discovery-address *discovery-address* [...]
  Adds a target to a list of discovery addresses. A discovery address (as in the syntax shown below) is an IP *address:port* combination used in a SendTargets discovery session. Using this discovery approach, a target device can inform an initiator of the target address and target name of each target exposed by that device. Connection to a target is not attempted unless the SendTargets method of discovery has been enabled on the host. You enable this method with the modify subcommand.

  The *discovery-address* parameter is formatted as:

  <*IP address*>[:*port*]

  If *port* is not specified, the default of 3260 will be used.

isns-server *isns-server* [...]

    Add an iSNS server to the list of iSNS server addresses. An iSNS server address (specified in the syntax shown below) is an IP address-port combination used in an iSNS discovery session. By using iSNS discovery, an iSNS server can provide an initiator with information about a portal and the name of each target that belongs to the same discovery domain as that of the initiator. Connection to the iSNS server is not attempted unless the iSNS method of discovery has been enabled on the host. You enable this method with the modify subcommand, described below.

    The *isns-server* parameter is formatted as:

    IP_address[:*port*]

    If a port is not specified, the default of 3205 is used.

static-config *static_target* [...]

    Adds a target to the list of statically configured targets. A connection to the target will not be attempted unless the static configuration method of discovery has been enabled.

    The *static_target* parameter is formatted as:

    <target-name>,*<target address>*[:*port-number*][,*tpgt*]

    <target-name> can be up to 223 characters.

list Subcommand   The syntax for the list subcommand is:

    # iscsiadm list *direct-object* [*options*]

The list subcommand displays data for the following *direct-object*s:

discovery

    Lists the discovery methods and their current activation state, enabled or disabled. Discovery methods are:

    ■ iSNS (Internet Storage Name Service)
    ■ Static
    ■ SendTargets

initiator-node

    Lists information for the initiator node on the host. The iSCSI initiator node represents a logical HBA and is a logical host connection point for iSCSI targets. The parameter values listed in the response are default parameter settings for the initiator. Each connected target for an initiator can have parameter values that differ from the parameter values on the initiator node.

static-config [*static_target*[, ...]]

    Lists the target name and address for specified targets or, if no static targets are specified, all statically discovered targets.

target [-S] [-v] [*target*[, ...]]

Lists a target's current parameters, connection state, and which method was used for the target's discovery. Reports information for specified targets or, if no targets are specified, all targets that have been discovered or have had parameters modified by the modify target subcommand.

When used with the -S option for a specified target, this subcommand returns:

- target name
- logical unit number
- vendor ID
- product ID
- OS device name (for example, /dev/rdsk/c0t2d0s0)

The -v options gives more details, such as the current login parameters, the detailed connection information, and the discovery method used to discover the target.

A return of NA as the discovery method parameter indicates that the target was created with a iscsiadm modify target-param command and does not exist as a discovered object. To remove such targets, use iscsiadm remove target-param.

target-param [-v] *target* [...]

Lists a target's default and user-defined parameters.

discovery-address [-v] [*discovery-address*[, ...]]

Lists the discovery-address objects that have been added using the iscsiadm add discovery-address subcommand.

When used with the -v option, lists all known targets at a specified *discovery-address*. The -v option returns one or more target names along with zero or more target addresses and associated target portal group tags (TPGT), if applicable.

isns-server [-v] [*isns-server*[, ...]]

Lists the isns-server objects that have been added using the iscsiadm add isns-server subcommand.

When used with the -v option, this subcommand lists all known targets at a specified isns-server address. The -v option returns one of more target names along with zero or more target addresses and associated target portal group tags, if applicable.

modify Subcommand The syntax for the modify subcommand is:

iscsiadm modify *direct_object* [*options*]

The modify subcommand supports the following *direct_object*s:

discovery [*options*]

Enabling a discovery method initiates a discovery using that method. Disabling a discovery method that is currently enabled does not affect connections to any targets that have already been discovered by that method.

Options for modify discovery are as follows:

-i, -iSNS enable | disable
  Enable or disable iSNS discovery.

-s, --static enable | disable
  Enable or disable static discovery.

-t, --sendtargets enable | disable
  Enable or disable SendTargets discovery.

initiator-node [*options*]
  Modifies an initiator's properties. If a target is currently connected, this operation can
  succeed. However, the modified set of parameters will not be in effect for that target until
  an existing connection session no longer exists and a new connection has been established.
  The options -C and --CHAP-secret require a CHAP secret entry in response to a prompt.

  For iSCSI booting when the Solaris I/O multipathing feature (formerly known as Sun
  StorEdge Traffic Manager [STMS] or MPxIO) is disabled, you can modify only the
  following initiator-node options:

  ■ -r, --radius-server
  ■ -R, --radius-access
  ■ -P, --radius-shared-secret

  For iSCSI booting when the Solaris I/O multipathing feature is enabled, you can modify
  only the following initiator-node options:

  ■ -h, --headerdigest
  ■ -d, --datadigest
  ■ -c, --configured-sessions

  Options for modify initiator-node are as follows:

  -A, --node-alias <*initiator node alias*>
    Modifies the initiator node alias. Maximum length of 223 characters.

  -a, --authentication chap | none
    Sets the authentication mode.

  -C, --CHAP-secret
    Sets the CHAP secret value. There is no default value. Maximum length is 16 characters;
    minimum required length is 12 characters.

  -c, --configured-sessions <*num_sessions*> | <*IP address*>[,<*IP address*>...]
    Sets the number of configured iSCSI sessions that will be created for each iSCSI target.
    The feature should be used in combination with the Solaris I/O multipathing feature
    described in scsi_vhci(7D).

  -d, --datadigest none | CRC32
    Sets whether CRC32 is enabled to check SCSI data transfers.

-H, --CHAP-name *CHAP name*
Specifies a CHAP username. If you do not use this option, upon initialization, the CHAP name is set to the initiator node name. When the authentication method is set to CHAP (see -a/--authentication option, above), the CHAP username is displayed with the command `iscsiadm list initiator-node`.

-h, --headerdigest none | CRC32
Sets whether CRC32 is enabled to check SCSI packet headers.

-m, --max-connections *number_connections*
Modifies the maximum connection number for iSCSI sessions. The default value is 1. The maximum number of connections for each session is 65535.

-N, --node-name <*initiator node name*>
Modifies the initiator node name. Maximum of 223 characters.

Note – During Solaris installation, the initiator node name is set to a globally unique value. Changing this value can adversely affect operation within the iSCSI network.

-P, --radius-shared-secret (exclusive)
Sets the RADIUS shared secret.

-R, --radius-access enable | disable
Sets whether a RADIUS server will be used.

-r, --radius-server <*IP address*>[:<*port*>]
Sets the IP address and port of the radius server to be used.

-T, --tunable-param <<*tunable-prop*>=<*value*>, ...>
Specify one or more tunable parameters for all targets that initiator node connected.

Note – These values should only be modified by an administrator with a good working knowledge of the parameter's impact within the iSCSI network.

Supported tunable-prop options are:

recv-login-rsp-timeout
Session Login Response Time

The recv-login-rsp-timeout option specifies how long iSCSI initiator will wait for the response of iSCSI session login request from the iSCSI target. Valid value is from 0 to 60*60, default to 60 seconds.

conn-login-max
Maximized Connection Retry Time

The conn-login-max option lets the iSCSI initiator reestablish the connection to the target in case of IO timeout or connection failure during the given time window. Valid value is from 0 to 60*60, default to 180 seconds.

polling-login-delay
  Login Retry Time Interval

  The polling-login-delay option specifies the time interval between each login
  retry when iSCSI initiator to target IO timeout or connection failure. Valid value is
  from 0 to 60*60, default to 60 seconds.

target-param [*options*] *target*
  Modifies a target's parameters. If a target is currently connected, the modify operation will
  succeed, although the modified settings might not take effect for a few seconds. To confirm
  that these settings are active, use iscsiadm list target -v. If a specified target is not
  associated with any discovery method, a target object is created with the specified
  parameters. After using this command to modify a target's parameters, the new parameters
  will persist until they are modified or removed with a iscsiadm remove target-param
  command on that target. The options -C and --CHAP-secret require a CHAP secret entry
  in response to a prompt.

