displays a rough estimate of performance of the backup/restore operation in megabytes per second.

**bk**

backup performance

**rs**

restore performance

**prcnt**

Display the comparative usage of resources, in percent.

**dsk**

disk I/O time

**tpe**

tape I/O time

**otr**

other time (memory or idle)

See EXAMPLES.

**Operands** The following operands are supported:

*count* Specifies the number of times that the statistics display is repeated.

*tape* Specifies which tapes are to be given priority in the output. A command line is limited to a maximum of four tape devices. A common tape name is `/dev/rmt/n`, where *n* is an integer.

*interval* Specifies the number of seconds over which ndmpstat summarizes activity. The specified interval remains in effect till the command is terminated.

**Examples** EXAMPLE 1 Using ndmpstat

The following command displays a summary of NDMP daemon activity at five-second intervals.

```
example% ndmpstat 5
wthr file disk tape bytes perf prcnt
r w b r rd wr rd wr rd wr rd wr bk rs dsk tpe otr
1 0 3 6 50 9 1250 0 32544 4455 42335 3234 5 4 20 40 40
1 0 0 1 1 0 128 0 0 128 64 64 1 0 0 80 20
1 0 0 1 2 0 128 0 0 0 64 0 1 0 80 0 20
1 0 0 1 1 0 128 0 0 0 64 0 1 0 80 0 20
1 0 0 1 3 0 128 0 0 0 64 0 0 0 80 0 20
1 0 0 1 1 0 128 0 0 128 64 64 1 0 0 80 20

```

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/storage/ndmp
Interface Stability	See below

Invocation is evolving. Human readable output is unstable.

**See Also** [iostat\(1M\)](#), [mpstat\(1M\)](#), [ndmpd\(1M\)](#), [ndmpadm\(1M\)](#), [attributes\(5\)](#)

**Notes** Performance numbers are not accurate and are rounded up at the MB/sec. boundary.

**Name** netcfgd – network configuration management daemon

**Synopsis** /lib/inet/netcfgd

**Description** netcfgd is a system daemon to manage network configuration. This daemon is started automatically by svc:/network/netcfg:default and should not be invoked directly. It does not constitute a programming interface.

netcfgd manages access to a network configuration repository, insuring that readers and writers have the appropriate authorizations. Specifically, an application wishing to read network configuration must have the `solaris.network.autoconf.read` authorization; while an application wishing to write network configuration must have the `solaris.network.autoconf.write` authorization. These authorizations are registered in [auth\\_attr\(4\)](#), and are included in the Network Autoconf profile found in [prof\\_attr\(4\)](#).

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsr
Interface Stability	Committed

**See Also** [svcs\(1\)](#), [nwamcfg\(1M\)](#), [nwamd\(1M\)](#), [svcadm\(1M\)](#), [auth\\_attr\(4\)](#), [prof\\_attr\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

See also [nwam-manager\(1M\)](#), available in the JDS/GNOME man page collection.

**Name** netservices – enable or disable network services

**Synopsis** netservices open  
netservices limited

**Description** The `net` services command uses the Solaris service management facility, [smf\(5\)](#), to control services that accept over the network from remote clients.

When `net` services is invoked with the `limited` command-line argument, all network services except the secure shell daemon, [sshd\(1M\)](#), are either disabled or constrained to respond to local requests only.

Invoking `net` services with the `open` command-line argument enables a large set of network services, as in previous releases of Solaris.

To customize the configuration set enabled by `net` services, use [svcadm\(1M\)](#) to enable or disable individual services. Use [svccfg\(1M\)](#) to set properties that determine whether a service accepts input from remote clients. See the man pages for individual services for the names of service instances and their properties.

Note that the `net` services command has an interface stability of `Obsolete`.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs
Interface Stability	Obsolete

**See Also** [svcadm\(1M\)](#), [svccfg\(1M\)](#), [sshd\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#)

**Name** netstat – show network status

**Synopsis** netstat [-anvR] [-f *address\_family*] [-P *protocol*]  
netstat -g [-nv] [-f *address\_family*]  
netstat -p [-n] [-f *address\_family*]  
netstat -s [-f *address\_family*] [-P *protocol*]  
[-T u | d ] [*interval* [*count*]]  
netstat -m [-T u | d ] [-v] [*interval* [*count*]]  
netstat -i [-I *interface*] [-an] [-f *address\_family*]  
[-T u | d ] [*interval* [*count*]]  
netstat -r [-anvR] [-f *address\_family* | *filter*]  
netstat -M [-ns] [-f *address\_family*]  
netstat -D [-I *interface*] [-f *address\_family*]  
netstat -d [-f *address\_family*]

**Description** The `netstat` command displays the contents of certain network-related data structures in various formats, depending on the options you select.

The `netstat` command has the several forms shown in the SYNOPSIS section, above, listed as follows:

- The first form of the command (with no required arguments) displays a list of active sockets for each protocol.
- The second, third, and fourth forms (-g, -p, and -s options) display information from various network data structures.
- The fifth form (-m option) displays STREAMS memory statistics.
- The sixth form (-i option) shows the state of the interfaces.
- The seventh form (-r option) displays the routing table.
- The eighth form (-M option) displays the multicast routing table.
- The ninth form (-D option) displays the state of DHCP on one or all interfaces.
- The tenth form (-d option) displays the table of destination cache entries.

These forms are described in greater detail below.

With no arguments (the first form), `netstat` displays connected sockets for PF\_INET, PF\_INET6, and PF\_UNIX, unless modified otherwise by the -f option.

**Options** -a

Show the state of all sockets, all routing table entries, or all interfaces, both physical and logical. Normally, listener sockets used by server processes are not shown. Under most conditions, only interface, host, network, and default routes are shown and only the status of physical interfaces is shown.

**-d**

Show the destination cache entry table. See **DISPLAYS**, below.

**-f *address\_family***

Limit all displays to those of the specified *address\_family*. The value of *address\_family* can be one of the following:

**inet** For the AF\_INET address family showing IPv4 information.

**inet6** For the AF\_INET6 address family showing IPv6 information.

**unix** For the AF\_UNIX address family.

**-f *filter***

With **-r** only, limit the display of routes to those matching the specified filter. A filter rule consists of a *keyword:value* pair. The known keywords and the value syntax are:

<b>af</b> :{inet inet6 unix  <i>number</i> }	Selects an address family. This is identical to <b>-f <i>address_family</i></b> and both syntaxes are supported.
<b>outif</b> :{ <i>name</i>   <i>ifIndex</i>  any none}	Selects an output interface. You can specify the interface by name (such as <code>hme0</code> ) or by <i>ifIndex</i> number (for example, 2). If any is used, the filter matches all routes having a specified interface (anything other than null). If none is used, the filter matches all routes having a null interface. Note that you can view the index number ( <i>ifIndex</i> ) for an interface with the <b>-a</b> option of <b>ifconfig(1M)</b> .
<b>dst</b> :{ <i>ip-address</i> [/ <i>mask</i> ] any none}	Selects a destination IP address. If specified with a mask length, then any routes with matching or longer (more specific) masks are selected. If any is used, then all but addresses but 0 are selected. If none is used, then address 0 is selected.
<b>flags</b> : [+ -]?[ABDGHMSU]+	Selects routes tagged with the specified flags. By default, the flags as specified must be set in order to match. With a leading +, the flags specified must be set but others are ignored. With a leading -, the flags specified must not be set and others are permitted.

You can specify multiple instances of **-f** to specify multiple filters. For example:

```
% netstat -nr -f outif:hme0 -f outif:hme1 -f dst:10.0.0.0/8
```

The preceding command displays routes within network 10.0.0.0/8, with mask length 8 or greater, and an output interface of either hme0 or hme1, and excludes all other routes.

- g  
Show the multicast group memberships for all interfaces. If the -v option is included, source-specific membership information is also displayed. See `DISPLAYS`, below.
- i  
Show the state of the interfaces that are used for IP traffic. Normally this shows statistics for the physical interfaces. When combined with the -a option, this will also report information for the logical interfaces. See `ifconfig(1M)`.
- m  
Show the STREAMS memory statistics.
- n  
Show network addresses as numbers. `netstat` normally displays addresses as symbols. This option may be used with any of the display formats.
- p  
Show the net to media tables. See `DISPLAYS`, below.
- r  
Show the routing tables. Normally, only interface, host, network, and default routes are shown, but when this option is combined with the -a option, all routes will be displayed, including cache. If you have not set up a multicast route, -ra might not show any multicast routing entries, although the kernel will derive such an entry if needed.
- s  
Show per-protocol statistics. When used with the -M option, show multicast routing statistics instead. When used with the -a option, per-interface statistics will be displayed, when available, in addition to statistics global to the system. See `DISPLAYS`, below.
- T u | d  
Display a time stamp.  
  
Specify u for a printed representation of the internal representation of time. See `time(2)`.  
Specify d for standard date format. See `date(1)`.
- v  
Verbose. Show additional information for the sockets, STREAMS memory statistics, routing table, and multicast group memberships.
- I *interface*  
Show the state of a particular interface. *interface* can be any valid interface such as hme0 or eri0. Normally, the status and statistics for physical interfaces are displayed. When this option is combined with the -a option, information for the logical interfaces is also reported.

- M  
Show the multicast routing tables. When used with the `-s` option, show multicast routing statistics instead.
- P *protocol*  
Limit display of statistics or state of all sockets to those applicable to *protocol*. The protocol can be one of `ip`, `ipv6`, `icmp`, `icmpv6`, `igmp`, `udp`, `tcp`, `rawip`. `rawip` can also be specified as `raw`. The command accepts protocol options only as all lowercase.
- D  
Show the status of DHCP configured interfaces.
- R  
This modifier displays extended security attributes for sockets and routing table entries. The `-R` modifier is available only if the system is configured with the Solaris Trusted Extensions feature.

With `-r` only, this option displays the routing entries' gateway security attributes. See [route\(1M\)](#) for more information on security attributes.

When displaying socket information using the first form of the command, this option displays additional information for Multi-Level Port (MLP) sockets. This includes:

- The label for the peer if the socket is connected.
- The following flags can be appended to the socket's "State" output:
  - P The socket is a MLP on zone-private IP addresses.
  - S The socket is a MLP on IP addresses shared between zones.

**Operands** *interval* Display statistics accumulated since last display every *interval* seconds, repeating forever, unless *count* is specified. When invoked with *interval*, the first row of netstat output shows statistics accumulated since last reboot.

The following options support *interval*: `-i`, `-m`, `-s` and `-Ms`. Some values are configuration parameters and are just redisplayed at each interval.

*count* Display interface statistics the number of times specified by *count*, at the interval specified by *interval*.

## Displays

Active Sockets (First Form) The display for each active socket shows the local and remote address, the send and receive queue sizes (in bytes), the send and receive windows (in bytes), and the internal state of the protocol.

The symbolic format normally used to display socket addresses is either:

`hostname.port`

when the name of the host is specified, or

*network.port*

if a socket address specifies a network but no specific host.

The numeric host address or network number associated with the socket is used to look up the corresponding symbolic hostname or network name in the *hosts* or *networks* database.

If the network or hostname for an address is not known, or if the `-n` option is specified, the numerical network address is shown. Unspecified, or “wildcard”, addresses and ports appear as an asterisk (\*). For more information regarding the Internet naming conventions, refer to [inet\(7P\)](#) and [inet6\(7P\)](#).

For SCTP sockets, because an endpoint can be represented by multiple addresses, the verbose option (`-v`) displays the list of all the local and remote addresses.

*TCP Sockets* The possible state values for TCP sockets are as follows:

BOUND	Bound, ready to connect or listen.
CLOSED	Closed. The socket is not being used.
CLOSING	Closed, then remote shutdown; awaiting acknowledgment.
CLOSE_WAIT	Remote shutdown; waiting for the socket to close.
ESTABLISHED	Connection has been established.
FIN_WAIT_1	Socket closed; shutting down connection.
FIN_WAIT_2	Socket closed; waiting for shutdown from remote.
IDLE	Idle, opened but not bound.
LAST_ACK	Remote shutdown, then closed; awaiting acknowledgment.
LISTEN	Listening for incoming connections.
SYN_RECEIVED	Initial synchronization of the connection under way.
SYN_SENT	Actively trying to establish connection.
TIME_WAIT	Wait after close for remote shutdown retransmission.

*SCTP Sockets* The possible state values for SCTP sockets are as follows:

CLOSED	Closed. The socket is not being used.
LISTEN	Listening for incoming associations.
ESTABLISHED	Association has been established.
COOKIE_WAIT	INIT has been sent to the peer, awaiting acknowledgment.

COOKIE_ECHOED	State cookie from the INIT-ACK has been sent to the peer, awaiting acknowledgement.
SHUTDOWN_PENDING	SHUTDOWN has been received from the upper layer, awaiting acknowledgement of all outstanding DATA from the peer.
SHUTDOWN_SENT	All outstanding data has been acknowledged in the SHUTDOWN_SENT state. SHUTDOWN has been sent to the peer, awaiting acknowledgement.
SHUTDOWN_RECEIVED	SHUTDOWN has been received from the peer, awaiting acknowledgement of all outstanding DATA.
SHUTDOWN_ACK_SENT	All outstanding data has been acknowledged in the SHUTDOWN_RECEIVED state. SHUTDOWN_ACK has been sent to the peer.

Network Data  
Structures (Second  
Through Fifth Forms)

The form of the display depends upon which of the -g, -m, -p, or -s options you select.

- g Displays the list of multicast group membership.
- m Displays the memory usage, for example, STREAMS mblks.
- p Displays the net to media mapping table. For IPv4, the address resolution table is displayed. See [arp\(1M\)](#). For IPv6, the neighbor cache is displayed.
- s Displays the statistics for the various protocol layers.

The statistics use the MIB specified variables. The defined values for `ipForwarding` are:

- `forwarding(1)` Acting as a gateway.
- `not-forwarding(2)` Not acting as a gateway.

The IPv6 and ICMPv6 protocol layers maintain per-interface statistics. If the -a option is specified with the -s option, then the per-interface statistics as well as the total sums are displayed. Otherwise, just the sum of the statistics are shown.

For the second, third, and fourth forms of the command, you must specify at least -g, -p, or -s. You can specify any combination of these options. You can also specify -m (the fifth form) with any set of the -g, -p, and -s options. If you specify more than one of these options, `netstat` displays the information for each one of them.

Interface Status (Sixth  
Form)

The interface status display lists information for all current interfaces, one interface per line. If an interface is specified using the -I option, it displays information for only the specified interface.

The list consists of the interface name, `mtu` (maximum transmission unit, or maximum packet size)(see [ifconfig\(1M\)](#)), the network to which the interface is attached, addresses for each interface, and counter associated with the interface. The counters show the number of input

packets, input errors, output packets, output errors, and collisions, respectively. For Point-to-Point interfaces, the Net/Dest field is the name or address on the other side of the link.

If the `-a` option is specified with either the `-i` option or the `-I` option, then the output includes names of the physical interface(s), counts for input packets and output packets for each logical interface, plus additional information.

If the `-n` option is specified, the list displays the IP address instead of the interface name.

If an optional *interval* is specified, the output will be continually displayed in *interval* seconds until interrupted by the user or until *count* is reached. See OPERANDS.

The physical interface is specified using the `-I` option. When used with the *interval* operand, output for the `-I` option has the following format:

input	eri0	output			input	(Total)	output		
packets	errs	packets	errs	colls	packets	errs	packets	errs	colls
227681	0	659471	1	502	261331	0	99597	1	502
10	0	0	0	0	10	0	0	0	0
8	0	0	0	0	8	0	0	0	0
10	0	2	0	0	10	0	2	0	0

If the input interface is not specified, the first interface of address family `inet` or `inet6` will be displayed.

#### Routing Table (Seventh Form)

The routing table display lists the available routes and the status of each. Each route consists of a destination host or network, and a gateway to use in forwarding packets. The *flags* column shows the status of the route. These flags are as follows:

- U Indicates route is up.
- G Route is to a gateway.
- H Route is to a host and not a network.
- M Redundant route established with the `-multirt` option.
- S Route was established using the `-setsrc` option.
- D Route was created dynamically by a redirect.
- B Packets will be silently dropped (RTF\_BLACKHOLE set).
- R Packets will be dropped with ICMP error sent (RTF\_REJECT set).
- I Indirect routes (gateway not directly reachable) established with the `-indirect` option.
- Z (non-global exclusive-IP zone only) The route was statically added on boot based on routing information configured using `zonecfg(1M)` in the global zone.

If the `-a` option is specified, there will be routing entries with the following flags:

- b Broadcast addresses.
- C Clones interface host route entries for on-link destinations.
- L Local addresses for the host.

Interface routes are created for each interface attached to the local host; the gateway field for such entries shows the address of the outgoing interface.

The use column displays the number of packets sent or forwarded using the route in question.

The *interface* entry indicates the network interface utilized for the route.

Multicast Routing  
Tables (Eighth Form)

The multicast routing table consists of the virtual interface table and the actual routing table.

DHCP Interface  
Information (Ninth  
Form)

The DHCP interface information consists of the interface name, its current state, lease information, packet counts, and a list of flags.

The states correlate with the specifications set forth in *RFC 2131*.

Lease information includes:

- when the lease began;
- when lease renewal will begin; and
- when the lease will expire.

The flags currently defined include:

**BOOTP** The interface has a lease obtained through BOOTP (IPv4 only).

**BUSY** The interface is busy with a DHCP transaction.

**PRIMARY** The interface is the primary interface. See `dhcplease(1)` and `ifconfig(1M)`.

**FAILED** The interface is in failure state and must be manually restarted.

Packet counts are maintained for the number of packets sent, the number of packets received, and the number of lease offers declined by the DHCP client. All three counters are initialized to zero and then incremented while obtaining a lease. The counters are reset when the period of lease renewal begins for the interface. Thus, the counters represent either the number of packets sent, received, and declined while obtaining the current lease, or the number of packets sent, received, and declined while attempting to obtain a future lease.

Destination Cache  
Entry Table (Tenth  
Form)

The destination cache entry display shows the recorded path MTU, the age (in seconds) of the entry, and flags. The P flag indicates that a path MTU is recorded. The S flag indicates that the path MTU is smaller than the minimum that IP will allow. The U flag indicates that some transport metrics (round-trip time, and so forth) are cached in the destination cache entry.

**Files** /etc/default/inet\_type    DEFAULT\_IP setting

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [arp\(1M\)](#), [dhcpcinfo\(1\)](#), [dhcpcagent\(1M\)](#), [ifconfig\(1M\)](#), [iostat\(1M\)](#), [kstat\(1M\)](#), [mibiisa\(1M\)](#), [savecore\(1M\)](#), [vmstat\(1M\)](#), [zonecfg\(1M\)](#), [hosts\(4\)](#), [inet\\_type\(4\)](#), [networks\(4\)](#), [protocols\(4\)](#), [services\(4\)](#), [attributes\(5\)](#), [dhcp\(5\)](#), [kstat\(7D\)](#), [inet\(7P\)](#), [inet6\(7P\)](#)

Droms, R., *RFC 2131, Dynamic Host Configuration Protocol*, Network Working Group, March 1997.

Droms, R. *RFC 3315, Dynamic Host Configuration Protocol for IPv6 (DHCPv6)*. Cisco Systems. July 2003.

**Notes** When displaying interface information, `netstat` honors the `DEFAULT_IP` setting in `/etc/default/inet_type`. If it is set to `IP_VERSION4`, then `netstat` will omit information relating to IPv6 interfaces, statistics, connections, routes and the like.

However, you can override the `DEFAULT_IP` setting in `/etc/default/inet_type` on the command-line. For example, if you have used the command-line to explicitly request IPv6 information by using the `inet6` address family or one of the IPv6 protocols, it will override the `DEFAULT_IP` setting.

If you need to examine network status information following a kernel crash, use the [mdb\(1\)](#) utility on the [savecore\(1M\)](#) output.

The `netstat` utility obtains TCP statistics from the system by opening `/dev/tcp` and issuing queries. Because of this, `netstat` might display an extra, unused connection in IDLE state when reporting connection status.

Previous versions of `netstat` had undocumented methods for reporting kernel statistics published using the [kstat\(7D\)](#) facility. This functionality has been removed. Use [kstat\(1M\)](#) instead.

`netstat` restricts its output to information that is relevant to the zone in which `netstat` runs. (This is true for both shared-IP and exclusive-IP zones.)

**Name** netstrategy – return network configuration information

**Synopsis** /sbin/netstrategy

**Description** The netstrategy command determines the network configuration strategy in use on a system and returns information in a form that is easily consumable by a script. The command returns three tokens:

*<root filesystem type>* *<primary interface>* *<network config strategy>*

These tokens are described as follows:

*<root filesystem type>*

Type of filesystem that contains the bootable kernel, as would be specified in the *fstype* column of the [mnttab\(4\)](#).

*<primary interface>*

Name of the primary network interface. For a diskless machine, this is the interface used to load the kernel.

*<network config strategy>*

The means by which a system obtains its IP address for booting. This can be one of rarp, dhcp, or none.

The netstrategy command is not intended for use on a command line.

**Options** The netstrategy command has no options.

**Exit Status** 0 Success.  
!=0 An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs
Interface Stability	Committed

**See Also** [ifconfig\(1M\)](#), [mnttab\(4\)](#), [attributes\(5\)](#)

**Name** newaliases – rebuild the data base for the mail aliases file

**Synopsis** newaliases

**Description** newaliases rebuilds the random access data base for the mail aliases file `/etc/mail/aliases`.

newaliases accepts all the flags that [sendmail\(1M\)](#) accepts. However, most of these flags have no effect, except for the `-C` option and three of the Processing Options that can be set from a configuration file with the `-o` option:

<code>-C /path/to/alt/config/file</code>	Use alternate configuration file.
<code>-oAfile</code>	Specify possible alias files.
<code>-oLn</code>	Set the default log level to <i>n</i> . Defaults to 9.
<code>-on</code>	Validate the RHS of aliases when rebuilding the <a href="#">aliases(4)</a> database.

newaliases runs in verbose mode (`-v` option) automatically.

**Examples** EXAMPLE 1 Running the newaliases Command

The following command runs newaliases on an alias file different from the `/etc/mail/aliases` default in [sendmail\(1M\)](#):

```
example% newaliases -oA/path/to/alternate/alias/file
```

**Exit Status** newaliases returns an exit status describing what it did. The codes are defined in `/usr/include/sysexits.h`.

EX_OK	Successful completion on all addresses.
EX_NOUSER	User name not recognized.
EX_UNAVAILABLE	Catchall. Necessary resources were not available.
EX_SYNTAX	Syntax error in address.
EX_SOFTWARE	Internal software error, including bad arguments.
EX_OSERR	Temporary operating system error, such as “cannot fork”.
EX_NOHOST	Host name not recognized.
EX_TEMPFAIL	Message could not be sent immediately, but was queued.

<b>Files</b>	<code>/etc/aliases</code>	Symbolic link to <code>/etc/mail/aliases</code>
	<code>/etc/mail/aliases.pag</code>	
	<code>/etc/mail/aliases.dir</code>	ndbm files maintained by newaliases
	<code>/etc/mail/aliases.db</code>	Berkeley DataBase file maintained by newaliases

---

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/smtp/sendmail

**See Also** [sendmail\(1M\)](#), [aliases\(4\)](#), [attributes\(5\)](#)

**Name** newfs – construct a UFS file system

**Synopsis** newfs [-NSBTv] [*mkfs-options*] *raw-device*

**Description** newfs is a "friendly" front-end to the [mkfs\(1M\)](#) program for making UFS file systems on disk partitions. newfs calculates the appropriate parameters to use and calls mkfs.

If run interactively (that is, standard input is a tty), newfs prompts for confirmation before making the file system.

If the -N option is not specified and the inodes of the device are not randomized, newfs calls [fsirand\(1M\)](#).

You must be super-user or have appropriate write privileges to use this command, except when creating a UFS file system on a *diskette*. See EXAMPLES.

Creating a Multiterabyte UFS File System

Keep the following limitations in mind when creating a multiterabyte UFS file system:

- *nbpi* is set to 1 Mbyte unless you specifically set it higher. You cannot set *nbpi* lower than 1 Mbyte on a multiterabyte UFS file system.
- *fragsize* is set equal to *bsize*.

**Options** The following options are supported:

-N

Print out the file system parameters that would be used to create the file system without actually creating the file system. [fsirand\(1M\)](#) is not called here.

-S

Sends to stdout a human-readable version of the superblock that would be used to create a filesystem with the specified configuration parameters.

-B

Sends to stdout a binary (machine-readable) version of the superblock that would be used to create a filesystem with the specified configuration parameters.

-T

Set the parameters of the file system to allow eventual growth to over a terabyte in total file system size. This option sets  *fragsize* to be the same as *bsize*, and sets *nbpi* to 1 Mbyte, unless the -i option is used to make it even larger. If you use the -f or -i options to specify a  *fragsize* or *nbpi* that is incompatible with this option, the user-supplied value of  *fragsize* or *nbpi* is ignored.

-v

Verbose. newfs prints out its actions, including the parameters passed to mkfs.

*mkfs-options*

Options that override the default parameters are:

**-a *apc***

The number of alternate sectors per cylinder to reserve for bad block replacement for SCSI devices only. The default is 0.

This option is not applicable for disks with EFI labels and is ignored.

**-b *bsize***

The logical block size of the file system in bytes, either 4096 or 8192. The default is 8192. The sun4u architecture does not support the 4096 block size.

**-c *cgsize***

The number of cylinders per cylinder group, ranging from 16 to 256. The default is calculated by dividing the number of sectors in the file system by the number of sectors in a gigabyte. Then, the result is multiplied by 32. The default value is always between 16 and 256.

mkfs can override this value. See [mkfs\\_ufs\(1M\)](#) for details.

This option is not applicable for disks with EFI labels and is ignored.

**-C *maxcontig***

The maximum number of logical blocks, belonging to one file, that are allocated contiguously. The default is calculated as follows:

$$\text{maxcontig} = \text{disk drive maximum transfer size} / \text{disk block size}$$

If the disk drive's maximum transfer size cannot be determined, the default value for `maxcontig` is calculated from kernel parameters as follows:

If `maxphys` is less than `ufs_maxmaxphys`, which is typically 1 Mbyte, then `maxcontig` is set to `maxphys`. Otherwise, `maxcontig` is set to `ufs_maxmaxphys`.

You can set `maxcontig` to any positive integer value.

The actual value will be the lesser of what has been specified and what the hardware supports.

You can subsequently change this parameter by using [tunefs\(1M\)](#).

**-d *gap***

Rotational delay. This option is obsolete in the Solaris 10 release. The value is always set to 0, regardless of the input value.

**-f *fragsize***

The smallest amount of disk space in bytes that can be allocated to a file. *fragsize* must be a power of 2 divisor of *bsize*, where:

$\text{bsize} / \text{fragsize}$  is 1, 2, 4, or 8.

This means that if the logical block size is 4096, legal values for *fragsize* are 512, 1024, 2048, and 4096. When the logical block size is 8192, legal values are 1024, 2048, 4096, and 8192. The default value is 1024.

For file systems greater than 1 terabyte or for file systems created with the *-T* option, *fragsize* is forced to match block size (*bsize*).

*-i nbpi*

The number of bytes per inode, which specifies the density of inodes in the file system. The number is divided into the total size of the file system to determine the number of inodes to create.

This value should reflect the expected average size of files in the file system. If fewer inodes are desired, a larger number should be used. To create more inodes, a smaller number should be given. The default for *nbpi* is as follows:

Disk size	Density
Less than 1GB	2048
Less than 2GB	4096
Less than 3GB	6144
3GB to 1 Tbyte	8192
Greater than 1 Tbyte or created with <i>-T</i>	1048576

The number of inodes can increase if the file system is expanded with the *growfs* command.

*-m free*

The minimum percentage of free space to maintain in the file system, between 0% and 99%, inclusively. This space is off-limits to users. Once the file system is filled to this threshold, only the super-user can continue writing to the file system.

The default is  $((64 \text{ Mbytes/partition size}) * 100)$ , rounded down to the nearest integer and limited between 1% and 10%, inclusively.

This parameter can be subsequently changed using the [tunefs\(1M\)](#) command.

*-n nrpos*

The number of different rotational positions in which to divide a cylinder group. The default is 8.

This option is not applicable for disks with EFI labels and is ignored.

*-o space | time*

The file system can either be instructed to try to minimize the *time* spent allocating blocks, or to try to minimize the *space* fragmentation on the disk. The default is *time*.

This parameter can subsequently be changed with the [tunefs\(1M\)](#) command.

**-r rpm**

The rotational speed of the disk in revolutions per minute. The default is driver- or device-specific.

Note that you specify *rpm* for *newfs* and *rps* for *mkfs*.

This option is not applicable for disks with EFI labels and is ignored.

**-s size**

The size of the file system in sectors. The default is to use the entire partition.

**-t ntrack**

The number of tracks per cylinder on the disk. The default is taken from the disk label.

This option is not applicable for disks with EFI labels and is ignored.

**Operands** The following operands are supported:

*raw-device*

The name of a raw special device residing in the `/dev` directory (for example, `/dev/rdisk/c0t0d0s6`) on which to create the file system.

**Usage** See [largefile\(5\)](#) for the description of the behavior of *newfs* when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

**Examples** **EXAMPLE 1** Displaying the Parameters for the Raw Special Device

The following example verbosely displays the parameters for the raw special device, `c0t0d0s6`. It does not actually create a new file system:

```
example# newfs -Nv /dev/rdisk/c0t0d0s6
mkfs -F ufs -o N /dev/rdisk/c0t0d0s6 1112940 54 15 8192 1024 16 10 60
2048 t 0 -1 8 /dev/rdisk/c0t0d0s6: 1112940 sectors in
1374 cylinders of 15 tracks, 54 sectors 569.8MB in 86 cyl
groups (16 c/g, 6.64MB/g, 3072 i/g) super-block backups
(for fsck -b #) at:
32, 13056, 26080, 39104, 52128, 65152, 78176, 91200, 104224, . . .
```

**EXAMPLE 2** Creating a UFS File System

The following example creates a UFS file system on a diskette that is managed by a volume manager that makes use of the mount point `/vol`.

```
example% newfs /vol/dev/aliases/floppy0
newfs: construct a new file system /vol/dev/aliases/floppy0: (y/n)? y
/vol/dev/aliases/floppy0: 2880 sectors in 80 cylinders of 2 tracks,
18 sectors 1.4MB in 5 cyl groups (16 c/g, 0.28MB/g, 128 i/g)
super-block backups (for fsck -F ufs -o b=#) at:
32, 640, 1184, 1792, 2336, . . .
```

**EXAMPLE 3** Creating a UFS File System That Will Eventually Be Grown to a Multiterabyte UFS File System

The following example creates a UFS file system that will eventually be grown to a multiterabyte UFS file system.

This command creates a 800-Gbyte file system on the volume, `/dev/md/rdisk/d99`.

```
newfs -T /dev/md/rdisk/d99
newfs: construct a new file system /dev/md/rdisk/d99: (y/n)? y
/dev/md/rdisk/d99: 1677754368 sectors in 45512 cylinders of
144 tracks, 256 sectors
819216.0MB in 1821 cyl groups (25 c/g, 450.00MB/g, 448 i/g) . . .
```

Then, if you increase the volume size for this file system, you can use the `growfs` command to expand the file system. The file system is grown to 1.2 terabytes in this example:

```
growfs -v /dev/md/rdisk/d99
/usr/lib/fs/ufs/mkfs -G /dev/md/rdisk/d99 2516631552 /dev/md/rdisk/d99:
2516631552 sectors in 68268 cylinders of 144 tracks, 256 sectors
1228824.0MB in 2731 cyl groups (25 c/g, 450.00MB/g, 448 i/g) . . .
```

**Exit Status** The following exit values are returned:

0

The operation was successful.

1, 10

Usage error or internal error. A message is output to `STDERR` explaining the error.

Other exit values may be returned by `mkfs(1M)`, which is called by `newfs`.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [fsck\(1M\)](#), [fsck\\_ufs\(1M\)](#), [fsirand\(1M\)](#), [mkfs\(1M\)](#), [mkfs\\_ufs\(1M\)](#), [tunefs\(1M\)](#), [attributes\(5\)](#), [largefile\(5\)](#), [ufs\(7FS\)](#)

**Diagnostics** `newfs`: No such file or directory  
The device specified does not exist, or a disk partition was not specified.

*special*: cannot open

You must write access to the device to use this command.

**Name** newkey – create a new Diffie-Hellman key pair in the publickey database

**Synopsis** newkey -h *hostname* [-s nis | files | ldap]  
 newkey -u *username* [-s nis | files | ldap]

**Description** newkey establishes new public keys for users and machines on the network. These keys are needed when using secure RPC or secure NFS service.

newkey prompts for a password for the given *username* or *hostname* and then creates a new public/secret Diffie-Hellman 192 bit key pair for the user or host. The secret key is encrypted with the given password. The key pair can be stored in the `/etc/publickey` file or the NIS `publickey` map.

newkey consults the `publickey` entry in the name service switch configuration file (see [nsswitch.conf\(4\)](#)) to determine which naming service is used to store the secure RPC keys. If the `publickey` entry specifies a unique name service, newkey will add the key in the specified name service. However, if there are multiple name services listed, newkey cannot decide which source to update and will display an error message. The user is required to specify the source explicitly with the `-s` option.

In the case of NIS, newkey should be run by the superuser on the master NIS server for that domain.

In the case of LDAP, newkey should be run by the superuser on a machine that also recognizes the directory manager's bind distinguished name (DN) and password to perform an LDAP update for the host.

**Options**

- h *hostname* Create a new public/secret key pair for the privileged user at the given *hostname*. Prompts for a password for the given *hostname*.
- u *username* Create a new public/secret key pair for the given *username*. Prompts for a password for the given *username*.
- s nis
- s files
- s ldap Update the database in the specified source: `nis` (for NIS), `files`, or `ldap` (LDAP). Other sources may be available in the future.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [chkey\(1\)](#), [keylogin\(1\)](#), [nsswitch.conf\(4\)](#), [publickey\(4\)](#), [attributes\(5\)](#)

**Name** nfs4cbd – NFS Version 4 callback daemon

**Synopsis** /usr/lib/nfs/nfs4cbd

**Description** The nfs4cbd daemon manages communication endpoints for the NFS Version 4 protocol callback program. nfs4cbd runs on the NFS Version 4 client and creates a listener port for each transport over which callbacks can be sent.

The nfs4cbd daemon is provided for the exclusive use of the NFS version 4 client.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/nfs

**See Also** [svcs\(1\)](#), [mount\\_nfs\(1M\)](#), [svcadm\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#)

**Notes** The nfs4cbd service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/nfs/cbd
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

If it is disabled, it will be enabled by [mount\\_nfs\(1M\)](#) and [automountd\(1M\)](#) on the first NFSv4 mount, unless its `application/auto_enable` property is set to `false`.

This daemon might not exist in a future release of Solaris.

---

<b>Name</b>	nfsd – NFS daemon
<b>Synopsis</b>	<code>/usr/lib/nfs/nfsd [-a] [-c #_conn] [-l listen_backlog] [-p protocol] [-t device] [nservers]</code>
<b>Description</b>	<p>nfsd is the daemon that handles client file system requests. Only users with {PRIV_SYS_NFS} and sufficient privileges to write to /var/run can run this daemon.</p> <p>The nfsd daemon is automatically invoked using <a href="#">share(1M)</a> with the -a option.</p> <p>By default, nfsd starts over the TCP and UDP transports for versions 2 and 3. By default, it starts over the TCP for version 4. You can change this with the -p option.</p> <p>A previously invoked nfsd daemon started with or without options must be stopped before invoking another nfsd command.</p> <p>To change startup parameters for nfsd, use the <a href="#">sharectl(1M)</a> and <a href="#">sharemgr(1M)</a> commands.</p>
<b>SMF Management</b>	<p>The nfsd service is managed by the service management facility, <a href="#">smf(5)</a>, under the service identifier:</p> <pre>svc:/network/nfs/server</pre> <p>Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using <a href="#">svcadm(1M)</a>. The service's status can be queried using the <a href="#">svcs(1)</a> command.</p> <p>If nfsd is killed with SIGTERM, it will not be restarted by the service management facility. Instead, nfsd can be restarted by other signals, such as SIGINT.</p> <p>The <a href="#">sharectl(1M)</a> command can be used to manage all the parameters related to nfsd. The following are the parameters currently supported:</p> <pre>server_versmax=num server_versmin=num</pre> <p>The NFS server only uses NFS versions in the range specified by these variables. Valid values or versions are: 2, 3, and 4. As with the client, the default is to leave these variables commented out and the default minimum version is 2, while the default maximum version is 4.</p> <pre>server_delegation=on   off</pre> <p>By default, this variable is on and the NFS server provides delegations to clients. The user can turn off delegations for all exported file systems by setting this variable to off (case-sensitive). This variable applies only to NFS Version 4.</p> <pre>max_connections=num</pre> <p>Sets the maximum number of concurrent, connection-oriented connections. The default is unlimited and is obtained by setting to -1. Equivalent to the -c option in nfsd.</p>

`listen_backlog=num`

Set connection queue length for the NFS over a connection-oriented transport. The default value is 32, meaning 32 entries in the queue. Equivalent to the `-l` option in `nfsd`.

`protocol=ALL`

Start `nfsd` over the specified protocol only. Equivalent to the `-p` option in `nfsd`. `ALL` is equivalent to `-a` on the `nfsd` command line. Mutually exclusive of NFS SMF parameter `device`. One or the other of NFS SMF parameters `device` and `protocol` must not be set. If both are set, the `nfs/server` service goes into maintenance mode. For the UDP protocol, only version 2 and version 3 service is established. NFS Version 4 is not supported for the UDP protocol. Equivalent to the `-p` option.

`device=devname`

Start NFS daemon for the transport specified by the specified device only. Equivalent to the `-t` option in `nfsd`. Mutually exclusive of NFS SMF parameter `protocol`. One or the other of NFS SMF parameters `device` and `protocol` must not be set.

`servers=num`

Maximum number of concurrent NFS requests. Equivalent to last numeric argument on the `nfsd` command line. The default is 16. Equivalent to the `nservers` operand.

See **EXAMPLES**, below.

**Options** The following options are supported:

- `-a` Start an NFS daemon over all available connectionless and connection-oriented transports, including UDP and TCP. Equivalent of setting the `protocol` parameter to `ALL` in the SMF for NFS using the `sharectl(1M)` command.
- `-c #_conn` This sets the maximum number of connections allowed to the NFS server over connection-oriented transports. By default, the number of connections is unlimited. Equivalent of the `max_connections` parameter in the SMF for NFS using the `sharectl(1M)` command.
- `-l` Set connection queue length for the NFS TCP over a connection-oriented transport. The default value is 32 entries. Equivalent of the `listen_backlog` parameter in the SMF for NFS using the `sharectl(1M)` command.
- `-p protocol` Start a NFS daemon over the specified protocol. Equivalent of the `protocol` parameter in the SMF for NFS using the `sharectl(1M)` command.
- `-t device` Start a NFS daemon for the transport specified by the given device. Equivalent of the `device` parameter in the SMF for NFS using the `sharectl(1M)` command.

**Operands** The following operands are supported:

*nservers* This sets the maximum number of concurrent NFS requests that the server can handle. This concurrency is achieved by up to *nservers* threads created as needed in the kernel. *nservers* should be based on the load expected on this server. 16 is the usual number of *nservers*. If *nservers* is not specified, the maximum number of concurrent NFS requests will default to 1. Equivalent of the *servers* parameter in the SMF for NFS using the `sharectl(1M)` command.

**Usage** If the `NFS_PORTMON` variable is set in `/etc/system`, then clients are required to use privileged ports (ports < `IPPORT_RESERVED`) to get NFS services. This variable is equal to zero by default. This variable has been moved from the “`nfs`” module to the “`nfssrv`” module. To set the variable, edit the `/etc/system` file and add this entry:

```
set nfssrv:nfs_portmon = 1
```

**Examples** EXAMPLE 1 Turning Off Delegation

The `nfsd` properties specified in these examples are described under “SMF Management,” above.

Delegation is an NFSv4 feature in which the server delegates the management of a file to a client. For example, the server could grant (or not grant) either a read delegation or a write delegation to a client. The following command does this, setting the `server_delegation` property to `off`.

```
sharectl set -p server_delegation=off nfs
```

EXAMPLE 2 Determining Value of Delegation

The following command obtains the current value of the `server_delegation` property.

```
sharectl get -p server_delegation nfs
delegation=off
```

EXAMPLE 3 Setting Maximum Number of Concurrent Requests

The following command sets the maximum number of concurrent NFS requests.

```
sharectl set -p servers=32 nfs
```

EXAMPLE 4 Setting Connection Queue Length

The following command sets the maximum queue length for the NFS over a connection-oriented transport.

```
sharectl set -p listen_backlog=48 nfs
```

**Exit Status** 0 Daemon started successfully.  
1 Daemon failed to start.

**Files** `.nfsXXX` Client machine pointer to an open-but-unlinked file.  
`/etc/system` System configuration information file.  
`/var/nfs/v4_state`  
`/var/nfs/v4_oldstate` Directories used by the server to manage client state information.  
These directories should not be removed.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/file-system/nfs

**See Also** [ps\(1\)](#), [svcs\(1\)](#), [mountd\(1M\)](#), [share\(1M\)](#), [sharectl\(1M\)](#), [sharemgr\(1M\)](#), [svcadm\(1M\)](#), [sharetab\(4\)](#), [system\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

*System Administration Guide: Network Services*

**Notes** Manually starting and restarting `nfsd` is not recommended. If it is necessary to do so, use `svcadm` to enable or disable the `nfs` service (`svc:/network/nfs/server`). If it is disabled, it will be enabled by [share\\_nfs\(1M\)](#), unless its `application/auto_enable` property is set to `false`. See the *System Administration Guide: Network Services*, and [svcadm\(1M\)](#) for more information.

- 
- Name** nfslogd – nfs logging daemon
- Synopsis** /usr/lib/nfs/nfslogd
- Description** The `nfslogd` daemon provides operational logging to the Solaris NFS server. It is the `nfslogd` daemon's job to generate the activity log by analyzing the RPC operations processed by the NFS server. The log will only be generated for file systems exported with logging enabled. This is specified at file system export time by means of the `share_nfs(1M)` command.

NFS server logging is not supported on Solaris machines that are using NFS Version 4.

Each record in the log file includes a time stamp, the IP address (or hostname if it can be resolved) of the client system, the file or directory name the operation was performed on, and the type of operation. In the basic format, the operation can either be an input (i) or output (o) operation. The basic format of the NFS server log is compatible with the log format generated by the Washington University FTPd daemon. The log format can be extended to include directory modification operations, such as `mkdir`, `rmdir`, and `remove`. The extended format is not compatible with the Washington University FTPd daemon format. See `nfslog.conf(4)` for details.

The NFS server logging mechanism is divided in two phases. The first phase is performed by the NFS kernel module, which records raw RPC requests and their results in work buffers backed by permanent storage. The location of the work buffers is specified in the `/etc/nfs/nfslog.conf` file. Refer to `nfslog.conf(4)` for more information. The second phase involves the `nfslogd` user-level daemon, which periodically reads the work buffers, interprets the raw RPC information, groups related RPC operations into single transaction records, and generates the output log. The `nfslogd` daemon then sleeps waiting for more information to be logged to the work buffers. The amount of time that the daemon sleeps can be configured by modifying the `IDLE_TIME` parameter in `/etc/default/nfslogd`. The work buffers are intended for internal consumption of the `nfslogd` daemon.

NFS operations use file handles as arguments instead of path names. For this reason the `nfslogd` daemon needs to maintain a database of file handle to path mappings in order to log the path name associated with an operation instead of the corresponding file handle. A file handle entry is added to the database when a client performs a lookup or other NFS operation that returns a file handle to the client.

Once an NFS client obtains a file handle from a server, it can hold on to it for an indefinite time, and later use it as an argument for an NFS operation on the file or directory. The NFS client can use the file handle even after the server reboots. Because the database needs to survive server reboots, it is backed by permanent storage. The location of the database is specified by the `htable` parameter in the `/etc/nfs/nfslog.conf` file. This database is intended for the internal use of the `nfslogd` daemon.

In order to keep the size of the file handle mapping database manageable, `nfslogd` prunes the database periodically. It removes file handle entries that have not been accessed in more than a specified amount of time. The `PRUNE_TIMEOUT` configurable parameter in

`/etc/default/nfslogd` specifies the interval length between successive runs of the pruning process. A file handle record will be removed if it has not been used since the last time the pruning process was executed. Pruning of the database can effectively be disabled by setting the `PRUNE_TIMEOUT` as high as `INT_MAX`.

When pruning is enabled, there is always a risk that a client may have held on to a file handle longer than the `PRUNE_TIMEOUT` and perform an NFS operation on the file handle after the matching record in the mapping database had been removed. In such case, the pathname for the file handle will not be resolved, and the log will include the file handle instead of the pathname.

There are various configurable parameters that affect the behavior of the `nfslogd` daemon. These parameters are found in `/etc/default/nfslogd` and are described below:

<code>UMASK</code>	Sets the file mode for the log files, work buffer files and file handle mapping database.
<code>MIN_PROCESSING_SIZE</code>	Specifies the minimum size, in bytes, that the buffer file must reach before processing the work information and writing to the log file. The value of <code>MIN_PROCESSING_SIZE</code> must be between 1 and <code>ulimit</code> .
<code>IDLE_TIME</code>	Specifies the amount of time, in seconds, the daemon should sleep while waiting for more information to be placed in the buffer file. <code>IDLE_TIME</code> also determines how often the configuration file will be reread. The value of <code>IDLE_TIME</code> must be between 1 and <code>INT_MAX</code> .
<code>MAX_LOGS_PRESERVE</code>	The <code>nfslogd</code> periodically cycles its logs. <code>MAX_LOGS_PRESERVE</code> specifies the maximum number of log files to save. When <code>MAX_LOGS_PRESERVE</code> is reached, the oldest files will be overwritten as new log files are created. These files will be saved with a numbered extension, beginning with <code>filename.0</code> . The oldest file will have the highest numbered extension up to the value configured for <code>MAX_LOGS_PRESERVE</code> . The value of <code>MAX_LOGS_PRESERVE</code> must be between 1 and <code>INT_MAX</code> .
<code>CYCLE_FREQUENCY</code>	Specifies how often, in hours, the log files are cycled. <code>CYCLE_FREQUENCY</code> is used to insure that the log files do not get too large. The value of <code>CYCLE_FREQUENCY</code> must be between 1 and <code>INT_MAX</code> .
<code>MAPPING_UPDATE_INTERVAL</code>	Specifies the time interval, in seconds, between updates of the records in the file handle to path mapping tables. Instead of updating the <code>atime</code> of a record each time that record is accessed, it is only updated if it has aged based on this

parameter. The record access time is used by the pruning routine to determine whether the record should be removed from the database. The value of this parameter must be between 1 and INT\_MAX.

PRUNE\_TIMEOUT

Specifies when a database record times out, in hours. If the time that elapsed since the record was last accessed is greater than PRUNE\_TIMEOUT then the record can be pruned from the database. The default value for PRUNE\_TIMEOUT is 168 hours (7 days). The value of PRUNE\_TIMEOUT must be between 1 and INT\_MAX.

**Exit Status** The following exit values are returned:

0 Daemon started successfully.

1 Daemon failed to start.

**Files** /etc/nfs/nfslogtab

/etc/nfs/nfslog.conf

/etc/default/nfslogd

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/file-system/nfs

**See Also** [share\\_nfs\(1M\)](#), [nfslog.conf\(4\)](#), [attributes\(5\)](#)

**Name** nfsmapid – NFS user and group id mapping daemon

**Synopsis** /usr/lib/nfs/nfsmapid

**Description** The `nfsmapid` daemon maps to and from NFS version 4 owner and owner\_group identification attributes and local UID and GID numbers used by both the NFS version 4 client and server.

`nfsmapid` uses the `passwd` and `group` entries in the `/etc/nsswitch.conf` file to direct how it performs the mappings.

The `nfsmapid` daemon has no external, customer-accessible interfaces. You can, however, administratively configure `nfsmapid` in one of the following ways:

- Specify the `nfsmapid_domain` parameter in the SMF for NFS using the [sharectl\(1M\)](#) command.
- Specify the `_nfsv4idmapdomain` DNS resource record.

Please refer to the *System Administration Guide: Network Services* [System Administration Guide: Network Services](#) for further details.

**SMF Management** The `nfsmapid` service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/nfs/mapid
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

If it is disabled, it will be enabled by [mount\\_nfs\(1M\)](#), [share\\_nfs\(1M\)](#), and [automountd\(1M\)](#), unless its `application/auto_enable` property is set to `false`.

`nfsmapid` caches a user's UID and GID. If a user subsequently changes a UID or GID, using one of the utilities listed below, the `nfsmapid` cache becomes stale. At this point, any NFS operation that gets or set attributes will result in the exchange of this stale information. To resolve this situation, restart `nfsmapid`, as follows:

```
svcadm restart svc:/network/nfs/mapid:default
```

The startup SMF parameter designating a domain name (`nfsmapid_domain`) can be manipulated with the [sharectl\(1M\)](#) command.

`nfsmapid_domain`

The setting for the NFS SMF parameter `nfsmapid_domain` overrides the domain used by `nfsmapid` for building and comparing outbound and inbound attribute strings, respectively. Also, this setting overrides any other mechanism for setting the NFSv4 domain. In the absence of a `nfsmapid_domain` setting, the `nfsmapid` daemon determines the NFSv4 domain as follows:

- If a properly configured `/etc/resolv.conf` (see [`resolv.conf\(4\)`](#)) exists, `nfsmapid` queries specified nameserver(s) for the domain.
- If a properly configured `/etc/resolv.conf` (see [`resolv.conf\(4\)`](#)) exists, but the queried name server does not have a proper record of the domain name, `nfsmapid` attempts to obtain the domain name through the BIND interface (see [`resolver\(3RESOLV\)`](#)).
- If `/etc/resolv.conf` exists, `nfsmapid` falls back on using the configured domain name (see [`domainname\(1M\)`](#)), which is returned with the leading domain suffix removed. For example, for `widgets.sales.acme.com`, `sales.acme.com` is returned.
- If `/etc/resolv.conf` does not exist, no domain name has been configured (or no `/etc/defaultdomain` exists), `nfsmapid` falls back on obtaining the domain name from the host name, if the host name contains a fully qualified domain name (FQDN).

If a domain name is still not obtained following all of the preceding steps, `nfsmapid` will have no domain configured. This results in the following behavior:

- Outbound `owner` and `owner_group` attribute strings are encoded as literal ID's. For example, the UID 12345 is encoded as 12345.
- `nfsmapid` ignores the domain portion of the inbound attribute string and performs name service lookups only for the user or group. If the user/group exists in the local system name service databases, then the proper UID/GID will be mapped even when no domain has been configured.

This behavior implies that the same administrative user/group domain exists between NFSv4 client and server (that is, the same UID/GIDs for users/groups on both client and server). In the case of overlapping ID spaces, the inbound attribute string could potentially be mapped to the wrong id. However, this is not functionally different from mapping the inbound string to nobody, yet provides greater flexibility. See [EXAMPLES](#), below.

The utilities that allow you to change UID and GID are:

- [`usermod\(1M\)`](#)
- [`userdel\(1M\)`](#)
- [`groupmod\(1M\)`](#)
- [`groupdel\(1M\)`](#)

#### Examples **EXAMPLE 1** Setting Domain Name

The following command uses `sharectl` to set the domain name.

```
sharectl set -p nfsmapid_domain=sun.com nfs
```

The `nfsmapid_domain` property is described under [NOTES](#), below.

#### **EXAMPLE 2** Obtaining Domain Name

The following command uses `sharectl` to obtain the current domain name.

**EXAMPLE 2** Obtaining Domain Name *(Continued)*

```
sharectl get -p nfsmapid_domain nfs
nfsmapid_domain=sun.com
```

Availability	system/file-system/nfs

**See Also** [svcs\(1\)](#), [automountd\(1M\)](#), [domainname\(1M\)](#), [groupdel\(1M\)](#), [groupmod\(1M\)](#), [mount\\_nfs\(1M\)](#), [svcadm\(1M\)](#), [share\\_nfs\(1M\)](#), [sharectl\(1M\)](#), [userdel\(1M\)](#), [usermod\(1M\)](#), [resolver\(3RESOLV\)](#), [resolv.conf\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

*System Administration Guide: Network Services*

**Notes** The `nfsmapid` daemon might not exist in a future release of Solaris.

**Name** nfsref – NFS referral utility

**Synopsis** `nfsref [-t svc_type] add path location [location ...]`  
`nfsref [-t svc_type] remove path`  
`nfsref [-t svc_type] lookup path`

**Description** The `nfsref` command manages NFS Version 4 referrals, which are server-side pointers used to redirect clients to actual locations of file systems. Referrals are based on reparse points (see [reparse\(1M\)](#) and [libreparse\(3LIB\)](#)). The path arguments in all forms of the synopsis refer to the path to the reparse point symbolic link. This command currently implements one “service type” - `nfs-basic`, which is the default.

The first form of the command, `nfsref add`, creates a referral pointing to the specified locations. If a reparse point does not exist, one is created. If it does exist, NFS service data is added or replaces existing NFS service data. Each location has a `host:/path` format. The path can contain spaces, which must be escaped to ensure proper shell parsing.

The second form of the command, `nfsref delete`, removes an NFS referral. It removes NFS service data from the specified reparse point, and removes the reparse point if there are no other types of service data present.

The third form of the command, `nfsref lookup`, displays the locations to which the specified NFS referral points.

**Options** The following options are supported:

`-t svc_type`  
Specify a service type. Currently, only `nfs-basic` is supported.

**Examples** **EXAMPLE 1** Adding an NFS Referral

The following command creates an NFS referral at the server path `/pool/home/bob`, pointing to the resource `homeserver:/homepool/bob`.

```
nfsref add /pool/home/bob homeserver:/homepool/bob
Created reparse point /pool/home/bob
```

```
nfsref lookup /pool/home/bob
homeserver:/homepool/bob
```

**EXAMPLE 2** Removing an NFS Referral

The following command removes an NFS referral at the server path `/pool/home/bob`.

```
nfsref remove /pool/home/bob homeserver:/homepool/bob
Removed svc_type 'nfs-basic' from /pool/home/bob
```

**Exit Status** 0  
Successful completion.

>0  
An error occurred.

**Files** /usr/lib/reparsed/\*.so.1  
Per-service plugins for reparsed.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/file-system/nfs
Interface Stability	Consolidation Private

**See Also** [reparsed\(1M\)](#), [libreparse\(3LIB\)](#), [attributes\(5\)](#)

**Name** nfsstat – NFS statistics

**Synopsis** nfsstat [-cnrsza] [-T u | d ] [-v *version*] [*interval* [*count*]]  
nfsstat -m [*pathname*]...

**Description** nfsstat displays statistical information about the NFS and RPC (Remote Procedure Call), interfaces to the kernel. It can also be used to reinitialize this information. If no options are given the default is as follows:

```
nfsstat -csnra
```

The default displays everything, but reinitializes nothing.

**Options** -a

Display NFS\_ACL information.

-c

Display client information. Only the client side NFS, RPC, and NFS\_ACL information is printed. Can be combined with the -n, -r, and -a options to print client side NFS, RPC, and NFS\_ACL information only.

-m [*pathname*...]

Display statistics for each NFS mounted file system. If *pathname* is not specified, displays statistics for all NFS mounted file systems. If *pathname* is specified, displays statistics for the NFS mounted file systems indicated by *pathname*.

This includes the server name and address, mount flags, current read and write sizes, the retransmission count, the attribute cache timeout values, failover information, and the timers used for dynamic retransmission. The dynamic retransmission timers are displayed only where dynamic retransmission is in use. By default, NFS mounts over the TCP protocols and NFS Version 3 mounts over either TCP or UDP do not use dynamic retransmission.

If you specify the -m option, this is the only option that nfsstat uses. If you specify other options with -m, you receive an error message alerting that the -m flag cannot be combined with other options.

-n

Display NFS information. NFS information for both the client and server side are printed. Can be combined with the -c and -s options to print client or server NFS information only.

-r

Display RPC information.

-s

Display server information.

-T u | d

Display a time stamp.

Specify *u* for a printed representation of the internal representation of time. See [time\(2\)](#).  
Specify *d* for standard date format. See [date\(1\)](#).

-v *version*

Specify which NFS version for which to print statistics. When followed by the optional *version* argument, (2|3|4), specifies statistics for that version. By default, prints statistics for all versions.

-z

Zero (reinitialize) statistics. This option is for use by the super user only, and can be combined with any of the above options to zero particular sets of statistics after printing them.

**Operands** The following operands are supported:

*count*

Display only count reports

*interval*

Report once each interval seconds.

*pathname*

Specify the pathname of a file in an NFS mounted file system for which statistics are to be displayed.

**Displays** The server RPC display includes the following fields:

*badcalls*

The total number of calls rejected by the RPC layer (the sum of *badlen* and *xdr call* as defined below).

*badlen*

The number of RPC calls with a length shorter than a minimum-sized RPC call.

*calls*

The total number of RPC calls received.

*dupchecks*

The number of RPC calls that looked up in the duplicate request cache.

*dupreqs*

The number of RPC calls that were found to be duplicates.

*nullrcv*

The number of times an RPC call was not available when it was thought to be received.

*xdr call*

The number of RPC calls whose header could not be XDR decoded.

The server NFS display shows the number of NFS calls received (*calls*) and rejected (*badcalls*), and the counts and percentages for the various calls that were made.

---

The server NFS\_ACL display shows the counts and percentages for the various calls that were made.

The client RPC display includes the following fields:

`calls`

The total number of RPC calls made.

`badcalls`

The total number of calls rejected by the RPC layer.

`badverfs`

The number of times the call failed due to a bad verifier in the response.

`badxids`

The number of times a reply from a server was received which did not correspond to any outstanding call.

`cantconn`

The number of times the call failed due to a failure to make a connection to the server.

`cantsend`

The number of times a client was unable to send an RPC request over a connectionless transport when it tried to do so.

`interrupts`

The number of times the call was interrupted by a signal before completing.

`newcreds`

The number of times authentication information had to be refreshed.

`nomem`

The number of times the call failed due to a failure to allocate memory.

`retrans`

The number of times a call had to be retransmitted due to a timeout while waiting for a reply from the server. Applicable only to RPC over connection-less transports.

`timeouts`

The number of times a call timed out while waiting for a reply from the server.

`timers`

The number of times the calculated time-out value was greater than or equal to the minimum specified time-out value for a call.

The client NFS display shows the number of calls sent and rejected, as well as the number of times a CLIENT handle was received (`clgets`), the number of times the CLIENT handle cache had no unused entries (`cltoomany`), as well as a count of the various calls and their respective percentages.

The client NFS\_ACL display shows the counts and percentages for the various calls that were made.

The `-m` option includes information about mount flags set by mount options, mount flags internal to the system, and other mount information. See [mount\\_nfs\(1M\)](#).

The following mount flags are set by mount options:

`forcedirectio`

Data transferred directly between client and server, with no buffering on client.

`grpuid`

BSD group id inheritance. See description in [mount\\_nfs\(1M\)](#).

`hard`

Hard mount.

`intr`

Interrupts allowed on hard mount.

`llock`

Local locking being used (no lock manager). Note that this is a private interface.

`noac`

Client is not caching attributes.

`nointr`

No interrupts allowed on hard mount.

`nocto`

No close-to-open consistency.

`retrans`

NFS retransmissions.

`rpctimesync`

RPC time sync.

`rsize`

Read buffer size in bytes.

`sec`

`sec` has one of the following values:

`dh`

des-style authentication (encrypted timestamps).

`krb5`

kerberos v5-style authentication.

`krb5i`

kerberos v5-style authentication with integrity.

`krb5p`  
kerberos v5-style authentication with privacy.

`none`  
No authentication.

`short`  
Short hand UNIX-style authentication.

`sys`  
UNIX-style authentication (UID, GID).

`soft`  
Soft mount.

`timeo`  
Initial NFS timeout, in tenths of a second.

`wsize`  
Write buffer size in bytes.

The following mount flags are internal to the system:

`acl`  
Server supports NFS\_ACL.

`down`  
Server is down.

`dynamic`  
Dynamic transfer size adjustment.

`link`  
Server supports links.

`mirrormount`  
Mounted automatically by means of the `mirrormount` mechanism.

`printed`  
“Not responding” message printed.

`readdironly`  
Use `readdir` instead of `readdirplus`.

`referral`  
Mounted automatically by means of the referral mechanism.

`symlink`  
Server supports symbolic links.

The following flags relate to additional mount information:

**proto**  
Protocol.

**vers**  
NFS version.

The **-m** option also provides attribute cache timeout values. The following fields in **-m** output provide timeout values for attribute cache:

**acdirmax**  
Maximum seconds to hold cached directory attributes.

**acdirmin**  
Minimum seconds to hold cached directory attributes.

**acregmax**  
Maximum seconds to hold cached file attributes.

**acregmin**  
Minimum seconds to hold cached file attributes.

The following fields in **-m** output provide failover information:

**currserver**  
Which server is currently providing NFS service. See the [System Administration Guide: IP Services](#) for additional details.

**failover**  
How many times a new server has been selected.

**noresponse**  
How many times servers have failed to respond.

**remap**  
How many times files have been re-evaluated to the new server.

The fields in **-m** output shown below provide information on dynamic retransmissions. These items are displayed only where dynamic retransmission is in use.

**cur**  
Current backed-off retransmission value, in milliseconds.

**dev**  
Estimated deviation, in milliseconds.

**srtt**  
The value for the smoothed round-trip time, in milliseconds.

**Exit Status** The following exit values are returned:

**0**  
Successful completion.

---

>0

An error occurred.

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

*System Administration Guide: IP Services*

**Name** nlsadmin – network listener service administration

**Synopsis** /usr/sbin/nlsadmin -x  
 /usr/sbin/nlsadmin [options] *net\_spec*  
 /usr/sbin/nlsadmin [options] -N *port\_monitor\_tag*  
 /usr/sbin/nlsadmin -V  
 /usr/sbin/nlsadmin -c *cmd* | -o *streamname* [-p *modules*]  
 [-A *address* | -D] [-R *prognum* : *versnum*]

**Description** nlsadmin is the administrative command for the network listener process(es) on a machine. Each network has at least one instance of the network listener process associated with it; each instance (and thus, each network) is configured separately. The listener process “listens” to the network for service requests, accepts requests when they arrive, and invokes servers in response to those service requests. The network listener process may be used with any network (more precisely, with any connection-oriented transport provider) that conforms to the transport provider specification.

nlsadmin can establish a listener process for a given network, configure the specific attributes of that listener, and start and kill the listener process for that network. nlsadmin can also report on the listener processes on a machine, either individually (per network) or collectively.

*net\_spec* represents a particular listener process. Specifically, *net\_spec* is the relative path name of the entry under /dev for a given network (that is, a transport provider). *address* is a transport address on which to listen and is interpreted using a syntax that allows for a variety of address formats. By default, *address* is interpreted as the symbolic ASCII representation of the transport address. An *address* preceded by \x will let you enter an address in hexadecimal notation. Note that *address* must appear as a single word to the shell, thus it must be quoted if it contains any blanks.

Changes to the list of services provided by the listener or the addresses of those services are put into effect immediately.

**Options** nlsadmin may be used with the following combinations of options and arguments:

-x	Report the status of all of the listener processes installed on this machine.
<i>net_spec</i>	Print the status of the listener process for <i>net_spec</i> .
-q <i>net_spec</i>	Query the status of the listener process for the specified network, and reflects the result of that query in its exit code. If a listener process is active, nlsadmin will exit with a status of 0; if no process is active, the exit code will be 1; the exit code will be greater than 1 in case of error.

- 
- `-v net_spec` Print a verbose report on the servers associated with *net\_spec*, giving the service code, status, command, and comment for each. It also specifies the *uid* the server will run as and the list of modules to be pushed, if any, before the server is started.
- `-z service_code net_spec` Print a report on the server associated with *net\_spec* that has service code *service\_code*, giving the same information as in the `-v` option.
- `-q -z service_code net_spec` Query the status of the service with service code *service\_code* on network *net\_spec*, and exits with a status of 0 if that service is enabled, 1 if that service is disabled, and greater than 1 in case of error.
- `-l address net_spec` Change or set the transport address on which the listener listens (the general listener service). This address can be used by remote processes to access the servers available through this listener (see the `-a` option, below).
- If *address* is just a dash (“-“), `nlsadmin` reports the address currently configured, instead of changing it.
- A change of address takes effect immediately.
- `-t address net_spec` Change or set the address on which the listener listens for requests for terminal service but is otherwise similar to the `-l` option above. A terminal service address should not be defined unless the appropriate remote login software is available; if such software is available, it must be configured as service code 1 (see the `-a` option, below).
- `-i net_spec` Initialize an instance of the listener for the network specified by *net\_spec*; that is, create and initialize the files required by the listener as well as starting that instance of the listener. Note that a particular instance of the listener should be initialized only once. The listener must be initialized before assigning addresses or services.
- `-a service_code` [ `-p modules` ] [ `-w name` ] `-c cmd -y comment net_spec`
- Add a new service to the list of services available through the indicated listener. *service\_code* is the code for the service, *cmd* is the command to be invoked in response to that service code, comprised of the full path name of the server and its arguments, and *comment* is a brief (free-form) description of the service for use in various reports. Note that *cmd* must appear as a single word to the shell; if arguments are required,

the *cmd* and its arguments must be enclosed in quotation marks. The *comment* must also appear as a single word to the shell. When a service is added, it is initially enabled (see the *-e* and *-d* options, below).

Service codes are alphanumeric strings, and are administered by AT&T. The numeric service codes 0 through 100 are reserved for internal use by the listener. Service code 0 is assigned to the nlps server, which is the service invoked on the general listening address. In particular, code 1 is assigned to the remote login service, which is the service automatically invoked for connections to the terminal login address.

If the *-p* option is specified, then *modules* will be interpreted as a list of STREAMS modules for the listener to push before starting the service being added. The modules are pushed in the order they are specified. *modules* should be a comma-separated list of modules, with no white space included.

If the *-w* option is specified, then *name* is interpreted as the user name from */etc/passwd* that the listener should look up. From the user name, the listener obtains the user ID, the group ID(s), and the home directory for use by the server. If *-w* is not specified, the default is to use the user name `listen`.

A service must explicitly be added to the listener for each network on which that service is to be available. This operation will normally be performed only when the service is installed on a machine, or when populating the list of services for a new network.

*-r service\_code net\_spec*

Remove the entry for the *service\_code* from that listener's list of services. This is normally done only in conjunction with the de-installation of a service from a machine.

*-e service\_code net\_spec*

*-d service\_code net\_spec*

Enable or disable (respectively) the service indicated by *service\_code* for the specified network. The service must previously have been added to the listener for that network (see the *-a* option, above). Disabling a service will cause subsequent service requests for that service to be denied, but the processes from any prior service requests that are still running will continue unaffected.

-s *net\_spec*  
 -k *net\_spec*

Start and kill (respectively) the listener process for the indicated network. These operations are normally performed as part of the system startup and shutdown procedures. Before a listener can be started for a particular network, it must first have been initialized (see the -i option, above). When a listener is killed, processes that are still running as a result of prior service requests will continue unaffected.

Under the Service Access Facility, it is possible to have multiple instances of the listener on a single *net\_spec*. In any of the above commands, the option -N *port\_monitor\_tag* may be used in place of the *net\_spec* argument. This argument specifies the tag by which an instance of the listener is identified by the Service Access Facility. If the -N option is not specified (that is, the *net\_spec* is specified in the invocation), then it will be assumed that the last component of the *net\_spec* represents the tag of the listener for which the operation is destined. In other words, it is assumed that there is at least one listener on a designated *net\_spec*, and that its tag is identical to the last component of the *net\_spec*. This listener may be thought of as the primary, or default, listener for a particular *net\_spec*.

nlsadmin is also used in conjunction with the Service Access Facility commands. In that capacity, the following combinations of options can be used:

-V

Write the current version number of the listener's administrative file to the standard output. It is used as part of the sacadm command line when sacadm adds a port monitor to the system.

-c *cmd* | -o *streamname* [ -p *modules* ] [ -A *address* | -D ] [ -R *prognum* : *versnum* ]

Format the port monitor-specific information to be used as an argument to pmadm(1M)

The -c option specifies the full path name of the server and its arguments. *cmd* must appear as a single word to the shell, and its arguments must therefore be surrounded by quotes.

The -o option specifies the full path name of a FIFO or named stream through which a standing server is actually receiving the connection.

If the -p option is specified, then *modules* will be interpreted as a list of STREAMS modules for the listener to push before starting the service being added. The modules are pushed in the order in which they are specified. *modules* must be a comma-separated list, with no white space included.

If the -A option is specified, then *address* will be interpreted as the server's private address. The listener will monitor this address on behalf of the service and will dispatch all calls arriving on this address directly to the designated service. This option may not be used in conjunction with the -D option.

If the `-D` option is specified, then the service is assigned a private address dynamically, that is, the listener will have the transport provider select the address each time the listener begins listening on behalf of this service. For RPC services, this option will be often be used in conjunction with the `-R` option to register the dynamically assigned address with the rpcbinder. This option may not be used in conjunction with the `-A` option.

When the `-R` option is specified, the service is an RPC service whose address, program number, and version number should be registered with the rpcbinder for this transport provider. This registration is performed each time the listener begins listening on behalf of the service. *prognum* and *versnum* are the program number and version number, respectively, of the RPC service.

`nlsadmin` may be invoked by any user to generate reports; all operations that affect a listener's status or configuration may only be run by a super-user.

The options specific to the Service Access Facility may not be used together with any other options.

**Errors** If successful, `nlsadmin` exits with a status of 0. If `nlsadmin` fails for any reason, it exits with a status greater than or equal to 2. See `-q` option for a return status of 1.

*System Administration Guide: Basic Administration*

**Notes** Dynamically assigned addresses are not displayed in reports as statically assigned addresses are.

- Name** nscadm – network storage control utility
- Synopsis** nscadm freeze *device*  
nscadm unfreeze *device*  
nscadm isfrozen *device*
- Description** The nscadm command performs several network storage control functions.
- The nscadm freeze command closes existing references to the specified device, and blocks future accesses. This allows maintenance of virtual volume device drivers (for example, RAID 0, RAID 1, RAID 5) to be performed without shutting down the system.
- The nscadm unfreeze command reverses the effects of nscadm freeze for the specified device.
- The nscadm isfrozen command returns the current status of the specified device.
- Options** The nscadm command supports the following option.
- h            Display the usage menu.
- Operands** The nscadm command line supports the following operand.
- device*  
Specifies the storage device to be acted upon by nscadm.
- Exit Status** For the freeze and unfreeze, subcommands nscadm returns the following exit values:
- 0            Success  
255         Error
- For the isfrozen subcommand, nscadm returns the following exit values:
- 0            Device is currently frozen.  
1            Device is not currently frozen.

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/storage/avs/cache-management, service/storage/avs/cache-management
Interface Stability	Committed

**See Also** [scmadm\(1M\)](#), [attributes\(5\)](#)

- Name** nscd – name service cache daemon
- Synopsis** /usr/sbin/nscd [-f *configuration-file*] [-g] [-e *cachename*, yes  
| no] [-i *cachename*]
- Description** The nscd daemon is a process that provides a cache for most name service requests. The default *configuration-file* /etc/nscd.conf determines the behavior of the cache daemon. See [nscd.conf\(4\)](#).
- nscd provides caching for the [passwd\(4\)](#), [group\(4\)](#), [hosts\(4\)](#), [ipnodes\(4\)](#), [exec\\_attr\(4\)](#), [prof\\_attr\(4\)](#), [user\\_attr\(4\)](#), [ethers\(4\)](#), [rpc\(4\)](#), [protocols\(4\)](#), [networks\(4\)](#), [bootparams\(4\)](#), [auth\\_attr\(4\)](#), [services\(4\)](#), [netmasks\(4\)](#), [printers\(4\)](#), [project\(4\)](#) databases through standard libc interfaces, such as [gethostbyname\(3NSL\)](#), [getipnodebyname\(3SOCKET\)](#), [gethostbyaddr\(3NSL\)](#), and others. The shadow file is specifically not cached. [getspnam\(3C\)](#) calls remain uncached as a result.
- Each cache has a separate time-to-live for its data. By default, modifying the local database (/etc/hosts, /etc/passwd, and so forth) causes that cache to become invalidated upon the next call to nscd.
- If [resolv.conf\(4\)](#) or [nsswitch.conf\(4\)](#) is modified (the file's modified-timestamp changes), it causes nscd to restart, which effectively clears all caches. See [nscd.conf\(4\)](#).
- nscd also acts as its own administration tool. If an instance of nscd is already running, commands are passed to the running version transparently.
- When running with per-user lookups enabled (see [nscd.conf\(4\)](#)), nscd forks one and only one child process (that is, a per-user nscd) on behalf of the user making the request. The per-user nscd will use the credentials of the user to open a per-user connection to the name repository configured for the per-user style of lookups. The lookup will be performed in the child process. The results are cached in the process and are available only to the same user. The caches are managed exactly the same as the main nscd daemon manages its own caches. Subsequent requests from the user will be handled by that per-user nscd until it terminates. The per-user nscd uses a configurable inactivity time-to-live (TTL) value and terminates itself after the inactivity TTL expires.
- The maximum number of per-user nscds that can be created by the main nscd is configurable (see [nscd.conf\(4\)](#)). After the maximum number of them are created, the main nscd will use an LRU algorithm to terminate less active child nscds as needed.
- The main nscd daemon creates, monitors, and manages all the child nscds. It creates a user's own nscd upon receiving the user's first per-user lookup. When the nscd daemon is started, if per-user lookups are enabled, it checks to ensure all conditions are met before getting ready to create a per-user nscd. When the daemon is stopped, it terminates all the per-user nscds under its control.
- Per-user nscds use the same configuration as the main nscd. They read and use the same default configuration file or the one specified with the -f command line option. Once the configuration is read, the per-user nscd will use it for its entire lifetime.

**Options** Several of the options described below require a *cachename* specification. Supported values for *cachename* are: *passwd*, *group*, *hosts*, *ipnodes*, *exec\_attr*, *prof\_attr*, *user\_attr*, *ethers*, *rpc*, *protocols*, *networks*, *bootparams*, *auth\_attr*, *services*, *netmasks*, *printers*, and *project*.

**-f** *configuration-file*

Causes nscd to read its configuration data from the specified file.

**-g**

Prints current configuration and statistics to standard output. This is the only option executable by non-root users.

**-e** *cachename*, *yes|no*

Enables or disables the specified cache.

**-i** *cachename*

Invalidate the specified cache.

**Examples** EXAMPLE 1 Stopping and restarting the nscd daemon.

```
example# svcadm disable system/name-service-cache
```

```
example# svcadm enable system/name-service-cache
```

**Files** */etc/nscd.conf* Determines the behavior of the cache daemon

**Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

**See Also** [svcs\(1\)](#), [svcadm\(1M\)](#), [getspnam\(3C\)](#), [gethostbyname\(3NSL\)](#), [getipnodebyname\(3SOCKET\)](#), [auth\\_attr\(4\)](#), [bootparams\(4\)](#), [ethers\(4\)](#), [exec\\_attr\(4\)](#), [group\(4\)](#), [hosts\(4\)](#), [netmasks\(4\)](#), [networks\(4\)](#), [nscd.conf\(4\)](#), [nsswitch.conf\(4\)](#), [passwd\(4\)](#), [printers\(4\)](#), [prof\\_attr\(4\)](#), [project\(4\)](#), [protocols\(4\)](#), [resolv.conf\(4\)](#), [rpc\(4\)](#), [services\(4\)](#), [user\\_attr\(4\)](#), [attributes\(5\)](#)

**Notes** The output from the **-g** option to nscd is subject to change. Do not rely upon it as a programming interface.

The nscd service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/name-service-cache
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

- 
- Name** nslookup – query Internet name servers interactively
- Synopsis** nslookup [-option] [name | -] [server]
- Description** The nslookup utility is a program to query Internet domain name servers. It has two modes: interactive and non-interactive. Interactive mode allows the user to query name servers for information about various hosts and domains or to print a list of hosts in a domain. Non-interactive mode is used to print just the name and requested information for a host or domain.
- Parameters** Interactive mode is entered in the following cases:
1. No arguments are given (the default name server is used).
  2. The first argument is a hyphen (-) and the second argument is the host name or Internet address of a name server.
- Non-interactive mode is used when the name or Internet address of the host to be looked up is given as the first argument. The optional second argument specifies the host name or address of a name server.
- Options can also be specified on the command line if they precede the arguments and are prefixed with a hyphen. For example, to change the default query type to host information, and the initial timeout to 10 seconds, type:
- ```
nslookup -query=hinfo -timeout=10
```
- Interactive Commands**
- host** [*server*]
Look up information for host using the current default server or using server, if specified. If host is an Internet address and the query type is A or PTR, the name of the host is returned. If host is a name and does not have a trailing period, the search list is used to qualify the name. To look up a host not in the current domain, append a period to the name.
- server** *domain*
lserver *domain*
Change the default server to *domain*; lserver uses the initial server to look up information about *domain*, while server uses the current default server. If an authoritative answer can't be found, the names of servers that might have the answer are returned.
- root**

help

Not implemented.

?

Not implemented.

exit

Exits the program.

set *keyword*[=*value*]

This command is used to change state information that affects the lookups. Valid keywords are:

all

Prints the current values of the frequently used options to set. Information about the current default server and host is also printed.

class=*value*

Change the query class to one of:

IN

the Internet class

CH

the Chaos class

HS

the Hesiod class

ANY

wildcard

The class specifies the protocol group of the information.

(Default = IN; abbreviation = cl)

[no]debug

Turn on or off the display of the full response packet and any intermediate response packets when searching.

(Default = nodebug; abbreviation = [no]deb)

[no]d2

Turn debugging mode on or off. This displays more about what nslookup is doing.

(Default = nod2)

domain=*name*

Sets the search list to *name*.

[no]search

If the lookup request contains at least one period but doesn't end with a trailing period, append the domain names in the domain search list to the request until an answer is received.

(Default = search)

port=*value*

Change the default TCP/UDP name server port to *value*.

(Default = 53; abbreviation = po)

querytype=*value***type=*value***

Change the top of the information query.

(Default = A; abbreviations = q, ty)

[no]recurse

Tell the name server to query other servers if it does not have the information. (Default = recurse; abbreviation = [no]rec)

retry=*number*

Set the number of retries to number.

timeout=*number*

Change the initial timeout interval for waiting for a reply to number seconds.