  Options for modify target-param are as follows:

  -B, --bi-directional-authentication enable | disable
    Sets the bidirectional option. If set to enable, the initiator performs bidirectional
    authentication for the specified target.

  -C, --CHAP-secret
    Sets the target's CHAP secret value. There is no default value. Maximum acceptable
    length is 16 characters.

  -c, --configured-sessions <*num_sessions*> | <*IP address*>[,<*IP address*>...]
    Sets the number of configured iSCSI sessions that will be created for each iSCSI target.
    The feature should be used in combination with the Solaris I/O multipathing feature
    described in scsi_vhci(7D).

  -d, --datadigest none | CRC32
    Sets whether CRC32 is enabled or disabled for the data.

  -H, --CHAP-name *CHAP name*
    Sets a CHAP username. If you do not use this option, upon initialization, the CHAP
    name is set to the target name. When the authentication method is set to CHAP (see
    -a/--authentication option, under the initiator-node direct object, above), the
    CHAP username is displayed with the command iscsiadm list initiator-node.

  -h, --headerdigest none | CRC32
    Sets whether CRC32 is enabled or disabled for the header.

  -p, --login-param
    Specify one or more login parameter settings.

    Note – These values should only be modified by an administrator with a good working
    knowledge of the parameter's impact within the iSCSI network.

The login parameters are derived from iSCSI proposed standard RFC 3720. Valid values are:

dataseqinorder	yes or no
defaulttime2retain	0–3600
defaulttime2wait	0–3600
firstburstlength	512 to 2^{24-1}
immediatedata	yes or no
initialr2t	yes or no
maxburstlength	512 to 2^{24-1}
datapduinorder	yes or no
maxoutstandingr2t	1 to 65535
maxrecvdataseglen	512 to 2^{24-1}

-T, --tunable-param <<*tunable-prop*>=<*value*>, ...>
Specify one or more tunable parameters for all targets that initiator node connected.

Note – Tunable values should only be modified by an administrator with a good working knowledge of the parameter's impact within the iSCSI network.

Supported *tunable-prop* options are:

recv-login-rsp-timeout
Session Login Response Time

The recv-login-rsp-timeout option specifies how long iSCSI initiator will wait for the response of iSCSI session login request from the iSCSI target. Valid value is from 0 to 60*60, default to 60 seconds.

conn-login-max
Maximized Connection Retry Time

The conn-login-max option lets the iSCSI initiator reestablish the connection to the target in case of IO timeout or connection failure during the given time window. Valid value is from 0 to 60*60, default to 180 seconds.

polling-login-delay
Login Retry Time Interval

The polling-login-delay option specifies the time interval between each login retry when iSCSI initiator to target IO timeout or connection failure. Valid value is from 0 to 60*60, default to 60 seconds.

remove Subcommand   The syntax for the remove subcommand is:

> # iscsiadm remove *direct_object*

The remove subcommand supports the following *direct_object*s:

discovery-address *discovery-address*, ...
> Removes a target device from the list of discovery addresses. A discovery address (as in the syntax shown below) is an IP address-port combination used in a SendTargets discovery session. Using this discovery approach, a target device can inform an initiator of the target address and target name of each target exposed by that device. If any target exposed by the discovery address is currently mounted or there is active I/O on the device, an error of "logical unit in use" is returned and the operation fails. If the associated devices are not in use, they are removed.
>
> *discovery-address* must be formatted as:
>
> *<IP address>*[:*<port>*]
>
> There are no options associated with this direct object.

isns-server *isns-server*, ...
> Removes an iSNS server from the list of iSNS server addresses. An iSNS server address (specified in the syntax shown below) is an IP address-port combination used in an iSNS discovery session. By using iSNS discovery, an iSNS server can provide an initiator with information about a portal and the name of each target that belongs to the same discovery domain as that of the initiator. If any target discovered by means of iSNS is currently mounted or there is active I/O on the device, an error of "logical unit in use" is returned and the operation fails. If the associated devices are not in use, they are removed.
>
> *isns-server* must be formatted as:
>
> *IP_address*[:*port*]
>
> There are no options associated with this direct object.

static-config *static_target*, ...
> Removes a target from the list of statically discovered targets. If the target being removed is currently mounted or there is active I/O on the device, an error of "logical unit in use" is returned and the operation fails. If a device is not in use, it will be removed.
>
> *static_target* must be formatted as:
>
> *<target-name>*,*<target-address>*[:*port-number*][,*tpgt*]
>
> There are no options associated with this direct object.

target-param *target-name*
> Removes target specified by *target-name*. The target name is formatted as:
>
> *<target-name>*

There are no options associated with this direct object. For iSCSI booting when the Solaris I/O multipathing feature (formerly known as Sun StorEdge Traffic Manager [STMS] or MPxIO) is enabled, you cannot remove the target.

Proper Use of Discovery Methods

Do not configure a target to be discovered by both static and dynamic discovery methods. The consequence of using redundant discovery methods might be slow performance when communicating with the iSCSI target device.

Options The following generic options are supported:

-V, --version   Displays version information. Stops interpretation of subsequent arguments.

-?, --help   Displays help information. Can be used following an iscsiadm command with no arguments, following a subcommand, or following a subcommand-direct object combination. Responds with help information appropriate for your entry. For example, if you enter:

iscsiadm modify initiator-node --help

...iscsiadm responds with a display of the options available for that combination of subcommand and direct object.

Examples EXAMPLE 1   Adding a Discovery Address

The following command uses the add subcommand to add a discovery address.

iscsiadm add discovery-address 10.0.0.1:3260 10.0.0.2:3260

EXAMPLE 2   Adding a Static Target

The following command uses the add subcommand to add a static target.

**iscsiadm add static-config \
iqn.1999-08.com.array:sn.01234567,10.0.0.1:3260**

EXAMPLE 3   Listing Current Discovery Settings

The following command uses the list subcommand to list current discovery settings.

iscsiadm list discovery
```
        Discovery:
                Static: enabled
                Send Targets: disabled
                iSNS: enabled
```

EXAMPLE 4   Obtaining Verbose Discovery Output

The following commands uses the -v option (one with, one without) with the list subcommand to obtain verbose output.

EXAMPLE 4   Obtaining Verbose Discovery Output   *(Continued)*

```
# iscsiadm list discovery-address
        Discovery Address: 10.0.0.1:3260
        Discovery Address: 10.0.0.2:3260

# iscsiadm list discovery-address -v 10.0.0.1:3260
        Discovery Address: 10.0.0.1:3260
                Target name: eui.210000203787d1f7
                        Target address:    10.0.0.1:3260
                Target name: eui.210000203787a693
                        Target address:    10.0.0.1:3260
```

EXAMPLE 5   Displaying Information on the Initiator

The following command uses the list subcommand to display information on the initiator.

```
# iscsiadm list initiator-node
Initiator node name: iqn.1986-03.com.company.central.interopv20-1
Initiator node alias: interopv20-1
        Login Parameters (Default/Configured):
                Header Digest: NONE/NONE
                Data Digest: NONE/NONE
        Authentication Type: CHAP
                CHAP Name: iqn.1986-03.com.company.central.interopv20-1
        RADIUS Server: NONE
        RADIUS access: disabled
        Tunable Parameters (Default/Configured):
                Session Login Response Time: 60/-
                Maximum Connection Retry Time: 180/-
                Login Retry Time Interval: 60/-
        Configured Sessions: 1
```

EXAMPLE 6   Displaying Static Configuration Information

The following command uses the list subcommand to display information about static configurations.

```
# iscsiadm list static-config
        Static target: eui.210000203787a693,10.0.0.1:3260
```

EXAMPLE 7   Displaying Target Information

The following commands show the use of the list subcommand with various options to display information about targets.

```
# iscsiadm list target
Target: iqn.2004-05.com.abcStorage:Tgt-1
        Alias: -
```

EXAMPLE 7 Displaying Target Information   *(Continued)*

```
        TPGT: 12288
        ISID: 4000002a0000
        Connections: 1# iscsiadm list target -v iqn.2004-05.com.abcStorage:Tgt-1
Target: iqn.2004-05.com.abcStorage:Tgt-1
        Alias: -
        TPGT: 12288
        ISID: 4000002a0000
        Connections: 1
                CID: 0
                  IP address (Local): 10.4.52.158:32803
                  IP address (Peer): 10.4.49.70:3260
                  Discovery Method: SendTargets
                  Login Parameters (Negotiated):
                        Data Sequence In Order: yes
                        Data PDU In Order: yes
                        Default Time To Retain: 20
                        Default Time To Wait: 2
                        Error Recovery Level: 0
                        First Burst Length: 65536
                        Immediate Data: yes
                        Initial Ready To Transfer (R2T): yes
                        Max Burst Length: 262144
                        Max Outstanding R2T: 1
                        Max Receive Data Segment Length: 65536
                        Max Connections: 1
                        Header Digest: NONE
                        Data Digest: NONE
# iscsiadm list target -S iqn.2004-05.com.abcStorage:Tgt-1
Target: iqn.2004-05.com.abcStorage:Tgt-1
        Alias: -
        TPGT: 12288
        ISID: 4000002a0000
        Connections: 1
        LUN: 6
            Vendor:  ABCStorage
            Product: iSCSI Target
            OS Device Name: /dev/rdsk/c3t1d0s2
        LUN: 5
            Vendor:  ABCStorage
            Product: iSCSI Target
            OS Device Name: /dev/rdsk/c3t0d0s2
```

EXAMPLE 8 Displaying Target Parameter Information

The following command uses the list subcommand to display target information for a specific target.

EXAMPLE 8   Displaying Target Parameter Information   *(Continued)*

```
# iscsiadm list target-param -v iqn.2004-05.com.abcStorage:Tgt-1
Target: iqn.2004-05.com.abcStorage:Tgt-1
        Alias: -
        Bi-directional Authentication: disabled
        Authentication Type: NONE
        Login Parameters (Default/Configured):
                Data Sequence In Order: yes/-
                Data PDU In Order: yes/-
                Default Time To Retain: 20/-
                Default Time To Wait: 2/-
                Error Recovery Level: 0/-
                First Burst Length: 65536/-
                Immediate Data: yes/-
                Initial Ready To Transfer (R2T): yes/-
                Max Burst Length: 262144/-
                Max Outstanding R2T: 1/-
                Max Receive Data Segment Length: 65536/-
                Max Connections: 1/-
                Header Digest: NONE/-
                Data Digest: NONE/-
        Tunable Parameters (Default/Configured):
                Session Login Response Time: 60/-
                Maximum Connection Retry Time: 180/-
                Login Retry Time Interval: 60/-
        Configured Sessions: 1
```

EXAMPLE 9   Enabling Static Discovery Method

The following command uses the modify subcommand to enable the static discovery method.

```
# iscsiadm modify discovery --static enable
```

EXAMPLE 10   Setting the IP Address for the Radius Server

The following command uses the modify subcommand to set the IP address for the radius server, which will be used for CHAP authentication.

```
# iscsiadm modify initiator --radius-server 10.0.0.1
```

EXAMPLE 11   Setting the Node Name for Initiator

The following command uses the modify subcommand to set the node name for the initiator node.

```
# iscsiadm modify initiator-node -N iqn.2004-10.com.SUN.host-1
```

EXAMPLE 12 Setting Max Connections for the Initiator Node

The following command uses the `modify` subcommand to set the max connection number for the initiator node. This enables multiple connections to exist in one session.

```
# iscsiadm modify initiator-node -m 3
```

EXAMPLE 13 Changing Target Parameters

The following command uses the `modify` subcommand to change the max connection number of the target parameters for a specified target.

```
# iscsiadm modify target-param -m 3 eui.210000203787a693
```

EXAMPLE 14 Removing a Discovery Address

The following command uses the `remove` subcommand to remove a discovery address.

```
# iscsiadm remove discovery-address 10.0.0.1:3260
```

EXAMPLE 15 Removing Target Parameters

The following command uses the `remove` subcommand to remove a set of target parameters.

```
# iscsiadm remove target-param eui.210000203787a693
```

EXAMPLE 16 Modifying Maximum Connection Number

The following command modifies the maximum number of connections for each session in the initiator's property. The modified value will be used in all sessions, to all targets.

```
# iscsiadm modify initiator-node --max-connections 4
```

Oracle Solaris Administration: Devices and File Systems

Name isns – Internet Storage Name Service

Synopsis /usr/sbin/isns

Description The Internet Storage Name Service (iSNS) provides consolidated discovery services for Internet SCSI (iSCSI) and Internet Fibre Channel Protocol (iFCP) devices in an IP network. iSNS uses a client/server mechanism: servers store configuration information for clients, and provide that information upon a client's request. IETF RFC 4171 describes the protocols between the server and client.

This man page provides a summary of the Solaris iSNS server implementation. The current implementation does not support iFCP devices.

Solaris iSNS server is implemented as the daemon isns, which binds to the well –known port 3205 to service client requests. The daemon is started by the service management facility (smf(5)), using the fault management resource identifier (FMRI):

svc:/network/isns_server

Use svcadm(1M) to enable isns. Enabling the service means that it starts and runs automatically whenever the operating system is booted. The state of service can be displayed with the svcs(1) command.

The service properties listed below can be managed using svccfg(1M). The default value is assigned per RFC 4171 and implementation choice.

data_store_location
    Configuration data store location. The default location is /etc/isns/isnsdata.xml.

ESI_retry_threshold_count
    Entity Status Inquiry retry threshold counter. The default count is 3.

Management_SCNs_Enabled
    Boolean that determines whether Management State Change Notification is enabled. The default is yes.

Authorized_Control_Nodes
    Control node names.

After changing a property value, you must use svcadm(1M) refresh to enable isns to recognize the new value. If you change the data_store_location property, you must enter a svcadm restart command for the change to take effect.

RFC 4171 defines the default discovery domain, the default domain set, and the "Default DD/DDS" setting with the intent of managing clients that have not been assigned to any user-defined discovery domain. The server adopts the following behaviors with respect to the default discovery domain and domain set:

- An unassigned client is added to the default discovery domain. A newly registered client or a client that was removed from its last discovery domain membership is considered to be an unassigned client.

- When a client gets assigned to a user-defined discovery domain, the server will remove the client from the default discovery domain.

- The default discovery domain set is allowed to be administratively activated or deactivated in order to let the administrator control discovery among clients in the default discovery domain.

- It is not allowed to administratively add a client to the default discovery domain, nor to administratively add a user-defined discovery domain to the default discovery domain set.

- The default state of the Default discovery domain set is inactive.

The isns server supports certain rbac(5) authorizations that allow you to administer isns activity. These authorizations include the following auth_attr(4) privileges:

solaris.isnsmgr.write
  Required to create a discovery domain or domain set, to enable/disable a discovery domain set and to change grouping of iSNS clients in a discovery domain or grouping of discovery domains in a discovery domain set.

solaris.smf.manage.isns
  Required to manage the isns server through the smf(5).

solaris.smf.value.isns
  Required to change the SMF service properties associated with isns.

The iSNS Server Management profile (see prof_attr(4)) includes all of the preceding authorizations. See rbac(5) for an overview of roles and authorizations.

Options There are no options supported by the isns daemon.

Examples EXAMPLE 1 Starting an isns Server

The following command starts the isns server.

```
# svcadm enable svc:/network/isns_server
```

EXAMPLE 2 Stopping an isns Server

The following command stops the isns server.

```
# svcadm disable svc:/network/isns_server
```

EXAMPLE 3 Changing an isns Property

The following sequence of commands changes the value of the ESI_retry_threshold_count property.

```
# svccfg -s svc:/network/isns_server setprop \
config/ESI_retry_threshold_count = 6
# svcadm refresh svc:/network/isns_server
```

Files /usr/sbin/isns
        iSNS daemon binary.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/storage/isns
Interface Stability	Committed
Standard	See standards(5).