[no]vc

Always use a virtual circuit when sending requests to the server.

(Default = novc)

[no]fail

Try the next nameserver if a nameserver responds with SERVFAIL or a referral (nofail) or terminate query (fail) on such a response.

(Default = nofail)

Files /etc/resolv.conf
resolver configuration file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------|
| Availability | network/dns/bind |
| Interface Stability | Volatile |

See Also [dig\(1M\)](#), [host\(1M\)](#), [named\(1M\)](#), [attributes\(5\)](#)

See the BIND 9 *Administrator's Reference Manual*. As of the date of publication of this man page, this document is available at <https://www.isc.org/software/bind/documentation>.

Notes BIND 9 nslookup is deprecated and not as full featured as its BIND 8 version. For more features and functionality refer to [dig\(1M\)](#).

nslookup and [dig\(1M\)](#) now report “Not Implemented” as NOTIMP rather than NOTIMPL. This will have impact on scripts that are looking for NOTIMPL.

Name nsupdate – Dynamic DNS update utility

Synopsis nsupdate [-dv] [-y *keyname:secret* | -k *keyfile*] [-t *timeout*]
[-u *udptimeout*] [-r *udp retries*] [*filename*]

Description The nsupdate utility submits Dynamic DNS Update requests as defined in RFC 2136 to a name server. This utility allows resource records to be added or removed from a zone without manually editing the zone file. A single update request can contain requests to add or remove more than one resource record.

Zones that are under dynamic control with nsupdate or a DHCP server should not be edited by hand. Manual edits could conflict with dynamic updates and cause data to be lost.

The resource records that are dynamically added or removed with nsupdate must be in the same zone. Requests are sent to the zone's master servers identified by the MNAME field of the zone's SOA record.

Transaction signatures can be used to authenticate the Dynamic DNS updates using the TSIG resource record type described in RFC 2845. The signatures rely on a shared secret that should only be known to nsupdate and the name server. Currently, the only supported encryption algorithm for TSIG is HMAC-MD5, which is defined in RFC 2104. Once other algorithms are defined for TSIG, applications will need to ensure that they select the appropriate algorithm as well as the key when authenticating each other. For instance, suitable key and server statements would be added to `/etc/named.conf` so that the name server can associate the appropriate secret key and algorithm with the IP address of the client application that will be using TSIG authentication. The nsupdate utility does not read `/etc/named.conf`.

The nsupdate utility uses the -y or -k option to provide the shared secret needed to generate a TSIG record for authenticating Dynamic DNS update requests. These options are mutually exclusive. See OPTIONS.

Options The following options are supported:

- d Operate in debug mode. This provides tracing information about the update requests that are made and the replies received from the name server.
- k *keyfile* Read the shared secret from the file *keyfile*, whose name is of the form `K{name}.+157. +{random}.private`. For historical reasons, the file `K{name}.+157. +{random}.key` must also be present.
- r *udp retries* Set the number of UDP retries. The default is 3 retries. If *udp retries* is set to zero, only one update request is made.
- t *timeout* Set *timeout* interval in seconds before update is aborted. The default is 300 seconds. A setting of zero disables the timeout.
- u *udptimeout* Set interval in seconds between UDP retries, the default is 3 seconds. A setting of zero causes the interval to be calculated based on the timeout (-t) and the number of UDP retries (-r).

- v** Use a TCP connection. Using a TCP connection could be preferable when a batch of update requests is made. By default, nsupdate uses UDP to send update requests to the name server.
- y *keyname:secret*** Generate a signature from *keyname:secret*, where *keyname* is the name of the key and *secret* is the base64 encoded shared secret.
- Use of the **-y** option is discouraged because the shared secret is supplied as a command line argument in clear text and could be visible in the output from `ps(1)` or in a history file maintained by the user's shell.

Input Format The nsupdate utility reads input from *filename* or the standard input. Each command is supplied on exactly one line of input. Some commands are for administrative purposes. The others are either update instructions or prerequisite checks on the contents of the zone. These checks set conditions that some name or set of resource records (RRset) either exists or is absent from the zone. These conditions must be met if the entire update request is to succeed. Updates will be rejected if the tests for the prerequisite conditions fail.

Every update request consists of zero or more prerequisites and zero or more updates. This condition allows a suitably authenticated update request to proceed if some specified resource records are present or missing from the zone. A blank input line (or the send command) causes the accumulated commands to be sent as one Dynamic DNS update request to the name server.

The command formats and their meaning are as follows:

`server servername [port]`

Send all dynamic update requests to the name server *servername*. When no `server` statement is provided, nsupdate sends updates to the master server of the correct zone. The `MNAME` field of that zone's SOA record identifies the master server for that zone. The *port* argument is the port number on *servername* where the dynamic update requests get sent. If no port number is specified, the default DNS port number of 53 is used.

`local address [port]`

Send all dynamic update requests using the local *address*. When no `local` statement is provided, nsupdate sends updates using an address and port chosen by the system. The *port* argument can also be used to make requests come from a specific port. If no port number is specified, the system assigns one.

`zone zonename`

Specify that all updates are to be made to the zone *zonename*. If no `zone` statement is provided, nsupdate attempts to determine the correct zone to update based on the rest of the input.

`class classname`

Specify the default class. If no class is specified the default class is IN.

key name secret

Specify that all updates are to be TSIG signed using the *name secret* pair. The key command overrides any key specified on the command line with *-y* or *-k*.

prereq nxdomain domain-name

Require that no resource record of any type exists with the name *domain-name*.

prereq yxdomain domain-name

Require that *domain-name* exists (has as at least one resource record, of any type).

prereq nxrrset domain-name [class] type

Require that no resource record exists of the specified *type*, *class* and *domain-name*. If *class* is omitted, IN (internet) is assumed.

prereq yxrrset domain-name [class] type

Require that a resource record of the specified *type*, *class* and *domain-name* must exist. If *class* is omitted, IN (internet) is assumed.

prereq yxrrset domain-name [class] type data...

The *data* from each set of prerequisites of this form sharing a common *type*, *class*, and *domain-name* are combined to form a set of RRs. This set of RRs must exactly match the set of RRs existing in the zone at the given *type*, *class*, and *domain-name*. The *data* are written in the standard text representation of the resource record's RDATA.

update delete domain-name [ttl] [class] [type [data...]]

Delete any resource records named *domain-name*. If *type* and *data* are provided, only matching resource records are removed. The internet class is assumed if *class* is not supplied. The *ttl* is ignored, and is only provided for compatibility.

update add domain-name ttl [class] type data...

Add a new resource record with the specified *ttl*, *class* and *data*.

show

Display the current message, containing all of the prerequisites and updates specified since the last send.

send

Sends the current message. This is equivalent to entering a blank line.

answer

Displays the answer.

Lines beginning with a semicolon are comments and are ignored.

Examples EXAMPLE 1 Inserting and Deleting Resource Records from the Zone

The examples below show how `nsupdate` could be used to insert and delete resource records from the `example.com` zone. Notice that the input in each example contains a trailing blank line so that a group of commands are sent as one dynamic update request to the master name server for `example.com`.

EXAMPLE 1 Inserting and Deleting Resource Records from the Zone *(Continued)*

```
# nsupdate
> update delete oldhost.example.com A
> update add newhost.example.com 86400 A 172.16.1.1
> send
```

Any A records for `oldhost.example.com` are deleted. An A record for `newhost.example.com` with IP address `172.16.1.1` is added. The newly-added record has a 1 day TTL (86400 seconds).

EXAMPLE 2 Adding CNAME Only If No Records Exist

The following command adds a CNAME only if no records already exist for it.

```
# nsupdate
> prereq nxdomain nickname.example.com
> update add nickname.example.com 86400 CNAME somehost.example.com
> send
```

The prerequisite condition gets the name server to check that there are no resource records of any type for `nickname.example.com`. If there are, the update request fails. If this name does not exist, a CNAME for it is added. This action ensures that when the CNAME is added, it cannot conflict with the long-standing rule in RFC 1034 that a name must not exist as any other record type if it exists as a CNAME. (The rule has been updated for DNSSEC in RFC 4035 to allow CNAMEs to have RSIG, DNSKEY, and NSEC records.)

| | | |
|--------------|---------------------------------------------|------------------------------------------------------------------------------|
| Files | <code>/etc/resolv.conf</code> | used to identify default name server |
| | <code>K{name}.+157.+{random}.key</code> | base-64 encoding of HMAC-MD5 key created by <code>dnssec-keygen(1M)</code> . |
| | <code>K{name}.+157.+{random}.private</code> | base-64 encoding of HMAC-MD5 key created by <code>dnssec-keygen(1M)</code> |

Bugs The TSIG key is redundantly stored in two separate files. This is a consequence of `nsupdate` using the DST library for its cryptographic operations and could change in future releases.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|--------------------------|
| Availability | service/network/dns/bind |
| Interface Stability | Volatile |

See Also [named\(1M\)](#), [dnssec-keygen\(1M\)](#), [attributes\(5\)](#)

RFC 2136, RFC 3007, RFC 2104, RFC 2845, RFC 1034, RFC 2535, RFC 2931, RFC 4035

Name ntfscat – display NTFS files and streams on the standard output

Synopsis ntfscat [*options*] *device* [*file*]

Description The ntfscat command reads a file or stream from an NTFS volume and display the contents on the standard output.

The case of the filename passed to ntfscat is ignored.

Options Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, -fv is the equivalent of -f -v. A full-name option can be abbreviated to a unique prefix of its name.

-a, --attribute *type*

Display the contents of a particular attribute type. By default, the unnamed \$DATA attribute will be shown. The attribute can be specified by a number in decimal or hexadecimal, or by name.

| Hex | Decimal | Name |
|-------|---------|---------------------------|
| 0x10 | 16 | "\$STANDARD_INFORMATION" |
| 0x20 | 32 | "\$ATTRIBUTE_LIST" |
| 0x30 | 48 | "\$FILE_NAME" |
| 0x40 | 64 | "\$OBJECT_ID" |
| 0x50 | 80 | "\$SECURITY_DESCRIPTOR" |
| 0x60 | 96 | "\$VOLUME_NAME" |
| 0x70 | 112 | "\$VOLUME_INFORMATION" |
| 0x80 | 128 | "\$DATA" |
| 0x90 | 144 | "\$INDEX_ROOT" |
| 0xA0 | 160 | "\$INDEX_ALLOCATION" |
| 0xB0 | 176 | "\$BITMAP" |
| 0xC0 | 192 | "\$REPARSE_POINT" |
| 0xD0 | 208 | "\$EA_INFORMATION" |
| 0xE0 | 224 | "\$EA" |
| 0xF0 | 240 | "\$PROPERTY_SET" |
| 0x100 | 256 | "\$LOGGED_UTILITY_STREAM" |

The attribute names can be specified without the leading dollar sign (\$) symbol. If you use the \$ symbol, you must quote the name to prevent the shell from interpreting the name.

-f, --force

Overrides some sensible defaults, such as not using a mounted volume. Use this option with caution.

-h, --help

Show a list of options with a brief description of each.

-i, --inode *num*

Specify a file by its inode number instead of its name.

- n, --attribute-name *name*
Display the attribute identified by *name*.
- q, --quiet
Suppress some debug, warning, and error messages.
- V, --version
Show the version number, copyright, and license information.
- v, --verbose
Display more debug, warning, and error messages.

Examples EXAMPLE 1 Displaying Contents of File in Root

The following command displays the contents of a file in the root of an NTFS volume.

```
# ntfscat /dev/dsk/c0d0p1 boot.ini
```

EXAMPLE 2 Displaying Contents of File in Subdirectory

The following command displays the contents of a file in a subdirectory of an NTFS volume.

```
# ntfscat /dev/dsk/c0d0p1 /winnt/system32/drivers/etc/hosts
```

EXAMPLE 3 Display Contents of an Attribute

The following command displays the contents of the \$INDEX_ROOT attribute of the root directory (inode 5).

```
# ntfscat /dev/dsk/c0d0p1 -a INDEX_ROOT -i 5
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------------------|
| Availability | system/file-system/ntfsprogs |
| Interface Stability | Uncommitted |

Authors ntfscat was written by Richard Russon, Anton Altaparmakov and Szabolcs Szakacsits.

Name ntfsclone – clone, image, restore, or rescue an NTFS

Synopsis `ntfsclone [options] source`
`ntfsclone --save-image [options] source`
`ntfsclone --resotore-image [options] source`
`ntfsclone --metadata [options] source`

Description The `ntfsclone` utility efficiently clones (which includes copy, save, backup, and restore operations) or rescues an NTFS filesystem to a sparse file, an image, a device (partition), or to standard output. It works at disk sector level and copies only the written data (that is, not empty space). Unused disk space becomes zero (cloning to sparse file), encoded with control codes (saving in special image format), left unchanged (cloning to a disk/partition) or filled with zeros (cloning to standard output).

`ntfsclone` can be useful in making backups—taking an exact snapshot of an NTFS filesystem—and restoring it later on. It also can be used to test NTFS read/write functionality and allows you to troubleshoot users' issues using the clone, without the risk of destroying the original file system.

If not using the special image format (see section of the same name below), the clone is an exact copy of the original NTFS file system, from sector to sector. Thus, it can also be mounted just like the original NTFS filesystem. For example, if you clone to a file and the kernel has a loopback device and NTFS support, then the file can be mounted using:

```
# mount -t ntfs -o loop ntfsclone.img
```

Windows Cloning You must exercise great care to copy, move or restore a system or boot partition to another computer, or to a different disk or partition (for example, `/dev/dsk/c0d0p1` to `/dev/dsk/c0d0p2`, `/dev/dsk/c0d0p1` to `/dev/dsk/c0d1p1` or to a different disk sector offset).

Under most circumstances, to enable Windows to boot you must copy, move, or restore NTFS to the same partition that has the following characteristics as the original partition and disk:

- starts at the same sector
- on the same type of disk
- having the same BIOS legacy cylinder setting

The `ntfsclone` utility guarantees an exact copy of NTFS but does not deal with booting issues. This is by design: `ntfsclone` is a file system, not a system, utility. Its goal is only NTFS cloning, not Windows cloning. Because of this, `ntfsclone` can be used as a very fast and reliable building block for Windows cloning, but is not a complete answer. You can find useful tips on NTFS cloning at the NTFS web site, <http://www.linux-ntfs.org/>.

Sparse Files A file containing unallocated blocks (holes) is referred to as a “sparse file”. The reported size of such files is always higher than the disk space consumed by them. The `du(1)` command reports the real disk space used by a sparse file. The holes are always read as zeros. All major Linux file

systems, such as, `ext2`, `ext3`, `reiserfs`, `Reiser4`, `JFS`, and `XFS` support sparse files. However, the ISO 9600 CD-ROM file system, as one example, does not.

Special Image Format It is recommended that you save an NTFS filesystem to a special image format. Instead of representing unallocated blocks as holes, they are encoded using control codes. Thus, the image saves space without requiring sparse file support. The image format is ideal for streaming file system images over the network. The disadvantage of the special image format is that you cannot mount the image directly; you must first restore it.

To save an image using the special image format, use the `-s` or the `--save-image` option. To restore an image, use the `-r` or the `--restore-image` option. Note that you can restore images from standard input by using a hyphen (`-`) as the source file.

Metadata-only Cloning Using the `-m` or `--metadata` option, `ntfscclone` can save only the NTFS metadata and the clone still will be mountable. In this usage, all non-metadata file content is lost; reading back the data results in all zeros.

The metadata-only image can be compressed very well, usually to a size in the range of 1 to 8 MB. It is convenient to transfer such an image for investigation and troubleshooting.

In metadata-only mode, `ntfscclone` saves none of the user's data, which includes the resident user's data embedded into metadata. All is filled with zeros. Moreover, all the file timestamps, and deleted and unused spaces inside the metadata are filled with zeros. Thus, this mode is inappropriate, for example, for forensic analyses.

Note that filenames are not removed. Because a filename might contain sensitive information, consider the possibilities for breaches of security or privacy before sending out a metadata-only image.

Options Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, `-fv` is the equivalent of `-f -v`. A full-name option can be abbreviated to a unique prefix of its name.

`-f, --force`

Forces `ntfscclone` to proceed, even if the filesystem is marked “dirty” following a consistency check.

`-h, --help`

Show a list of options with a brief description of each one.

`-i, --ignore-fs-check`

Ignore the result of the file system consistency check. This option can be used only with the `--metadata` option. Any clusters that cause an inconsistency are saved.

`-m, --metadata`

Clone only metadata. With this option, you must clone only to a file.

`-o, --output file`

Clone NTFS to the non-existent *file*. If *file* is a hyphen (`-`), clone to the standard output.

- O, --overwrite *file*
Clone NTFS to *file*, overwriting *file* if it already exists.
- rescue
Ignore disk read errors so that a disk having bad sectors, for example, a failing disk, can be rescued with minimal impact on the disk. `ntfsclone` works at the lowest, sector level in this mode, enabling more data to be rescued. The contents of the unreadable sectors are filled with the question mark (?) character; the beginning of such sectors are marked by the string: `BadSector`.
- r, --restore-image *source*
Restore from the special image format specified by *source*. If *source* is a hyphen (-), the image is read from the standard input.
- s, --save-image
Save to the special image format. In terms of space usage and speed, this is the most efficient option if imaging is done to the standard output. This option is useful for image compression, encryption, or streaming through a network.

Examples EXAMPLE 1 Cloning with Overwrite Option

The following command clones with the `--overwrite` option.

```
# ntfsclone --overwrite /dev/dsk/c0d2p1 /dev/dsk/c0d0p1
```

EXAMPLE 2 Saving to Special Image Format

The following command clones to the special image format to its original partition.

```
# ntfsclone --save-image --output backup.img /dev/dsk/c0d0p1
```

EXAMPLE 3 Restoring from a Special Image File

The following command restores an NTFS from a special image file.

```
# ntfsclone --restore-image --overwrite /dev/dsk/c0d0p1 backup.img
```

EXAMPLE 4 Saving to a Compressed Image

The following command saves an NTFS to a compressed image file.

```
# ntfsclone --save-image -o - /dev/dsk/c0d0p1
```

EXAMPLE 5 Restoring from a Compressed Image

The following command restores an NTFS volume from a compressed image file.

```
# gunzip -c backup.img.gz | \  
ntfsclone --restore-image --overwrite /dev/dsk/c0d0p1 -
```

EXAMPLE 6 Backing up to a Remote Host Using `ssh`

The following command backs up to a remote host, using `ssh(1)`. Note that `ssh` will probably require a password.

```
# ntfscclone --save-image --output - /dev/dsk/c0d0p1 | \
gzip -c | ssh host 'cat > backup.img.gz'
```

EXAMPLE 7 Restoring from a Remote Host Using `ssh`

The following command backs up to a remote host, using `ssh(1)`. Note that `ssh` will probably require a password.

```
# ssh host 'cat backup.img.gz' | gunzip -c | \
ntfscclone --restore-image --overwrite /dev/dsk/c0d0p1 -
```

EXAMPLE 8 Streaming an Image File from a Web Server

The following command streams an image file from a web server and restore it to a partition.

```
# wget -qO - http://server/backup.img | \
ntfscclone --restore-image --overwrite /dev/dsk/c0d0p1 -
```

EXAMPLE 9 Cloning to a New File

The following command clones an NTFS volume to a non-existent file.

```
# ntfscclone --output ntfs-clone.img /dev/dsk/c0d0p1
```

EXAMPLE 10 Packing NTFS Metadata

The following command packs NTFS metadata into an image file. Note that `bzip2` takes a much longer time than `gzip`, but produces an archive that is up to ten times smaller than the latter produces.

```
# ntfscclone --metadata --output ntfsmeta.img /dev/dsk/c0d0p1
bzip2 ntfsmeta.img
```

EXAMPLE 11 Unpacking NTFS Metadata

The following command unpacks NTFS metadata into a sparse file.

```
# bunzip2 -c ntfsmeta.img.bz2 | \
cp --sparse=always /proc/self/fd/0 ntfsmeta.img
```

Exit Status The return code is zero on success, non-zero otherwise.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|------------------------------|
| Availability | system/file-system/ntfsprogs |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

Authors ntfscclone was written by Szabolcs Szakacsits with contributions from Per Olofsson (special image format support) and Anton Altaparmakov.

Name ntfscluster – identify files in a specified region of an NTFS volume

Synopsis ntfscluster [*options*] *device*

Description The ntfscluster utility has three modes of operation: info, sector, and cluster, described as follows.

Info

The default mode, info is currently not implemented. It will display general information about the NTFS volume when it is working.

Sector

The sector mode displays a list of files that have data in the specified range of sectors. This mode is put in effect by the --sector option.

Cluster

The cluster mode displays a list of files that have data in the specified range of clusters.

When the cluster size is one sector, this is equivalent to the sector mode of operation. This mode is put in effect by the --cluster option.

Options Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, -fv is the equivalent of -f -v. A full-name option can be abbreviated to a unique prefix of its name.

-c, --cluster *range*

Any files whose data is in this range of clusters will be displayed.

-F, --filename *filename*

Display information about *filename*.

-f, --force

Overrides some sensible defaults, such as not working with a mounted volume. Use this option with caution.

-h, --help

Show a list of options with a brief description of each.

-I, --inode *num*

Show information about this inode.

-i, --info

This option is not yet implemented.

-q, --quiet

Suppress some debug, warning, and error messages.

-s, --sector *range*

Any files whose data is in this range of sectors will be displayed.

-V, --version

Show the version number, copyright, and license information.

`-v, --verbose`
 Display more debug, warning, and error messages.

Examples EXAMPLE 1 Displaying Information About a Volume

The following command displays information about the volume `/dev/dsk/c0d0p1`.

```
# ntfscluster /dev/dsk/c0d0p1
```

EXAMPLE 2 Displaying List of Files in a Cluster Range

The following command looks for files in the first 500 clusters of `/dev/dsk/c0d0p1`.

```
# ntfscluster -c 0-500 /dev/dsk/c0d0p1
```

Name ntfscmp – compare two NTFS file systems and report the differences

Synopsis ntfscmp [*options*] *device1 device2*

Description The ntfscmp utility compares all aspects of two NTFS file systems and reports all differences it finds. The file systems can be on block devices or in image files. ntfscmp can be used for volume verification. However, its primary purpose is to be an efficient development tool, used to quickly locate, identify, and check the correctness of the metadata changes made to NTFS.

If one is interested only in the NTFS metadata changes, it can be useful to compare the metadata images created by using the --metadata option of [ntfscclone\(1M\)](#) to eliminate the usually uninteresting timestamp changes.

The terse output of ntfscmp is intentional, because the provided information is sufficient to determine exact differences. More copious output can be obtained by using [diff\(1\)](#) to compare the verbose output of [ntfsinfo\(1M\)](#) for each reported inode.

Options Supported options are listed below. Options have both single-letter and full-name forms.

-h, --help

Display help and exit.

-P, --no-progress-bar

Do not show progress bars.

-v, --verbose

Display more debug, warning, and error messages.

Exit Status The exit code is 0 on success, non-zero otherwise.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

<http://www.linux-ntfs.org/>

Authors ntfscmp was written by Szabolcs Szakacsits.

- Name** ntfsdp – copy file to an NTFS volume
- Synopsis** ntfsdp [*options*] *device source_file destination*
- Description** The ntfsdp utility copies files to an NTFS volume. *destination* (see Synopsis) can be either a file or a directory. If *destination* is a directory specified by name, *source_file* is copied into this directory. If *destination* is a directory specified by inode number, an unnamed data attribute is created for this inode and *source_file* is copied into it. Consider possible negative consequence before specifying a directory by inode number: it is unusual to have an unnamed data stream in a directory.
- Data Streams** All data on NTFS is stored in streams, which can have names. A file can have more than one data stream, but exactly one must have no name. The size of a file is the size of its unnamed data stream. Usually, when you do not specify a stream name, you are seeking access to the unnamed data stream. If you want access to a named data stream, you need to add *:stream_name* to the filename. For example, by opening *some.mp3:artist* you will open stream *artist* in *some.mp3*. In an operating system, such as Windows, that prevents you from accessing named data streams, you need to use some program like FAR or utilities from cygwin to access those streams.
- Options** Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, *-fv* is the equivalent of *-f -v*. A full-name option can be abbreviated to a unique prefix of its name.
- a, --attribute num*
Write to attribute designated by *num*.
 - f, --force*
Overrides some sensible defaults, such as not working with a mounted volume. Use this option with caution.
 - h, --help*
Show a list of options with a brief description of each one.
 - i, --inode*
Treat *destination* (see Synopsis) as inode number.
 - N, --attr-name name*
Write to attribute with this name.
 - n, --no-action*
Use this option to make a test run before doing the actual copy operation. Volume will be opened read-only and no write will be done.
 - q, --quiet*
Suppress some debug, warning, and error messages.
 - V, --version*
Show the version number, copyright, and license information.

-v, --verbose

Display more debug, warning, and error messages.

Examples EXAMPLE 1 Copying from Home to Root Directory

The following command copies `new_boot.ini` from `/home/user` as `boot.ini` to the root of an `/dev/dsk/c0d0p1` NTFS volume.

```
# ntfscp /dev/dsk/c0d0p1 /home/user/new_boot.ini boot.ini
```

EXAMPLE 2 Copying a Stream

The following command copies `myfile` to `C:\some\path\myfile:stream` (assume that `/dev/dsk/c0d0p1` drive designator is C).

```
# ntfscp -N stream /dev/dsk/c0d0p1 myfile /some/path
```

Name ntfsfix – fix common errors and force operating system to check NTFS

Synopsis ntfsfix [*options*] *device*

Description The `ntfsfix` utility fixes some common NTFS problems. Note that it is not a version of `chkdsk`. It repairs some fundamental NTFS inconsistencies, resets the NTFS journal file, and schedules an NTFS consistency check for the next reboot of the operating system.

Run `ntfsfix` on an NTFS volume if you think it was damaged by the operating system or in some other way and it cannot be mounted.

Options Supported options are listed below.

`-h, --help`

Show a list of options with a brief description of each.

`-V, --version`

Show the version number, copyright, and license information.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------------------|
| Availability | system/file-system/ntfsprogs |
| Interface Stability | Uncommitted |

<http://www.linux-ntfs.org/>

Authors `ntfsfix` was written by Anton Altaparmakov, with contributions from Szabolcs Szakacsits.

Name ntfsinfo – dump a file's attributes

Synopsis ntfsinfo [*options*] *device*

Description The `ntfsinfo` utility dumps the attributes of inode *inode-number* or the file *path-filename* and/or information about the MFT (`-m` option). Run `ntfsinfo` without arguments for a full list of options.

Options Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, `-fv` is the equivalent of `-f -v`. A full-name option can be abbreviated to a unique prefix of its name.

`-F, --file file`

Show information about *file*.

`-f, --force`

Overrides some sensible defaults, such as not overwriting an existing file. Use this option with caution.

`-h, --help`

Show a list of options with a brief description of each.

`-i, --inode num`

Show information about inode identified by *num*.

`-m, --mft`

Show information about the volume.

`-q, --quiet`

Suppress some debug, warning, and error messages.

`-t, --notime`

Do not display timestamps in the output.

`-V, --version`

Show the version number, copyright, and license information.

`-v, --verbose`

Display more debug, warning, and error messages.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------------------|
| Availability | system/file-system/ntfsprogs |
| Interface Stability | Uncommitted |

<http://www.linux-ntfs.org/>

Authors `ntfsinfo` was written by Matthew J. Fanto, Anton Altaparmakov, Richard Russon, Szabolcs Szakacsits, Yuval Fleidel, Yura Pakhuchiy and Cristian Klein.

Name ntfslabel – display or change the label on an NTFS file system

Synopsis ntfslabel [*options*] *device* [*new_label*]

Description The `ntfslabel` utility displays or changes the file system label on the NTFS file system located on *device* (see Synopsis).

If the optional argument *new_label* is not present, `ntfslabel` displays the current file system label.

If the optional argument *new_label* is present, `ntfslabel` sets the file system label to be *new_label*. NTFS file system labels can be at most 128 Unicode characters long; if *new_label* is longer than 128 Unicode characters, `ntfslabel` truncates it and displays a warning message.

It is also possible to set the file system label using the `-L` option of `mkntfs(1M)` during creation of the file system.

Options Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, `-fv` is the equivalent of `-f -v`. A full-name option can be abbreviated to a unique prefix of its name.

`-f, --force`

Overrides some sensible defaults, such as not working with a mounted volume. Use this option with caution.

`-h, --help`

Show a list of options with a brief description of each.

`-n, --no-action`

Do not actually write a new label to disk.

`-q, --quiet`

Suppress some debug, warning, and error messages.

`-V, --version`

Show the version number, copyright, and license information.

`-v, --verbose`

Display more debug, warning, and error messages.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------------------|
| Availability | system/file-system/ntfsprogs |
| Interface Stability | Uncommitted |

See Also `mkntfs(1M)`, `ntfsprogs(1M)`, `parted(1M)`, `attributes(5)`

<http://www.linux-ntfs.org/>

Authors `ntfslabel` was written by Matthew J. Fanto, with contributions from Anton Altaparmakov and Richard Russon.

Name ntfsls – list directory contents on an NTFS file system

Synopsis ntfsls [*options*] *device*

Description The `ntfsls` utility lists information about the files specified by the `PATH` option (the root directory by default). *device* (see Synopsis) is the special file corresponding to the device (for example, `/dev/dsk/c0d0p0num`) or an NTFS image file.

Options Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, `-fv` is the equivalent of `-f -v`. A full-name option can be abbreviated to a unique prefix of its name.

`-a, --all`

Display all files. If this option is not specified file names in the POSIX namespace are not displayed.

`-F, --classify`

Append one of the indicators shown below to entries.

* / = @ |

`-f, --force`

Force execution. For example, this option is necessary to run on an NTFS partition stored in a normal file.

`-h, --help`

Display usage information and exit.

`-i, --inode`

Display the inode number of each file. This is the MFT reference number, in NTFS terminology.

`-l, --long`

Use a long listing format.

`-p, --path path`

The directory whose contents to list or the file (including the path) about which to display information.

`-q, --quiet`

Suppress some debug, warning, and error messages.

`-R, --recursive`

Show the contents of all directories beneath the specified directory.

`-s, --system`

Unless this options is specified, all files beginning with a dollar sign character will not be listed, as these files are usually system files.

`-v, --verbose`

Display more debug, warning, and error messages.

-V, --version

Display the ntfsls version number and exit.

-x, --dos

Display short file names, that is, files in the DOS namespace, instead of long file names, that is, files in the WIN32 namespace.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------------------|
| Availability | system/file-system/ntfsprogs |
| Interface Stability | Uncommitted |

See Also , [ntfsprogs\(1M\)](#), [parted\(1M\)](#), [attributes\(5\)](#)

<http://www.linux-ntfs.org/>

Authors This version of ntfsls was written by Lode Leroy, Anton Altaparmakov, Richard Russon, Carmelo Kintana and Giang Nguyen.

Name ntfsprogs – list of NTFS tools

Synopsis ntfsprogs

Description ntfsprogs is the name of a suite of NTFS utilities based around a shared library. The tools are available for free and come with full source code. The tools are listed below.

[mkntfs\(1M\)](#)

Create an NTFS filesystem.

[ntfscat\(1M\)](#)

Dump a file's content to the standard output.

[ntfscclone\(1M\)](#)

Efficiently clone, backup, restore, or rescue NTFS.

[ntfsccluster\(1M\)](#)

Locate the files that use the specified sectors or clusters.

[ntfscmp\(1M\)](#)

Compare two NTFS file systems and report the differences.

[ntfscp\(1M\)](#)

Copy a file to an NTFS volume.

[ntfsfix\(1M\)](#)

Check and fix some common errors, clear the log file, and make the operating system perform a thorough check next time it boots.

[ntfsinfo\(1M\)](#)

Show information about NTFS or one of the files or directories within it.

[ntfslabel\(1M\)](#)

Show, or set, an NTFS filesystem's volume label.

[ntfsls\(1M\)](#)

List information about files in a directory residing on an NTFS.

[ntfsmount\(1M\)](#) (not a SunOS man page)

Read-write NTFS user space driver.

[ntfsresize\(1M\)](#)

Resize NTFS without losing data.

[ntfsundelete\(1M\)](#)

Recover deleted files from NTFS.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------------------|
| Availability | system/file-system/ntfsprogs |
| Interface Stability | Uncommitted |

See Also [parted\(1M\)](#), [attributes\(5\)](#)

<http://www.linux-ntfs.org/>

Authors The tools were written by Anton Altaparmakov, Carmelo Kintana, Cristian Klein, Erik Sornes, Giang Nguyen, Holger Ohmacht, Lode Leroy, Matthew J. Fanto, Per Olofsson, Richard Russon, Szabolcs Szakacsits, Yura Pakhuchiy, and Yuval Fleidel.

Name `ntfsresize` – resize an NTFS file system without data loss

Synopsis `ntfsresize [options] --info device`
`ntfsresize [options] [--size size[k|M|G]] device`

Description The `ntfsresize` program safely resizes Windows XP, Windows Server 2003, Windows 2000, Windows NT4 and Longhorn NTFS filesystems without data loss. All NTFS versions used by 32-bit and 64-bit Windows “operating systems” are supported. Defragmentation is not required prior to resizing, because `ntfsresize` can relocate any data if needed, without risking data integrity.

`ntfsresize` can be used to shrink or enlarge any NTFS file system located on an unmounted device (usually a disk partition). The new file system will have a size that you specify. The size parameter can have one of the optional modifiers `k`, `M`, `G`, denoting, respectively, kilobytes, megabytes, or gigabytes. `ntfsresize` conforms to the SI, ATA, an IEEE standards and the disk manufacturers by supporting $k=10^3$, $M=10^6$ and $G=10^9$.

If both `---info` and `---size` options are omitted then the NTFS file system will be enlarged to the underlying device size.

To resize a file system on a partition, you must resize both the file system and the partition, by editing the partition table on the disk. Similarly to other command-line file system resizers, `ntfsresize` does not manipulate the size of the partitions. To do that you must use a disk partitioning tool, such as `fdisk(1M)`. Alternatively, you could use one of the many user friendly partitioners that uses `ntfsresize` internally. Such partitioners include, among others, Mandriva's DiskDrake, QTParted, SUSE/Novell's YaST Partitioner, IBM's EVMS, GParted, or Debian/Ubuntu's Partman.

Back up your data and your partition table before using any partitioning tool. For an NTFS file system, you can use `ntfsclone(1M)` as a means of backup.

To shrink an NTFS partition, first use `ntfsresize` to shrink the size of the file system. Then use a utility such as `fdisk(1M)` to shrink the size of the partition by deleting the partition and recreating it with the smaller size. Do not make the partition smaller than the new size of NTFS; otherwise, you will not be able to boot from that partition. If you mistakenly made a too-small partition, you would have to recreate the partition to be as large as newly sized NTFS file system.

To enlarge an NTFS file system, you must first enlarge the size of the underlying partition. You can use `fdisk(1M)` to delete the partition and recreate it with a larger size. Make sure the newly sized partition does not overlap with any other partition. Then use `ntfsresize` to enlarge the file system.

When recreating a partition, make sure you create it at the same starting sector and with the same partition type as was used in the partition you are replacing. Otherwise, you will not be able to access your file system. Use the `fdisk u` command to switch from the default cylinder

unit to the reliable sector unit. Also, if the bootable flag was set in the old partition, make sure to set it in the recreated partition. Otherwise, you might not be able to boot from the new partition.

Extended Description There are a handful of very rarely met restrictions in the use of `ntfsresize`. An example of such a restriction occurs with a file system stored on a disk having unknown bad sectors. Relocation of the first MFT extent and resizing into the middle of a `$MFTMirr` extent are not supported. These cases are detected and resizing is restricted to a safe size or the closest safe size is displayed.

Upon completion of a resizing, `ntfsresize` schedules an NTFS consistency check. In Windows, this check is performed by `chkdsk`. Upon the first subsequent reboot into Windows, you will note `chkdsk` running in a blue background. This is normal. Windows might force a quick reboot after the consistency check. Depending on your hardware configuration, Windows might alert you to a systems setting change and recommend or require a reboot. Acknowledge the message and reboot a second time.

Options Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, `-fv` is the equivalent of `-f -v`. A full-name option can be abbreviated to a unique prefix of its name.

`-b, --bad-sectors`

By default, `ntfsresize` exits upon encountering bad sectors. This option allows the utility to proceed in spite of such sectors.

Prior using this option, it is strongly recommended that you use `ntfscclone(1M)` with the `--rescue` option to make a backup, then, in Windows, run `chkdsk /f /r volume:` from the command line. If the disk guarantee displays as valid, then replace it, as it is defective. Note that no software can repair bad sector errors. The most that can be done is to work around these defects.

This option has no effect if a disk has no bad sectors.

`-f, --force`

`ntfsresize` always marks a file system for consistency check before a real (not using `--no-action`) resize operation and it leaves that way for extra safety. Thus, if an NTFS file system was marked by `ntfsresize`, it is safe to use this option. You must use this option, if you need to resize several times without booting into Windows between each resizing step.

`-h, --help`

Display usage information and exit.

`-i, --info`

Used when you want to shrink a file system. Causes `ntfsresize` to determine the smallest shrunken file system size supported. Most of the time the smallest size is the space already used on the file system. `ntfsresize` does not shrink a file system to a smaller size than what is returned by this option. Depending on several factors, it might be unable to shrink to this

theoretical size. Although the integrity of your data should be never at risk, it is nevertheless strongly recommended to make a test run by using the `--no-action` option before actual resizing.

Based on testing, the smallest attainable size is approximately space used in the file system plus 20–200 MB. Note also that Windows might need an additional 50–100 MB to boot safely.

This option never causes any changes to the file system; the partition is opened read-only.

`-n, --no-action`

Use this option to make a test run before doing the resize operation. Volume will be opened read-only and `ntfsresize` displays what it would do if it were to resize the file system. Proceed with the actual resizing only if the test run passed.

`-P, --no-progress-bar`

Do not display progress bars during `ntfsresize` operation.

`-s, --size size[k|M|G]`

Resize file system to *size* bytes. The new file system will have a size that you specify. The size parameter can have one of the optional modifiers `k`, `M`, `G`, denoting, respectively, kilobytes, megabytes, or gigabytes. `ntfsresize` conforms to the SI, ATA, an IEEE standards and the disk manufacturers by supporting $k=10^3$, $M=10^6$ and $G=10^9$. Before performing an actual resizing, run `ntfsresize` with the `--no-action` option, along with this option, first.

`-v, --verbose`

Display copious output.

`-V, --version`

Display the version number of `ntfsresize`.

Exit Status Display zero on success, non-zero otherwise.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------------------|
| Availability | system/file-system/ntfsprogs |
| Interface Stability | Uncommitted |

See Also [fdisk\(1M\)](#), [ntfscclone\(1M\)](#), [parted\(1M\)](#), [attributes\(5\)](#)

<http://www.linux-ntfs.org/>

Notes In Linux version 2.6, with partitions that have been manipulated by [parted\(1M\)](#), use of `ntfsresize` preceded corruption of partition tables, which resulted in unbootable Windows systems. This occurred even if the NTFS file system was consistent. This problem is independent of NTFS and, thus, `ntfsresize`. Moreover, `ntfsresize` never touches the

partition table. Under the conditions just described, you can, in the BIOS, change Disk Access Mode to LBA to regain the ability to boot. For further discussion of this condition see the ntfsresize FAQ at: <http://mlf.linux.rulez.org/mlf/ezaz/ntfsresize.html>.

Authors ntfsresize was written by Szabolcs Szakacsits, with contributions from Anton Altaparmakov and Richard Russon.

| Name | ntfsundelete – recover a deleted file from an NTFS volume |
| Synopsis | ntfsundelete [<i>options</i>] <i>device</i> |
| Description | <p>The ntfsundelete utility can, under the right circumstances, recover a deleted file from an NTFS volume. The command has three modes of operation:</p> <p>Scan
The default mode, scan simply reads an NTFS Volume and looks for files that have been deleted. It then displays a list, giving the inode number, name, and size of each deleted file.</p> <p>Undelete
The undelete mode takes the files either matching the regular expression (option -m) or specified by the <i>inode-expressions</i> and recovers as much of the data as possible. It saves the result to another location.</p> <p>Copy
The “wizard's” option. Saves a portion of the MFT to a file, which can be useful when debugging ntfsundelete.</p> <p>There are many circumstances under which ntfsundelete is unable to recover a file. For example, consider the following scenario. When a file is deleted the MFT Record is marked as not in use and the bitmap representing the disk usage is updated. If the power is not turned off immediately, the free space, where the file used to reside might get overwritten. Worse, the MFT Record might be reused for another file. If this happens, it is impossible to tell where the file was on disk.</p> <p>Even if all the clusters of a file are not in use, there is no guarantee that they have not been overwritten by some short-lived file.</p> <p>ntfsundelete cannot recover compressed or encrypted files. During a scan, it will display such a file as being 0% recoverable.</p> |
| Locale | In NTFS, all filenames are stored as Unicode. A filename is converted into the current locale for display by ntfsundelete. The utility has successfully displayed Chinese pictogram filenames and then correctly recovered them. |
| Extended MFT Records | In rare circumstances, a single MFT Record will not be large enough to hold the metadata describing a file (a file would have to be in hundreds of fragments for this to happen). In these cases, one MFT record might hold the filename, while another will hold the information about the data. ntfsundelete will not try and piece together such records. It will simply list unnamed files with data. |
| Recovered File's Size and Creation Date | To recover a file, ntfsundelete has to read the file's metadata. Unfortunately, when a file is deleted, the metadata can be left in an inconsistent state. For example, the file size might be recorded as zero; the creation date of a file might be set to the time it was deleted or to a random time. In such situations, ntfsundelete picks the largest file size it finds and writes that to disk. It also tries to set the file's creation date to the last-modified date. This date might be the correct last modified date, or something unexpected. |

Options Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, `-fv` is the equivalent of `-f -v`. A full-name option can be abbreviated to a unique prefix of its name.

`-b, --byte num`

Fill in the parts of unrecoverable file clusters with byte represented by *num*. The default is zeros.

`-C, --case`

Make filename search, when attempting a match with the `--match` option, case-sensitive. The default filename search is case-insensitive.

`-c, --copy range`

This “wizard” option writes a block of MFT FILE records to a file. The default file is mft which will be created in the current directory. This option can be combined with the `--output` and `--destination` options.

`-d, --destination dir`

Specify the location of the output file for the `--copy` and `--undelete` options.

`-f, --force`

Overrides some sensible defaults, such as not overwriting an existing file. Use this option with caution.

`-h, --help`

Show a list of options with a brief description of each one.

`-i, --inodes range`

Recover the files within the specified range of inode numbers. *range* can be a single inode number, several numbers separated by commas, or a range separated by a dash (-).

`-m, --match pattern`

Filter the output by looking only for filenames that match *pattern*. The pattern can include the wildcards `?`, matching exactly one character, or `*`, matching zero or more characters. By default, the matching is case-insensitive. To make the search case-sensitive, use the `--case` option.

`-O, --optimistic`

Recover parts of the file even if they are currently marked as in use.

`-o, --output file`

Set the name of the output file created by the `--copy` or `--undelete` options.

`-P, --parent`

Display the parent directory of a deleted file.

`-p, --percentage num`

Filter the output of the `--scan` option by matching only files with *num* percent of recoverable content.

- q, --quiet
Reduce the amount of output to a minimum. This option is not useful with the --scan option.
- s, --scan
Search through an NTFS volume and display a list of files that could be recovered. This is the default action of `ntfsundelete`. This list can be filtered by filename, size, percentage recoverable, or last modification time, using the --match, --size, --percent, and --time options, respectively.

In the output from this option, the %age (percentage) field displays how much of a file can potentially be recovered.

- S, --size *range*
Filter the output of the --scan option by looking for a particular range of file sizes. *range* can be specified as two numbers separated by a hyphen (-). A unit of size can be abbreviated using the suffixes k, m, g, and t, for kilobytes, megabytes, gigabytes, and terabytes respectively.
- t, --time *since*
Filter the output of the --scan option. Match only files that have been altered since this time. The time must be given as number and a suffix of d, w, m, or y for, respectively, days, weeks, months, or years.
- T, --truncate
The default behavior of `ntfsundelete` is to round *up* a file's size to the nearest cluster (which will be a multiple of 512 bytes). In cases where the utility has complete data about the size of a file, this option restores the file to exactly that size.
- u, --undelete
Specifies undelete mode. You can specify the files to be recovered using by using --match or --inodes options. This option can be combined with --output, --destination, and --byte.

When the file is recovered it will be given its original name, unless the --output option is used.
- v, --verbose
Increase the amount of output that `ntfsundelete` displays.
- V, --version
Display the version number, copyright, and license for `ntfsundelete`.

Examples **EXAMPLE 1** Searching for Deleted Files

The following command searches for deleted files on a specific device.

```
# ntfsundelete /dev/dsk/c0d0p1
```

EXAMPLE 2 Scanning for Files Matching a Wildcard

The following command searches for deleted files that match *.doc.

```
# ntfsundelete /dev/dsk/c0d0p1 -s -m '*.doc'
```

EXAMPLE 3 Searching for Files of a Certain Size

The following command looks for deleted files between 5000 and 6000000 bytes, with at least 90% of the data recoverable, on /dev/dsk/c0d0p1.

```
# ntfsundelete /dev/dsk/c0d0p1 -S 5k-6m -p 90
```

EXAMPLE 4 Searching for Recently Changed Files

The following command searches for deleted files altered in the last two days.

```
# ntfsundelete /dev/dsk/c0d0p1 -t 2d
```

EXAMPLE 5 Specifying an Inode Range

The following command undeletes inodes 2, 5 and 100 to 131 of device /dev/sda1.

```
# ntfsundelete /dev/sda1 -u -i 2,5,100-131
```

EXAMPLE 6 Specifying an Output File and Directory

The following command undeletes inode number 3689, names the file work.doc, and stores it in the user's home directory.

```
# ntfsundelete /dev/dsk/c0d0p1 -u -i 3689 -o work.doc -d ~
```

EXAMPLE 7 Saving MFT Records

The following command saves MFT records 3689 to 3690 to a file debug.

```
# ntfsundelete /dev/dsk/c0d0p1 -c 3689-3690 -o debug
```

Authors ntfsundelete was written by Richard Russon and Holger Ohmacht, with contributions from Anton Altaparmakov.

Name nwamadm – administer network configuration profiles

Synopsis nwamadm enable [-p *profile-type*] [-c *ncu-class*] *profile-name*
 nwamadm disable [-p *profile-type*] [-c *ncu-class*] *profile-name*
 nwamadm list [-x] [-p *profile-type*] [-c *ncu-class*]
 [*profile-name*]
 nwamadm show-events
 nwamadm scan-wifi *linkname*
 nwamadm select-wifi *linkname*
 nwamadm help

Description The nwamadm help utility is used to administer NWAM profiles and interact with the NWAM daemon.

There are three types of NWAM profiles: Network Configuration Profiles (NCPs), Locations, and External Network Modifiers (ENMs).

At any given time, there is one active NCP and one active Location on a system. Enabling a different NCP or Location (with activation-mode manual) will implicitly disable the current active NCP or Location. The current Location (if its activation-mode is manual) can also be disabled, though the effect of this will be to “turn off” some aspects of the system's networking capabilities, such as name services. Explicitly disabling an NCP is not permitted, as that would effectively shut down the basic network connectivity of the system. An NCP is only disabled implicitly when a different NCP is enabled.

Conversely, there can be zero or more active ENMs at any given time. Thus enabling or disabling one ENM has no effect on other active ENMs.

Enabling and disabling of individual NCUs is also allowed; the specified NCU must be part of the currently active NCP, and must have its activation mode set to manual. If an NCU class is not specified, all NCUs (one link and/or one interface) with the given name will be enabled or disabled.

Enabling and disabling of objects is performed asynchronously. Thus, the request to enable or disable can succeed, while the action itself fails. A failure of this sort will be reflected in the object state; maintenance state indicates that the last action taken failed.

Sub-commands The following subcommands are supported:

enable [-p *profile-type*] [-c *ncu-class*] *profile-name*
 Enable the specified profile. If the profile name is not unique, the profile type must be specified to identify the profile to be enabled. If the profile type is NCU and the name is not unique (that is, there is both a link and interface NCU with the same name), both NCUs will be enabled, unless the -c option is used to specify the NCU class. Profile type must be one of ncp, ncu, loc, or enm; NCU class must be one of phys or ip.

`disable [-p profile-type] [-c ncu-class] profile-name`

Disable the specified profile. If the profile name is not unique, the profile type must be specified to identify the profile to be disabled. If the profile type is NCU and the name is not unique (that is, there is both a link and interface NCU with the same name), both NCUs will be disabled, unless the `-c` option is used to specify the NCU class. Profile type must be one of `ncu`, `loc`, or `enm`; NCU class must be one of `phys` or `ip`.

`list [-x] [-p profile-type] [-c ncu-class] [profile-name]`

List all available profiles and their current state. If a specific profile is specified by name, list only the current state of that profile. If the profile name is not unique, all profiles with the given name will be listed; or the profile type and/or NCU class can be included to identify a specific profile. If only a type is provided, list all profiles of that type. Listing the active NCP will include the NCUs that make up that NCP.

Possible state values are:

`disabled`

A manually-activated profile that has not been activated.

`offline`

A conditionally- or system-activated profile that has not been activated. It might not be active because its conditions have not been satisfied; or it might be that another profile has more specific conditions that are met and has been activated instead (in the case of profile types that must be activated one at a time, such as Locations).

`online`

A conditionally- or system-activated profile whose conditions have been met and that has been successfully activated; or a manually-activated profile that has been successfully activated at the request of the user.

`maintenance`

Activation of the profile was attempted, but failed.

`initialized`

The profile represents a valid configuration object for which no action has yet been taken.

`uninitialized`

The profile represents a configuration object not present in the system; for example, an NCU corresponding to a physical link that has been removed.

`show-events`

Listen for stream of events from the NWAM daemon and display them.

`scan-wifi linkname`

Initiate a wireless scan on link *linkname*.

`select-wifi linkname`

Select a wireless network to connect to from scan results on link *linkname*. Prompts for selection, WiFi key, and so forth, if necessary.

help

Display a usage message with short descriptions for each subcommand.

Examples EXAMPLE 1 Enabling a User-Specified Location

The following command enables a user-specified location.

```
# nwamadm enable -p loc office
Disabled loc 'home'.
Enabled loc 'office'
```

EXAMPLE 2 Disabling an ENM

The following command disables an ENM.

```
# nwamadm disable -p enm myvpn
Disabled enm 'myvpn'.
```

EXAMPLE 3 Listing All NCPs

The following command lists all NCPs.

```
# nwamadm list -xp ncp
TYPE          PROFILE      STATE      AUXILIARY STATE
ncp           Automatic   disabled   disabled by administrator
ncp           User        online     active
ncu:phys      nge0        online     interface/link is up
ncu:ip        nge0        online     interface/link is up
ncu:phys      nge1        offline    interface/link is down
ncu:ip        nge1        offline    conditions for activation are
unmet
```

EXAMPLE 4 Listing NCUs in Active NCP

The following command lists all ip NCUs in the active NCP.

```
# nwamadm list -c ip
TYPE          PROFILE      STATE
ncu:ip        bge0         online
ncu:ip        bge1         disabled
```

EXAMPLE 5 Forcing a Scan

The following command forces a scan on the wireless interface wpi0.

```
# nwamadm scan-wifi wpi0
```

EXAMPLE 6 Selecting a WiFi Network

The following command selects a WiFi network that is broadcasting its ESSID.

```
# nwamadm select-wifi wpi0
1: ESSID testing BSSID 0:40:96:29:e9:d8
2: ESSID sunwifi BSSID 0:b:e:9f:b5:80
```

EXAMPLE 6 Selecting a WiFi Network (Continued)

```
3: ESSID sunwifi BSSID 0:b:e:85:26:c0
4: ESSID sunwifi BSSID 0:b:e:49:2f:80
5: Other
```

```
Choose WLAN to connect to [1-5]: 2
#
```

EXAMPLE 7 Selecting a WiFi Network (Alternative)

The following command selects a WiFi network that is not broadcasting its ESSID.

```
# nwamadm select-wifi wpi0
1: ESSID testing BSSID 0:40:96:29:e9:d8
2: ESSID sunwifi BSSID 0:b:e:85:26:c0
3: ESSID sunwifi BSSID 0:b:e:9f:b5:80
4: ESSID sunwifi BSSID 0:b:e:49:2f:80
5: ESSID sunwifi BSSID 0:b:e:49:62:c0
6: Other
```

```
Choose WLAN to connect to [1-6]: 6
```

```
Enter WLAN name: oraclewifi
```

```
1: None
2: WEP
3: WPA
```

```
Enter security mode: 2
```

```
Enter WLAN key for ESSID oraclewifi: 123456
```

```
Enter key slot [1-4]: 1
```

```
#
```

EXAMPLE 8 Monitoring `nwamd`

The following command monitors `nwamd(1M)` when switching locations.

```
# nwamadm show-events
EVENT          DESCRIPTION
OBJECT_ACTION  loc Automatic -> action refresh
OBJECT_STATE   loc Automatic -> state offline*, method/service executi
OBJECT_STATE   loc Automatic -> state online, active
OBJECT_ACTION  loc home -> action refresh
OBJECT_ACTION  loc NoNet -> action refresh
OBJECT_ACTION  loc User -> action refresh
OBJECT_ACTION  loc home -> action enable
OBJECT_STATE   loc home -> state offline*, method/service executing
OBJECT_STATE   loc Automatic -> state offline, conditions for activati
OBJECT_STATE   loc home -> state online, active
```

EXAMPLE 8 Monitoring nwamd (Continued)

```
^C
#
```

Name nwamcfg – create and modify network configuration profiles

Synopsis nwamcfg
 nwamcfg *subcommand* [*options...*]
 nwamcfg [-d] -f *command-file*
 nwamcfg help [*subcommand*]

Description The nwamcfg utility manipulates system network configuration profiles. nwamcfg can be invoked interactively, with an individual subcommand, or by specifying a command file that contains a series of subcommands.

nwamcfg commands are performed within a scope. There are three scopes: global, profile, and NCP. When nwamcfg is invoked without any arguments, the editing session begins in the global scope. In the global scope, NCPs, Location and ENM profiles, and Known WLAN entries are available to operate on. (To flesh out the acronyms: NCP is Network Configuration Profiles; ENM is External Network Modifier.) Selecting an NCP will move the editing session to the NCP scope; from there, individual NCUs may be created or selected to move into the profile scope. Also, at the global scope, selecting or creating a Location, ENM, or Known WLAN will move the editing session to the profile scope.

Within a given profile scope, profile properties may be viewed and modified.

In interactive mode, changes are not stored to persistent storage until commit is invoked. Commit is implicitly invoked at “end” or “exit”, or can be explicitly invoked by the user. When commit is invoked, the entire profile is committed. In order to maintain the consistency of persistent storage, the commit operation includes a verify step; if verification fails, the commit also fails. If an implicit commit fails, the user will be given the option of ending or exiting without committing the current changes, or remaining in the current scope to make further changes.

Properties nwamcfg supports the following types of properties:

- NCU properties
- properties of interface NCUs
- properties common to all link NCUs
- location properties
- ENM properties
- known WLAN properties

These properties are described in the following subsections.

NCU Properties The following properties are common to all NCUs.

type: enumerated value: *link* | *interface*

Specifies the NCU type, either *link* or *interface*. The value is implicitly determined based on the specified class.

`class`: enumerated value: *phys* for link NCUs; *ip* for interface NCU
Specifies the NCU class.

`parent`: string: *name of parent NCP*
Specifies the NCP of which this NCU is a component.

The `type`, `class`, and `parent` properties are set when the NCU is created and cannot be changed later.

`enabled`: boolean: `true` | `false`
If the activation-mode is `manual`, the `enabled` property reflects the NCU's current state. This property is read-only; it is changed indirectly by enabling or disabling the NCU using [nwamadm\(1M\)](#).

The default value is `true`.

Properties of Interface NCUs `ip-version`: list of enumerated values: `ipv4` | `ipv6`
The version(s) of IP that should be used on this NCU.

The default value is `ipv4, ipv6`.

`ipv4-addrsrc`: list of enumerated values: `dhcp` | `static`
Identifies the source of IPv4 addresses assigned to this NCU; multiple values may be assigned. If one of the values assigned is `static`, the `ipv4-addr` property must include at least one IPv4 address to be assigned to the NCU.

The default value is `dhcp`.

`ipv4-addr`: list of IPv4 address(es)
One or more IPv4 addresses to be assigned to this NCU.

`ipv4-default-route`: *IPv4 address*
The IPv4 address of the default router; if this property is set, a default route for IPv4 traffic will be associated with this interface when it is brought up.

`ipv6-addrsrc`: list of enumerated values: `dhcp` | `autoconf` | `static`
Identifies the source of IPv6 addresses assigned to this NCU; multiple values can be assigned. If one of the values assigned is `static`, the `ipv6-addr` property must include at least one IPv6 address to be assigned to the NCU.

The default value is `dhcp, autoconf`.

`ipv6-addr`: list of IPv6 address(es)
One or more IPv6 addresses to be assigned to this NCU.

`ipv6-default-route`: *IPv6 address*
The IPv6 address of the default router; if this property is set, a default route for IPv6 traffic will be associated with this interface when it is brought up.

Properties Common to
All LINK NCUs

`activation-mode`: enumerated value: `manual` | `prioritized`

The type of trigger for automatic activation of this NCU.

The default value is `manual`.

`priority-group`: `uint64`: *group priority number*

If `activation-mode` is set to `prioritized`, this property specifies the priority group to which this NCU belongs. A group consists of one or more NCUs; smaller numbers are higher priority. The highest priority group that is determined to be available will be activated by `nwamd(1M)`, and will remain so until it is no longer available, or until a higher priority group becomes available.

`priority-mode`: enumerated value: `exclusive` | `shared` | `all`

If `activation-mode` is set to `prioritized`, this property specifies the mode used to determine availability and activation behavior for a priority group.

`exclusive`

At least one NCU must be available to make the group available, and only one NCU will be activated. If more than one member NCU is available, `nwamd(1M)` will randomly choose one to activate.

`shared`

At least one NCU must be available to make the group available; all available NCUs will be activated.

`all`

All group member NCUs must be available to make the group available; all member NCUs will be activated.

`link-mac-addr`: `string`: 48-bit MAC address

The MAC address assigned to this link. By default, NWAM will request the factory-assigned or default MAC address for the link; set a different value here to override that selection.

`link-autopush`: `list of strings`: modules to be pushed over the link

Identifies a list of modules that should be automatically pushed over the link when it is opened.

`link-mtu`: `uint64`: MTU size for this link

This property will be automatically set to the default MTU for the physical link; that value may be overridden by setting this property to a different value.

Note that the range of allowed MTU values depends on the underlying hardware. Because NCUs may be created before the underlying hardware is present with driver attached, it is not possible to verify the value set at the time the NCU is edited. If an NCU fails to activate because of an invalid MTU size, this will be indicated in the system log, and the NCU will be placed in maintenance state.

Location Properties `activation-mode: enumerated value: manual | system | conditional-all | conditional-any`

The type of trigger for automatic activation of this location.

The default value is `manual`.

`enabled: boolean: true | false`

If the `activation-mode` is `manual`, the `enabled` property reflects the location's current state. This property is read-only; it is changed indirectly by enabling or disabling the location using `nwamadm(1M)`.

The default value is `false`.

`conditions: list of strings: conditional expressions`

If `activation-mode` is set to `conditional-all` or `conditional-any`, this property specifies the test to determine whether this location should be activated. The conditional expression is made up of a sequence of conditions that can be assigned a boolean value, such as “`advertised-domain is sun.com`” or “`ip:bge0 is-not active.`” The format of these expressions is defined in the “Condition Expressions” section, below. If multiple conditions are specified, either all must be true to meet the activation requirements (when `activation-mode` is `conditional-all`) or any one may be true (when `activation-mode` is `conditional-any`).

Note the distinction between `advertised-domain` and `system-domain`. The advertised domain is learned by means of external communication, such as the `DNSdomain` or `NISdomain` advertised by a DHCP server. This attribute is useful for conditional activation of locations; for example, if the advertised domain is `mycompany.com`, activate the “work” location. The system domain is the domain which is currently assigned to the system; that is, it is the value returned by the `domainname(1M)` command. This attribute is useful for conditional activation of ENMs, as it will only become true after a location has been activated and the system is configured for that particular domain.

`default-domain: string: system domain name`

The domain name that should be applied to the system; this domain name will be used by NIS and LDAP.

`nameservices: enum value list: files | dns | nis | ldap`

Specifies the name services that should be configured, such as DNS, NIS, and LDAP.

`nameservices-config-file: string: path to nsswitch.conf file`

Specifies the `nsswitch.conf` file to be used. This property must always have a value. If the `nameservices` property specifies a single name service, this property will, by default, contain `/etc/nsswitch.nameservice` for the name service specified in the `nameservices` property; this value can be changed by the user. If the `nameservices` property identifies more than one name service, the user must specify an additional value for this property.

`dns-nameservice-configsrc`: enum value list: `manual` | `dhcp`

Specifies the source(s) that should be used to obtain configuration information for the DNS name service. If `manual` is included, the remaining `dns-nameservice-*` properties will be used.

`dns-nameservice-domain`: string: *domain name*

`dns-nameservice-servers`: string list: *name server address(es)*

`dns-nameservice-search`: string: *domain search string*

If DNS is one of the configured name services and `manual` is one of its configuration sources, these properties specify its configuration parameters. Only the `servers` property is required; `search` and `domain` are optional.

`nis-nameservice-configsrc`: enum value list: `manual` | `dhcp`

Specifies the source(s) that should be used to obtain configuration information for the NIS name service. If `manual` is included, the remaining `nis-nameservice-*` properties will be used.

`nis-nameservice-servers`: string list: *name server address(es)*

If NIS is one of the configured name services and `manual` is one of its configuration sources, this property specifies its server address. If this property is not specified, the NIS client will be started in broadcast mode.

`ldap-nameservice-configsrc`: enum value list: `manual`

Specifies the source that should be used to obtain configuration information for the LDAP name service. `manual` is currently the only option for LDAP; thus the `ldap-nameservice-*` properties must be provided to complete LDAP configuration.

`ldap-nameservice-servers`: string list: *name server address(es)*

If LDAP is one of the configured name services, this property specifies its server address. This property is required, and it is expected that the specified server will have a client profile which will be used to complete client configuration.

`nfsv4-domain`: string: *domain name to be used for NFSv4*

Specifies the NFSv4 domain to be used. If this value is unspecified, the name service domain will be used.

`ipfilter-config-file`: string: *path to ipfilter IPv4 configuration file*

`ipfilter-v6-config-file`: string: *path to ipfilter IPv6*

`ipnat-config-file`: string: *path to ipnat configuration file*

`ippool-config-file`: string: *path to ippool configuration file*

These properties each specify the path to the rules file for a component of the `ipfilter(5)` configuration. If a given `config-file` property is set, the corresponding IP filter component will be enabled, reading configuration from the specified file.

`ike-config-file`: string: *path to IKE configuration file*

Specifies the IKE configuration file. If a value is specified, the `svc:/network/ipsec/ike` service will be enabled, reading configuration from the specified file.

`ipsecpolicy-config-file`: string: *path to IPsec policy configuration file*
 Specifies the IPsec policy configuration file. If a value is specified, the `svc:/network/ipsec/policy` service will be enabled, reading configuration from the specified file.

ENM Properties `activation-mode`: enumerated value: `manual` | `conditional-all` | `conditional-any`
 The type of trigger for automatic activation of this ENM.

The default value is `manual`.

`enabled`: boolean: `true` | `false`

If the `activation-mode` is `manual`, the `enabled` property reflects the ENM's current state. This property is read-only; it is changed indirectly by enabling or disabling the ENM using [nwamadm\(1M\)](#).

The default value is `false`.

`conditions`: list of strings: *conditional expressions*

If `activation-mode` is set to `conditional-all` or `conditional-any`, this property specifies the test to determine whether or not this ENM should be activated. The conditional expression is made up of a sequence of conditions that can be assigned a boolean value, such as “`system-domain is sun.com`” or “`ip:bge0 is-not active`.” The format of these expressions is defined in the “Condition Expressions” section below. If multiple conditions are specified, either all must be true to meet the activation requirements (when `activation-mode` is `conditional-all`) or any one may be true (when `activation-mode` is `conditional-any`).

Note the distinction between `advertised-domain` and `system-domain`. The `advertised-domain` is learned by means of external communication, such as the `DNSdomain` or `NISdomain` advertised by a DHCP server. This attribute is useful for conditional activation of locations; for example, if the `advertised-domain` is `mycompany.com`, activate the “work” location. The `system-domain` is the domain which is currently assigned to the system; that is, it is the value returned by the `|domainname|(1M)` command. This attribute is useful for conditional activation of ENMs, as it will only become true after a location has been activated and the system configured for that particular domain.

`fmri`: string: *service FMRI*

If this ENM is implemented as an SMF service, this property identifies that service. If this property is specified, the ENM will be activated by enabling the service and deactivated by disabling the service.

`start`: string: *start command*

If this ENM is not implemented as an SMF service, this property identifies the command that should be exec'ed to start or activate the ENM. This property will be ignored if the `FMRI` property is set.

`stop`: string: *stop command*

If this ENM is not implemented as an SMF service, this property identifies the command that should be executed to stop/deactivate the ENM. This property will be ignored if the FMRI property is set.

Known WLAN
Properties

`bssids`: list of strings: WLAN BSSID(s) (AP MAC addresses)

If a specific Access Point should be preferred over others with the same name/ESSID, this property allows the AP's BSSID to be specified.

`priority`: uint64: a numeric priority value

The relative priority of this WLAN; a smaller number represents higher priority.

Note that this number can be changed if subsequent changes to the set of Known WLAN objects require such a change. For example, consider a system that is configured with two Known WLAN objects, `wlanA` and `wlanB`. `wlanA` has priority 1, and `wlanB` has priority 2. A new Known WLAN, `wlanC`, is created and assigned priority 2. In this case, the complete list will be updated such that `wlanA` has priority 1, `wlanC` has priority 2, and `wlanB` has priority 3. No two WLANs can have the same priority value, so the addition of `wlanC` at priority 2 forces `wlanB` to be shifted down in priority. If any additional WLANs existed at lower priorities than `wlanB`, they would be shifted accordingly.

`keyslot`: uint64: the key slot to be used for this WLAN

If the WLAN uses an encryption mode that supports multiple keyslots, the slot to place the key can be specified in this property. If unspecified, slot 1 is used by default.

`keyname`: list of strings: Secure object name(s)

Allows the user to associate secure objects created using [dladm\(1M\)](#) with Known WLANs.

Condition Expressions Locations and ENMs can be activated based on a set of user-specified conditions. The following table summarizes the syntax of those condition expressions.

| Object Type | Object | Condition |
|--------------------------------|-------------------------------------|---------------------------------------------|
| <code>npc ncu enm loc</code> | name | is/is-not active |
| Object Type | Condition | Object |
| ----- | ----- | ----- |
| <code>ssid</code> | is/is-not/contains/does-not-contain | name string |
| <code>bssid</code> | is/is-not | bssid string |
| <code>ip-address</code> | is/is-not | IPv4 or IPv6 address |
| <code>ip-address</code> | is-in-range/is-not-in-range | IPv4 or IPv6 address plus netmask/prefixlen |
| <code>advertised-domain</code> | is/is-not/contains/does-not-contain | name string |
| <code>system-domain</code> | is/is-not/contains/does-not-contain | name string |

Options The following options are not associated with any particular `nwamcfg` subcommand:

`-d`

Removes all configuration before reading subcommands from the command file (see following option).

`-f command_file`

Reads and executes `nwamcfg` subcommands from *command_file*.

Sub-commands The following subcommands are supported.

`cancel`

End the current profile specification without committing the current changes to persistent storage, and pop up to the next higher scope.

This subcommand is valid in the NCP and profile scopes.

`clear prop-name`

Clear the value for the specified property.

This subcommand is valid in the profile scope.

`commit`

Commit the current profile to persistent storage. Because a configuration must be correct to be committed, this operation automatically performs a verify on the object as well. The commit operation is attempted automatically upon leaving the current scope (with either the `end` or `exit` subcommand).

This subcommand is valid in the profile scope.

Note that, in non-interactive mode, a commit is not required, as the commit is implicit for any subcommand that changes a value.

`create [-t template] object-type [class] object-name`

Create an in-memory profile of the specified type and name. The `-t template` option specifies that the new object should be identical to *template*, where *template* is the name of an existing object of the same type. If the `-t` option is not used, the new object is created with default values. For NCPs, only a “User” NCP can be created.

This subcommand is valid in the global and NCP scopes.

`destroy { -a | object-type [class] object-name }`

Remove all or the specified profile from memory and persistent storage. This action is immediate; it does not need to be committed. A destroyed object cannot be reverted.

This subcommand is valid in the global and NCP scopes if a specific object is specified; the `-a` option is only valid in the global scope.

end

End the current profile specification, and pop up to the next higher scope. The current object is verified and committed before ending; if either the verify or commit fails, an appropriate error message is issued and the user is given the opportunity to end without committing the current changes, or to remain in the current scope and continue editing.

This subcommand is valid in any scope.

exit

Exit the nwamcfg session. The current profile is verified and committed before ending; if either fails, an appropriate error message is issued and the user is given the opportunity to exit without committing the current changes, or to remain in the current scope and continue editing.

This subcommand is valid in any scope.

export [-d] [-f *output-file*] [*object-type* [*class*] *object-name*]

Print the current configuration at the current or specified scope to standard out, or to a file specified with the -f option. The -d option generates a `destroy -a` as the first line of output. This subcommand produces output in a form suitable for use in a command file. System created objects, including the Automatic NCP and the Automatic, NoNet, and User locations, cannot be exported.

This subcommand is valid in any scope.

get [-V] *prop-name*

Get the current (in-memory) value of the specified property. By default, both the property name and value are printed; if the -V option is specified, only the property value is displayed.

This subcommand is valid in the profile scope.

help [*subcommand*]

Display general help or help about a specific subcommand.

This subcommand is valid in any scope.

list [-a] [*object-type* [*class*] *object-name*]

List all profiles, property-value pairs and resources that exist at the current or specified scope. When listing properties of an object, the default behavior is to only list properties that apply to the specified configuration. That is, if listing an IP NCU for which `ipv4-addrsrc` is `dhcp`, the `ipv4-addr` property will not be listed. Including the -a option will result in all properties being listed, whether or not they apply to the current settings.

This subcommand is valid in any scope.

revert

Delete any current changes to the current profile and revert to the values from persistent storage.

This subcommand is valid in the profile scope.

`select object-type [class] object-name`

Select one of the profiles available at the current scope level and jump down into that object's scope. The selected object will be loaded into memory from persistent storage.

This subcommand is valid in the global and NCP scopes.

`set prop-name=value1[,value2...]`

Set the current (in-memory) value of the specified property. If performed in non-interactive mode, the change is also committed to persistent storage.

The delimiter for values of multi-valued properties is “,” (comma). If any of the individual values in such a property contains a comma, it must be escaped (that is, written as \,). Commas within properties that can only have a single value are not interpreted as delimiters and need not be escaped.

This subcommand is valid in the profile scope.

`verify`

Verify that the current in-memory object has a valid configuration.

This subcommand is valid in the profile scope.

`walkprop [-a]`

Walk each property associated with the current profile. For each property, the name and current value are displayed, and a prompt is given to allow the user to change the current value.

The delimiter for values of multi-valued properties is “,” (comma). If any of the individual values in such a property contains a comma, it must be escaped (that is, written as \,). Commas within properties that can only have a single value are not interpreted as delimiters and need not be escaped.

By default, only properties that are required based on properties that are already set will be walked; that is, if `ipv4-addrsrc` is set to `dhcp`, `ipv4-addr` will not be walked. Including the `-a` option will result in all available properties being walked.

This subcommand is valid in the profile scope.

This subcommand is only meaningful in interactive mode.

Examples **EXAMPLE 1** Setting an NCU Property

The following command sets an NCU property from the command line (that is, in non-interactive mode).

```
# nwamcfg "select ncp User; select ncu phys net1; set link-mtu=1492"
```

EXAMPLE 2 Listing Top-Level Profiles

The following command lists all top-level profiles from the command line.

```
# nwamcfg list
NCPs:
    Automatic
    User
Locations:
    Automatic
    home
    NoNet
    office
ENMs:
    enmtest
    myenm
WLANS:
    sunwifi
    coffeeshop
    linksys
```

EXAMPLE 3 Destroying a Location Profile

The following command destroys a Location profile from the command line.

```
# nwamcfg destroy loc home
Destroyed loc 'home'
```

EXAMPLE 4 Creating an NCU Profile

The following command sequence interactively creates an NCU profile.

```
# nwamcfg
nwamcfg> select ncp user
nwamcfg:ncp:User> create ncu ip net1
Created ncu 'net1'. Walking properties ...
ip-version (ipv4,ipv6) [ipv4|ipv6]> ipv4
ipv4-addrsrc (dhcp) [dhcp|static]> static
ipv4-addr> 168.1.2.3
nwamcfg:ncp:User:ncu:net1> list
ncu:net1
    type:                interface
    class:                ip
    parent:               "User"
    enabled:              true
    ip version:           ipv4
    ipv4-addrsrc:         static
    ipv4-addr:            "168.1.2.3"
    ipv6-addrsrc:         dhcp,autoconf
nwamcfg:ncp:User:ncu:net1> commit
Committed changes
```

EXAMPLE 4 Creating an NCU Profile *(Continued)*

```
nwamcfg:ncp:User:ncu:net1> end
nwamcfg:ncp:User> exit
```

EXAMPLE 5 Manipulating an ENM

The following command sequence selects an existing ENM, display its contents, and changes a property value.

```
# nwamcfg
nwamcfg>select enm myenm
nwamcfg:enm:myenm>list
ENM:myenm
    activation-mode manual
    enabled             true
    start               "/usr/local/bin/myenm start"
    stop                "/usr/local/bin/myenm stop"
nwamcfg:enm:myenm>set stop="/bin/alt_stop"
nwamcfg:enm:myenm>list
ENM:myenm
    activation-mode manual
    enabled             true
    start               "/usr/local/bin/myenm start"
    stop                "/bin/alt_stop"
nwamcfg:enm:myenm>exit
Committed changes
```

EXAMPLE 6 Configuring a Static Address

The following command sequence configures a static address of 192.168.2.12/24 on interface `bge0` using the Home NCP. This interface is enabled by default when the Home NCP is activated.

```
# nwamcfg
nwamcfg> create ncp Home
```

First configure phys NCU:

```
nwamcfg:ncp:Home> create ncu phys bge0
Created ncu 'bge0'. Walking properties ...
activation-mode (manual) [manual|prioritized]>
link-mac-addr>
link-autopush>
link-mtu>
nwamcfg:ncp:Home:ncu:bge0> end
Committed changes
nwamcfg:ncp:Home>
```

Then, configure IP NCU:

EXAMPLE 6 Configuring a Static Address (Continued)

```

nwamcfg:ncp:Home> create ncu ip bge0
Created ncu 'bge0'. Walking properties ...
ip-version (ipv4,ipv6) [ipv4|ipv6]>
ipv4-addrsrc (dhcp) [dhcp|static]> static
ipv4-addr> 192.168.2.10/24
ipv4-default-route>
ipv6-addrsrc (dhcp,autoconf) [dhcp|autoconf|static]>
ipv6-default-route>
nwamcfg:ncp:Home:ncu:bge0> list
ncu:bge0
      type                interface
      class               ip
      parent              "Home"
      enabled              true
      ip-version           ipv4,ipv6
      ipv4-addrsrc         static
      ipv4-addr            "192.168.2.10/24"
      ipv6-addrsrc         dhcp,autoconf
nwamcfg:ncp:Home:ncu:bge0> exit
Committed changes
#

```

Switch to the Home NCP using [nwamadm\(1M\)](#).

EXAMPLE 7 Configuring Location Based on a Condition

The following command sequences configures a location based on a condition. The location is activated whenever the IP address is in the 10.0.8.0/24 subnet. Also, NIS is configured in this location.

```

nwamcfg> select loc office
nwamcfg:loc:office> list
loc:office
      activation-mode      conditional-any
      conditions           "ip-address is 10.0.8.0/24"
      enabled              false
      nameservices         dns,nis
      nameservices-config-file "/etc/nsswitch.nis"
      dns-nameservice-configsrc dhcp
      nis-nameservice-configsrc manual
      nis-nameservice-servers "10.2.18.24"
      default-domain       "labs.east.sun.com"
nwamcfg:loc:office>

```

EXAMPLE 8 Creating a Known WLAN

The following command sequence establishes a known WLAN named coffeeshop with a WEP key.

```
nwamcfg> select wlan coffeeshop
nwamcfg:wlan:coffeeshop> list
known wlan:coffeeshop
    priority          2
    keyname           "foo"
    security-mode     wep
nwamcfg:wlan:coffeeshop> set priority=1
nwamcfg:wlan:coffeeshop> end
Committed changes
```

EXAMPLE 9 Exporting Current Configuration to a File

The following command exports the current configuration to a file.

```
nwamcfg> export -f /tmp/nwam.config
```

Or, perform the same task from the Unix command line:

```
# nwamcfg export -f /tmp/nwam.config
```

EXAMPLE 10 Importing Current Configuration from a File

The following command imports the current configuration from a file.

```
# nwamcfg -f /tmp/nwam.config
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcsr |
| Interface Stability | Committed |

See Also [dladm\(1M\)](#), [domainname\(1M\)](#), [netcfgd\(1M\)](#), [nwamadm\(1M\)](#), [nwamd\(1M\)](#), [attributes\(5\)](#), [ipfilter\(5\)](#)

See also `nwam-manager(1M)`, available in the JDS/GNOME man page collection.

Name nwamd – network auto-magic daemon

Synopsis /lib/inet/nwamd

Description nwamd is a system daemon to manage network interfaces.

This daemon is started automatically and should not be invoked directly. It does not constitute a programming interface.

Operation Whether this daemon is enabled or not depends on your installation medium. To check from within the GNOME desktop environment, double click on the “Network Manager” icon to open the “Connection Properties” window. If “Configure network automatically” is checked, then auto-magic mode is enabled. To check from the command line, enter the following:

```
% svcs svc:/network/physical
```

Two instances will be listed, one online and the other disabled. If the “nwam” instance is online, then this daemon is running.