See Also svcs(1), isnsadm(1M), svcadm(1M), svccfg(1M), auth_attr(4), prof_attr(4),
attributes(5), rbac(5), smf(5)

Notes It is strongly recommended that you restart the server (svcadm restart) after a service
property is changed. This allows the server to apply a uniform setting for existing and new
clients.

A control node, as described in RFC 4171, is not required to administer the server. Control
node operations can be achieved through the isnsadm(1M) command interface on the local
host. For example, isnsadm enables you to create a discovery domain and a discovery domain
set and to add a member to it, in order to create discovery domain and discovery domain set
associations.

Name isnsadm – administer the internet Storage Name Server (iSNS) server

Synopsis isnsadm *options*

isnsadm *subcommand* [*subcommand_options*] [*operand*]

Description The isnsadm command is the command-line interface to the Internet Storage Name Service (iSNS) server. isnsadm comprises a set of subcommands, described in their own section, each of which accomplishes one of the iSNS server management functions.

For any operations that will change the iSNS configurations the solaris.isnsmgr.write authorization is required. Refer to isns(1M). For read operations, the command does not require special authorizations.

isnsadm has a set of general options and a set of subcommand-specific options. The first category is described under OPTIONS; the second category is described in the context of each subcommand description.

Options The following options are supported:

-?, --help
  Displays context help. Stops interpretation of any subsequent arguments.

-V, --version
  Displays version information. Stops interpretation of any subsequent arguments.

Operands The following operands are used by one or more isnsadm subcommands.

iscsi-node-name
  iSCSI target or iSCSI initiator symbolic name. A string with a maximum length of 223 characters.

discovery-domain-name
  Discovery domain symbolic name. A string with a maximum length of 256 characters.

discovery-domain-set-name
  Discovery domain set symbolic name. A string with a maximum length of 256 characters.

Subcommands The isnsadm command supports the subcommands described below.

add-dd The add-dd subcommand adds a discovery domain to a discovery domain set.

The add-dd subcommand has the following syntax:

isnsadm add-dd *option discovery-domain-name, ...*

add-dd has the following option:

-s *discovery-domain-set-name*
  Specifies a discovery domain set.

add-node   The add-node subcommand adds a node to a specified discovery-domain.

The add-node subcommand has the following syntax:

isnsadm add-node *option iscsi-node-name,...*

add-node has the following options:

-d,--dd *discovery-domain-name*
  Specifies a discovery domain.

create-dd   The create-dd subcommand creates a discovery domain with the name you specify.

The create-dd subcommand has the following syntax:

isnsadm create-dd *discovery-domain-name, ...*

create-dd has no options.

create-dd-set   The create-dd-set subcommand creates a discovery domain set with the name you specify.

The create-dd-set subcommand has the following syntax:

isnsadm create-dd-set *discovery-domain-set-name, ...*

create-dd-set has no options.

delete-dd   The delete-dd subcommand deletes a discovery domain of the name you specify.

The delete-dd subcommand has the following syntax:

isnsadm delete-dd *discovery-domain-name, ...*

delete-dd has no options.

delete-dd-set   The delete-dd-set subcommand deletes a discovery domain set of the name you specify.

The delete-dd-set subcommand has the following syntax:

isnsadm delete-dd-set *discovery-domain-set-name, ...*

delete-dd-set has no options.

disable-dd-set   The disable-dd-set subcommand disables a discovery domain set.

The disable-dd-set subcommand has the following syntax:

isnsadm disable-dd-set *discovery-domain-set-name, ...*

disable-dd-set has no options.

enable-dd-set The enable-dd-set subcommand enables a discovery domain set.

The enable-dd-set subcommand has the following syntax:

isnsadm enable-dd-set *discovery-domain-set-name*, ...

enable-dd-set has no options.

list-dd The list-dd subcommand displays information about discovery domains. If no operand is
specified, it lists all discovery domains that currently exist on the iSNS server.

The list-dd subcommand has the following syntax:

isnsadm list-dd [*option***] [***discovery-domain-name***, ...]**

list-dd supports the following option:

-v, --verbose
   Displays the member contents of the discovery domain(s).

list-dd-set The list-dd-set subcommand lists the discovery domain sets, both enabled and disabled,
that exist on the iSNS server. Note that there is no dd-set registration. If no operand is
specified, it lists all of the discovery domain sets.

The list-dd-set subcommand has the following syntax:

isnsadm list-dd-set [*option***] [***discovery-domain-set-name***, ...]**

list-dd-set supports the following option:

-v, --verbose
   Shows all discovery domains within the discovery domain set.

list-node The list-node subcommand displays information about nodes that are currently registered
with the iSNS server or that are not registered and belong to non-default discovery-domain(s).
For the latter case, the node has its type field shown as unknown. If no operand is specified,
list-node lists all nodes known by the iSNS server.

The list-node subcommand has the following syntax:

isnsadm list-node [*options***] [***iscsi-node-name***, ...]**

list-node supports the following options:

-t, --target
   Filters the list to display only iSCSI target nodes.

-i, --initiator
   Filters the list to display only iSCSI initiator nodes.

-v, --verbose
   Displays details about a node. Without this option, only the name, alias, and type
   information are displayed.

modify-dd   The modify-dd subcommand modifies an attribute of a specified discovery domain.

The modify-dd subcommand has the following syntax:

isnsadm modify-dd *option discovery-domain-name*

modify-dd has the following option:

-n *discovery-domain-name*
    Specifies the new name of a discovery domain to be applied to an existing
    discovery-domain.

modify-dd-set   The modify-dd-set subcommand modifies a discovery domain set.

The modify-dd-set subcommand has the following syntax:

isnsadm modify-dd-set *option discovery-domain-set-name*

modify-dd-set has the following option:

-n *discovery-domain-set-name*
    Specifies the new name of a discovery domain set to be applied to an existing
    discovery-domain-set.

remove-dd   The remove-dd subcommand removes the association with a specified discovery domain set.

The remove-dd subcommand has the following syntax:

isnsadm remove-dd *option discovery-domain-name,* **...**

remove-dd has the following option:

-s *discovery-domain-set-name*
    Specifies the discovery domain set from which the discovery domain will be removed.

remove-node   The remove-node subcommand removes a node.

The remove-node subcommand has the following syntax:

isnsadm remove-node *option iscsi-node-name,* **...**

remove-node has the following option:

-d *discovery-domain-name*
    Specifies the discovery domain from which a node will be removed.

show-config   The show-config subcommand displays the iSNS server administrative settings. Note that the
setting can be modified by means of the service management facility (see smf(5)). Refer to
isns(1M).

The show-config subcommand has the following syntax:

isnsadm show-config

show-config has no options.

Examples **EXAMPLE 1**   Displaying Clients

The following use of the list-node subcommand displays clients.

```
# isnsadm list-node -v
iSCSI Name: iqn.1986-03.com.sun:01:000e0c9f10da.45173FEA.engr
        Alias: STK5320_NAS
        Type: Target
        Network Entity: SE5310
        Portal: 172.20.57.95:3260
                Portal Group: 1
        Portal: 172.20.56.95:3260
                Portal Group: 1
        DD Name: Default
iSCSI Name: iqn.1986-03.com.sun:01:000e0c9f10da.454F00A2.acct
        Alias:
        Type: Target
        Network Entity: SE5310
        Portal: 172.20.57.95:3260
                Portal Group: 1
        Portal: 172.20.56.95:3260
                Portal Group: 1
        DD Name: Default
iSCSI Name: iqn.1986-03.com.sun:01:e00000000000.46fd8e2b
        Alias: host-x2100
        Type: Initiator
        Network Entity: iqn.1986-03.com.sun:01:e00000000000.46fd8e2b
        Portal: 172.20.236.123:58530
                Portal Group: 1
        DD Name: Default
```

EXAMPLE 2   Displaying a Discovery Domain

The following use of the list-dd subcommand displays discovery domains.

```
# isnsadm list-dd -v
DD name: Default
        DD set(s): Default
    iSCSI Name: iqn.1986-03.com.sun:01:000e0c9f10da.45173FEA.engr
    iSCSI Name: iqn.1986-03.com.sun:01:000e0c9f10da.454F00A2.acct
        iSCSI name: iqn.1986-03.com.sun:01:e00000000000.46fd8e2b
DD name: acct-dd
DD name: engineering-dd
```

EXAMPLE 3   Adding a Node

The following use of the add-node subcommand adds a node to a discovery domain, creating
a discovery domain membership.