To switch between manual and auto-magic mode, you can use the Network Monitor applet available within the GNOME desktop environment. You can also switch manually from the command line by entering:

```
% svcadm disable svc:/network/physical:default  
% svcadm enable svc:/network/physical:nwam
```

To go from auto-magic mode to manual mode:

```
% svcadm disable svc:/network/physical:nwam  
% svcadm enable svc:/network/physical:default
```

When switching modes like this, keep in mind that all network interfaces will be brought down then back up. Therefore, if a different IP address is configured in this process, existing applications and sessions might be disrupted.

The default configuration policy is to have one link active at a time. If a wired link is available (that is, physically connected), it will be preferred over wireless links. This default policy can be changed by creating alternate Network Configuration Profiles (NCPs); the `nwam-manager` GUI tool or the `nwamcfg(1M)` command can be used to create and modify NCPs.

If you used an earlier version of `nwamd`, which created an `/etc/nwam/ulp` configuration file, configuration present in that file will automatically be incorporated into the “User” NCP upon upgrade to the current version of `nwamd`.

The automatic behavior provided by the NWAM service requires that management of the network configuration be handed over to `nwamd`. Thus, any manual changes to the network configuration might be lost if conditions change such that a new profile is activated, or if `nwamd` is restarted. If persistent changes are desired, the recommended approach is to create an External Network Modifier (ENM), which can be activated and deactivated as needed by the NWAM service.

Service Properties The following list takes the form:

property_name *property_type* *default_value*
description

`debug` boolean `false`

Enables debug logging using `daemon.debug`.

`version` count `1`

Indicates whether legacy configuration has been imported and updated to the current version. The property does not exist until a pre-version-1 configuration has been updated, at which time it is created with value set to 1.

`autoconf` boolean `false`

Indicates whether open WLANs should be connected automatically, in the absence of a better (more preferred) choice.

`ncu_wait_time` count `60`

The number of seconds to wait for an NCU (or link/interface NCU pair, as appropriate) to come up before trying the next available NCU. The bringup activity will not be cancelled, and may eventually succeed, at which time the more preferred NCU will be activated and the alternate might be disabled, depending on the specified configuration conditions.

`condition_check_interval` count `120`

The number of seconds between periodic condition checks for conditionally activated objects. Minimum value is 30 seconds.

`scan_interval` count `120`

The number of seconds between periodic wireless scans.

`scan_level` astring `weak`

A signal strength threshold; if the currently connected AP drops below this signal level, and equivalent APs (of the same ESSID) are available at higher signal strength, the existing connection will be dropped in favor of a connection to an AP with stronger signal.

`strict_bssid` boolean `false`

If true, both ESSID and BSSID must be matched in order to connect to a previously connected WLAN. If false, only an ESSID match is required.

`active_ncp` astring `Automatic`

The currently active NCP. This property should not be set by the user; it is used internally by the NWAM service for persistence across restarts. The appropriate user interface to change the currently active NCP is by means of the `nwam-manager` GUI or the `nwamadm` command's `enable` subcommand.

Profiles The NWAM service manages network configuration by storing desired property values in profiles. It then determines which profile should be active at a given time, depending on current network conditions, and activates that profile. In addition to the Network Configuration Profiles (NCPs) discussed in the previous section, `nwamd` also manages Location and ENM profiles.

Network Configuration Profiles (NCPs) An NCP specifies the configuration of the local network components, including physical links, IP tunnel links, and IP interfaces. An IP interface must be associated with an underlying link of either type. These components are collectively referred to as Network Configuration Units, or NCUs.

There can be any number of NCPs configured on a system. The Automatic NCP is created and managed by `nwamd`, and cannot be modified by the user. This NCP consists of one link NCU and one interface NCU for each physical link present in the system. As links are added or removed from the system, their corresponding NCUs will be added or removed from the Automatic NCP. The policy implemented in this NCP is to prefer wired links over wireless, and to plumb IP on all connected wired links, or one wireless link if no wired links are connected.

The system will also create a User NCP upon upgrade from an earlier version of the NWAM service, based on the configuration found in the old `/etc/nwam/ulp` file. In most cases, the Automatic NCP will be active initially, even if a User NCP is created. However, if explicit changes, such as a static IP address, are detected in the old configuration, the User NCP will be active initially.

Finally, the user can create any number of additional NCPs. These NCPs are managed entirely by the user; NCUs must be added or removed explicitly, and it is possible to add NCUs that do not map to any link currently installed in the system, or to remove NCUs that do map to a link present in the system. The user can determine the policy for these NCPs.

After making its initial NCP selection, the system will not change the active NCP. The user may do this at any time using the GUI or the `nwamadm(1M)` command.

Locations A Location specifies system-wide network configuration, including areas such as name services, domain, IP Filter, and IPsec configuration.

External Network Modifiers (ENMs) External Network Modifiers are, as the name suggests, applications external to the NWAM service that can modify and/or create network configuration. `nwamd` will activate/deactivate an ENM depending on conditions that are specified as part of the ENM profile. Alternatively, the user might choose to manually activate/deactivate ENMs as needed.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcsr |
| Interface Stability | Volatile |

See Also [svcs\(1\)](#), [netcfgd\(1M\)](#), [nwamadm\(1M\)](#), [nwamcfg\(1M\)](#), [svcadm\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#)

See also `nwam-manager(1M)`, available in the JDS/GNOME man page collection.

Notes The networking service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/physical
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Name obpsym – Kernel Symbolic Debugging for OpenBoot Firmware

Synopsis modload -p misc/obpsym

Description obpsym is a kernel module that installs OpenBoot callback handlers that provide kernel symbol information to OpenBoot. OpenBoot firmware user interface commands use the callbacks to convert numeric *addresses* to kernel symbol names for display purposes, and to convert kernel symbol names to numeric *literals* allowing symbolic names to be used as input arguments to user interface commands.

Once obpsym is installed, kernel symbolic names may be used anywhere at the OpenBoot firmware's user interface command prompt in place of a literal (numeric) string. For example, if obpsym is installed, the OpenBoot firmware commands `ct race` and `dis` typically display symbolic names and offsets in the form *modname:symbolname + offset*. User interface Commands such as `dis` can be given a kernel symbolic name such as `ufs:ufs_mount` instead of a numeric address.

Placing the command

```
forceload: misc/obpsym
```

into the `system(4)` file forces the kernel module `misc/obpsym` to be loaded and activates the kernel callbacks during the kernel startup sequence.

obpsym may be useful as a kernel debugger in situations where other kernel debuggers are not useful. For example, on SPARC machines, if obpsym is loaded, you may be able to use the OpenBoot firmware's `ct race` command to display symbolic names in the stack backtrace after a watchdog reset.

Kernel Symbolic Name Syntax The syntax for a kernel symbolic name is:

```
[ module-name : ] symbol-name
```

Where *module-name* is the name of the kernel module that the symbol *symbol-name* appears in. A NULL module name is taken as “all modules, in no particular order” by obpsym. The module name `unix` is equivalent to a NULL module name, so that conflicts with words defined in the firmware's vocabulary can be avoided.

Typically, OpenBoot firmware reads a word from the input stream and looks the word up in its internal *vocabulary* before checking if the word is a *literal*. Thus, kernel symbols, such as `reset` may be given as `unix:reset` to avoid the unexpected side effect of the firmware finding and executing a matching word in its vocabulary.

| | | |
|--------------|----------------------------------------------------------------|----------------------------------------------|
| Files | <code>/etc/system</code> | System configuration information file. |
| | <code>/platform/<i>platform-name</i>/kernel/misc/obpsym</code> | Platform-specific kernel symbol information. |

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|--------------------------|
| Availability | system/library/processor |

See Also [kmdb\(1\)](#), [uname\(1\)](#), [kernel\(1M\)](#), [modload\(1M\)](#), [modunload\(1M\)](#), [system\(4\)](#), [attributes\(5\)](#)

OpenBoot 2.x Command Reference Manual

Warnings Some OpenBoot firmware user interface commands may use system resources incompatibly with the way they are used by the Unix kernel. These commands and the use of this feature as a kernel debugger may cause interactions that the Unix kernel is not prepared to deal with. If this occurs, the Unix kernel and/or the OpenBoot firmware user interface commands may react unpredictably and may panic the system, or may hang or may cause other unpredictable results. For these reasons, the use of this feature is only minimally supported and recommended to be used only as a kernel debugger of last resort.

If a breakpoint or watchpoint is triggered while the console frame buffer is powered off, the system can crash and be left in a state from which it is difficult to recover. If one of these is triggered while the monitor is powered off, you will not be able to see the debugger output.

Notes *platform-name* can be found using the `-i` option of [uname\(1\)](#)

obpsym is supported only on architectures that support OpenBoot firmware.

On some systems, OpenBoot must be completely RAM resident so the obpsym symbol callback support can be added to the firmware, if the firmware doesn't include support for the symbol callbacks. On these systems, obpsym may complain that it requires that “you must use ramforth to use this module”.

See the *OpenBoot 2.x Command Reference Manual* for details on how to use the *ramforth* command, how to place the command into *nvrामrc*, and how to set *use-nvrामrc?* to true. On systems with version 1.x OpenBoot firmware, *nvrामrc* doesn't exist, and the *ramforth* command must be typed manually after each reset, in order to use this module.

Once installed, the symbol table callbacks can be disabled by using the following OpenBoot firmware command:

```
0 0 set-symbol-lookup
```

Name oplhpd – Hot plug daemon for SPARC Enterprise Server line

Synopsis /usr/platform/SUNW,SPARC-Enterprise/lib/sparcv9/lib/oplhp

Description The hot plug daemon for SPARC Enterprise Servers is a daemon process that runs on the SUNW,SPARC-Enterprise family of servers. The daemon is started by the service management facility (see [smf\(5\)](#)) and communicates with the service processor when hot plug PCI cassettes change their dynamic reconfiguration state.

The service FMRI for oplhpd is:

```
svc:/platform/sun4u/oplhp:default
```

A domain supports only one running oplhpd process at a time.

Errors OPLHPD uses [syslog\(3C\)](#) to report status and error messages. All of the messages are logged with the LOG_DAEMON facility.

Error messages are logged with the LOG_ERR and LOG_NOTICE priorities, and informational messages are logged with the LOG_DEBUG priority. The default entries in the /etc/syslog.conf file log all of the OPLHPD error messages to the /var/adm/messages log.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------------------------------------------------|
| Availability | system/domain-configuration/sparc-enterprise,
SUNWdcsr |
| Interface Stability | Committed |

See Also [svcs\(1\)](#), [inetadm\(1M\)](#), [svcadm\(1M\)](#), [syslog\(3C\)](#), [syslog.conf\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Name parse_dynamic_clustertoc – parse clustertoc file based on dynamic entries

Synopsis *cdrom/export/exec/sparc.Solaris_2.x/sbin/install.d/parse_dynamic_clustertoc*
cdrom/export/exec/i386.Solaris_2.x/sbin/install.d/parse_dynamic_clustertoc

Description This script parses the `clustertoc` file before the [suninstall\(1M\)](#) process is run. `parse_dynamic_clustertoc` is called by a modified `sysconfig` script on the install CD. When `parse_dynamic_clustertoc` runs, it reads the `clustertoc` and when it encounters `SUNW_CSRMBRIFF` lines, it either checks the platform using the script's builtin function, or calls an external script. The script exits with a 0 if the cluster entry is included, otherwise it will be ignored. If the cluster entry is to be included, the `SUNW_CSRMBRIFF=(test test_arg)cluster` line is converted to `SUNW_CSRMEMBER=cluster`.

Examples **EXAMPLE 1** Checking For an SX Framebuffer

The following is an example of a simple external test to check for an SX Framebuffer. The entry in the `clustertoc` file is shown and following that is the script that must be placed in the `install.d/dynamic_test` directory.

```
SUNW_CSRMBRIFF=(smcc.dctoc sx)SUNWCsx
#!/bin/sh
#
# Likewise, this file is expected to live under $(TESTDIR).
#
case "$1"
in
    sx)      prtconf -p | grep 'SUNW,sx' 1> /dev/null;;
esac
```

Files *cdrom/Solaris_2.x/locale/C/.clustertoc.dynamic*
 Dynamic version of the `clustertoc` file

cdrom/export/exec/sparc.Solaris_2.x/sbin/install.d/dynamic_test
 Directory that contains any additional tests

cdrom/export/exec/i386.Solaris_2.x/sbin/install.d/dynamic_test
 Directory that contains any additional tests

Name parted – partition manipulation program

Synopsis parted [*options*] [*device* [*options...*...]...]

Description parted is a disk partitioning and partition resizing program. It allows you to create, destroy, resize, move, and copy ext2, ext3, linux-swaps, FAT, FAT32, and reiserfs partitions. It can create, resize, and move Macintosh HFS partitions, as well as detect jfs, ntfs, ufs, and xfs partitions. It is useful for creating space for new operating systems, reorganizing disk usage, and copying data to new hard disks.

This manual page documents parted briefly. Complete parted documentation is distributed with the package in “GNU Info” format.

parted is implemented with a set of top-level options and a set of subcommands, most of which have their own options and operands. These subcommands are described below. parted has an optional operand:

device The block device to be used. When none is given, parted uses the first block device it finds.

Options The following options are supported:

- h, --help
Displays a help message.
- i, --interactive
Prompts for user intervention.
- l, --list
Lists partition layout on all block devices.
- m, --machine
Displays machine-parseable output.
- s, --script
Never prompts for user intervention.
- v, --version
Displays the version number.

Sub-commands If you omit a subcommand in a parted command line, the utility issues a command prompt.

check *partition*
Do a simple check on *partition*.

cp [*source-device*] *source* *dest*
Copy the source partition's filesystem on *source-device* (or the current device if no other device was specified) to the *dest* partition on the current device.

help *command*
Display general help, or help on a command, if specified.

mkfs *partition fs-type*

Make a filesystem *fs-type* on partition. *fs-type* can be one of fat16, fat32, ext2, linux-wap, or reiserfs.

mklabel *label-type*

Create a new disk label (partition table) of *label-type*. *label-type* should be one of bsd, dvh, gpt, loop, mac, msdos, pc98, or sun.

mkpart *part-type* [*fs-type*] *start end*

Make a *part-type* partition with file system *fs-type* (if specified), beginning at *start* and ending at *end* (by default, in megabytes). *fs-type* can be one of fat16, fat32, ext2, HFS, linux-swap, NTFS, reiserfs, or ufs. *part-type* should be one of primary, logical, or extended.

mkpartfs *part-type fs-type start end*

Make a *part-type* partition with file system *fs-type*, beginning at *start* and ending at *end* (by default, in megabytes).

move *partition start end*

Move partition so that it begins at *start* and ends at *end*. Note that move never changes the minor number.

name *partition name*

Set the name of partition to *name*. This option works only on Mac, PC98, and GPT disk labels. The name can be placed in quotes, if necessary.

print

Display the partition table.

quit

Exit from parted.

rescue *start end*

Rescue a lost partition that was located somewhere between *start* and *end*. If a partition is found, parted will ask if you want to create an entry for it in the partition table.

resize *partition start end*

Resize the file system on *partition* so that it begins at *start* and ends at *end* (by default, in megabytes).

rm *partition*

Delete *partition*.

select *device*

Choose *device* as the current device to edit. *device* should usually be a Solaris or Linux hard disk device, but it can be a partition, software raid device, or an SVM or LVM logical volume if necessary.

set *partition flag state*

Change the state of the *flag* on *partition* to *state*. Supported flags are: boot, root, swap, hidden, raid, lvm, lba, and palo. *state* should be either on or off.

unit *unit*

Set *unit* as the unit to use when displaying locations and sizes, and for interpreting those given by the user when not suffixed with an explicit unit. *unit* can be one of s (sectors), B (bytes), kB, MB, GB, TB, % (percentage of device size), cyl (cylinders), chs (cylinders, heads, sectors), or compact (megabytes for input, and a human-friendly form for output).

version

Display version information and a copyright message.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------------|-----------------------|
| Availability | system/storage/parted |
| Interface Stability | Uncommitted |

The parted program is fully documented in the `info(1)` format GNU partitioning software manual.

Author This manual page was written by Timshel Knoll for the Debian GNU/Linux system. It is here adapted for the Solaris operating system.

Name pbind – control and query bindings of processes or LWPs

Synopsis pbind -b *processor_id pid [/lwpid]*...

pbind [-q] [*pid [/lwpid]*]...

pbind -Q [*processor_id*]...

pbind -u *pid [/lwpid]*...

pbind -U [*processor_id*]...

Description pbind controls and queries bindings of processes and LWPs (lightweight processes) to processors. pbind can also remove processor bindings that were previously established.

When an LWP is bound to a processor, it will be executed only by that processor except when the LWP requires a resource that is provided only by another processor. The binding is not exclusive, that is, the processor is free to execute other LWPs as well.

Bindings are inherited, so new LWPs and processes created by a bound LWP will have the same binding. Binding an interactive shell to a processor, for example, binds all commands executed by the shell.

Superusers may bind or unbind any process or LWP, while other users can bind or unbind any process or LWP for which they have permission to signal, that is, any process that has the same effective user ID as the user.

Options The following options are supported:

-b *processor_id*

Binds all or a subset of the LWPs of the specified processes to the processor *processor_id*. Specify *processor_id* as the processor ID of the processor to be controlled or queried. *processor_id* must be present and on-line. Use the `psrinfo` command to determine whether or not *processor_id* is present and on-line. See [psrinfo\(1M\)](#).

-q

Displays the bindings of the specified processes or of all processes. If a process is composed of multiple LWPs which have different bindings and the LWPs are not explicitly specified, the bindings of only one of the bound LWPs will be displayed. The bindings of a subset of LWPs can be displayed by appending “/lwpids” to the process IDs. Multiple LWPs may be selected using “-” and “;” delimiters. See [EXAMPLES](#).

-Q

Displays the LWPs bound to the specified list of processors, or all LWPs with processor bindings. For processes composed of multiple LWPs, the bindings of individual LWPs will be displayed.

-u

Removes the bindings of all or a subset of the LWPs of the specified processes, allowing them to be executed on any on-line processor.

-U

Removes the bindings of all LWPs bound to the specified list of processors, or to any processor if no argument is specified.

Operands The following operands are supported:

pid

The process ID of the process to be controlled or queried.

lwpid

The set of LWP IDs of the specified process to be controlled or queried. The syntax for selecting LWP IDs is as follows:

| | |
|---------|-------------------------------|
| 2,3,4-8 | LWP IDs 2, 3, and 4 through 8 |
| -4 | LWPs whose IDs are 4 or below |
| 4- | LWPs whose IDs are 4 or above |

processor_id

The processor ID of the processor to be controlled or queried.

Examples EXAMPLE 1 Binding Processes

The following example binds processes 204 and 223 to processor 2:

```
example% pbind -b 2 204 223
process id 204: was 2, now 2
process id 223: was 3, now 2
```

EXAMPLE 2 Unbinding a Process

The following example unbinds process 204:

```
example% pbind -u 204
```

EXAMPLE 3 Querying Bindings

The following example queries bindings. It demonstrates that process 1 is bound to processor 0, process 149 has at least one LWP bound to CPU3, and process 101 has no bound LWPs.

```
example% pbind -q 1 149 101
process id 1: 0
process id 149: 3
process id 101: not bound
```

EXAMPLE 4 Querying LWP Bindings

The following example queries bindings of LWPs. It demonstrates that LWP 1 of process 149 is bound to CPU3, and LWP 2 of process 149 is not bound.

```
example% pbind -q 149/1-2
lwp id 149/1: 3
lwp id 149/2: not bound
```

EXAMPLE 5 Querying LWP Bindings for Processor 2:

The following example queries all LWPs bound to processor 2:

```
example% pbind -Q 2
lwp id 149/4: 2
lwp id 149/5: 2
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

Exit Status The following exit values are returned:

0
Successful completion.

>0
An error occurred.

See Also [psradm\(1M\)](#), [psrinfo\(1M\)](#), [psrset\(1M\)](#), [processor_bind\(2\)](#), [processor_info\(2\)](#), [sysconf\(3C\)](#), [attributes\(5\)](#)

Diagnostics pbind: cannot query pid 31: No such process
The process specified did not exist or has exited.

pbind: cannot bind pid 31: Not owner
The user does not have permission to bind the process.

pbind: cannot bind pid 31: Invalid argument
The specified processor is not on-line.

Name pcitool – interrupt routing tool

Synopsis /usr/sbin/pcitool -h

x86:

```
/usr/sbin/pcitool pci@unit-address -i cpu#,ino# | all [-r [-c] |
-w cpu# [-g] ] [-v] [-q]
```

SPARC:

```
/usr/sbin/pcitool pci@unit-address -i ino# | all [-r [-c] |
-w cpu# [-g] ] [-v] [-q]
```

```
/usr/sbin/pcitool pci@unit-address -m msi# | all [-r [-c] |
-w cpu# [-g] ] [-v] [-q]
```

Description PCIttool is a low-level tool that provides a facility for getting and setting interrupt routing information.

Interrupt Routing The `pcitool -i` command displays device and CPU routing information for INOs on a given nexus, and allows rerouting of a given INO or INO group to a specific CPU.

On SPARC platforms, the INO is mapped to an interrupt mondo, where as one or more MSI/Xs are mapped to an INO. So, INO and MSI/Xs are individually retargetable. Use the `-i` option to retrieve or reroute a given INO; use the `-m` option for MSI/Xs.

Specifying `cpu#` is available on the x86 platform. In combination with `ino#`, this identifies an exclusive vector. The `cpu#` argument is not supported on the SPARC platform.

Required Privileges A user must have all privileges in order to access interrupt information. A regular user can access interrupt information following an `su(1M)` to root or if he is granted the “Maintenance and Repair” rights profile in the `user_attr` file. See `user_attr(4)` and `rbac(5)`.

Options The following options are supported:

-h

Display command usage.

-q

No errors are displayed as messages. However, `pcitool` still returns Unix error codes.

-r [-c]

Display device and CPU routing information for INOs on a given nexus. The device path and instance number of each device for each displayed INO is displayed. On some platforms, interrupts dedicated to the root complex are indicated by the string (Internal) appended to their pathnames.

With `-c`, dump interrupt controller information.

If neither `-r` nor `-w` are provided on the command line, `-r` is assumed. See Examples.

-v

Verbose output.

-w *cpu#* [-g]

Route the given INO or MSI/X to the given CPU. Display the new and original routing information. The INO or MSI/X must be specified.

On some platforms (such as x86) multiple MSI interrupts of a single function need to be rerouted together. Use -g to do this. The -g option works only on supported platforms and only for groups of MSI interrupts. (A “group” of 1 is accepted.) When -g is used, the vector provided must be the lowest-numbered vector of the group. The size of the group is determined internally. See Examples.

Examples EXAMPLE 1 Displaying All INOs

The command for showing all INOs on /pci@0,0 is:

```
# pcitool /pci@0,0 -i all
```

EXAMPLE 2 Displaying Output for Specific INO

The command for showing INO 0x0,0x21 on the root nexus /pci@0,0 differs slightly between x86 and SPARC platforms.

On an x86 platform:

```
# pcitool /pci@0,0 -i 0,21
0x0,0x21:                               mpt                               0
/pci@7b,0/pci1022,7458@11/pci1000,3060@2
```

On a SPARC platform:

```
# pcitool /pci@0,0 -i 21
0x0,0x21:                               mpt                               0
/pci@7b,0/pci1022,7458@11/pci1000,3060@2
```

Output shown above is an example and might vary from your output.

EXAMPLE 3 Displaying Output for Specific MSI

The command for showing MSI 0x1 on the root nexus /pci@0,0, along with sample output, is shown below.

```
# pcitool /pci@0,0 -m 0x1
0x0,0x1: pcieb      0      /pci@7b,0/pci10de,5d@e
```

EXAMPLE 4 Rerouting an INO from One CPU to Another

Successful rerouting INO 21 from CPU 0 to CPU 1 produces the output shown below.

On an x86 platform:

EXAMPLE 4 Rerouting an INO from One CPU to Another (Continued)

```
# pcitool /pci@0,0 -i 0,21 -w 1
0x0,0x21 -> 0x1,0x20
```

On a SPARC platform:

```
# pcitool /pci@0,0 -i 21 -w 1
0x0,0x21 -> 0x1,0x20
```

EXAMPLE 5 Rerouting an MSI from One CPU to Another

Successful rerouting MSI 1 from CPU 1 to CPU 0 produces the output shown below.

```
# pcitool /pci@0,0 -m 1 -w 0
0x1,0x1 -> 0x0,0x1
```

EXAMPLE 6 Rerouting a Group of INOs

Successful rerouting of a group of INOs starting at 24 from CPU 0 to CPU 1 produces the output shown below.

On an x86 platform:

```
# pcitool /pci@0,0 -i 3,24 -w 1 -g
0x3,0x24 => 0x1,0x22
```

On a SPARC platform:

```
# pcitool /pci@0,0 -i 24 -w 1 -g
0x3,0x24 => 0x1,0x22
```

Exit Status 0

No error.

EINVAL

Out-of-range, misaligned, or otherwise invalid argument has been passed in.

ETIME

Timeout waiting for pending interrupt to settle before changing interrupts to a new CPU.

EIO

An I/O error occurred.

PCI specification (available from www.pcisig.org)

Notes All values are entered in hex.

Not all commands are applicable to all platforms.

Name pfinstall – tests installation profiles

Synopsis /usr/sbin/install.d/pfinstall -D | -d *disk_config*
[-c *CDpath*] *profile*

Description After you create a profile, you can use the `pfinstall` command to test the profile and see if it does what you want before using it to install or upgrade a system. `pfinstall` enables you to test a profile against:

- The system's disk configuration where `pfinstall` is being run.
- Other disks by using a disk configuration file that represents a structure of a disk. See **NOTES** on how to create a disk configuration file.

To successfully and accurately test a profile for a particular Solaris release, you must test a profile within the Solaris environment of the same release. For example, if you want to test a profile for Solaris 2.10, you have to run the `pfinstall` command on a system running Solaris 2.10.

So, on a system running Solaris 2.10, you can test Solaris 2.10 initial installation profiles. However, if you want to test a Solaris 2.10 upgrade profile on a system running a previous version of Solaris, or if you don't have a Solaris 2.10 system installed yet to test Solaris 2.10 initial installation profiles, you have to boot a system from a Solaris 2.10 CD image and temporarily create a Solaris 2.10 install environment. Then, you can run `pfinstall` in the Solaris 2.10 install environment to test your profiles.

To create a temporary Solaris operating system install environment, boot a system from a Solaris CD image (just as you would to install), answer any system identification questions, choose the Solaris Interactive Installation program, and exit out of the first screen that is presented. Then, from the shell, you can execute the `pfinstall` command.

Options The following options are supported:

- c *CDpath* The path to the Solaris installation image. This is required if the image is not mounted on `/cdrom`. (For example, use this option if you copied the installation image to disk or mounted the CD-ROM on a directory other than `/cdrom`.) When testing a profile on an x86 machine, the miniroot needs to be unpacked before using -c option. See **EXAMPLES**, below, for the procedure to unpack the miniroot.
- d *disk_config* `pfinstall` uses a disk configuration file, *disk_config*, to test the profile. See **NOTES** on how to create a disk configuration file. You must specify either this option or the -D option to test the profile (see **WARNINGS**). This option cannot be used with an upgrade profile (`install_type upgrade`). You must always test an upgrade profile against a system's disk configuration (-D option).
- D `pfinstall` uses the system's disk configuration to test the profile. You must specify either this option or the -d option to test the profile (see **WARNINGS**).

Operands The following operands are supported:

profile The file name of the profile to test. If *profile* is not in the directory where `pfinstall` is being run, you must specify the path.

Examples **EXAMPLE 1** Testing an Upgrade Profile

The following example tests an upgrade profile, `upgrade.prof`, on a system with a previous version of the Solaris software installed.

1. Boot the system to be upgraded from the Solaris image chosen for the upgrade, just as you would to install. The image can be located in the system's local CD-ROM or on an install server.
2. Answer the system configuration questions, if prompted.
3. If you are presented with a choice of installation options, choose the Solaris Interactive Installation program.
4. Exit from the first screen of the Solaris Interactive Installation program.

After the Solaris Interactive Installation program exits, a shell prompt is displayed.

5. Create a temporary mount point:

```
example# mkdir /tmp/mnt
```

6. Mount the directory that contains the profile(s) you want to test.

If you want to mount a remote NFS file system (for systems on the network), enter:

```
example# mount -F nfs server_name:path /tmp/mnt
```

If you want to mount a UFS-formatted diskette, enter:

```
example# mount -F ufs /dev/diskette /tmp/mnt
```

If you want to mount a PCFS-formatted diskette, enter:

```
example# mount -F pcfs /dev/diskette /tmp/mnt
```

7. Change directory to `/tmp/mnt` where the profile resides:

```
example# cd /tmp/mnt
```

8. Test the `upgrade.prof` profile:

```
example# /usr/sbin/install.d/pfinstall -D upgrade.prof
```

EXAMPLE 2 Testing the `basic.prof` Profile on an x86 Machine (Includes Unpacking miniroot)

The following example tests the `basic.prof` profile against the disk configuration on a Solaris 8 system where `pfinstall` is being run. The path to the Solaris CD image is specified because Volume Management is being used.

```
example# /usr/sbin/install.d/pfinstall -D -c /cdrom/cdrom0/s0 basic.prof
```

EXAMPLE 2 Testing the `basic.prof` Profile on an x86 Machine (Includes Unpacking miniroot)
(Continued)

When testing a profile on an x86 machine, before using `pfinstall` with `-c` option, use the following procedure to unpack the miniroot:

1. Uncompress the miniroot archive into a temporary file. The miniroot archive is under `/cdrom/cdrom0/s0`.

```
# /usr/bin/gzcat /cdrom/cdrom0/boot/x86.miniroot > \
/tmp/x86_miniroot_gz
```
2. Create the miniroot device using `lofiadm(1M)`:

```
/usr/sbin/lofiadm -a /tmp/x86_miniroot_gz
/dev/lofi/1
```
3. Mount the miniroot under miniroot directory using the `lofi` device returned by `lofiadm` in the previous step:

```
# /usr/sbin/mount -F ufs /dev/lofi/1 \
/cdrom/cdrom0/Solaris_10/Tools/Boot
```
4. Now run `pfinstall` with `-D` option:

```
# /usr/sbin/install.d/pfinstall -D -c /cdrom/cdrom0/ jumpstart.profile
```
5. After `pfinstall` testing is completed, unmount the `lofi` device:

```
# /usr/sbin/umount /dev/lofi/1
```
6. Delete the `lofi` device:

```
# /usr/sbin/lofiadm -d /tmp/x86_miniroot_gz
```

EXAMPLE 3 Testing the `basic.prof` Profile Against Disk Config File

The following example tests the `basic.prof` profile against the `535_test` disk configuration file. This example uses a Solaris CD image located in the `/export/install` directory, and `pfinstall` is being run on a Solaris 2.6 system.

```
example# /usr/sbin/install.d/pfinstall -d 535_test \
-c /export/install basic.prof
```

- Exit Status**
- 0 Successful (system rebooted).
 - 1 Successful (system not rebooted).
 - 2 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWinst |

See Also [fdisk\(1M\)](#), [lofiadm\(1M\)](#), [prtvtoc\(1M\)](#), [attributes\(5\)](#)

Warnings If the `-d` or `-D` option is not specified, `pfinstall` may perform an actual installation on the system by using the specified profile, and the data on the system may be overwritten.

Notes You have to test a profile on a system with the same platform type for which the profile was created.

SPARC To create a disk configuration file (`-d` option) for a SPARC based system:

1. Locate a SPARC based system with a disk that you want to test.
2. Create a disk configuration file by redirecting the output of the [prtvtoc\(1M\)](#) command to a file.

```
example# prtvtoc /dev/rdisk/c0t3d0s2 > 535_disk
```

3. (Optional.) Concatenate disk configuration files into a single file to test a profile against multiple disks. The target numbers in the disk device names must be unique.

```
example# cat 535_disk 1G_disk > mult_disks
```

x86 To create a disk configuration file (`-d` option) for an x86 based system:

1. Locate an x86 based system with a disk that you want to test.
2. Create part of the disk configuration file by saving the output of the [fdisk\(1M\)](#) command to a file:

```
example# fdisk -R -W 535_disk /dev/rdisk/c0t3d0p0
```

3. Append the output of the [prtvtoc\(1M\)](#) command to the disk configuration file.

```
example# prtvtoc /dev/rdisk/c0t3d0s2 >> 535_disk
```

4. (Optional.) Concatenate disk configuration files into a single file to test a profile against multiple disks. The target numbers in the disk device names must be unique.

```
example# cat 535_disk 1G_disk > mult_disks
```

To test a profile with a specific system memory size, set `SYS_MEMSIZE` to the specific memory size (in Mbytes) before running `pfinstall`:

```
example# SYS_MEMSIZE=memory_size
```

```
example# export SYS_MEMSIZE
```

Name pginfo – display information about processor groups

Synopsis pginfo [-T] [-p] [-v] [-r *string*] [-R *string*]
 [*pg ...* | -c *processor_id ...*]
 pginfo -s [-v] [-r *string*] [-R *string*] [*pg ...* | -c *processor_id ...*]
 pginfo -c | -I [-r *string*] [-R *string*] [*pg ...* | -c *processor_id ...*]
 pginfo -h

Description The `pginfo` displays information about the Processor Group (PG) hierarchy, its contents, and its characteristics. A PG is a set of CPUs that are grouped together by a common characteristic.

PGs are used by the operating system to represent the CPUs that share performance relevant hardware such as the execution pipelines, caches, and so forth. These PGs are organized into a hierarchy that models the processor topology of the machine. In this hierarchy, each CPU (strand) has a leaf PG that represents the CPUs that share the most hardware with it. Each successive ancestor of the leaf PG shares progressively less hardware with the CPU until the root PG is reached. The root PG contains all of the CPUs in the system and represents the group of CPUs sharing the least hardware with each other. (See `EXAMPLES` below for an example of PG hierarchy.)

If a machine does not have any performance-relevant hardware sharing relationships, then `pginfo` displays only a root PG that contains all of the CPUs in the system.

By default, `pginfo` displays information about each PG in the system, including its PG ID, sharing relationship, and online and offline CPUs. It displays the PGs in depth first order by default and uses indentation to help show how the PGs are related to each other (see `EXAMPLES` below).

You can specify options to:

- Display the PG hierarchy graphically
- List the PG sharing relationships that exist on the running system
- Give current PG utilization information, specifying PGs of interest by PG ID, CPU ID, or sharing relationship
- Specify that only CPU or PG IDs be displayed

In addition, there is a `-p` option to show which PGs contain the CPUs that correspond to the CPUs with a common physical relationship such as `system`, `chip`, and `core`. These physical relationships describe the physical characteristics of the CPUs and might or might not encapsulate performance-relevant processor sharing relationships.

If the system configuration repeatedly changes when `pginfo` is obtaining a snapshot of system data, `pginfo` displays an error message and terminates with exit status 1.

Options The following options are supported:

-c *processor_id* ...

Interpret arguments as processor IDs and display only information about PGs that contain the specified processors.

When used with the -T option, this option limits the PG hierarchy displayed to include only the lineage of each of the specified CPUs. This option cannot be used when specifying PGs of interest by PG ID.

-C

Display only CPU IDs for all CPUs belonging to the PGs. This option cannot be used at the same time as the -I option.

-h

Display short help message and exit with exit status 0.

-I

Display only PG IDs for the PGs. This option cannot be used at the same time as the -C option.

-p

Display the physical relationship that corresponds to a PGs. If a PG has the same CPUs as the whole system, a processor core, or a chip, `system`, `core`, or `chip` will be displayed, as appropriate, after the sharing relationship of the PG in square brackets (“[]”).

-r *string1,string2*,...

Display only information about PGs with a sharing relationship name that matches any of the specified strings.

Each specified string can be a whole relationship name or a portion of one or more relationship names and the string matching is case-insensitive. The possible relationship names are in the list of sharing relationships that the -s option displays.

You can specify multiple -r options, which results in matching all PGs with a relationship name that contain any of the specified strings. When used with the -T option, this option limits the PG hierarchy displayed to include only the lineage of each of the PGs with the specified relationship.

-R *string1,string2*,...

Display only information about PGs with a sharing relationship name *other* than the one(s) specified.

String matching is the same as described above for the -r option. Multiple -R options can be entered.

-s

Display all sharing relationships supported on the running system for the specified PGs. The -v option can be used with this option to get the list of PGs for each sharing relationship.

-T

In the resulting hierarchy, the lineage of each CPU (hardware strand) is arranged from the PGs that share the most hardware in common with the CPU to the PGs that share the least with the CPU. If any CPUs, PGs, or relationships of interest are specified, the resulting PG hierarchy is limited to the lineages of the PGs with the specified CPUs, PGs, or relationships in the PG hierarchy.

-v

Verbose mode. Display additional information about PGs. When used without `-s`, `-C`, or `-I`, it is equivalent to giving the `-T` and `-p` options together at the same time. When used with the `-s` option, it gives the list of PGs for each sharing relationship.

Operands The following operands can be given on the command line by specifying one or more of their corresponding IDs or the keyword `all`. Multiple IDs can be specified as a space-separated list (for example, `1 3`), a range of numbers (for example, `5-8`), or both (for example, `1 3 5-8 13-16`). PGs and CPUs cannot be specified at the same time.

pg PGs of interest can be specified on the command line by PG ID.

processor_id When the `-c` option is entered, CPUs of interest can be specified on the command line by CPU ID.

If an invalid PG or CPU is specified, the `pginfo` command displays a message on standard error showing the invalid ID and continues processing other PGs or CPUs specified on the command line. When none of the specified PGs or CPUs are valid, `pginfo` exits with an exit status of 2.

Examples In the examples below, the system contains one UltraSPARC T1 processor chip with 8 cores and 32 strands.

EXAMPLE 1 Displaying Information About Every PG

The following command, using no arguments, displays information about every PG.

```
$ pginfo
PG RELATIONSHIP          CPUs
0  System                0-31
3  Data_Pipe_to_memory   0-31
2  Floating_Point_Unit   0-31
1  Integer_Pipeline      0-3
4  Integer_Pipeline      4-7
5  Integer_Pipeline      8-11
6  Integer_Pipeline      12-15
7  Integer_Pipeline      16-19
8  Integer_Pipeline      20-23
9  Integer_Pipeline      24-27
10 Integer_Pipeline      28-31
```

EXAMPLE 2 Displaying Information About All Sharing Relationships

The following command displays information about all sharing relationships.

```
$ pginfo -s -v
RELATIONSHIP          PGs
-----
System                0
Data_Pipe_to_memory  3
Floating_Point_Unit   2
Integer_Pipeline      1 4-10
```

EXAMPLE 3 Displaying PG Hierarchy

The following command displays general information about all PGs in the system. The output shows which PGs belong to chips and cores.

```
$ pginfo -p -T
0 (System) CPUs: 0-31
'-- 3 (Data_Pipe_to_memory [system,chip]) CPUs: 0-31
    |-- 2 (Floating_Point_Unit [system,chip]) CPUs: 0-31
        |-- 1 (Integer_Pipeline [core]) CPUs: 0-3
        |-- 4 (Integer_Pipeline [core]) CPUs: 4-7
        |-- 5 (Integer_Pipeline [core]) CPUs: 8-11
        |-- 6 (Integer_Pipeline [core]) CPUs: 12-15
        |-- 7 (Integer_Pipeline [core]) CPUs: 16-19
        |-- 8 (Integer_Pipeline [core]) CPUs: 20-23
        |-- 9 (Integer_Pipeline [core]) CPUs: 24-27
        '-- 10 (Integer_Pipeline [core]) CPUs: 28-31
```

EXAMPLE 4 Displaying List with Specific Criterion

The following command displays a list of CPUs sharing integer pipeline with CPU 0. This example also demonstrates the use of `-r` option to filter PGs by sharing relationship name.

```
$ pginfo -r integer_pipeline -C -c 0
0 1 2 3
```

EXAMPLE 5 Using Option to Exclude by Specific Criterion

The following command lists all PGs other than the ones that have `Integer_Pipeline` as their relationship.

```
$ pginfo -R Integer_Pipeline
PG RELATIONSHIP          CPUs
0 System                0-31
3 Data_Pipe_to_memory    0-31
2 Floating_Point_Unit     0-31
```

- Exit Status** 0
Successful completion.
- 1
An error occurred.
- 2
Invalid syntax.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------------|----------------|
| Availability | SUNWesu |

Name pgstat – report utilization statistics for Processor Groups

Synopsis pgstat [-A] [-C] [-p] [-s *key* | -S *key*] [-t *number*] [-T u | d] [-v]
[-r *string*] [-R *string*] [-P *pg* ...] [-c *processor_id*...]
[*interval* [*count*]]

pgstat -h

Description The `pgstat` displays utilization statistics about Processor Groups (PGs). A PG is a set of CPUs that are grouped together by a common characteristic.

PGs are used by the operating system to represent CPUs that share performance relevant hardware, such as execution pipelines, caches, and so forth. These PGs are organized into a hierarchy that models the processor topology of the machine. In this hierarchy, each CPU (strand) has a leaf PG that represents the CPUs that share the most hardware with it. Each successive ancestor of the leaf PG shares progressively less hardware with the CPU until the root PG is reached. The root PG contains all of the CPUs in the system and represents the group of CPUs sharing the least hardware with each other. (See “Examples” below for an example of PG hierarchy).

If a machine does not have any performance-relevant hardware sharing relationships, then `pgstat` displays only a root PG that contains all of the CPUs in the system.

By default, `pgstat` does the following:

- Measures the hardware and software utilization of all PGs in the PG hierarchy over a one second interval.
- Displays the utilization of the PGs in depth first order using indentation to help show how the PGs relate to each other.
- Displays the ID, sharing relationship, hardware load, software load, and online CPUs for each PG at the end of each interval.

The interval and count can be given as arguments to specify the number of seconds in the sampling interval and number of times to measure and display the utilization for the specified PGs.

You can specify options to further tailor the output, organize the output a certain way, and specify PGs of interest (see “Options” below for details).

A hyphen (“-”) is displayed when the utilization for a given PG is not supported and a question mark (?) is displayed when the utilization is not available. On systems where the CPU hardware performance counters are needed to measure the hardware utilization, the hardware utilization might be unavailable because the counters are being used by a `cpc(3CPC)` consumer such as `attributes(5)`, `cpurack(1)`, `dtrace(1M)`, or another application that uses `libcpc(3LIB)`.

Options The following options are supported:

- A
Display summary of utilization data when `pgstat` is run over multiple intervals.
- c *processor_id...*
Display utilization about PGs that contain the specified CPUs. The CPUs can be specified as a comma separated list of CPU IDs. A hyphen (“-”) can be used to specify contiguous ranges of CPU IDs (for example, 0-3).
- C
Display utilization of each CPU in each PG.
- h
Display short help message and exit with exit status 0.
- p
Display the physical relationship that corresponds to a PG. If a PG has the same CPUs as the whole system, a processor core, or a chip, `system`, `core`, or `chip`, as appropriate, is displayed after the sharing relationship of the PG in square brackets (“[]”).
- P *pg,...*
Display utilization for specified PGs. Multiple PGs can be specified as a comma-separated list of PG IDs. A hyphen (“-”) can be used to specify a contiguous range of PG IDs (for example, 0-3).
- r *string1,string2,...*
Display utilization only for PGs with a sharing relationship name that matches any of the specified strings. The string can be a whole relationship name or a portion of one or more relationship names. The string matching is case-insensitive.

Multiple -r options can be entered, which results in matching all PGs with a relationship name that matches any of the specified strings.
- R *string1,string2,...*
Display information only about PGs with a sharing relationship name *other* than the one(s) specified.

String matching is the same as described above for the -r option. Multiple -R options can be entered.
- s *key*
Sort output lines by the specified key in descending order. The specified key can be one of the following:
 - pg
Sort by PG ID.
 - hwLoad
Sort by hardware utilization.

`swload`
Sort by software utilization.

`user`
Sort by user time.

`sys`
Sort by system time.

`idle`
Sort by idle time.

`depth`
Sort by descending PG tree from root to leaves, depth-first (default).

`breadth`
Sort by descending PG tree from root to leaves, breadth-first.

`-S key`
Sort output lines by the specified key in ascending order. Possible key values are the same as for the `-s` option.

`-t number`
Show the top number of PGs for the specified integer number.

`-T u | d`
Display timestamp for each sampling interval in Unix time (see [time\(2\)](#)) or the standard date format used by [date\(1\)](#).

`-v`
Display extra information about each PG including hardware utilization and capacity and software user, system, and idle times.

Output Headings `pgstat` displays the column headings, which are listed below, along with the meanings of those headings.

PG
Processor Group ID.

RELATIONSHIP
Sharing relationship for PG.

HW
Hardware load in percent (calculated as `UTIL/CAP` for interval).

UTIL
Hardware utilization of PG's shared hardware component over the interval. This can be a large number, so K, M, B, and T are used for denoting thousand, million, billion, and trillion, respectively.

CAP

Approximate maximum possible utilization for PG's shared hardware component over the interval. This can be a large number, so K, M, B, and T are used for denoting thousand, million, billion, and trillion, respectively.

SW

Software load in percent (calculated as (USR + SYS) / (USR + SYS + IDLE))

USR

Percentage of time that software threads ran in user mode on CPUs in PG during interval.

SYS

Percentage of time that software threads ran in system mode on CPUs in PG during interval.

IDLE

Percentage of time that no software threads ran on CPUs in PG during interval.

CPUS

CPU IDs for CPUs in PG.

Examples In the following examples, the system contains one UltraSPARC T1 processor chip with 8 cores and 32 strands.

EXAMPLE 1 Displaying Utilization for Specified Period

The following command displays utilization for all PGs over the last two seconds.

```
$ pgstat 1 2
PG RELATIONSHIP      HW   SW  CPUS
0 System              -  0.4% 0-31
3 Data_Pipe_to_memory -  0.4% 0-31
2 Floating_Point_Unit 0%  0.4% 0-31
1 Integer_Pipeline    0%   0% 0-3
4 Integer_Pipeline    0%   0% 4-7
5 Integer_Pipeline    0%   0% 8-11
6 Integer_Pipeline    0%  0.2% 12-15
7 Integer_Pipeline    0%   0% 16-19
8 Integer_Pipeline    2.8% 2.7% 20-23
9 Integer_Pipeline    0.1% 0.2% 24-27
10 Integer_Pipeline   0%   0% 28-31
PG RELATIONSHIP      HW   SW  CPUS
0 System              -  0.4% 0-31
3 Data_Pipe_to_memory -  0.4% 0-31
2 Floating_Point_Unit 0%  0.4% 0-31
1 Integer_Pipeline    0%  0.2% 0-3
4 Integer_Pipeline    0%   0% 4-7
5 Integer_Pipeline    0%   0% 8-11
6 Integer_Pipeline    0%   0% 12-15
7 Integer_Pipeline    0%   0% 16-19
```

EXAMPLE 1 Displaying Utilization for Specified Period *(Continued)*

```

8   Integer_Pipeline  3.1% 2.5% 20-23
9   Integer_Pipeline   0%  0% 24-27
10  Integer_Pipeline   0% 0.2% 28-31

```

EXAMPLE 2 Displaying Information about Integer Pipeline

The following command displays detailed information about the two most utilized integer pipelines over the last two seconds.

```

$ pgstat -v -t 2 -r 'Integer_Pipeline' 1 2
PG RELATIONSHIP          HW UTIL  CAP    SW    USR    SYS  IDLE CPUS
 1 Integer_Pipeline    0.2% 2.2M 1.4B   0.2%  0.0%  0.2% 99.8% 0-3
 4 Integer_Pipeline   13.1% 181M 1.4B  14.9%  0.0% 14.9% 85.1% 4-7
PG RELATIONSHIP          HW UTIL  CAP    SW    USR    SYS  IDLE CPUS
 1 Integer_Pipeline    0.2% 1.9M 1.2B   0.2%  0.0%  0.2% 99.8% 0-3
 4 Integer_Pipeline   13.1% 163M 1.2B  14.9%  0.0% 14.9% 85.1% 4-7

```

EXAMPLE 3 Displaying Core Utilization over Specified Period

The following command displays information about core utilization over the last two minutes.

```

$ pgstat -A 60 2
PG RELATIONSHIP          HW      SW  CPUS
 0 System                -      56.9% 0-31
 3 Data_Pipe_to_memory   -      56.9% 0-31
 2 Floating_Point_Unit   0.0%   56.9% 0-31
 1 Integer_Pipeline     36.7%   58.7% 0-3
 4 Integer_Pipeline     41.9%   58.3% 4-7
 5 Integer_Pipeline     31.0%   58.0% 8-11
 6 Integer_Pipeline     30.7%   57.9% 12-15
 7 Integer_Pipeline     30.1%   55.8% 16-19
 8 Integer_Pipeline     40.2%   54.8% 20-23
 9 Integer_Pipeline     35.0%   56.0% 24-27
10 Integer_Pipeline     40.3%   55.8% 28-31
PG RELATIONSHIP          HW      SW  CPUS
 0 System                -     10.7% 0-31
 3 Data_Pipe_to_memory   -     10.7% 0-31
 2 Floating_Point_Unit   0.0%   10.7% 0-31
 1 Integer_Pipeline      9.0%   10.7% 0-3
 4 Integer_Pipeline      9.6%   10.8% 4-7
 5 Integer_Pipeline      8.6%    9.9% 8-11
 6 Integer_Pipeline     10.5%   11.9% 12-15
 7 Integer_Pipeline      9.1%   10.4% 16-19
 8 Integer_Pipeline      9.6%   10.9% 20-23
 9 Integer_Pipeline      8.9%   10.0% 24-27
10 Integer_Pipeline      9.5%   10.7% 28-31

```

EXAMPLE 3 Displaying Core Utilization over Specified Period (Continued)

SUMMARY: UTILIZATION OVER 120 SECONDS

| PG | RELATIONSHIP | -----HARDWARE----- | | | -----SOFTWARE----- | | | CPUS |
|----|---------------------|--------------------|-------|-------|--------------------|-------|-------|-------|
| | | MIN | AVG | MAX | MIN | AVG | MAX | |
| 0 | System | - | - | - | 10.7% | 10.7% | 56.9% | 0-31 |
| 3 | Data_Pipe_to_memory | - | - | - | 10.7% | 10.7% | 56.9% | 0-31 |
| 2 | Floating_Point_Unit | 0.0% | 0.0% | 0.0% | 10.7% | 10.7% | 56.9% | 0-31 |
| 1 | Integer_Pipeline | 9.0% | 8.5% | 36.7% | 10.7% | 10.7% | 58.7% | 0-3 |
| 4 | Integer_Pipeline | 9.6% | 9.1% | 41.9% | 10.8% | 10.8% | 58.3% | 4-7 |
| 5 | Integer_Pipeline | 8.6% | 8.1% | 31.0% | 9.9% | 9.9% | 58.0% | 8-11 |
| 6 | Integer_Pipeline | 10.5% | 10.0% | 30.7% | 11.9% | 11.9% | 57.9% | 12-15 |
| 7 | Integer_Pipeline | 9.1% | 8.6% | 30.1% | 10.4% | 10.4% | 55.8% | 16-19 |
| 8 | Integer_Pipeline | 9.6% | 9.1% | 40.2% | 10.9% | 10.9% | 54.8% | 20-23 |
| 9 | Integer_Pipeline | 8.9% | 8.4% | 35.0% | 10.0% | 10.0% | 56.0% | 24-27 |
| 10 | Integer_Pipeline | 9.5% | 8.9% | 40.3% | 10.7% | 10.7% | 55.8% | 28-31 |

Exit Status The following exit values are returned:

- 0
Successful completion.
- 1
Unable to get PG information from the system.
- 2
Specified interval, count, or all CPUs, PGs, and sharing relationships invalid.
- 3
Invalid syntax.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWesu |
| Interface Stability | Uncommitted |

The command line options and output are Uncommitted.

See Also [cputrack\(1\)](#), [attributes\(5\)](#), [dtrace\(1M\)](#), [pginfo\(1M\)](#), [cpc\(3CPC\)](#), [libcpc\(3LIB\)](#), [attributes\(5\)](#)

Name pgxconfig, GFXconfig, TSIGfxp_config – configure the PGX32 (Raptor GFX) Graphics Accelerator

Synopsis /usr/sbin/pgxconfig [-dev *device-filename*]
 [-res *video-mode* [try | noconfirm | nocheck]]
 [-file *machine* | system] [-depth 8 | 24]
 [-24only true | false] [-cachedpixmap true | false]
 [-defaults]
 /usr/sbin/pgxconfig [-propt] [-prconf]
 /usr/sbin/pgxconfig [-help] [-res ?]
 /usr/sbin/pgxconfig [-i]

Description The pgxconfig utility configures the PGX32 (Raptor GFX) Graphics Accelerator and some of the X11 window system defaults for PGX32 (Raptor GFX). A previous version of this utility was named GFXconfig.

The first form of pgxconfig shown in the synopsis above stores the specified options in the OWconfig file. These options are used to initialize the PGX32 (Raptor GFX) device the next time the window system is run on that device. Updating options in the OWconfig file provides persistence of these options across window system sessions and system reboots.

The second, third, and fourth forms, which invoke only the -prconf, -propt, -help, and -res ? options, do not update the OWconfig file. For the third form all other options are ignored.

The -i option starts pgxconfig in interactive mode.

Options may be specified for only one PGX32 (Raptor GFX) device at a time.

Only PGX32 (Raptor GFX)-specific options can be specified through pgxconfig. The normal window system options for specifying default depth, default visual class and so forth are still specified as device modifiers on the openwin command line. See the Xsun(1) manual page available with the SUNWxwman package.

The user can also specify the OWconfig file that is to be updated. By default, the machine-specific file in the /usr/openwin directory tree is updated. The -file option can be used to specify an alternate file to use. For example, the system-global OWconfig file in the /etc/openwin directory tree can be updated instead.

Both of these standard OWconfig files can only be written by root.

Options The following options are supported:

-cachedpixmap true | false

When set to false, it forces the PGX32 (Raptor GFX) device to use 24-bit only when running OpenWindows. The default value is true.

| | |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | Certain applications make use of a cached pixmap when writing to the display device. Such a technique can cause garbled output and can cause the X server to crash. If you experience such behavior, try setting the <code>-cachedpixmap</code> option to <code>false</code> . |
| <code>-defaults</code> | Reset all option values to their default values. |
| <code>-depth 8 24</code> | Sets the screen depth to 8 or 24 bits per pixel. 24 bits per pixel enables TrueColor graphics in the window system. |
| <code>-dev <i>device-filename</i></code> | Specify the PGX32 (Raptor GFX) special file. The default is <code>/dev/fbs/gfxp0</code> , or <code>/dev/fbs/raptor0</code> if applicable. |
| <code>-file <i>machine</i> <i>system</i></code> | Specifies which <code>OWconfig</code> file to update. If <i>machine</i> is specified, the machine-specific <code>OWconfig</code> file in the <code>/etc/openwin</code> directory tree is updated. If <i>system</i> is specified, the global <code>OWconfig</code> file in the <code>/usr/openwin</code> directory tree is updated. If the specified file does not exist, it is created. This option has no effect unless other options are specified. The default is <i>machine</i> . |
| <code>-help</code> | Print a list of the <code>pgxconfig</code> command line options, along with a brief explanation of each. |
| <code>-i</code> | Start <code>pgxconfig</code> in interactive mode. |
| <code>-prconf</code> | Print the PGX32 (Raptor GFX) hardware configuration. The following is a typical display: |
| | <pre> --- Hardware Configuration for /dev/fbs/gfxp0 --- DAC: version 0x0 Type: Board: PROM: version 0x0 PROM Information: RAM: EDID Data: Monitor Sense ID: </pre> |

 1280x1024x67, 960x680x112S, vga, svga, 1152, 1280
 stereo

Current resolution setting: 1280x1024x76

Possible depths: 8, 24, 8+24

Current depth: 8

-propt

Print the current values of all PGX32 (Raptor GFX) options in the `OWconfig` file specified by the `-file` option for the device specified by the `-dev` option. Print the values of options as they would be in the `OWconfig` file after the call to `pgxconfig` would have completed. The following is a typical display:

```
--- OpenWindows Configuration for /dev/fbs/gfxp0 ---
```

```
OWconfig: machine
```

```
Video Mode: not set
```

```
Depth: 8+24
```

-res *video-mode* [try | noconfirm | nocheck]

Specify the built-in video mode used to drive the monitor connected to the specified PGX32 (Raptor GFX) device.

The format for *video-mode* can be one of the following:

widthxheightxrate The *width* is the screen width in pixels, *height* is the screen height in pixels, and *rate* is the vertical frequency of the screen refresh. As a convenience, -res

also accepts formats with @ prepended to the refresh rate rather than x. For example: 1280x1024@76. The list can be obtained by running `pgxconfig` with the `-res ?` option (the third form shown in the command synopsis above). Note that not all resolutions are supported by both the video board and by the monitor. The `pgxconfig` utility will not permit you to set a resolution not supported by the board unless the `noconfirm` or `nocheck` option is specified. It will also request confirmation before setting a resolution not supported by the monitor if the `nocheck` option is not specified.

Symbolic names

For convenience, the video modes listed below have symbolic names defined. Rather than the form *widthxheightxrate*, the symbolic name may be supplied as the argument to

- res. If the symbolic name is none, the screen resolution will be the video mode that is currently programmed in the device when the window system is run.

| | |
|------|----------------------------------|
| svga | 1024x768x60 |
| 1152 | 1152x900x76 |
| 1280 | 1280x1024x76 |
| vga | 640x480x60 |
| none | default
console
resolution |

The - res option also accepts additional, optional arguments immediately following the video mode specification. Any or all of these may be present.

`noconfirm` Using the - res option, the user could put the system into an unusable state, a state where there is no video output. This can happen if there is ambiguity in the monitor sense codes for the particular code read. To reduce the chance of this occurring, the default behavior of `pgxconfig` is to print a warning message to this effect and to prompt the user to find out if it is okay to continue. The `noconfirm` option instructs `pgxconfig` to bypass this confirmation and to

| | |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | <p>program the requested video mode anyway. This option is useful when <code>pgxconfig</code> is being run from a shell script.</p> |
| <code>nocheck</code> | <p>If present, normal error checking based on the monitor sense code is suspended. The video mode specified by the user will be accepted regardless of whether it is appropriate for the currently attached monitor. (This option is useful if a different monitor is to be connected to the PGX32 (Raptor GFX) device). Use of this option implies <code>noconfirm</code> as well.</p> |
| <code>try</code> | <p>This option allows the user to test the specified resolution before committing it. It displays a pattern on the screen with the specified resolution. If the test pattern appears correctly, the user may answer "y" to the query. The other permissible answer is "n".</p> <p>This sub-option should not be used with <code>pgxconfig</code> while the configured device is being used (for example, while running the window system) as unpredictable results may occur. To run <code>pgxconfig</code> with the <code>try</code> sub-option, the window system should be brought down first.</p> |

- res ? Print the list of possible resolutions supported by the PGX32 and the monitor.
- 24only Force the PGX32 (Raptor GFX) device to use 24 bit only when running Openwindows.

Defaults For a given invocation of `pgxconfig`, if an option does not appear on the command line, the corresponding `OWconfig` option is not updated; it retains its previous value, except for `-depth` and `-24only`.

A default value is used if a PGX32 (Raptor GFX) option has not been specified with `pgxconfig` when the window system is run. The option defaults are as follows:

- dev /dev/fbs/gfxp0
- file system
- res none

The default of `none` for the `- res` option indicates that when the window system is run, the screen resolution will be the video mode that is currently programmed in the device.

Examples **EXAMPLE 1** Switching the Resolution on the Monitor Type

The following example switches the monitor type to the resolution of 1280 x 1024 at 76 Hz:

```
example# /usr/sbin/pgxconfig -res 1280x1024x76
```

| | | |
|--------------|----------------------------------|----------------------------|
| Files | /dev/fbs/gfxp0 | device special file |
| | /usr/openwin/server/etc/OWconfig | system configuration file |
| | /etc/openwin/server/etc/OWconfig | machine configuration file |

|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name | picld – PICL daemon |
| Synopsis | /usr/lib/picl/picld |
| Description | <p>The Platform Information and Control Library (PICL) provides a mechanism to publish platform-specific information for clients to access in a platform-independent way. <code>picld</code> maintains and controls access to the PICL information from clients and plug-in modules. The daemon is started in both single-user and multi-user boot mode.</p> <p>Upon startup, the PICL daemon loads and initializes the plug-in modules. These modules use the <code>libpicltree(3PICLTREE)</code> interface to create nodes and properties in the PICL tree to publish platform configuration information. After the plug-in modules are initialized, the daemon opens the PICL daemon door to service client requests to access information in the PICL tree.</p> |
| PICL Tree | <p>The PICL tree is the repository of all the nodes and properties created by the plug-in modules to represent the platform configuration. Every node in the PICL tree is an instance of a well-defined PICL class. The name of the base PICL class is <code>picl</code>, which defines a basic set of properties that all nodes in the tree must possess. Two of those properties are <code>name</code> and <code>_class</code>, where <code>name</code> contains the name of the node, and the <code>_class</code> contains the PICL class name of the node. Certain nodes in the PICL tree have well-known names. For example, the name of the root node of the PICL tree is <code>/</code> and the name of the root node of the sub-tree containing platform device nodes is <code>platform</code>.</p> |
| PICL plug-in Modules | <p>The PICL plug-in modules are shared objects that publish platform-specific data in the PICL tree. They are located in well-known directories so that the daemon can locate and load them.</p> <p>Plug-in modules are located in one of the following plug-in directories depending on the platform-specific nature of the data that they collect and publish:</p> <pre> /usr/platform/'uname -i'/lib/picl/plugins /usr/platform/'uname -m'/lib/picl/plugins </pre> <p>A plug-in module can specify its dependency on another plug-in module using the <code>-l</code> or <code>-R</code> linker option. The plug-ins are loaded by the daemon using <code>dlopen(3C)</code> according to the specified dependencies. Each plug-in module must define a <code>.init</code> section, which is executed when the plug-in module is loaded, to register themselves with the daemon. See <code>picld_plugin_register(3PICLTREE)</code> for additional information on plug-in registration.</p> <p>The plug-in modules use the <code>libpicltree(3PICLTREE)</code> interface to publish nodes and properties in the PICL tree so that clients can access them.</p> <p>When the PICL daemon invokes the initialization routine of the plug-in module, the plug-in collects the platform information and creates nodes and/or properties to represent the configuration in the PICL tree. A plug-in can create additional threads to monitor the platform configuration and update the PICL tree with any changes. This enables a PICL plug-in to operate as a daemon within the PICL framework.</p> |

An environmental monitor is an example of a plug-in module that uses a thread to monitor the temperatures and fan speeds of the platform, then publishes the environmental information in the PICL tree so clients can access them.

Clients use the `libpicl(3PICL)` interface to send requests to `picld` for accessing the PICL tree.

Exit Status `picld` does not return an exit status.

Files `/var/run/picld_door` PICL daemon door
`/usr/lib/picl/picld` PICL daemon

Attributes See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | service/picl |

See Also `svcs(1)`, `svcadm(1M)`, `dlopen(3C)`, `libpicl(3PICL)`, `libpicltree(3PICLTREE)`, `picld_log(3PICLTREE)`, `picld_plugin_register(3PICLTREE)`, `attributes(5)`, `smf(5)`

Notes The `picld` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/system/picl
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

Name ping – send ICMP (ICMP6) ECHO_REQUEST packets to network hosts

Synopsis /usr/sbin/ping *host* [*timeout*]

```
/usr/sbin/ping -s [-l | -U] [-abdLLnrRv] [-A addr_family]
  [-c traffic_class] [-g gateway [-g gateway...]]
  [-N next_hop_router] [-F flow_label] [-I interval]
  [-i interface] [-P tos] [-p port] [-t tll] host
  [data_size] [npackets]
```

Description The utility ping utilizes the ICMP (ICMP6 in IPv6) protocol's ECHO_REQUEST datagram to elicit an ICMP (ICMP6) ECHO_RESPONSE from the specified *host* or network *gateway*. If *host* responds, ping will print:

host is alive

on the standard output and exit. Otherwise, after *timeout* seconds, it will write:

no answer from *host*

The default value of *timeout* is 20 seconds.

When you specify the *s* flag, sends one datagram per second (adjust with *-I*) and prints one line of output for every ECHO_RESPONSE that it receives. ping produces no output if there is no response. In this second form, ping computes round trip times and packet loss statistics; it displays a summary of this information upon termination or timeout. The default *data_size* is 56 bytes, or you can specify a size with the *data_size* command-line argument. If you specify the optional *npackets*, ping sends ping requests until it either sends *npackets* requests or receives *npackets* replies.

When using ping for fault isolation, first ping the local host to verify that the local network interface is running.

Options The following options are supported:

-A addr_family

Specify the address family of the target host. *addr_family* can be either *inet* or *inet6*.

Address family determines which protocol to use. For an argument of *inet*, IPv4 is used.

For *inet6*, IPv6 is used.

By default, if the name of a host is provided, not the literal IP address, and a valid IPv6 address exists in the name service database, ping will use this address. Otherwise, if the name service database contains an IPv4 address, it will try the IPv4 address.

Specify the address family *inet* or *inet6* to override the default behavior. If the argument specified is *inet*, ping will use the IPv4 address associated with the host name. If none exists, ping will state that the host is unknown and exit. It does not try to determine if an IPv6 address exists in the name service database.

If the specified argument is *inet6*, ping uses the IPv6 address that is associated with the host name. If none exists, ping states that the host is unknown and exits.

-F *flow_label*

Specify the flow label of probe packets. The value must be an integer in the range from 0 to 1048575. This option is valid only on IPv6.

-D

Turn off fragmentation. For IPv4, this means setting the Don't Fragment bit. For IPv4 and IPv6, this means do not allow fragmentation as the datagrams are sent. If the *data_size* exceeds the MTU, then ping might report that sending failed due to Message too long.

-I *interval*

Turn on the statistics mode and specify the interval between successive transmissions. The default is one second. See the discussion of the **-s** option.

-L

Turn off loopback of multicast packets. Normally, members are in the host group on the outgoing interface, a copy of the multicast packets will be delivered to the local machine.

-N *next_hop_router*

Specify a next-hop router so that the probe packet goes through the specified router along its path to the target host. This option essentially bypasses the system routing table and leaves the probe packet header unmodified. Only one next-hop router can be specified.

-P *tos*

Set the type of service (*tos*) in probe packets to the specified value. The default is zero. The value must be an integer in the range from 0 to 255. Gateways also in the path can route the probe packet differently, depending upon the value of *tos* that is set in the probe packet. This option is valid only on IPv4.

-R

Record route. Sets the IPv4 record route option, which stores the route of the packet inside the IPv4 header. The contents of the record route are only printed if the **-v** and **-s** options are given. They are only set on return packets if the target host preserves the record route option across echos, or the **-l** option is given. This option is valid only on IPv4.

-U

Send UDP packets instead of ICMP (ICMP6) packets. ping sends UDP packets to consecutive ports expecting to receive back ICMP (ICMP6) PORT_UNREACHABLE from the target host.

-a

ping all addresses, both IPv4 and IPv6, of the multihomed destination. The output appears as if ping has been run once for each IP address of the destination. If this option is used together with **-A**, ping probes only the addresses that are of the specified address family. When used with the **-s** option and *npackets* is not specified, ping continuously probes the destination addresses in a round robin fashion. If *npackets* is specified, ping sends *npackets* number of probes to each IP address of the destination and then exits.

- b
Bypass the global IPsec policy and send and receive packets in the clear for this connection only. This option can be used to troubleshoot network connectivity independent of IPsec. Because this option bypasses system-wide policy for this connection, it can only be used by superuser or a user granted the `sys_net_config` privilege.
- c *traffic_class*
Specify the traffic class of probe packets. The value must be an integer in the range from 0 to 255. Gateways along the path can route the probe packet differently, depending upon the value of *traffic_class* set in the probe packet. This option is valid only on IPv6.
- d
Set the `SO_DEBUG` socket option.
- g *gateway*
Specify a loose source route gateway so that the probe packet goes through the specified host along the path to the target host. The maximum number of gateways is 8 for IPv4 and 127 for IPv6. Note that some factors such as the link MTU can further limit the number of gateways for IPv6.
- i *interface_address*
Specify the outgoing interface address to use for multicast packets for IPv4 and both multicast and unicast packets for IPv6. The default interface address for multicast packets is determined from the (unicast) routing tables. *interface_address* can be a literal IP address, for example, `10.123.100.99`, or an interface name, for example, `eri0`, or an interface index, for example `2`.
- l
Use to send the probe packet to the given host and back again using loose source routing. Usually specified with the `-R` option. If any gateways are specified using `-g`, they are visited twice, both to and from the destination. This option is ignored if the `-U` option is used.
- n
Show network addresses as numbers. `ping` normally does a reverse name lookup on the IP addresses it extracts from the packets received. The `-n` option blocks the reverse lookup, so `ping` prints IP addresses instead of host names.
- p *port*
Set the base UDP *port* number used in probes. This option is used with the `-U` option. The default base *port* number is 33434. The `ping` utility starts setting the destination port number of UDP packets to this base and increments it by one at each probe.
- r
Bypass the normal routing tables and send directly to a host on an attached network. If the host is not on a directly attached network, an error is returned. This option can be used to `ping` a local host through an interface that has been dropped by the router daemon. See [in.routed\(1M\)](#).

- s
Send one datagram per second and collect statistics.
- t *tll*
Specify the IPv4 time to live, or IPv6 hop limit, for unicast and multicast packets. The default time to live (hop limit) for unicast packets can be set with the `ndd` module, `/dev/icmp`, using the `icmp_ipv4_ttl` variable for IPv4 and the `icmp_ipv6_hoplimit` variable for IPv6. The default time to live (hop limit) for multicast is one hop. See EXAMPLES. For further information, see [ndd\(1M\)](#).
- v
Verbose output. List any ICMP (ICMP6) packets, other than replies from the target host.

Operands *host*
The network host

Examples EXAMPLE 1 Using ping With IPv6

This example shows ping sending probe packets to all the IPv6 addresses of the host xyz, one at a time. It sends an ICMP6 ECHO_REQUEST every second until the user interrupts it.

```
istanbul% ping -s -A inet6 -a xyz
PING xyz: 56 data bytes
64 bytes from xyz (4::114:a00:20ff:ab3d:83ed): icmp_seq=0. time=0.479 ms
64 bytes from xyz (fec0::114:a00:20ff:ab3d:83ed): icmp_seq=1. time=0.843 ms
64 bytes from xyz (4::114:a00:20ff:ab3d:83ed): icmp_seq=2. time=0.516 ms
64 bytes from xyz (fec0::114:a00:20ff:ab3d:83ed): icmp_seq=3. time=4.943 ms
64 bytes from xyz (4::114:a00:20ff:ab3d:83ed): icmp_seq=4. time=0.485 ms
64 bytes from xyz (fec0::114:a00:20ff:ab3d:83ed): icmp_seq=5. time=2.201 ms
^C
----xyz PING Statistics----
6 packets transmitted, 6 packets received, 0% packet loss
round-trip (ms)  min/avg/stddev = 0.479/1.583/4.943/1.823
```

EXAMPLE 2 Using `ndd` to Set the `icmp_ipv6_hoplimit`

This example shows the `ndd` module, `/dev/icmp`, used to set the `icmp_ipv6_hoplimit`.

```
# ndd -set /dev/icmp icmp_ipv6_hoplimit 100
```

Exit Status The following exit values are returned:

0
Successful operation; the machine is alive.

non-zero
An error has occurred. Either a malformed argument has been specified, or the machine was not alive.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | network/ftp |

See Also [ifconfig\(1M\)](#), [in.routed\(1M\)](#), [ndd\(1M\)](#), [netstat\(1M\)](#), [rpcinfo\(1M\)](#), [traceroute\(1M\)](#), [attributes\(5\)](#), [icmp\(7P\)](#), [icmp6\(7P\)](#)

Name pkg2du – convert driver packages to Driver Update format

Synopsis /usr/bin/pkg2du [-f] [-v] [-d *dir*] [-o *iso*] [-l *label*]
[-r *release*] *pkg* [*pkg* ...]

Description The /usr/bin/pkg2du utility takes one or more packages as input and converts them to Driver Update (DU) format. If the -d option is specified, the resulting DU directory tree is placed in the directory *dir*. If the -o option is specified, a Solaris ISO image of the DU directory tree is written in the file *iso*. The ISO image can be burned onto CD/DVD using `cdrw(1)` or `cdrecord(1)` (not a SunOS man page) and used during Solaris installation.

At least one of the -d and -o options must be specified. If both are specified, then both an ISO image and a directory tree are generated.

Options The following options are supported:

-d *dir*

Directory where the DU directory should be created.

-o *iso*

Create a Solaris ISO image of the DU directory.

-f

If *dir*/DU or *iso* exists, remove it without asking first.

-l *label*

Label/volume name of the ISO image (if -o option is specified).

-r *release*

Solaris release number to use. It takes the form of the return from `uname -r` command, for example, 5.10. If unspecified, the release number of the currently running Solaris is used.

-v

Verbose. Multiple -v options increase verbosity.

Operands The following operands are supported:

pkg [*pkg*...]

One or more packages to be converted to DU format.

Examples EXAMPLE 1 Creating a DU CD/DVD

The following commands create a DU CD or DVD containing packages SUNWfoo and SUNWbar.

```
# /usr/bin/pkg2du -r 5.10 -o my.iso SUNWfoo SUNWbar
```

```
# /usr/bin/cdrw -i my.iso
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | Committed |

See Also [cdrw\(1\)](#), [mkbootmedia\(1M\)](#), [attributes\(5\)](#)

[mkisofs\(8\)](#), (`/usr/share/man/man8/mkisofs.8`), in the SUNWfsman package (not a SunOS man page)

Name pkgadd – transfer software packages to the system

Synopsis pkgadd [-nv] [-a *admin*] [-G] [-x *proxy*]
 [[-M] -R *root_path*] [-r *response*] [-k *keystore*]
 [-P *passwd*] [-V *fs_file*]
 [-d *device* | -d *datastream pkginst* | all]
 [*pkginst* | -Y *category* [, *category*]...]
 pkgadd -s [-d *device* | -d *datastream pkginst* | all]
 [*pkginst* | -Y *category* [, *category*]...]

Description pkgadd transfers the contents of a software package from the distribution medium or directory to install it onto the system. Used without the -d *device* source specifier, pkgadd looks in the default spool directory (/var/spool/pkg) for the package. Used with the -s option, it writes the package to a spool directory instead of installing it.

The pkgadd utility requires an amount of temporary space the size of the package that is being installed. pkgadd determines which temporary directory to use by checking for the existence of the \$TMPDIR environment variable. If \$TMPDIR is not defined, pkgadd uses P_tmpdir from stdio.h. P_tmpdir has a default of /var/tmp/.

Certain unbundled and third-party packages are no longer entirely compatible with the latest version of pkgadd. These packages require user interaction throughout the installation and not just at the very beginning, or require that their request scripts be run as the root user.

To install these older packages (released prior to Solaris 2.4), set the following environment variable: NONABI_SCRIPTS=TRUE

As long as this environment variable is set, pkgadd permits keyboard interaction throughout the installation and package request scripts are run as root.

If you have package request scripts that require running as user root (instead of noaccess [the default] or user install), use the rscript_alt parameter in the [admin\(4\)](#) file to make an appropriate selection. See [admin\(4\)](#).

Note that, in Solaris 8 and Solaris 9, the default user when running a request script was either root or nobody, depending on the operating system's patch level. In the current release, the default user is noaccess.

When running pkgadd in the global zone (see [zones\(5\)](#)), a package that contains a request script (see [pkgask\(1M\)](#)) is added only to the global zone. The package is not propagated to any current or yet-to-be-installed non-global zone. This behavior mimics the effect of the -G option, described below.

Package commands are [largefile\(5\)](#)-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, pkgadd, [pkgtrans\(1\)](#) and other package commands can process a datastream of up to 4 GB.

The -d, -Y, and *pkginst* arguments shown in the SYNOPSIS are described under OPERANDS, following OPTIONS.

Options The supported options are described as follows. The *-d device* source specifier is described under OPERANDS, below.

-a admin

Define an installation administration file, *admin*, to be used in place of the default administration file. The token *none* overrides the use of any *admin* file, and thus forces interaction with the user. Unless a full path name is given, *pkgadd* first looks in the current working directory for the administration file. If the specified administration file is not in the current working directory, *pkgadd* looks in the */var/sadm/install/admin* directory for the administration file.

-G

Add package(s) in the current zone only. When used in the global zone, the package is added to the global zone only and is not propagated to any existing or yet-to-be-created non-global zone. When used in a non-global zone, the package(s) are added to the non-global zone only.

This option causes package installation to fail if, in the *pkginfo* file for a package, *SUNW_PKG_ALLZONES* is set to true. See [pkginfo\(4\)](#).

-k keystore

Use *keystore* as the location from which to get trusted certificate authority certificates when verifying digital signatures found in packages. If no *keystore* is specified, then the default keystore locations are searched for valid trusted certificates. See *KEYSTORE LOCATIONS* for more information.

-M

Instruct *pkgadd* not to use the *\$root_path/etc/vfstab* file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.

-n

Installation occurs in non-interactive mode. Suppress output of the list of installed files. The default mode is interactive.

-P passwd

Password to use to decrypt keystore specified with *-k*, if required. See *PASS PHRASE ARGUMENTS* for more information about the format of this option's argument.

-r response

Identify a file or directory which contains output from a previous [pkgask\(1M\)](#) session. This file supplies the interaction responses that would be requested by the package in interactive mode. *response* must be a full pathname.

-R root_path

Define the full path name of a directory to use as the *root_path*. All files, including package system information files, are relocated to a directory tree starting in the specified *root_path*. The *root_path* may be specified when installing to a client from a server (for example, */export/root/client1*).

Note – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).

`-s spool`

Write the package into the directory *spool* instead of installing it.

`-v`

Trace all of the scripts that get executed by `pkgadd`, located in the `pkginst/install` directory. This option is used for debugging the procedural and non-procedural scripts.

`-V fs_file`

Specify an alternative *fs_file* to map the client's file systems. For example, used in situations where the `$root_path/etc/vfstab` file is non-existent or unreliable.

`-x proxy`

Specify a HTTP[S] proxy to use when downloading packages. The format of proxy is *host:port*, where *host* is the hostname of the HTTP[S] proxy, and *port* is the port number associated with the proxy. This switch overrides all other methods of specifying a proxy. See ENVIRONMENT VARIABLES for more information on alternate methods of specifying a default proxy.

When executed without options or operands, `pkgadd` uses `/var/spool/pkg` (the default spool directory).