EXAMPLE 3   Adding a Node   *(Continued)*

```
# isnsadm add-node -d engineering-dd \
iqn.1986-03.com.sun:01:000e0c9f10da.454F00A2.engr
```

EXAMPLE 4   Removing a Node

The following use of the remove-node subcommand removes a node from a discovery domain, thereby removing a discovery domain membership.

```
# isnsadm remove-node -d acct-dd \
iqn.1986-03.com.sun:01:000e0c9f10da.454F00A2.acct
```

EXAMPLE 5   Creating a Discovery Domain Set

The following use of the create-dd-set subcommand creates a discovery domain set.

```
# isnsadm create-dd-set operation-dd-set
```

EXAMPLE 6   Displaying a Discovery Domain Set

The following use of the list-dd-set subcommand displays discovery domain sets.

```
# isnsadm list-dd-set -v
DD Set name: Default
        State: Disabled
        DD Name: Default
DD Set name: operation-dd-set
        State: Disabled
```

EXAMPLE 7   Adding a Discovery Domain

The following use of the add-dd subcommand adds a discovery domain to a discovery domain set.

```
# isnsadm add-dd -s operation-dd-set engineering-dd
```

EXAMPLE 8   Displaying a Discovery Domain Set

The following use of the list-dd-set displays the attributes of a discovery domain set.

```
# isnsadm list-dd-set
DD Set name: Default
        State: Disabled
        DD Name: Default
DD Set name: operation-dd-set
        State: Disabled
        DD Name: engineering-dd
```

EXAMPLE 9 Enabling a Discovery Domain Set

The following use of the enable-dd-set subcommand enables a discovery domain set.

```
# isnsadm enable-dd-set Default
```

EXAMPLE 10 Disabling a Discovery Domain Set

The following use of the disable-dd-set subcommand disables a discovery domain set.

```
# isnsadm disable-dd-set Default
```

EXAMPLE 11 Displaying Administrative Settings

The following use of the show-config subcommand displays current administrative settings.

```
# isnsadm show-config
        Data Store Location: /etc/isns/isnsdata.xml
        Entity Status Inquiry Non-Response Threshold: 3
        Management SCN Enabled: yes
        Authorized Control Node Names: -
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/storage/isns
Interface Stability	Volatile

See Also iscsiadm(1M), isns(1M), attributes(5), smf(5)

Notes When a subcommand is invoked with multiple operands and there are failures on one or more, but not all, operands, isnsadm displays a generic message indicating partial failure, with list of failed operands. An error on a specific operand can be found by issuing the same subcommand on the failing operand.

Name itadm – administer iSCSI targets

Synopsis itadm create-target [-a,--auth-method radius | chap | none | default]
        [-s,--chap-secret] [-S,--chap-secret-file *path*]
        [-u,--chap-user *chap-user-name*] [-n,--node-name *target_node_name*]
        [-l,--alias *alias*] [-t,--tpg *tpg-name*[,*tpg-name*]]

itadm modify-target [-a,--auth-method radius | chap | none | default]
        [-s,--chap-secret] [-S,--chap-secret-file *path*]
        [-u,--chap-user *chap-user-name*] [-n,--node-name *new_target_node_name*]
        [-l,--alias *alias*] [-t,--tpg *tpg-name*[,*tpg-name*]] *target_node_name*

itadm delete-target [-f,--force] *target_node_name*

itadm list-target [-v,--verbose] [*target_node_name*]

itadm create-tpg *tpg_name IP-address*[:*port*] [*IP-address*[:*port*]]...

itadm list-tpg [-v,--verbose] [*tpg_name*]

itadm delete-tpg [-f,--force] *tpg_name*

itadm create-initiator [-s,--chap-secret] [-S,--chap-secret-file *path*]
        [-u,--chap-user *chap-user-name*] *initiator_node_name*

itadm modify-initiator [-s,--chap-secret] [-S,--chap-secret-file *path*]
        [-u,--chap-user *chap-user-name*] *initiator_node_name*

itadm list-initiator [-v,--verbose] *initiator_node_name*

itadm delete-initiator *initiator_node_name*

itadm modify-defaults [-a,--auth-method radius | chap | none]
        [-r,--radius-server *IP-address*[:*port*]] [-d,--radius-secret]
        [-D,--radius-secret-file *path*][-i,--isns enable | disable]
        [-I,--isns-server *IP-address*[:*port*][,*IP-address*[:*port*]]]

itadm list-defaults

Description The itadm command manages Internet SCSI (iSCSI) target nodes within the SCSI Target
        Mode Framework described in stmfadm(1M) and libstmf(3LIB). This allows the iSCSI
        initiators to access STMF logical units using the iSCSI protocol. In addition to iSCSI target
        nodes, itadm manages two other classes of managed objects: iSCSI Target Portal Groups, and
        iSCSI Initiator Node Contexts.

        itadm is implemented as a set of subcommands with options and operands for each
        subcommand. These subcommands are described in their own section, below. In addition to
        its subcommands, itadm has a help command, which displays the utility's usage information.
        The help command is invoked with the -? option.

iSCSI Target Portal Groups An iSCSI Target Network Portal is an IP address and TCP port that can be used by an initiator
        node to connect to an iSCSI target. A collection of these portals is called a Target Portal Group
        (TPG). You can use a TPG to limit access to an iSCSI target. Use the itadm modify -t

command to bind a specific iSCSI target to the TPG. An iSCSI listener is created on each IP address that belongs to the TPG, and listens for connections to the iSCSI target.

A TPG is identified by a unique name provided when the TPG is created. A numerical "Target Portal Group Tag" from the range 2-65535 is automatically generated when the TPG is created. The Target Portal Group Tag 1 is reserved for the "default" target portal group that is used when no explicit Target Portal Groups are set on the target. The portal for the default TPG matches requests from all network interfaces on port 3260.

iSCSI Initiator Node Contexts   Certain operations such as authentication by means of Challenge Handshake Authentication Protocol (CHAP) require parameters associated with a remote iSCSI Initiator Node. These parameters are associated with an iSCSI Initiator Node Context. An iSCSI Initiator Node Context is identified by its Initiator Node Name, formatted in either IQN or EUI format (see RFC 3720). For example:

```
iqn.1986-03.com.sun:01:e00000000000.47d55444
eui.02004567A425678D
```

Specifying IP Addresses   A number of `itadm` subcommands require that you specify one or more IP addresses with optional port numbers. For IPv4, use standard dotted decimal notation. For IPv6, enclose addresses in square brackets. The following are example specifications.

```
IPv4:  10.2.4.1
       10.2.4.1:3260
IPv6:  [1080:0:0:0:8:800:200C:417A]
       [1080:0:0:0:8:800:200C:417A]:3260
```

Sub-commands   The following are the `itadm` subcommands with their options.

itadm create-target

```
itadm create-target [-a,--auth-method radius | chap | none | default]
      [-s,--chap-secret]
      [-S,--chap-secret-file path] [-u,--chap-user chap-user-name]
      [-n,--node-name target_node_name] [-l,--alias alias]
      [-t,--tpg tpg-name[,tpg-name,...]]
```

Create a iSCSI target with the specified options. Options are as follows.

-a,--auth-method radius | chap | none | default
  Specifies the authentication method to use for the target. Valid values are radius, chap, and none. chap indicates that initiators connecting to this target must be authenticated using the Challenge Handshake Authentication Protocol (CHAP). radius indicates initiators should also be authenticated by means of CHAP but the required authentication parameters should be obtained from a central RADIUS server (see the radius-server and radius-secret options). none means that no authentication is required to connect to the target. default means the target will use the global setting of this property. (See the modify-defaults subcommand.)

-s,--chap-secret
  The CHAP secret to send during mutual CHAP authentication. There is no default for this property. Maximum length is 255 characters; minimum required length is 12 characters.

-S,--chap-secret-file *path*
    Path to a temporary file containing the CHAP secret as described in the -s option.

-u,--chap-user *chap-user-name*
    Specifies the CHAP username for a target for use in mutual CHAP authentication. This value is allowed only for targets, cannot be set globally, and is used only when the initiator node is configured to use mutual CHAP authentication. If no value is specified then the target node name is used as the username. See iscsiadm(1M).

-n,--node-name *target_node_name*
    An iSCSI Target Node is identified by its Target Node Name, formatted in either IQN or EUI format (see RFC 3720). This option establishes that name.

-l,--alias *alias*
    An alternate identifier associated with a target node. The identifier does not need to be unique.

-t,--tpg *tpg-name*[,*tpg-name*,...]
    A list of Target Portal Group (TPG) identifiers that specifies the TPGs that an initiator can use to access a specific target or the keyword default. If default is specified, the target will use the default portal, INADDR_ANY:3260.

itadm
modify-target

    itadm modify-target [-a,--auth-method radius | chap | none | default]
            [-s,--chap-secret] [-S,--chap-secret-file *path*]
            [-u,--chap-user *chap-user-name*] [-n,--node-name *new_tgt_node_name*]
            [-l,--alias *alias*] [-t,--tpg *tpg-name*[,*tpg-name*]] *target_node_name*

Modify an iSCSI target according to the specified options. Options are as follows.

-a,--auth-method radius | chap | none | default
    As described under the create-target subcommand, above.

-s,--chap-secret
    As described under the create-target subcommand, above.

-S,--chap-secret-file *path*
    As described under the create-target subcommand, above.

-u,--chap-user *chap-user-name*
    As described under the create-target subcommand, above. To remove an explicitly set CHAP username use -u none.

-n,--node-name *target_node_name*
    Renames the target. See also the description of -n under the create-target subcommand, above.

-l,--alias *alias*
    As described under the create-target subcommand, above. To remove an explicitly set alias use -l none.

-t,--tpg *tpg-name*[,*tpg-name*,...]
>As described under the create-target subcommand, above.

itadm list-target itadm list-target [-v,--verbose] [*target_node_name*]

>List information about the configured targets. If *target_node_name* is specified, list only the information for that target. Option is as follows.

>-v,--verbose
>>Verbose mode.

itadm delete-target itadm delete-target [-f,--force] *target_node_name*

>Delete the target specified by *target_node_name*. The target must be offline before it can be deleted. Option is as follows.

>-f,--force
>>If the target persists in an online state, this option attempts to offline the target before deleting it.

itadm create-tpg itadm create-tpg *tpg_name IP-address*[:*port*]...

>Create an iSCSI target portal group made up of the specified portals and assign it the identifier *tpg_name*. Each portal is an IP address and port pair. IPv4 portals are specified in dotted address notation, for example, 172.31.255.255. IPv6 portal addresses must be enclosed in square brackets.

>This subcommand has no options.

itadm list-tpg itadm list-tpg [-v,--verbose] [*tpg_name*]

>List information about the configured target portal group. If *tpg_name* is specified then list only the information about the target portal group associated with that *tpg_name*. Option is as follows.

>-v,--verbose
>>Verbose mode.

itadm delete-tpg itadm delete-tpg [-f,--force] *tpg_name*

>Delete the target portal group associated with *tpg_name*. Option is as follows.

>-f,--force
>>If the TPG is associated with any targets, the request to delete will be denied unless this option is specified.

itadm create-initiator itadm create-initiator [-s,--chap-secret] [-S,--chap-secret-file *path*]
>   [-u,--chap-user *chap-user-name*] *initiator_node_name*

>Configure parameters associated with the remote initiator named *initiator_node_name*. Options are as follows.

-s,--chap-secret
  As described under the create-target subcommand, above.

-S,--chap-secret-file *path*
  As described under the create-target subcommand, above.

-u,--chap-user *chap-user-name*
  Specifies the CHAP username for an initiator, for use in CHAP authentication. If no value
  is specified then the initiator node name is used as the username.

itadm
modify-initiator
itadm modify-initiator [-s,--chap-secret] [-S,--chap-secret-file *path*]
        [-u,--chap-user *chap-user-name*] *initiator_node_name*

Modify parameters associated with the remote initiator named *initiator_node_name*. Options
are as follows.

-s,--chap-secret
  As described under the create-target subcommand, above.

-S,--chap-secret-file *path*
  As described under the create-target subcommand, above.

-u,--chap-user *chap-user-name*
  Specifies the CHAP username for an initiator, for use in CHAP authentication. If no value
  is specified then the initiator node name is used as the username.

itadm
delete-initiator
itadm delete-initiator *initiator_node_name*

Delete parameters associated with the remote initiator named *initiator_node_name*. This
subcommand has no options.

itadm
list-initiator
itadm list-initiator [-v,--verbose] *initiator_node_name*

List parameters associated with the initiator named *initiator_node_name*. Option is as
follows.

-v,--verbose
  Verbose mode.

itadm
modify-defaults
itadm modify-defaults [-a,--auth-method radius | chap | none]
        [-r,--radius-server *IP-address*[:*port*]] [-d,--radius-secret]
        [-D,--radius-secret-file *path*][-i,--isns enable | disable]
        [-I,--isns-server *IP-address*[:*port*][,*IP-address*[:*port*]]]

Modify default parameters. Options are as follows.

-a,--auth-method radius | chap | none
  Specifies the default authentication method to use for all targets. Valid values are radius,
  chap, and none. chap indicates that initiators connecting to this target must be
  authenticated using Challenge Handshake Authentication Protocol (CHAP). radius
  indicates initiators should also be authenticated by means of CHAP, but the required
  authentication parameters should be obtained from a central RADIUS server. (See

--radius-server and --radius-secret options.) none means that no authentication is required to connect to the target. Individual targets can override this global setting using the -a option of the create-target and modify-target subcommands.

-d,--radius-secret
RADIUS Shared Secret for centralized CHAP authentication.

-D,--radius-secret-file *path*
Path to a temporary file containing the CHAP secret as described in the -d option.

-i,--sns enable | disable
Specifies whether targets should be registered with the set of defined iSCSI Name Service (iSNS) servers.

-I,--isns-server *IP-address*[:*port*][,*IP-address*[:*port*],...]
Defines a list of iSNS servers with which iSCSI target nodes will be registered when the isns option associated with the respective target is set. Up to eight iSNS servers can be specified. To remove all iSNS servers, use -I none.

-r,--radius-server *IP-address*[:*port*]
Specify the IP address of the RADIUS server used for centralized CHAP authentication.

itadm list-defaults   itadm list-defaults

List information about the default properties. This subcommand has no options.

Examples   **EXAMPLE 1**   Creating a Target

The following command creates a target.

```
# itadm create-target
Target iqn.1986-03.com.sun:02:72e1b181-7bce-c0e6-851e-ec0d8cf14b7a
successfully created
```

EXAMPLE 2   Creating a Target with a Specific Name

The following command creates a target with a specific IQN.

```
# itadm create-target -n eui.20387ab8943ef7548
or:
# itadm create-target \
-n iqn.1986-03.com.sun:02:a9a366f8-cc2b-f291-840948c7f29e
```

EXAMPLE 3   Changing a Name

The following command changes an IQN for an existing target.

```
# itadm modify-target -n eui.20387ab8943ef7548 \
iqn.1986-03.com.sun:02:a9a366f8-909b-cc2b-f291-840948c7f29e
```

EXAMPLE 4 Setting up CHAP Authentication

The following command sets up CHAP authentication for a target using the default CHAP username.