Operands The following operands are supported:

Sources By default, `pkgadd` looks in the `/var/spool/pkg` directory when searching for instances of a package to install or spool. Optionally, the source for the package instances to be installed or spooled can be specified using:

`-d device`

`-d datastream pkgname,... | all`

Install or copy a package from *device*. *device* can be any of the following:

- A full path name to a directory or the identifiers for tape, floppy disk, or removable disk (for example, `/var/tmp` or `/floppy/floppy_name`).
- A device alias (for example, `/floppy/floppy0`).
- A datastream created by `pkgtrans` (see [pkgtrans\(1\)](#)).
- A URL pointing to a datastream created by `pkgtrans`. The supported Universal Resource Identifiers (URIs) are `http:` and `https:`.

The second form of the `-d` specifier, above, indicates the syntax you use when specifying a datastream. In this case you must specify either a comma-separated list of package names or the keyword `all`.

Instances By default, pkgadd searches the specified source, and presents an interactive menu allowing the user to select which package instances found on the source are to be installed. As an alternative, the package instances to be installed can be specified using:

pkginst

The package instance or list of instances to be installed. The token `all` may be used to refer to all packages available on the source medium. The format *pkginst*.`*` can be used to indicate all instances of a package.

The asterisk character (`*`) is a special character to some shells and may need to be escaped. In the C-Shell, the asterisk must be surrounded by single quotes (`'`) or preceded by a backslash (`\`).

`-Y category[,category...]`

Install packages based on the value of the CATEGORY parameter stored in the package's `pkginfo(4)` file. All packages on the source medium whose CATEGORY matches one of the specified categories will be selected for installation or spooling.

Keystore Locations Package such as pkgadd use a set of trusted certificates to perform signature validation on any signatures found within the packages. If there are no signatures included in the packages then signature validation is skipped. The certificates can come from a variety of locations. If `-k keystore` is specified, and *keystore* is a directory, then *keystore* is assumed to be the base directory of the certificates to be used. If *keystore* is a file, then the file itself is assumed to have all required keys and certificates. When `-k` is not specified, then `/var/sadm/security` is used as the base directory.

Within the specified base directory, the store locations to be searched are different based on the application doing the searching and the type of store being searched for. The following directories are searched in the specified order:

1. `<store_dir>/<app_name>/<store_type>`
2. `<store_dir>/<store_type>`

Where `<store_dir>` is the directory specified by `-k`, `<app_name>` is the name of the application doing the searching, and `<store_type>` is one of `keystore` (for private keys), `certstore` (for untrusted public key certificates), or `truststore` (for trusted certificate authority certificates).

For example, when pkgadd is run with `-k /export/certs`, then the following locations are successively searched to find the trust store:

1. `/export/certs/pkgadd/truststore`
2. `/export/certs/truststore`

This searching order enables administrators to have a single location for most applications, and special certificate locations for certain applications.

Keystore And Certificate Formats The packaging utilities, such as `pkgtrans`, require access to a set of keys and certificates in order to sign, and optionally verify, packages.

The keystore files found by following the search pattern specified in `KEYSTORE LOCATIONS` must each be a self-contained PKCS#12-format file.

When signing a package with `pkgtrans`, if a `certstore` has more than one public key certificate, then each public key must have a `friendlyName` attribute in order to be identifiable and selectable with the `-a` option when signing packages. In addition, the public key certificate selected with `-a` and found in the `certstore` must have an associated private key in the keystore.

Several browsers and utilities can be used to export and import certificates and keys into a PKCS#12 keystore. For example, a trusted certificate can be exported from Mozilla, and then imported into a PKCS#12 keystore for use with `pkgadd` with the OpenSSL Toolkit.

Pass Phrase Arguments `pkgtrans` and `pkgadd` accept password arguments, typically using `-p` to specify the password. These allow the password to be obtained from a variety of sources. Both of these options take a single argument whose format is described below. If no password argument is given and a password is required then the user is prompted to enter one: this will typically be read from the current terminal with echoing turned off.

`pass:password`

The actual password is *password*. Because the password is visible to utilities such as `ps` this form should only be used where security is not important.

`env:var`

Obtain the password from the environment variable *var*. Because the environment of other processes is visible on certain platforms this option should be used with caution.

`file:pathname`

The first line contained within *pathname* is the password. *pathname* need not refer to a regular file: it could, for example, refer to a device or named pipe. For example, to read the password from standard input, use `file:/dev/stdin`.

`console`

Read the password from `/dev/tty`.

Examples **EXAMPLE 1** Installing a Package from a Solaris DVD

The following example installs a package from a Solaris DVD. You are prompted for the name of the package you want to install.

```
example# pkgadd -d /cdrom/cdrom0/s0/Solaris_10/Product
```

EXAMPLE 2 Installing a Set of Packages from a Datastream

The example command shown below installs all of the packages in the datastream specified by the `-d` source specifier. Prior to this command, this datastream must have been created with the `pkgtrans(1)` command.

EXAMPLE 2 Installing a Set of Packages from a Datastream *(Continued)*

```
example# pkgadd -d /var/tmp/datastream all
```

The keyword `all` specifies that all of the packages found in the designated datastream will be installed.

Exit Status

- 0 Successful completion
- 1 Fatal error.
- 2 Warning.
- 3 Interruption.
- 4 Administration.
- 5 Administration. Interaction is required. Do not use `pkgadd -n`.
- 10 Reboot after installation of all packages.
- 20 Reboot after installation of this package.

Environment Variables

HTTPPROXY
Specifies an HTTP proxy host. Overrides administration file setting, and `http_proxy` environment variable.

HTTPPROXYPORT
Specifies the port to use when contacting the host specified by `HTTPPROXY`. Ignored if `HTTPPROXY` is not set.

http_proxy
URL format for specifying proxy host and port. Overrides administration file setting.

Files `/var/sadm/install/logs/`
Location where `pkgadd` logs an instance of software installation.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | package/svr4 |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Interface Stability | Committed |

See Also [pkginfo\(1\)](#), [pkgmk\(1\)](#), [pkgparam\(1\)](#), [pkgproto\(1\)](#), [pkgtrans\(1\)](#), [installf\(1M\)](#), [pkgadm\(1M\)](#), [pkgask\(1M\)](#), [pkgchk\(1M\)](#), [pkgrm\(1M\)](#), [removef\(1M\)](#), [admin\(4\)](#), [pkginfo\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#), [zones\(5\)](#)

Application Packaging Developer's Guide

<http://www.openssl.org>

Notes When transferring a package to a spool directory, the `-r`, `-n`, and `-a` options cannot be used.

The `-r` option can be used to indicate a directory name as well as a filename. The directory can contain numerous response files, each sharing the name of the package with which it should be associated. This would be used, for example, when adding multiple interactive packages with one invocation of `pkgadd`. In this situation, each package would need a response file. If you create response files with the same name as the package (for example, `pkinst1` and `pkinst2`), then name the directory in which these files reside after the `-r`.

The `-n` option causes the installation to halt if any interaction is needed to complete it.

If the default `admin` file is too restrictive, the administration file may need to be modified to allow for total non-interaction during a package installation. See [admin\(4\)](#) for details.

If a package stream is specified with `-d`, and a digital signature is found in that stream, the default behavior is to attempt to validate the certificate and signature found. This behavior can be overridden with `admin` file settings. See [admin\(4\)](#) for more information.

|--------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name | pkgadm – manage packaging and patching system |
| Synopsis | <pre> pkgadm addcert [-ty] [-a <i>app</i>] [-k <i>keystore</i>] [-e <i>keyfile</i>] [-f <i>format</i>] [-n <i>name</i>] [-P <i>passarg</i>] [-p <i>import_passarg</i>] [-R <i>rootpath</i>] certfile pkgadm removecert [-a <i>app</i>] [-k <i>keystore</i>] -n <i>name</i> [-P <i>passarg</i>] [-R <i>rootpath</i>] pkgadm listcert [-a <i>app</i>] [-f <i>format</i>] [-k <i>keystore</i>] -n <i>name</i> [-P <i>passarg</i>] [-o <i>outfile</i>] [-R <i>rootpath</i>] pkgadm dbstatus [-R <i>rootpath</i>] pkgadm sync [-R <i>rootpath</i>] [-q] pkgadm -V pkgadm -?</pre> |
| Description | The pkgadm utility is used for managing the packaging and patching system. It has several subcommands that perform various operations relating to packaging. The pkgadm command includes subcommands for managing certificates and keys used. |
| Managing Keys and Certificates | <p>pkgadm maintains the packaging-system-wide keystore in /var/sadm/security, and individual user's certificates in ~/.pkg/security. The following subcommands operate on the package keystore database:</p> <p>addcert
Add (import) a certificate into the database, with optional trust. Once added, trusted certificates can be used to verify signed packages and patches. Non-trusted user certificates and their associated keys can be used to sign packages and patches. Added user certificates are <i>not</i> used to build certificate chains during certificate verification.</p> <p>removecert
Removes a user certificate/private key pair, or a trusted certificate authority certificate from the keystore. Once removed, the certificate and keys cannot be used.</p> <p>listcert
Print details of one or more certificates in the keystore.</p> <p>sync
Writes the contents file and rolls the contents log file. With use of the -q option, forces the contents file server to quit.</p> |
| Internal Install Database | The Solaris operating system relies upon enhanced System V revision 4 (SVr4) packages as the basis for its software installation and revision management. The package maintenance software stores information about installed packages in an internal database. The pkgadm subcommand dbstatus is used to determine how the package internal database is implemented. The dbstatus command returns a string that indicates the type of internal database in use. In |

the current implementation, the `dbstatus` command always returns the string `text`, which indicates that the `contents(4)` package database is in use. Future releases of Solaris might supply alternative database implementations.

Options The following options are supported:

-a *app*

If this option is used, then the command only affects the keystore associated with a particular application. Otherwise, the global keystore is affected.

-e *keyfile*

When adding a non-trusted certificate/key combination, this option can be used to specify the file that contains the private key. If this option is not used, the private key must be in the same file as the certificate being added.

-f *format*

When adding certificates, this specifies the format to expect certificates and private keys in. Possible values when adding are:

`pem`

Certificate and any private key uses PEM encoding.

`der`

Certificate and any private key uses DER encoding.

When printing certificates, this specifies the output format used when printing. Acceptable values for `format` are:

`pem`

Output each certificate using PEM encoding.

`der`

Output each certificate using DER encoding.

`text`

Output each certificate in human-readable format.

-k *keystore*

Overrides the default location used when accessing the keystore.

-n *name*

Identifies the entity in the store on which you want to operate. When adding a user certificate, or removing certificates, this name is required. The name is associated with the certificate/key combination, and when adding, can be used later to reference the entity. When printing certificates, if no alias is supplied, then all keystore entities are printed.

-o *outfile*

Output the result of the command to *outfile*. Only used when examining (printing) certificates from the key store. Standard out is the default.

- P *passarg*
Password retrieval method to use to decrypt keystore specified with -k, if required. See PASS PHRASE ARGUMENTS in [pkgadd\(1M\)](#) for more information about the format of this option's argument. `console` is the default.
- p *import_passarg*
This option's argument is identical to -P, but is used for supplying the password used to decrypt the certificate and/or private key being added. `console` is the default.
- q
(Applies to sync subcommand.) Shuts down the contents file cache daemon.
- R *rootpath*
Defines the full name of a directory to use as the root (/) path. The default user location of the certificate operations is `${HOME}/.pkg`. If the -R option is supplied, the certificates and keys will be stored under `<alroot>/var/sadm/security`. Note that this operation fails if the user does not have sufficient permissions to access this directory. The `listcert` command requires read permission, while `addcert` and `removecert` require both read and write permission.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).
- t
Indicates the certificate being added is a trusted CA certificate. The details of the certificate (including the Subject Name, Validity Dates, and Fingerprints) are printed and the user is asked to verify the data. This verification step can be skipped with -y. When importing a trusted certificate, a private key should not be supplied, and will be rejected if supplied. Once a certificate is trusted, it can be used as a trust anchor when verifying future untrusted certificates.
- V
Print version associated with packaging tools.
- y
When adding a trusted certificate, the details of the certificate (Subject name, Issuer name, Validity dates, Fingerprints) are shown to the user and the user is asked to verify the correctness before proceeding. With -y, this additional verification step is skipped.
- ?
Print help message.

Operands The following operand is supported:

certfile

File containing the certificate and optional private key, used when adding a trust anchor or certificate/key combination. Certificates must be encoded using PEM or binary DER.

Keystore Aliases All keystore entries (user cert/key and trusted certificate entries) are accessed via unique aliases. Aliases are case-sensitive.

An alias is specified when you add an entity to a keystore using the `addcert` or `trustcert` subcommand. If an alias is not supplied for a trust anchor, the trust anchor's Common Name is used as the alias. An alias is required when adding a signing certificate or chain certificate. Subsequent `pkgetcrt` or other package tool commands must use this same alias to refer to the entity.

Keystore Passwords See the [pkgadd\(1M\)](#) man page for a description of the passwords supplied to the `pkgadm` utility.

Examples **EXAMPLE 1** Adding a Trust Anchor

The following example adds a well-known and trusted certificate to be used when verifying signatures on packages.

```
example% pkgadm addcert -t /tmp/certfile.pem
```

EXAMPLE 2 Adding a Signing Certificate

The following example adds a signing certificate and associated private key, each of which is in a separate file, which can then be used to sign packages.

```
example% pkgadm addcert -a pkgtrans -e /tmp/keyfile.pem \
/tmp/certfile.pem
```

EXAMPLE 3 Printing Certificates

The following example prints all certificates in the root keystore.

```
example% pkgadm listcert
```

Exit Status 0
successful completion

non-zero
fatal error

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | package/svr4 |
| Interface Stability | Committed |

See Also [pkginfo\(1\)](#), [pkgmk\(1\)](#), [pkgparam\(1\)](#), [pkgproto\(1\)](#), [pkgtrans\(1\)](#), [svcs\(1\)](#), [installf\(1M\)](#), [pkgadd\(1M\)](#), [pkgask\(1M\)](#), [pkgrm\(1M\)](#), [removef\(1M\)](#), [svcadm\(1M\)](#), [admin\(4\)](#), [contents\(4\)](#), [exec_attr\(4\)](#), [pkginfo\(4\)](#), [attributes\(5\)](#), [rbac\(5\)](#), [smf\(5\)](#)

Application Packaging Developer's Guide

Notes The service for pkgadm is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/pkgserv
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Name pkgask – stores answers to a request script

Synopsis pkgask [-d *device*] [-R *root_path*] -r *response pkginst...*

Description pkgask allows the administrator to store answers to an interactive package (one with a request script, that is, a user-created file that must be named request). Invoking this command generates a response file that is then used as input at installation time. The use of this response file prevents any interaction from occurring during installation since the file already contains all of the information the package needs.

Options The following options are supported

-d *device* Run the request script for a package on *device*. *device* can be a directory pathname or the identifiers for tape, floppy disk or removable disk (for example, /var/tmp, /dev/diskette, and /dev/dsk/c1d0s0). The default device is the installation spool directory.

-R *root_path* Define the full path name of a directory to use as the *root_path*. All files, including package system information files, are relocated to a directory tree starting in the specified *root_path*.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).

-r *response* Identify a file or directory which should be created to contain the responses to interaction with the package. The name must be a full pathname. The file, or directory of files, can later be used as input to the [pkgadd\(1M\)](#) command.

Operands The following operands are supported:

pkginst Specify the package instance, or list of instances for which request scripts will be created. The token all may be used to refer to all packages available on the source medium.

Exit Status 0 Successful completion.

>0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [pkginfo\(1\)](#), [pkgmk\(1\)](#), [pkgparam\(1\)](#), [pkgproto\(1\)](#), [pkgtrans\(1\)](#), [installf\(1M\)](#), [pkgadd\(1M\)](#), [pkgchk\(1M\)](#), [pkgrm\(1M\)](#), [removef\(1M\)](#), [admin\(4\)](#), [attributes\(5\)](#)

Application Packaging Developer's Guide

Notes The `-r` option can be used to indicate a directory name as well as a filename. The directory name is used to create numerous response files, each sharing the name of the package with which it should be associated. This would be used, for example, when you will be adding multiple interactive packages with one invocation of `pkgadd(1M)`. Each package would need a response file. To create multiple response files with the same name as the package instance, name the directory in which the files should be created and supply multiple instance names with the `pkgask` command. When installing the packages, you will be able to identify this directory to the `pkgadd(1M)` command.

If the default `admin` file is too restrictive, the administration file may need to be modified to allow for total non-interaction during a package installation. See `admin(4)` for details.

Name pkgchk – check package installation accuracy

Synopsis pkgchk [-l | -acfnqv] [-i *file* | -]
[-p *path...* | -P *partial-path...*] [-R *root_path*]
[[-m *pkgmap* [-e *envfile*]] | pkginst... | -Y *category,category...*]

pkgchk -d *device* [-l | -fv] [-i *file* | -] [-M] [-p *path*]...
[-V *fs_file*]
[pkginst... | -Y *category[,category...]*]

Description pkgchk checks the accuracy of installed files or, by using the -l option, displays information about package files. pkgchk checks the integrity of directory structures and files. Discrepancies are written to standard error along with a detailed explanation of the problem.

The first synopsis defined above is used to list or check the contents and/or attributes of objects that are currently installed on the system, or in the indicated pkgmap. Package names may be listed on the command line, or by default, the entire contents of a machine will be checked.

The second synopsis is used to list or check the contents of a package which has been spooled on the specified device, but not installed. Note that attributes cannot be checked for spooled packages.

Options The following options are supported:

- a
Audit the file attributes only and do not check file contents. Default is to check both.
- c
Audit the file contents only and do not check file attributes. Default is to check both.
- d *device*
Specify the device on which a spooled package resides. *device* can be a directory path name or the identifiers for tape, floppy disk, or removable disk (for example, /var/tmp or /dev/diskette).
- e *envfile*
Request that the package information file named as *envfile* be used to resolve parameters noted in the specified pkgmap file.
- f
Correct file attributes if possible. If used with the -x option, this option removes hidden files. When pkgchk is invoked with this option, it creates directories, named pipes, links, and special devices if they do not already exist. If the -d option calls out an uninstalled package, the -f option will only take effect if the package is in directory (not stream) format. All file attributes will be set to agree with the entries in the pkgmap file except that setuid, setgid, and sticky bits will not be set in the mode.

-
- i *file* | -**
Read a list of path names from *file* or from stdin (-) and compare this list against the installation software database or the indicated pkgmap file. Path names that are not contained in *file* or stdin are not checked.
- l**
List information on the selected files that make up a package. This option is not compatible with the -a, -c, -f, -g, and -v options.
- m pkgmap**
Check the package against the package map file, pkgmap.
- M**
Instruct pkgchk not to use the *\$root_path/etc/vfstab* file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.
- n**
Do not check volatile or editable files' contents. This should be used for most post-installation checking.
- p *path***
Check the accuracy only of the path name or path names listed. *path* can be one or more path names separated by commas (or by whitespace, if the list is quoted).
- To specify a *path* that includes a comma, you must use the -i option, described above. See EXAMPLES.
- P *partial-path***
Check the accuracy of only the partial path name or path names listed. *partial-path* can be one or more partial path names separated by commas (or by whitespace, if the list is quoted). This option can be used instead of -p and is not compatible with the other option. This option matches any path name that contains the string contained in the partial path. See the note about paths that contain commas in the description of -p.
- q**
Quiet mode. Do not give messages about missing files.
- R *root_path***
Define the full name of a directory to use as the *root_path*. All files, including package system information files, are relocated to a directory tree starting in the specified *root_path*. The *root_path* may be specified when installing to a client from a server (for example, /export/root/client1).
- Note** – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).

- v
Verbose mode. Files are listed as processed.
- V *fs_file*
Specify an alternative *fs_file* to map the client's file systems. For example, used in situations where the *\$root_path/etc/vfstab* file is non-existent or unreliable.
- x
Search exclusive directories, looking for files which exist that are not in the installation software database or the indicated pkgmap file.
- Y *category*
Check packages based on the value of the CATEGORY parameter stored in the installed or spooled package's `pkginfo(4)` file.

Operands *pkginst*

The package instance or instances to be checked. The format *pkginst*. * can be used to check all instances of a package. The default is to display all information about all installed packages.

The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, an asterisk must be surrounded by single quotes (') or preceded by a backslash (\);

partial-path

A portion of a path, such as a file or directory name.

Examples EXAMPLE 1 Using pkgchk for Displaying Package Installation Information

The following example displays package installation information for `/usr/bin/ls`:

```
example% pkgchk -l -p /usr/bin/ls
```

EXAMPLE 2 Checking on Java Font Properties

The following example displays package installation information for all Java font properties installed on the system.

```
example% pkgchk -l -P font.properties
```

EXAMPLE 3 Specifying a Path That Contains a Comma

Assume you want to specify the path:

```
/platform/SUNW,Netra-T12/lib
```

List this path in a file. Here is one way in which you can do that:

```
example% echo "/platform/SUNW,Netra-T12/lib" > /tmp/p
```

You can then enter:

EXAMPLE 3 Specifying a Path That Contains a Comma *(Continued)*

```
example% pkgchk -i /tmp/p -l
Pathname: /platform/SUNW,Netra-T12/lib
Type: directory
Expected mode: 0755
Expected owner: root
Expected group: bin
Referenced by the following packages:
    SUNWcar
Current status: installed
```

Exit Status 0
Successful completion.

>0
An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [pkginfo\(1\)](#), [pkgtrans\(1\)](#), [pkgadd\(1M\)](#), [pkgask\(1M\)](#), [pkgrm\(1M\)](#), [pkginfo\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

Application Packaging Developer's Guide

Notes Package commands are [largefile\(5\)](#)-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, [pkgadd\(1M\)](#), [pkgtrans\(1\)](#) and other package commands can process a datastream of up to 4 GB.

Name pkgcond – determine type and capability of target

Synopsis /usr/bin/pkgcond [-nv] *condition*

Description The pkgcond command allows you to determine the type of target being operated on (global zone, non-global zone, diskless client, and so forth) and the capabilities available for that type of client (can add a driver, path is writable, and so forth). The pkgcond command is intended to be invoked from package and patch scripts, but can also be used in situations that mimic the context of these scripts. See NOTES for further guidance.

pkgcond has one mandatory argument, a condition. The command tests whether the condition is true for the specified path. The condition can be one of the following:

- can_add_driver [*path*]
- can_remove_driver [*path*]
- can_update_driver [*path*]
- is_alternative_root [*path*]
- is_boot_environment [*path*]
- is_diskless_client [*path*]
- is_global_zone [*path*]
- is_mounted_miniroot [*path*]
- is_netinstall_image [*path*]
- is_nonglobal_zone [*path*]
- is_path_writable *path*
- is_running_system [*path*]
- is_sparse_root_nonglobal_zone [*path*]
- is_what [*path*]
- is_whole_root_nonglobal_zone [*path*]

The *path* argument usually denotes the root of the global zone or non-global zone, or alternate root. If *path* is optional and not specified, the default is /.

The behavior of the `is_what` condition is somewhat special, because it displays results of all other conditions to standard output.

Options The following options are supported:

-n

Negate return status (0 becomes 1 and 1 becomes 0). It negates results in the case of `is_what` condition.

-v

Verbose mode. Displays detailed data about intermediate checks performed.

Examples EXAMPLE 1 Listing All Available Information

The following command lists all available information about the current running system, in a user-friendly way.

```
example# pkgcond -n is_what
```

EXAMPLE 2 Determining if Target is an Alternate Root

The following command determines whether an alternate boot environment exists under `/altroot_mount`.

```
example# pkgcond is_alternative_root /altroot_mount
```

Exit Status 0

Condition is true unless `-n` was specified.

1

Condition is false unless `-n` was specified.

2

Command line usage error.

3

Command failed to perform the test due to a fatal error.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | Uncommitted |

See Also [pkgtrans\(1\)](#), [pkgadd\(1M\)](#), [pkgask\(1M\)](#), [pkgchk\(1M\)](#), [pkgrm\(1M\)](#), [pkginfo\(4\)](#), [attributes\(5\)](#)

Notes Supported usage of `pkgcond` is subject to the following constraints:

1. Do not use `pkgcond` outside of the Solaris marketing release in which it is provided (for example, do not use Solaris 10 `pkgcond` against a Solaris 9 target).
2. Restrict use of the optional path argument according to the following rules:
 - The command `pkgcond condition $ROOTDIR` can be used in patch level scripts.
 - The command `pkgcond condition $PKG_INSTALL_ROOT` can be used in package level scripts.
 - A command of the form `pkgcond condition without` the optional path argument can be used in any context.

Use of `pkgcond` with an arbitrary path argument is *not* recommended or supported, as the results returned might not be accurate.

Name pkgrm – remove a package from the system

Synopsis pkgrm [-nv] [-a *admin*] [[-A | -M] -R *root_path*]
[-V *fs_file*]
[pkginst... | -Y *category[,category...]*]

pkgrm -s *spool*
[pkginst... | -Y *category[,category...]*]

Description pkgrm will remove a previously installed or partially installed package from the system. A check is made to determine if any other packages depend on the one being removed. If a dependency exists, the action taken is defined in the *admin* file.

The default state for the command is in interactive mode, meaning that prompt messages are given during processing to allow the administrator to confirm the actions being taken. Non-interactive mode can be requested with the *-n* option.

The *-s* option can be used to specify the directory from which spooled packages should be removed.

Certain unbundled and third-party packages are no longer entirely compatible with the latest version of pkgrm. These packages require user interaction throughout the removal and not just at the very beginning.

To remove these older packages (released prior to Solaris 2.4), set the following environment variable:NONABI_SCRIPTS=TRUE pkgrm permits keyboard interaction throughout the removal as long as this environment variable is set.

Options The following options are supported:

-a admin

Use the installation administration file, *admin*, in place of the default *admin* file. pkgrm first looks in the current working directory for the administration file. If the specified administration file is not in the current working directory, pkgrm looks in the */var/sadm/install/admin* directory for the administration file.

-A

Remove the package files from the client's file system, absolutely. If a file is shared with other packages, the default behavior is to not remove the file from the client's file system.

-M

Instruct pkgrm not to use the *\$root_path/etc/vfstab* file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.

-n

Non-interactive mode. If there is a need for interaction, the command will exit.

Use of this option requires that at least one package instance be named upon invocation of the command. Certain conditions must exist for a package to be removed non-interactively or a non-restrictive admin file needs to be used.

-R *root_path*

Defines the full path name of a directory to use as the *root_path*. All files, including package system information files, are relocated to a directory tree starting in the specified *root_path*.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).

-s *spool*

Remove the specified package(s) from the directory *spool*. The default directory for spooled packages is `/var/sadm/pkg`.

-v

Trace all of the scripts that get executed by `pkgrm`, located in the `pkginst/install` directory. This option is used for debugging the procedural and non-procedural scripts.

-V *fs_file*

Specify an alternative *fs_file* to map the client's file systems. Used in situations where the `$root_path/etc/vfstab` file is non-existent or unreliable.

-Y *category*

Remove packages based on the value of the CATEGORY parameter stored in the installed or spooled package's `pkginfo(4)` file. No package with the CATEGORY value of `system` can be removed from the file system with this option.

Operands The following operand is supported:

pkginst

Specifies the package to be removed. The format `pkginst.*` can be used to remove all instances of a package.

The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, "*" must be surrounded by single quotes (') or preceded by a backslash (\).

Examples **EXAMPLE 1** Removing All Instances of SUNWjunk from client1

The following example removes all instances of SUNWjunk from client1:

```
example% pkgrm -R /export/root/client1 SUNWjunk*
```

Note the caveat on the use of the -R option in the description of that option, above.

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 Fatal error.
- 2 Warning.
- 3 Interruption.
- 4 Administration.
- 10 Reboot after removal of all packages.
- 20 Reboot after removal of this package.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [pkginfo\(1\)](#), [pkgmk\(1\)](#), [pkgparam\(1\)](#), [pkgproto\(1\)](#), [pkgtrans\(1\)](#), [installf\(1M\)](#), [pkgadd\(1M\)](#), [pkgask\(1M\)](#), [pkgchk\(1M\)](#), [removef\(1M\)](#), [admin\(4\)](#), [pkginfo\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

Application Packaging Developer's Guide

Notes Package commands are [largefile\(5\)](#)-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, [pkgadd\(1M\)](#), [pkgtrans\(1\)](#) and other package commands can process a datastream of up to 4 GB.

Name plockstat – report user-level lock statistics

Synopsis plockstat [-vACHV] [-n *count*] [-s *depth*] [-e *secs*]
 [-x *arg* [=val]] *command* [*arg*] . . .

plockstat [-vACHV] [-n *count*] [-s *depth*] [-e *secs*]
 [-x *arg* [=val]] -p *pid*

Description The plockstat utility gathers and displays user-level locking statistics. By default, plockstat monitors all lock contention events, gathers frequency and timing data about those events, and displays the data in decreasing frequency order, so that the most common events appear first.

plockstat gathers data until the specified command completes or the process specified with the -p option completes.

plockstat relies on DTrace to instrument a running process or a command it invokes to trace events of interest. This imposes a small but measurable performance overhead on the processes being observed. Users must have the dttrace_proc privilege and have permission to observe a particular process with plockstat. Refer to the *Solaris Dynamic Tracing Guide* for more information about DTrace security features.

Options The following options are supported:

- A Watch all lock events. This option is equivalent to -CH.
- C Watch contention events.
- H Watch hold events.
- e *secs* Exit after the number of seconds specified have elapsed.
- n *count* Display only the specified number of entries for each output category.
- s *depth* Record a stack trace rather than just the calling function.
- p *pid* Specify a process ID from which plockstat is to gather data.
- v Print out a message to indicate that tracing has started.
- x *arg*[=*val*] Enable or modify a DTrace runtime option or D compiler option. The list of options is found in the *Solaris Dynamic Tracing Guide*. Boolean options are enabled by specifying their name. Options with values are set by separating the option name and value with an equals sign (=).
- V Print the Dtrace commands used to gather the data. The output can then be used directly with the [dttrace\(1M\)](#) command.

Operands The following operands are supported:

- arg* A string to be passed as an argument to *command*.
- command* The name of a utility to be invoked.

count A positive integer value.
pid A process identifier for a process to be monitored.
secs Duration specified as a positive integer number of seconds.

Display Headers The following headers appear over columns of data in `plockstat` output.

Count
Number of times an event occurred.
nsec
Average duration of an event, in nanoseconds.
Lock
Address of a lock, displayed symbolically if possible.
Caller
Address of a caller, displayed symbolically if possible.

Exit Status The following exit values are returned:

0 Successful completion.
>0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------|
| Availability | developer/dtrace |
| Interface Stability | See below. |

The command-line syntax is Committed. The human-readable output is Uncommitted.

Solaris Dynamic Tracing Guide

Name pmadm – port monitor administration

Synopsis pmadm -a [-p *pmtag* | -t *type*] -s *svctag* -i *id* -m *pmspecific* -v *ver*
 [-f *xu*]
 [-y *comment*] [-z *script*]

pmadm -r -p *pmtag* -s *svctag*

pmadm -e -p *pmtag* -s *svctag*

pmadm -d -p *pmtag* -s *svctag*

pmadm -l [-t *type* | -p *pmtag*] [-s *svctag*]

pmadm -L [-t *type* | -p *pmtag*] [-s *svctag*]

pmadm -g -p *pmtag* -s *svctag* [-z *script*]

pmadm -g -s *svctag* -t *type* -z *script*

Description pmadm is the administrative command for the lower level of the Service Access Facility hierarchy, that is, for service administration. A port may have only one service associated with it although the same service may be available through more than one port. In order to uniquely identify an instance of a service, the pmadm command must identify both the port monitor or port monitors through which the service is available (-p or -t) and the service (-s). See [Options](#).

pmadm performs the following functions:

- adds or removes a service
- enables or disables a service
- installs or replaces a per-service configuration script
- prints requested service information

Any user on the system may invoke pmadm to request service status (-l or -L) or to print per-service configuration scripts (-g without the -z option). pmadm with other options may be executed only by a privileged user.

Options The following options are supported:

- a Add a service. pmadm adds an entry for the new service to the port monitor's administrative file. Because of the complexity of the options and arguments that follow the -a option, it may be convenient to use a command script or the menu system to add services.
- d Disable a service. Add x to the flag field in the entry for the service *svctag* in the port monitor's administrative file. This is the entry used by port monitor *pmtag*. See the -f option, below, for a description of the flags available.

- e Enable a service. Remove *x* from the flag field in the entry for the service *svctag* in the port monitor administrative file. This is the entry used by port monitor *pmtag*. See the *-f* option, below, for a description of the flags available.

- f *xu* The *-f* option specifies one or both of the following two flags which are then included in the flag field of the entry for the new service in the port monitor's administrative file. If the *-f* option is not included, no flags are set and the default conditions prevail. By default, a new service is enabled and no *utmpx* entry is created for it. An *-f* option without a following argument is illegal.
 - x* Do not enable the service *svctag* available through port monitor *pmtag*.
 - u* Create a *utmpx* entry for service *svctag* available through port monitor *pmtag*.

- g Print, install, or replace a per-service configuration script. The *-g* option with a *-p* option and a *-s* option prints the per-service configuration script for service *svctag* available through port monitor *pmtag*. The *-g* option with a *-p* option, a *-s* option, and a *-z* option installs the per-service configuration script contained in the file *script* as the per-service configuration script for service *svctag* available through port monitor *pmtag*. The *-g* option with a *-s* option, a *-t* option, and a *-z* option installs the file *script* as the per-service configuration script for service *svctag* available through any port monitor of type *type*. Other combinations of options with *-g* are invalid.

- i *id* *id* is the identity that is to be assigned to service *svctag* when it is started. *id* must be an entry in */etc/passwd*.

- l The *-l* option requests service information. Used by itself and with the options described below, it provides a filter for extracting information in several different groupings.
 - l By itself, the *-l* option lists all services on the system.
 - l -p *pmtag* Lists all services available through port monitor *pmtag*.
 - l -s *svctag* Lists all services with tag *svctag*.
 - l -p *pmtag*-*ssvctag* Lists service *svctag*.
 - l -t *type* Lists all services available through port monitors of type *type*.
 - l -t *type*-*ssvctag* Lists all services with tag *svctag* available through a port monitor of type *type*.

- Other combinations of options with `-l` are invalid.
- `-L` The `-L` option is identical to the `-l` option except that output is printed in a condensed format.
 - `-m pmspecific` *pmspecific* is the port monitor-specific portion of the port monitor administrative file entry for the service.
 - `-p pmtag` Specifies the tag associated with the port monitor through which a service (specified as `-s svctag`) is available.
 - `-r` Remove a service. When `pmadm` removes a service, the entry for the service is removed from the port monitor's administrative file.
 - `-s svctag` Specifies the service tag associated with a given service. The service tag is assigned by the system administrator and is part of the entry for the service in the port monitor's administrative file.
 - `-t type` Specifies the port monitor type.
 - `-v ver` Specifies the version number of the port monitor administrative file. The version number may be given as
`-v 'pmspec -V`
 where *pmspec* is the special administrative command for port monitor *pmtag*. This special command is `ttysadm` for `ttymon` and `nlsadmin` for `listen`. The version stamp of the port monitor is known by the command and is returned when *pmspec* is invoked with a `-V` option.
 - `-y comment` Associate *comment* with the service entry in the port monitor administrative file.
 - `-z script` Used with the `-g` option to specify the name of the file that contains the per-service configuration script. Modifying a configuration script is a three-step procedure. First a copy of the existing script is made (`-g` alone). Then the copy is edited. Finally, the copy is put in place over the existing script (`-g` with `-z`).

Options that request information write the requested information to the standard output. A request for information using the `-l` option prints column headers and aligns the information under the appropriate headings. In this format, a missing field is indicated by a hyphen. A request for information in the condensed format using the `-L` option prints the information in colon-separated fields; missing fields are indicated by two successive colons. `#` is the comment character.

Examples EXAMPLE 1 Adding a Service to a Port Monitor with the Tag pmtag

The following command adds a service to a port monitor with tag pmtag and gives the service the tag svctag. The port monitor-specific information is generated by specpm. The service defined by svctag will be invoked with identity root.

```
pmadm -a -p pmtag -s svctag -i root -m 'specpm -a arg1 -b arg2' -v 'specpm -V'
```

EXAMPLE 2 Adding a Service with Service Tab svctag

The following command adds a service with service tag svctag, identity guest, and port monitor-specific information generated by specpm to all port monitors of type type:

```
pmadm -a -s svctag -i guest -t type -m 'specpm -a arg1 -b arg2' -v 'specpm -V'
```

EXAMPLE 3 Removing a Service

The following command removes the service svctag from port monitor pmtag:

```
pmadm -r -p pmtag -s svctag
```

EXAMPLE 4 Enabling a Service

The following command enables the service svctag available through port monitor pmtag:

```
pmadm -e -p pmtag -s svctag
```

EXAMPLE 5 Disabling a Service

The following command disables the service svctag available through port monitor pmtag:

```
pmadm -d -p pmtag -s svctag
```

EXAMPLE 6 Listing Status Information

The following command lists status information for all services:

```
pmadm -l
```

EXAMPLE 7 Listing Status Information

The following command lists status information for all services available through the port monitor with tag ports:

```
pmadm -l -p ports
```

EXAMPLE 8 Listing Status Information in Condensed Format

The following command lists the status information for all services available through the port monitor with tag ports in condensed format:

```
pmadm -L -p ports
```

EXAMPLE 9 Listing Status Information for All Services

List status information for all services available through port monitors of type `listen`:

```
pmdm -l -t listen
```

EXAMPLE 10 Printing the per-service Configuration

The following command prints the per-service configuration script associated with the service `svctag` available through port monitor `pmtag`:

```
pmdm -g -p pmtag -s svctag
```

Exit Status The following exit values are returned:

0 Successful operation.

>0 Operation failed.

Files `/etc/saf/pmtag/_config`

`/etc/saf/pmtag/svctag`

`/var/saf/pmtag/*`

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| Availability | SUNWcs |

See Also [sac\(1M\)](#), [sacadm\(1M\)](#), [doconfig\(3NSL\)](#), [attributes\(5\)](#)

Name pmconfig – Configure the Power Management system

Synopsis /usr/sbin/pmconfig [-r]

Description The `pmconfig` utility sets the Power Management and suspend-resume configuration. User has permission to change Power Management configuration using `pmconfig` only if he is allowed to do so according to `PMCHANGEPERM` keyword of `/etc/default/power`. User has permission to change the suspend-resume configuration using `pmconfig` only if he is allowed to do so according to the `CPRCHANGEPERM` keyword of `/etc/default/power`. See `FILES` section below for a description of the `PMCHANGEPERM` and `CPRCHANGEPERM` keywords of `/etc/default/power`.

Based on user permissions, `pmconfig` first resets the Power Management and/or suspend-resume state back to its default and then reads the new Power Management and/or suspend-resume configuration from `/etc/power.conf` and issues the commands to activate the new configuration. The `pmconfig` utility is run at system boot. This utility can also be run from the command line after manual changes have been made to the `/etc/power.conf` file. For editing changes made to the `/etc/power.conf` file to take effect, users must run `pmconfig`.

The preferred interface for changing Power Management and suspend-resume configuration is `dtpower(1M)`.

Options The following options are supported:

-r Reset Power Management and suspend-resume state to default and exit. User must have both Power Management and suspend-resume configuration permission for this option.

Exit Status The following exit values are returned:

0 Upon successful completion
>0 An error occurred

Files `/etc/power.conf` System Power Management configuration file
`/etc/default/power` File that controls permissions for system's Power Management and suspend-resume features. The `PMCHANGEPERM` keyword controls the Power Management configuration permissions, while the `CPRCHANGEPERM` keyword controls the suspend-resume configuration permissions.

Allowed values are:

all Any user can change the configuration.
- No one except super-user can change the configuration.

- <user1, user2, ...> A user in this user list or a super-user can change the configuration. The user list is a space and/or comma (,) separated list. You must enclose the list in < and > characters.
- console-owner A user who owns the system console device node or a super-user can change the configuration.

The default values are PMCHANGEPERM=console-owner and CPRCHANGEPERM=console-owner.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|---------------------|
| Availability | system/kernel/power |
| Interface stability | Uncommitted |

See Also [svcs\(1\)](#), [powerd\(1M\)](#), [power.conf\(4\)](#), [svcadm\(1M\)](#), [attributes\(5\)](#), [smf\(5\)](#), [cpr\(7\)](#), [pm\(7D\)](#)

Using Power Management

Notes The pmconfig service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/power:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Diagnostics If the program cannot open the configuration file, it prints an error message to standard error. If the program encounters a syntax error in the configuration file, it prints an error message and the line number of the error in the configuration file. It then skips the rest of the information on that line and processes the next line. Any configuration information already processed on the line containing the error is used. If user does not have permission to change Power Management and/or suspend-resume configuration, and configuration file has entries for which user doesn't have permission, it process the entries for which user has permissions and prints error on rest.

Name pntadm – DHCP network table management utility

Synopsis pntadm -C [-r *resource*] [-p *path*] [-u *uninterpreted*] *network*

```
pntadm -A name_IP_address [-c comment] [-e mm/dd/yyyy]
[-f num | keywords] [-h client_hostname]
[-i [-a] client_ID] [-m [-y] macro] [-s server]
[-r resource] [-p path] [-u uninterpreted] network
```

```
pntadm -M name_IP_address [-c comment] [-e mm/dd/yyyy]
[-f num | keywords] [-h client_hostname]
[-i [-a] client ID] [-m [-y] macro]
[-n new_client_IP_address] [-s server] [-r resource]
[-p path] [-u uninterpreted] network
```

```
pntadm -D name_IP_address [-y] [-r resource] [-p path]
[-u uninterpreted] network
```

```
pntadm -P [-v] [-x] [-r resource] [-p path]
[-u uninterpreted] network
```

```
pntadm -R [-r resource] [-p path] [-u uninterpreted] network
```

```
pntadm -L [-r resource] [-p path] [-u uninterpreted]
```

```
pntadm -B [-v] [batchfile]
```

Description The pntadm command is used to manage the Dynamic Host Configuration Protocol (DHCP) network tables. It is used to add and remove networks under DHCP management, and add, delete, or modify IP address records within network tables, or to view tables. For a description of the format of DHCP network tables, see [dhcp_network\(4\)](#).

pntadm can be run as root or by other users assigned to the DHCP Management profile. See [rbac\(5\)](#) and [user_attr\(4\)](#).

If the networks you want to add are subnetted, you need to update the [netmasks\(4\)](#) table.

One of the following options (function flags) must be specified with the pntadm command: -A, -B, -C, -D, -L, -M, -P, or -R.

Options The following options are supported:

-A *name_IP_address*

Add a client entry with hostname or client IP address, *name_IP_address*, to the named DHCP network table.

The following sub-options are optional:

-c *comment*

Comment text. The default is NULL.

-e *mm/dd/yyyy*

Absolute lease. The default is 0.

-f *num* | *keywords*
 Flag value. The default is 00.

The flag (-f) option can be specified either as a single number denoting the intended flag value, or as a series of the following keywords, combined using the plus (+) symbol:

DYNAMIC or 00
 Server manager's assignment.

PERMANENT or 01
 Lease on entry is permanent.

MANUAL or 02
 Administrator managed assignment.

UNUSABLE or 04
 Entry is not valid.

BOOTP or 08
 Entry reserved for BOOTP clients.

For a more detailed description of the flag values, see [dhcp_network\(4\)](#).

-h *client_hostname*
 Client hostname. The default is NULL.

When the -h option is used in this mode, the *client_hostname* is added to the hosts table within the resource used for storing host names (files or DNS). The command will fail if this *client_hostname* is already present in the hosts table.

-i *client_ID* [-a]
 Client identifier [-a]. The default is 00.

The -i option modified with -a specifies that the client identifier is in ASCII format, and thus needs to be converted to hexadecimal format before insertion into the table.

-m *macro* [-y]
 Macro name. Default is UNKNOWN.

The -m option modified with -y verifies the existence of the named macro in the dhcpstab table before adding the entry.

-s *server*
 Server IP or name. Default is system name (uname -n).

-B
 Activate batch mode. pntadm will read from the specified file or from standard input a series of pntadm commands and execute them within the same process. Processing many pntadm commands using this method is much faster than running an executable batchfile itself. Batch mode is recommended for using pntadm in scripts.

The following sub-option is optional:

-v
Display commands to standard output as they are processed.

-C
Create the DHCP network table for the network specified by *network*. See [Operands](#). For details, see [dhcp_network\(4\)](#) and [networks\(4\)](#).

-D *name_IP_address*
Delete the specified client entry with hostname or client IP address, *name_IP_address*, in the named DHCP network table. (See [dhcp_network\(4\)](#).)

The following sub-option is optional:

-y
Remove associated host table entry. The -y option requests that all hostnames associated with the IP address in the hosts table in the resource be removed.

-L
List the DHCP network tables presently configured, one per line, on standard output. If none are found, no output is printed and an exit status of 0 is returned.

-M *name_IP_address*
Modify the specified client entry with hostname or client IP address, *name_IP_address*, in the named DHCP network table. See [dhcp_network\(4\)](#). The default for the sub-options is what they currently are set to.

The following sub-options are optional.

-c *comment*
New comment text.

-e *mm/dd/yy*
New absolute lease expiration date. Time defaults to 12:00 AM of the day specified.

-f *num | keyboard*
New flag value, see explanation following the description of the -A option.

-h *host_name*
New client hostname.

The -h option allows you to change the current *hostname* associated with the IP address or to add a new *hostname* to the hosts table if an entry associated with this IP address does not exist.

-i *client_ID*
New client identifier [-a].

-m *macro* [-y]
Macro name defined in `dhcptab`.

-n *new_client_IP_address*

New IP address.

-s *server*

New server IP or name.

For more detailed description of the sub-options and flag values, see [dhcp_network\(4\)](#).

-P

Display the named DHCP network table.

The following sub-options are optional:

-v

Display lease time in full verbose format and resolve IP addresses for the clients and server to hostnames.

-x

Display lease time in raw format.

These flag codes are used with the -P sub-options:

| -v | -x | Description |
|----|----|-------------|
| D | 00 | DYNAMIC |
| P | 01 | PERMANENT |
| M | 02 | MANUAL |
| U | 04 | UNUSABLE |
| B | 08 | BOOTP |

See [dhcp_network\(4\)](#) for information on these sub-options and associated flag codes.

-p *path*

Override the [dhcpcsvc.conf\(4\)](#) configuration value for data store resource path, *path* See [dhcpcsvc.conf\(4\)](#)

-R

Remove the named DHCP network table. See [dhcp_network\(4\)](#).

-r *data_store_resource*

Override the `/etc/inet/dhcpcsvc.conf` configuration value for RESOURCE= with the *data_store_resource* specified. See the [dhcpcsvc.conf\(4\)](#) man page for more details on resource type, and the *Oracle Solaris DHCP Service Developer's Guide* for more information about adding support for other data stores.

-u uninterpreted

Data which will be ignored by pntadm, but passed to the currently configured public module to be interpreted by the data store. This might be used for a database account name or other authentication or authorization parameters required by a particular data store.

Operands The following operand is supported:

network

The network address or network name which corresponds to the dhcp network table. See [dhcp_network\(4\)](#).

Examples **EXAMPLE 1** Creating a Table for the 10.0.0.0 DHCP Network

The following command creates a table for the 10.0.0.0 (subnetted to class C) DHCP network table. Note that if you have an alias for this network in your [networks\(4\)](#) table, you can use that value rather than the dotted Internet Address notation.

```
example# pntadm -C 10.0.0.0
```

EXAMPLE 2 Adding an Entry to the 10.0.0.0 Table

The following command adds an entry to the 10.0.0.0 table in the files resource in the /var/mydhcp directory:

```
example# pntadm -r SUNWfiles -p /var/mydhcp -A 10.0.0.1 10.0.0.0
```

EXAMPLE 3 Modifying the 10.0.0.1 Entry of the 10.0.0.0 Table

The following command modifies the 10.0.0.1 entry of the 10.0.0.0 table, changing the macro name to Green, setting the flags field to MANUAL and PERMANENT:

```
example# pntadm -M 10.0.0.1 -m Green -f 'PERMANENT+MANUAL' 10.0.0.0
```

EXAMPLE 4 Changing the 10.0.0.1 Entry to 10.0.0.2

The following command changes the 10.0.0.1 entry to 10.0.0.2, making an entry in the [hosts\(4\)](#) table called myclient:

```
example# pntadm -M 10.0.0.1 -n 10.0.0.2 -h myclient 10.0.0.0
```

EXAMPLE 5 Setting the Client ID as ASCII

The following command sets the client ID as ASCII aruba.foo.com for the myclient entry:

```
example# pntadm -M myclient -i 'aruba.foo.com' -a 10.0.0.0
```

EXAMPLE 6 Deleting the myclientEntry from the 10.0.0.0 Table

The following command deletes the myclient (10.0.0.2) entry from the 10.0.0.0 table:

```
example# pntadm -D myclient 10.0.0.0
```

EXAMPLE 7 Listing the Configured DHCP Network Tables

The following command lists the configured DHCP network tables:

```
example# pntadm -L
192.168.0.0
10.0.0.0
```

EXAMPLE 8 Executing pntadm Commands in Batch Mode

The following command runs a series of pntadm commands contained in a batch file:

```
example# pntadm -B addclients
```

Exit Status 0 Successful completion.

1 Object already exists.

2 Object does not exist.

3 Non-critical error.

4 Critical error.

Files

- /etc/inet/dhcpsvc.conf
- /etc/inet/hosts

Name polkit-is-privileged – check PolicyKit privileges

Synopsis `polkit-is-privileged [-hvV] -u user -p privilege [-r resource]`

Description The `polkit-is-privileged` command queries system policy to determine whether a user is allowed for a given privilege and resource. The resource name can be omitted. On the Solaris operating system, RBAC authorization names should be used as privilege names.

Currently, the only consumer of PolicyKit is [hald\(1M\)](#).

Options The following options are supported:

| | |
|----------------------------------------------------------------|---------------------------------------------------------------------------------------|
| <code>-h, --help</code> | Display list of options and exit. |
| <code>-p <i>privilege</i>, --privilege <i>privilege</i></code> | Name of privilege associated with user. Command tests for this privilege. |
| <code>-r <i>resource</i>, --resource <i>resource</i></code> | Name of resource associated with user and privilege. Command tests for this resource. |
| <code>-u <i>user</i>, --user <i>user</i></code> | User name or user id that is tested for. |
| <code>-v, --verbose</code> | Verbose mode. |
| <code>-V, --version</code> | Displays version number. |

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | service/hal |
| Interface Stability | Volatile |

See Also [auths\(1\)](#), [profiles\(1\)](#), [hald\(1M\)](#), [getauthattr\(3SECDB\)](#), [auth_attr\(4\)](#), [policy.conf\(4\)](#), [prof_attr\(4\)](#), [user_attr\(4\)](#), [attributes\(5\)](#)

Name pooladm – activate and deactivate the resource pools facility

Synopsis /usr/sbin/pooladm [-n] [-s] [-c] [*filename*] | -x
/usr/sbin/pooladm [-d | -e]

Description The pooladm command provides administrative operations on pools and sets. pooladm reads the specified filename and attempts to activate the pool configuration contained in it.

Before updating the current pool run-time configuration, pooladm validates the configuration for correctness.

Without options, pooladm prints out the current running pools configuration.

Options The following options are supported:

-c Instantiate the configuration at the given location. If a filename is not specified, it defaults to /etc/pooladm.conf.

-d Disable the pools facility so that pools can no longer be manipulated.

-e Enable the pools facility so that pools can be manipulated.

-n Validate the configuration without actually updating the current active configuration. Checks that there are no syntactic errors and that the configuration can be instantiated on the current system. No validation of application specific properties is performed.

-s Update the specified location with the details of the current dynamic configuration.

This option requires update permission for the configuration that you are going to update. If you use this option with the -c option, the dynamic configuration is updated before the static location.

-x Remove the currently active pool configuration. Destroy all defined resources, and return all formerly partitioned components to their default resources.

Operands The following operands are supported:

filename Use the configuration contained within this file.

Examples EXAMPLE 1 Instantiating a Configuration

The following command instantiates the configuration contained at /home/admin/newconfig:

```
example# /usr/sbin/pooladm -c /home/admin/newconfig
```

EXAMPLE 2 Validating the Configuration Without Instantiating It

The following command attempts to instantiate the configuration contained at /home/admin/newconfig. It displays any error conditions that it encounters, but does not actually modify the active configuration.

EXAMPLE 2 Validating the Configuration Without Instantiating It (Continued)

```
example# /usr/sbin/pooladm -n -c /home/admin/newconfig
```

EXAMPLE 3 Removing the Current Configuration

The following command removes the current pool configuration:

```
example# /usr/sbin/pooladm -x
```

EXAMPLE 4 Enabling the Pools Facility

The following command enables the pool facility:

```
example# /usr/sbin/pooladm -e
```

EXAMPLE 5 Enabling the Pools Facility Using SMF

The following command enables the pool facility through use of the Service Management Facility. See [smf\(5\)](#).

```
example# /usr/sbin/svcadm enable svc:/system/pools:default
```

EXAMPLE 6 Saving the Active Configuration to a Specified Location

The following command saves the active configuration to `/tmp/state.backup`:

```
example# /usr/sbin/pooladm -s /tmp/state.backup
```

Files `/etc/pooladm.conf` Configuration file for `pooladm`.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------------|
| Availability | service/resource-pools |
| Interface Stability | See below. |

The invocation is Committed. The output is Uncommitted.

See Also [poolcfg\(1M\)](#), [poolbind\(1M\)](#), [psrset\(1M\)](#), [svcadm\(1M\)](#), [pset_destroy\(2\)](#), [libpool\(3LIB\)](#), [attributes\(5\)](#), [smf\(5\)](#)

System Administration Guide: Oracle Solaris Zones, Oracle Solaris 10 Containers, and Resource Management

Notes Resource bindings that are not presented in the form of a binding to a partitionable resource, such as the scheduling class, are not necessarily modified in a `pooladm -x` operation.

The pools facility is not active by default when Solaris starts. `pooladm -e` explicitly activates the pools facility. The behavior of certain APIs related to processor partitioning and process binding are modified when pools is active. See [libpool\(3LIB\)](#).

You cannot enable the pools facility on a system where processor sets have been created. Use the [psrset\(1M\)](#) command or [pset_destroy\(2\)](#) to destroy processor sets manually before you enable the pools facility.

Because the Resource Pools facility is an [smf\(5\)](#) service, it can also be enabled and disabled using the standard SMF interfaces.

Name poolbind – bind processes, tasks, or projects or query binding of processes to resource pools

Synopsis /usr/sbin/poolbind -p *poolname* -e *command* [*arguments*]...

/usr/sbin/poolbind -p *poolname* [-i *idtype*] *id*...

/usr/sbin/poolbind -q *pid*...

/usr/sbin/poolbind -Q *pid*...

Description The `poolbind` command allows an authorized user to bind zones, projects, tasks, and processes to pools. With the `-e` option (see below), it can execute a command you specify, placing the executed command in a specified pool. It can also enable you to query a process to determine which pool a process is bound to.

Options The following options are supported:

- e *command* [*arguments*...] Executes *command*, bound to the pool you specify with `-p`.
- i *idtype* This option, together with the *idlist* arguments, specifies one or more processes to which the `poolbind` command is to apply. The interpretation of *idlist* depends on the value of *idtype*. The valid *idtype* arguments and corresponding interpretations of *idlist* are as follows:
 - pid* *idlist* is a list of process IDs. Binds the specified processes to the specified pool. This is the default behavior if no *idtype* is specified.
 - taskid* *idlist* is a list of task IDs. Bind all processes within the list of task IDs to the specified pool.
 - projid* *idlist* is a list of project IDs. Bind all processes within the list of projects to the specified pool. Each project ID can be specified as either a project name or a numerical project ID. See [project\(4\)](#).
 - zoneid* *idlist* is a list of zone IDs. Bind all processes within the list of zones to the specified pool. Each zone ID can be specified as either a zone name or a numerical zone ID. See [zones\(5\)](#).
- p *poolname* Specifies the name of a pool to which the specified zone, project, tasks, or processes are to be bound.
- q *pid* ... Queries the pool bindings for a given list of process IDs. If the collection of resources associated with the process does not correspond to any currently existing pool, or if there are multiple pools with the set of resources that the process is bound to, the query fails for that particular process ID.

`-Q pid ...` Queries the resource bindings for a given list of process IDs. The resource bindings are each reported on a separate line.

Examples EXAMPLE 1 Binding All Processes

The following command binds all processes in projects 5 and 7 to the pool `web_app`:

```
example# /usr/sbin/poolbind -p web_app -i projid 5 7
```

EXAMPLE 2 Binding the Running Shell

The following command binds the running shell to the pool `web_app`:

```
example# /usr/sbin/poolbind -p web_app $$
```

EXAMPLE 3 Querying the Pool Bindings

The following command queries the bindings to verify that the shell is bound to the given pool:

```
example# /usr/sbin/poolbind -q $$
```

EXAMPLE 4 Querying the Resource Bindings

The following command queries the bindings to verify that the shell is bound to the given resources:

```
example# /usr/sbin/poolbind -Q $$
```

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 Requested operation could not be completed.
- 2 Invalid command line options were specified.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------------|
| Availability | service/resource-pools |
| Interface Stability | See below. |

The invocation is Committed. The output is Uncommitted.

See Also [pooladm\(1M\)](#), [poolcfg\(1M\)](#), [libpool\(3LIB\)](#), [project\(4\)](#), [attributes\(5\)](#), [zones\(5\)](#)

System Administration Guide: Oracle Solaris Zones, Oracle Solaris 10 Containers, and Resource Management

-
- Name** poolcfg – create and modify resource pool configuration files
- Synopsis** /usr/sbin/poolcfg -c *command* [-d | [*filename*]]
 /usr/sbin/poolcfg -f *command_file* [-d | [*filename*]]
 /usr/sbin/poolcfg -h
- Description** The poolcfg utility provides configuration operations on pools and sets. These operations are performed upon an existing configuration and take the form of modifications to the specified configuration file. If you use the -d option, the modifications occur to the kernel state. Actual activation of the resulting configuration is achieved by way of the pooladm(1M) utility.
- Pools configuration files are structured files that must have been constructed using poolcfg itself or libpool(3LIB) directly.
- An invocation of poolcfg with the pool dynamic location and write permission will hang if the dynamic location has already been opened for writing.
- The configurations which are created by this utility can be used by pooladm to instantiate the configuration upon a target host.
- Options** The following options are supported:
- c *command* Specify *command* as an editing command. See USAGE.
 - d Operate directly on the kernel state. No *filename* is allowed.
 - f *command_file* Take the commands from *command_file*. *command_file* consists of editing commands, one per line.
 - h Display extended information about the syntax of editing commands.
- Usage**
- Scripts A script consists of editing commands, one per line, of the following:
- info [*entity-name*]
 Display configuration (or specified portion) in human readable form to standard output. If no entity is specified, system information is displayed. Therefore, poolcfg -c 'info' afile is an equivalent invocation to poolcfg -c 'info system name' afile.
 - create *entity-name* [*property-list*]
 Make an entity of the specified type and name.
 - destroy *entity-name*
 Remove the specified entity.
 - modify *entity-name* [*property-list*]
 Change the listed properties on the named entity.
 - associate *pool-name* [*resource-list*]
 Connect one or more resources to a pool, or replace one or more existing connections.

transfer to [*resourcetype*] *name*[*component-list*]

Transfer one or more discrete components to a resource .

transfer [*quantity*] from [*resourcetype*] [*src*] to [*tgt*]

Transfer a resource quantity from *src* to *tgt*.

transfer [*quantity*] to [*resourcetype*] [*tgt*] from [*src*]

Transfer a resource quantity to *tgt* from *src*.

discover

Create a system entity, with one pool entity and resources to match current system configuration. All discovered resources of each resource type are recorded in the file, with the single pool referring to the default resource for each resource type.

This command is a NO-OP when `poolcfg` operates directly on the kernel. See the `-d` option.

You should avoid use of this command. The preferred method for creating a configuration is to export the dynamic configuration using `pooladm(1M)` with the `-s` option.

rename *entity-name* to *new-name*

Change the name of an entity on the system to its new name.

Property Lists The property list is specified by:

```
( proptype name = value [ ; proptype name = value ]* )
```

where the last definition in the sequence for a given proptype, name pair is the one that holds. For property deletion, use `~ proptype name`.

Resource Lists A resource list is specified by:

```
( resourcetype name [ ; resourcetype name ]* )
```

where the last specification in the sequence for a resource is the one that holds. There is no deletion syntax for resource lists.

Component Lists A component list is specified by:

```
( componenttype name [ ; componenttype name ]* )
```

where the last specification in the sequence for a component is the one that holds. There is no deletion syntax for component lists.

| | | |
|---------------------|--------|-------------------------------------------|
| Recognized Entities | system | Machine level entity |
| | pool | Named collection of resource associations |
| Resource Types | pset | Processor set resource |

| | | |
|----------------|---------|-------------------------------------------------------------------------------------------------------------------------|
| Property Types | boolean | Takes one of two values true or false. |
| | int | A 64-bit signed integer value. |
| | uint | A 64-bit unsigned integer value. |
| | string | Strings are delimited by quotes ("), and support the character escape sequences defined in formats(5) . |
| | float | Scientific notation is not supported. |

Examples EXAMPLE 1 Writing a poolcfg Script

The following `poolcfg` script creates a pool named `Accounting`, and a processor set, `small-1`. The processor set is created first, then the pool is created and associated with the set.

```
create pset small-1 ( uint pset.min = 1 ; uint pset.max = 4 )
create pool Accounting
associate pool Accounting ( pset small-1 )
```

EXAMPLE 2 Reporting on `pool_0`

The following command reports on `pool_0` to standard output in human readable form:

```
# poolcfg -c 'info pool pool_0' /etc/pooladm.conf
```

EXAMPLE 3 Destroying `pool_0` and Its Associations

The following command destroys `pool_0` and associations, but not the formerly associated resources:

```
# poolcfg -c 'destroy pool pool_0' /etc/pooladm.conf
```

EXAMPLE 4 Displaying the Current Configuration

The following command displays the current configuration:

```
$ poolcfg -c 'info' /etc/pooladm.conf
system example_system
    int system.version 1
    boolean system.bind-default true
    string system.comment Discovered by libpool

    pool pool_default
        boolean pool.default true
        boolean pool.active true
        int pool.importance 5
        string pool.comment
        string.pool.scheduler FSS
        pset pset_default

    pset pset_default
```

EXAMPLE 4 Displaying the Current Configuration *(Continued)*

```

int pset.sys_id -1
string pset.units population
boolean pset.default true
uint pset.max 4294967295
uint pset.min 1
string pset.comment
boolean pset.escapable false
uint pset.load 0
uint pset.size 2

cpu
  int cpu.sys_id 0
  string cpu.comment

cpu
  int cpu.sys_id 2
  string cpu.comment

```

EXAMPLE 5 Moving cpu with ID 2 to Processor Set pset1 in the Kernel

The following command moves cpu with ID 2 to processor set pset1 in the kernel:

```
# poolcfg -dc 'transfer to pset pset1 ( cpu 2 )'
```

EXAMPLE 6 Moving 2 cpus from Processor Set pset1 to Processor Set pset2 in the Kernel

The following command moves 2 cpus from processor set pset1 to processor set pset2 in the kernel:

```
# poolcfg -dc 'transfer 2 from pset pset1 to pset2'
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------------|
| Availability | service/resource-pools |
| Interface Stability | See below. |

The invocation is Committed. The output is Uncommitted.

See Also [pooladm\(1M\)](#), [poolbind\(1M\)](#), [libpool\(3LIB\)](#), [attributes\(5\)](#), [formats\(5\)](#)

System Administration Guide: Oracle Solaris Zones, Oracle Solaris 10 Containers, and Resource Management

Name poold – automated resource pools partitioning daemon

Synopsis poold [-l *level*]

Description poold provides automated resource partitioning facilities. poold can be enabled or disabled using the Solaris Service Management Facility, [smf\(5\)](#). poold requires the Resource Pools facility to be active in order to operate.

The dynamic resource pools service's fault management resource identifier (FMRI) is:

```
svc:/system/pools/dynamic
```

The resource pools service's FMRI is:

```
svc:/system/pools
```

poold's configuration details are held in a [libpool\(3LIB\)](#) configuration and you can access all customizable behavior from this configuration.

poold periodically examines the load on the system and decides whether intervention is required to maintain optimal system performance with respect to resource consumption. poold also responds to externally initiated (with respect to poold) changes of either resource configuration or objectives.

If intervention is required, poold attempts to reallocate the available resources to ensure that performance objectives are satisfied. If it is not possible for poold to meet performance objectives with the available resources, then a message is written to the log. poold allocates scarce resources according to the objectives configured by the administrator. The system administrator must determine which resource pools are most deserving of scarce resource and indicate this through the importance of resource pools and objectives.

Options The following options are supported:

-l *level* Specify the verbosity level for logging information.

Specify *level* as ALERT, CRIT, ERR, WARNING, NOTICE, INFO, and DEBUG. If *level* is not supplied, then the default logging level is INFO.

ALERT A condition that should be corrected immediately, such as a corrupted system database.

CRIT Critical conditions, such as hard device errors.

ERR Errors.

WARNING Warning messages.

NOTICE Conditions that are not error conditions, but that may require special handling.

INFO Informational messages.

DEBUG Messages that contain information normally of use only when debugging a program.

When invoked manually, with the `-l` option, all log output is directed to standard error.

Examples **EXAMPLE 1** Modifying the Default Logging Level

The following command modifies the default logging level to ERR:

```
# /usr/lib/pool/poold -l ERR
```

EXAMPLE 2 Enabling Dynamic Resource Pools

The following command enables dynamic resource pools:

```
# /usr/sbin/svcadm enable svc:/system/pools/dynamic
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------------|
| Availability | service/resource-pools |
| Interface Stability | See below. |

The invocation is Committed. The output is Uncommitted.

See Also [pooladm\(1M\)](#), [poolbind\(1M\)](#), [poolcfg\(1M\)](#), [poolstat\(1M\)](#), [svcadm\(1M\)](#), [pool_set_status\(3POOL\)](#), [libpool\(3LIB\)](#), [attributes\(5\)](#), [smf\(5\)](#)

System Administration Guide: Oracle Solaris Zones, Oracle Solaris 10 Containers, and Resource Management

Name poolstat – report active pool statistics

Synopsis poolstat [-p *pool-list*] [-r *rset-list*] [-T u | d] [*interval* [*count*]]
 poolstat [-p *pool-list*] [-o *format* -r *rset-list*]
 [-T u | d] [*interval* [*count*]]

Description The poolstat utility iteratively examines all active pools on the system. It reports statistics based on the selected output mode. poolstat provides options to examine only specified pools and report resource set-specific statistics.

Without options, poolstat examines all pools, reports basic statistics for their resource sets, and exits.

DISPLAY FORMATS In default output format, poolstat outputs a header line and a line for each pool. The line begins with the pool ID and its name, followed by a column of statistical data for the processor set attached to the pool.

The columns are defined as follows:

| | |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| id | Pool ID. |
| pool | Pool name. |
| rid | Resource set id. |
| rset | Resource set name. |
| type | Resource set type. |
| min | Minimum resource set size. |
| max | Maximum resource set size. |
| size | Current resource set size. |
| used | The measure of how much of the resource set is currently in use. This is calculated as the percentage utilization of the resource set multiplied by its size. If resource set has been reconfigured during last sampling interval, this value might be not reported (-). |
| load | The absolute representation of the load that is put on the resource set. For the definition of this property see libpool(3LIB) . |

Options The following options are supported:

-o *format* Report statistics according to the format specification given in format. See DISPLAY FORMATS.

The -o option accepts lists as arguments. Items in a list can be either separated by commas or enclosed in quotes and separated by commas or spaces.

You can specify multiple -o options. The format specification is interpreted as the whitespace separated concatenation of all the format option arguments.

- The `-o` option must be used in conjunction with the `-r` option.
- `-p pool-list` Report only pools whose names are in the given list. If the `-r` option is also used, this option selects only resource sets which belong to pools in the given list. Statistics for pools or resource sets are reported in the same order in which pool names are listed on the `pool-list`. Pool can be specified by name or by ID.
- The `-p` option accepts lists as arguments. Items in a `pool-list` can only be separated by spaces.
- `-r rset-list` Report resource set statistics. If the `rset-list` argument is “all”, then all possible resource set types are selected.
- The `-r` option accepts lists as arguments. Items in a list can be either separated by commas or enclosed in quotes and separated by commas or spaces.
- The following resource set types are supported:
- | | |
|------|------------------------|
| all | All resource set types |
| pset | Processor set |
- `-T u | d` Display a time stamp.
- Specify `u` for a printed representation of the internal representation of time. See [time\(2\)](#). Specify `d` for standard date format. See [date\(1\)](#).

Operands The following operands are supported:

- `count` The number of times that the statistics are repeated. By default, `poolstat` reports statistics only once.
- If neither interval nor count are specified, statistics are reported once. If interval is specified and count is not, statistics are reported indefinitely.
- `interval` The sampling interval in seconds.
- If neither interval nor count are specified, statistics are reported once. If interval is specified and count is not, statistics are reported indefinitely.

Examples EXAMPLE 1 Using `poolstat`

The following example shows the default output from the `poolstat` utility:

```
% poolstat
           pset
id pool      size used load
0 pool_default 4 3.6 6.2
1 pool_admin  4 3.3 8.4
```

EXAMPLE 2 Reporting Resource Set Statistics

The following example reports resource set statistics.

```
% poolstat -r pset
id pool          type rid rset          min max size used load
0 pool_default  pset  -1 pset_default    1 65K  2 1.2 8.3
1 pool_admin    pset   1 pset_admin      1   1  1 0.4 5.2
2 pool_other     pset  -1 pset_default    1 65K  2 1.2 8.3
```

Resource sets attached to multiple pools, as `pset_default` in the example above, are listed multiple times, once for each pool.

EXAMPLE 3 Restricting the Output to the List of Pools

The following example restricts the output to the list of pools

```
% poolstat -p pool_default
           pset
id pool          size used load
0 pool_default   8 5.3 10.3

% poolstat -p 'pool_admin pool_default'
           pset
id pool          size used load
1 pool_admin     6 4.3 5.3
0 pool_default   2 1.9 2.0

% poolstat -r all -p 'pool_admin pool_default'
id pool          type rid rset          min max size used load
1 pool_admin    pset   1 pset_admin      1   1  1 0.9 2.3
2 pool_default  pset  -1 pset_default    1 65K  2 2.0 2.0
```

EXAMPLE 4 Customizing Output

The following example customizes output:

```
% poolstat -r -o pool,rset,size,load
pool          rset          size load
pool_default  pset_default    4 4.5
pool_admin    pset_admin      4 2.1
```

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.
- 2 Invalid command line options were specified.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|------------------------|
| Availability | service/resource-pools |
| Interface Stability | Committed |

See Also [libpool\(3LIB\)](#), [attributes\(5\)](#)

System Administration Guide: Oracle Solaris Zones, Oracle Solaris 10 Containers, and Resource Management

Notes The system ids associated with resources can change after the system reboots or the resource configuration is altered.

Name ports – creates /dev entries and inittab entries for serial lines

Synopsis /usr/sbin/ports [-r *rootdir*]

Description [devfsadm\(1M\)](#) is now the preferred command for /dev and /devices and should be used instead of ports.

The ports command creates symbolic links in the /dev/term and /dev/cua directories to the serial-port character device files in /devices and adds new entries in /etc/inittab for non-system ports found. System-board ports are given single lower-case letters for names (such as a and b) while other ports are named numerically.

ports searches the kernel device tree to find the serial devices attached to the system. It also checks /dev/term and /dev/cua to see what symbolic links to serial devices already exist. ports then performs the following:

1. Assigns new numbers (or letters for system-board ports) to ports that are attached to the system but do not have /dev/term and /dev/cua entries. The numbers or letters assigned are the lowest-unused numbers or letters.
2. Removes dangling links: links from /dev/term and /dev/cua pointing to no-longer-existing ports.
3. Creates new /dev/term and /dev/cua links for new serial devices.
4. Invokes [sacadm\(1M\)](#) to make new port monitor entries for the new devices. This is not done automatically for on-board ports; on workstations these ports are often not used for dial-in sessions, so a port-monitor for one of these ports must be created explicitly.

If the configuration has not changed, ports exits without doing anything.

Notice to Driver Writers ports considers devices with a node type of DDI_NT_SERIAL, DDI_NT_SERIAL_MB, DDI_NT_SERIAL_DO, or DDI_NT_SERIAL_MB_DO to be serial port devices. Devices with one of these node types must create minor device names that obey the following conventions when calling [ddi_create_minor_node\(9F\)](#).

- The minor name for non-system port devices (DDI_NT_SERIAL) consists of an ASCII numeric string, where the first port on the device is named 0, the second named 1, the third named 2, up to the number of ports provided by the device.
- The minor name for non-system dialout devices (DDI_NT_SERIAL_DO) is the ASCII numeric port name, concatenated with ,cu. For example, the minor name for the first dialout port on the serial board is 0,cu.
- The minor name for system-board port devices (DDI_NT_SERIAL_MB) consists of a string containing a single ASCII lowercase character, where the first port on the device is named a, the second is named b, the third is named c, for all ports on the device (or up through port z).
- The minor name for system-board dialout devices (DDI_NT_SERIAL_MB_DO) consists of the lowercase character port name, concatenated with ,cu. For example, the minor name for the first dialout port on the on-board serial device is a,cu.

To prevent disks from attempting to automatically generate links for a device, drivers must specify a private node type and refrain from using one of the above node types when calling `ddi_create_minor_node(9F)`.

Options The following options are supported:

`-r rootdir` Causes ports to presume that the `/dev/term`, `/dev/cua`, and `/devices` directories are found under `rootdir`, not directly under `/`. If this argument is specified, `sacadm(1M)` is not invoked, since it would update terminal administration files under `/etc` without regard to the `rootdir`.

Examples EXAMPLE 1 Creating the Serial and Dialout Minor Device Nodes

The following example creates the serial and dialout minor device nodes from the `xkserial` driver's `attach(9E)` function:

```

/*
 * Create the minor number by combining the instance number
 * with the port number.
 */ #define XKNUMPORTS      8
#define XKMINORNUM(i, p) ((i) << 4 | (p))
#define XKMINORNUM_DO(i, p) ((i) << 4 | (p) | 0x80)
int
xkserialattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
    int instance, portnum;
    char name[8];
    /* other stuff in attach... */
    instance = ddi_get_instance(dip);
    for (portnum = 0; portnum < XKNUMPORTS; portnum++) {
        /*
         * create the serial port device
         */
        sprintf(name, "%d", portnum);
        ddi_create_minor_node(dip, name, S_IFCHR,
            XKMINORNUM(instance, portnum), DDI_NT_SERIAL, 0);

        /*
         * create the dialout device
         */
        sprintf(name, "%d,cu", portnum);
        ddi_create_minor_node(dip, name, S_IFCHR,
            XKMINORNUM_DO(instance, portnum), DDI_NT_SERIAL_DO, 0);
    }
}

```

EXAMPLE 2 Installing the xkserial Port Driver on a Sun Fire 4800

The following example installs the xkserial port driver on a Sun Fire 4800 (with the driver controlling the fictional XKSerial 8 port serial board), with these special files in /devices:

```
# ls -l /devices/ssm@0,0/pci@18,700000/pci@1/xkserial@f,800000/
crw-r----- 1 root sys  32,  16 Aug 29 00:02 xkserial@2000:0
crw-r----- 1 root sys  32, 144 Aug 29 00:02 xkserial@2000:1,cu
crw-r----- 1 root sys  32,  17 Aug 29 00:02 xkserial@2000:1
crw-r----- 1 root sys  32, 145 Aug 29 00:02 xkserial@2000:1,cu
crw-r----- 1 root sys  32,  18 Aug 29 00:02 xkserial@2000:2
crw-r----- 1 root sys  32, 146 Aug 29 00:02 xkserial@2000:2,cu
crw-r----- 1 root sys  32,  19 Aug 29 00:02 xkserial@2000:3
crw-r----- 1 root sys  32, 147 Aug 29 00:02 xkserial@2000:3,cu
crw-r----- 1 root sys  32,  20 Aug 29 00:02 xkserial@2000:4
crw-r----- 1 root sys  32, 148 Aug 29 00:02 xkserial@2000:4,cu
crw-r----- 1 root sys  32,  21 Aug 29 00:02 xkserial@2000:5
crw-r----- 1 root sys  32, 149 Aug 29 00:02 xkserial@2000:5,cu
crw-r----- 1 root sys  32,  22 Aug 29 00:02 xkserial@2000:6
crw-r----- 1 root sys  32, 150 Aug 29 00:02 xkserial@2000:6,cu
crw-r----- 1 root sys  32,  23 Aug 29 00:02 xkserial@2000:7
crw-r----- 1 root sys  32, 151 Aug 29 00:02 xkserial@2000:7,cu
```

/dev/term contain symbolic links to the serial port device nodes in /devices

```
# ls -l /dev/term
/dev/term/0 -> ../../devices/[...]/xkserial@2000:0
/dev/term/1 -> ../../devices/[...]/xkserial@2000:1
/dev/term/2 -> ../../devices/[...]/xkserial@2000:2
/dev/term/3 -> ../../devices/[...]/xkserial@2000:3
/dev/term/4 -> ../../devices/[...]/xkserial@2000:4
/dev/term/5 -> ../../devices/[...]/xkserial@2000:5
/dev/term/6 -> ../../devices/[...]/xkserial@2000:6
/dev/term/7 -> ../../devices/[...]/xkserial@2000:7
```

and /dev/cua contain symbolic links to the dialout port device nodes in /devices

```
# ls -l /dev/cua
/dev/cua/0 -> ../../devices/[...]/xkserial@2000:0,cu
/dev/cua/1 -> ../../devices/[...]/xkserial@2000:1,cu
/dev/cua/2 -> ../../devices/[...]/xkserial@2000:2,cu
/dev/cua/3 -> ../../devices/[...]/xkserial@2000:3,cu
/dev/cua/4 -> ../../devices/[...]/xkserial@2000:4,cu
/dev/cua/5 -> ../../devices/[...]/xkserial@2000:5,cu
/dev/cua/6 -> ../../devices/[...]/xkserial@2000:6,cu
/dev/cua/7 -> ../../devices/[...]/xkserial@2000:7,cu
```

Writing Device Drivers

Name powerd – power manager daemon

Synopsis /usr/lib/power/powerd [-n]

Description The powerd daemon is started by [pmconfig\(1M\)](#) to monitor system activity and perform an automatic shutdown using the suspend-resume feature. When the system is suspended, complete current state is saved on the disk before power is removed. On reboot, the system automatically starts a resume operation and the system is restored to the same state it was in immediately prior to suspend.

Immediately prior to system shutdown, the daemon notifies [syslogd\(1M\)](#) of the shutdown, which broadcasts a notification.

Options The following option is supported:

-n No broadcast mode. The daemon silently shuts down the system without notifying [syslogd\(1M\)](#).

Files /etc/power.conf Power Management configuration information file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|---------------------|
| Availability | system/kernel/power |
| Interface Stability | Uncommitted |

Using Power Management

Name powertop – report and analyze events that affect power management

Synopsis powertop [-c *processor_id*] [-d *count*] [-t *interval*] [-v] [-h]

Description PowerTOP is an observability tool that shows how effectively the system is taking advantage of the CPU's power management features. By running the tool on an otherwise idle system, the user can see for how long the CPU is running at different power states. Ideally, an unutilized (idle) system spends 100% of its time running at the lowest power state, but because of background user and kernel activity (random software periodically waking to poll status), idle systems can consume more power than they should.

The tool analyzes system activity periodically and displays a summary of how long the processor is executing at each supported power state. It also displays the top activities responsible for causing the CPU to wake up and use more energy. This report allows the user to identify and diagnose problematic areas of the system and optimize its power efficiency.

PowerTOP averages the amount of activity that is preventing the CPU from entering a lower power state and presents it on the “Wakeup-from-idle per second” field. This value represents the total number of wake-ups divided by the current interval. Notice that not all events are displayed on the screen at all times.

During execution, a user can force a refresh of the analysis by pressing the R key. The interval time is restored to the default or to a specified value. To quit the application, the user must press the Q key.

If you are running as root (superuser) or in the Primary Administrator role, the tool makes suggestions as how the system can be improved from a power management perspective.

PowerTOP allows you to freeze each of its three subwindows, enabling you to better analyze each subwindow's contents. When you have three different DTrace scripts running at the same time, freezing subwindows lowers CPU consumption. This feature is activated by pressing the i, f, or e key while the tool running. Pressing one of these keys freezes the idle, frequency, or event report, respectively. Pressing it once more, unfreezes it. This feature is most useful when invoked while the application being analyzed is running.

PowerTOP runs on xVM(5) domains. However, the report for idle state transitions might or might not be accurate as the physical CPU can be shared by different virtual CPUs. Both wakeup count and event report displays information regarding the current virtualized environment.

Options The following options are supported:

-c [*processor_id*]
Specifies which CPU the tool should observe.

-d [*count*]
Dumps the results of *count* analysis of system activity to the screen.

-h
Displays the command's usage.

-t [*interval*]

Specifies the interval, in seconds, at which the tool analyzes the system. The possible values are in the range of 1 through 30; the default is 5 seconds.

-v

Switches to verbose mode, including noting firings of the kernel cyclic subsystem in the event report.

Examples EXAMPLE 1 Setting the Interval

The following command sets the interval to two seconds.

```
% powertop -t 2
```

EXAMPLE 2 Analyzing and Dumping System Activity

The following command analyzes and dumps system activity to the standard output four times.

```
% powertop -d 4
```

EXAMPLE 3 Reporting Cyclic Subsystem Activity

The following command reports cyclic subsystem activity.

```
% powertop -v
```

EXAMPLE 4 Analyzing Activity on a Specific Processor

The following command runs PowerTOP and only displays data for CPU 3:

```
% powertop -c 3
```

Exit Status 0

Successful operation.

1

An error occurred.

2

Incorrect usage.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------------|---------------------|
| Architecture | x86, SPARC |
| Availability | diagnostic/powertop |
| Interface Stability | Volatile |

See Also [kstat\(1M\)](#), [pmconfig\(1M\)](#), [powerd\(1M\)](#), [psrinfo\(1M\)](#), [uadmin\(2\)](#), [libdevinfo\(3LIB\)](#), [attributes\(5\)](#), [xVM\(5\)](#), [cpr\(7\)](#), [pm\(7D\)](#), [pm-components\(9P\)](#), [removable-media\(9P\)](#)

Among non-SunOS man pages, [xscreensaver\(1\)](#) and [dtpower\(1M\)](#).

Usage You must have DTtrace privileges to run PowerTOP and root (superuser) privileges or assume the Primary Administrator role for the tool to suggest improvements to the system.

Name ppdmgr – utility for managing PPD files

Synopsis ppdmgr -a *ppd_filename_path* [-L *label*] [-R *ppd_repository_name*] [-w]
 ppdmgr -r [-L *label*] [-R *ppd_repository_name*]
 ppdmgr -u [-L *label*] [-R *ppd_repository_name*]

Description The PPD File Manager adds PPD files to the print system's PPD file repositories. When changes in the PPD file repositories are made by the utility, they are reflected in the Solaris Print Manager (see [printmgr\(1M\)](#)) GUI printer driver field when adding or modifying local attached or network attached printers.

Multiple PPD file repositories may be available. PPD files that are supplied with the system are available in the “system” repository. PPD files that are supplied by third party vendors may be available in the “vendor” repository. PPD files that are supplied by system administrators may be available in the “admin” repository, and PPD files that are added using this utility are available in the “user” repository. When this utility is used to update or rebuild printer information reflected in the [printmgr\(1M\)](#), the special reserved repository name “all” can be used to specify all of the available PPD file repositories.

PPD files are grouped under a user-provided “label” within the print system's PPD file repository to allow easier selection of a printer driver through the [printmgr](#) GUI. The special reserved label name “all” can be used to specify all of the available labels in a PPD file repository. The results are undefined if a label name contains characters that are not in the portable filename character set or if a label name starts with a hyphen (-). A label name may not contain a semi-colon (:).

Options The following subcommand are supported:

-a *ppd_file_path*

Adds a copy of *ppd_file_path* to the system under the specified label in the specified repository, where *ppd_file_path* is the full path and file name to the PPD file. The utility accepts a valid PPD file with either a .ppd or .ppd.gz (gzipped) extension.

-L *label*

Specifies a label to group PPD files under. When specified with the -a option, the default label is “user”. When specified with the -r or -u option, the default label is “all”. The following are reserved labels:

 caches may never be specified

 ppdcache may never be specified

 manufaliases may never be specified

 all applies the specified action to all labels in a repository, and may only be specified with the -r or -u option.

 SUNW* anything starting with SUNW is reserved and should not be specified with the -a option.

-R repository_name

Specifies the name of a PPD file repository representing one of the PPD file installation locations. Possible repository names include: “user”, “admin”, “vendor”, “system”, and “all”.

The repository name “all” signifies all of the possible repository names. The default repository name is “user”. Only the “user” or “admin” repository may be specified with the -a option.

-r

Rebuilds the cache information for the specified label in the specified repository.

-u

Updates the cache information for the specified label in the specified repository.

-w

Write the full path of the added PPD file. This option is only valid with the -a option. Otherwise, this option is ignored.

Examples EXAMPLE 1 Adding a copy of a PPD file to the repository

The following commands add a copy of a PPD file to the “user” repository under the “user” label:

```
# ppdmgr -a /net/somesystem/ppdfiles/ppdfile.ppd
```

or

```
# ppdmgr -a /net/somesystem/ppdfiles/ppdfile.ppd -L user
```

The following command adds a copy of a PPD file to the “user” repository under the “Photo” label and write the full path of the added copy to standard output:

```
# ppdmgr -a /net/somesystem/ppdfiles/ppdfile.ppd -L "Photo" -w
```

EXAMPLE 2 Updating the cache for the PPD files

The following commands update the cache for the PPD files under the “all” labels in the “user” repository:

```
# ppdmgr -u
```

or

```
# ppdmgr -u -R user -L all
```

The following command updates the cache for the PPD files under the “photo” label in the “user” repository:

```
# ppdmgr -u -R user -L Photo
```

EXAMPLE 3 Rebuilding the cache for the PPD files

The following command rebuilds the cache for the PPD files under the “Photo” label in the “user” repository:

```
# ppdmgr -r -R user -L Photo
```

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | print/lp |
| Interface Stability | Committed |

See Also [printmgr\(1M\)](#), [attributes\(5\)](#)

Name pppd – point to point protocol daemon

Synopsis pppd [*tty_name*] [*speed*] [*options*]

Description The point-to-point protocol (PPP) provides a method for transmitting datagrams over serial point-to-point links. PPP is composed of three components: a facility for encapsulating datagrams over serial links, an extensible link control protocol (LCP), and a family of network control protocols (NCP) for establishing and configuring different network-layer protocols.

The encapsulation scheme is provided by driver code in the kernel. pppd provides the basic LCP authentication support and several NCPs for establishing and configuring the Internet Protocol (referred to as the IP Control Protocol or “IPCP”) and IPv6 (IPV6CP).

Options The following sections discuss the pppd options:

Options Files Options are taken from files and the command line. pppd reads options from the files `/etc/ppp/options`, `$HOME/.ppprc` and `/etc/ppp/options.ttyname` (in that order) before processing the options on the command line. (Command-line options are scanned for the terminal name before the `options.ttyname` file is read.) To form the name of the `options.ttyname` file, the initial `/dev/` is removed from the terminal name, and any remaining forward slash characters (`/`) are replaced with dots. For example, with serial device `/dev/cua/a`, option file `/etc/ppp/options.cua.a` is read.

An options file is parsed into a series of words that are delimited by whitespace. Whitespace can be included in a word by enclosing the word in double-quotes (“”). A backslash (`\`) quotes the succeeding character. A hash (`#`) starts a comment, which continues until the end of the line. There is no restriction on using the `file` or `call` options within an options file.

| | | |
|-------------------------|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Frequently Used Options | <code><tty_name></code> | Communicate over the named device. The string <code>/dev/</code> is prepended if necessary. If no device name is given, or if the name of the terminal connected to the standard input is given, pppd uses that terminal and does not fork to put itself in the background. A value for this option from a privileged source cannot be overridden by a non-privileged user. |
| | <code><speed></code> | Set the baud rate to <code><speed></code> (a decimal number). The default is to leave the baud rate unchanged. This option is normally needed for dial-out only. |
| | <code>asynmap <map></code> | Set the async character map to <code><map></code> . The map describes which control characters cannot be successfully received over the serial line. pppd asks the peer to send these characters as a 2-byte escape sequence. The argument is a 32 bit hex number, with each bit representing a character to escape. Bit 0 (00000001) represents the character 0x00; bit 31 (80000000) represents the character 0x1f or <code>^_</code> . If multiple <code>asynmap</code> options are given, the values are ORed together. If no <code>asynmap</code> option is given, pppd attempts to negotiate a value of 0. If the |

| | |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | peer agrees, this disables escaping of the standard control characters. Use the <code>default-asynmap</code> option to disable negotiation and escape all control characters. |
| <code>auth</code> | Require the peer to authenticate itself before allowing network packets to be sent or received. This option is the default if the system has a default route. If the <code>auth</code> or the <code>noauth</code> option is not specified, <code>pppd</code> allows the peer to use only those IP addresses to which the system does not already have a route. |
| <code>call name</code> | Read options from the file <code>/etc/ppp/peers/name</code> . This file may contain privileged options, including <code>noauth</code> , even if <code>pppd</code> is not being run by root. The <code>name</code> string may not begin with a slash (“/”) or include consecutive periods (“.”) as a pathname component. |
| <code>callback number</code> | Request a callback to the given telephone number using Microsoft CBCP. |
| <code>connect script</code> | Use the executable or shell command specified by <code>script</code> to set up the serial line. This script would typically use the <code>chat(1M)</code> program to dial the modem and start the remote PPP session. A value for this option originating from a privileged source cannot be overridden by a non-privileged user. |
| <code>crtscts</code> | Use hardware flow control, that is, RTS/CTS, to control the flow of data on the serial port. If the <code>crtscts</code> , <code>nocrtscts</code> , <code>cdtrcts</code> or <code>nocdtrcts</code> option is not provided, the hardware flow control setting for the serial port is left unchanged. Some serial ports lack a true RTS output and use this mode to implement unidirectional flow control. The serial port suspends transmission when requested by the modem by means of CTS but cannot request the modem to stop sending to the computer. This mode allows the use of DTR as a modem control line. |
| <code>defaultroute</code> | Add a default route to the system routing tables when IPCP negotiation successfully completes, using the peer as the gateway. This entry is removed when the PPP connection is broken. This option is privileged if the <code>nodefaultroute</code> option is specified. |
| <code>disconnect script</code> | Run the executable or shell command specified by <code>script</code> after <code>pppd</code> terminates the link. Typically, this script is used to command the modem to hang up if hardware modem control signals are not available. <code>disconnect</code> is not run if the modem has already hung up. A value for this option originating from a privileged source cannot be overridden by a non-privileged user. |
| <code>escape xx,yy,...</code> | Specifies that certain characters be escaped on transmission regardless of whether the peer requests them to be escaped with its <code>asyncontrol</code> |

character map. The characters to be escaped are specified as a list of hex numbers separated by commas. Note that almost any character can be specified for the escape option, unlike the `asynmap` option which allows only control characters to be specified. Characters that cannot be escaped are those containing hex values 0x20 through 0x3f and 0x5e.

| | |
|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>file name</code> | Read options from file <i>name</i> . If this option is used on the command line or in <code>\$HOME/.ppprc</code> , the file must be readable by the user invoking <code>pppd</code> . See Options Files for a list of files that <code>pppd</code> always reads, regardless of the use of this option. |
| <code>init script</code> | Run the executable or shell command specified by <i>script</i> to initialize the serial line. This script would typically use the <code>chat(1M)</code> program to configure the modem to enable auto-answer. A value for this option from a privileged source cannot be overridden by a non-privileged user. |
| <code>lock</code> | Directs <code>pppd</code> to create a UUCP-style lock file for the serial device to ensure exclusive access to the device. |
| <code>mru n</code> | Set the Maximum Receive Unit (MRU) value to <i>n</i> . <code>pppd</code> asks the peer to send packets of no more than <i>n</i> bytes. Minimum MRU value is 128. Default MRU value is 1500. A value of 296 is recommended for slow links (40 bytes for TCP/IP header + 256 bytes of data). For IPv6, MRU must be at least 1280. |
| <code>mtu n</code> | Set the Maximum Transmit Unit (MTU) value to <i>n</i> . Unless the peer requests a smaller value via MRU negotiation, <code>pppd</code> requests the kernel networking code to send data packets of no more than <i>n</i> bytes through the PPP network interface. For IPv6, MTU must be at least 1280. |
| <code>passive</code> | Enables the "passive" option in the LCP. With this option, <code>pppd</code> attempts to initiate a connection; if no reply is received from the peer, <code>pppd</code> waits passively for a valid LCP packet instead of exiting, as it would without this option. |

Options `<local_IP_address>:<remote_IP_address>`

Set the local and/or remote interface IP addresses. Either one may be omitted, but the colon is required. The IP addresses are specified with a host name or in decimal dot notation, for example: `:10.1.2.3`. The default local address is the first IP address of the system unless the `noipdefault` option is provided. The remote address is obtained from the peer if not specified in any option. Thus, in simple cases, this option is not required. If a local and/or remote IP address is specified with this option, `pppd` will not accept a different value from the peer in the IPCP negotiation unless the `ipcp-accept-local` and/or `ipcp-accept-remote` options are given, respectively.

allow-fcs *fcs-type*

Set allowable FCS type(s) for data sent to the peer. The *fcs-type* is a comma-separated list of "crc16", "crc32", "null", or integers. By default, all known types are allowed. If this option is specified and the peer requests a type not listed, a LCP Configure-Nak is sent to request only the listed types.

allow-ip *address(es)*

Allow peers to use the given IP address or subnet without authenticating themselves. The parameter is parsed in the same manner as each element of the list of allowed IP addresses is parsed in the secrets files. See the [Authentication](#) section for more details.

bsdcomp *nr,nt*

Request that the peer compress packets that it sends using the BSD-Compress scheme, with a maximum code size of *nr* bits, and agree to compress packets sent to the peer with a maximum code size of *nt* bits. If *nt* is not specified, it defaults to the value given for *nr*. Values in the range 9 to 15 may be used for *nr* and *nt*; larger values provide better compression but consume more kernel memory for compression dictionaries. Alternatively, a value of 0 for *nr* or *nt* disables compression in the corresponding direction. Use `nobsdcomp` or `bsdcomp 0` to disable BSD-Compress compression entirely. If this option is read from a privileged source, a nonprivileged user may not specify a code size larger than the value from the privileged source.

cdtrcts

Use a non-standard hardware flow control such as DTR/CTS to control the flow of data on the serial port. If the `crtcts`, `nocrtcts`, `cdtrcts` or `nocdtrcts` option is not specified, the hardware flow control setting for the serial port is left unchanged. Some serial ports lack a true RTS output. Such serial ports use this mode to implement true bi-directional flow control. Note that this flow control mode does not permit using DTR as a modem control line.

chap-interval *n*

If this option is given, `pppd` will rechallenge the peer every *n* seconds.

chap-max-challenge *n*

Set the maximum number of CHAP challenge transmissions to *n* (default 10).

chap-restart *n*

Set the CHAP restart interval (retransmission timeout for challenges) to *n* seconds. The default is 3.

connect-delay *n*

Wait for up to *n* milliseconds after the connect script finishes for a valid PPP packet from the peer. When the wait period elapses or when a valid PPP packet is received from the peer, `pppd` begins negotiation by sending its first LCP packet. The default value is 1000 (1 second). A wait period applies only if the `connect` or `pty` option is used.

datarate *n*

Set maximum data rate to *n* (in bytes per second) when using the `pty`, `notty`, `record`, or `socket` options.

debug

Enables connection debugging facilities. If this option is given, pppd logs the contents of all control packets sent or received in a readable form. The packets are logged through syslog with facility daemon and level debug. This information can be directed to a file by configuring `/etc/syslog.conf` appropriately.

default-asynctmap

Disable asynctmap negotiation, forcing all control characters to be escaped for both the transmit and the receive direction.

default-fcs

Disable FCS Alternatives negotiation entirely. By default, no FCS Alternatives option is sent to the peer, but the option is accepted. If this option is specified by the peer, then LCP Configure-Reject is sent.

default-mru

Disable MRU [Maximum Receive Unit] negotiation. With this option, pppd uses the default MRU value of 1500 bytes for the transmit and receive directions.

deflate *nr,nt,e*

Request that the peer compress packets that it sends, using the deflate scheme, with a maximum window size of 2^{nr} bytes, and agree to compress packets sent to the peer with a maximum window size of 2^{nt} bytes and effort level of e (1 to 9). If nt is not specified, it defaults to the value given for nr . If e is not specified, it defaults to 6. Values in the range 9 to 15 may be used for nr and nt ; larger values provide better compression but consume more kernel memory for compression dictionaries. (Value 8 is not permitted due to a zlib bug.) Alternatively, a value of 0 for nr or nt disables compression in the corresponding direction. Use `nodeflate` or `deflate 0` to disable deflate compression entirely. (Note: pppd requests deflate compression in preference to BSD-Compress if the peer can do either.) If this option is read from a privileged source, a nonprivileged user may not specify a code size larger than the value from the privileged source.

demand

Initiate the link only on demand, that is, when data traffic is present. With this option, the remote IP address must be specified by the user on the command line or in an options file. pppd initially configures and enables the interface for IP traffic without connecting to the peer. When traffic is available, pppd connects to the peer and performs negotiation, authentication and other actions. When completed, pppd passes data packets across the link. The demand option implies the `persist` option. If this behavior is not desired, use the `nopersist` option after the demand option. The `idle` and `holdoff` options can be used in conjunction with the demand option.

domain *d*

Append the domain name d to the local host name for authentication purposes. For example, if `gethostname()` returns the name `porsche`, but the fully qualified domain name is `porsche.Quotron.COM`, you could specify `domain Quotron.COM`. With this configuration, pppd uses the name `porsche.Quotron.COM` for accessing secrets in the secrets file and as the default name when authenticating to the peer. This option is privileged.

endpoint endpoint-value

Set the endpoint discriminator (normally used for RFC 1990 Multilink PPP operation). The *endpoint-value* consists of a class identifier and a class-dependent value. The class identifier is one of "null," "local," "IP," "MAC," "magic," "phone," or a decimal integer. If present, the class-dependent value is separated from the identifier by a colon (":") or period ("."). This value may be a standard dotted-decimal IP address for class "IP," an optionally colon-or-dot separated hex Ethernet address for class "MAC" (must have 6 numbers), or an arbitrary string of bytes specified in hex with optional colon or dot separators between bytes. Although this option is available, this implementation does not support multilink.

fcs fcs-type

Set FCS type(s) desired for data sent by the peer. The *fcs-type* is a comma-separated list of `crc16`, `crc32`, `null`, or integers. By default, an FCS Alternatives option is not specified, and the medium-dependent FCS type is used. If this option is specified and the peer sends an LCP Configure-Nak, only the listed types are used. If none are in common, the FCS Alternatives option is omitted from the next LCP Configure-Request to drop back to the default.

hide-password

When logging the contents of PAP packets, this option causes `pppd` to exclude the password string from the log. This is the default.

holdoff n

Specifies how many seconds to wait before re-initiating the link after it terminates. This option is effective only if the `persist` or `demand` option is used. The holdoff period is not applied if the link is terminated because it was idle.

ident string

Set the LCP Identification string. The default value is a version string similar to that displayed by the `--version` option.

idle n

Specifies that `pppd` must disconnect if the link is idle for *n* seconds. The link is idle when no data packets (i.e. IP packets) are being sent or received. Do not use this option with the `persist` option but without the `demand` option.

ipcp-accept-local

With this option, `pppd` accepts the peer's idea of the local IP address, even if the local IP address is specified in an option.

ipcp-accept-remote

With this option, `pppd` accepts the peer's idea of its remote IP address, even if the remote IP address is specified in an option.

ipcp-max-configure n

Set the maximum number of IPCP Configure-Request transmissions to *n* (default 10).

`ipcp-max-failure n`

Set the maximum number of IPCP Configure-NAKs sent before sending Configure-Rejects instead to *n* (default 10).

`ipcp-max-terminate n`

Set the maximum number of IPCP terminate-request transmissions to *n* (default 3).

`ipcp-restart n`

Set the IPCP restart interval (retransmission timeout) to *n* seconds (default 3).

`ipparam string`

Provides an extra parameter to the ip-up and ip-down scripts. When this option is given, the *string* supplied is given as the sixth parameter to those scripts. See the [Scripts](#) section.

`ipv6 <local_interface_identifier>, <remote_interface_identifier>`

Set the local and/or remote 64-bit interface identifier. Either one may be omitted. The identifier must be specified in standard ASCII notation of IPv6 addresses (for example: `::dead:beef`). If the `ipv6cp-use-ipaddr` option is given, the local and remote identifiers are derived from the respective IPv4 addresses (see above). The `ipv6cp-use-persistent` option can be used instead of the `ipv6 <local>, <remote>` option.

`ipv6cp-accept-local`

Accept peer's interface identifier for the local link identifier.

`ipv6cp-max-configure n`

Set the maximum number of IPv6CP Configure-Request transmissions to *n* (default 10).

`ipv6cp-max-failure n`

Set the maximum number of IPv6CP Configure-NAKs sent before sending Configure-Rejects instead to *n* (default 10).

`ipv6cp-max-terminate n`

Set the maximum number of IPv6CP terminate-request transmissions to *n* (default 3).

`ipv6cp-restart n`

Set the IPv6CP restart interval (retransmission timeout) to *n* seconds (default 3).

`ipv6cp-use-ipaddr`

If either the local or remote IPv6 address is unspecified, use the corresponding configured IPv4 address as a default interface identifier. (This option uses the configured addresses, not the negotiated addresses. Do not use it with `ipcp-accept-local` if the local IPv6 identifier is unspecified or with `ipcp-accept-remote` if the remote IPv6 identifier is unspecified.)

`ipv6cp-use-persistent`

Use uniquely-available persistent value for link local address.

`kdebug n`

Enable debugging code in the kernel-level PPP driver. Argument *n* is the sum of the following values: 1 to enable general debug messages, 2 to request that contents of received

packets be printed, and 4 to request contents of transmitted packets be printed. Messages printed by the kernel are logged by `syslogd(1M)` to a file directed in the `/etc/syslog.conf` configuration file. Do not use the `kdebug` option to debug failed links. Use the `debug` option instead.

`lcp-echo-failure` *n*

If this option is given, `pppd` presumes the peer to be dead if *n* LCP Echo-Requests are sent without receiving a valid LCP Echo-Reply. If this happens, `pppd` terminates the connection. This option requires a non-zero value for the `lcp-echo-interval` parameter. This option enables `pppd` to terminate after the physical connection is broken (for example, if the modem has hung up) in situations where no hardware modem control lines are available.

`lcp-echo-interval` *n*

If this option is given, `pppd` sends an LCP Echo-Request frame to the peer every *n* seconds. Normally the peer responds to the Echo-Request by sending an Echo-Reply. This option can be used with the `lcp-echo-failure` option to detect that the peer is no longer connected.

`lcp-max-configure` *n*

Set the maximum number of LCP Configure-Request transmissions to *n* (default 10).

`lcp-max-failure` *n*

Set the maximum number of LCP Configure-NAKs sent before starting to send Configure-Rejects instead to *n* (default 10).

`lcp-max-terminate` *n*

Set the maximum number of LCP Terminate-Request transmissions to *n* (default 3).

`lcp-restart` *n*

Set the LCP restart interval (retransmission timeout) to *n* seconds (default 3).

`linkname` *name*

Sets the logical name of the link to *name*. `pppd` creates a file named `ppp-name.pid` in `/var/run` containing its process ID. This is useful in determining which instance of `pppd` is responsible for the link to a given peer system. This is a privileged option.

`local`

Do not use modem control lines. With this option, `pppd` ignores the state of the CD (Carrier Detect) signal from the modem and does not change the state of the DTR (Data Terminal Ready) signal.

`logfd` *n*

Send log messages to file descriptor *n*. `pppd` sends log messages to (at most) one file or file descriptor (as well as sending the log messages to `syslog`), so this option and the `logfile` option are mutually exclusive. By default `pppd` sends log messages to `stdout` (file descriptor 1) unless the serial port is open on `stdout`.

`logfile` *filename*

Append log messages to the file *filename* (and send the log messages to `syslog`). The file is opened in append mode with the privileges of the user who invoked `pppd`.

login

Use the system password database for authenticating the peer using PAP, and record the user in the system `wtmp` file. Note that the peer must have an entry in the `/etc/ppp/pap-secrets` file and the system password database to be allowed access.

maxconnect *n*

Terminate the connection after it has been available for network traffic for *n* seconds (that is, *n* seconds after the first network control protocol starts). An LCP Time-Remaining message is sent when the first NCP starts, and again when 5, 2, and 0.5 minutes are remaining.

maxfail *n*

Terminate after *n* consecutive failed connection attempts. A value of 0 means no limit. The default value is 10.

modem

Use the modem control lines. This option is the default. With this option, `pppd` waits for the CD (Carrier Detect) signal from the modem to be asserted when opening the serial device (unless a connect script is specified), and drops the DTR (Data Terminal Ready) signal briefly when the connection is terminated and before executing the connect script.

ms-dns <*addr*>

If `pppd` is acting as a server for Microsoft Windows clients, this option allows `pppd` to supply one or two DNS (Domain Name Server) addresses to the clients. The first instance of this option specifies the primary DNS address; the second instance (if given) specifies the secondary DNS address. If the first instance specifies a name that resolves to multiple IP addresses, then the first two addresses are used. (This option is present in some older versions of `pppd` under the name `dns-addr`.)

ms-lanman

If `pppd` connects as a client to a Microsoft server and uses MS-CHAPv1 for authentication, this option selects the LAN Manager password style instead of Microsoft NT.

ms-wins <*addr*>

If `pppd` acts as a server for Microsoft Windows or Samba clients, this option allows `pppd` to supply one or two WINS (Windows Internet Name Services) server addresses to the clients. The first instance of this option specifies the primary WINS address; the second instance (if given) specifies the secondary WINS address. As with `ms-dns`, if the name specified resolves to multiple IP addresses, then the first two will be taken as primary and secondary.

name *name*

Set the name of the local system for authentication purposes to *name*. This is a privileged option. With this option, `pppd` uses lines in the secrets files that have *name* as the second field to look for a secret to use in authenticating the peer. In addition, unless overridden with the `user` option, *name* is used as the name to send to the peer when authenticating the local system. (Note that `pppd` does not append the domain name to *name*.)

no-accm-test

Disable use of `asynmap` (ACCM) checking using LCP Echo-Request messages. If the `lcp-echo-failure` is used on an asynchronous line, `pppd` includes all control characters in the first *n* LCP Echo-Request messages. If the `asynmap` is set incorrectly, the link drops rather than continue operation with random failures. This option disables that feature.

noaccomp

Disable HDLC Address/Control compression in both directions (send and receive).

noauth

Do not require the peer to authenticate itself. This option is privileged.

nobsdcomp

Disables BSD-Compress compression; `pppd` will not request or agree to compress packets using the BSD-Compress scheme. This option is not necessary if `noccp` is specified.

noccp

Disable CCP (Compression Control Protocol) negotiation. This option should only be required if the peer has bugs or becomes confused by requests from `pppd` for CCP negotiation. If CCP is disabled, then BSD and deflate compression do not need to be separately disabled.

nocrtscts

Disable hardware flow control (i.e. RTS/CTS) on the serial port. If the `crtscts`, `nocrtscts`, `cdtrcts` or `nocdtrcts` options are not given, the hardware flow control setting for the serial port is left unchanged.

nocdtrcts

This option is a synonym for `nocrtscts`. Either option will disable both forms of hardware flow control.

nodefaultroute

Disable the `default route` option. You can prevent non-root users from creating default routes with `pppd` by placing this option in the `/etc/ppp/options` file.

nodeflate

Disables deflate compression; `pppd` will not request or agree to compress packets using the deflate scheme. This option is not necessary if `noccp` is specified.

nodeflatedraft

Do not use Internet Draft (incorrectly assigned) algorithm number for deflate compression. This option is not necessary if `noccp` is specified.

nodetach

Do not detach from the controlling terminal. Without this option, `pppd` forks to become a background process if a serial device other than the terminal on the standard input is specified.

noendpoint

Do not send or accept the Multilink Endpoint Discriminator option.

noident

Disable use of LCP Identification. LCP Identification messages will not be sent to the peer, but received messages will be logged. (Specify this option twice to completely disable LCP Identification. In this case, pppd sends LCP Code-Reject in response to received LCP Identification messages.)

noip

Disable IPCP negotiation and IP communication. Use this option only if the peer has bugs or becomes confused by requests from pppd for IPCP negotiation.

noipv6

Disable IPv6CP negotiation and IPv6 communication. IPv6 is not enabled by default.

noipdefault

Disables the default behavior when no local IP address is specified, which is to determine (if possible) the local IP address from the hostname. With this option, the peer must supply the local IP address during IPCP negotiation (unless it specified explicitly on the command line or in an options file).

nolog

Do not send log messages to a file or file descriptor. This option cancels the `logfd` and `logfile` options. `nologfd` acts as an alias for this option.

nomagic

Disable magic number negotiation. With this option, pppd cannot detect a looped-back line. Use this option only if the peer has bugs. Do not use this option to work around the “Serial line is looped back” error message.

nopam

This privileged option disables use of pluggable authentication modules. If this option is specified, pppd reverts to standard authentication mechanisms. The default is not to use PAM.

nopcomp

Disable protocol field compression negotiation in the receive and the transmit direction.

nopersist

Exit once a connection has been made and terminated. This is the default unless the `persist` or `demand` option is specified.

noplink

Cause pppd to use `I_LINK` instead of `I_PLINK`. This is the default. When `I_LINK` is used, the system cleans up terminated interfaces (even when `SIGKILL` is used) but does not allow `ifconfig(1M)` to unplumb PPP streams or insert or remove modules dynamically. Use the `plink` option if `ifconfig(1M)` `modinsert`, `modremove` or `unplumb` support is needed.

nopredictor1

Do not accept or agree to Predictor-1 compression. (This option is accepted for compatibility. The implementation does not support Predictor-1 compression.)

noproxyarp

Disable the proxyarp option. If you want to prevent users from creating proxy ARP entries with pppd, place this option in the `/etc/ppp/options` file.

notty

Normally, pppd requires a terminal device. With this option, pppd allocates itself a pseudo-tty master/slave pair and uses the slave as its terminal device. pppd creates a child process to act as a character shunt to transfer characters between the pseudo-tty master and its standard input and output. Thus, pppd transmits characters on its standard output and receives characters on its standard input even if they are not terminal devices. This option increases the latency and CPU overhead of transferring data over the ppp interface as all of the characters sent and received must flow through the character shunt process. An explicit device name may not be given if this option is used.

novj

Disable Van Jacobson style TCP/IP header compression in both the transmit and the receive direction.

novjccomp

Disable the connection-ID compression option in Van Jacobson style TCP/IP header compression. With this option, pppd does not omit the connection-ID byte from Van Jacobson compressed TCP/IP headers, nor does it ask the peer to do so. This option is unnecessary if novj is specified.

pam

This privileged option enables use of PAM. If this is specified, pppd uses the [pam\(3PAM\)](#) framework for user authentication with a service name of "ppp" if the `login` option and PAP authentication are used. The default is not to use PAM.

papcrypt

Indicates that pppd should not accept a password which, before encryption, is identical to the secret from the `/etc/ppp/pap-secrets` file. Use this option if the secrets in the `pap-secrets` file are in [crypt\(3C\)](#) format.

pap-max-authreq *n*

Set the maximum number of PAP authenticate-request transmissions to *n* (default 10).

pap-restart *n*

Set the PAP restart interval (retransmission timeout) to *n* seconds (default 3).

pap-timeout *n*

Set the maximum time that pppd waits for the peer to authenticate itself with PAP to *n* seconds (0= no limit). The default is 30 seconds.

password *string*

Password string for authentication to the peer.

persist

Do not exit after a connection is terminated; instead try to reopen the connection.

plink

Cause pppd to use I_PLINK instead of I_LINK. The default is to use I_LINK, which cleans up terminated interface (even if SIGKILL is used), but does not allow **ifconfig(1M)** to unplumb PPP streams or insert or remove modules dynamically. Use this option if **ifconfig(1M)** modinsert/modremove/unplumb support is needed. See also the **plumbed** option.

plugin filename

Load the shared library object file *filename* as a plugin. This is a privileged option. Unless the filename specifies an explicit path, `/etc/ppp/plugins` and `/usr/lib/inet/ppp` will be searched for the object to load in that order.

plumbed

This option indicates that pppd should find a plumbed interface and use that for the session. If IPv4 addresses or IPv6 interface IDs or link MTU are otherwise unspecified, they are copied from the interface selected. This mode mimics some of the functionality of the older `aspppd` implementation and may be helpful when pppd is used with external applications that use **ifconfig(1M)**.

pppmux timer

Enable PPP Multiplexing option negotiation and set transmit multiplexing timeout to *timer* microseconds.

privgroup group-name

Allows members of group *group-name* to use privileged options. This is a privileged option. Because there is no guarantee that members of *group-name* cannot use pppd to become root themselves, you should be careful using this option. Consider it equivalent to putting the members of *group-name* in the root or sys group.

proxyarp

Add an entry to the system's Address Resolution Protocol (ARP) table with the IP address of the peer and the Ethernet address of this system. When you use this option, the peer appears to other systems to be on the local Ethernet. The remote address on the PPP link must be in the same subnet as assigned to an Ethernet interface.

pty script

Specifies that the command *script*, and not a specific terminal device is used for serial communication. pppd allocates itself a pseudo-tty master/slave pair and uses the slave as its terminal device. *script* runs in a child process with the pseudo-tty master as its standard input and output. An explicit device name may not be given if this option is used. (Note: if the record option is used in conjunction with the pty option, the child process will have pipes on its standard input and output.)

receive-all

With this option, pppd accepts all control characters from the peer, including those marked in the receive `asynmap`. Without this option, pppd discards those characters as specified in *RFC 1662*. This option should be used only if the peer has bugs, as is often found with dial-back implementations.

record *filename*

Directs pppd to record all characters sent and received to a file named *filename*. *filename* is opened in append mode, using the user's user-ID and permissions. Because this option uses a pseudo-tty and a process to transfer characters between the pseudo-tty and the real serial device, it increases the latency and CPU overhead of transferring data over the PPP interface. Characters are stored in a tagged format with timestamps that can be displayed in readable form using the pppdump(1M) program. This option is generally used when debugging the kernel portion of pppd (especially CCP compression algorithms) and not for debugging link configuration problems. See the debug option.

remotename *name*

Set the assumed name of the remote system for authentication purposes to *name*. Microsoft WindowsNT does not provide a system name in its CHAP Challenge messages, and this option is often used to work around this problem.

refuse-chap

With this option, pppd will not agree to authenticate itself to the peer using standard Challenge Handshake Authentication Protocol (CHAP). (MS-CHAP is not affected.)

refuse-mschap

Do not agree to authenticate to peer with MS-CHAPv1. If this option is specified, requests for MS-CHAPv1 authentication from the peer are declined with LCP Configure-Nak. That option does not disable any other form of CHAP.

refuse-mschapv2

Do not agree to authenticate to peer with MS-CHAPv2. If specified, this option requests that MS-CHAPv2 authentication from the peer be declined with LCP Configure-Nak. That option does not disable any other form of CHAP.

refuse-pap

With this option, pppd will not agree to authenticate itself to the peer using Password Authentication Protocol (PAP).

require-chap

Require the peer to authenticate itself using standard CHAP authentication. MS-CHAP is not affected.

require-mschap

Require the peer to authenticate itself using MS-CHAPv1 authentication.

require-mschapv2

Require the peer to authenticate itself using MS-CHAPv2 authentication.

require-pap

Require the peer to authenticate itself using PAP authentication.

show-password

When logging contents of PAP packets, this option causes pppd to show the password string in the log message.

silent

With this option, `pppd` will not transmit LCP packets to initiate a connection until a valid LCP packet is received from the peer. This is like the “passive” option with older versions of `pppd` and is retained for compatibility, but the current `passive` option is preferred.

small-accm-test

When checking the `asynctest` (ACCM) setting, `pppd` uses all 256 possible values by default. See `no-accm-test`. This option restricts the test so that only the 32 values affected by standard ACCM negotiation are tested. This option is useful on very slow links.

socket *host:port*

Connect to given host and port using TCP and run PPP over this connection.

sync

Use synchronous HDLC serial encoding instead of asynchronous. The device used by `pppd` with this option must have sync support. Currently supports `zs`, `se`, and `hsi` drivers.

unit *n*

Set PPP interface unit number to *n*, if possible.

updetach

With this option, `pppd` detaches from its controlling terminal after establishing the PPP connection. When this is specified, messages sent to `stderr` by the connect script, usually `chat(1M)`, and debugging messages from the `debug` option are directed to `pppd`'s standard output.

usehostname

Enforce the use of the hostname with domain name appended, if given, as the name of the local system for authentication purposes. This overrides the `name` option. Because the `name` option is privileged, this option is normally not needed.

usepeerdns

Ask the peer for up to two DNS server addresses. Addresses supplied by the peer, if any, are passed to the `/etc/ppp/ip-up` script in the environment variables `DNS1` and `DNS2`. In addition, `pppd` creates an `/etc/ppp/resolv.conf` file containing one or two nameserver lines with the address(es) supplied by the peer.

user *name*

Sets the name used for authenticating the local system to the peer to *name*.

vj-max-slots *n*

Sets the number of connection slots to be used by the Van Jacobson TCP/IP header compression and decompression code to *n*, which must be between 2 and 16 (inclusive).

welcome *script*

Run the executable or shell command specified by *script* before initiating PPP negotiation, after the connect script, if any, has completed. A value for this option from a privileged source cannot be overridden by a non-privileged user.

xonxoff

Use software flow control, that is, XON/XOFF, to control the flow of data on the serial port.

Obsolete Options The following options are obsolete:

- +ua *name* Read a PAP user name and password from the file *name*. This file must have two lines for name and password. Name and password are sent to the peer when the peer requests PAP authentication.
- +ipv6 Enable IPv6 and IPv6CP without specifying interface identifiers.
- version Show version number and exit.
- help Show brief help message and exit.

Extended Description

The following sections discuss miscellaneous features of pppd:

Security

pppd allows system administrators to provide legitimate users with PPP access to a server machine without fear of compromising the security of the server or the network it runs on. Access control is provided by restricting IP addresses the peer may use based on its authenticated identity (if any), and through restrictions on options a non-privileged user may use. Options that permit potentially insecure configurations are privileged. Privileged options are accepted only in files that are under the control of the system administrator or when pppd is being run by root.

By default, pppd allows an unauthenticated peer to use a given IP address only if the system does not already have a route to that IP address. For example, a system with a permanent connection to the wider Internet will normally have a default route, meaning all peers must authenticate themselves to set up a connection. On such a system, the `auth` option is the default. Conversely, a system with a PPP link that comprises the only connection to the Internet probably does not possess a default route, so the peer can use virtually any IP address without authenticating itself.

Security-sensitive options are privileged and cannot be accessed by a non-privileged user running pppd, either on the command line, in the user's `$HOME/.ppprc` file, or in an options file read using the `file` option. Privileged options may be used in `/etc/ppp/options` file or in an options file read using the `call` option. If pppd is run by the root user, privileged options can be used without restriction. If the `/etc/ppp/options` file does not exist, then only root may invoke pppd. The `/etc/ppp/options` file must be created (but may be empty) to allow ordinary non-root users to access pppd.

When opening the device, pppd uses the invoking user's user ID or the root UID (that is, 0), depending if the device name was specified by the user or the system administrator. If the device name comes from a privileged source, that is, `/etc/ppp/options` or an options file read using the `call` option, pppd uses full root privileges when opening the device. Thus, by creating an appropriate file under `/etc/ppp/peers`, the system administrator can allow users

to establish a PPP connection via a device that they would not normally have access to. Otherwise pppd uses the invoking user's real UID when opening the device.

Authentication During the authentication process, one peer convinces the other of its identity by sending its name and some secret information to the other. During authentication, the first peer becomes the "client" and the second becomes the "server." Authentication names can (but are not required to) correspond to the peer's Internet hostnames.

pppd supports four authentication protocols: the Password Authentication Protocol (PAP) and three forms of the Challenge Handshake Authentication Protocol (CHAP). With the PAP protocol, the client sends its name and a cleartext password to the server to authenticate itself. With CHAP, the server initiates the authentication exchange by sending a challenge to the client who must respond with its name and a hash value derived from the shared secret and the challenge.

The PPP protocol is symmetrical, meaning that each peer may be required to authenticate itself to the other. Different authentication protocols and names can be used for each exchange.

By default, pppd authenticates if requested and does not require authentication from the peer. However, pppd does not authenticate itself with a specific protocol if it has no secrets that can do so.

pppd stores authentication secrets in the `/etc/ppp/pap-secrets` (for PAP), and `/etc/ppp/chap-secrets` (for CHAP) files. Both files use the same format. pppd uses secrets files to authenticate itself to other systems and to authenticate other systems to itself.

Secrets files contain one secret per line. Secrets are specific to a particular combination of client and server and can only be used by that client to authenticate itself to that server. Each line in a secrets file has a minimum of three fields that contain the client and server names followed by the secret. Often, these three fields are followed by IP addresses that are used by clients to connect to a server.

A secrets file is parsed into words, with client name, server name and secrets fields allocated one word each. Embedded spaces or other special characters within a word must be quoted or escaped. Case is significant in all three fields.

A secret beginning with an at sign ("@") is followed by the name of a file containing the secret. An asterisk (*) as the client or server name matches any name. When choosing a match, pppd selects the one with the fewest wildcards. Succeeding words on a line are interpreted by pppd as acceptable IP addresses for that client. IP Addresses are disallowed if they appear in lines that contain only three words or lines whose first word begins with a hyphen ("-"). To allow any address, use "*". An address starting with an exclamation point ("!") indicates that the specified address is not acceptable. An address may be followed by "/" and a number *n* to indicate a whole subnet (all addresses that have the same value in the most significant *n* bits).

In this form, the address may be followed by a plus sign ("+") to indicate that one address from the subnet is authorized, based on the ppp network interface unit number in use. In this case, the host part of the address is set to the unit number, plus one.

When authenticating the peer, pppd chooses a secret with the peer's name in the first field of the secrets file and the name of the local system in the second field. The local system name defaults to the hostname, with the domain name appended if the `domain` option is used. The default can be overridden with the `name` option unless the `usehostname` option is used.

When authenticating to the peer, pppd first determines the name it will use to identify itself to the peer. This name is specified with the `user` option. If the `user` option is not used, the name defaults to the host name of the local system. pppd then selects a secret from the secrets file by searching for an entry with a local name in the first field and the peer's name in the second field. pppd will know the name of the peer if standard CHAP authentication is used because the peer will have sent it in the Challenge packet. However, if MS-CHAP or PAP is being used, pppd must determine the peer's name from the options specified by the user. The user can specify the peer's name directly with the `remotename` option. Otherwise, if the remote IP address was specified by a name, rather than in numeric form, that name will be used as the peer's name. If that fails, pppd uses the null string as the peer's name.

When authenticating the peer with PAP, the supplied password is compared with data in the secrets file. If the password and secret do not match, the password is encrypted using `crypt()` and checked against the secret again. If the `papcrypt` option is given, the first unencrypted comparison is omitted for better security, and entries must thus be in encrypted `crypt(3C)` form.

If the `login` option is specified, the username and password are also checked against the system password database. This allows you to set up the `pap-secrets` file to enable PPP access only to certain users, and to restrict the set of IP addresses available to users. Typically, when using the `login` option, the secret in `/etc/ppp/pap-secrets` would be "", which matches any password supplied by the peer. This makes having the same secret in two places unnecessary. When `login` is used, the `pam` option enables access control through `pam(3PAM)`.

Authentication must be completed before IPCP (or other network protocol) can be started. If the peer is required to authenticate itself and fails, pppd closes LCP and terminates the link. If IPCP negotiates an unacceptable IP address for the remote host, IPCP is closed. IP packets are sent or received only when IPCP is open.

To allow hosts that cannot authenticate themselves to connect and use one of a restricted set of IP addresses, add a line to the `pap-secrets` file specifying the empty string for the client name and secret.

Additional pppd options for a given peer may be specified by placing them at the end of the secrets entry, separated by two dashes (--). For example

```
peername servername secret ip-address -- novj
```

Routing When IPCP negotiation is complete, pppd informs the kernel of the local and remote IP addresses for the PPP interface and creates a host route to the remote end of the link that enables peers to exchange IP packets. Communication with other machines generally requires further modification to routing tables and/or Address Resolution Protocol (ARP) tables. In most cases the default route and/or proxyarp options are sufficient for this, but further intervention may be necessary. If further intervention is required, use the `/etc/ppp/ip-up` script or a routing protocol daemon.

To add a default route through the remote host, use the `default route` option. This option is typically used for “client” systems; that is, end-nodes that use the PPP link for access to the general Internet.

In some cases it is desirable to use proxy ARP, for example on a server machine connected to a LAN, to allow other hosts to communicate with the remote host. `proxyarp` instructs pppd to look for a network interface on the same subnet as the remote host. That is, an interface supporting broadcast and ARP that is not a point-to-point or loopback interface and that is currently up. If found, pppd creates a permanent, published ARP entry with the IP address of the remote host and the hardware address of the network interface.

When the `demand` option is used, the interface IP addresses are already set at the time when IPCP comes up. If pppd cannot negotiate the same addresses it used to configure the interface, it changes the interface IP addresses to the negotiated addresses. This may disrupt existing connections. Using demand dialing with peers that perform dynamic IP address assignment is not recommended.

Scripts pppd invokes scripts at various stages during processing that are used to perform site-specific ancillary processing. These scripts may be shell scripts or executable programs. pppd does not wait for the scripts to finish. The scripts are executed as root (with the real and effective user-id set to 0), enabling them to update routing tables, run privileged daemons, or perform other tasks. Be sure that the contents of these scripts do not compromise your system's security. pppd runs the scripts with standard input, output and error redirected to `/dev/null`, and with an environment that is empty except for some environment variables that give information about the link. The pppd environment variables are:

| | |
|-----------------|------------------------------------------------------------------------------------|
| DEVICE | Name of the serial tty device. |
| IFNAME | Name of the network interface. |
| IPLOCAL | IP address for the link's local end. This is set only when IPCP has started. |
| IPREMOTE | IP address for the link's remote end. This is set only when IPCP has started. |
| PEERNAME | Authenticated name of the peer. This is set only if the peer authenticates itself. |
| SPEED | Baud rate of the tty device. |
| ORIG_UID | Real user-id of user who invoked pppd. |

PPPLOGNAME Username of the real user-id who invoked pppd. This is always set.

pppd also sets the following variables for the ip-down and auth-down scripts:

CONNECT_TIME Number of seconds between the start of PPP negotiation and connection termination.

BYTES_SENT Number of bytes sent at the level of the serial port during the connection.

BYTES_RCVD Number of bytes received at the level of the serial port during the connection.

LINKNAME Logical name of the link, set with the `linkname` option.

If they exist, pppd invokes the following scripts. It is not an error if they do not exist.

| | |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>/etc/ppp/auth-up</code> | Program or script executed after the remote system successfully authenticates itself. It is executed with five command-line arguments: <code>interface-name peer-name user-name tty-device speed</code> . Note that this script is not executed if the peer does not authenticate itself, for example, when the <code>noauth</code> option is used. |
| <code>/etc/ppp/auth-down</code> | Program or script executed when the link goes down if <code>/etc/ppp/auth-up</code> was previously executed. It is executed in the same manner with the same parameters as <code>/etc/ppp/auth-up</code> . |
| <code>/etc/ppp/ip-up</code> | A program or script that is executed when the link is available for sending and receiving IP packets (that is, IPCP has come up). It is executed with six command-line arguments: <code>interface-name tty-device speed local-IP-address remote-IP-address ipparam</code> . |
| <code>/etc/ppp/ip-down</code> | A program or script which is executed when the link is no longer available for sending and receiving IP packets. This script can be used for undoing the effects of the <code>/etc/ppp/ip-up</code> script. It is invoked in the same manner and with the same parameters as the <code>ip-up</code> script. |
| <code>/etc/ppp/ipv6-up</code> | Similar to <code>/etc/ppp/ip-up</code> , except that it is executed when the link is available for sending and receiving IPv6 packets. Executed with six command-line arguments: <code>interface-name tty-device speed local-link-local-address remote-link-local-address ipparam</code> . |
| <code>/etc/ppp/ipv6-down</code> | Similar to <code>/etc/ppp/ip-down</code> , but executed when IPv6 packets can no longer be transmitted on the link. Executed with the same parameters as the <code>ipv6-up</code> script. |

Examples EXAMPLE 1 Using the auth Option

The following examples assume that the `/etc/ppp/options` file contains the `auth` option.

EXAMPLE 1 Using the auth Option (Continued)

pppd is commonly used to dial out to an ISP. You can do this using the “pppd call isp” command where the `/etc/ppp/peers/isp` file is set up to contain a line similar to the following:

```
cua/a 19200 crtscts connect '/usr/bin/chat -f /etc/ppp/chat-isp' noauth
```

For this example, [chat\(1M\)](#) is used to dial the ISP's modem and process any login sequence required. The `/etc/ppp/chat-isp` file is used by chat and could contain the following:

```
ABORT "NO CARRIER"
ABORT "NO DIALTONE"
ABORT "ERROR"
ABORT "NO ANSWER"
ABORT "BUSY"
ABORT "Username/Password Incorrect"
"" "at"
OK "at&f&d2&c1"
OK "atdt2468135"
"name:" "^Umyuserid"
"word:" "\qmypassword"
"ispts" "\q^Uppp"
"--^Uppp--"
```

See the [chat\(1M\)](#) man page for details of chat scripts.

EXAMPLE 2 Using pppd with proxyarp

pppd can also provide a dial-in ppp service for users. If the users already have login accounts, the simplest way to set up the ppp service is to let the users log in to their accounts and run pppd as shown in the following example:

```
example% pppd proxyarp
```

EXAMPLE 3 Providing a User with Access to PPP Facilities

To provide a user with access to the PPP facilities, allocate an IP address for the user's machine, create an entry in `/etc/ppp/pap-secrets` or `/etc/ppp/chap-secrets`. This enables the user's machine to authenticate itself. For example, to enable user “Joe” using machine “joespc” to dial in to machine “server” and use the IP address “joespc.my.net,” add the following entry to the `/etc/ppp/pap-secrets` or `/etc/ppp/chap-secrets` files:

```
joespc    server    "joe's secret"    joespc.my.net
```

Alternatively, you can create another username, for example “ppp,” whose login shell is `/usr/bin/pppd` and whose home directory is `/etc/ppp`. If you run pppd this way, add the options to the `/etc/ppp/.ppprc` file.

EXAMPLE 3 Providing a User with Access to PPP Facilities (Continued)

If your serial connection is complex, it may be useful to escape such control characters as XON (^Q) and XOFF (^S), using `asynmap a0000`. If the path includes a telnet, escape ^] (`asynmap 200a0000`). If the path includes a `rlogin` command, add escape `ff` option to the options, because `rlogin` removes the window-size-change sequence [0xff, 0xff, 0x73, 0x73, followed by any 8 bytes] from the stream.

- Exit Status** The `pppd` exit status indicates errors or specifies why a link was terminated. Exit status values are:
- 0 `pppd` has detached or the connection was successfully established and terminated at the peer's request.
 - 1 An immediately fatal error occurred. For example, an essential system call failed.
 - 2 An error was detected in the options given. For example, two mutually exclusive options were used, or `/etc/ppp/options` is missing and the user is not root.
 - 3 `pppd` is not `setuid - root` and the invoking user is not root.
 - 4 The kernel does not support PPP. For example, the PPP kernel driver is not included or cannot be loaded.
 - 5 `pppd` terminated because it was sent a SIGINT, SIGTERM or SIGHUP signal.
 - 6 The serial port could not be locked.
 - 7 The serial port could not be opened.
 - 8 The connect script failed and returned a non-zero exit status.
 - 9 The command specified as the argument to the `pty` option could not be run.
 - 10 The PPP negotiation failed because no network protocols were able to run.
 - 11 The peer system failed or refused to authenticate itself.
 - 12 The link was established successfully, but terminated because it was idle.
 - 13 The link was established successfully, but terminated because the connect time limit was reached.
 - 14 Callback was negotiated and an incoming call should arrive shortly.
 - 15 The link was terminated because the peer is not responding to echo requests.
 - 16 The link was terminated by the modem hanging up.
 - 17 The PPP negotiation failed because serial loopback was detected.
 - 18 The init script failed because a non-zero exit status was returned.
 - 19 Authentication to the peer failed.

| | |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Files /var/run/spppn.pid | Process-ID for pppd process on PPP interface unit <i>n</i> . |
| /var/run/ppp- <i>name</i> .pid | Process-ID for pppd process for logical link name (see the <code>Linkname</code> option). |
| /etc/ppp/pap-secrets | Username, passwords and IP addresses for PAP authentication. This file should be owned by root and not readable or writable by any other user, otherwise pppd will log a warning. |
| /etc/ppp/chap-secrets | Names, secrets and IP addresses for all forms of CHAP authentication. The <code>/etc/ppp/pap-secrets</code> file should be owned by root should not readable or writable by any other user, otherwise, pppd will log a warning. |
| /etc/ppp/options | System default options for pppd, read before user default options or command-line options. |
| \$HOME/.ppprc | User default options, read before <code>/etc/ppp/options.ttyname</code> . |
| /etc/ppp/options.ttyname | System default options for the serial port in use; read after <code>\$HOME/.ppprc</code> . The <code>ttyname</code> component of this filename is formed when the initial <code>/dev/</code> is stripped from the port name (if present), and slashes (if any) are converted to dots. |
| /etc/ppp/peers | Directory with options files that may contain privileged options, even if pppd was invoked by a user other than root. The system administrator can create options files in this directory to permit non-privileged users to dial out without requiring the peer to authenticate, but only to certain trusted peers. |

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|--------------------|
| Availability | system/network/ppp |
| Interface Stability | Committed |

Simpson, W. *RFC 1662, HDLC-like Framing*. Network Working Group. July 1994.

Notes These signals affect pppd behavior:

| | |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SIGINT, SIGTERM | Terminate the link, restore the serial device settings and exit. |
| SIGHUP | Terminate the link, restore the serial device settings and close the serial device. If the <code>persist</code> or <code>demand</code> option is specified, pppd attempts to reopen the serial device and start another connection after the holdoff period. Otherwise pppd exits. If received during the holdoff period, SIGHUP causes pppd to end the holdoff period immediately. |
| SIGUSR1 | Toggles the state of the debug option and prints link status information to the log. |
| SIGUSR2 | Causes pppd to renegotiate compression. This is useful to re-enable compression after it has been disabled as a result of a fatal decompression error. (Fatal decompression errors generally indicate a bug in an implementation.) |

Diagnostics Messages are sent to the syslog daemon using facility LOG_DAEMON. To see error and debug messages, edit the `/etc/syslog.conf` file to direct the messages to the desired output device or file, or use the `updetach` or `logfile` options.

The debug option causes the contents of all LCP, PAP, CHAP or IPCP control packets sent or received to be logged. This is useful if PPP negotiation does not succeed or if authentication fails.

Debugging can also be enabled or disabled by sending a SIGUSR1 signal, which acts as a toggle to the pppd process.

Name pppoe – PPPoE chat utility

Synopsis pppoe [-omillisecs] [-smillisecs] [-v] *device*
 [*service* [[except]*server*... [only]]]

pppoe [-omillisecs] [-v] -i [*device*]

Description The pppoe utility implements the client-side negotiation of PPPoE. It is intended to be used with the pppd(1M) connect option, in the same manner as the chat(1M) utility is used for asynchronous dial-up PPP.

When given with the -i flag, pppoe sends out a broadcast query on the given interface named by the *device* parameter. You can specify no other arguments in this mode. All responding PPPoE servers and the offered services are displayed on standard output.

Otherwise, when given without the -i flag, pppoe does the full PPPoE client-side negotiation. The *device* parameter is the intended Ethernet interface, and must already be plumbed with sppptun(1M). The optional *service* parameter specifies a particular service desired; other offered services will be ignored. The optional *server* parameter specifies a specific server desired. You can specify *server* as an Ethernet address in the usual x:x:x:x:x format (with "*" in any of the six byte positions interpreted to mean "any"), or as a symbolic name resolved through /etc/ethers (or NIS), or as a PPPoE access concentrator name. The sense of the match (true or false) can be inverted by specifying the keyword *except* before this string. This parameter can be specified more than once, and the first match is taken.

If you specify the *server* parameter, then the selected servers become "preferred." If no preferred server responds, then the first responding server is used instead. To exclude non-matching servers entirely, append the keyword *only*.

Options The following options are supported:

- i Sends out broadcast query over interface specified by *device*.
- o Sets the initial wait time in milliseconds for PADO from the server before PADI is retried. The default is 500 milliseconds for normal operation, or 3000 milliseconds (3 seconds) for inquiry (-i) mode.
- s Sets the initial wait time in milliseconds for PADS from the server before PADR is retried. The default is 2000 milliseconds (2 seconds).
- v Displays verbose progress messages, including all PPPoE messages sent, and all state machine transitions.

You normally do not need to adjust the parameters set with -o and -s. They are provided for coping with unusually slow servers.

Operands The following operands are supported:

device plumbed Ethernet interface

server preferred server or, if you specify only, the specified server
service desired service; other available services are ignored

Examples EXAMPLE 1 Connecting to Any Service on hme0

The following command enables you to connect to any PPPoE service on hme0:

```
# /usr/bin/pppd sppptun plugin pppoe.so \  
connect "/usr/lib/inet/pppoe hme0" debug
```

Often, a command such as the preceding is specified in an `/etc/ppp/peers` file instead. For example, enter the following in `/etc/ppp/peers/myisp`:

```
sppptun  
plugin pppoe.so  
connect "/usr/lib/inet/pppoe hme0"  
debug
```

To invoke the PPP connection described in the file, enter:

```
% /usr/bin/pppd call myisp
```

Note that, because the `/etc/ppp/peers` files are considered privileged by `pppd`, you need not be root to invoke the preceding command.

EXAMPLE 2 Connecting to a Particular Service

A more complex example: on hme0, connect to only the internet service offered by PPPoE servers with access concentrator name `isp`, but not to any Ethernet addresses starting with `40:0:1a`.

```
# /usr/lib/inet/pppoe hme0 internet except 40:0:1a:*:* * isp only
```

Note that the `except 40:0:1a:*:* *` filter must come before `isp`, because the filters are first-match.

Exit Status The following exit values are returned:

```
0 Successful completion.  
>0 An error occurred.
```

| | | |
|--------------|--------------------------------------|-----------------------------------------------------------------|
| Files | <code>/usr/lib/inet/pppoe</code> | executable command |
| | <code>/dev/sppptun</code> | Solaris PPP tunneling device driver. |
| | <code>/etc/ppp/connect-errors</code> | usual location of error output (see DIAGNOSTICS , below) |

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|---------------------------|
| Availability | system/network/ppp/tunnel |

See Also [pppd\(1M\)](#), [sppptun\(1M\)](#), [pppoed\(1M\)](#), [sppptun\(7M\)](#)

RFC 2516, Method for Transmitting PPP Over Ethernet (PPPoE), Mamakos et al, February 1999

Diagnostics Error messages are written to standard error, which is normally redirected by `pppd` to `/etc/ppp/connect-errors`. The errors can also be redirected to `pppd`'s standard output by using the `updetach` option.

If you specify the `-v`, verbose progress messages are displayed, including all PPPoE messages sent, and all state machine transitions. Specifying the `updetach` or `nodetach` `pppd` option is helpful when using verbose mode.

Name pppoed – PPPoE server daemon

Synopsis pppoed [*options*]

Description The pppoed daemon implements the server-side negotiation of PPPoE. When a client requests service from this daemon, a copy of [pppd\(1M\)](#) is invoked to handle the actual PPP communication.

At startup, options are read from the command line and the `/etc/ppp/pppoe` file. After these options have been read, options in the per-device `/etc/ppp/pppoe.device` files are read, using the device names specified on the command line or in `/etc/ppp/pppoe`. Device names are not permitted in the per-device files. It is not an error if any of these files are absent; missing files are ignored.

Options are reread in the same order on SIGHUP. Except for the possibility of short delays due to the processing time, SIGHUP does not interfere with any client operations. Current status, including options read, is dumped to `/tmp/pppoed.pid` on SIGINT.

The options are used to set up a list of services to be offered to PPPoE clients on the broadcast domains (Ethernet subnets) specified by the named devices. Option parsing is always in one of two modes, either global mode or service mode. The initial mode at the beginning of each file (and the command line) is global mode. Options specified in global mode serve as default values for subsequently defined services. Service mode is entered by the `service name` option. In this mode, the named option is defined. Options that appear in this mode override any global mode definitions for the current service.

The option parsing follows standard shell tokenizing rules, using whitespace to delimit tokens, quotes to enclose strings that can contain whitespace, and escape sequences for special characters. Environment variables are substituted using familiar `$VAR` and `${VAR}` syntax and set using `NEWVAR=string`. Variables are both usable in subsequent options and provided to the [pppd\(1M\)](#) processes spawned for each client, but they are interpreted as they are encountered during option processing. Thus, all set variables are seen by all processes spawned; position in the configuration files has no effect on this.

Options The pppoed daemon supports the following options:

`client` [*except*] *client-list* This option restricts the clients that may receive the service. If the `except` keyword is given, then the clients on the list cannot access the service, but others can. If this keyword is not given, then only the listed clients can access the service.

This option can be specified more than once for a given service. For a given client, first match among all listed options encountered specifies the handling. If it matches an option with `except` specified, then access is denied. Otherwise, it is granted. The `client` list within a service is prepended to any list specified in the global context.

If no `client` options are given or if all options are specified with `except`, then all clients are permitted by default. If any `client` options without `except` are specified, then no clients are permitted by default.

The *client-list* is a comma-separated list of client identifiers. The match is made if any client on the list matches; thus, these are logically "ORed" together. Each client identifier can be either a symbolic name (resolved through `/etc/ethers` or NIS, as defined by `/etc/nsswitch.conf`) or a hexadecimal Ethernet address in the format `x:x:x:x:x:x`. In the latter case, any byte of the address can be "*", which matches any value in that position. For example, `40:0:1a:*:*` matches Ethernet adapters from the manufacturer assigned block `40:0:1a`.

- `debug` Increase debug logging detail level by one. The detail levels are 0 (no logging), 1 (errors only; the default), 2 (warnings), 3 (informational messages), and 4 (debug messages). Log messages are written by default to `syslog(3C)` using facility *daemon* (see the `log` option below). When specified on the command line or in the global context of the `/etc/ppp/pppoe` file, this option also sets the daemon's default (non-service-related) detail level.
- `device device-list` Specify the devices on which the service is available. The *device-list* is a comma-separated list of logical device names (without the leading `/dev/`), such as `hme0`. This option is ignored if encountered in the per-device `/etc/ppp/pppoe.device` files.
- `extra string` Specifies extra options to `pppd(1M)`. It defaults to "`plugin pppoe.so directtty`" and usually does not need to be overridden.
- `file path` Suspends parsing of the current file, returns to global mode, and reads options from *path*. This file must be present and readable; if it is not, an error is logged. When the end of that file is reached, processing returns to the current file and the mode is reset to global again.

The global mode options specified in files read by this command use the options set in the current file's global mode; this condition extends to any file included by those files. All files read are parsed as though the command line had specified this option, and thus inherit the command line's global modes.

| | |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | This option can be used to revert to global mode at any point in an option file by specifying <code>file /dev/null</code> . |
| <code>group name</code> | Specifies the group ID (symbolic or numeric) under which <code>pppd</code> is executed. If <code>pppoed</code> is not run as root, this option is ignored. |
| <code>log path</code> | Specifies an alternate debug logging file. Debug messages are sent to this file instead of <code>syslog</code> . The special name <code>syslog</code> is recognized to switch logging back to <code>syslog</code> . When specified on the command line or in the global context of the <code>/etc/ppp/pppoe</code> file, this option also sets the daemon's default (non-service-related) log file. |
| <code>nodebug</code> | Set debug logging detail level to 0 (no logging). When specified on the command line or in the global context of the <code>/etc/ppp/pppoe</code> file, this option also sets the daemon's default (non-service-related) detail level. |
| <code>nowildcard</code> | Specifies that the current service should not be included in response to clients requesting "any" service. The client must ask for this service by name. When specified on the command line or in the global context of the <code>/etc/ppp/pppoe</code> file, this option causes <code>pppoed</code> to ignore all wildcard service requests. |
| <code>path path</code> | Specifies the path to the <code>pppd</code> executable. Defaults to <code>/usr/bin/pppd</code> . |
| <code>pppd string</code> | Passes command-line arguments to <code>pppd</code> . It can be used to set the IP addresses or configure security for the session. The default value is the empty string. |
| <code>server string</code> | Specifies the PPPoE Access Concentrator name to be sent to the client. It defaults to "Solaris PPPoE". |
| <code>service name</code> | Closes any service being defined and begins definition of a new service. The same service name can be used without conflict on multiple devices. If the same service name is used on a single device, then the last definition encountered during parsing overrides all previous definitions. |
| <code>user name</code> | Specifies the user ID, symbolic or numeric, under which <code>pppd</code> is executed. If <code>pppoed</code> is not run as root, this option is ignored. |
| <code>wildcard</code> | Specifies that the service should be included in responses to client queries that request "any" service, which is done by requesting a service name of length zero. When specified on the command line or in the global context of the |

/etc/ppp/pppoe file, this option causes pppoed to ignore all wildcard service requests. This is the default.

Examples EXAMPLE 1 Configuring for Particular Services

In the /etc/ppp/pppoe file:

```
service internet
    device $DEV
    pppd "proxyarp 192.168.1.1:"
service debugging
    device hme0,$DEV
    pppd "debug proxyarp 192.168.1.1:"
```

You then invoke the daemon with:

```
example% /usr/lib/inet/pppoed DEV=eri0
```

The lines in /etc/ppp/pppoe and the preceding command result in offering services "internet" and "debugging" (and responding to wildcard queries) on interface eri0, and offering only service "debugging" on interface hme0.

Signals The pppoed daemon responds to the following signals:

SIGHUP Causes pppoed to reparse the original command line and all configuration files, and close and reopen any log files.

SIGINT Causes a snapshot of the state of the pppoed daemon to be written to /tmp/pppoed.*pid* (where *pid* is the decimal process ID of the daemon).

Files

| | |
|-------------------------------|------------------------------------------------------------|
| /usr/lib/inet/pppoed | executable command |
| /dev/spptun | Solaris PPP tunneling device driver |
| /etc/ppp/pppoe | main configuration option file |
| /etc/ppp/pppoe. <i>device</i> | per-device configuration option file |
| /etc/ppp/pppoe-errors | location of output from pppd's stderr |
| /etc/ppp/pppoe.if | list of Ethernet interfaces to be plumbed at boot time |
| /tmp/pppoed. <i>pid</i> | ASCII text file containing dumped pppoed state information |

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|---------------------------|
| Availability | system/network/ppp/tunnel |

See Also [pppd\(1M\)](#), [pppoec\(1M\)](#), [sppptun\(1M\)](#), [sppptun\(7M\)](#)

Mamakos, L., et al. *RFC 2516, A Method for Transmitting PPP Over Ethernet (PPPoE)*. Network Working Group. February 1999

Notes Because `pppd` is installed setuid root, this daemon need not be run as root. However, if it is not run as root, the `user` and `group` options are ignored.

The Ethernet interfaces to be used must be plumbed for PPPoE using the [sppptun\(1M\)](#) utility before services can be offered.

The daemon operate runs even if there are no services to offer. If you want to modify a configuration, it is not necessary to terminate the daemon. Simply use `kill -HUP pppoed` after updating the configuration files.

The PPPoE protocol is far from perfect. Because it runs directly over Ethernet, there is no possibility of security and the MTU is limited to 1492 (violating RFC 1661's default value of 1500). It is also not possible to run the client and the server of a given session on a single machine with a single Ethernet interface for testing purposes. The client and server portions of a single session must be run on separate Ethernet interfaces with different MAC addresses.

Name pppstats – print PPP statistics

Synopsis pppstats [-a] [-v] [-r] [-z] [-c <count>] [-w <secs>]
[*interface*]

Description The pppstats utility reports PPP-related statistics at regular intervals for the specified PPP interface. If the interface is unspecified, pppstats defaults to sppp0. The display is split horizontally into input and output sections containing columns of statistics describing the properties and volume of packets received and transmitted by the interface.

Options The pppstats options are:

- a Display absolute values rather than deltas. With this option, all reports show statistics for the time elapsed since the link was initiated. Without this option, the second and subsequent reports show statistics for the time since the last report.
- c *count* Repeat the display *count* times. If this option is not specified, the default repeat count is 1 if the -w option is not specified, otherwise infinity.
- r Display additional statistics summarizing the compression ratio achieved by the packet compression algorithm in use.
- v Display additional statistics relating to the performance of the Van Jacobson TCP header compression algorithm.
- w *wait* Pause *wait* seconds between each display. If this option is not specified, the default interval is five seconds.
- z Instead of the standard display, show statistics indicating the performance of the packet compression algorithm in use.

Extended Description The following fields are printed on the input side when the -z option is not used:

- IN Total number of bytes received by this interface.
- PACK Total number of packets received by this interface.
- VJCOMP Number of header-compressed TCP packets received by this interface.
- VJUNC Number of header-uncompressed TCP packets received by this interface. Not reported when the -r option is specified.
- VJERR Number of corrupted or bogus header-compressed TCP packets received by this interface. Not reported when the -r option is specified.
- VJT0SS Number of VJ header-compressed TCP packets dropped on reception by this interface because of preceding errors. Only reported when the -v option is specified.
- NON-VJ Total number of non-TCP packets received by this interface. Only reported when the -v option is specified.

| | |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RATIO | Compression ratio achieved for received packets by the packet compression scheme in use, defined as the uncompressed size divided by the compressed size. Only reported when the - r option is specified. |
| UBYTE | Total number of bytes received, after decompression of compressed packets. Only reported when the - r option is specified. |

The following fields are printed on the output side:

| | |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OUT | Total number of bytes transmitted from this interface. |
| PACK | Total number of packets transmitted from this interface. |
| VJCOMP | Number of TCP packets transmitted from this interface with VJ-compressed TCP headers. |
| VJUNC | Number of TCP packets transmitted from this interface with VJ-uncompressed TCP headers. Not reported when the - r option is specified. |
| NON-VJ | Total number of non-TCP packets transmitted from this interface. Not reported when the - r option is specified. |
| VJSRCH | Number of searches for the cached header entry for a VJ header compressed TCP packet. Only reported when the - v option is specified. |
| VJMISS | Number of failed searches for the cached header entry for a VJ header compressed TCP packet. Only reported when the - v option is specified. |
| RATIO | Compression ratio achieved for transmitted packets by the packet compression scheme in use, defined as the size before compression divided by the compressed size. Only reported when the - r option is specified. |
| UBYTE | Total number of bytes to be transmitted before packet compression is applied. Only reported when the - r option is specified. |

When the - z option is specified, pppstats displays the following fields relating to the packet compression algorithm currently in use. If packet compression is not in use, these fields display zeroes. The fields displayed on the input side are:

| | |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| COMPRESSED BYTE | Number of bytes of compressed packets received. |
| COMPRESSED PACK | Number of compressed packets received. |
| INCOMPRESSIBLE BYTE | Number of bytes of incompressible packets (that is, those which were transmitted in uncompressed form) received. |
| INCOMPRESSIBLE PACK | Number of incompressible packets received. |
| COMP RATIO | Recent compression ratio for incoming packets, defined as the uncompressed size divided by the compressed size (including both compressible and incompressible packets). |

The fields displayed on the output side are:

| | |
|---------------------|----------------------------------------------------------------------------------------------------------------------------|
| COMPRESSED BYTE | Number of bytes of compressed packets transmitted. |
| COMPRESSED PACK | Number of compressed packets transmitted. |
| INCOMPRESSIBLE BYTE | Number of bytes of incompressible packets received; that is, those that were transmitted by the peer in uncompressed form. |
| INCOMPRESSIBLE PACK | Number of incompressible packets transmitted. |
| COMP RATIO | Recent compression ratio for outgoing packets. |

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------------|--------------------|
| Availability | system/network/ppp |
| Interface Stability | Committed |

See Also [pppd\(1M\)](#), [attributes\(5\)](#)

Name pprosetup – setup program for Patch Manager

Synopsis /usr/sbin/pprosetup [-a *admin-email-addr*] [-b *backout-dir*]
 [-c *config-name*] [-C] [-d *patch-dir*]
 [[-D | -M *day-of-month* | -W *day-of-week*] [-s *hh:mm*]]
 [-h] [-H] [-i [none | *patch-property-list*]] [-L]
 [-p [none | standard]] [-P *patch-source-url*]
 [-q *sequester-dir*] [-u *user-name*]
 [-U *proxy-user-name*] [-x [*host:port*]]

Description **Note** – This command is deprecated. Use the `smpatch set`, `smpatch unset`, and `smpatch get` commands instead. See the [smpatch\(1M\)](#) man page.

Use the `pprosetup` command, as superuser, to configure your patch management environment by doing the following:

- Scheduling the patch operations
- Setting a patch policy
- Specifying patch directories
- Specifying the hardware on the system
- Specifying alternate configurations

Scheduling the Patch Operations

Schedule the automatic synchronization of patches with Sun's patch base. This scheduling makes the `pprosv` command run in *automatic mode*. This mode is set up by using the `cron` interface. Use the `-C`, `-D`, `-M`, `-s`, and `-W` options to perform the scheduling tasks.

If you do not want to schedule patch operations, you can run the `pprosv` and `smpatch` commands in *manual mode*, which means running the tool from the command line.

Note that midnight is represented as 00:00.

Note – The `smpatch` command does not directly support this mechanism for scheduling patch operations. You can set up a schedule by using `cron` to run `smpatch` in local mode. See the [smpatch\(1M\)](#) man page.

Setting a Patch Policy

Patches are classified as being standard or nonstandard. A *standard patch* can be applied by `pprosv` in automatic mode. Such a patch is associated with the `standard` patch property. A *nonstandard patch* is one that has one of the following characteristics:

- A patch that is associated with the `rebootafter`, `rebootimmediate`, `reconfigafter`, `reconfigimmediate`, or `singleuser` properties. This nonstandard patch can be applied by running the `pprosv` command or the `smpatch` command in manual mode.
- A patch that is associated with the `interactive` property. Such a patch cannot be applied by using the `smpatch` command.

Use `pprosetup` to schedule patch operations to run in *automatic mode*. Patches are applied based on the policy, which you can set by running `pprosetup`.

Use `pprosetup -p` to specify the types of patches to apply in automatic mode. You can set a policy to apply no patches (`none`) or standard patches (`standard`).

Use `pprosetup -i` to specify the types of patches to apply in *manual* mode. Such patches might include those that require a reboot and those that must be applied while the system is in single-user mode. Specify the types of patches that can be applied by using the following command:

```
# pprosetup -i patch-property-list
```

patch-property-list is a colon-separated list of one or more of the following patch properties:

| | |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>interactive</code> | A patch that cannot be applied by running the usual patch management tools (<code>pprosv</code> or <code>smpatch</code>). Before this patch is applied, the user must perform special actions. Such actions might include checking the serial number of a disk drive, stopping a critical daemon, or reading the patch's README file. |
| <code>rebootafter</code> | The effects of this patch are not visible until after the system is rebooted. |
| <code>rebootimmediate</code> | When this patch is applied, the system becomes unstable until the system is rebooted. An unstable system is one in which the behavior is unpredictable and data might be lost. |
| <code>reconfigafter</code> | The effects of this patch are not visible until after a reconfiguration reboot (<code>boot -r</code>). See the boot(1M) man page. |
| <code>reconfigimmediate</code> | When this patch is applied, the system becomes unstable until the system gets a reconfiguration reboot (<code>boot -r</code>). An unstable system is one in which the behavior is unpredictable and data might be lost. |
| <code>singleuser</code> | Do not apply this patch while the system is in multiuser mode. You must apply this patch on a quiet system with no network traffic and with extremely restricted I/O activity. |
| <code>standard</code> | This patch can be applied while the system is in multiuser mode. The effects of the patch are visible as soon as it is applied unless the application being patched is running while the patch is applied. In this case, the effects of the patch are visible after the affected application is restarted. |

Note – The `smpatch` command only supports the patch policy for manual mode.

Specifying Patch Directories

Use the following options to specify the directories in which to store patch-related data:

- Use the `-b` option to specify the directory in which to store backout data. During a patch backout operation, the data is retrieved from this directory to restore the system to its state prior to applying the patch.
- Use the `-d` option to specify the download directory in which to store patches that are downloaded from the Sun patch server. This directory is also the location from which patches are applied.