```
# itadm modify-initiator -s iqn.1986-03.com.sun:01:e00000000000.47d55444
Enter CHAP secret: *********
Re-enter secret: *********

# itadm modify-target -a chap eui.20387ab8943ef7548
```

EXAMPLE 5 Creating Target Portal Groups

The following command creates two target portal groups, A and B, using port 8000 for the addresses in TPG 2.

```
# itadm create-tpg A 192.168.0.1 192.168.0.2
# itadm create-tpg B 192.168.0.2:8000 192.168.0.2:8000
```

EXAMPLE 6 Configuring a Target to Use TPGs

The following command configures a target to use TPGs A and B.

```
# itadm modify-target -t A,B eui.20387ab8943ef7548
```

EXAMPLE 7 Setting up RADIUS Authentication for Specific Target

The following command sets up RADIUS authentication for a specific target.

```
# itadm modify-defaults -r 192.168.10.1 -d
Enter RADIUS secret: *********
Re-enter secret: *********

# itadm modify-target -a radius eui.20387ab8943ef7548
```

EXAMPLE 8 Setting up RADIUS Authentication for All Targets

The following command sets up RADIUS authentication for all targets.

```
# itadm modify-defaults -d -r 192.168.10.1 -a radius
Enter RADIUS secret: *********
Re-enter secret: *********
```

The preceding command assumes all targets were created with -a default.

EXAMPLE 9 Listing Default Properties

The following command lists default properties.

```
# itadm list-defaults
iSCSI Target Default Properties:

alias:          none
```

EXAMPLE 9 Listing Default Properties   *(Continued)*

```
auth:           none
radiusserver:   none
radiussecret:   unset
isns:           disabled
isnsserver:     2.3.4.5,4.5.6.7
```

EXAMPLE 10 Listing Targets

The following command lists targets.

```
# itadm list-target
TARGET NAME                                                STATE    SESSIONS
iqn.1986-03.com.sun:02:72e1b181-7bce-c0e6-851e-ec0d8cf14b7a  online   0
iqn.1986-03.com.sun:02:2cb0c526-c05a-e279-e396-a367006f4227  online   0
iqn.1986-03.com.sun:02:d14125bb-1c9d-c28d-97b0-f89259b642f3  online   0
iqn.1986-03.com.sun:02:03ff9fc5-794a-e9b4-a081-bb82917c292a  online   0
```

EXAMPLE 11 Listing Targets (Verbose)

The following command lists targets with the verbose option.

```
# itadm list-target -v
TARGET NAME                                                STATE    SESSIONS
iqn.1986-03.com.sun:02:d23e68d8-2d79-c988-98e7-a6361689d33c  online   0
        alias:                -
        auth:                 none (defaults)
        targetchapuser:       -
        targetchapsecret:     unset
        tpg-tags:             default
iqn.1986-03.com.sun:02:94ec46d4-c8e1-6993-ef03-ffc1dcd66606  online   1
        alias:                -
        auth:                 chap
        targetchapuser:       -
        targetchapsecret:     unset
        tpg-tags:             nge1_ipv4 = 3
```

EXAMPLE 12 Listing a Specific Target

The following command lists targets with the verbose option.

```
# itadm list-target -v \
iqn.1986-03.com.sun:02:2cb0c526-c05a-e279-e396-a367006f4227
TARGET NAME                                                STATE    SESSIONS
iqn.1986-03.com.sun:02:2cb0c526-c05a-e279-e396-a367006f4227  online   1
        alias:                -
        auth:                 chap
        targetchapuser:       -
        targetchapsecret:     unset
        tpg-tags:             nge1_ipv4 = 3
```

Name   itu – convert packages to Driver Update format and patch Solaris install media for Install Time Update

Synopsis   itu makedu -r *solaris_release* [-v] [-f] [-d *output_dir*] [-o *iso_file*]
        [-l *iso_label*] *package* [*package*...]

itu updatemedia -R *media_root* [-v] [-f] [-o *iso_file*]
        [-l *iso_label*] *pkg_or_patch* [*pkg_or_patch*...]

itu makeiso -o *iso_file* [-v] [-l *iso_label*] *media_root*

Description   The itu utility converts driver packages to Driver Update (DU) format and patches a Solaris install media with driver packages and patches for Install Time Update (ITU). itu has three subcommands: makedu, updatemedia and makeiso.

Options   The following options are supported:

-d *output_dir*
   Directory where the Driver Update directory is to be created.

-f
   If *output_dir*/DU or *iso_file* already exists, remove it without asking first.

-l *iso_label*
   Label/volume name of the ISO image (if -o option is specified).

-o *iso_file*
   Path of the ISO image file to be created. For subcommands updatemedia and makeiso, it will be a bootable ISO image. This option must be specified for subcommand makeiso.

-R *media_root*
   Top-level directory of on-disk image of Solaris installation media. This option must be specified for subcommand updatemedia.

-r *solaris_release*
   Solaris release number for which the Driver Update is intended. It takes the form of the output of uname -r, for example, 5.10. This option must be specified for subcommand makedu.

-v
   Verbose. Multiple -v options increase verbosity.

Sub-commands   The itu subcommands are described as follows.

makedu   The makedu subcommand takes one or more driver packages as input and converts them to DU format. At the beginning of an interactive Solaris installation session, these driver updates can be applied to the running kernel, which will then also automatically apply them to the newly installed Solaris at the end of the installation process.

The -r option is required to specify the Solaris release number for which the driver updates apply. The *solaris_release* option argument takes the form uname -r output, for example, 5.10 or 5.11.

If the -d option is specified, the resulting DU directory tree is placed in the directory *output_dir*.

If the -o option is specified, a (non-bootable) ISO image of the DU directory tree is written in the file *iso_file*. This ISO image can be burned onto a CD/DVD using cdrw(1) or cdrecord(1) (not a SunOS man page).

At least one of -d and -o option must be specified. If both are specified, then both an ISO image and a directory tree are generated.

updatemedia   The updatemedia subcommand takes a list of driver packages and patches as input and applies them to the miniroot of a Solaris install media. It also places them in a subdirectory called ITUs under the Solaris install media's top-level directory:

media_root/ITUs

When booting a system from the updated media, the patches and packages will be part of the booted Solaris image. They will also be applied to the target system being installed at the end of the installation process.

The -R option must be entered on the command line to specify the Solaris install media. Note that the install media must be on a location that is writable by itu.

If the -o option is specified, a bootable ISO image of the patched install media is also created in the file *iso_file*. The ISO image can then be burned onto a CD or DVD.

makeiso   The makeiso subcommand runs mkisofs(8) to create a bootable Solaris ISO image of the Solaris install media *media_root* and writes it to the file *iso_file*. The ISO image file can then be burned onto a CD or DVD with utilities such as cdrw(1) or cdrecord(1). (Note that mkisofs(8) and cdrecord(1) are not SunOS man pages.)

Caution – The Solaris install media *media-root* must contain the file boot/grub/stage2_eltorito, which will be written to the media boot sectors. This file will be modified with some boot information, thus it has to be writable. If necessary, first save a copy, prior to running this subcommand.

Operands   The following operands are supported:

package [*package*...]
    One or more driver packages.

pkg_or_patch [*pkg_or_patch*...]
    One or more patches or packages.

media_root
    The top-level directory of a Solaris install media.

Examples   EXAMPLE 1   Creating a DU CD/DVD

The following commands create a Driver Update CD/DVD containing the packages
SAMPLEpkg1 and SAMPLEpkg2.

```
# itu makedu -r 5.10 -o my.iso SAMPLEpkg1 SAMPLEpkg2
# cdrw -i my.iso
```

EXAMPLE 2   Patching the Solaris Install Media

The following command patches the Solaris install media in /export/s10u1 with patch
/opt/patches/123456-07 and driver package /opt/pkgs/MYdriver. The command also
creates a bootable ISO image with ISO label "MyS10U1" in the file /tmp/dvd.iso.