- Use the `-q` option to specify the directory in which to store patches that cannot be applied automatically. Such patches are called *sequestered patches*.

Note – The `sequester` directory is not used by the `smpatch` command.

Specifying the Hardware on the System

Use the `-H` option to run a program that helps you determine the hardware that is attached to the host system, such as firmware, disk array systems, and tape storage systems.

Use this option to select the hardware that applies to this system. Select the sequence number of the specific hardware. A confirmation page lists the selections.

Save the specified hardware configuration information to a file. Then, the system responds by performing the appropriate actions.

Note – The `smpatch` command does not support this feature for specifying hardware on your system.

Specifying Alternate Configurations

The `pprosetup` command uses a configuration file to specify the collection of patches with which to perform patch operations. By default, all of the patches from the Sun patch server are available for patch operations.

The `-c` option enables you to specify an alternate configuration.

Sun currently provides one alternate configuration, which is called the recommended configuration. This configuration includes only those patches that have been declared significant. Such patches include security patches and patches that address known performance and availability problems.

You can use the `-c recommended` option when you schedule patch operations. For example, the following command schedules monthly patch operations that use the recommended configuration:

```
# pprosetup -c recommended -M 15 -s 23:30
```

To cancel a schedule that uses the recommended configuration, type:

```
# pprosetup -c recommended -C
```

You are permitted to modify the recommended configuration by using the `-c` option. See **EXAMPLES**.

Note – The `smpatch` command does not support this feature for specifying alternate configurations.

Options The following options are supported:

| | |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>-a admin-email-addr</code> | Is the email address of the patch administrator. Email notification is sent to describe the patches downloaded, the |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------|

patches applied, and any error events that occurred when running the `pprosv -i -n` command.

Note – This option does not affect the `smpatch` command.

`-b backout-dir`

Stores backout data in the specified directory.

The backout data is used whenever you use the `patchrm` command to remove a patch that has already been applied to your system. The data is used to restore a system to the state it was in before you applied a particular patch. Since backout data might be quite large, store the data in a large partition that holds large transitory data. Such a partition might be `/var`.

If you do not specify the `-b` option, the backout data is stored in the default locations used by `patchadd`. These locations are the `save` directories of the packages that were modified by the patch. For example, if a patch modifies the `SUNWcsr` package, the backout data for that package is stored in the `/var/sadm/pkg/SUNWcsr/save` directory.

To specify the backout directory, use the `smpatch set` command to set the `patchpro.backout.directory` parameter.

Note – The root file system of any non-global zones must not be referenced with the `-b` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).

`-C`

Clears the existing patch service schedule.

Note – This feature is not supported by the `smpatch` command.

`-c config-name`

Uses the `config-name` configuration for patch operations. When this option is included in any `pprosetup` command, the entire command applies to the specified configuration.

Note – This feature is not supported by the `smpatch` command.

`-d patch-dir`

Is the directory in which to download the patches that are appropriate for this host system. This directory is also the

- location from which patches are applied. By default, the download directory is `/var/sadm/spool`.
- Note** – To specify the download directory, use the `smatch set` command to set the `patchpro.download.directory` parameter.
- D Schedules the automatic analysis, download, and optional application of patches on a daily basis. This option is equivalent to executing the `pprosv -i -n` command on a daily basis. See the [crontab\(1\)](#) man page.
- The policy defined by the `-p` option determines whether no patches (`pprosetup -p none`) are applied or whether standard patches (`pprosetup -p standard`) are applied. By default, no patches are applied.
- This option is mutually exclusive with the `-M` option and the `-W` option.
- Note** – This feature is not supported by the `smatch` command.
- h Displays information about command-line options.
- H Establishes a dialog with the user to determine what hardware is attached to the host system.
- Note** – This feature is not supported by the `smatch` command.
- i [`none` | *patch-property-list*] Specifies the policy for applying patches in manual mode.
- No patches are applied when `none` is specified. *patch-property-list* is a colon-separated list of one or more of the following patch properties: `interactive`, `rebootafter`, `rebootimmediate`, `reconfigafter`, `reconfigimmediate`, `singleuser`, and `standard`. See [Setting a Patch Policy](#).
- Note** – To specify the patch policy, use the `smatch set` command to set the `patchpro.install.types` parameter.
- L Displays the configuration parameter settings of your patch management environment.
- This option is mutually exclusive with the other options.

| | |
|-----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | <p>Note – To view the configuration parameter settings, use the <code>smpatch get</code> command.</p> |
| <code>-M <i>day-of-month</i></code> | <p>Schedules the automatic analysis, download, and optional application of patches on a monthly basis.</p> <p>The policy defined by the <code>-p</code> option determines whether no patches (<code>pprosetup -p none</code>) are applied or whether standard patches (<code>pprosetup -p standard</code>) are applied. By default, no patches are applied.</p> <p><i>day-of-month</i> is a numerical value from 1-28, which represents the day of the month. Note that the values 29, 30, and 31 are invalid. See the crontab(1) man page.</p> <p>This option is mutually exclusive with the <code>-D</code> option and the <code>-W</code> option.</p> <p>Note – This feature is not supported by the <code>smpatch</code> command.</p> |
| <code>-p [none standard]</code> | <p>Specifies the policy for applying patches in automatic mode.</p> <p>No patches are applied when <code>none</code>, the default, is specified.</p> <p>When <code>standard</code> is specified, only standard patches are applied.</p> <p>Note – This feature is not supported by the <code>smpatch</code> command.</p> |
| <code>-P <i>patch-source-url</i></code> | <p>Is the URL that points to the collection of patches. The default is the Sun patch server, which has the following URL:</p> <pre>https://updateserver.sun.com/solaris/</pre> <p>Note – To specify the URL that points to the collection of patches, use the <code>smpatch set</code> command to set the <code>patchpro.patch.source</code> parameter.</p> |
| <code>-q <i>sequester-dir</i></code> | <p>Is the directory in which patches are moved if they cannot be automatically applied. By default, the sequester directory is <code>/var/sadm/spool/patchproSequester</code>.</p> <p>Note – The sequester directory is not used by the <code>smpatch</code> command.</p> |

-
- s *hh:mm*** Optionally sets the time of day to perform patch operations, which by default, is midnight local time.
- hh* is a value from 00-23, which specifies the hour. *mm* is a value from 00-59, which specifies the minute.
- Use this option with the **-D**, **-M**, and **-W** options.
- Note** – This feature is not supported by the `smpatch` command.
- u *user-name*** Is the user name with which to obtain contract patches from Sun.
- Store the corresponding SunSpectrum user's password in the `lib/.sunolvepw` file. If PatchPro is installed in the default location, this file is in the `/opt/SUNWppro` directory.
- Keep the password safe by setting the owner, group, and permissions to `root`, `sys`, and `0600`, respectively.
- Note** – This file method of supplying passwords is no longer supported.
- Note** – To specify this user, use the `smpatch set` command to set the `patchpro.sun.user` parameter. Also, specify this user's password by setting the `patchpro.sun.passwd` parameter.
- U *proxy-user-name*** Is the user name required for authentication of the web proxy, if applicable.
- Store the corresponding user's password in the `lib/.proxypw` file. If PatchPro is installed in the default location, this file is in the `/opt/SUNWppro` directory.
- Keep the password safe by setting the owner, group, and permissions to `root`, `sys`, and `0600`, respectively.
- Note** – This file method of supplying passwords is no longer supported.
- Note** – To specify this user, use the `smpatch set` command to set the `patchpro.proxy.user` parameter. Also, specify this user's password by setting the `patchpro.proxy.passwd` parameter.

`-W day-of-week`

Schedules the automatic analysis, download, and optional application of patches on a weekly basis.

day-of-week is a numerical value from 0-6, which represents the day of the week. 0 represents Sunday. See the [crontab\(1\)](#) man page.

The policy defined by the `-p` option determines whether no patches (`pprosetup -p none`) are applied or whether standard patches (`pprosetup -p standard`) are applied. By default, no patches are applied.

This option is mutually exclusive with the `-D` option and the `-M` option.

Note – This feature is not supported by the `smpatch` command.

`-x [host:port]`

Specifies the web proxy. If your system is behind a firewall, use this option to specify your web proxy. Get the name of the web proxy and its port from your system administrator or network administrator.

Note – To specify the web proxy host name and port, use the `smpatch set` command to set the `patchpro.proxy.host` and `patchpro.proxy.port` parameters, respectively.

Examples EXAMPLE 1 Scheduling Daily Patch Operations in Automatic Mode

```
# pprosetup -D
```

Schedules `smpatch update` to run in automatic mode daily at midnight local time.

EXAMPLE 2 Scheduling Weekly Patch Operations in Automatic Mode

```
# pprosetup -W 0 -s 00:45
```

Schedules `smpatch update` to run in automatic mode every Sunday at 12:45 a.m. local time.

EXAMPLE 3 Scheduling Monthly Patch Operations in Automatic Mode

```
# pprosetup -M 15 -s 02:30
```

Schedules `smpatch update` to run in automatic mode on the 15th day of every month at 2:30 a.m. local time.

EXAMPLE 4 Canceling Scheduled Jobs

```
# pprosetup -C
```

Cancels the scheduled jobs that use the default configuration.

EXAMPLE 5 Specifying the Patch Policy for Manual Mode

```
# pprosetup -i standard:singleuser:reconfigafter:rebootafter
```

Specifies the policy for applying patches in manual mode. This policy permits you to apply the following types of patches to your system in manual mode:

- Standard patches
- Patches that must be applied in single-user mode
- Patches that require that the system undergo a reconfiguration reboot after they have been applied
- Patches that require that the system undergo a reboot after they have been applied

EXAMPLE 6 Specifying the Patch Policy for Automatic Mode

```
# pprosetup -p none
```

Specifies that no patches are automatically applied.

```
# pprosetup -p standard
```

Specifies that *only* standard patches can be downloaded and applied.

EXAMPLE 7 Specifying an Alternate Download Directory

```
# pprosetup -d /export/home/patches
```

Specifies that patches are downloaded to the /export/home/patches directory.

EXAMPLE 8 Specifying an Alternate Sequester Directory

```
# pprosetup -q /export/home/patches/sequester
```

Specifies that sequestered patches are stored in the /export/home/patches/sequester directory.

EXAMPLE 9 Identifying the Hardware on Your System

```
# pprosetup -H
```

Enables a patch analysis to determine whether your system needs specific patches based on your hardware configuration. This command only helps you identify hardware products from Sun Network Storage.

EXAMPLE 10 Configuring Your System to Obtain Contract Patches

```
# pprosetup -u myuser
# echo mypasswd > /opt/SUNWppro/lib/.sunsolvepw
```

Enables your contract user, `myuser`, to obtain the contract patches.

Ensure that the contract user's password is safe by setting the owner, group, and permissions of the `.sunsolvepw` file to `root`, `sys`, and `0600`, respectively.

EXAMPLE 11 Specifying a Web Proxy

```
# pprosetup -x webaccess.corp.net.com:8080
```

Specifies the host name, `webaccess.corp.net.com`, and port, `8080`, of the web proxy to use.

EXAMPLE 12 Scheduling Daily Patch Operations to Use the recommended Configuration

```
# pprosetup -c recommended -D -s 23:00
```

Schedules a daily patch analysis that uses the recommended configuration. You can use the alternate configuration in conjunction with or in place of a full analysis.

```
# pprosetup -c recommended -C
```

Cancels this job that uses the recommended configuration.

EXAMPLE 13 Modifying the recommended Configuration

```
# pprosetup -c recommended -a recommended@local
```

Modifies the recommended configuration to send email notifications to the `recommended@local` email alias about each scheduled analysis that uses the recommended cluster. Any scheduled operation that uses the recommended configuration will send notification to the alias you specify.

EXAMPLE 14 Creating a New Configuration

```
# pprosetup -c export -d /export/patches
```

Creates a new configuration named `export` that downloads patches to the `/export/patches` directory. After executing this command, you can schedule patch operations or manually run patch operations that use the `export` configuration by running the `pprosetup` or `pprosvc` commands, respectively.

```
# pprosvc -c export -d
```

Downloads patches to the download directory specified by the `export` configuration.

Attributes See the [attributes\(5\)](#) man page for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWppro |
| Interface Stability | Obsolete |

See Also [crontab\(1\)](#), [boot\(1M\)](#), [pprosv\(1M\)](#), [smpatch\(1M\)](#), [attributes\(5\)](#)

Name pprosv – automation service program for Patch Manager

Synopsis /usr/sbin/pprosv [-c *config-name*]
 [-d [-p *patch-id* [,*patch-id*]...]] [-h]
 [-i [-n] [-p *patch-id* [,*patch-id*]...]] [-l]

Description **Note** – This command is deprecated. Use the `smpatch analyze`, `smpatch download`, and `smpatch update` commands instead. See the [smpatch\(1M\)](#) man page.

Use the `pprosv` command to analyze a system to determine the list of appropriate patches, download the patches, and apply them. This command invokes patch operations in response to a user request or at a scheduled time. You must run this command as superuser.

The `pprosv` command enables you to do the following:

- Analyze the host system for appropriate patches based on an established configuration
- Generate the list of appropriate patches
- Download the patches to your host system from the Sun patch server
- Apply the patches based on a patch policy

Use the `pprosv -i` command to analyze a system, download the appropriate patches, and apply them. If analysis determines that patches are needed, the `pprosv` command downloads them and applies them.

Specify other options to automate a subset of the patch management tasks. If you specify the `-d` option, your system is analyzed and the appropriate patches are downloaded to your system. If you specify the `-l` option, your system is analyzed and the appropriate patches are listed.

The list of patches that is generated by the analysis is based on all of the available patches from the Sun patch server. No explicit information about your host system or its network configuration is transmitted to Sun. Only a request for the Sun patch set is transmitted. The patch set is scanned for patches that are appropriate for this host system, the results are displayed, and those patches are optionally downloaded.

The `-d`, `-i`, and `-l` options are mutually exclusive.

Use the `-p` option to specify the patches on which to operate. You can use the `-p` option with the `-d` and `-i` options.

Options The following options are supported:

`-c config-name` Uses an alternate configuration for the current patch operation. Use the `pprosetup` command to create new configurations.

A configuration named `recommended` is included. For more information, see “Specifying Alternate Configurations” in the [pprosetup\(1M\)](#) man page.

- Note** – This feature is not supported by the `smpatch` command.
- d** Downloads the patches that are appropriate for this host system. The patches are downloaded to the designated download directory.
- This option generates a list of appropriate patches, as does the `-l` option. However, instead of just displaying the list of patches, the `-d` option displays and downloads the patches from the Sun patch server. The patches are downloaded using a secure connection, and all patches are authenticated using digital signature technology. Only patches that are signed with a Sun digital signature are stored in your download directory.
- Note** – Specifying this option is equivalent to running the `smpatch download` command.
- h** Displays information about the command-line options.
- i** Applies the patches based on the patch policy. This option analyzes your system to generate a list of appropriate patches. If analysis determines that patches are needed, the patches are downloaded and applied. If no patches are permitted to be applied in *automatic* mode (by running `pprosetup -p none`), this option is identical to specifying the `-d` option.
- If only standard patches are permitted to be applied in automatic mode (by running `pprosetup -p standard`), all standard patches are applied.
- Note** – Specifying this option is equivalent to running the `smpatch update` command.
- l** Generates a list of the patches that are appropriate for this host system.
- Note** – Specifying this option is equivalent to running the `smpatch analyze` command.
- n** Runs `pprosv` in *automatic mode*. The command that the cron job specifies is `pprosv -i -n`. To schedule patch operations to run in automatic mode, see the [pprosetup\(1M\)](#) man page.
- In automatic mode, the patch administrator (specified by the `-a` option) receives email notifications that describe the patches you downloaded and applied, and any error events that occurred.

Do not use this option on the command line.

Standard patches do not require any special actions on the part of the user. Such patches can be applied by using the `patchadd` command and do not need the host system to reboot for the patch to take effect.

All nonstandard patches are moved to the sequester directory if you use the `-n` option to run in automatic mode. If you run in manual mode, however, nonstandard patches that have properties that match the policy specified by `pprosetup -i` are applied. The rest of the nonstandard patches are moved to the sequester directory. You can apply patches from this directory at a later time. Patches, whether standard or nonstandard, that depend on sequestered patches are not applied under any circumstances. Such patches are placed in the sequester directory.

For any patch that is placed in the sequester directory, refer to the patch's README file to determine how to apply it to your system.

Note – This feature is not supported by the `smatch` command.

`-p [patch-id[,patch-id,...]]`

Designates the specific patches on which to operate. Use this option with the `-d` option or the `-i` option. The list of patch IDs must be separated by commas.

The specified patches are adjusted to use the current versions based on the patch baseline. Patches that are required by the specified patches are added to the complete list of patches to be applied.

Note – Specifying this option is equivalent to specifying the `-i` option to the `smatch analyze`, `smatch download`, and `smatch update` commands.

Examples EXAMPLE 1 Applying Specific Patches in Manual Mode

```
# pprosv -i -p 102893-01,106895-09,106527-05
```

Applies patches 102893-01, 106895-09, and 106527-05 to the local system in manual mode.

EXAMPLE 2 Analyzing a System and Downloading Appropriate Patches

```
# pprosv -i
```

EXAMPLE 2 Analyzing a System and Downloading Appropriate Patches *(Continued)*

Performs an analysis of the current system and downloads the appropriate patches based on all the patches from the Sun patch server. The resulting list of patches can be very long.

EXAMPLE 3 Applying Patches From the Recommended Configuration

```
# pprosv -c recommended -i
```

Uses the recommended configuration to perform an analysis of the current system and downloads the appropriate patches. Standard patches and those needed from the recommended configuration are applied to the system based on the established patch policy. For information about setting the patch policy for manual mode, see the description of the `-i` option on the [pprosetup\(1M\)](#) man page.

Attributes See the [attributes\(5\)](#) man page for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWppro |
| Interface Stability | Obsolete |

See Also [pprosetup\(1M\)](#), [smc\(1M\)](#), [smpatch\(1M\)](#), [attributes\(5\)](#)

Name praudit – print contents of an audit trail file

Synopsis praudit [-lrsx] [-ddel] [filename]...

Description praudit reads the listed *filenames* (or standard input, if no *filename* is specified) and interprets the data as audit trail records as defined in [audit.log\(4\)](#). By default, times, user and group IDs (UIDs and GIDs, respectively) are converted to their ASCII representation. Record type and event fields are converted to their ASCII representation. A maximum of 100 audit files can be specified on the command line.

Options The following options are supported:

-ddel

Use *del* as the field delimiter instead of the default delimiter, which is the comma. If *del* has special meaning for the shell, it must be quoted. The maximum size of a delimiter is three characters. The delimiter is not meaningful and is not used when the -x option is specified.

-l

Print one line per record.

-r

Print records in their raw form. Times, UIDs, GIDs, record types, and events are displayed as integers. This option is useful when naming services are offline. The -r option and the -s option are exclusive. If both are used, a format usage error message is output.

-s

Display records in their short form. Numeric fields' ASCII equivalents are looked up by means of the sources specified in the `/etc/nsswitch.conf` file (see [nsswitch.conf\(4\)](#)). All numeric fields are converted to ASCII and then displayed. The short ASCII representations for the record type and event fields are used. This option and the -r option are exclusive. If both are used, a format usage error message is output.

-x

Print records in XML form. Tags are included in the output to identify tokens and fields within tokens. Output begins with a valid XML prolog, which includes identification of the DTD which can be used to parse the XML.

Files `/etc/security/audit_event`
Audit event definition and class mappings.

`/etc/security/audit_class`
Audit class definitions.

`/usr/share/lib/xml/dtd`
Directory containing the versioned DTD file referenced in XML output, for example, `adt_record.dtd.1`.

`/usr/share/lib/xml/style`
Directory containing the versioned XSL file referenced in XML output, for example, `adt_record.xsl.1`.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | See below |

The command stability is evolving. The output format is unstable.

See Also [getent\(1M\)](#), [audit\(2\)](#), [getauditflags\(3BSM\)](#), [getpwuid\(3C\)](#), [gethostbyaddr\(3NSL\)](#), [ethers\(3SOCKET\)](#), [getipnodebyaddr\(3SOCKET\)](#), [audit.log\(4\)](#), [audit_class\(4\)](#), [audit_event\(4\)](#), [group\(4\)](#), [nsswitch.conf\(4\)](#), [passwd\(4\)](#), [attributes\(5\)](#)

See the section on Solaris Auditing in *System Administration Guide: Security Services*.

Notes This functionality is available only if the Solaris Auditing feature has been enabled.

Name printmgr – Solaris Print Manager is a graphical user interface for managing printers in a network

Synopsis /usr/sadm/admin/bin/printmgr

Description Solaris Print Manager is a Java-based graphical user interface that enables you to manage local and remote printer access. This tool can be used in the following name service environments: LDAP, NIS, and files. You must be logged in as superuser to use this tool.

Using Solaris Printer Manager is the preferred method for managing printer access because Solaris Print Manager centralizes printer information when it is used in a name service environment.

Adding printer information to a name service makes access to printers available to all systems on the network and generally makes printer administration easier because all the information about printers is centralized.

Solaris Print Manager may be run on a remote system with the display sent to the local system. See the *System Administration Guide: Printing* for instructions on setting the DISPLAY environment variable.

Using Solaris Print Manager to perform printer-related tasks automatically updates the appropriate printer databases. Solaris Print Manager also includes a command-line console that displays the lp command line for the add, modify, and delete printer operations. Errors and warnings may also be displayed when Printer Manager operations are performed.

Help is available by clicking the Help button.

Usage Solaris Print Manager enables you to do the following tasks:

| | |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| Select a Name Service | Select a name service for retrieving or changing printer information. |
| Add Access to a Printer | Add printer access on a printer client using Solaris Print Manager. |
| Add an Attached Printer | After physically attaching the printer to a system, use Solaris Print Manager to install a local printer and make it available for printing. |
| Add a Network Printer | After physically attaching the printer to a system, use Solaris Print Manager to install a local printer and make it available for printing. |
| Modify Printer Properties | After adding access to a printer or adding an attached or network printer, you can modify certain printer attributes. |
| Delete a Printer | Delete access to a printer from the print client or delete a printer from the print server or from the name service environment. |

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-------------------------------|
| Availability | print/lp/print-manager/legacy |

See Also [ldap\(1\)](#), [lpget\(1M\)](#), [lpset\(1M\)](#), [attributes\(5\)](#)

System Administration Guide: Printing for information on LDAP server replication.

Although users can use the LDAP command line utilities [ldapadd\(1\)](#) and [ldapmodify\(1\)](#) to update printer entries in the directory, the preferred method is to use [lpset](#). Otherwise, if the [lpadd](#) and [lpmodify](#) utilities are used, the administrator must ensure that the `printer-name` attribute value is unique within the `ou=printers` container on the LDAP server. If the value is not unique, the result of modifications done using [lpset](#) or the Solaris Print Manager, [printmgr](#) may be unpredictable.

Name print-service – select, report, import, export active print service on a system

Synopsis print-service [-s *service* [-m] | -q | -e *file* | -i *file*]

Description The print-service utility manages print service selection, as well as export and import of basic print queue configuration.

Only a user root privileges or with the Printer Management profile can change the active print service or import print queue configuration.

Options The following options are supported:

-s *service*

Select the active print service for on a host. *service* can be one of lp or cups.

-m

Migrate print queue configuration during print service selection.

-q

Report the active print service on a host.

-e *file*

Export basic print queue configuration to a file.

-i *file*

Import basic print queue configuration from a file.

Examples EXAMPLE 1 Selecting a Print Service

The following command selects the CUPS print service as the active print service on a host.

```
# print-service -s cups
```

EXAMPLE 2 Reporting the Active Print Service

The following command reports the active print service on a host.

```
# print-service -q
```

EXAMPLE 3 Exporting a Print Queue Configuration

The following command exports the print queue configuration from the active print service.

```
# print-service -e /tmp/queues
```

EXAMPLE 4 Importing a Print Queue Configuration

The following command imports the print queue configuration to the active print service.

```
# print-service -i /tmp/queues
```

Exit Status 0
Successful completion.

non-zero
An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|--------------------------------|
| Availability | print/lp/print-client-commands |
| Interface Stability | Obsolete |

See Also [Intro\(1\)](#), [attributes\(5\)](#)

Notes The print queue configuration saved and restored during export, import, and migration is limited to queue name and device name. It is likely that further configuration changes will be required before imported or migrated print queues become usable.

Name privatepw – administer FTP Server enhanced group access file

Synopsis privatepw [-c] [-f *ftpgroups*] [-g *real_group_name*] *accessgroup*
privatepw -d [-f *ftpgroups*] *accessgroup*
privatepw -l [-f *ftpgroups*]
privatepw -V

Description The privatepw utility is an administrative tool to add, delete and list enhanced access group information in the *ftpgroups* file. See [ftpgroups\(4\)](#).

When privatepw is used without options, the help usage message is displayed. The privatepw utility prompts for a password when adding an enhanced access group entry or modifying an existing one.

Options The following options are supported by the privatepw utility:

- c Create a new *ftpgroups* file for the specified *accessgroup*.
- d Delete information about the specified *accessgroup* from the *ftpgroups* file.
- f *ftpgroups* Use the specified *ftpgroups* file for all updates.
- g *group* Set the real system group to the *group* specified. *group* is a valid group name returned by [getgrnam\(3C\)](#). If the real system group is not supplied with the -g option when adding an enhanced access group entry, the privatepw utility prompts for it.
- l List the contents of the *ftpgroups* file.
- V Display program copyright and version information, then terminate.

Operands The following operands are supported:

accessgroup The name of the enhanced access group to create or update. It consists of an arbitrary string of alphanumeric and punctuation characters. See [ftpgroups\(4\)](#).

Exit Status The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

Files /etc/ftpd/ftpgroups
/etc/group

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|---------------------|
| Availability | service/network/ftp |
| Interface Stability | Volatile |

See Also [in.ftpd\(1M\)](#), [getgrnam\(3C\)](#), [ftpgroups\(4\)](#), [attributes\(5\)](#)

Name prodreg – Solaris Product Registry administration

Synopsis prodreg [-help] | [*subcommand operand ...*]

Description The prodreg utility browses, unregisters, and uninstalls components in the Solaris Product Registry.

Some installers make use of the [libwsreg\(3LIB\)](#) interface to register information. The Solaris Product Registry contains information about this installed software.

The database associated with the Solaris Product Registry is relative to the root of the installed file system. Normally, this is the root of the file system (/). Sometimes, an alternate root, with a different Solaris Product Registry install database is used, as during live upgrade installation. See [live_upgrade\(5\)](#).

The Registry database informs installers about installed software. The Registry and the prodreg utility do not directly perform installation or deinstallation. prodreg supports installers which are executed externally and launched by the prodreg utility or other means.

Depending on the subcommand, the prodreg command offers equivalent functions from the command line or a GUI viewer. Two versions of the GUI viewer are available. The default is the Java Swing GUI. The other version, the Java awt GUI is provided for environments without Java Swing support.

The only feature which exists in the CLI which is not present in the GUI is the `unregister` subcommand. It is possible for the product registry to become corrupted, if for example, some software is removed manually instead of by means of an uninstaller program. These entries can confuse installers which are run subsequently. The `unregister` subcommand allows stale entries to be removed, even forcefully. Care should be exercised when unregistering software with the recursive or force options so that valid entries in the registry are not removed by mistake.

The prodreg command, whether it launches the GUI or the command line interface browser, displays the contents of the registry at that time only. If software is installed or uninstalled subsequent to or concurrent with launching either prodreg viewer, the view can be inconsistent with the Solaris Product Registry.

Subcommands You can specify options to the prodreg command without specifying a subcommand. If the subcommand is omitted, the swing subcommand is assumed.

The following subcommands are supported:

awt Launch the Java awt GUI.

The awt subcommand has the following format:

```
awt [-R alt_root | --help]
```

browse

Display the Solaris Product Registry using a command line interface. The text output of this command displays identifying information of any component in the product registry tree, including its ancestors and children. If you repeatedly invoke this subcommand, you can interactively browse the product registry.

The database components are related as a tree. Components may have one or more children. Except for the root, components have one parent. This subcommand displays the ancestors and children for a given component in the Solaris Product Registry database.

Each time the `prodreg browse` subcommand is executed, one component in the Registry is shown, along with its ancestry to the root of the Registry, as well as the component's children. To browse in the `prodreg` GUI, a user selects a node to expand and clicks on it. The analogous activity using the command line interface is to browse on children of nodes successively, which effectively expands a view into the registry.

Start by browsing the root of the Registry with `prodreg browse`. Select components to expand the scope of the browsing activity. Use browse numbers as a convenience during this interactive browsing, but not in scripts. Browse numbers can change from one session to the next or on different systems. This is because browse numbers are generated as they are first used, by a given user on a particular system.

The `browse` subcommand has the following format:

```

browse [-R alt_root] [-u uuid [-i instance | -p location]]
browse [-R alt_root] -n bnum [-i instance | -p location]
browse [-R alt_root] -m name
browse --help

```

This following information is output for each component:

BROWSE # This is the browse number associated with each component. This number can be used as an argument to either the `prodreg browse` or `info` subcommands as a convenience

+/-/. The `+` indicates a component in the tree with children who are not shown. `-` indicates a component with children of which at least one child is being shown. The `.` indicates a component which has no children. This field is

arranged so that each space (reading left to right) depicts a successive generation.

| | |
|------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| UUID | This is the component's unique identifier. |
| # | This is the instance number of the component. Software components can be installed multiple times. The software registry assigns a unique instance to each one. |
| NAME | Each component in the Solaris Product Registry database has a localized name which is displayed in this field. It is possible that this name may not be unique in the registry since there could be another component that has the same name. |

The browse subcommand provides four distinct options for viewing the registry database. If multiple instances are associated with the same component, then the output of the subcommand is the ambiguous list. The request must be made unambiguous. The instance or location operands can be used to disambiguate the browse subcommand when used with the -u or -n options.

- If no operand information is given, the root of the registry tree is displayed, as well as its children. This is the starting point for interactive browsing of the entire registry database.
- If the browse number is given, the component associated is output.
- If the uuid is given, the component associated with it is output.
- If the name is given, the component associated with it is output.

info

Display attributes for any component in the Solaris Product Registry by supplying identifying information for the component.

Components in the product registry are associated with attributes. These attributes are composed of a *name* and a single *value* string.

This subcommand outputs attribute information associated with components in the Solaris Product Registry. Individual components in the product registry are specified as for the browse subcommand, except that either the *uuid*, *name* or *bnum* must be specified.

If a component requested is ambiguous as it has more than one instance or the name is assigned to more than one component in the registry, the list of possibilities is output, not the attribute information.

The default output of this subcommand is a complete list of each attributes, each on a new line. The attribute name is followed by a colon (:) and a SPACE. The attribute value follows, after which a RETURN is appended. Other options include can be specified using `-a` and `-d`.

The `info` subcommand has the following format:

```
info --help
info [-R alt_root] -u uuid [-i instance | -p location]
info [-R alt_root] -n bnum [-i instance | -p location]
info [-R alt_root] -m name [-a attr | -d ]
```

`help | --help | -?`

Display help text.

The `help` subcommand has the following format:

```
help | --help | -?
```

`swing`

Launch the Java Swing GUI. If the Java Swing GUI is not available, this subcommand fails.

The `swing` subcommand has the following format:

```
swing [-R alt_root | --help]
```

`version | --version | -V`

Outputs a current version string.

The `version` subcommand has the following format:

```
version | --version | -V
```

`unregister`

Unregister an entry in the registry.

Remove a component from the Solaris Product Registry. The component corresponding to the `uuid` specified with the `-u` option must be a single instance. If it is not, the subcommand fails and returns the list of instances with the associated `uuid`. The subcommand must be reissued using either `-p` or `-i` to uniquely determine which component instance to unregister.

The `unregister` subcommand fails if there are components in the registry which depend on the component which is to be unregistered.

The `unregister` subcommand fails if the user does not have write access to the registry. See [wsreg_can_access_registry\(3WSREG\)](#). The `unregister` subcommand fails if the user attempts to unregister a system component, instead of a component registered with the Solaris Product Registry. System components include those which include the attribute `PKG` and certain special Registry nodes including the following:

| UUID | Name |
|--------------------------------------|-------------------------------|
| ===== | ===== |
| root | System Registry |
| a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b | Solaris System Software |
| 8f64eabf-1dd2-11b2-a3f1-0800209a5b6b | Unclassified Software |
| b96ae9a9-1dd1-11b2-a3f2-0800209a5b6b | System Software Localizations |
| b1c43601-1dd1-11b2-a3f2-0800209a5b6b | Additional System Software |
| a8dcab4f-1dd1-11b2-a3f2-0800209a5b6b | Software Localizations |

Before the `unregister` subcommand with the `-f` option is used, you should carefully review what components depend upon the component which is to be unregistered. The `-r` option is even more dangerous, since all children and software components depending upon the component are also deregistered. You can obtain the list of dependent components for a component with UUID *uuid* using:

```
prodreg info -u uuid -a "Dependent Components"
```

You can obtain a list of required components using:

```
prodreg info -u <uuid> -a "Required Components"
```

The output lists the name, UUID and instance of the component.

The `unregister` subcommand has the following format:

```
unregister [-R alt_root] [-fr] -u uuid [-p location | -i instance]
unregister --help
```

`uninstall`

Launch an uninstaller program.

Each component in the registry can have an uninstaller associated with it. This subcommand executes this associated installer, if there is one, for a component in the registry given by the `-u` option. If there is no uninstaller associated with the component, the subcommand fails. If the component given by the `-u` option is not unique (as there is more than one instance of the component installed), the subcommand outputs a list of all instances. The subcommand must then be reissued using `-i` or `-p`

to disambiguate the uuid given with the `-u` option. Finally, if the component to uninstall is depended upon by other components, the command fails.

The command may also launch an uninstaller with a `-x` option. No checks for whether this uninstalls a component upon which other components depend in this case.

The `uninstall` command is not executed if the user does not have write access to the registry. See [wsreg_can_access_registry\(3WSREG\)](#).

The `uninstall` command has the following format:

```
uninstall [-R alt_root] [-f] -u uuid -p location
uninstall [-R alt_root] -i instance[arguments ...]
uninstall --help
```

Options The `awt` subcommand supports the following options:

- `--help` Display help text, do not launch the viewer.
- `-R alt_root` Use the specified alternate root to locate the database to display with the GUI viewer.

See OPERANDS for information regarding specification of *alt_root*.

Note – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).

The `browse` subcommand supports the following options:

- `-help` Display help text, do not execute the browse subcommand.
- `-i instance` Output the specified component instance.
- `-m name` Output the component instances associated with the name.
- `-n bnum` Output the component instances associated with the browse number.
- `-p location` Output the component instance installed in the specified location. The install location for a component can be obtained using the 'info' subcommand.
- `-R alt_root` Use the specified alternate root to locate the database.

Note – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).

`-u uuid` Output the component instances associated with the `uuid`.

The `info` subcommand supports the following options:

`-a attr` Output only the attribute whose name is given by the operand '`attr`', instead of all attributes of the specified component.

`-d` Output only the attribute whose name is `isDamaged`, instead of all attributes of the specified component. If the value is set to `true`, this attribute indicates that the component in the registry

`--help` Output help text, do not execute the `browse` subcommand.

`-i instance` The instance operand distinguishes among multiple instances of components with the same `uuid` or `browse` number.

`-m name` The name operand indicates one or more components in the registry.

`-n bnum` Output the attributes of the component instance associated with the `browse` number `bnum`. If there is more than one instance, the command must be disambiguated using the `-i` or `-p` options.

`-p location` The install location indicated distinguishes among multiple instances of components with the same `uuid` or `browse` number.

`-R alt_root` Use the specified alternate root to locate the database.

Note – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).

`-u uuid` Output the attributes of the component instance associated with the `uuid`. If there is more than one instance, the subcommand must be disambiguated using the `-i` or `-p` options.

The `swing` subcommand supports the following options:

`--help` Output help text, do not execute the `install` subcommand.

`-R alt_root` Use the specified alternate root to locate the database.

Note – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global

zone's file system. See [zones\(5\)](#).

The `uninstall` subcommand supports the following options:

- f Force the uninstall. A forced subcommand uninstalls all instances of a component, even if there are multiple ambiguous instances of the `uuid` operand.
 - help Output help text, do not execute the `unregister` subcommand.
 - i *instance* Disambiguate the `uuid` operand.
 - p *location* Disambiguate the `uuid` operand. *location* corresponds to the where the software component was installed.
 - R *alt_root* Use the specified alternate root to locate the database.
- Note** – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).
- u *uuid* Unregister the `uuid` component. If this component has been installed multiple times, the instance to unregister must be indicated unambiguously by using the `-i` or `-p` option.

The `unregister` subcommand supports the following options:

- f Force the unregistration. A forced subcommand unregisters a component even if there are other components which are dependent on this component.
 - help Output help text, do not execute the `unregister` subcommand.
 - i *instance* Disambiguate the `uuid` operand.
 - p *location* Disambiguate the `uuid` operand. The *location* corresponds to the where the software component was installed.
 - r Causes a recursive deregistration of a component as well as that component's children and dependencies.
 - R *alt_root* Use the specified alternate root to locate the database.
- Note** – The root file system of any non-global zones must not be referenced with the `-R` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).
- u *uuid* Unregister component `uuid` of the component to unregister. If this component has been installed multiple times, the instance to unregister must be indicated unambiguously by using the `-i` or `-p` option.

Operands The following operands are supported:

alt_root Pathname to a file indicating an alternate root. The Solaris Product Registry database is located relative to the alternate root. If database relative to this location does not exist, it is created.

Note – The root file system of any non-global zones must not be referenced by *alt_root*. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).

attr Name of an attribute. This operand is used only with the `info` subcommand. If *attr* is associated with a component, the attribute name and value is displayed.

bnum The browse number.

Each component in the Solaris Product Registry is associated with a browse number. This number is generated for the convenience of an interactive user. The browse number can change if the system is rebooted or reinstalled. Do not store or use the browse number except to facilitate the `browse` and `info` subcommands. Browse numbers are always output by the `prodreg browse` subcommand. Only these values can be used as input values to the `browse` or `info` subcommand.

instance Software can be installed in more than one location. The Solaris Product Registry associates a unique instance number for each. The `browse` subcommand shows the instance number associated with each component in the registry. The *instance* operand is used to distinguish between installed, and possibly different, copies of software, when such exist.

location A path to a specific file or directory in the file system. This operand indicates the installed location of registered software. For instance, if software is installed relative to `/usr/local` the value of this operand would be `/usr/local`. The *install location* is used to installer or to indicate the location of an installer or to disambiguate which instance is intended, of a software component which can have multiple instances.

name Each software component in the Solaris Product Registry is associated with a name. This name is output by the `browse` subcommand. Some subcommands allow the user to input the software by name as an operand as a convenience. These names might not be unique. If the user supplies an ambiguous name, for which more than one components exist, the subcommand outputs a list of possible choices. The name can be localized; depending on the language setting the name can differ.

uuid Each software component in the Solaris Product Registry is associated with a unique identifier. This identifier is a handle which accesses an entry in the registry database. The *uuid* corresponds to the component irrespective of how many

instances of the component have been installed, and what the localized name of the component is.

Examples EXAMPLE 1 Using the prodreg Command to Browse

Browsing is performed by means of the prodreg browse subcommand. Using these requests iteratively, one can peruse the tree, much as one would using a GUI by expanding components which are collections of other components. Browsing using browse numbers for convenience should be done only during this iterative browsing process, since the numbers are generated as a result of the browsing operation.

Evoking the browse subcommand without any arguments browses from the top of the registry. The output varies depending on the software installed on a particular system.

```
$ prodreg browse
BROWSE # +/-/.  UUID                                     #  NAME
=====  =====  =====
1        -      root                                     1  System
                                           Registry
2        +      a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b  1  Solaris 10
                                           System
                                           Software
3        +      8f64eabf-1dd2-11b2-a3f1-0800209a5b6b  1  Unclassified
                                           Software
```

The output of this command lists the browse number, UUID, instance number and name of the root component and its children. The ancestors of a component, each parent up to the root, are also shown. The +/-/. column indicates whether the component in the tree is an expanded parent (-), a child with children (+) or a child without children (.).

EXAMPLE 2 Requesting Information About the Components in a Tree

The UUID, name and browse number fields can be used to request browsing information about components in the tree. The next example shows how a component can be browsed by UUID.

```
$ prodreg browse -u a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b
BROWSE # +/-/.  UUID                                     #  NAME
=====  =====  =====
1        -      root                                     1  System
                                           Registry
2        -      a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b  1  Solaris 10
                                           System
                                           Software
4        +      b96ae9a9-1dd1-11b2-a3f2-0800209a5b6b  1  System
                                           Software
                                           Localizations
5        +      SUNWCa11                               1  Entire
```

```

EXAMPLE 4 Browsing Iteratively

Additional output has been omitted. As a convenience, the browse number can be used for iterative browsing. This number should not be stored, as it differs depending on which system the prodreg command is run on, which user is running the command, and the log in session in which the command is run.

```
$ prodreg browse -n 3
BROWSE # +/-/. UUID # NAME
=====
1 - root 1 System
Registry

EXAMPLE 5 Browsing Using an Ambiguous Value

If the requested value is ambiguous, the list of ambiguous instances are displayed. In the following example, there are two distinct software components with the same name.

```
$ ./prodreg browse -m JavaVM
```

The request failed because multiple components correspond to the criteria given. Use the list of possible components given below, select one and try again.

| BROWSE # | +/-/. | UUID | # | NAME |
|----------|-------|--------------------|---|--------|
| 12 | . | org.spybeam.javavm | 1 | JavaVM |
| 51 | . | SUNWCjv | 1 | JavaVM |

Issue one of the following requests again:

```
$ prodreg browse -u SUNWCjv
```

or

```
$ prodreg browse -u org.spybeam.javavm
```

EXAMPLE 6 Browsing Multiple Installations of Software

Another possible ambiguous response arises when a particular software component is installed multiple times. In the example below Example software is registered three times.

```
$ prodreg browse -m Example
```

The request failed because multiple components correspond to the criteria given. Use the list of possible components given below, select one and try again.

| BROWSE # | +/-/. | UUID | # | NAME |
|----------|-------|-------|---|-------|
| ===== | ===== | ===== | = | ===== |

EXAMPLE 6 Browsing Multiple Installations of Software (Continued)

```

7      .      org.spybeam.example          2 Example
7      .      org.spybeam.example          3 Example
7      .      org.spybeam.example          1 Example

```

The component requested could not be found.

EXAMPLE 7 Browsing Using a Particular Instance

The request can be repeated specifying a particular instance to disambiguate it. It is also possible to disambiguate a request with the `-p` option, followed by the install location. In this case, to browse the first instance of the Example software, one would use the command:

```
$ prodreg browse -u org.spybeam.example -i 1
```

EXAMPLE 8 Using the info Subcommand

The install location, as well as other attributes of a component can be obtained with the `info` subcommand. The `info` subcommand accepts the same disambiguating options and returns all the attributes of a component, each on a single line.

```
$ prodreg info -m Example
```

The request failed because multiple components correspond to the criteria given. Use the list of possible components given below, select one and try again.

```

BROWSE # +/-/. UUID                                # NAME
===== =====
7      .      org.spybeam.example          2 Example
7      .      org.spybeam.example          3 Example
7      .      org.spybeam.example          1 Example

```

The component requested could not be found.

This variation of the `info` subcommand outputs all information associated with instance 1 of the Example component. The output from this variation is not displayed

```
$ prodreg info -u org.spybeam.example -i 1
```

EXAMPLE 9 Obtaining Information on the Install Location

You can use the `info` subcommand to obtain the install location and other attributes of a component. The `info` subcommand accepts the same disambiguating options as the `browse` subcommand. It returns all the attributes of a component, each on a single line. You can also request a single attribute.

The following command outputs the value of the install location attribute:

```
$ prodreg info -n 23 -a Location
```

EXAMPLE 10 Identifying and Unregistering Damaged Software

Removing installed software without using the associated uninstaller can damage the software in the registry. A damaged component indicates that certain software is installed, when in fact it is not present. A component can be damaged by removing files or packages directly, without running the associated uninstaller. The general rule to follow is: If software has been installed by an installer program, it should be uninstalled using the supplied uninstaller program.

This example shows how to identify and repair damaged software components so that software can be reinstalled.

Browsing for `Examplesoft`, produces the following:

```
$ prodreg browse -m Examplesoft
BROWSE # +/-/. UUID # NAME
=====
1 - root 1 System
Registry
2 + a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b 1 Solaris 10
System
Software
3 + 8f64eabf-1dd2-11b2-a3f1-0800209a5b6b 1 Unclassified
Software
4 - 95842091-725a-8501-ef29-0472985982be 1 ExampleSoft
233 . 90209809-9785-b89e-c821-0472985982be 1 Example Doc
234 . EXS0zzt 1
235 . EXS0blob 1 Example Data
```

The `Examplesoft` child `EXS0zzt`, representing a package component of registered software does not display its name. This is likely to be because the software `Examplesoft` is damaged. Verify this with the following command:

```
$ prodreg info -u 95842091-725a-8501-ef29-0472985982be \
-i l -d
isDamaged=TRUE
```

Since `Damaged` is `TRUE`, some part of `Examplesoft` is damaged. The following command lists the packages which make up `Examplesoft`:

```
$ prodreg info \
-u 95842091-725a-8501-ef29-0472985982be\
-i l -a PKGS pkgs:
EXS0zzt EXS0blob
```

Use the `pkginfo` command to verify if `EXS0` is installed:

```
$ pkginfo EXS0zzt
ERROR: information for "EXS0zzt" was not found
```

EXAMPLE 10 Identifying and Unregistering Damaged Software (Continued)

```
$ pkginfo EXS0blob
application EXS0blob      Example Data
```

The output of these commands shows that the package EXS0zzt has been removed, probably with the `pkgrm` command. The `ExampleSoft` software will probably not function. To repair the software, one should run the uninstaller registered with `ExampleSoft`. You probably need to run the uninstaller with root permissions, as it unregisters the software and runs `pkgrm` commands. Both of these operations require root permissions.

```
# prodreg uninstall -u 95842091-725a-8501-ef29-0472985982be -i 1
The install program requested could not be found.
```

Something is wrong, or else you would be able to access `uninstall program` to uninstall the software. One possibility is that the uninstaller program has been removed manually. It is possible to determine where the uninstaller is located by requesting the `uninstall program` attribute:

```
$ prodreg info -m ExampleSoft -a uninstallprogram
uninstallprogram: /usr/bin/java -mx64m -classpath
/var/sadm/prod/org.example.ExampleSoft/987573587 uninstall_ExampleSoft
```

Check to see if there is an uninstaller in the registered location.

```
# ls /var/sadm/prod/org.example.ExampleSoft/987573587
/var/sadm/prod/org.example.ExampleSoft/987573587:
No such file or directory
```

Since there is no uninstaller at the desired location, you have two options. One is to load the uninstaller from back up storage and run it manually. Use the command line stored in the registry:

```
# /usr/bin/java -mx64m -classpath \
    /var/sadm/prod/org.example.ExampleSoft/987573587 \
    uninstall_ExampleSoft
```

If there is no other possibility, manually unregister the software.

```
# prodreg unregister -u 95842091-725a-8501-ef29-0472985982be -i 1
```

This does not remove the remaining package `EXS0blob`. You must do this manually.

```
# pkgrm EXS0blob
```

EXAMPLE 11 Removing Multiple Components

Component A has children B and C, and C has children D and E, and the you wish to remove all of the components at once. This is useful if the whole hierarchy has to be reinstalled and the uninstaller has been lost or cannot be run

EXAMPLE 11 Removing Multiple Components (Continued)

```

$ prodreg browse -u UUID-of-C
BROWSE # +/-/. UUID # NAME
=====
1 - root 1 System
Registry
2 + a01ee8dd-1dd1-11b2-a3f2-0800209a5b6b 1 Solaris 10
System
Software
3 + 8f64eabf-1dd2-11b2-a3f1-0800209a5b6b 1 Unclassified
Software
1423 - UUID-of-A 1 Example A
1436 . UUID-of-B 1 Example B
1437 - UUID-of-C 1 Example C
1462 . UUID-of-D 1 Example D
1463 . UUID-of-E 1 Example E

# prodreg uninstall -u UUID-of-A -i 1

```

The `uninstall` subcommand can fail various ways, for example if the java classes have been removed, if the user has insufficient permissions or if Java software is not present on the system. The recursive unregistration subcommand is very powerful and dangerous. Not only does it unregister every child of a component, it also unregisters every component which depends upon the component to unregister. It is a good idea to view all information about the component to determine if any components will be unintentionally unregistered with `UUID-of-A`.

```

$ prodreg info -u UUID-of-A
Title: Example A Software
Version: 5.8.0.2001.11.02
Location: /usr
Vendor: Example Vendor
uninstallprogram: /usr/bin/java -mx64m -classpath
/var/sadm/prod/org.example.ExampleA/90820965 uninstall_ExampleA
vendorurl: http://www.example.org
description: Example A Software has many uses
Supported Languages: en

Child Components:
Name                               UUID                               #
-----
Example B                          UUID-of-B                          1
Example C                          UUID-of-C                          1

Required Components:
Name                               UUID                               #

```

EXAMPLE 11 Removing Multiple Components *(Continued)*

```

-----
Example B          UUID-of-B          1
Example C          UUID-of-C          1

```

No software depends on Example A, or else an additional field, Dependent Components would be shown. To further ensure that there are no surprises, one should examine the dependent components and children of UUID-of-B and UUID-of-C, all the components which depend on UUID-of-B, UUID-of-C and their children, and so on.

If you examine the browse tree, you know the entire list of descendents of UUID-of-A. You can also examine the dependent component attributes of all of Example A's descendents.

```

$ prodreg info -u UUID-of-B -i 1 -a "Dependent Components"
Dependent Components:
Name          UUID          #
-----
Example A     UUID-of-A     1

```

```

$ prodreg info -u UUID-of-C -i 1 -a "Dependent Components"
Dependent Components:
Name          UUID          #
-----
Example A     UUID-of-A     1

```

```

$ prodreg info -u UUID-of-D -i 1 -a "Dependent Components"
Dependent Components:
Name          UUID          #
-----
Example C     UUID-of-C     1

```

```

$ prodreg info -u UUID-of-E -i 1 -a "Dependent Components"
Dependent Components:
Name          UUID          #
-----
Example C     UUID-of-C     1

```

A recursive unregistration of Example A only results in unregistering Example A and its descendents, as intended.

```
# prodreg unregister -r -u UUID-of-A -i 1
```

EXAMPLE 12 Reinstalling a Damaged Component

In this example, there is a component, Software *ZZZ* which is depended upon by other software. Software *ZZZ* has been damaged and you need to reinstall it. The reinstallation is impossible until Software *ZZZ* is unregistered.

EXAMPLE 12 Reinstalling a Damaged Component (Continued)

First, you check what depends upon Software ZZZ:

```
$ prodreg info -m "Software ZZZ" -a "Dependent Components"
Dependent Components:
```

```
Name                               UUID                               #
-----                               -
Software Foobar                     d9723500-9823-1432-810c-0100e09832ff 1
```

Normally, you would have to uninstall Software Foobar before unregistering Software ZZZ, since Software Foobar depends on Software ZZZ. You decide that it is impossible or unreasonable to reinstall Software Foobar. Performing a recursive unregister of Software ZZZ is not an option as it would unregister Software Foobar as well. Instead you can do a forced unregister of Software ZZZ. The UUID of Software ZZZ is 90843fb1-9874-3a20-9b88-984b32098432.

```
# prodreg unregister -f -u 90843fb1-9874-3a20-9b88-984b32098432 -i 1
```

You can then reinstall Software ZZZ:

```
# /usr/bin/java -cp /usr/installers/org.example.softwarezzz
```

Bugs The registry can become out of date because of software being manually removed, or removed using [pkgrm\(1M\)](#) directly. To avoid damaging the registry, use uninstall programs to remove software which was initially installed using an install program.

Environment Variables The following environment variable affects the execution of prodreg:

PKG_INSTALL_ROOT If present, defines the full path name of a directory to use as the system's PKG_INSTALL_ROOT path. All product and package information files are then looked for in the directory tree, starting with the specified PKG_INSTALL_ROOT path. If not present, the default system path of / is used.

Exit Status The following exit values are returned:

```
0    Successful completion.
>0   An error occurred.
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------------------------------|
| Availability | system/management/product-registry, SUNWwsrv |
| Interface Stability | Committed |

See Also [pkgadd\(1M\)](#), [pkgrm\(1M\)](#), [wsreg_can_access_registry\(3WSREG\)](#), [libwsreg\(3LIB\)](#), [live_upgrade\(5\)](#), [attributes\(5\)](#)

Application Packaging Developer's Guide

Notes The prodreg GUI and command line interface view both the Solaris Product Registry and the package database. Both look like components in the registry, but some of these cannot be unregistered or uninstalled. Packages do not have an associated uninstaller, so they cannot be uninstalled using the `prodreg uninstall` subcommand. Solaris packages cannot be unregistered using the `prodreg unregister` subcommand. Packages are removed using the [pkgrm\(1M\)](#) command, after which time the packages do not appear in the GUI or CLI prodreg viewer.

It is preferable to remove software using the uninstaller associated with the software installed than to remove individual packages using `pkgrm(1M)`, since the uninstaller software takes care of comprehensive removal of all resources associated with the installed software, including unregistering information in Registry and removing the appropriate packages.

The `prodreg uninstall` subcommand launches an external program. The command line conventions of these programs have to be used to indicate the alternate root for the product registry. Another possibility is to use the `PKG_INSTALL_ROOT` environment variable for this purpose as the install program is executed in the same environment as prodreg. Uninstall programs are frequently java classes which require Java to be installed. If Java software has been removed or is missing from a Solaris distribution, it is impossible to run java based uninstallers.

Only the `prodreg unregister` and `uninstall` subcommands can only be run with root permissions. This is because they modify the product registry in the case of `unregister`, and remove packages in the case of `uninstall`. The other operations merely read the registry and can be run with any user permissions. The `prodreg uninstall` subcommand might require root permissions as well, as installers can execute commands such as [pkgadd\(1M\)](#) or [pkgrm\(1M\)](#) which require root permissions to run.

Attributes associated with components are documented in various places -primarily in the *Application Packaging Developer's Guide*. The attributes associated with the Solaris Product Registry itself are described in the following glossary.

| | |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Dependent Components | List of components upon which the component depends. |
| Location | The location relative to which software was installed. |
| pkgs | List of packages which correspond to the component. These packages are added with <code>pkgadd</code> after the component is registered. They are removed with <code>pkgrm</code> before the component is unregistered. |
| Required Components | List of components on which the component depends. |
| Source | Media from which the install was done. |

| | |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Supported Languages | List of locales for which there are registered titles. |
| Title | <i>Name</i> given by the <code>prodreg browse</code> subcommand. This name can be localized to the locale in which the shell is running. |
| Unique Name | Name used by previous versions of the Solaris Product Registry. This value is often set to the package name corresponding to a given component in the registry. |
| Vendor | Vendor who produced the component. |
| Version | Version string associated with the component. |

The Registry can contain components which do not correspond to software actually installed on the system. This can be detected several ways. The easiest is to check using the `info` subcommand if a component is damaged. Another way is to determine where software was installed using the `info` subcommand, and verify it is still there.

Name projadd – administer a new project on the system

Synopsis projadd [-n] [-f *filename*] [-p *projid* [-o]] [-c *comment*]
 [-U *user* [,*user*]...] [-G *group* [,*group*]...]
 [[-K *name* [=value [,value]...]...]] *project*

Description projadd adds a new project entry to the /etc/project file. If the files backend is being used for the project database, the new project is available for use immediately upon the completion of the projadd command.

Options The following options are supported:

- c *comment* Add a project comment. Comments are stored in the project's entry in the /etc/project file. Generally, comments contain a short description of the project and are used as the field for the project's full name.

Specify *comment* as a text string. *comment* cannot contain a colon (:) or NEWLINE.
- f *filename* Specify the project file to modify. If no *filename* is specified, the system project file, /etc/project, is modified.
- G *group*[,*group*...] Specify a group list for the project.
- K *name*[=*value*[,*value*...]] Specify an attribute list for the project. Multiple -K options can be specified to set values on multiple keys, such as:

-K *key1=value1* -K "*key2=(value2a) , (value2b)*"

Resource control attributes use parentheses to specify values for a key. Because many user shells interpret parentheses as special characters, it is best to enclose an argument to -K that contains parentheses with double quotes, as shown above and in EXAMPLES, below. See [resource_controls\(5\)](#) for a description of the resource controls you can specify for a project.
- n Syntax check. Check the format of the existing system project file and modifications only. The contents of the existing project file, such as user names, group names, and resources that are specified in the project attributes are not checked.
- o This option allows the project ID specified by the -p option to be non-unique within the project file.
- p *projid* Set the project ID of the new project.

Specify *projid* as a non-negative decimal integer below UID_MAX as defined in `limits.h`. *projid* defaults to the next available

unique number above the highest number currently assigned. For example, if *projids* 100, 105, and 200 are assigned, the next default *projid* is 201. *projids* between 0-99 are reserved by SunOS.

`-U user[,user...]` Specify a user list for the project.

Operands The following operands are supported:

project The name of the project to create. The *project* operand is a string consisting of characters from the set of alphabetic characters, numeric characters, underline (`_`), and hyphen (`-`). The period (`.`) is reserved for projects with special meaning to the operating system. The first character of the project name must be a letter. An error message is displayed if these restrictions are not met.

Examples EXAMPLE 1 Adding a Project

The following command creates the project `salesaudit` and sets the resource controls specified as arguments to the `-K` option.

```
projadd -p 111 -G sales,finance -c "Auditing Project" \
-K "rcap.max-rss=10GB" \
-K "process.max-file-size=(priv,50MB,deny)" \
-K "task.max-lwps=(priv,100,deny)" salesaudit
```

This command would produce the following entry in `/etc/project`:

```
salesaudit:111:Auditing Project::sales,finance: \
process.max-file-size=(priv,52428800,deny); \
rcap.max-rss=10737418240;task.max-lwps=(priv,100,deny)
```

Note that the preceding would appear as one line in `/etc/project`.

Comparing the `projadd` command and resulting output in `/etc/project`, note the effect of the scaling factor in the resource cap (`rcap.max-rss=10GB`) and the resource control (`process.max-file-size=(priv,50MB,deny)`). Modifiers, such as B, KB, and MB, and scaling factors are specified in [resource_controls\(5\)](#).

Exit Status The following exit values are returned:

- 0 Successful completion.
- 2 The command syntax was invalid. A usage message for `projadd` is displayed.
- 3 An invalid argument was provided to an option.
- 4 The *projid* given with the `-p` option is already in use.
- 5 The project files contain an error. See [project\(4\)](#).
- 6 The project to be added, group, user, or resource does not exist.

- 9 The project is already in use.
- 10 Cannot update the /etc/project file.

Files /etc/project System project file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------------------|
| Availability | system/extended-system-utilities |
| Interface Stability | See below. |

Invocation is evolving. Human readable output is unstable.

See Also [projects\(1\)](#), [groupadd\(1M\)](#), [groupdel\(1M\)](#), [groupmod\(1M\)](#), [grpck\(1M\)](#), [projdel\(1M\)](#), [projmod\(1M\)](#), [useradd\(1M\)](#), [userdel\(1M\)](#), [usermod\(1M\)](#), [project\(4\)](#), [attributes\(5\)](#), [resource_controls\(5\)](#)

Notes In case of an error, projadd prints an error message and exits with a non-zero status.

projadd adds a project definition only on the local system. If a network name service such as NIS or LDAP is being used to supplement the local /etc/project file with additional entries, projadd cannot change information supplied by the network name service.

- Name** projdel – delete a project from the system
- Synopsis** projdel [-f *filename*] *project*
- Description** The projdel utility deletes a project from the system and makes the appropriate changes to the system file.
- Options** The following options are supported:
- f *filename* Specify the project file to modify. If no *filename* is specified, the system project file, /etc/project, is modified.
- Operands** The following operands are supported:
- project* The name of the project to be deleted.
- Exit Status** The following exit values are returned:
- 0 Successful completion.
 - 2 The command syntax was invalid. A usage message for projdel is displayed.
 - 3 An invalid argument was provided to an option.
 - 4 The *projid* given with the -p option is already in use.
 - 5 The project files contain an error. See [project\(4\)](#).
 - 6 The project to be modified, group, user, or resource does not exist.
 - 9 The project is already in use.
 - 10 Cannot update the /etc/project file.
- Files** /etc/project System project file
- Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------------------|
| Availability | system/extended-system-utilities |
| Interface stability | See below. |

Invocation is evolving. Human readable output is unstable.

See Also [projects\(1\)](#), [groupadd\(1M\)](#), [groupdel\(1M\)](#), [groupmod\(1M\)](#), [grpck\(1M\)](#), [logins\(1M\)](#), [projadd\(1M\)](#), [projmod\(1M\)](#), [useradd\(1M\)](#), [userdel\(1M\)](#), [usermod\(1M\)](#), [project\(4\)](#), [attributes\(5\)](#)

Diagnostics In case of an error, `projdel` prints an error message and exits with a non-zero status.

Notes `projdel` deletes a project definition only on the local system. If a network name service such as NIS or LDAP is being used to supplement the local `/etc/project` file with additional entries, `projdel` cannot change information supplied by the network name service.

Name projmod – modify a project's information on the system

Synopsis projmod [-n] [-A|-f *filename* | -]
 projmod [-n] [-A|-f *filename* | -] [-p *projid* [-o]]
 [-c *comment*] [-a|-s|-r] [-U *user* [,*user*]...]
 [-G *group* [,*group*]...]
 [[-K *name* [=value [,value]...]...]]
 [-l *new_projectname*] *project*

Description The projmod utility modifies a project's definition on the system. projmod changes the definition of the specified project and makes the appropriate project-related system file and file system changes.

Options The following options are supported:

- A Apply the project's resource controls, as defined in the system's project database, to the project if it is active.
- a Specify that the users, groups, attributes, or attribute values specified by the -U, -G or -K options should be added to the project, rather than replacing the existing member or attribute list.
- c *comment* Specify *comment* as a text string. Generally, *comment* contains a short description of the project. This information is stored in the project's /etc/project entry.
- f *filename* | - Specify the project file to modify or validate or specify input from stdin for validation. As noted under OPERANDS, if you do not specify a project in a projmod command line, projmod validates the argument to -f. If you do not use this option, the system project file, /etc/project, is modified.
- G *group* [,*group*...] Specify a replacement list of member groups of the project. When used in conjunction with the -a or -r options, this option specifies a list of groups to be added or removed from the project.
- K *name*[=*value*[,*value*...]] Specify a replacement list of project attributes for the project. When used in conjunction with the -a, -r, or -s options, this option specifies a list of attribute values to be added, removed, or replaced in the project. Attributes must be delimited by semicolons (;). Multiple -K options can be specified to set, add, remove, or substitute values on multiple keys, such as:

```
-K key1=value1 -K "key2=(value2a) , (value2b)"
```

Resource control attributes use parentheses to specify values for a key. Because many user shells interpret parentheses as special

characters, it is best to enclose an argument to `-K` that contains parentheses with double quotes, as shown above and in EXAMPLES, below. See [resource_controls\(5\)](#) for a description of the resource controls you can specify for a project.

- `-l new_projectname` Specify the new project name for the project. The *new_projectname* argument is a string consisting of characters from the set of alphabetic characters, numeric characters, period (`.`), underline (`_`), and hyphen (`-`). The first character should be alphabetic. An error message is written if these restrictions are not met. The project name must also be unique within the project file.
- `-n` Syntax check. Check the format of the existing system project file and modifications only. The contents of the existing project file, such as user names, group names, and resources that are specified in the project attributes are not checked.
- `-o` This option allows the project ID specified by the `-p` option to be non-unique within the project file.
- `-p projid` Specify a new project ID for the project. It must be a non-negative decimal integer less than MAXUID as defined in `param.h`. This value must be unique within the project file if the `-o` option is not specified.
- `-r` Specify that the users, groups, attributes, or attribute values specified by the `-U`, `-G` or `-K` options should be removed from the project, rather than replacing the existing member or attribute list.
- `-s` Specify that the list of attributes specified by the `-K` option should have their values replaced. If the attributes do not exist, they are added as if the `a` option was used. This option has no effect the `-U` or `-G` options.
- `-U user [,user...]` Specify a replacement list of member users of the project. When used in conjunction with the `-a` or `-r` options, this option specifies a list of users to be added or removed from the project.

Operands The following operands are supported:

- project* An existing project name to be modified or displayed.
- (*none*) If no operand is given, the project file is validated without modifying any project.

Examples EXAMPLE 1 Using the -K Option for Addition of an Attribute Value

Consider the following `project(4)` entry:

```
salesaudit:111:Auditing Project::sales,finance: \
  process.max-file-size=(priv,52428800,deny); \
  task.max-lwps=(priv,100,deny)
```

The preceding would appear as one line in `/etc/project`. For this and the following examples, the focus is on the attributes field in the `project` entry. That is, the last field, the field following the last semicolon.

The attributes field for the project `salesaudit` lists the following resource control:

```
task.max-lwps=(priv,1000,signal=KILL)
```

The following `projmod` command adds an action clause to the preceding entry:

```
# projmod -a -K "task.max-lwps=(priv,100,deny)" salesaudit
```

...with the resulting attributes field in the entry for `salesaudit`:

```
task.max-lwps=(priv,100,deny),(priv,1000,signal=KILL)
```

EXAMPLE 2 Using the -K Option for the Substitution of an Attribute Value

Assume an attributes field in a `project(4)` entry for the project `salesaudit` that lists the following resource control:

```
task.max-lwps=(priv,100,deny),(priv,1000,signal=KILL)
```

The following `projmod` command substitutes the action clause specified in the command for the action clauses in the preceding entry:

```
# projmod -s -K "task.max-lwps=(priv,500,signal=SIGSTOP)" salesaudit
```

...with the resulting attributes field in the entry for `salesaudit`:

```
task.max-lwps=(priv,500,signal=SIGSTOP)
```

EXAMPLE 3 Using the -K Option for Removal of an Attribute Value

Assume an attributes field in a `project(4)` entry for a project `salesaudit` that lists the following resource control:

```
task.max-lwps=(priv,100,deny),(priv,1000,signal=KILL)
```

The following `projmod` command removes the first action clause from the preceding entry:

```
# projmod -r -K "task.max-lwps=(priv,100,deny)" salesaudit
```

...with the resulting attributes field in the entry for `salesaudit`:

EXAMPLE 3 Using the -K Option for Removal of an Attribute Value *(Continued)*

```
task.max-lwps=(priv,1000,signal=KILL)
```

EXAMPLE 4 Specifying Multiple Attribute Values

Suppose you want to achieve the following resource controls for the project salesaudit:

```
task.max-lwps=(priv,100,deny)
process.max-file-size=(priv,50MB,deny)
```

The following projmod command adds these resource controls for salesaudit:

```
# projmod -a -K "task.max-lwps=(priv,100,deny)" \
-K "process.max-file-size=(priv,50MB,deny)" salesaudit
```

...with the resulting attributes field in the entry for salesaudit:

```
task.max-lwps=(priv,100,deny);process.max-file-size=(priv,52428800,deny)
```

In this example, note the effect of the use of the modifier and scaling factor for the resource control process.max-file-size. The specification in projmod:

```
"process.max-file-size=(priv,50MB,deny)"
```

...becomes, in /etc/project:

```
process.max-file-size=(priv,52428800,deny)
```

That is, 50MB is expanded to 52428800. The modifiers, such as MB, and scaling factors you can use for resource controls are specified in [resource_controls\(5\)](#).

EXAMPLE 5 Binding a Pool to a Project

The following command sets the project.pool attribute for the project sales.

```
# projmod -a -K project.pool=salespool sales
```

EXAMPLE 6 Evaluating Input from stdin

The following command uses the -f option without a project name operand to evaluate the contents of an NIS projects map.

```
# ypcat project | projmod -f -
```

Exit Status In case of an error, projmod prints an error message and exits with one of the following values:

The following exit values are returned:

- 0 Successful completion.
- 2 The command syntax was invalid. A usage message for projmod is displayed.

- 3 An invalid argument was provided to an option.
- 4 The *projid* given with the -p option is already in use.
- 5 The project files contain an error. See [project\(4\)](#).
- 6 The project to be modified, group, user, or resource does not exist.
- 9 The project is already in use.
- 10 Cannot update the /etc/project file.

| | | |
|--------------|--------------|---------------------------------------------------------------------------|
| Files | /etc/group | System file containing group definitions |
| | /etc/project | System project file |
| | /etc/passwd | System password file |
| | /etc/shadow | System file containing users' encrypted passwords and related information |

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------------------|
| Availability | system/extended-system-utilities |
| Interface Stability | See below. |

Invocation is evolving. Human readable output is unstable.

See Also [groupadd\(1M\)](#), [groupdel\(1M\)](#), [groupmod\(1M\)](#), [projadd\(1M\)](#), [projdel\(1M\)](#), [useradd\(1M\)](#), [userdel\(1M\)](#), [usermod\(1M\)](#), [passwd\(4\)](#), [project\(4\)](#), [attributes\(5\)](#), [resource_controls\(5\)](#)

Notes The `projmod` utility modifies project definitions only in the local `/etc/project` file. If a network name service such as NIS or LDAP is being used to supplement the local files with additional entries, `projmod` cannot change information supplied by the network name service. However `projmod` verifies the uniqueness of project name and project ID against the external name service.

Name prstat – report active process statistics

Synopsis prstat [-achJLmRrtTv] [-d u | d] [-C *psrsetlist*] [-h *lgrplist*]
[-j *projlist*] [-k *tasklist*] [-n *ntop*[, *nbottom*]]
[-p *pidlist*] [-P *cpulist*] [-s *key* | -S *key*]
[-u *eidlist*] [-U *uidlist*] [-z *zoneidlist*] [-Z]
[*interval* [*count*]]

Description The `prstat` utility iteratively examines all active processes on the system and reports statistics based on the selected output mode and sort order. `prstat` provides options to examine only processes matching specified PIDs, UIDs, zone IDs, CPU IDs, and processor set IDs.

The `-j`, `-k`, `-C`, `-p`, `-P`, `-u`, `-U`, and `-z` options accept lists as arguments. Items in a list can be either separated by commas or enclosed in quotes and separated by commas or spaces.

If you do not specify an option, `prstat` examines all processes and reports statistics sorted by CPU usage.

Options The following options are supported:

`-a`

Report information about processes and users. In this mode `prstat` displays separate reports about processes and users at the same time.

`-c`

Print new reports below previous reports instead of overprinting them.

`-C psrsetlist`

Report only processes or lwps that are bound to processor sets in the given list. Each processor set is identified by an integer as reported by [psrset\(1M\)](#). The load averages displayed are the sum of the load averages of the specified processor sets (see [pset_getloadavg\(3C\)](#)). Processes with one or more LWPs bound to processor sets in the given list are reported even when the `-L` option is not used.

`-d u | d`

Specify `u` for a printed representation of the internal representation of time. See [time\(2\)](#). Specify `d` for standard date format. See [date\(1\)](#).

`-h lgrplist`

Report only processes or lwps whose home *lgroup* is in the given list of *lgroups*. No processes or lwps will be listed for invalid *lgroups*.

`-H`

Report information about home *lgroup*. In this mode, `prstat` adds an extra column showing process or lwps home *lgroup* with the header LGRP.

`-j projlist`

Report only processes or lwps whose project ID is in the given list. Each project ID can be specified as either a project name or a numerical project ID. See [project\(4\)](#).

-
- J
Report information about processes and projects. In this mode `prstat` displays separate reports about processes and projects at the same time.
 - k *tasklist*
Report only processes or lwps whose task ID is in *tasklist*.
 - L
Report statistics for each light-weight process (LWP). By default, `prstat` reports only the number of LWPs for each process.
 - m
Report microstate process accounting information. In addition to all fields listed in `-v` mode, this mode also includes the percentage of time the process has spent processing system traps, text page faults, data page faults, waiting for user locks and waiting for CPU (latency time).
 - n *ntop*[,*nbottom*]
Restrict number of output lines. The *ntop* argument determines how many lines of process or lwp statistics are reported, and the *nbottom* argument determines how many lines of user, task, or projects statistics are reported if the `-a`, `-t`, `-T`, or `-J` options are specified. By default, `prstat` displays as many lines of output that fit in a window or terminal. When you specify the `-c` option or direct the output to a file, the default values for *ntop* and *nbottom* are 15 and 5.
 - p *pidlist*
Report only processes whose process ID is in the given list.
 - P *cpulist*
Report only processes or lwps which have most recently executed on a CPU in the given list. Each CPU is identified by an integer as reported by `psrinfo(1M)`.
 - R
Put `prstat` in the real time scheduling class. When this option is used, `prstat` is given priority over time-sharing and interactive processes. This option is available only for superuser.
 - r
Disable lookups for user names and project names. (Note that this does not apply to lookups for the `-j`, `-u`, or `-U` options.)
 - s *key*
Sort output lines (that is, processes, lwps, or users) by *key* in descending order. Only one *key* can be used as an argument.

There are five possible key values:

`cpu`
Sort by process CPU usage. This is the default.

pri
Sort by process priority.

rss
Sort by resident set size.

size
Sort by size of process image.

time
Sort by process execution time.

-S *key*
Sort output lines by *key* in ascending order. Possible *key* values are the same as for the **-s** option. See **-s**.

-t
Report total usage summary for each user. The summary includes the total number of processes or LWPs owned by the user, total size of process images, total resident set size, total cpu time, and percentages of recent cpu time and system memory.

-T
Report information about processes and tasks. In this mode `prstat` displays separate reports about processes and tasks at the same time.

-u *euidlist*
Report only processes whose effective user ID is in the given list. Each user ID may be specified as either a login name or a numerical user ID.

-U *uidlist*
Report only processes whose real user ID is in the given list. Each user ID may be specified as either a login name or a numerical user ID.

-v
Report verbose process usage. This output format includes the percentage of time the process has spent in user mode, in system mode, and sleeping. It also includes the number of voluntary and involuntary context switches, system calls and the number of signals received. Statistics that are not reported are marked with the **-** sign.

-z *zoneidlist*
Report only processes or LWPs whose zone ID is in the given list. Each zone ID can be specified as either a zone name or a numerical zone ID. See [zones\(5\)](#).

-Z
Report information about processes and zones. In this mode, `prstat` displays separate reports about processes and zones at the same time.

Output The following list defines the column headings and the meanings of a `prstat` report:

PID
The process ID of the process.

USERNAME

The real user (login) name or real user ID.

SWAP

The total virtual memory size of the process, including all mapped files and devices, in kilobytes (K), megabytes (M), or gigabytes (G).

RSS

The resident set size of the process (RSS), in kilobytes (K), megabytes (M), or gigabytes (G). The RSS value is an estimate provided by [proc\(4\)](#) that might underestimate the actual resident set size. Users who want to get more accurate usage information for capacity planning should use the -x option to [pmap\(1\)](#) instead.

STATE

The state of the process:

cpuN

Process is running on CPU N.

sleep

Sleeping: process is waiting for an event to complete.

wait

Waiting: process is waiting for CPU usage to drop to the CPU-caps enforced limits. See the description of CPU-caps in [resource_controls\(5\)](#).

run

Runnable: process in on run queue.

zombie

Zombie state: process terminated and parent not waiting.

stop

Process is stopped.

PRI

The priority of the process. Larger numbers mean higher priority.

NICE

Nice value used in priority computation. Only processes in certain scheduling classes have a nice value.

TIME

The cumulative execution time for the process.

CPU

The percentage of recent CPU time used by the process. If executing in a non-global zone and the pools facility is active, the percentage will be that of the processors in the processor set in use by the pool to which the zone is bound.

PROCESS

The name of the process (name of executed file).

LWPID

The lwp ID of the lwp being reported.

NLWP

The number of lwps in the process.

With the some options, in addition to a number of the column headings shown above, there are:

NPROC

Number of processes in a specified collection.

MEMORY

Percentage of memory used by a specified collection of processes.

The following columns are displayed when the -v or -m option is specified

USR

The percentage of time the process has spent in user mode.

SYS

The percentage of time the process has spent in system mode.

TRP

The percentage of time the process has spent in processing system traps.

TFL

The percentage of time the process has spent processing text page faults.

DFL

The percentage of time the process has spent processing data page faults.

LCK

The percentage of time the process has spent waiting for user locks.

SLP

The percentage of time the process has spent sleeping.

LAT

The percentage of time the process has spent waiting for CPU.

VCX

The number of voluntary context switches.

ICX

The number of involuntary context switches.

SCL

The number of system calls.

SIG

The number of signals received.

Under the `-L` option, one line is printed for each `lwp` in the process and some reporting fields show the values for the `lwp`, not the process.

The following column is displayed when the `-H` option is specified:

LGRP

The home *lgroup* of the process or `lwp`.

Operands The following operands are supported:

count

Specifies the number of times that the statistics are repeated. By default, `prstat` reports statistics until a termination signal is received.

interval

Specifies the sampling interval in seconds; the default interval is 5 seconds.

Examples **EXAMPLE 1** Reporting the Five Most Active Super-User Processes

The following command reports the five most active super-user processes running on CPU1 and CPU2:

```
example% prstat -u root -n 5 -P 1,2 1 1
```

| PID | USERNAME | SWAP | RSS | STATE | PRI | NICE | TIME | CPU | PROCESS/LWP | |
|--------|----------|-------------------------------------|-------|-------|-----|------|---------|------|-------------|--|
| 306 | root | 3024K | 1448K | sleep | 58 | 0 | 0:00.00 | 0.3% | sendmail/1 | |
| 102 | root | 1600K | 592K | sleep | 59 | 0 | 0:00.00 | 0.1% | in.rdisc/1 | |
| 250 | root | 1000K | 552K | sleep | 58 | 0 | 0:00.00 | 0.0% | utmpd/1 | |
| 288 | root | 1720K | 1032K | sleep | 58 | 0 | 0:00.00 | 0.0% | sac/1 | |
| 1 | root | 744K | 168K | sleep | 58 | 0 | 0:00.00 | 0.0% | init/1 | |
| TOTAL: | | 25, load averages: 0.05, 0.08, 0.12 | | | | | | | | |

EXAMPLE 2 Displaying Verbose Process Usage Information

The following command displays verbose process usage information about processes with lowest resident set sizes owned by users `root` and `john`.

```
example% prstat -S rss -n 5 -vc -u root,john
```

| PID | USERNAME | USR | SYS | TRP | TFL | DFL | LCK | SLP | LAT | VCX | ICX | SCL | SIG | PROCESS/LWP |
|--------|----------|-------------------------------------|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-------------|
| 1 | root | 0.0 | 0.0 | - | - | - | - | 100 | - | 0 | 0 | 0 | 0 | init/1 |
| 102 | root | 0.0 | 0.0 | - | - | - | - | 100 | - | 0 | 0 | 3 | 0 | in.rdisc/1 |
| 250 | root | 0.0 | 0.0 | - | - | - | - | 100 | - | 0 | 0 | 0 | 0 | utmpd/1 |
| 1185 | john | 0.0 | 0.0 | - | - | - | - | 100 | - | 0 | 0 | 0 | 0 | csh/1 |
| 240 | root | 0.0 | 0.0 | - | - | - | - | 100 | - | 0 | 0 | 0 | 0 | powerd/4 |
| TOTAL: | | 71, load averages: 0.02, 0.04, 0.08 | | | | | | | | | | | | |

Exit Status The following exit values are returned:

0
Successful completion.

1
An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [date\(1\)](#), [lgrpinfo\(1\)](#), [plgrp\(1\)](#), [proc\(1\)](#), [ps\(1\)](#), [time\(2\)](#), [psrinfo\(1M\)](#), [psrset\(1M\)](#), [sar\(1M\)](#), [pset_getloadavg\(3C\)](#), [proc\(4\)](#), [project\(4\)](#), [attributes\(5\)](#), [resource_controls\(5\)](#), [zones\(5\)](#)

Notes The snapshot of system usage displayed by `prstat` is true only for a split-second, and it may not be accurate by the time it is displayed. When the `-m` option is specified, `prstat` tries to turn on microstate accounting for each process; the original state is restored when `prstat` exits. See [proc\(4\)](#) for additional information about the microstate accounting facility.

The total memory size reported in the SWAP and RSS columns for groups of processes can sometimes overestimate the actual amount of memory used by processes with shared memory segments.

Name prtconf – print system configuration

Synopsis /usr/sbin/prtconf [-V] | [-F] | [-x] | [-bpv] | [-acdDPv]
[dev_path]

Description The prtconf command prints the system configuration information. The output includes the total amount of memory, and the configuration of system peripherals formatted as a device tree.

If a device path is specified on the command line for those command options that can take a device path, prtconf will only display information for that device node.

Options The following options are supported:

- a Display all the ancestors device nodes, up to the root node of the device tree, for the device specified on the command line.
- b Display the firmware device tree root properties for the purpose of platform identification. These properties are “name”, “compatible”, “banner-name” and “model”.
- c Display the device subtree rooted at the device node specified on the command line, that is, display all the children of the device node specified on the command line.
- d Display vendor ID and device ID for PCI and PCI Express devices, in addition to the nodename.
- D For each system peripheral in the device tree, displays the name of the device driver used to manage the peripheral.
- F Returns the device path name of the console frame buffer, if one exists. If there is no frame buffer, prtconf returns a non-zero exit code. This flag must be used by itself. It returns only the name of the console, frame buffer device or a non-zero exit code. For example, if the console frame buffer on a SUNW,Ultra-30 is ffb, the command returns: /SUNW,ffb@1e,0:ffb0. This option could be used to create a symlink for /dev/fb to the actual console device.
- p Displays information derived from the device tree provided by the firmware (PROM) on SPARC platforms or the booting system on x86 platforms. The device tree information displayed using this option is a snapshot of the initial configuration and may not accurately reflect reconfiguration events that occur later.
- P Includes information about pseudo devices. By default, information regarding pseudo devices is omitted.
- v Specifies verbose mode.
- V Displays platform-dependent PROM (on SPARC platforms) or booting system (on x86 platforms) version information. This flag must be used by itself. The output is a string. The format of the string is arbitrary and platform-dependent.

- x Reports if the firmware on this system is 64-bit ready. Some existing platforms may need a firmware upgrade in order to run the 64-bit kernel. If the operation is not applicable to this platform or the firmware is already 64-bit ready, it exits silently with a return code of zero. If the operation is applicable to this platform and the firmware is not 64-bit ready, it displays a descriptive message on the standard output and exits with a non-zero return code. The hardware platform documentation contains more information about the platforms that may need a firmware upgrade in order to run the 64-bit kernel.

This flag overrides all other flags and must be used by itself.

Operands The following operands are supported:

dev_path The path to a target device minor node, device nexus node, or device link for which device node configuration information is displayed

Exit Status The following exit values are returned:

0 No error occurred.

non-zero With the -F option (SPARC only), a non-zero return value means that the output device is not a frame buffer. With the -x option, a non-zero return value means that the firmware is not 64-bit ready. In all other cases, a non-zero return value means that an error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------------------|
| Availability | system/extended-system-utilities |
| Interface Stability | Uncommitted |

See Also [fuser\(1M\)](#), [modinfo\(1M\)](#), [sysdef\(1M\)](#), [attributes\(5\)](#)

Sun Hardware Platform Guide

SPARC Only [openprom\(7D\)](#)

Notes The output of the `prtconf` command is highly dependent on the version of the PROM installed in the system. The output will be affected in potentially all circumstances.

The `driver not attached` message means that no driver is currently attached to that instance of the device. In general, drivers are loaded and installed (and attached to hardware instances) on demand, and when needed, and may be uninstalled and unloaded when the device is not in use.

On x86 platforms, the use of `prtconf -vp` provides a subset of information from `prtconf -v`. The value of integer properties from `prtconf -vp` might require byte swapping for correct interpretation.

Name prtdiag – display system diagnostic information

Synopsis /usr/sbin/prtdiag [-v] [-l]

Description prtdiag displays system configuration and diagnostic information on sun4u, sun4v, and x86 systems.

The diagnostic information lists any failed field replaceable units (FRUs) in the system.

The interface, output, and location in the directory hierarchy for prtdiag are uncommitted and subject to change in future releases.

prtdiag does not display diagnostic information and environmental status when executed on the Sun Enterprise 10000 server. See the /var/opt/SUNWssp/adm/\${SUNW_HOSTNAME}/messages file on the system service processor (SSP) to obtain such information for this server.

Options The following options are supported:

- l Log output. If failures or errors exist in the system, output this information to [syslogd\(1M\)](#) only.
- v Verbose mode. Displays the time of the most recent AC Power failure, and the most recent hardware fatal error information, and (if applicable) environmental status. The hardware fatal error information is useful to repair and manufacturing for detailed diagnostics of FRUs.

Exit Status The following exit values are returned:

- 0 No failures or errors are detected in the system.
- 1 Failures or errors are detected in the system.
- 2 An internal prtdiag error occurred, for example, out of memory.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-------------------------|
| Availability | system/library/platform |
| Interface Stability | Uncommitted* |

*The output is unstable.

See Also [modinfo\(1M\)](#), [prtconf\(1M\)](#), [psrinfo\(1M\)](#), [sysdef\(1M\)](#), [syslogd\(1M\)](#), [attributes\(5\)](#), [openprom\(7D\)](#)

Notes Not all diagnostic and system information is available on every Solaris platform, and therefore cannot be displayed by `prtdiag`. On those platforms, further information can be obtained from the System Controller.

Name prtdscp – display DSCP IP addresses

Synopsis prtdscp [-v]
prtdscp [-v] -h
prtdscp [-v] -d
prtdscp [-v] -s

Description prtdscp displays the IP addresses associated with a Domain to Service Processor Communications Protocol (DSCP) link. If no arguments are specified, prtdscp displays the IP addresses on both ends of the DSCP link. The IP address of either the Service Processor or domain side can be displayed separately by the use of the -s or -d options, respectively.

Options The following options are supported:

- v Verbose mode. Print additional details about the program's internal progress to stderr.
- h Help. Print a brief synopsis of the program's usage and exit. All other command line arguments are ignored.
- d Display only the local domain's IP address.
- s Display only the remote Service Processor's IP address.

Examples EXAMPLE 1 Displaying both addresses

The following example displays both the local domain's IP address and the remote SP's IP address:

```
# prtdscp
Domain Address: 192.168.103.2
SP Address: 192.168.103.1
```

EXAMPLE 2 Displaying the local IP address

The following example displays the local domain's IP address:

```
# prtdscp -d
192.168.103.2
```

EXAMPLE 3 Displaying the remote IP address

The following example display the remote SP's IP address:

```
# prtdscp -s
192.168.103.1
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|---------------------------------------------------------------------------|
| Availability | system/domain-service-processor-protocol/sparc-enterprise,
SUNWdscpu.u |
| Interface Stability | Committed |

See Also [attributes\(5\)](#)

Name prtfu – print FRUID-specific information about the FRUs on a system or domain

Synopsis /usr/sbin/prtfu [-d] | [-clx] [*container*]

Description The prtfu utility is used to obtain FRUID data from the system or domain. Its output is that of a tree structure echoing the path in the FRU (Field-Replaceable Unit) tree to each container. When a container is found, the data from that container is printed in a tree-like structure as well.

prtfu without any arguments will print the FRU hierarchy and all of the FRUID container data. prtfu prints to stdout which may be redirected to a file.

Options The following options are supported:

- c Prints *only* the containers and their data. This option does not print the FRU tree hierarchy.
- d Prints a DTD for the current registry to stdout.
- l Prints *only* the FRU tree hierarchy. This option does not print the container data.
- x Prints in XML format with a system identifier (SYSTEM) of prtfureg.dtd.

Options -c and -l can be used together to obtain a list of the containers.

Operands The following operand is supported:

container The name of a particular container in the FRU hierarchy, that is, either the name or path/name of a container as displayed in the -l option.

Exit Status The following exit values are returned:

- 0 All information was found and printed successfully.
- >0 An error has occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | system/fru-id |

See Also [fruadm\(1M\)](#), [attributes\(5\)](#)

Name prtpicl – print PICL tree

Synopsis /usr/sbin/prtpicl [-c *picl_class*] [-v]

Description The prtpicl command prints the PICL tree maintained by the PICL daemon. The output of prtpicl includes the name and PICL class of the nodes.

Options The following options are supported:

-c *picl_class* Print only the nodes of the named PICL class.

-v Print in verbose mode. In verbose mode, prtpicl prints a list of properties and values for each node. Verbose mode is disabled by default.

Exit Status The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | service/picl |

See Also [picld\(1M\)](#), [attributes\(5\)](#)

Name prvtoc – report information about a disk geometry and partitioning

Synopsis prvtoc [-fhs] [-t *vfstab*] [-m *mnttab*] *device*

Description The `prvtoc` command allows the contents of the label to be viewed. The command can be used only by the super-user.

The *device* name can be the file name of a raw device in the form of `/dev/rdisk/c?t?d?s2` or can be the file name of a block device in the form of `/dev/dsk/c?t?d?s2`.

Options The following options are supported:

- f Report on the disk free space, including the starting block address of the free space, number of blocks, and unused partitions.
- h Omit the headers from the normal output.
- m *mnttab* Use *mnttab* as the list of mounted filesystems, in place of `/etc/mnttab`.
- s Omit all headers but the column header from the normal output.
- t *vfstab* Use *vfstab* as the list of filesystem defaults, in place of `/etc/vfstab`.

Examples EXAMPLE 1 Using the `prvtoc` Command

The following example uses the `prvtoc` command on a 424-megabyte hard disk:

```
example# prvtoc /dev/rdisk/c0t3d0s2
* /dev/rdisk/c0t3d0s2 partition map
*
* Dimension:
*   512 bytes/sector
*   80 sectors/track
*   9 tracks/cylinder
*   720 sectors/cylinder
*   2500 cylinders
*   1151 accessible cylinders
*
* Flags:
* 1: unmountable
* 10: read-only
* *
* Partition  Tag  Flags  First  Sector  Last  Mount Directory
* 0          2    00      0    76320   76319  /
* 1          3    01   76320  132480  208799
* 2          5    00      0    828720  828719
* 5          6    00  208800  131760  340559  /opt
* 6          4    00  340560  447120  787679  /usr
* 7          8    00  787680  41040   828719  /export/home
example#
```

EXAMPLE 1 Using the `prvtoc` Command (Continued)

The data in the `Tag` column above indicates the type of partition, as follows:

| <i>Name</i> | <i>Number</i> |
|-------------|---------------|
| UNASSIGNED | 0x00 |
| BOOT | 0x01 |
| ROOT | 0x02 |
| SWAP | 0x03 |
| USR | 0x04 |
| BACKUP | 0x05 |
| STAND | 0x06 |
| VAR | 0x07 |
| HOME | 0x08 |
| ALTSCTR | 0x09 |
| CACHE | 0x0a |
| RESERVED | 0x0b |

The data in the `Flags` column above indicates how the partition is to be mounted, as follows:

| <i>Name</i> | <i>Number</i> |
|---------------------------|---------------|
| MOUNTABLE, READ AND WRITE | 0x00 |
| NOT MOUNTABLE | 0x01 |
| MOUNTABLE, READ ONLY | 0x10 |

EXAMPLE 2 Using the `prvtoc` Command with the `-f` Option

The following example uses the `prvtoc` command with the `-f` option on a 424-megabyte hard disk:

```
example# prvtoc -f /dev/rdisk/c0t3d0s2
FREE_START=0 FREE_SIZE=0 FREE_COUNT=0 FREE_PART=34
```

EXAMPLE 3 Using the `prvtoc` Command on a Disk Over One Terabyte

The following example uses the `prvtoc` command on a disk over one terabyte:.

EXAMPLE 3 Using the prvtoc Command on a Disk Over One Terabyte (Continued)

```

example# prvtoc /dev/rdisk/c1t1d0s2
* /dev/rdisk/c1t1d0s2 partition map
*
* Dimensions:
*   512 bytes/sector
* 3187630080 sectors
* 3187630013 accessible sectors
*
* Flags:
*   1: unmountable
*  10: read-only
*
*
* Partition Tag  Flags      First   Sector   Last
* Partition Tag  Flags      Sector  Count   Sector  Mount Directory
0      2    00          34   262144   262177
1      3    01     262178   262144   524321
6      4    00     524322 3187089340 3187613661
8      11   00  3187613662   16384 318763004

```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [devinfo\(1M\)](#), [fmthard\(1M\)](#), [format\(1M\)](#), [mount\(1M\)](#), [attributes\(5\)](#)

Warnings The mount command does not check the "not mountable" bit.

Name psradm – change processor operational status

Synopsis psradm -f | -i | -n | -s [-v] [-F] *processor_id*
psradm -a -f | -i | -n | -s [-v] [-F]

Description The psradm utility changes the operational status of processors. The legal states for the processor are on-line, off-line, spare, faulted, and no-intr.

An on-line processor processes LWPs (lightweight processes) and can be interrupted by I/O devices in the system.

An off-line processor does not process any LWPs. Usually, an off-line processor is not interruptible by I/O devices in the system. On some processors or under certain conditions, it might not be possible to disable interrupts for an off-line processor. Thus, the actual effect of being off-line might vary from machine to machine.

A spare processor does not process any LWPs. A spare processor can be brought on-line, off-line or to no-intr by a privileged user of the system or by the kernel in response to changes in the system state.

A faulted processor is identified by the kernel, which monitors the behavior of processors over time. A privileged user can set the state of a faulted processor to be on-line, off-line, spare or no-intr, but must use the force option to do so.

A no-intr processor processes LWPs but is not interruptible by I/O devices.

A processor can not be taken off-line or made spare if there are LWPs that are bound to the processor unless the additional -F option is used. The -F option removes processor bindings of such LWPs before changing the processor's operational status. On some architectures, it might not be possible to take certain processors off-line or spare if, for example, the system depends on some resource provided by the processor.

At least one processor in the system must be able to process LWPs. At least one processor must also be able to be interrupted. Since an off-line or spare processor can be interruptible, it is possible to have an operational system with one processor no-intr and all other processors off-line or spare but with one or more accepting interrupts.

If any of the specified processors are powered off, psradm might power on one or more processors.

Only users with the PRIV_SYS_RES_CONFIG privilege can use the psradm utility.

Options The following options are supported:

- a Perform the action on all processors, or as many as possible.
- f Take the specified processors off-line.

- F Force the transition to the additional specified state. Required if one or more of the specified processors was in the faulted state. Set the specified processors to faulted, if no other transition option was specified. Forced transitions can only be made to faulted, spare, or off-line states. Administrators are encouraged to use the -Q option for [pbind\(1M\)](#) to find out which threads will be affected by forced a processor state transition.
- i Set the specified processors no-intr.
- n Bring the specified processors on-line.
- s Make the specified processors spare.
- v Output a message giving the results of each attempted operation.

Operands The following operands are supported:

processor_id The processor ID of the processor to be set on-line or off-line, spare, or no-intr.

Specify *processor_id* as an individual processor number (for example, 3), multiple processor numbers separated by spaces (for example, 1 2 3), or a range of processor numbers (for example, 1-4). It is also possible to combine ranges and (individual or multiple) *processor_ids* (for example, 1-3 5 7-8 9).

Examples **EXAMPLE 1** Setting Processors to off-line

The following example sets processors 2 and 3 off-line:

```
% psradm -f 2 3
```

EXAMPLE 2 Setting Processors to no-intr

The following example sets processors 1 and 2 no-intr:

```
% psradm -i 1 2
```

EXAMPLE 3 Setting Processors to spare

The following example sets processors 1 and 2 spare, even if either of the processors was in the faulted state:

```
% psradm -F -s 1 2
```

EXAMPLE 4 Setting All Processors on-Line

```
% psradm -a -n
```

EXAMPLE 5 Forcing Processors to off-line

The following example sets processors 1 and 2 offline, and revokes the processor bindings from the processes bound to them:

```
% psradm -F -f 1 2
```

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Files /etc/wtmpx Records logging processor status changes

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [pbind\(1M\)](#), [psrinfo\(1M\)](#), [psrset\(1M\)](#), [p_online\(2\)](#), [processor_bind\(2\)](#), [attributes\(5\)](#)

Diagnostics psradm: processor 4: Invalid argument

The specified processor does not exist in the configuration.

psradm: processor 3: Device busy

The specified processor could not be taken off-line because it either has LWPs bound to it, is the last on-line processor in the system, or is needed by the system because it provides some essential service.

psradm: processor 3: Device busy

The specified processor could not be set no-interrupt because it is the last interruptible processor in the system, or it is the only processor in the system that can service interrupts needed by the system.

psradm: processor 3: Device busy

The specified processor is powered off, and it cannot be powered on because some platform-specific resource is unavailable.

psradm: processor 0: Not owner

The user does not have permission to change processor status.

psradm: processor 2: Operation not supported

The specified processor is powered off, and the platform does not support power on of individual processors.

Name psrinfo – displays information about processors

Synopsis psrinfo [-p] [-v] [*processor_id*]...

psrinfo [-p] -s *processor_id*

Description psrinfo displays information about processors. Each physical processor may support multiple virtual processors. Each virtual processor is an entity with its own interrupt ID, capable of executing independent threads.

Without the *processor_id* operand, psrinfo displays one line for each configured processor, displaying whether it is on-line, non-interruptible (designated by no-intr), spare, off-line, faulted or powered off, and when that status last changed. Use the *processor_id* operand to display information about a specific processor. See OPERANDS.

Options The following options are supported:

-s *processor_id* Silent mode. Displays 1 if the specified processor is fully on-line. Displays 0 if the specified processor is non-interruptible, spare, off-line, faulted or powered off.

Use silent mode when using psrinfo in shell scripts.

-p Display the number of physical processors in a system.

When combined with the -v option, reports additional information about each physical processor.

-v Verbose mode. Displays additional information about the specified processors, including: processor type, floating point unit type and clock speed. If any of this information cannot be determined, psrinfo displays unknown.

When combined with the -p option, reports additional information about each physical processor.

Operands The following operands are supported:

processor_id The processor ID of the processor about which information is to be displayed.

Specify *processor_id* as an individual processor number (for example, 3), multiple processor numbers separated by spaces (for example, 1 2 3), or a range of processor numbers (for example, 1-4). It is also possible to combine ranges and (individual or multiple) *processor_ids* (for example, 1-3 5 7-8 9).

Examples EXAMPLE 1 Displaying Information About All Configured Processors in Verbose Mode

The following example displays information about all configured processors in verbose mode.

```
psrinfo -v
```

EXAMPLE 2 Determining If a Processor is On-line

The following example uses `psrinfo` in a shell script to determine if a processor is on-line.

```
if [ "$psrinfo -s 3 2> /dev/null" -eq 1 ]
then
    echo "processor 3 is up"
fi
```

EXAMPLE 3 Displaying Information About the Physical Processors in the System

With no additional arguments, the `-p` option displays a single integer: the number of physical processors in the system:

```
> psrinfo -p
      8
```

`psrinfo` also accepts command line arguments (processor IDs):

```
> psrinfo -p 0 512 # IDs 0 and 512 exist on the
1                # same physical processor
```

```
> psrinfo -p 0 1  # IDs 0 and 1 exist on different
2                # physical processors
```

In this example, virtual processors 0 and 512 exist on the same physical processor. Virtual processors 0 and 1 do not. This is specific to this example and is not a general rule.

Exit Status The following exit values are returned:

```
0      Successful completion.
>0    An error occurred.
```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [psradm\(1M\)](#), [p_online\(2\)](#), [processor_info\(2\)](#), [attributes\(5\)](#)

Diagnostics `psrinfo: processor 9: Invalid argument` The specified processor does not exist.

Name psrset – creation and management of processor sets

Synopsis psrset -a [-F] *processor_set_id processor_id...*
psrset -b *processor_set_id pid [/lwpid]...*
psrset -c [-F] [*processor_id*]...
psrset -d *processor_set_id...*
psrset -e *processor_set_id command [argument(s)]*
psrset -f *processor_set_id*
psrset [-i] [*processor_set_id*]...
psrset -n *processor_set_id*
psrset -p [*processor_id*]...
psrset [-q] [*pid [/lwpid]*]...
psrset -Q [*processor_set_id*]...
psrset -r [-F] *processor_id...*
psrset -u *pid [/lwpid]*...
psrset -U [*processor_set_id*]...

Description The psrset utility controls the management of processor sets. Processor sets allow the binding of processes or LWPs to groups of processors, rather than just a single processor. Processors assigned to processor sets can run only LWPs that have been bound to that processor set.

This command cannot be used to modify processor disposition when pools are enabled. Use [pooladm\(1M\)](#) and [poolcfg\(1M\)](#) to modify processor set configuration through the resource pools facility.

Options The following options are supported:

- a Assign the specified processors to the specified processor set. With the additional -F option, all LWPs bound to the specified processors will be unbound prior to changing processor sets.

This option is restricted to users with the PRIV_SYS_RES_CONFIG privilege.

- b Bind all or a subset of the LWPs of the specified processes to the specified processor set.

LWPs bound to a processor set are restricted to run only on the processors in that set. Processes can only be bound to non-empty processor sets, that is, processor sets that have had processors assigned to them.

Bindings are inherited, so new LWPs and processes created by a bound LWP have the same binding. Binding an interactive shell to a processor, for example, binds all commands executed by the shell.

This option is restricted to users with the `PRIV_SYS_RES_CONFIG` privilege.

- c Create a new processor set and displays the new processor set ID. With the additional `-F` option, all LWPs bound to the specified processors will be unbound prior to assigning them to the processor set being created.

If a list of processors is given, it also attempts to assign those processors to the processor set. If this succeeds, the processors are idle until LWPs are bound to the processor set. This option is restricted to users with the `PRIV_SYS_RES_CONFIG` privilege.

Only a limited number of processor sets can be active (created and not destroyed) at a given time. This limit is always be greater than the number of processors in the system. If the `-c` option is used when the maximum number of processor sets is already active, the command fails.

The following format is used for the first line of output of the `-c` option when the `LC_MESSAGES` locale category specifies the “C” locale. In other locales, the strings `created`, `processor`, and `set` can be replaced with more appropriate strings corresponding to the locale.

```
"created processor set %d\n" processor set ID
```

- d Remove the specified processor set, releasing all processors and processes associated with it.

This option is restricted to users with the `PRIV_SYS_RES_CONFIG` privilege.

- e Execute a command (with optional arguments) in the specified processor set.

The command process and any child processes are executed only by processors in the processor set.

This option is restricted to users with the `PRIV_SYS_RES_CONFIG` privilege.

- f Disables interrupts for all processors within the specified processor set. See [psradm\(1M\)](#).

If some processors in the set cannot have their interrupts disabled, the other processors still have their interrupts disabled, and the command reports an error and return non-zero exit status.

This option is restricted to users with the `PRIV_SYS_RES_CONFIG` privilege.

- F Forces the specified processor set operation by unbinding all threads bound to the specified processor. Only the -a or the -r option can be used in combination with this option. Administrators are encouraged to use the -Q option for [pbind\(1M\)](#) to find out which threads will be affected by such operation.
- i Display a list of processors assigned to each named processor set. If no argument is given, a list of all processor sets and the processors assigned to them is displayed. This is also the default operation if the `psrset` command is not given an option.
- n Enable interrupts for all processors within the specified processor set. See [psradm\(1M\)](#).

This option is restricted to users with the `PRIV_SYS_RES_CONFIG` privilege.
- p Display the processor set assignments for the specified list of processors. If no argument is given, the processor set assignments for all processors in the system is given.
- q Display the processor set bindings of the specified processes or of all processes. If a process is composed of multiple LWPs which have different bindings and the LWPs are not explicitly specified, the bindings of only one of the bound LWPs is displayed. The bindings of a subset of LWPs can be displayed by appending “/lwpids” to the process IDs. Multiple LWPs may be selected using “-” and “,” delimiters. See EXAMPLES.
- Q Display the LWPs bound to the specified list of processor sets, or all LWPs with processor set bindings.
- r Remove a list of processors from their current processor sets. Processors that are removed return to the general pool of processors.

Processors with LWPs bound to them using [pbind\(1M\)](#) can be assigned to or removed from processor sets using the -F option.

This option is restricted to users with the `PRIV_SYS_RES_CONFIG` privilege.
- u Remove the processor set bindings of a subset or all the LWPs of the specified processes, allowing them to be executed on any on-line processor if they are not bound to individual processors through `pbind`.

Users with the `PRIV_SYS_RES_CONFIG` privilege can unbind any process or LWP from any active processor set. Other users can unbind processes and LWPs from processor sets that do not have the `PSET_NOESCAPE` attribute set. In addition, the user must have permission to control the affected processes; the real or effective user ID of the user must match the real or saved user ID of the target processes.
- U Removes the bindings of all LWPs bound to the specified list of processor sets, or to any processor set if no argument is specified.

Operands The following operands are supported:

| | | | | | | | |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|-------------------------------|----|-------------------------------|----|-------------------------------|
| <i>pid</i> | Specify <i>pid</i> as a process ID. | | | | | | |
| <i>lwpid</i> | The set of LWPIDs of the specified process to be controlled or queried.
The syntax for selecting LWP IDs is as follows: <table> <tr> <td>2,3,4-8</td> <td>LWP IDs 2, 3, and 4 through 8</td> </tr> <tr> <td>-4</td> <td>LWPs whose IDs are 4 or below</td> </tr> <tr> <td>4-</td> <td>LWPs whose IDs are 4 or above</td> </tr> </table> | 2,3,4-8 | LWP IDs 2, 3, and 4 through 8 | -4 | LWPs whose IDs are 4 or below | 4- | LWPs whose IDs are 4 or above |
| 2,3,4-8 | LWP IDs 2, 3, and 4 through 8 | | | | | | |
| -4 | LWPs whose IDs are 4 or below | | | | | | |
| 4- | LWPs whose IDs are 4 or above | | | | | | |
| <i>processor_id</i> | Specify <i>processor_id</i> as an individual processor number (for example, 3), multiple processor numbers separated by spaces (for example, 1 2 3), or a range of processor numbers (for example, 1-4). It is also possible to combine ranges and (individual or multiple) <i>processor_ids</i> (for example, 1-3 5 7-8 9). | | | | | | |
| <i>processor_set_id</i> | Specify <i>processor_set_id</i> as a processor set ID. | | | | | | |

Exit Status The following exit values are returned:

| | |
|-------|------------------------|
| 0 | Successful completion. |
| non-0 | An error occurred. |

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| Interface Stability | Committed |

See Also [pbind\(1M\)](#), [pooladm\(1M\)](#), [poolcfg\(1M\)](#), [psradm\(1M\)](#), [psrinfo\(1M\)](#), [processor_bind\(2\)](#), [processor_info\(2\)](#), [pset_bind\(2\)](#), [pset_create\(2\)](#), [pset_info\(2\)](#), [sysconf\(3C\)](#), [libpool\(3LIB\)](#), [attributes\(5\)](#), [privileges\(5\)](#)

Diagnostics The following output indicates that the specified process did not exist or has exited:

```
psrset: cannot query pid 31: No such process
```

The following output indicates that the user does not have permission to bind the process:

```
psrset: cannot bind pid 31: Not owner
```

The following output indicates that the user does not have permission to assign the processor:

```
psrset: cannot assign processor 4: Not owner
```

The following output indicates that the specified processor is not on-line, or the specified processor does not exist.

```
psrset: cannot assign processor 8: Invalid argument
```

The following output indicates that an LWP in the specified process is bound to a processor and cannot be bound to a processor set that does not include that processor:

```
psrset: cannot bind pid 67: Device busy
```

The following output indicates that the specified processor could not be added to the processor set. This can be due to bound LWPs on that processor, or because that processor cannot be combined in the same processor set with other processors in that set, or because the processor is the last one in its current processor set:

```
psrset: cannot assign processor 7: Device busy
```

The following output indicates that the specified processor set does not exist:

```
psrset: cannot execute in processor set 8: Invalid argument
```

The following output indicates that the maximum number of processor sets allowed in the system is already active:

```
psrset: cannot create processor set: Not enough space
```

The following output indicates that the pools facility is active.

```
psrset: cannot assign processor 7: Operation not supported
psrset: cannot bind pid 31: Operation not supported
psrset: cannot bind pid 31: Operation not supported
psrset: could not create processor set: Operation not supported
psrset: could not remove processor set 1: Operation not supported
psrset: cannot exec in processor set 1: Operation not supported
psrset: cannot remove processor 7: Operation not supported
psrset: cannot unbind pid 31: Operation not supported
```

Name putdev – edits device table

Synopsis putdev -a *alias* [*attribute=value* [...]]
 putdev -m *device attribute=value* [*attribute = value* [...]]
 putdev -d *device* [*attribute* [...]]

Description putdev adds a new device to the device table, modifies an existing device description or removes a device entry from the table. The first synopsis is used to add a device. The second synopsis is used to modify existing entries by adding or changing attributes. If a specified attribute is not defined, this option adds that attribute to the device definition. If a specified attribute is already defined, it modifies the attribute definition. The third synopsis is used to delete either an entire device entry or, if the attribute argument is used, to delete an attribute assignment for a device.

Options The following options are supported:

- a Add a device to the device table using the specified attributes. The device must be referenced by its `alias`.
- d Remove a device from the device table, when executed without the *attributes* argument. Used with the *attribute* argument, it deletes the given attribute specification for *device* from the table.
- m Modify a device entry in the device table. If an entry already exists, it adds any specified attributes that are not defined. It also modifies any attributes which already have a value with the value specified by this command.

Operands The following operands are supported:

- alias* Designates the alias of the device to be added.
- attribute* Designates a device attribute to be added, modified, or deleted. Can be any of the device attributes described under `DEVICE ATTRIBUTES` except `alias`. This prevents an accidental modification or deletion of a device's alias from the table.
- device* Designates the pathname or alias of the device whose attribute is to be added, modified, or removed.
- value* Designates the value to be assigned to a device's attribute.

Device Attributes The following list shows the standard device attributes, used by applications such as `ufsdump(1M)` and `ufsrestore(1M)`, which can be defined for a device. You are not limited to this list, you can define any attribute you like.

- `alias` The unique name by which a device is known. No two devices in the database may share the same alias name. The name is limited in length to 14 characters and should contain only alphanumeric characters and the following special characters if they are escaped with a backslash: underscore (`_`), dollar sign (`$`), hyphen (`-`), and period (`.`).

| | |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>bdevice</code> | The pathname to the block special device node associated with the device, if any. The associated major/minor combination should be unique within the database and should match that associated with the <code>cdevice</code> field, if any. (It is the administrator's responsibility to ensure that these major/minor numbers are unique in the database.) |
| <code>capacity</code> | The capacity of the device or of the typical volume, if removable. |
| <code>cdevice</code> | The pathname to the character special device node associated with the device, if any. The associated major/minor combination should be unique within the database and should match that associated with the <code>bdevice</code> field, if any. (It is the administrator's responsibility to ensure that these major/minor numbers are unique in the database.) |
| <code>cyl</code> | Used by the command specified in the <code>mkfscmd</code> attribute. |
| <code>desc</code> | A description of any instance of a volume associated with this device (such as floppy diskette). |
| <code>dpartlist</code> | The list of disk partitions associated with this device. Used only if <code>type=disk</code> . The list should contain device aliases, each of which must have <code>type=dpart</code> . |
| <code>dparttype</code> | The type of disk partition represented by this device. Used only if <code>type=dpart</code> . It should be either <code>fs</code> (for file system) or <code>dp</code> (for data partition). |
| <code>erasescmd</code> | The command string that, when executed, erases the device. |
| <code>fmtcmd</code> | The command string that, when executed, formats the device. |
| <code>fsname</code> | The file system name on the file system administered on this partition, as supplied to the <code>/usr/sbin/labelit</code> command. This attribute is specified only if <code>type=dpart</code> and <code>dparttype=fs</code> . |
| <code>gap</code> | Used by the command specified in the <code>mkfscmd</code> attribute. |
| <code>mkfscmd</code> | The command string that, when executed, places a file system on a previously formatted device. |
| <code>mountpt</code> | The default mount point to use for the device. Used only if the device is mountable. For disk partitions where <code>type=dpart</code> and <code>dparttype=fs</code> , this attribute should specify the location where the partition is normally mounted. |
| <code>nblocks</code> | The number of blocks in the file system administered on this partition. Used only if <code>type=dpart</code> and <code>dparttype=fs</code> . |
| <code>ninodes</code> | The number of inodes in the file system administered on this partition. Used only if <code>type=dpart</code> and <code>dparttype=fs</code> . |
| <code>norewind</code> | The name of the character special device node that allows access to the serial device without rewinding when the device is closed. |

| | |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>pathname</code> | Defines the pathname to an i-node describing the device (used for non-block or character device pathnames, such as directories). |
| <code>type</code> | A token that represents inherent qualities of the device. Standard types include: 9-track, ctape, disk, directory, diskette, dpart, and qtape. |
| <code>volname</code> | The volume name on the file system administered on this partition, as supplied to the <code>/usr/sbin/labelit</code> command. Used only if <code>type=dpart</code> and <code>dparttype=fs</code> . |
| <code>volume</code> | A text string used to describe any instance of a volume associated with this device. This attribute should not be defined for devices which are not removable. |

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 Command syntax was incorrect, an invalid option was used, or an internal error occurred.
- 2 The device table could not be opened for reading, or a new device table could not be created.
- 3 If executed with the `-a` option, indicates that an entry in the device table with the alias `alias` already exists. If executed with the `-m` or `-d` options, indicates that no entry exists for device *device*.
- 4 Indicates that `-d` was requested and one or more of the specified attributes were not defined for the device.

System Administration Guide: Basic Administration

Name putdgrp – edits device group table

Synopsis putdgrp [-d] *dgroup* [*device*] . . .

Description putdgrp modifies the device group table. It performs two kinds of modification. It can modify the table by creating a new device group or removing a device group. It can also change group definitions by adding or removing a device from the group definition.

When the command is invoked with only a *dgroup* specification, the command adds the specified group name to the device group table if it does not already exist. If the -d option is also used with only the *dgroup* specification, the command deletes the group from the table.

When the command is invoked with both a *dgroup* and a *device* specification, it adds the given device name(s) to the group definition. When invoked with both arguments and the -d option, the command deletes the device name(s) from the group definition.

When the command is invoked with both a *dgroup* and a *device* specification and the device group does not exist, it creates the group and adds the specified devices to that new group.

Options The following options are supported:

-d Delete the group or, if used with *device*, delete the device from a group definition.

Operands The following operands are supported:

dgroup Specify a device group name.

device Specify the pathname or alias of the device that is to be added to, or deleted from, the device group.

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 Command syntax was incorrect, an invalid option was used, or an internal error occurred.
- 2 Device group table could not be opened for reading or a new device group table could not be created.
- 3 If executed with the -d option, indicates that an entry in the device group table for the device group *dgroup* does not exist and so cannot be deleted. Otherwise, indicates that the device group *dgroup* already exists and cannot be added.
- 4 If executed with the -d option, indicates that the device group *dgroup* does not have as members one or more of the specified devices. Otherwise, indicates that the device group *dgroup* already has one or more of the specified devices as members.

Examples EXAMPLE 1 Adding a new device group.

The following example adds a new device group:

```
example# putdgrp floppies
```

EXAMPLE 2 Adding a device to a device group.

The following example adds a device to a device group:

```
example# putdgrp floppies diskette2
```

EXAMPLE 3 Deleting a device group.

The following example deletes a device group:

```
example# putdgrp -d floppies
```

EXAMPLE 4 Deleting a device from a device group.

The following example deletes a device from a device group:

```
example# putdgrp -d floppies diskette2
```

Name pwck, grpck – password/group file checkers

Synopsis /usr/sbin/pwck [*filename*]

/usr/sbin/grpck [*filename*]

Description pwck scans the password file and notes any inconsistencies. The checks include validation of the number of fields, login name, user ID, group ID, and whether the login directory and the program-to-use-as-shell exist. The default password file is /etc/passwd.

grpck verifies all entries in the group file. This verification includes a check of the number of fields, group name, group ID, whether any login names belong to more than NGROUPS_MAX groups, and that all login names appear in the password file. grpck also issues a warning if it finds an entry (a single line) in the group file longer than 2047 characters. Such an entry causes group maintenance commands, such as [groupdel\(1M\)](#) and [groupmod\(1M\)](#), to fail.

The default group file is /etc/group.

All messages regarding inconsistent entries are placed on the stderr stream.

Files

- /etc/group
- /etc/passwd

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [groupdel\(1M\)](#), [groupmod\(1M\)](#), [getpwent\(3C\)](#), [group\(4\)](#), [passwd\(4\)](#), [attributes\(5\)](#)

Diagnostics Group entries in /etc/group with no login names are flagged.

Group file '*filename*' is empty

The /etc/passwd or /etc/group file is an empty file.

cannot open file *filename*: No such file or directory

The /etc/passwd or /etc/group file does not exist.

Notes If no filename argument is given, grpck checks the local group file, /etc/group, and also makes sure that all login names encountered in the checked group file are known to the system [getpwent\(3C\)](#) routine. This means that the login names may be supplied by a network name service.

Name pwconv – installs and updates `/etc/shadow` with information from `/etc/passwd`

Synopsis pwconv

Description The `pwconv` command creates and updates `/etc/shadow` with information from `/etc/passwd`.

`pwconv` relies on a special value of 'x' in the password field of `/etc/passwd`. This value of 'x' indicates that the password for the user is already in `/etc/shadow` and should not be modified.

If the `/etc/shadow` file does not exist, this command will create `/etc/shadow` with information from `/etc/passwd`. The command populates `/etc/shadow` with the user's login name, password, and password aging information. If password aging information does not exist in `/etc/passwd` for a given user, none will be added to `/etc/shadow`. However, the last changed information will always be updated.

If the `/etc/shadow` file does exist, the following tasks will be performed:

Entries that are in the `/etc/passwd` file and not in the `/etc/shadow` file will be added to the `/etc/shadow` file.

Entries that are in the `/etc/shadow` file and not in the `/etc/passwd` file will be removed from `/etc/shadow`.

Password attributes (for example, password and aging information) that exist in an `/etc/passwd` entry will be moved to the corresponding entry in `/etc/shadow`.

The `pwconv` command can only be used by the super-user.

- Files**
- `/etc/opasswd`
 - `/etc/oshadow`
 - `/etc/passwd`
 - `/etc/shadow`

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [passwd\(1\)](#), [usermod\(1M\)](#), [passwd\(4\)](#), [attributes\(5\)](#)

Diagnostics `pwconv` exits with one of the following values:

- 0 SUCCESS.
- 1 Permission denied.
- 2 Invalid command syntax.
- 3 Unexpected failure. Conversion not done.

- 4 Unexpected failure. Password file(s) missing.
- 5 Password file(s) busy. Try again later.
- 6 Bad entry in `/etc/shadow` file.

-
- Name** quot – summarize file system ownership
- Synopsis** quot [-acfhnv] *filesystem* . . .
 quot -a [-cfhnv]
- Description** quot displays the number of blocks (1024 bytes) in the named *filesystem* (one or more) currently owned by each user. There is a limit of 2048 blocks. Files larger than this will be counted as a 2048 block file, but the total block count will be correct.
- Options** The following options are supported:
- a Generate a report for all mounted file systems.
 - c Display three columns giving a file size in blocks, the number of files of that size, and a cumulative total of blocks containing files of that size or a smaller size.
 - f Display three columns giving, for each user, the number of blocks owned, the count of number of files, and the user name. This option is incompatible with the -c and -v options.
 - h Estimate the number of blocks in the file. This does not account for files with holes in them.
 - n Attach names to the list of files read from standard input. quot -n cannot be used alone, because it expects data from standard input. For example, the pipeline

```
ncheck myfilesystem | sort +0n | quot -n myfilesystem
```

 will produce a list of all files and their owners. This option is incompatible with all other options.
 - v In addition to the default output, display three columns containing the number of blocks not accessed in the last 30, 60, and 90 days.
- Operands** *filesystem* mount-point of the filesystem(s) being checked
- Usage** See [largefile\(5\)](#) for the description of the behavior of quot when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).
- Exit Status** 0 Successful operation.
 32 Error condition (bad or missing argument, bad path, or other error).
- Files** /etc/mnttab Lists mounted file systems.
 /etc/passwd Used to obtain user names
- Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------|----------------|
| Availability | SUNWcs |

See Also [du\(1\)](#), [mnttab\(4\)](#), [passwd\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

Notes This command can only be used by the super-user.

- Name** quota – display a user's ufs or zfs file system disk quota and usage
- Synopsis** quota [-v] [*username*]
- Description** quota displays users' UFS or ZFS disk usage and limits. Only the super-user may use the optional *username* argument to view the limits of other users.
- quota without options only display warnings about mounted file systems where usage is over quota. Remotely mounted file systems which do not have quotas turned on are ignored.
- username* can be the numeric UID of a user.
- Options** -v Display user's quota on all mounted file systems where quotas exist.
- Usage** See [largefile\(5\)](#) for the description of the behavior of quota when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).
- Files** /etc/mnttab list of currently mounted filesystems
- Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [edquota\(1M\)](#), [quotaon\(1M\)](#), [quotacheck\(1M\)](#), [repquota\(1M\)](#), [rquotad\(1M\)](#), [attributes\(5\)](#), [largefile\(5\)](#), [zones\(5\)](#)

Notes quota displays quotas for NFS mounted UFS- or ZFS-based file systems if the rquotad daemon is running. See [rquotad\(1M\)](#). In a [zones\(5\)](#) environment, quota displays quotas only for the zone in which it is invoked.

quota can display entries for the same file system multiple times for multiple mount points. For example,

```
# quota -v user1
```

might display identical quota information for user1 at the mount points /home/user1, /home/user2, and /home/user, if all three mount points are mounted from the same file system with quotas turned on.

Name quotacheck – ufs file system quota consistency checker

Synopsis quotacheck [-fp] [-v] *filesystem*...

quotacheck -a [-fpv]

Description quotacheck examines each mounted ufs file system, builds a table of current disk usage, and compares this table against the information stored in the file system's disk quota file. If any inconsistencies are detected, both the quota file and the current system copy of the incorrect quotas are updated.

filesystem is either a file system mount point or the block device on which the file system resides.

quotacheck expects each file system to be checked to have a quota file named quotas in the root directory. If none is present, quotacheck will not check the file system.

quotacheck accesses the character special device in calculating the actual disk usage for each user. Thus, the file systems that are checked should be quiescent while quotacheck is running.

Options The following options are supported:

- a Check the file systems which /etc/mnttab indicates are ufs file systems. These file systems must be read-write mounted with disk quotas enabled, and have an rq entry in the mntopts field in /etc/vfstab.
- f Force check on file systems with logging enabled. Use in combination with the -p option.
- p Check quotas of file systems in parallel. For file systems with logging enabled, no check is performed unless the -f option is also specified.
- v Indicate the calculated disk quotas for each user on a particular file system. quotacheck normally reports only those quotas modified.

Usage See [largefile\(5\)](#) for the description of the behavior of quotacheck when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files /etc/mnttab Mounted file systems
/etc/vfstab List of default parameters for each file system

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [edquota\(1M\)](#), [quota\(1M\)](#), [quotaon\(1M\)](#), [repquota\(1M\)](#), [attributes\(5\)](#), [largefile\(5\)](#), [quotactl\(7I\)](#), [mount_ufs\(1M\)](#)

Name quotaon, quotaoff – turn ufs file system quotas on and off

Synopsis quotaon [-v] *filesystem* . . .

quotaon -a [-v]

quotaoff [-v] *filesystem* . . .

quotaoff -a [-v]

Description quotaon turns on disk quotas for one or more ufs file systems.

Before a file system may have quotas enabled, a file named `quotas`, owned by root, must exist in the root directory of the file system. See [edquota\(1M\)](#) for details on how to modify the contents of this file.

quotaoff turns off disk quotas for one or more ufs file systems.

The file systems specified must already be mounted.

These commands update the `mntopts` field of the appropriate entries in `/etc/mnttab` to indicate when quotas are on or off for each file system. If quotas are on, the string `quota` will be added to `mntopts`; if quotas are off, the `quota` string is not present.

filesystem must be either the mount point of a file system, or the block device on which the file system resides.

Options

- quotaon -a This option is normally used at boot time to enable quotas. It applies only to those file systems in `/etc/vfstab` which have “rq” in the `mntopts` field, are currently mounted “rw”, and have a `quotas` file in the root directory.
- v Display a message for each file system after quotas are turned on.
- quotaoff -a Force all file systems in `/etc/mnttab` to have their quotas disabled.
- v Display a message for each file system affected.

Usage See [largefile\(5\)](#) for the description of the behavior of `quotaon` and `quotaoff` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files `/etc/mnttab` mounted file systems
`/etc/vfstab` list of default parameters for each file system

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [edquota\(1M\)](#), [quota\(1M\)](#), [quotacheck\(1M\)](#), [repquota\(1M\)](#), [mnttab\(4\)](#), [vfstab\(4\)](#), [attributes\(5\)](#), [largefile\(5\)](#), [quotactl\(7I\)](#)

Name raidctl – RAID hardware utility

Synopsis raidctl -C "disks" [-r *raid_level*] [-z *capacity*] [-s *stripe_size*] [-f] controller

raidctl -d [-f] *volume*

raidctl -F *filename* [-f] *controller...*

raidctl -a {set | unset} -g *disk* {*volume* | *controller*}

raidctl -p "*param=value*" [-f] *volume*

raidctl -c [-f] [-r *raid_level*] *disk1 disk2 [disk3...]*

raidctl -l -g *disk controller*

raidctl -l *volume*

raidctl -l *controller...*

raidctl [-l]

raidctl -S [*volume* | *controller*]

raidctl -S -g *disk controller*

raidctl -h

Description The `raidctl` utility is a hardware RAID configuration tool that supports different RAID controllers by providing a CLI (command-line interface) to end-users to create, delete or display RAID volume(s). The utility can also used to set properties of a volume, assign hot-spare (HSP) disks to volumes or controllers, and to update firmware/fcode/BIOS for RAID controllers.

The `raidctl` utility requires privileges that are controlled by the underlying file-system permissions. Only privileged users can manipulate the RAID system configuration. If a non-privileged user attempts to run `raidctl`, the command fails with an exit status of 1.

The `raidctl` utility, as described in this man page, defines a broad set of command line options to provide management for full-featured RAID controllers. However, support for a given option depends on two elements:

- the presence of a software driver
- the firmware level of the RAID device

The dependency on a software driver is due to the design of `raidctl`. The utility is built on a common library that enables the insertion of plug-in modules for different drivers. Currently, the Solaris operating system is shipped with a plug-in for the `mpt` driver. This plug-in does not support all of the `raidctl` options. On a given storage device, options might be further limited by the device's firmware level.

The level of support for the various `raidctl` options cannot be determined by `raidctl`. The user must rely on the documentation for his RAID controller or hardware platform.

Currently, `raidctl` provides some level of support for the following RAID controllers:

- LSI1020 SCSI HBA
- LSI1030 SCSI HBA
- LSI1064 SAS HBA
- LSI1068 SAS HBA

All of the above HBAs are maintained by the `mpt` driver, on X86-32/64 and SPARC platforms.

Options The following options are supported:

`-C "disks" [-r raid_level] [-z capacity] [-s stripe_size] [-f] controller`
Create a RAID volume using specified disks.

When creating a RAID volume using this option, the identity of the newly created volume is automatically generated and `raidctl` reports it to the user.

The argument specified by this option contains the elements used to form the volume that will be created. Elements can be either disks or sub-volumes, where disks are separated by space(s) and a sub-volume is a set of disks grouped by parenthesis. All disks should be in C.I.D.L expression (for example, `0.1.2` represents a physical disk of channel 0, target id 1, and logical unit number 2). The argument must match the RAID level specified by the `-r` option, even if it's omitted. This means the argument can only be:

for RAID 0

At least 2 disks

for RAID 1

Only 2 disks

for RAID 1E

At least 3 disks

for RAID 5

At least 3 disks

for RAID 10

At least 2 sub-volumes, each sub-volume must be formed by 2 disks

for RAID 50

At least 2 sub-volumes, each sub-volume must be formed by at least 3 disks, and the disk amount in each sub-volume should be the same

For example, the expression "0.0.0 0.1.0" means that the 2 specified disks form a RAID volume, which can either be a RAID 0 or a RAID 1 volume. "(0.0.0 0.1.0)(0.2.0 0.3.0)" means that the first 2 disks and the last 2 disks form 2 sub-volumes, and that these 2 sub-volumes form a RAID 10 volume. See the EXAMPLES section for more samples.

The `-r` option specifies the RAID level of the volume that will be created. Possible levels are 0, 1, 1E, 5, 10, 50. If this option is omitted, `raidctl` creates a RAID 1 volume by default.

The `-z` option specifies the capacity of the volume that will be created. The unit can be tera-bytes, giga-bytes, or mega-bytes (for example, 2t, 10g, 20m, and so on). If this option is omitted, `raidctl` calculates the maximum capacity of the volume that can be created by the specified disks and uses this value to create the volume.

The `-s` option specifies the stripe size of the volume that will be created. The possible values are 512, 1k, 2k, 4k, 8k, 16k, 32k, 64k, or 128k. If this option is omitted, `raidctl` chooses an appropriate value for the volume (for example, 64k).

In some cases, the creation of a RAID volume may cause data on specified disks to be lost (for instance, on LSI1020, LSI1030, SAS1064, or SAS1068 HBAs), and `raidctl` prompts the user for confirmation about the creation. Use the `-f` option to force the volume creation without prompting the user for confirmation.

The controller argument is used to identify which RAID controller the specified disks belongs. The `-l` option can be used to list the controller's ID number.

`-d [-f] volume`

Delete the RAID volume specified as `volume`. The volume is specified in canonical form (for example, `c0t0d0`).

When a volume is deleted, all data is lost. Therefore, unless the `-f` option is specified, `raidctl` prompts the user for confirmation before deleting the volume.

When a RAID 1 volume is deleted from a LSI1020, LSI1030, SAS1064, or SAS1068 HBA, the primary and secondary disks are “split”. If the volume was in `SYNCING` state, the primary will contain the data, and the secondary will not. If the volume state was `OPTIMAL`, both disks will contain a complete image of the data.

`-F filename [-f] controller...`

Update the firmware running on the specified controller(s). The `raidctl` utility prompts the user for confirmation of this action, unless the `-f` option is provided.

`-a {set | unset} -g disk {volume | controller}`

If the volume is specified, `raidctl` sets or unsets the disk as a local hot-spare disk dedicated to the volume, depending on the value specified by the `-a` option. If the controller is specified, `raidctl` sets or unsets the disk as a global hot-spare disk.

`-p "param=value" [-f] volume`

Change the property value for a given RAID volume. This option can be used to change cache write policy or to activate a volume. When changing the cache write policy, `param` should be the string `wp` (`SET_WR_POLICY`), and `value` can be either `on` or `off`. When used to activate a volume, `param` should be `state` and `value` should be `activate`.

Changing a RAID volume's property may affect the internal behavior of the RAID controller, so `raidctl` prompts the user for a confirmation before applying the change, unless the `-f` option is specified.

-c [-f] [-r *raid_level*] *disk1 disk2 [disk3...]*

Create a volume using the specified disks. This is an alternative to the -C option with similar functionality. This option is preserved for compatibility reasons, but only works with LSI1020, LSI1030, SAS1064, and SAS1068 HBAs to create RAID 0, RAID 1, or RAID 1E volumes. For other HBAs, the user can only use the -C option.

The -r option can be used to specify the RAID level of the target volume. If the -r option is omitted, `raidctl` will create a RAID 1 volume.

Disks must be specified in Solaris canonical format (for example, `c0t0d0`).

Creating a RAID 1 volume with this option replaces the contents of `disk2` with the contents of `disk1`.

When the user creates a RAID volume with this option, the RAID volume assumes the identity of `disk1`. Other disks become invisible and the RAID volume appears as one disk.

Creating a volume with this option is by default interactive. The user must answer a prompt affirmatively to create the volume. Use the -f option to force the volume creation without prompting the user for confirmation.

-l -g *disk controller*

Display information about the specified disk of the given controller. The output includes the following information:

Disk

Displays the disk in C . ID . L expression `disk`.

Vendor

Displays the vendor ID string.

Product

Displays the product ID string.

Capacity

Displays the total capacity of the disk.

Status

Displays the current status of disk. The status can be either "GOOD" (operating normally), "FAILED" (non-functional), or "MISSING" (disk not present).

HSP

Indicates if the disk has been set as a global hot-spare disk, local hot-spare disk, or a normal one. If it is a local hot-spare disk, all volumes which this disk is assigned to are displayed.

GUID

GUID string for the specified disk. This is an additional datum and might be unavailable in some cases.

-l volume

Display information about the specified volume. The output includes the following information:

Volume

Displays volume in canonical format.

Sub

Displays sub-volumes, if the specified volume is of RAID 10 or RAID 50 volume.

Disk

Displays all disks that form the specified volume.

Stripe Size

Displays the stripe size of the volume.

Status

Displays the status of the specified volume, or the sub-volumes or disks that form the specified volume. For an inactive volume, the status should be **INACTIVE**; otherwise it can be **OPTIMAL** (operating optimally), **DEGRADED** (operating with reduced functionality), **FAILED** (non-functional), or **SYNC** (disks are syncing). For a disk, the status can be **GOOD**, **FAILED**, or **MISSING**.

Cache

Indicates whether the cache is applied to I/O write activities. The cache can be either "ON" or "OFF".

RAID level

Displays the RAID level. The RAID level can be either 0, 1, 1E, 5, 10, or 50.

-l controller ...

Display information about the specified controller(s). The output includes the following information:

Controller

Displays the RAID controller's ID number.

Type

Displays the RAID controller's product type.

fw_version

Displays the controller's firmware version.

[-l]

List all RAID related objects that the `raidctl` utility can manipulate, including all available RAID controllers, RAID volumes, and physical disks. The `-l` option can be omitted.

The output includes the following information:

Controller

Displays the RAID controller's ID number.

Volume

Displays the logical RAID volume name.

Disk

Displays the RAID disk in C . ID . L expression.

-S [volume | controller]

Takes a snapshot of the RAID configuration information including all available RAID devices, RAID controllers, volumes, and disks.

Each line of the output specifies a RAID device and its related information, separated by space(s). All volumes and disks belong to the last specified controller.

The output lists the following information:

Controller

Displays the controller ID number, and the controller type string in double-quotations marks.

Volume

Displays the RAID volume name, number of component disks, the C . ID . L expression of the component disks, the RAID level, and the status. The status can be either OPTIMAL, DEGRADED, FAILED, or SYNCING.

Disk

Displays the C . ID . L expression of the disk, and the status. The status can be either GOOD, FAILED, or HSP (disk has been set as a stand-by disk).

If a volume or a controller is specified, a snapshot is only taken of the information for the specified volume or controller.

-S -g *disk controller*

Takes a snapshot of the information for the specified disk.

-h

Print out the usage string.

Examples EXAMPLE 1 Creating the RAID Configuration

The following command creates a RAID 0 volume of 10G on controller 0, and the stripe size will be set to 64k:

```
# raidctl -C "0.0.0 0.2.0" -r 0 -z 10g -s 64k 0
```

The following command creates a RAID 1 volume on controller 2:

```
# raidctl -C "0.0.0 1.1.0" -r 1 2
```

The following command creates a RAID 5 volume on controller 2:

```
# raidctl -C "0.0.0 0.1.0 0.2.0" -r 5 2
```

The following command creates a RAID 10 volume on controller 0:

EXAMPLE 1 Creating the RAID Configuration *(Continued)*

```
# raidctl -C "(0.0.0 0.1.0)(0.2.0 0.3.0)" -r 10 0
```

The following command creates a RAID 50 volume on controller 0:

```
# raidctl -C "(0.0.0 0.1.0 0.2.0)(0.3.0 0.4.0 0.5.0)" -r 50 0
```

EXAMPLE 2 Displaying the RAID Configuration

The following command displays all available controllers, volumes, and disks:

```
# raidctl -l
```

```
Controller: 0
Controller: 2
    Volume: c2t0d0
    Disk: 0.0.0
    Disk: 0.1.0
    Disk: 0.2.0
    Disk: 0.3.0(HSP)
```

The following command displays information about controller 2:

```
# raidctl -l 2
```

| Controller | Type | Fw_version |
|------------|----------|------------|
| c2 | LSI 1030 | 1.03.39.00 |

The following command displays information about the specified volume:

```
# raidctl -l c2t0d0
```

| Volume | Sub | Disk | Size | Stripe Size | Status | Cache | RAID Level |
|--------|-----|-------|--------|-------------|---------|-------|------------|
| c2t0d0 | | | 10240M | 64K | OPTIMAL | ON | RAID5 |
| | | 0.0.0 | 5120M | | GOOD | | |
| | | 0.1.0 | 5120M | | GOOD | | |
| | | 0.2.0 | 5120M | | GOOD | | |

The following command displays information about disk 0.0.0 on controller 0:

```
# raidctl -l -g 0.0.0 0
```

| Disk | Vendor | Product | Firmware | Capacity | Status | HSP |
|-----------------------|---------|-----------------|----------|----------|--------|-----|
| 0.0.0 | HITACHI | H101473SCSUN72G | SQ02 | 68.3G | GOOD | N/A |
| GUID:2000000cca02536c | | | | | | |

EXAMPLE 3 Deleting the RAID Configuration

The following command deletes a volume:

```
# raidctl -d c0t0d0
```

EXAMPLE 4 Updating Flash Images on the Controller

The following command updates flash images on the controller 0:

```
# raidctl -F lsi_image.fw 0
```

EXAMPLE 5 Setting or Unsetting a Hot-Spare Disk

The following command sets disk 0.3.0 on controller 2 as a global hot-spare disk:

```
# raidctl -a set -g 0.3.0 2
```

The following command sets disk 0.3.0 on controller 2 as a local hot-spare disk to volume c2t0d0:

```
# raidctl -a set -g 0.3.0 c2t0d0
```

The following command converts disk 0.3.0 on controller 2 from a global hot-spare disk to a normal one:

```
# raidctl -a unset -g 0.3.0 2
```

The following command removes disk 0.3.0 from being a local hot-spare disk from volume c2t0d0:

```
# raidctl -a unset -g 0.3.0 c2t0d0
```

EXAMPLE 6 Setting the Volume's Property

The following command sets the write policy of the volume to "off":

```
# raidctl -a set -p "wp=off" c0t0d0
```

EXAMPLE 7 Creating Volumes with the -c Option

The following command creates a RAID 1 volume:

```
# raidctl -c c0t0d0 c0t1d0
```

The following command creates a RAID 0 volume:

```
# raidctl -c -r 0 c0t1d0 c0t2d0 c0t3d0
```

EXAMPLE 8 Taking a Snapshot of the RAID Configuration

The following command takes a snapshot of all RAID devices:

```
# # raidctl -S
```

```
1 "LSI 1030"
```

EXAMPLE 8 Taking a Snapshot of the RAID Configuration (Continued)

```
c1t1d0 2 0.2.0 0.3.0 1 DEGRADED
0.2.0 GOOD
0.3.0 FAILED
```

The following command takes a snapshot about volume c1t0d0:

```
# raidctl -S c1t0d0
```

```
c1t0d0 2 0.0.0 0.1.0 1 OPTIMAL
```

The following command takes a snapshot about disk 0.1.0 on controller 1:

```
# raidctl -S -g 0.1.0 1
```

```
0.1.0 GOOD
```

Exit Status The following exit values are returned:

- 0
Successful completion.
- 1
Invalid command line input or permission denied.
- 2
Request operation failed.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | Committed |

See Also [attributes\(5\)](#), [mpt\(7D\)](#)

System Administration Guide: Basic Administration

Warnings Do not create raid volumes on internal SAS disks if you are going to use the Solaris Multipathing I/O feature (also known as MPxIO). Creating a new raid volume under Solaris Multipathing will give your root device a new GUID which does not match the GUID for the existing devices. This will cause a boot failure since your root device entry in `/etc/vfstab` will not match.

Notes The -z option is not supported on systems that use the mpt driver and LSI RAID controllers.

Name ramdiskadm – administer ramdisk pseudo device

Synopsis `/usr/sbin/ramdiskadm -a name size [g | m | k | b]`
`/usr/sbin/ramdiskadm -d name`
`/usr/sbin/ramdiskadm`

Description The `ramdiskadm` command administers [ramdisk\(7D\)](#), the ramdisk driver. Use `ramdiskadm` to create a new named ramdisk device, delete an existing named ramdisk, or list information about existing ramdisks.

Ramdisks created using `ramdiskadm` are not persistent across reboots.

Options The following options are supported:

`-a name size` Create a ramdisk named *name* of size *size* and its corresponding block and character device nodes.

name must be composed only of the characters a-z, A-Z, 0-9, _ (underbar), and - (hyphen), but it must not begin with a hyphen. It must be no more than 32 characters long. Ramdisk names must be unique.

The size can be a decimal number, or, when prefixed with `0x`, a hexadecimal number, and can specify the size in bytes (no suffix), 512-byte blocks (suffix `b`), kilobytes (suffix `k`), megabytes (suffix `m`) or gigabytes (suffix `g`). The size of the ramdisk actually created might be larger than that specified, depending on the hardware implementation.

If the named ramdisk is successfully created, its block device path is printed on standard out.

`-d name` Delete an existing ramdisk of the name *name*. This command succeeds only when the named ramdisk is not open. The associated memory is freed and the device nodes are removed.

You can delete only ramdisks created using `ramdiskadm`. It is not possible to delete a ramdisk that was created during the boot process.

Without options, `ramdiskadm` lists any existing ramdisks, their sizes (in decimal), and whether they can be removed by `ramdiskadm` (see the description of the `-d` option, above).

Examples **EXAMPLE 1** Creating a 2MB Ramdisk Named `mydisk`

```
# ramdiskadm -a mydisk 2m
/dev/ramdisk/mydisk
```

EXAMPLE 2 Listing All Ramdisks

```
# ramdiskadm
Block Device          Size  Removable
/dev/ramdisk/miniroot 134217728  No
/dev/ramdisk/certfs   1048576   No
/dev/ramdisk/mydisk   2097152   Yes
```

Exit Status ramdiskadm returns the following exit values:

- 0 Successful completion.
- >0 An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | Committed |

See Also [attributes\(5\)](#), [ramdisk\(7D\)](#)

Notes The abilities of ramdiskadm and the privilege level of the person who uses the utility are controlled by the permissions of /dev/ramdiskctl. Read access allows query operations, for example, listing device information. Write access is required to do any state-changing operations, for example, creating or deleting ramdisks.

As shipped, /dev/ramdiskctl is owned by root, in group sys, and mode 0644, so all users can do query operations but only root can perform state-changing operations. An administrator can give write access to non-privileged users, allowing them to add or delete ramdisks. However, granting such ability entails considerable risk; such privileges should be given only to a trusted group.

Name rcapadm – configure resource capping daemon

Synopsis rcapadm

```
rcapadm [ [-n] -E | -D]
          [-i interval=value, . . . ,interval=value] [-c percent]
          [-z zonename -m maxvalue]
```

Description The rcapadm command allows a user with the privileges described below to configure various attributes of the resource capping daemon. If used without arguments, rcapadm displays the current status of the resource capping daemon if it has been configured. See [rcapd\(1M\)](#) for more information.

In the current release of the Solaris operating environment, rcapadm is available to users with all privileges and to users who have the Process Management profile in their list of profiles. The System Administrator role includes the Process Management profile.

| | | |
|----------------|----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Options | -c <i>percent</i> | Set the minimum physical memory utilization for memory cap enforcement. Caps will not be enforced until the physical memory available to processes is low. The <i>percent</i> value should be in the range 0 to 100. The minimum (and default) value is 0, which means that memory caps are always enforced. |
| | -D | Disable the resource capping daemon so that it will not be started when the system is booted. Also stop the resource capping daemon now, if the -n option is not specified and it is currently running. |
| | -E | Enable the resource capping daemon so that it will be started each time the system is booted. Also start the resource capping daemon now, if the -n option is not specified and it is not currently running. |
| | -i <i>interval=value, ...,interval=value</i> | Set intervals for various periodic operations performed by rcapd. All intervals are specified in seconds. You can set the following intervals: |
| | scan | The interval at which rcapd scans for new processes. The default scan interval is every 15 seconds. The minimum value is 1 second. |
| | sample | The interval of process resident set size sampling. The default sample interval is every 5 seconds. The minimum value is 1 second. |

| | |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>report</code> | The interval at which various paging statistics are updated by <code>rcapd</code> , in seconds. These statistics can be viewed by using <code>rcapstat(1SRM)</code> . The default reporting interval is every 5 seconds. When the interval is set to <code>0</code> , statistics will not be updated. |
| | Note – Paging refers to the act of relocating portions of memory, called pages, to or from physical memory. <code>rcapd</code> pages out the most infrequently used pages. |
| <code>config</code> | The reconfiguration interval, in seconds. At each reconfiguration event, <code>rcapd</code> checks its configuration file for updates, and scans the project databases for new project caps. The default reconfiguration interval is every 60 seconds. The minimum interval is <code>0</code> . When the interval is set to <code>0</code> , no periodic reconfiguration occurs, although the running daemon can still be reconfigured by sending it <code>SIGHUP</code> . |
| <code>-m maxvalue</code> | Used in conjunction with the <code>-z</code> option. Specifies a value for <code>rcap.max-rss</code> , a dynamically-set cap on the usage of physical memory for the zone specified by <code>-z</code> . You can apply a scale (K, M, G, T) to the value you specify. K means kilobyte; M, megabyte; G, gigabyte; and T, terabyte. For example, <code>100M</code> is 100 megabytes. |
| <code>-n</code> | Do not affect the running state of the resource capping daemon when enabling or disabling it. |
| <code>-z zonename</code> | Used in conjunction with the <code>-m</code> option. Specifies the zone for which you are dynamically specifying a cap on physical memory usage (using <code>-m</code>). |

Note – To set a persistent cap on memory usage within a zone, use [zonecfg\(1M\)](#).

Examples EXAMPLE 1 Configuring the Resource Capping Daemon with Immediate Enforcement

```
# rcapadm -E -i scan=15,sample=5,report=5,config=60 -c 0
```

EXAMPLE 2 Specifying a Resource Cap for a Zone

The command shown below specifies the maximum amount of memory that can be consumed by a specified zone. Note that this value lasts only until the next reboot. To set a persistent cap, use [zonecfg\(1M\)](#).

```
# rcapadm -z testzone -m 512M
```

Exit Status The following exit values are returned:

- 0 Successful completion. The modifications to the current configuration were valid and made successfully.
- 1 An error occurred. A fatal error occurred either in obtaining or modifying the resource capping configuration.
- 2 Invalid command-line options were specified.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------------|----------------------|
| Availability | service/resource-cap |
| Interface Stability | Committed |

The -z and -m options are committed interfaces.

See Also [rcapstat\(1\)](#), [rcapd\(1M\)](#), [zonecfg\(1M\)](#), [project\(4\)](#), [attributes\(5\)](#), [zones\(5\)](#)

“Physical Memory Control Using the Resource Capping Daemon” in *System Administration Guide: Oracle Solaris Zones, Oracle Solaris 10 Containers, and Resource Management*

Name rcapd – resource cap enforcement daemon

Synopsis rcapd [-d]

Description The rcapd daemon enforces resource caps on collections of processes. Per-project and per-zone physical memory caps are supported. For information about projects, see [project\(4\)](#). For zones information, see [zones\(5\)](#)

When the resident set size (RSS) of a collection of processes exceeds its cap, rcapd takes action and reduces the RSS of the collection.

The virtual memory system divides physical memory into segments known as pages. To read data from a file into memory, the virtual memory system reads in individual pages. To reduce resource consumption, the daemon can page out, or relocate, infrequently used pages to an area outside of physical memory.

In the project file, caps are defined for projects that have positive values for the following project attribute:

`rcap.max-rss` The total amount of physical memory, in bytes, that is available to the project's member processes

See [project\(4\)](#) for a description of project attributes.

For a system with one or more zones, you can dynamically set the `rcap.max-rss` value for a zone with [rcapadm\(1M\)](#). To set a persistent cap on memory usage within a zone, you use [zonecfg\(1M\)](#).

You configure rcapd through the use of [rcapadm\(1M\)](#). The daemon can be monitored with [rcapstat\(1\)](#). Configuration changes are incorporated into rcapd by sending it SIGHUP (see [kill\(1\)](#)), or according to the configuration interval (see [rcapadm\(1M\)](#)).

Options The following option is supported:

-d Enable debug mode. Messages are displayed on the invoking user's terminal.

Examples **EXAMPLE 1** Setting Resident Set Size Cap Attribute

The following line in the `/etc/project` database sets an RSS cap of 1073741824 bytes for a project named `foo`.

```
foo:100::foo,root::rcap.max-rss=10737418240
```

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 An error occurred.
- 2 Invalid command-line options were specified.

Files /etc/project Project database.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|----------------------|
| Availability | service/resource-cap |
| Interface Stability | Committed |

See Also [rcapstat\(1\)](#), [svcs\(1\)](#), [rcapadm\(1M\)](#), [zonecfg\(1M\)](#), [svcadm\(1M\)](#), [project\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#), [zones\(5\)](#)

“Physical Memory Control Using the Resource Capping Daemon” in *System Administration Guide: Oracle Solaris Zones, Oracle Solaris 10 Containers, and Resource Management*

Notes If killed with SIGKILL, rcapd can leave processes in a stopped state. Use SIGTERM to cause rcapd to terminate properly.

A collection's RSS can exceed its cap for some time before the cap is enforced, even if sufficient pageable memory is available. This period of time can be reduced by shortening the RSS sampling interval with rcapadm.

The rcapd service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/system/rcap:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Name rctldm – display or modify global state of system resource controls

Synopsis rctldm [-lu] [-e *action*] [-d *action*] [*name...*]

Description The rctldm command allows the examination and modification of active resource controls on the running system. An instance of a resource control is referred to as an *rctl*. See [setrctl\(2\)](#) for a description of an rctl; see [resource_controls\(5\)](#) for a list of the rctls supported in the current release of the Solaris operating system. Logging of rctl violations can be activated or deactivated system-wide and active rctls (and their state) can be listed.

An rctldm command without options is the equivalent of an rctldm with the -l option. See the description of -l below.

Options The following options are supported:

-d *action*

-e *action*

Disable (-d) or enable (-e) the global action on the specified rctls. If no rctl is specified, no action is taken and an error status is returned. You can use the special token `all` with the disable option to deactivate all global actions on a resource control.

You can set the `syslog` action to a specific degree by assigning a severity level. To do this, specify `syslog=level`, where *level* is one of the string tokens given as valid severity levels in [syslog\(3C\)](#). You can omit the common `LOG_` prefix on the severity level. Note that not all rctls support the `syslog` action. See [resource_controls\(5\)](#).

-l

List information about rctls. The name, global event actions and statuses, and global flags are displayed. If one or more name operands are specified, only those rctls matching the names are displayed.

-u

Configure resource controls based on the contents of `/etc/rctldm.conf`. Any name operands are ignored.

Operands The following operands are supported:

name

The name of the rctl to operate on. Multiple rctl names can be specified. If no names are specified, and the list action has been specified, then all rctls are listed. If the enable or disable action is specified, one or more rctl names must be specified.

Examples **EXAMPLE 1** Activating System Logging for Specific Violations

The following command activates system logging of all violations of `task.max-lwps`.

```
# rctldm -e syslog task.max-lwps
#
```

EXAMPLE 2 Examining the Current Status of a Specific Resource

The following command examines the current status of the `task.max-lwps` resource.

```
$ rctladm -l task.max-lwps
task.max-lwps          syslog=DEBUG
$
```

Exit Status The following exit values are returned:

- 0
Successful completion.
- 1
A fatal error occurred. A message is written to standard error to indicate each resource control for which the operation failed. The operation was successful for any other resource controls specified as operands.
- 2
Invalid command line options were specified.

Files `/etc/rctladm.conf`
Each time `rctladm` is executed, it updates the contents of `rctladm.conf` with the current configuration.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|----------------------------------|
| Availability | system/extended-system-utilities |

See Also [setrctl\(2\)](#), [getrctl\(2\)](#), [prctl\(1\)](#), [rctlblk_get_global_flags\(3C\)](#), [rctlblk_get_global_action\(3C\)](#), [attributes\(5\)](#), [resource_controls\(5\)](#)

Notes By default, there is no global logging of `rctl` violations.

Name rdate – set system date from a remote host

Synopsis rdate *hostname*

Description rdate sets the local date and time from the *hostname* given as an argument. You must have the authorization `solaris.system.date` on the local system. Typically, rdate is used in a startup script.

rdate requests are responded to by the “time” service on the specified host. To enable the “time” service, use the following commands:

```
svcadm enable time:stream
svcadm enable time:dgram
```

Usage The rdate command is IPv6-enabled. See [ip6\(7P\)](#).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTETYPE | ATTRIBUTEVALUE |
|---------------|---------------------------------|
| Availability | service/network/network-clients |

See Also [inetd\(1M\)](#), [inetd.conf\(4\)](#), [attributes\(5\)](#), [ip6\(7P\)](#)

Name reboot – restart the operating system

Synopsis /usr/sbin/reboot [-dlnq] [-f | -p] [*boot_arguments*]
/usr/sbin/reboot [-f [-e *environment*] | -p] [-dlnq] [*boot_arguments*]

Description The reboot utility restarts the kernel. The kernel is loaded into memory by the PROM monitor, which transfers control to the loaded kernel.

On x86 systems, when the `-f` flag is specified, the running kernel will load the next kernel into memory, then transfer control to the newly loaded kernel. This form of reboot is shown in the second synopsis, above.

Although reboot can be run by the super-user at any time, [shutdown\(1M\)](#) is normally used first to warn all users logged in of the impending loss of service. See [shutdown\(1M\)](#) for details.

The reboot utility performs a [sync\(1M\)](#) operation on the disks, and then a multi-user reboot is initiated. See [init\(1M\)](#) for details. On x86 systems, reboot may also update the boot archive as needed to ensure a successful reboot.

The reboot utility normally logs the reboot to the system log daemon, [syslogd\(1M\)](#), and places a shutdown record in the login accounting file `/var/adm/wtmpx`. These actions are inhibited if the `-n` or `-q` options are present.

Normally, the system reboots itself at power-up or after crashes.

Options The following options are supported:

`-d`

Force a system crash dump before rebooting. See [dumpadm\(1M\)](#) for information on configuring system crash dumps.

`-e`

If `-f` is present, reboot to the specified boot environment.

This option is currently available only on x86 systems.

`-f`

For x86 systems:

Fast reboot, bypassing firmware and boot loader. The new kernel will be loaded into memory by the running kernel, and control will be transferred to the newly loaded kernel. If disk or kernel arguments are specified, they must be specified before other boot arguments.

For SPARC systems:

Speeds up rebooting by skipping some POST tests.

The service `svc:/system/boot-config:default` is enabled by default. It requires `solaris.system.shutdown` as `action_authorization` and `value_authorization`. When the `config/fastreboot_default` property is set to `true`, `reboot` will behave as `reboot -f`. The value of this property can be changed using [svccfg\(1M\)](#) and [svcadm\(1M\)](#), to control the default reboot behavior.

See EXAMPLES for details.

`-l`

Suppress sending a message to the system log daemon, [syslogd\(1M\)](#) about who executed `reboot`.

`-n`

Avoid calling [sync\(2\)](#) and do not log the reboot to [syslogd\(1M\)](#) or to `/var/adm/wtmpx`. The kernel still attempts to sync filesystems prior to reboot, except if the `-d` option is also present. If `-d` is used with `-n`, the kernel does not attempt to sync file systems.

`-p`

Reboot to prom. This flag can be used to reboot the system through firmware without changing the default reboot behavior as denoted by the `config/fastreboot_default` property setting in `system/boot-config` service.

The `-p` and `-f` options are mutually exclusive.

`-q`

Quick. Reboot quickly and ungracefully, without shutting down running processes first.

Operands The following operands are supported:

boot_arguments

An optional *boot_arguments* specifies arguments to the [uadmin\(2\)](#) function that are passed to the boot program and kernel upon restart. The form and list of arguments is described in the [boot\(1M\)](#) and [kernel\(1M\)](#) man pages. If the arguments are specified, whitespace between them is replaced by single spaces unless the whitespace is quoted for the shell. If the *boot_arguments* begin with a hyphen, they must be preceded by the `--` delimiter (two hyphens) to denote the end of the reboot argument list.

Examples EXAMPLE 1 Passing the `-r` and `-v` Arguments to `boot`

In the following example, the delimiter `--` (two hyphens) must be used to separate the options of `reboot` from the arguments of [boot\(1M\)](#).

```
example# reboot -dl -- -rv
```

EXAMPLE 2 Rebooting Using a Specific Disk and Kernel

The following example reboots using a specific disk and kernel.

```
example# reboot disk1 kernel.test/unix
```

EXAMPLE 3 Fast Rebooting

The following examples use the `-f` option to perform fast reboots.

If the service `svc:/system/boot-config:default` is enabled and property `config/fastreboot_default` is set to `true`, the `-f` option can be omitted.

On an x86 system, the following command reboots to the default entry in the GRUB (see [grub\(5\)](#)) menu file `menu.lst`.

```
example# reboot -f
```

The following command reboots to another UFS root disk.

```
example# reboot -f -- '/dev/dsk/c1d0s0'
```

The following command reboots to another ZFS root pool.

```
example# reboot -f -- 'rpool/ROOT/root2'
```

The following command reboots to `mykernel` on the same disk with `-k` option.

```
example# reboot -f -- '/platform/i86pc/mykernel/amd64/unix -k'
```

The following command reboots to `mykernel` off another root disk mounted on `/mnt`.

```
example# reboot -f -- '/mnt/platform/i86pc/mykernel/amd64/unix -k'
```

The following command reboots to `/platform/i86pc/kernel/$ISADIR/unix` on another boot environment named `second_root`.

```
example# reboot -f -e second_root
```

The following command reboots to the same kernel with `-kv` options.

```
example# reboot -f -- '-kv'
```

The following commands disable the fast-reboot-by-default behavior.

```
example# svccfg -s "system/boot-config:default" \  
setprop config/fastreboot_default=false  
example# svcadm refresh svc:/system/boot-config:default
```

The following commands re-enable the fast-reboot-by-default behavior.

```
example# svccfg -s "system/boot-config:default" \  
setprop config/fastreboot_default=true  
example# svcadm refresh svc:/system/boot-config:default
```

EXAMPLE 4 Rebooting to a Particular GRUB Menu

The following commands will reboot to entry 2 in the GRUB menu.

```
example# bootadm list-menu  
the location for the active GRUB menu is: /rpool/boot/grub/menu.lst  
default 0
```

EXAMPLE 4 Rebooting to a Particular GRUB Menu *(Continued)*

```

timeout 10
0 zfsbe1
1 zfsbe1 failsafe
2 zfsbe2
3 zfsbe2 Solaris xVM
4 zfsbe2 failsafe
example# reboot 2

```

Files /var/adm/wtmpx
login accounting file

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcsu |

See Also [mdb\(1\)](#), [boot\(1M\)](#), [dumpadm\(1M\)](#), [fsck\(1M\)](#), [halt\(1M\)](#), [init\(1M\)](#), [kernel\(1M\)](#), [shutdown\(1M\)](#), [svcadm\(1M\)](#), [svccfg\(1M\)](#), [sync\(1M\)](#), [syslogd\(1M\)](#), [sync\(2\)](#), [uadmin\(2\)](#), [reboot\(3C\)](#), [attributes\(5\)](#), [grub\(5\)](#)

Notes The reboot utility does not execute the scripts in `/etc/rcnum.d` or execute shutdown actions in [inittab\(4\)](#). To ensure a complete shutdown of system services, use [shutdown\(1M\)](#) or [init\(1M\)](#) to reboot a Solaris system.

Name rem_drv – remove a device driver from the system

Synopsis rem_drv [-b *basedir*] [-C] [-n] *device_driver*

Description The `rem_drv` command informs the system that the device driver *device_driver* is no longer valid. If possible, `rem_drv` unloads *device_driver* from memory. `rem_drv` also updates the system driver configuration files.

If `rem_drv` has been executed, the next time the system is rebooted it automatically performs a reconfiguration boot (see [kernel\(1M\)](#)).

Options The following options are supported:

-b *basedir*

Sets the path to the root directory of the diskless client. Used on the server to execute `rem_drv` for a client. The client machine must be rebooted to unload the driver.

Note – The root file system of any non-global zones must not be referenced with the `-b` option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).

-C

Remove dangling device attribute nodes bound to the driver being removed. This causes any device ownership or permissions customizations made to any node not to be preserved if the driver is added back. Recommended for use when reprovisioning a machine from one configuration or use to another where past administrative customizations might not be desired.

-n

Do not try to detach and unload *device_driver*, just modify the system configuration files for that driver.

Examples EXAMPLE 1 Removing the sd Driver

The following example removes the `sd` driver from use:

```
example% rem_drv sd
```

EXAMPLE 2 Removing a Diskless Client

The following example removes the driver from the `sun1` diskless client. The driver is not uninstalled or unloaded until the client machine is rebooted.

```
example% rem_drv -b /export/root/sun1 sd
```

Note the caveat on the use of the `-b` option in the description of that option, above.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcsu |

Name `remove_allocatable` – remove entries from allocation databases

Synopsis `/usr/sbin/remove_allocatable [-f] -n name`
`/usr/sbin/remove_allocatable [-f] [-d] -t dev-type`

Description `remove_allocatable` removes entries of user allocatable devices from the device allocation mechanism. `remove_allocatable` also removes entries of some non-allocatable devices, such as printers, whose label range is managed by the mechanism.

Options The following options are supported:

- d Removes system-supplied default attributes of the device type that is specified with -t.
- f Force the removal of an entry. `remove_allocatable` exits with an error if this option is not specified when an entry with the specified device name no longer exists.
- n *name* Removes the entry for the device *name*.
- t *dev-type* Removes devices of type *dev-type*.

Exit Status When successful, `remove_allocatable` returns an exit status of 0 (true). `remove_allocatable` returns a nonzero exit status in the event of an error. The exit codes are as follows:

- 1 Invocation syntax error
- 2 Unknown system error
- 3 Device *name* or *dev-type* not found. This error occurs only when the -f option is not specified.
- 4 Permission denied. User does not have DAC or MAC access to database.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | system/trusted |
| Interface Stability | See below. |

The invocation is Uncommitted. The options are Uncommitted. The output is Not-an-Interface.

See Also [allocate\(1\)](#), [deallocate\(1\)](#), [add_allocatable\(1M\)](#), [attributes\(5\)](#), [device_clean\(5\)](#)

Notes The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

Name removef – remove a file from software database

Synopsis removef [[-M] -R *root_path*] [-V *fs_file*] *pkginst path*...
removef [[-M] -R *root_path*] [-V *fs_file*] -f *pkginst*

Description removef informs the system that the user, or software, intends to remove a pathname. Output from removef is the list of input pathnames that may be safely removed (no other packages have a dependency on them).

Options The following options are supported:

-f

After all files have been processed, removef should be invoked with the -f option to indicate that the removal phase is complete.

-M

Instruct removef not to use the *\$root_path/etc/vfstab* file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.

-R *root_path*

Define the full path name of a directory to use as the *root_path*. All files, including package system information files, are relocated to a directory tree starting in the specified *root_path*. The *root_path* may be specified when installing to a client from a server (for example, */export/root/client1*).

removef inherits the value of the `PKG_INSTALL_ROOT` environment variable. (See ENVIRONMENT VARIABLES, below.) If `PKG_INSTALL_ROOT` is set, such as when the -R option is used with [pkgadd\(1M\)](#) or [pkgrm\(1M\)](#)

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).

-V *fs_file*

Specify an alternative *fs_file* to map the client's file systems. For example, used in situations where the *\$root_path/etc/vfstab* file is non-existent or unreliable.

Operands The following operands are supported:

path

The pathname to be removed.

pkginst

The package instance from which the pathname is being removed.

Examples EXAMPLE 1 Using removef

The following example uses the removef command in an optional pre-install script:

```
echo "The following files are no longer part of this package
and are being removed."
removef $PKGINST /myapp/file1 /myapp/file2 |
while read pathname
do
    echo "$pathname"
    rm -f $pathname
done
removef -f $PKGINST || exit 2
```

Environment Variables removef inherits the value of the following environment variable. This variable is set when [pkgadd\(1M\)](#) or [pkgrm\(1M\)](#)

PKG_INSTALL_ROOT

If present, defines the full path name of a directory to use as the system's PKG_INSTALL_ROOT path. All product and package information files are then looked for in the directory tree, starting with the specified PKG_INSTALL_ROOT path. If not present, the default system path of / is used.

Exit Status 0

Successful completion.

>0

An error occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [pkginfo\(1\)](#), [pkgmk\(1\)](#), [pkgparam\(1\)](#), [pkgproto\(1\)](#), [pkgtrans\(1\)](#), [installf\(1M\)](#), [pkgadd\(1M\)](#), [pkgask\(1M\)](#), [pkgchk\(1M\)](#), [pkgrm\(1M\)](#), [attributes\(5\)](#), [largefile\(5\)](#)

Application Packaging Developer's Guide

Notes Package commands are [largefile\(5\)](#)-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, [pkgadd\(1M\)](#), [pkgtrans\(1\)](#) and other package commands can process a datastream of up to 4 GB.

Name reparse – reparse point daemon

Synopsis /usr/lib/reparse/reparse

Description The reparse daemon processes kernel upcalls to interpret “reparse points”, which are the basis of Microsoft DFS referrals and NFS referrals support on Solaris SMB and NFS file servers. Only the root user or a user with equivalent privileges can run this daemon. The daemon is under SMF control.

Exit Status 0

Daemon started successfully.

>0

Daemon failed to start.

Error information is reported to sys log at level LOG_ERR.

Files /usr/lib/reparse/*.so.1

Per-service plugins for reparse.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------------|
| Availability | SUNWcs |
| Interface Stability | Consolidation Private |

See Also [nfsref\(1M\)](#), [svcadm\(1M\)](#), [syslogd\(1M\)](#), [libreparse\(3LIB\)](#), [attributes\(5\)](#)

Notes Do not manually stop, start or restart the reparse daemon. If you need to change the state of the daemon, use these commands:

```
# svcadm disable svc:/system/filesystem/reparse
# svcadm enable svc:/system/filesystem/reparse
# svcadm restart svc:/system/filesystem/reparse
```

See [svcadm\(1M\)](#) for additional information.

Name repquota – summarize quotas for a ufs file system

Synopsis repquota [-v] *filesystem* . . .
repquota -a [-v]

Description repquota prints a summary of the disk usage and quotas for the specified ufs file systems. The current number of files and amount of space (in kilobytes) is printed for each user along with any quotas created with [edquota\(1M\)](#).

The *filesystem* must have the file quotas in its root directory.

Only the super-user may view quotas which are not their own.

Options The following options are supported:

- a Report on all mounted ufs file systems that have `rq` in the `mntopts` field of the `/etc/vfstab` file.
- v Report quotas for all users, even those who do not consume resources.

Usage See [largefile\(5\)](#) for the description of the behavior of repquota when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [edquota\(1M\)](#), [quota\(1M\)](#), [quotacheck\(1M\)](#), [quotaon\(1M\)](#), [attributes\(5\)](#), [largefile\(5\)](#), [quotactl\(7I\)](#)

Name re-preinstall – installs the JumpStart software on a system

Synopsis `cdrom-mnt-pt/Solaris_XX/Tools/Boot/usr/sbin/install.d/re-preinstall`
[-m *Solaris_boot_dir*]
[-k *platform_name*] *target-slice*

Description re-preinstall installs the JumpStart software (preinstall boot image) on a system, so you can power-on the system and have it automatically install the Solaris software (perform a JumpStart installation on the system). When you turn on a re-preinstalled system, the system looks for the JumpStart software on the system's default boot disk. All new SPARC systems have the JumpStart software already preinstalled. The *XX* in *Solaris_XX* is the version number of the Solaris release being used.

You can use the re-preinstall command in several ways. The most common way is to run re-preinstall on a system to install the JumpStart software on its own default boot disk. This is useful if you want to restore a system to its original factory conditions. (See the first procedure described in EXAMPLES.)

You can also run re-preinstall on a system to install JumpStart software on any attached disk (non-boot disk). After you install the JumpStart software on a disk, you can move the disk to a different system and perform a JumpStart installation on the different system. (See the second procedure described in EXAMPLES.)

re-preinstall creates a standard file system on the specified *target-slice* (usually slice 0), and re-preinstall makes sure there is enough space on the *target-slice* for the JumpStart software. If sufficient space is not available, re-preinstall fails with the following message:

```
re-preinstall: target-slice too small xx Megabytes required
```

You can use the [format\(1M\)](#) command to create sufficient space on the *target-slice* for the JumpStart software.

Options The following options are supported:

-k *platform_name* Platform name of the system that will use the disk with the JumpStart software. The default is the platform name of the system running re-preinstall. (Use the [uname\(1\)](#) command (-i option) to determine a system's platform name.)

-m *Solaris_boot_dir* Absolute path to the *Solaris_XX/Tools/Boot* subdirectory of a mounted Solaris CD or a Solaris CD copied to disk that re-preinstall uses to install the JumpStart software. The default is root (/), which is where the Solaris CD is mounted in single-user mode.

Operands The following operands are supported:

target-slice Device name of the disk slice where the JumpStart software will be installed (usually slice 0), for example, `c0t3d0s0`.

Examples EXAMPLE 1 Installing the JumpStart Software on a System's Own Default Boot Disk

The following procedure installs the JumpStart software on a system's own default boot disk:

1. From the ok prompt, boot the system from the Solaris media CD or DVD in single-user mode:

```
ok boot cdrom -s
```

2. The following command installs the Jumpstart software on the System default boot disk, c0t0d0s0 on a Solaris system:

```
example# /usr/sbin/install.d/re-preinstall c0t0d0s1
```

3. Reboot the slice:

```
example# reboot disk:b
```

EXAMPLE 2 Installing the JumpStart Software on a System's Attached (non-boot) Disk

The following procedure installs the JumpStart software on a system's attached (non-boot) disk:

1. Mount the Solaris CD or DVD if volume management is not running or CD or DVD is not mounted.
2. Use the [format\(1M\)](#) command to determine the target-slice where JumpStart will be installed.
3. Use the [uname\(1\)](#) command (-i option) to determine the platform name of the system that will use the re-preinstalled disk
4. Run re-preinstall with the -m *Solaris_boot_dir* option if the Solaris CD or DVD is not mounted on /cdrom.

The following command installs the JumpStart software on the system's attached disk for a system with a Sun4u kernel architecture, and it uses the Solaris CD or DVD mounted with a volume manager on a Solaris system:

```
example# /cdrom/cdrom/s1/usr/bin/install.d/re-preinstall -m
/cdrom/cdrom/s1 -k sun4u c0t2d0s0
```

Exit Status The following exit values are returned:

- 0 Successful completion.
- 1 An error has occurred.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|------------------------------------------------|
| Availability | SUNWcdrom (Solaris CD, SPARC Platform Edition) |

See Also [uname\(1\)](#), [eeprom\(1M\)](#), [format\(1M\)](#), [mount\(1M\)](#), [attributes\(5\)](#)

Name rmmount – removable media mounter for CD-ROM, floppy, Jaz drive, and others

Synopsis /usr/sbin/rmmount [-D]

Description The rmmount utility is a removable media mounter that is executed by volume management whenever a removable medium, such as a CD-ROM or a floppy, is inserted. Removable media is managed by an application or a volume manager. rmmount can also be called by using [volrmmount\(1\)](#).

Upon insertion of a medium and following invocation of the [volcheck\(1\)](#) command, rmmount determines what type of file system (if any) is on that medium. If a file system is present, rmmount mounts the file system in one of the locations listed below.

For a diskette (floppy):

| | |
|------------------------|-------------------------------------------------------|
| /floppy/floppy0 | symbolic link to mounted floppy in local floppy drive |
| /floppy/floppy_name | mounted named floppy |
| /floppy/unnamed_floppy | mounted unnamed floppy |

For a CD-ROM or a DVD-ROM:

| | |
|------------------------------|-------------------------------------------------------|
| /cdrom/cdrom0 | symbolic link to mounted CD-ROM in local CD-ROM drive |
| /cdrom/CD-ROM_name | mounted named CD-ROM |
| /cdrom/CD-ROM_name/partition | mounted named CD-ROM with partitioned file system |
| /cdrom/unnamed_cdrom | mounted unnamed CD-ROM |

For a Zip drive:

| | |
|----------------------------|--------------------------------------------------------|
| /rmdisk/zip0 | symbolic link to mounted Zip medium in local Zip drive |
| /rmdisk/Zip_name | mounted named Zip medium |
| /rmdisk/Zip_name/partition | mounted named Zip medium with partitioned file system |
| /rmdisk/unnamed_zip | mounted unnamed Zip medium |

For a Jaz drive:

| | |
|----------------------------|--------------------------------------------------------|
| /rmdisk/jaz0 | symbolic link to mounted Jaz medium in local Jaz drive |
| /rmdisk/Jaz_name | mounted named Jaz medium |
| /rmdisk/Jaz_name/partition | mounted named Jaz medium with partitioned file system |
| /rmdisk/unnamed_Jaz | mounted unnamed Jaz medium |

For a generic “rmdisk” drive:

| | |
|--------------------------------------------|---------------------------------------------------------------------------|
| <code>/rmdisk/rmdisk0</code> | symbolic link to mounted removable medium in local removable medium drive |
| <code>/rmdisk/rmdisk_name</code> | mounted named removable medium |
| <code>/rmdisk/rmdisk_name/partition</code> | mounted named removable medium with partitioned file system |
| <code>/rmdisk/unnamed_rmdisk</code> | mounted unnamed removable medium |

If the media is read-only (for example, a CD-ROM or a floppy with write-protect tab set), the file system is mounted read-only.

If a file system is not identified, `rmmount` does not mount a file system. See the [System Administration Guide: Basic Administration](#) for more information on the location of CD-ROM, floppy, and other media without file systems.

If a file system type has been determined, it is then checked to see that it is “clean.” If the file system is “dirty,” `fsck -p` (see [fsck\(1M\)](#)) is run in an attempt to clean it. If `fsck` fails, the file system is mounted read-only.

After the mount is complete, “actions” associated with the media type are executed. These actions allow for the notification to other programs that new media are available.

Actions are executed in the order in which they appear in the configuration file. The action function can return either 1 or 0. If it returns 0, no further actions will be executed. This allows the function to control which applications are executed.

In order to execute an action, `rmmount` performs a `dlopen(3C)` on the shared object and calls the action function defined within it. The definition of the interface to actions can be found in `/usr/include/rmmount.h`.

File systems mounted by `rmmount` are always mounted with the `nosuid` flag set, thereby disabling setuid programs and access to block or character devices in that file system. Upon ejection, `rmmount` unmounts mounted file systems and executes actions associated with the media type. If a file system is “busy” (that is, it contains the current working directory of a live process), the ejection will fail.

Options `-D` Turn on the debugging output from the `rmmount` `dprintf` calls.

Files `/usr/lib/rmmount/*.so.1` shared objects used by `rmmount`.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWvolu |

See Also [volcheck\(1\)](#), [volrmmount\(1\)](#), [fsck\(1M\)](#), [dlopen\(3C\)](#), [attributes\(5\)](#)

System Administration Guide: Basic Administration

Name rmt – remote magtape protocol module

Synopsis /usr/sbin/rmt

Description rmt is a program used by the remote dump and restore programs in manipulating a magnetic tape drive through an interprocess communication connection. rmt is normally started up with an [rexec\(3SOCKET\)](#) or [rcmd\(3SOCKET\)](#) call.

The rmt program accepts requests that are specific to the manipulation of magnetic tapes, performs the commands, then responds with a status indication. All responses are in ASCII and in one of two forms. Successful commands have responses of:

Anumber\n where *number* is an ASCII representation of a decimal number.

Unsuccessful commands are responded to with:

Error-number\n*error-message*\n where *error-number* is one of the possible error numbers described in [Intro\(3\)](#), and *error-message* is the corresponding error string as printed from a call to [perror\(3C\)](#).

The protocol consists of the following commands:

| | |
|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>S</i> \n | Return the status of the open device, as obtained with a <code>MTIOCGET</code> <code>ioctl</code> call. If the operation was successful, an “ack” is sent with the size of the status buffer, then the status buffer is sent (in binary). |
| <i>Cdevice</i> \n | Close the currently open device. The <i>device</i> specified is ignored. |
| <i>Ioperation</i> \n <i>ncount</i> \n | Perform a <code>MTIOCOP</code> <code>ioctl(2)</code> command using the specified parameters. The parameters are interpreted as the ASCII representations of the decimal values to place in the <i>mt_op</i> and <i>mt_count</i> fields of the structure used in the <code>ioctl</code> call. When the operation is successful the return value is the <i>count</i> parameter. |
| <i>Loffset</i> \n <i>nwhence</i> \n | Perform an <code>lseek(2)</code> operation using the specified parameters. The response value is returned from the <code>lseek</code> call. |
| <i>Odevice</i> \n <i>mode</i> \n | Open the specified <i>device</i> using the indicated <i>mode</i> . <i>device</i> is a full pathname, and <i>mode</i> is an ASCII representation of a decimal number suitable for passing to open(9E) . If a device is already open, it is closed before a new open is performed. |
| <i>Rcount</i> \n | Read <i>count</i> bytes of data from the open device. rmt performs the requested read(9E) and responds with <i>Acount-read</i> \n if the read was successful; otherwise an error in standard format is returned. If the read was successful, the data read is sent. |
| <i>Wcount</i> \n | Write data onto the open device. rmt reads <i>count</i> bytes from the connection, aborting if a premature EOF is encountered. The |

response value is returned from the `write(9E)` call.

Any other command causes `rmt` to exit.

Attributes See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|---------------------------------|
| Availability | service/network/network-clients |

See Also `ufsdump(1M)`, `ufsrestore(1M)`, `Intro(3)`, `ioctl(2)`, `lseek(2)`, `perror(3C)`, `rcmd(3SOCKET)`, `rexec(3SOCKET)`, `attributes(5)`, `mtio(7I)`, `open(9E)`, `read(9E)`, `write(9E)`

Diagnostics All responses are of the form described above.

Bugs Do not use this for a remote file access protocol.

Name rmvolmgr – HAL-aware removable volume manager

Synopsis /usr/sbin/rmvolmgr [-chns]

Description The `rmvolmgr` command is a volume manager that can automatically mount and unmount removable media and hot-pluggable storage. The default mount point is `/media`.

`rmvolmgr` is one of a number of Hardware Abstraction Layer (HAL)-aware tools that are shipped with the Solaris operating system. See [hald\(1M\)](#).

Multiple instances of `rmvolmgr` can be run simultaneously. A system instance of `rmvolmgr` runs by default as a service management facility (SMF) service (see [smf\(5\)](#)). Its fault management resource identifier (FMRI) is:

```
svc:/system/filesystem/rmvolmgr
```

You can run your own instance of `rmvolmgr` by adding it to the `.xinitrc` file or a similar session startup script. In such a case, the *system* `rmvolmgr` instance will not manage volumes that belong to you, the owner of the startup script. For example, a user logged on to the workstation console (`/dev/console`) who invokes his own instance of `rmvolmgr` will own locally connected devices, such as CD-ROM drives and devices connected to the local USB or FireWire ports.

In addition to mounting volumes under `/media`, `rmvolmgr` also creates legacy symbolic links under `/cdrom`, `/floppy`, and `/rmdisk`.

`rmvolmgr` also provides backwards compatibility with CDE removable media interfaces by maintaining notification files under `/tmp/.removable`. This functionality can be disabled by using the `-c` option.

The `-c` and `-n` options can also be specified as SMF properties. See “Examples.”

Options The following options are supported:

- c Disable CDE compatibility.
- h Display help information and exit.
- n Do not create legacy mountpoint symbolic links.
- s Invoke in system instance mode.

Examples EXAMPLE 1 Using SMF Properties to Set Options

The following [svccfg\(1M\)](#) command and subcommands use SMF properties to set the `-c` and `-n` options.

```
example# svccfg
svc:> select rmvolmgr
svc:/system/filesystem/rmvolmgr> listprop rmvolmgr/*
rmvolmgr/legacy_mountpoints   boolean true
```

EXAMPLE 1 Using SMF Properties to Set Options *(Continued)*

```

rmvolmgr/cde_compatible          boolean  true
svc:/system/filesystem/rmvolmgr> setprop \
  rmvolmgr/legacy_mountpoints=false
svc:/system/filesystem/rmvolmgr> setprop rmvolmgr/cde_compatible=false
svc:/system/filesystem/rmvolmgr> exit
example#

```

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | service/hal |
| Interface Stability | Volatile |

See Also [hald\(1M\)](#), [svccfg\(1M\)](#), [attributes\(5\)](#), [hal\(5\)](#), [smf\(5\)](#)

Name `rndc` – name server control utility

Synopsis `rndc [-V] [-b src-addr] [-c config-file] [-k key-file] [-s server]
[-p port] [-y key_id] command`

Description The `rndc` utility controls the operation of a name server. It supersedes the `ndc` utility that was provided in previous BIND releases. If `rndc` is invoked with no command line options or arguments, it prints a short summary of the supported commands and the available options and their arguments.

The `rndc` utility communicates with the name server over a TCP connection, sending commands authenticated with digital signatures. The only supported authentication algorithm in the current versions of `rndc` and [named\(1M\)](#) is HMAC-MD5, which uses a shared secret on each end of the connection. This algorithm provides TSIG-style authentication for the command request and the name server's response. All commands sent over the channel must be signed by a *key_id* known to the server.

The `rndc` utility reads a configuration file to determine how to contact the name server and decide what algorithm and key it should use.

Options The following options are supported:

`-b source-address`

Use *source-address* as the source address for the connection to the server. Multiple instances are permitted to allow setting of both the IPv4 and IPv6 source addresses.

`-c config-file`

Use *config-file* as the configuration file instead of the default `/etc/rndc.conf`.

`-k key-file`

Use *key-file* as the key file instead of the default, `/etc/rndc.key`. The key in `/etc/rndc.key` is used to authenticate commands sent to the server if the *config-file* does not exist.

`-s server`

The *server* argument is the name or address of the server that matches a server statement in the configuration file for `rndc`. If no server is supplied on the command line, the host named by the default-server clause in the options statement of the `rndc` configuration file is used.

`-p port`

Send commands to TCP port *port* instead of BIND 9's default control channel port, 953.

`-V`

Enable verbose logging.

`-y key_id`

Use the key *key_id* from the configuration file. The *key_id* argument must be known by named with the same algorithm and secret string for control message validation to succeed. If no *key_id* is specified, `rndc` will first look for a key clause in the server statement of the

server being used, or if no server statement is present for that host, then the `default-key` clause of the options statement. The configuration file contains shared secrets that are used to send authenticated control commands to name servers. It should therefore not have general read or write access.

For the complete set of commands supported by `rndc`, see the *BIND 9 Administrator Reference Manual* or run `rndc` without arguments to see its help message.

Limitations The `rndc` utility does not support all the commands of the BIND 8 `ndc` utility.

There is no way to provide the shared secret for a `key_id` without using the configuration file.

Several error messages tend toward the cryptic.

Name rndc-confgen – rndc key generation tool

Synopsis rndc-confgen [-ah] [-b *keysize*] [-c *keyfile*] [-k *keyname*]
[-p *port*] [-r *randomfile*] [-s *address*] [-t *chrootdir*]
[-u *user*]

Description The rndc-confgen utility generates configuration files for rndc(1M). This utility can be used as a convenient alternative to writing by hand the rndc.conf(4) file and the corresponding controls and key statements in named.conf. It can also be run with the -a option to set up a rndc.key file and avoid altogether the need for a rndc.conf file and a controls statement.

Options The following options are supported:

-a

Perform automatic rndc configuration. This option creates a file rndc.key in /etc (or however *sysconfdir* was specified when BIND was built) that is read by both rndc and named(1M) on startup. The rndc.key file defines a default command channel and authentication key allowing rndc to communicate with named with no further configuration.

Running rndc-confgen with -a specified allows BIND 9 and rndc to be used as drop-in replacements for BIND 8 and ndc, with no changes to the existing BIND 8 named.conf file.

If a more elaborate configuration than that generated by rndc-confgen -a is required, for example if rndc is to be used remotely, you should run rndc-confgen without the -a option and set up rndc.conf and named.conf files, as directed.

-b *keysize*

Specify the size of the authentication key in bits. The *keysize* argument must be between 1 and 512 bits; the default is 128.

-c *keyfile*

Used with the -a option to specify an alternate location for rndc.key.

-h

Print a short summary of the options and arguments to rndc-confgen.

-k *keyname*

Specify the key name of the rndc authentication key. The *keyname* argument must be a valid domain name. The default is rndc-key.

-p *port*

Specify the command channel port where named listens for connections from rndc. The default is 953.

-r *randomfile*

Specify a source of random data for generating the authorization. By default, /dev/random is used. The *randomdev* argument specifies the name of a character device or file containing random data to be used instead of the default. The special value *keyboard* indicates that keyboard input should be used.

-s address

Specify the IP address where named listens for command channel connections from rncd. The default is the loopback address 127.0.0.1.

-t chrootdir

Used with the -a option to specify a directory where named will run after the root directory is changed with [chroot\(2\)](#). An additional copy of the rncd.key file will be written relative to this directory so that it will be found by the named in the new directory.

-u user

Used with the -a option to set the owner of the rncd.key file generated. If -t is also specified only the file in the chroot area has its owner changed.

Examples EXAMPLE 1 Create Automatic rncd Configuration

The following command creates an automatic rncd configuration, so that rncd can be used immediately.

```
# rncd-confgen -a
```

EXAMPLE 2 Print a Sample rncd.conf File

The following command prints a sample rncd.conf file with corresponding controls and key statements. These statements can subsequently be manually inserted in the file named.conf.

```
# rncd-confgen
```

Name roleadd – administer a new role account on the system

Synopsis roleadd [-c *comment*] [-d *dir*] [-e *expire*] [-f *inactive*]
 [-g *group*] [-G *group* [, *group*...]] [-m [-k *skel_dir*]]
 [-u *uid* [-o]] [-s *shell*]
 [-A *authorization* [,*authorization*...]] [-K *key=value*] *role*

roleadd -D [-b *base_dir*] [-e *expire*] [-f *inactive*]
 [-g *group*] [-A *authorization* [,*authorization*...]]
 [-P *profile* [,*profile*...]] [-K *key=value*]]

Description roleadd adds a role entry to the /etc/passwd and /etc/shadow and /etc/user_attr files. The -A and -P options respectively assign authorizations and profiles to the role. Roles cannot be assigned to other roles. The -K option adds a *key=value* pair to /etc/user_attr for a role. Multiple *key=value* pairs can be added with multiple -K options.

roleadd also creates supplementary group memberships for the role (-G option) and creates the home directory (-m option) for the role if requested. The new role account remains locked until the [passwd\(1\)](#) command is executed.

Specifying roleadd -D with the -g, -b, -f, -e, or -K option (or any combination of these option) sets the default values for the respective fields. See the -D option. Subsequent roleadd commands without the -D option use these arguments.

The system file entries created with this command have a limit of 512 characters per line. Specifying long arguments to several options can exceed this limit.

The role (*role*) field accepts a string of no more than eight bytes consisting of characters from the set of alphabetic characters, numeric characters, period (.), underscore (_), and hyphen (-). The first character should be alphabetic and the field should contain at least one lower case alphabetic character. A warning message is written if these restrictions are not met. A future Solaris release might refuse to accept role fields that do not meet these requirements.

The *role* field must contain at least one character and must not contain a colon (:) or a newline (\n).

Options The following options are supported:

- A *authorization* One or more comma separated authorizations defined in [auth_attr\(4\)](#). Only a user or role who has grant rights to the authorization can assign it to an account
- b *base_dir* The default base directory for the system if -d *dir* is not specified. *base_dir* is concatenated with the account name to define the home directory. If the -m option is not used, *base_dir* must exist.
- c *comment* Any text string. It is generally a short description of the role. This information is stored in the role's /etc/passwd entry.

- d *dir*** The home directory of the new role. It defaults to *base_dir/account_name*, where *base_dir* is the base directory for new login home directories and *account_name* is the new role name.
- D** Display the default values for *group*, *base_dir*, *skel_dir*, *shell*, *inactive*, *expire* and *key=value* pairs. When used with the **-g**, **-b**, **-f**, or **-K**, options, the **-D** option sets the default values for the specified fields. The default values are:
- | | |
|-------------------------------------------------------------------|------------------|
| <i>group</i> | other (GID of 1) |
| <i>base_dir</i> | /home |
| <i>skel_dir</i> | /etc/skel |
| <i>shell</i> | /bin/pfsh |
| <i>inactive</i> | 0 |
| <i>expire</i> | Null |
| <i>auths</i> | Null |
| <i>profiles</i> | Null |
| <i>key=value</i> (pairs defined in user_attr(4)) | not present |
- e *expire*** Specify the expiration date for a role. After this date, no user is able to access this role. The expire option argument is a date entered using one of the date formats included in the template file */etc/datems.k*. See [getdate\(3C\)](#).
- If the date format that you choose includes spaces, it must be quoted. For example, you can enter `10/6/90` or `October 6, 1990`. A null value (" ") defeats the status of the expired date. This option is useful for creating temporary roles.
- f *inactive*** The maximum number of days allowed between uses of a role ID before that ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status.
- g *group*** An existing group's integer ID or character-string name. Without the **-D** option, it defines the new role's primary group membership and defaults to the default group. You can reset this default value by invoking `roleadd -D -g group`.
- G *group*** An existing group's integer ID or character-string name. It defines the new role's supplementary group membership. Duplicates between *group* with the **-g** and **-G** options are ignored. No more than `NGROUPS_MAX` groups can be specified.

- k *skel_dir*** A directory that contains skeleton information (such as `.profile`) that can be copied into a new role's home directory. This directory must already exist. The system provides the `/etc/skel` directory that can be used for this purpose.
- K *key=value*** A *key=value* pair to add to the role's attributes. Multiple `-K` options can be used to add multiple *key=value* pairs. The generic `-K` option with the appropriate key can be used instead of the specific implied key options (`-A` and `-P`). See [user_attr\(4\)](#) for a list of valid *key=value* pairs. The "type" key is not a valid key for this option. Keys can not be repeated.
- m** Create the new role's home directory if it does not already exist. If the directory already exists, it must have read, write, and execute permissions by *group*, where *group* is the role's primary group.
- o** This option allows a UID to be duplicated (non-unique).
- P *profile*** One or more comma-separated execution profiles defined in [prof_attr\(4\)](#).
- s *shell*** Full pathname of the program used as the user's shell on login. It defaults to an empty field causing the system to use `/bin/pfsh` as the default. The value of *shell* must be a valid executable file.
- u *uid*** The UID of the new role. This UID must be a non-negative decimal integer below `MAXUID` as defined in `<sys/param.h>`. The UID defaults to the next available (unique) number above the highest number currently assigned. For example, if UIDs 100, 105, and 200 are assigned, the next default UID number is 201. (UIDs from 0-99 are reserved for possible use in future applications.)

Files `/etc/datemsk`

`/etc/passwd`

`/etc/shadow`

`/etc/group`

`/etc/skel`

`/usr/include/limits.h`

`/etc/user_attr`

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | Committed |

See Also [passwd\(1\)](#), [pfexec\(1\)](#), [profiles\(1\)](#), [roles\(1\)](#), [users\(1B\)](#), [groupadd\(1M\)](#), [groupdel\(1M\)](#), [groupmod\(1M\)](#), [grpck\(1M\)](#), [logins\(1M\)](#), [pwck\(1M\)](#), [userdel\(1M\)](#), [usermod\(1M\)](#), [getdate\(3C\)](#), [auth_attr\(4\)](#), [passwd\(4\)](#), [prof_attr\(4\)](#), [user_attr\(4\)](#), [attributes\(5\)](#)

Diagnostics In case of an error, `roleadd` prints an error message and exits with a non-zero status.

The following indicates that `login` specified is already in use:

```
UX: roleadd: ERROR: login is already in use. Choose another.
```

The following indicates that the `uid` specified with the `-u` option is not unique:

```
UX: roleadd: ERROR: uid uid is already in use. Choose another.
```

The following indicates that the `group` specified with the `-g` option is already in use:

```
UX: roleadd: ERROR: group group does not exist. Choose another.
```

The following indicates that the `uid` specified with the `-u` option is in the range of reserved UIDs (from 0-99):

```
UX: roleadd: WARNING: uid uid is reserved.
```

The following indicates that the `uid` specified with the `-u` option exceeds `MAXUID` as defined in `<sys/param.h>`:

```
UX: roleadd: ERROR: uid uid is too big. Choose another.
```

The following indicates that the `/etc/passwd` or `/etc/shadow` files do not exist:

```
UX: roleadd: ERROR: Cannot update system files - login cannot be created.
```

Notes If a network name service such as NIS is being used to supplement the local `/etc/passwd` file with additional entries, `roleadd` cannot change information supplied by the network name service.

Name roledel – delete a role's login from the system

Synopsis roledel [-r] *role*

Description The roledel utility deletes a role account from the system and makes the appropriate account-related changes to the system file and file system. roledel also removes the role from each user's list of assumable roles.

Options The following options are supported:

-r Remove the role's home directory from the system. This directory must exist. The files and directories under the home directory will no longer be accessible following successful execution of the command.

Operands The following operands are supported:

role An existing role name to be deleted.

Exit Status The following exit values are returned:

0 Successful completion.
 2 Invalid command syntax. A usage message for the roledel command is displayed.
 6 The account to be removed does not exist.
 8 The account to be removed is in use.
 10 Cannot update the /etc/group or /etc/user_attr file but the login is removed from the /etc/passwd file.
 12 Cannot remove or otherwise modify the home directory.

Files

| | |
|----------------|---------------------------------------------------------------------------|
| /etc/passwd | system password file |
| /etc/shadow | system file containing roles' encrypted passwords and related information |
| /etc/group | system file containing group definitions |
| /etc/user_attr | system file containing additional role attributes |

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability | SUNWcs |

See Also [auths\(1\)](#), [passwd\(1\)](#), [profiles\(1\)](#), [roles\(1\)](#), [users\(1B\)](#), [groupadd\(1M\)](#), [groupdel\(1M\)](#), [groupmod\(1M\)](#), [logins\(1M\)](#), [roleadd\(1M\)](#), [rolemod\(1M\)](#), [useradd\(1M\)](#), [userdel\(1M\)](#), [usermod\(1M\)](#), [passwd\(4\)](#), [prof_attr\(4\)](#), [user_attr\(4\)](#), [attributes\(5\)](#)

Notes The `roledel` utility only deletes an account definition that is in the local `/etc/group`, `/etc/passwd`, `/etc/shadow`, and `/etc/user_attr` file. If a network name service such as NIS or NIS+ is being used to supplement the local `/etc/passwd` file with additional entries, `roledel` cannot change information supplied by the network name service.

Name rolemod – modify a role's login information on the system

Synopsis `rolemod [-u uid [-o]] [-g group] [-G group [, group...]]`
`[-d dir [-m]] [-s shell] [-c comment] [-l new_name]`
`[-f inactive] [-e expire]`
`[-A authorization [, authorization]]`
`[-P profile [, profile]] [-K key=value] role`

Description The `rolemod` utility modifies a role's login information on the system. It changes the definition of the specified login and makes the appropriate login-related system file and file system changes.

The system file entries created with this command have a limit of 512 characters per line. Specifying long arguments to several options may exceed this limit.

Options The following options are supported:

-A authorization

One or more comma separated authorizations as defined in [auth_attr\(4\)](#). Only role with grant rights to the `authorization` can assign it to an account. This replaces any existing authorization setting. If no authorization list is specified, the existing setting is removed.

-c comment

Specify a comment string. *comment* can be any text string. It is generally a short description of the login, and is currently used as the field for the user's full name. This information is stored in the user's `/etc/passwd` entry.

-d dir

Specify the new home directory of the role. It defaults to `base_dir/login`, where `base_dir` is the base directory for new login home directories, and `login` is the new login.

-e expire

Specify the expiration date for a role. After this date, no role will be able to access this login. The expire option argument is a date entered using one of the date formats included in the template file `/etc/datemsk`. See [getdate\(3C\)](#).

For example, you may enter `10/6/90` or `October 6, 1990`. A value of `''` defeats the status of the expired date.

-f inactive

Specify the maximum number of days allowed between uses of a login ID before that login ID is declared invalid. Normal values are positive integers. A value of `0` defeats the status.

-g group

Specify an existing group's integer ID or character-string name. It redefines the role's primary group membership.

-G group

An existing group's integer ID or character-string name. It defines the new user's supplementary group membership. Duplicates between group with the `-g` and `-G` options

are ignored. No more than `NGROUPS_MAX` groups can be specified. GIDs 0-99 are reserved for allocation by the Solaris Operating System.

-K *key=value*

Replace existing or add to a role's *key=value* pair attributes. Multiple `-K` options can be used to replace or add multiple *key=value* pairs. However, keys must not be repeated. The generic `-K` option with the appropriate key may be used instead of the specific implied key options (`-A` and `-P`). See [user_attr\(4\)](#) for a list of valid *key=value* pairs.

The keyword `type` can be specified with the value `role` or the value `normal`. When using the value `normal`, the account changes from a role user to a normal user; using the value `role` keeps the account a role user.

-l *new_logname*

Specify the new login name for the role. The *new_logname* argument is a string no more than eight bytes consisting of characters from the set of alphabetic characters, numeric characters, period (`.`), underline (`_`), and hyphen (`-`). The first character should be alphabetic and the field should contain at least one lower case alphabetic character. A warning message will be written if these restrictions are not met. A future Solaris release may refuse to accept login fields that do not meet these requirements. The *new_logname* argument must contain at least one character and must not contain a colon (`:`) or NEWLINE (`\n`).

-m

Move the role's home directory to the new directory specified with the `-d` option. If the directory already exists, it must have permissions read/write/execute by *group*, where *group* is the role's primary group.

-o

This option allows the specified UID to be duplicated (non-unique).

-P *profile*

One or more comma-separated execution profiles defined in [auth_attr\(4\)](#). This replaces any existing profile setting. If no profile list is specified, the existing setting is removed.

-s *shell*

Specify the full pathname of the program that is used as the role's shell on login. The value of *shell* must be a valid executable file.

-u *uid*

Specify a new UID for the role. It must be a non-negative decimal integer less than `MAXUID` as defined in `<param.h>`. The UID associated with the role's home directory is not modified with this option; a role will not have access to their home directory until the UID is manually reassigned using [chown\(1\)](#).

Operands The following operands are supported:

login

An existing login name to be modified.

Exit Status In case of an error, `rolemod` prints an error message and exits with one of the following values:

- 2
The command syntax was invalid. A usage message for the `rolemod` command is displayed.
- 3
An invalid argument was provided to an option.
- 4
The *uid* given with the `-u` option is already in use.
- 5
The password files contain an error. [pwconv\(1M\)](#) can be used to correct possible errors. See [passwd\(4\)](#).
- 6
The login to be modified does not exist, the *group* does not exist, or the login shell does not exist.
- 8
The login to be modified is in use.
- 9
The *new_logname* is already in use.
- 10
Cannot update the `/etc/group` or `/etc/user_attr` file. Other update requests will be implemented.
- 11
Insufficient space to move the home directory (`-m` option). Other update requests will be implemented.
- 12
Unable to complete the move of the home directory to the new home directory.

Files

- `/etc/group`
system file containing group definitions
- `/etc/datemsk`
system file of date formats
- `/etc/passwd`
system password file
- `/etc/shadow`
system file containing users' and roles' encrypted passwords and related information
- `/etc/user_attr`
system file containing additional user and role attributes

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | Committed |

See Also [chown\(1\)](#), [passwd\(1\)](#), [users\(1B\)](#), [groupadd\(1M\)](#), [groupdel\(1M\)](#), [groupmod\(1M\)](#), [logins\(1M\)](#), [pwconv\(1M\)](#), [roleadd\(1M\)](#), [roledel\(1M\)](#), [useradd\(1M\)](#), [userdel\(1M\)](#), [usermod\(1M\)](#), [getdate\(3C\)](#), [auth_attr\(4\)](#), [passwd\(4\)](#), [attributes\(5\)](#)

Name root_archive – manage bootable miniroot archives

Synopsis /boot/solaris/bin/root_archive pack *archive* *root*
/boot/solaris/bin/root_archive unpack *archive* *root*
/boot/solaris/bin/root_archive packmedia *solaris_image* *root*
/boot/solaris/bin/root_archive unpackmedia *solaris_image* *root*

Description The root_archive utility is used to manipulate boot archives and the bootable miniroot(s) in a Solaris install image. The utility can pack and unpack boot archives and image miniroots. Both ufs and hfs (iso9660) format archives can be unpacked, although only ufs format is generated when packing.

For normal, boot-related system administration, [bootadm\(1M\)](#) is recommended. root_archive's primary purpose is to enable OEMs to add or update a driver or other component on the Solaris install media.

A miniroot and a boot archive is closely associated with the release it is intended to boot. To ensure that the tools and system services used to construct the miniroot match, miniroot manipulation must be performed only on a system running the same release for which the miniroot is intended to install.

Subcommands The root_archive command has the following subcommands:

| | |
|----------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| pack <i>archive</i> <i>root</i> | Pack the contents of the root directory into the boot archive <i>archive</i> . |
| unpack <i>archive</i> <i>root</i> | Unpack the contents of the boot archive named <i>archive</i> to the directory named <i>root</i> . |
| packmedia <i>solaris_image</i> <i>root</i> | Create and pack the miniroot(s) in <i>solaris_image</i> from the contents of the directory named <i>root</i> . |
| unpackmedia <i>solaris_image</i> <i>root</i> | Unpack the contents of the miniroot(s) in <i>solaris_image</i> to the directory named <i>root</i> . |

The contents of a miniroot are constructed to need the requirements of the release. When unpacking a miniroot, all the contents of the miniroot(s) are unpacked. When packing a miniroot, the source directory must contain all the necessary components with which to construct a miniroot. In general, this can only be achieved by first unpacking an existing miniroot.

Examples **EXAMPLE 1** Unpacking the Miniroots in a Solaris x86 Install Image

The following command unpacks the miniroots in a Solaris image to the root directory in /export/release/latest.

```
# root_archive unpackmedia \  
/export/nv/solarisdvd.nvx_dvd/latest /export/release/latest/root
```

EXAMPLE 1 Unpacking the Miniroots in a Solaris x86 Install Image *(Continued)*

In the preceding, `/export/nv/solarisdvd.nvx_dvd/latest` represents a path to a Solaris x86 install image and `/export/release/latest/root` is a directory that will be purged or created, as necessary.

EXAMPLE 2 Packing the Miniroots in a Solaris x86 Install Image

The following command creates and packs the miniroot(s) in a Solaris image from the contents of the directory `/export/release/latest/root`.

```
# root_archive packmedia \  
/export/nv/solarisdvd.nvx_dvd/latest /export/release/latest/root
```

Exit Status The following exit values are returned:

- 0 The command completed successfully.
- 1 The command exited due to an error.

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

Name route – manually manipulate the routing tables

Synopsis route [-fnvq] *sub-command* [[*modifiers*] *args*]

route [-fnvq] [-p [-R *root-dir*]] add | delete [*modifiers*] *destination gateway* [*args*]

route [-fnvq] change | get [*modifiers*] *destination* [*gateway* [*args*]]

route [-fn] monitor [*modifiers*]

route [-fnvq] flush [*modifiers*]

route -p [-R *root-dir*] show

Description route manually manipulates the network routing tables. These tables are normally maintained by the system routing daemon, such as [in.routed\(1M\)](#) and [in.ripngd\(1M\)](#).

route supports a limited number of general options, but a rich command language. Users can specify an arbitrary request that can be delivered by means of the programmatic interface discussed in [route\(7P\)](#).

route uses a routing socket and the new message types RTM_ADD, RTM_DELETE, RTM_GET, and RTM_CHANGE. While only superusers can modify routing tables, the RTM_GET operation is allowed for non-privileged users.

- Options**
- f Flush the routing tables of all gateway entries. If you use the -f option in conjunction with any of the route sub-commands, route flushes the gateways before performing the sub-command. Specify the table to flush by placing the `inet` or `inet6` modifier immediately after the -f option. If unspecified, flushing IPv4 (`inet`) routes is the default.
 - n Prevent attempts to print host and network names symbolically when reporting actions. This option is useful when name servers are unavailable.
 - p Make changes to the network route tables persistent across system restarts. The operation is applied to the network routing tables first and, if successful, is then applied to the list of saved routes used at system startup. In determining whether an operation was successful, a failure to add a route that already exists or to delete a route that is not in the routing table is ignored. Particular care should be taken when using host or network names in persistent routes, as network-based name resolution services are not available at the time routes are added at startup.
 - q Suppress all output.
 - R *root-dir* Specify an alternate root directory where route applies changes. This option is ignored unless used in conjunction with the -p option. When -R is specified, route changes are applied only to the list of saved routes to be used at startup, *not* to the network routing tables. In addition, certain checks, such as the

existence of network interfaces used with `-ifp`, are skipped. This can be useful from within JumpStart scripts, where the root directory of the system being modified is in a location other than `/`.

`-v` Print additional details in verbose mode.

Subcommands The following subcommands are supported:

`add` Add a route.

`change` Change aspects of a route (such as its gateway).

`delete` Delete a specific route.

`flush` Remove all gateway entries from the routing table.

`get` Look up and display the route for a destination.

`monitor` Continuously report any changes to the routing information base, routing lookup misses, or suspected network partitionings.

`show` Display the list of routes to be applied at system startup. Can be used only in conjunction with the `-p` option.

The `add` and `delete` sub-commands have the following syntax:

```
route [ -fnvq ] cmd destination gateway [metric/netmask]
```

where *cmd* is `add` or `delete`, *destination* is the destination host or network, and *gateway* is the next-hop intermediary through which packets should be routed. Modifiers described in OPERANDS can be placed anywhere on the command line.

The `get` and `change` sub-commands have the following syntax:

```
route [ -fnvq ] cmd destination [gateway [metric/netmask]]
```

where *cmd* is `get` or `change`, *destination* is the destination host or network, and *gateway* is the next-hop intermediary through which packets should be routed. Modifiers described in OPERANDS can be placed anywhere on the command line.

The `monitor` sub-command has the following syntax:

```
route monitor [ -inet | -inet6 ]
```

Operands `route` executes its sub-commands on routes to destinations by way of gateways.

Destinations and Gateways By default, destination and gateway addresses are interpreted as IPv4 addresses. All symbolic names are tried first as a host name, using `getipnodebyname(3SOCKET)`. If this lookup fails in the `AF_INET` case, `getnetbyname(3SOCKET)` interprets the name as that of a network.

Including an optional modifier on the command line before the address changes how the route sub-command interprets it.

The following modifiers are supported:

- inet Force the address to be interpreted as an IPv4 address, that is, under the AF_INET address family.
- inet6 Force the address to be interpreted as an IPv6 address, that is, under the AF_INET6 address family.

For IPv4 addresses, routes to a particular host are by default distinguished from those to a network by interpreting the Internet address specified as the destination. If the destination has a *local address part* (that is, the portion not covered by the netmask) of 0, or if the destination is resolved as the symbolic name of a network, then the route is assumed to be to a network; otherwise, it is presumed to be a route to a host.

You can force this selection by using one of the following modifiers:

- host Force the destination to be interpreted as a host.
- net Force the destination to be interpreted as a network.

For example:

| Destination | Destination Equivalent |
|-----------------|------------------------|
| 128.32 | -host 128.0.0.32 |
| 128.32.130 | -host 128.32.0.130 |
| -net 128.32 | 128.32.0.0 |
| -net 128.32.130 | 128.32.130.0 |

Two modifiers avoid confusion between addresses and keywords (for example, host used as a symbolic host name). You can distinguish a *destination* by preceding it with the `-dst` modifier. You can distinguish a gateway address by using the `-gateway` modifier. If the destination is directly reachable by way of an interface requiring no intermediary IP router to act as a gateway, this can be indicated by using the `-interface` or `-iface` modifier.

In the following example, the route does not refer to an external gateway (router), but rather to one of the machine's interfaces. Packets with IP destination addresses matching the destination and mask on such a route are sent out on the interface identified by the gateway address. For interfaces using the ARP protocol, this type of route is used to specify that all matching destinations are local to the physical link. That is, a host could be configured to ARP for all addresses, without regard to the configured interface netmask, by adding a default route using this command. For example:

```
example# route add default hostname -interface
```

where gateway address *hostname* is the name or IP address associated with the network interface over which all matching packets should be sent. On a host with a single network interface, *hostname* is usually the same as the *nodename* returned by the `uname -n` command. See [uname\(1\)](#).

For backward compatibility with older systems, directly reachable routes can also be specified by placing a `0` after the gateway address:

```
example# route add default hostname 0
```

This value was once a route metric, but this metric is no longer used. If the value is specified as `0`, then the destination is directly reachable (equivalent to specifying `-interface`). If it is non-zero but cannot be interpreted as a subnet mask, then a gateway is used (default).

With the `AF_INET` address family or an IPv4 address, a separate subnet mask can be specified. This can be specified in one of the following ways:

- IP address following the gateway address. This is typically specified in *decimal dot* notation as for `inet_addr(3SOCKET)` rather than in symbolic form.
- IP address following the `-netmask` qualifier.
- Slash character and a decimal length appended to the destination address.

If a subnet mask is not specified, the mask used is the subnet mask of the output interface selected by the gateway address, if the classful network of the destination is the same as the classful network of the interface. Otherwise, the classful network mask for the destination address is used.

Each of the following examples creates an IPv4 route to the destination `192.0.2.32` subnet with a subnet mask of `255.255.255.224`:

```
example# route add 192.0.2.32/27 somegateway
example# route add 192.0.2.32 -netmask 255.255.255.224 somegateway
example# route add 192.0.2.32 somegateway 255.255.255.224
```

For IPv6, only the slash format is accepted. The following example creates an IPv6 route to the destination `33fe::` with a netmask of 16 one-bits followed by 112 zero-bits.

```
example# route add -inet6 3ffe::/16 somegateway
```

In cases where the gateway does not uniquely identify the output interface (for example, when several interfaces have the same address), you can use the `-ifp ifname` modifier to specify the interface by name. For example, `-ifp lo0` associates the route with the `lo0` interface. If the named interface is an underlying interface in an IPMP (IP multipathing) group, then requests to add a route will automatically be translated to the corresponding IPMP IP interface, and requests to delete or change a route on an underlying interface will fail.

When the routing table contains several equal routes, that is, routes for the same destination and mask, then IP attempts to spread the traffic over those routes. The spreading is such that an individual transport connection uses the same route to avoid packet reordering as seen by, for example, TCP. The details of the spreading algorithm is not documented and is likely to evolve over time.

Routing Flags Routes have associated flags that influence operation of the protocols when sending to destinations matched by the routes. These flags can be set (and in some cases cleared, indicated by ~) by including the following modifiers on the command line:

| Modifier | Flag | Description |
|------------|---------------|-----------------------------------------------------|
| -interface | ~RTF_GATEWAY | Destination is directly reachable |
| -iface | ~RTF_GATEWAY | Alias for interface modifier |
| -static | RTF_STATIC | Manually added route |
| -nostatic | ~RTF_STATIC | Pretend route was added by kernel or routing daemon |
| -reject | RTF_REJECT | Emit an ICMP unreachable when matched |
| -blackhole | RTF_BLACKHOLE | Silently discard packets during updates |
| -proto1 | RTF_PROTO1 | Set protocol specific routing flag #1 |
| -proto2 | RTF_PROTO2 | Set protocol specific routing flag #2 |
| -private | RTF_PRIVATE | Do not advertise this route |
| -multirt | RTF_MULTIRT | Creates the specified redundant route |
| -setsrc | RTF_SETSRC | Assigns the default source address |
| -indirect | RTF_INDIRECT | Allows adding routes where gateway is not on-link |

The optional `-indirect` modifier allows adding routes where the gateway is not directly reachable. When an indirect route is the best match for a packet to be sent or forwarded, then IP proceeds to look up that gateway to find a route that is directly reachable. The `-indirect` modifier can be used even if the gateway is directly reachable.

The optional modifiers `-rtt`, `-rttvar`, `-sendpipe`, `-recvpipe`, `-mtu`, `-hopcount`, `-expire`, and `-sssthresh` provide initial values to quantities maintained in the routing entry by transport level protocols, such as TCP. These can be individually locked either by preceding each modifier to be locked by the `-lock` meta-modifier, or by specifying that all ensuing metrics can be locked by the `-lockrest` meta-modifier.

Some transport layer protocols can support only some of these metrics. The following optional modifiers are supported:

`-expire` Lifetime for the entry. This optional modifier is not currently supported.

- hopcount Maximum hop count. This optional modifier is not currently supported.
- mtu Maximum MTU in bytes.
- recvpipe Receive pipe size in bytes.
- rtt Round trip time in microseconds.
- rttvar Round trip time variance in microseconds.
- sendpipe Send pipe size in bytes.
- ssthresh Send pipe size threshold in bytes.
- secattr Security attributes of the route. This modifier is available only if the system is configured with the Solaris Trusted Extensions feature.

The `-secattr` modifier has the following format:

```
min_sl=val,max_sl=val,doi=val,cipso
```

or:

```
sl=VAL,doi=VAL,cipso
```

In the first form, above, the *val* for `min_sl` and `max_sl` is a sensitivity label in either hex or string form. The *val* for `doi` is a non-negative integer. The route will apply only for packets with the same domain of interpretation as defined by the `doi` value and within the accreditation range defined by the `min_sl` and `max_sl` values. The `cipso` keyword is optional and set by default. Valid `min_sl`, `max_sl` and `doi` keyword/value pairs are mandatory. Note that if *val* contains a space, it must be protected by double quotes.

The second form, above, is equivalent to specifying the first form with the same `VAL` for `min_sl` and `max_sl`. The second form should be used for the `get` command, because `get` uses only a single sensitivity label.

Compatibility The modifiers `host` and `net` are taken to be equivalent to `-host` and `-net`. To specify a symbolic address that matches one of these names, use the `dst` or `gateway` keyword to distinguish it. For example: `-dst host`

The following two flags are also accepted for compatibility with older systems, but have no effect.

| Modifier | Flag |
|------------------------|---------------------------|
| <code>-cloning</code> | <code>RTF_CLONING</code> |
| <code>-xresolve</code> | <code>RTF_XRESOLVE</code> |

The `-ifa` hostname modifier is also accepted, but has no effect.

Diagnostics

| | |
|------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>add [host network] destination:gateway flags</code> | The specified route is being added to the tables. The values printed are from the routing table entry supplied in the ioctl(2) call. If the gateway address used was not the primary address of the gateway (the first one returned by getipnodebyname(3SOCKET)) the gateway address is printed numerically as well as symbolically. |
| <code>delete [host network] destination:gateway flags</code> | |
| <code>change [host network] destination:gateway flags</code> | As add, but when deleting or changing an entry. |
| <code>destination done</code> | When the <code>-f</code> flag is specified, or the <code>flush</code> sub-command is used, each routing table entry deleted is indicated with a message of this form. |
| Network is unreachable | An attempt to add a route failed because the gateway listed was not on a directly-connected network. Give the next-hop gateway instead. |
| not in table | A delete operation was attempted for an entry that is not in the table. |
| entry exists | An add operation was attempted for a route that already exists in the kernel. |

routing table overflow

An operation was attempted, but the system was unable to allocate memory to create the new entry.

insufficient privileges

An attempt to add, delete, change, or flush a route failed because the calling process does not have appropriate privileges.

Notes Specifying that destinations are local (with the `-interfacemodifier`) assumes that the routers implement proxy ARP, meaning that they respond to ARP queries for all reachable destinations. Normally, using either router discovery or RIP is more reliable and scalable than using proxy ARP. See [in .routed\(1M\)](#) for information related to RIP.

Combining the all destinations are local route with subnet or network routes can lead to unpredictable results. The search order as it relates to the all destinations are local route are undefined and can vary from release to release.

Name routeadm – IP forwarding and routing configuration

Synopsis routeadm [-p *option*]

```
routeadm [-R root-dir] [-e option ...] [-d option...]
  [-r option...] [-s var=value]
```

```
routeadm [-l fmri]
```

```
routeadm [-m fmri key=value [key=value]...]
```

```
routeadm [-u]
```

Description The routeadm command is used to administer system-wide configuration for IP forwarding and routing. IP forwarding is the passing of IP packets from one network to another; IP routing is the use of a routing protocol to determine routes.

IP forwarding and routing functions are also represented as services within the service management facility (SMF), and can be administered by means of [svcadm\(1M\)](#) also, using the following fault management resource identifiers (FMRIs):

```
svc:/network/ipv4-forwarding:default
svc:/network/ipv6-forwarding:default
svc:/network/routing/route:default
svc:/network/routing/ripng:default
```

See EXAMPLES for relevant examples.

Note – It is strongly encouraged to use [ipadm\(1M\)](#) to enable or disable forwarding. Use of routeadm and the SMF service to administer IP forwarding, for both IPv4 and IPv6, will be made obsolete in a future release, replaced by ipadm. See [ipadm\(1M\)](#) for further information.

In addition to enabling and disabling routing and forwarding, routeadm is used to interact with SMF-based routing daemon services. Routing daemon services are identified by the presence of a routeadm application property group, which routeadm uses in administering the given service. Routing daemon services can also specify properties relating to their operation in the routing application property group; these can be modified by means of routeadm -m. If an FMRI for a service without such a property group is specified, an error is issued and the operation is not carried out. If a routing daemon has not been converted to SMF, the `ipv4[or 6]-routing-daemon`, `ipv4[or 6]-routing-daemon-args`, and `ipv4[or 6]-routing-stop-cmd` variables can be used to specify the appropriate daemon for IPv4 or IPv6 routing. routeadm will then run that daemon using the `svc:/network/routing/legacy-routing:ipv4[or 6]` service as appropriate. This conversion process occurs when you issue an enable (-e), disable (-d) or an update (-u) command.

The first usage, in the SYNOPSIS above, reports the current configuration.

Options The following command-line options are supported:

- p [*option*]
Print the configuration in parseable format. If *option* is specified, only the configuration for the specified option or variable is displayed.
- R *root-dir*
Specify an alternate root directory where routeadm applies changes. This can be useful from within JumpStart scripts, where the root directory of the system being modified is mounted elsewhere.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See [zones\(5\)](#).
- e *option...*
Enable the specified option. The effect is to prepare the associated services (svc:/network/ipv4-forwarding:default in the case of ipv4-forwarding) for enabling. By means of the routing-svcs variable, the routing daemons are specified to be enabled on subsequent boot or when routeadm -u is run.
- d *option...*
Disable the specified option. The effect is to prepare the associated services (svc:/network/ipv4-forwarding:default in the case of ipv4-forwarding) for enabling. By means of the routing-svcs variable, the routing daemons are specified to be disabled on subsequent boot or when routeadm -u is run.
- l *fmri*
List all properties in the routing application property group for the SMF routing daemon service.
- m *fmri key=value*
Change property value of property *key* to *value* in routing application property group for the SMF routing daemon service. For multi-valued properties, the property name can be used multiple times in the modify operation, and each associated value will be added.
- r *option...*
Revert the specified option to the system default. The system defaults are specified in the description of each *option*.
- u
Apply the currently configured options to the running system. These options might include enabling or disabling IP forwarding and launching or killing routing daemons, if any are specified. It does not alter the state of the system for those settings that have been set to default. This option is meant to be used by administrators who do not want to reboot to apply their changes. In addition, this option upgrades non-SMF configurations from the invocations of daemon stop commands, which might include a set of arguments, to a simple enabling of the appropriate service.

-s key=value

Specify string values for specific variables in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is displayed and the program exits. The following variables can be specified:

routing-svcs=fmrlist

Specifies the routing daemon services to be enabled. Routing daemon services are determined to be IPv4 or IPv6 (and so enabled or disabled when `routeadm -e/-d ipv4(6)-routing` is run) on the basis of property values in the `routeadm` application property group. Default: `route:default ripng:default`

ipv4-routing-daemon=<full_path_to_routing_daemon>

Specifies the routing daemon to be started when `ipv4-routing` is enabled. The routing daemon specified must be an executable binary or shell-script. If the specified program maps to an SMF service, the service will be used, and daemon arguments to the program will be transferred to the properties of the service at enable time. Default: ""

ipv4-routing-daemon-args=<args>

Specifies the startup arguments to be passed to the `ipv4-routing-daemon` when `ipv4-routing` is enabled. Default: no arguments

ipv4-routing-stop-cmd=<command>

Specifies the command to be executed to stop the routing daemon when `ipv4-routing` is disabled. `<command>` can be an executable binary or shell-script, or a string that can be parsed by `system(3C)`. Default: ""

ipv6-routing-daemon=<full_path_to_routing_daemon>

Specifies the routing daemon to be started when `ipv6-routing` is enabled. The routing daemon specified must be an executable binary or shell-script. If the specified program maps to an SMF service, the service will be used, and daemon arguments to the program will be transferred to the properties of the service at enable time. Default: ""

ipv6-routing-daemon-args=<args>

Specifies the startup arguments to be passed to the `ipv6-routing-daemon` when `ipv6-routing` is enabled. Default: ""

ipv6-routing-stop-cmd=<command>

Specifies the command to be executed to stop the routing daemon when `ipv6-routing` is disabled. `<command>` can be an executable binary or shell-script, or a string that can be parsed by `system(3C)`. Default: ""

Multiple `-e`, `-d`, and `-r` options can be specified on the command line. Changes made by `-e`, `-d`, and `-r` are persistent, but are not applied to the running system unless `routeadm` is called later with the `-u` option.

Use the following options as arguments to the `-e`, `-d`, and `-r` options (shown above as *option...*).

ipv4-forwarding

Controls the global forwarding configuration for all IPv4 interfaces. The system default is disabled. If enabled, IP will forward IPv4 packets to and from interfaces when appropriate. If disabled, IP will not forward IPv4 packets to and from interfaces when appropriate. The SMF service associated with this configuration variable is `svc:/network/routing/ipv4-forwarding`. This service will be enabled or disabled as appropriate when `routeadm` is called with the `u` option. As an alternative, you can use `svcadm(1M)`. Services that require `ipv4-forwarding` to be enabled should specify a dependency on this service.

ipv4-routing

Determines whether an IPv4 routing daemon is run. The system default is enabled unless the `/etc/defaultrouter` file exists (see `defaultrouter(4)`), in which case the default is disabled. The value of this option reflects the state of all IPv4 routing services, such that if any IPv4 routing service is enabled, `ipv4-routing` is enabled. This allows users to interact with routing services using `svcadm(1M)`, as well as through `routeadm`. IPv4 routing services, specified by means of the `routing-svcs` variable, will be prepared for enable on next boot when the user explicitly enables `ipv4-routing`. The SMF routing daemon service for `in.routed` (`svc:/network/routing/route:default`) is specified by default.

ipv6-forwarding

Controls the global forwarding configuration for all IPv6 interfaces. The system default is disabled. If enabled, IP will forward IPv6 packets to and from interfaces when appropriate. If disabled, IP will not forward IPv6 packets to and from interfaces when appropriate. The SMF service associated with this configuration variable is `svc:/network/routing/ipv6-forwarding`. This service will be enabled or disabled as appropriate when `routeadm` is called with the `-u` option, or `svcadm(1M)` is used. Services that require `ipv6-forwarding` to be enabled should specify a dependency on this service.

ipv6-routing

Determines whether an IPv6 routing daemon is run. The system default is disabled. The value of this option reflects the state of all IPv6 routing services, such that, if any IPv6 routing service is enabled, `ipv6-routing` is enabled. This allows users to interact with routing services via `svcadm(1M)` as well as through `routeadm`. IPv6 routing services, specified by means of the `routing-svcs` variable, will be prepared for enable on next boot when the user explicitly enables `ipv6-routing`. The SMF routing daemon service for `in.ripngd` (`svc:/network/routing/ripng:default`) is specified by default.

The forwarding and routing settings are related but not mutually dependent. For example, a router typically forwards IP packets and uses a routing protocol, but nothing would prevent an administrator from configuring a router that forwards packets and does not use a routing protocol. In that case, the administrator would enable forwarding, disable routing, and populate the router's routing table with static routes.

The forwarding settings are global settings. Each interface also has an `IFF_ROUTER` forwarding flag that determines whether packets can be forwarded to or from a particular interface. That flag can be independently controlled by means of `ifconfig(1M)`'s router option. When the

global forwarding setting is changed (that is, `-u` is issued to change the value from `enabled` to `disabled` or vice-versa), all interface flags in the system are changed simultaneously to reflect the new global policy. Interfaces configured by means of DHCP automatically have their interface-specific `IFF_ROUTER` flag cleared.

When a new interface is plumbed by means of `ifconfig`, the value of the interface-specific forwarding flag is set according to the current global forwarding value. Thus, the forwarding value forms the “default” for all new interfaces.

Examples EXAMPLE 1 Enabling IPv4 Forwarding

IPv4 forwarding is disabled by default. The following command enables IPv4 forwarding:

```
example# routeadm -e ipv4-forwarding
```

EXAMPLE 2 Apply Configured Settings to the Running System

In the previous example, a system setting was changed, but will not take effect until the next reboot unless a command such as the following is used:

```
example# routeadm -u
```

An alternative to the above two steps is to simply enable the equivalent SMF service:

```
example# svcadm enable svc:/network/ipv4-forwarding
```

...or, using the abbreviated FMRI:

```
example# svcadm enable ipv4-forwarding
```

EXAMPLE 3 Making a Setting Revert to its Default

To make the setting changed in the first example revert to its default, enter the following:

```
example# routeadm -r ipv4-forwarding
```

```
example# routeadm -u
```

EXAMPLE 4 Starting `in.routed` with the `-q` Flag

Setting the `-q` flag is represented in the SMF service by setting the `quiet_mode` property to `true`. The following sequence of commands starts `in.routed` with the `-q` flag:

```
example# routeadm -m route:default quiet_mode=true
```

```
example# routeadm -e ipv4-routing -u
```

See [in.routed\(1M\)](#) for details of property names and how they relate to daemon behavior.

Exit Status The following exit values are returned:

- 0 Successful completion.
- !=0 An error occurred while obtaining or modifying the system configuration.

Files /etc/inet/routing.conf Parameters for IP forwarding and routing. (Not to be edited.)

Name rpcbind – universal addresses to RPC program number mapper

Synopsis rpcbind [-d] [-w]

Description rpcbind is a server that converts RPC program numbers into universal addresses. It must be running on the host to be able to make RPC calls on a server on that machine.

When an RPC service is started, it tells rpcbind the address at which it is listening, and the RPC program numbers it is prepared to serve. When a client wishes to make an RPC call to a given program number, it first contacts rpcbind on the server machine to determine the address where RPC requests should be sent.

rpcbind should be started before any other RPC service. Normally, standard RPC servers are started by port monitors, so rpcbind must be started before port monitors are invoked.

When rpcbind is started, it checks that certain name-to-address translation-calls function correctly. If they fail, the network configuration databases can be corrupt. Since RPC services cannot function correctly in this situation, rpcbind reports the condition and terminates.

rpcbind maintains an open transport end for each transport that it uses for indirect calls. This is the UDP port on most systems.

The rpcbind service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/rpc/bind
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). rpcbind can only be started by the superuser or someone in the Primary Administrator role.

The configuration properties of this service can be modified with [svccfg\(1M\)](#).

The following SMF property is used to allow or disallow access to rpcbind by remote clients:

```
config/local_only = true
```

The default value, `true`, shown above, disallows remote access; a value of `false` allows remote access. See [EXAMPLES](#).

The FMRI `svc:/network/rpc/bind` property group `config` contains the following property settings:

| | |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>enable_tcpwrappers</code> | Specifies that the TCP wrappers facility is used to control access to TCP services. The value <code>true</code> enables checking. The default value for <code>enable_tcpwrappers</code> is <code>false</code> . If the <code>enable_tcpwrappers</code> parameter is enabled, then all calls to rpcbind originating from non-local addresses are automatically wrapped by the TCP wrappers facility. The <code>syslog</code> facility code <code>daemon</code> is used to log |
|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| | |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | allowed connections (using the <code>info</code> severity level) and denied traffic (using the <code>warning</code> severity level). See syslog.conf(4) for a description of <code>syslog</code> codes and severity levels. The Interface Stability of the TCP wrappers facility and its configuration files is Volatile. As the TCP wrappers facility is not controlled by Sun, intrarelease incompatibilities are not uncommon. See attributes(5) . |
| <code>verbose_logging</code> | Specifies whether the TCP wrappers facility logs all calls or just the denied calls. The default is <code>false</code> . This option has no effect if TCP wrappers are not enabled. |
| <code>allow_indirect</code> | Specifies whether <code>rpcbind</code> allows indirect calls at all. By default, <code>rpcbind</code> allows most indirect calls, except to a number of standard services (<code>key serv</code> , <code>automount</code> , <code>mount</code> , <code>nfs</code> , <code>rquota</code> , and selected NIS and <code>rpcbind</code> procedures). Setting <code>allow_indirect</code> to <code>false</code> causes all indirect calls to be dropped. The default is <code>true</code> . NIS broadcast clients rely on this functionality on NIS servers. |

Options The following options are supported:

- d Run in debug mode. In this mode, `rpcbind` does not fork when it starts. It prints additional information during operation, and aborts on certain errors. With this option, the name-to-address translation consistency checks are shown in detail.
- w Do a warm start. If `rpcbind` aborts or terminates on `SIGINT` or `SIGTERM`, it writes the current list of registered services to `/var/run/portmap.file` and `/var/run/rpcbind.file`. Starting `rpcbind` with the `-w` option instructs it to look for these files and start operation with the registrations found in them. This allows `rpcbind` to resume operation without requiring all RPC services to be restarted.

Examples **EXAMPLE 1** Allowing Remote Access

The following sequence of commands allows remote access to `rpcbind`.

```
# svccfg -s svc:/network/rpc/bind setprop config/local_only = false
# svcadm refresh svc:/network/rpc/bind
```

| | | |
|--------------|------------------------------------|------------------------------------------------------------------------------------------------------|
| Files | <code>/var/run/portmap.file</code> | Stores the information for RPC services registered over IP based transports for warm start purposes. |
| | <code>/var/run/rpcbind.file</code> | Stores the information for all registered RPC services for warm start purposes. |

Attributes See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability | SUNWcs |
| Interface Stability | See below. |

TCP wrappers is Volatile.

See Also [smf\(5\)](#), [rpcinfo\(1M\)](#), [svcadm\(1M\)](#), [svccfg\(1M\)](#), [rpcbind\(3NSL\)](#), [syslog.conf\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

For information on the TCP wrappers facility, see the `hosts_access(4)` man page, delivered as part of the Solaris operating environment in `/usr/sfw/man` and available in the `SUNWtcpd` package.

Notes Terminating `rpcbind` with `SIGKILL` prevents the warm-start files from being written.

All RPC servers are restarted if the following occurs: `rpcbind` crashes (or is killed with `SIGKILL`) and is unable to write the warm-start files; `rpcbind` is started without the `-w` option after a graceful termination. Otherwise, the warm start files are not found by `rpcbind`.

- Name** rpc.bootparamd, bootparamd – boot parameter server
- Synopsis** /usr/sbin/rpc.bootparamd [-d]
- Description** rpc.bootparamd is a server process that provides information from a bootparams database to diskless clients at boot time. See [bootparams\(4\)](#)
- The source for the bootparams database is determined by the [nsswitch.conf\(4\)](#) file (on the machine running the rpc.bootparamd process).
- Options** The following options are supported:
- d Display debugging information.
- Files** /etc/bootparams boot parameter data base
/etc/nsswitch.conf configuration file for the name-service switch
- Attributes** See [attributes\(5\)](#) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|---------------------|
| Availability | system/boot/network |

See Also [svcs\(1\)](#), [svcadm\(1M\)](#), [bootparams\(4\)](#), [nsswitch.conf\(4\)](#), [attributes\(5\)](#), [smf\(5\)](#)

Notes A diskless client requires service from at least one rpc.bootparamd process running on a server that is on the same IP subnetwork as the diskless client.

Some routines that compare hostnames use case-sensitive string comparisons; some do not. If an incoming request fails, verify that the case of the hostname in the file to be parsed matches the case of the hostname called for, and attempt the request again.

The rpc.bootparamd service is managed by the service management facility, [smf\(5\)](#), under the service identifier:

```
svc:/network/rpc/bootparams
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using [svcadm\(1M\)](#). The service's status can be queried using the [svcs\(1\)](#) command.

Name rpcinfo – report RPC information

Synopsis rpcinfo [-m | -s] [*host*]
rpcinfo -p [*host*]
rpcinfo -T *transport host prognum [versnum]*
rpcinfo -l [-T *transport*] *host prognum versnum*
rpcinfo [-n *portnum*] -u *host prognum [versnum]*
rpcinfo [-n *portnum*] -t *host prognum [versnum]*
rpcinfo -a *serv_address -T transport prognum [versnum]*
rpcinfo -b [-T *transport*] *prognum versnum*
rpcinfo -d [-T *transport*] *prognum versnum*

Description rpcinfo makes an RPC call to an RPC server and reports what it finds.

In the first synopsis, `rpcinfo` lists all the registered RPC services with `rpcbind` on *host*. If *host* is not specified, the local host is the default. If `-s` is used, the information is displayed in a concise format.

In the second synopsis, `rpcinfo` lists all the RPC services registered with `rpcbind`, version 2. Note that the format of the information is different in the first and the second synopsis. This is because the second synopsis is an older protocol used to collect the information displayed (version 2 of the `rpcbind` protocol).

The third synopsis makes an RPC call to procedure 0 of *prognum* and *versnum* on the specified *host* and reports whether a response was received. *transport* is the transport which has to be used for contacting the given service. The remote address of the service is obtained by making a call to the remote `rpcbind`.

The *prognum* argument is a number that represents an RPC program number (see [rpc\(4\)](#)).

If a *versnum* is specified, `rpcinfo` attempts to call that version of the specified *prognum*. Otherwise, `rpcinfo` attempts to find all the registered version numbers for the specified *prognum* by calling version 0, which is presumed not to exist; if it does exist, `rpcinfo` attempts to obtain this information by calling an extremely high version number instead, and attempts to call each registered version. Note that the version number is required for `-b` and `-d` options.

The EXAMPLES section describe other ways of using `rpcinfo`.

Options `-T transport` Specify the transport on which the service is required. If this option is not specified, `rpcinfo` uses the transport specified in the `NETPATH` environment variable, or if that is unset or `NULL`, the transport in the [netconfig\(4\)](#) database is used. This is a generic option, and can be used in conjunction with other options as shown in the SYNOPSIS.

-
- a** *serv_address* Use *serv_address* as the (universal) address for the service on *transport* to ping procedure 0 of the specified *prognum* and report whether a response was received. The **-T** option is required with the **-a** option. If *versnum* is not specified, `rpcinfo` tries to ping all available version numbers for that program number. This option avoids calls to remote `rpcbind` to find the address of the service. The *serv_address* is specified in universal address format of the given transport.
- b** Make an RPC broadcast to procedure 0 of the specified *prognum* and *versnum* and report all hosts that respond. If *transport* is specified, it broadcasts its request only on the specified transport. If broadcasting is not supported by any transport, an error message is printed. Use of broadcasting should be limited because of the potential for adverse effect on other systems.