```
# /usr/bin/itu updatemedia -R /export/s10u1 -o /tmp/dvd.iso -l MyS10U1 \
        /opt/patches/123456-07 /opt/pkgs/MYdriver
```

EXAMPLE 3   Creating a Bootable ISO Image

The following commands create the bootable ISO image mydvd.iso of the Solaris install image
/export/solaris-10u1 with ISO label "Special-S10".

```
# /usr/bin/itu makeiso -o mydvd.iso -l "Special-S10" \
    /export/solaris-10u1
# cdrw -i mydvd.iso
```

man page)

Name k5srvutil – host key table (keytab) manipulation utility

Synopsis /usr/sbin/k5srvutil *operation* [-ik] [-f *filename*]

Description The k5srvutil command allows a system manager to list or change keys currently in his keytab or to add new keys to the keytab.

The operand *operation* must be one of the following:

list   Lists the keys in a keytab, showing version number and principal name.

change   Changes all the keys in the keytab to new randomly-generated keys, updating the keys in the Kerberos server's database to match those by using the kadmin protocol. If a key's version number does not match the version number stored in the Kerberos server's database, the operation fails. The old keys are retained so that existing tickets continue to work. If the -i flag is specified, k5srvutil prompts for yes or no before changing each key. If the -k option is used, the old and new keys are displayed.

delold   Deletes keys that are not the most recent version from the keytab. This operation should be used at some point after a change operation to remove old keys. If the -i flag is specified, k5srvutil asks the user whether the old keys associated with each principal should be removed.

delete   Deletes particular keys in the keytab, interactively prompting for each key.

In all cases, the default keytab file is /etc/krb5.keytab file unless this is overridden by the -f option.

k5srvutil uses the kadmin(1M) program to edit the keytab in place. However, old keys are retained, so they are available in case of failure.

Options The following options are supported:

-f *filename*   Specify a keytab file other than the default file, /etc/krb5.keytab.

-i   Prompts user before changing keys when using the change or delold operands.

-k   Displays old and new keys when using the change operand.

Attributes See attributes(5) for descriptions of the following attributes:

Name   kadb – a kernel debugger

Synopsis

SPARC   ok boot *device_specifier* kadb [-d] [*boot-flags*]

x86   select (b)oot or (i)nterpreter: b kadb [-d] [*boot-flags*]

Description   kadb, an interactive kernel debugger, has been replaced by kmdb(1). For backwards compatibility, the methods used to load kadb will be interpreted as requests to load kmdb(1). Unlike with the compatibility link from adb(1) to mdb(1), kmdb(1) will always load in its native user interface mode, regardless of the name used to load it.

kmdb(1) is based on mdb(1), and thus shares mdb's user interface style and feature set. The mdb(1) man page describes the features and operation of mdb. The kmdb(1) man page describes the differences between mdb and kmdb. This man page describes the major changes and incompatibilities between kadb and kmdb.

Consult the *Solaris Modular Debugger Guide* for a detailed description of both mdb and kmdb.

Major changes   This section briefly lists the major differences between kadb and kmdb. It is not intended to be exhaustive.

Debugger Loading and Unloading	kmdb(1) may be loaded at boot, as with kadb. It may also be loaded after boot, thus allowing for kernel debugging and execution control without requiring a system reboot. If kmdb(1) is loaded after boot, it may be unloaded.
mdb Feature Set	The features introduced by mdb(1), including access to kernel type data, debugger commands (dcmds), debugger modules (dmods), and enhanced execution control facilities, are available under kmdb(1). Support for changing the representative CPU (:x) is available for both SPARC and x86. Furthermore, full execution-control facilities are available after the representative CPU has been changed.

Significant Incompatibilities   This section lists the significant features that have changed incompatibly between kadb and kmdb(1). It is not intended to be exhaustive. All kmdb(1) commands referenced here are fully described in the kmdb(1) man page. A description as well as examples can be found in the *Solaris Modular Debugger Guide*.

Deferred Breakpoints	The kadb-style "module#symbol:b" syntax is not supported under kmdb(1). Instead, use "::bp module'symbol".
Watchpoints	The ::wp dcmd is the preferred way to set watchpoint with kmdb. Various options are available to control the type of watchpoint set, including -p for physical watchpoints

(SPARC only), and -i for I/O port watchpoints (x86 only). $l is not supported, therefore, the watchpoint size must be specified for each watchpoint created.

Access to I/O Ports (x86 only)   The commands used to access I/O ports under kadb have been replaced with the ::in and ::out dcmds. These two dcmds allow both read and write of all I/O port sizes supported by kadb.

Attributes   See attributes(5) for descriptions of the following attributes:

Solaris Modular Debugger Guide

Name kadmin, kadmin.local – Kerberos database administration program

Synopsis /usr/sbin/kadmin [-r *realm*] [-p *principal*] [-q *query*]
[-s *admin_server* [:*port*]] [[-c *credential_cache*]
| [-k [-t *keytab*] | [-n]] | [-w *password*]] [-x *db_args*]...

/usr/sbin/kadmin.local [-r *realm*] [-p *principal*]
[-q *query*] [-d *dbname*] [-e "*enc:salt...*"] [-m] [-D]

Description kadmin and kadmin.local are interactive command-line interfaces to the Kerberos V5 administration system. They provide for the maintenance of Kerberos principals, policies, and service key tables (keytabs). kadmin and kadmin.local provide identical functionality; the difference is that kadmin.local can run only on the master KDC and does not use Kerberos authentication.

Except as explicitly noted otherwise, this man page uses kadmin to refer to both versions.

By default, both versions of kadmin attempt to determine your user name and perform operations on behalf of your "*username*/*admin*" instance. Operations performed are subject to privileges granted or denied to this user instance by the Kerberos ACL file (see kadm5.acl(4)). You may perform administration as another user instance by using the -p option.

The remote version, kadmin, uses Kerberos authentication and an encrypted RPC to operate securely from anywhere on the network. It normally prompts for a password and authenticates the user to the Kerberos administration server, kadmind, whose service principal is kadmin/*fqdn*. Some options specific to the remote version permit the password prompt to be bypassed. The -c option searches the named credentials cache for a valid ticket for the kadmin/*fqdn* service and uses it to authenticate the user to the Kerberos admin server without a password. The -k option searches a keytab for a credential to authenticate to the kadmin/*fqdn* service, and again no password is collected. If kadmin has collected a password, it requests a kadmin/*fqdn* Kerberos service ticket from the KDC, and uses that service ticket to interact with kadmind.

The local version, kadmin.local, must be run with an effective UID of root, and normally uses a key from the /var/krb5/.k5.*realm* stash file (see kdb5_util(1M)) to decrypt information from the database rather than prompting for a password. The -m option will bypass the .k5.*realm* stash file and prompt for the master password.

Options The following options are supported:

-c *credentials_cache*
Search *credentials_cache* for a service ticket for the kadmin/*fqdn* service; it can be acquired with the kinit(1) program. If this option is not specified, kadmin requests a new service ticket from the KDC, and stores it in its own temporary credentials cache.

-d *dbname*
Specify a non-standard database name. [Local only]

-D
Turn on debug mode. [Local only]

-e "*enc:salt ...*"

Specify a different encryption type and/or key salt. [Local only]

-k [-t *keytab*]

Use the default keytab (-k) or a specific keytab (-t *keytab*) to decrypt the KDC response instead of prompting for a password. In this case, the default principal will be host/hostname. This is primarily used for keytab maintenance.

-m

Accept the database master password from the keyboard rather than using the /var/krb5/.k5.*realm* stash file. [Local only]

-n

Requests anonymous processing. Two types of anonymous principals are supported. For fully anonymous Kerberos, configure pkinit on the KDC and configure pkinit_anchors in the client's krb5.conf. Then use the -n option with a principal of the form @*REALM* (an empty principal name followed by the at-sign and a realm name). If permitted by the KDC, an anonymous ticket will be returned. A second form of anonymous tickets is supported; these realm-exposed tickets hide the identity of the client but not the client's realm. For this mode, use kinit -n with a normal principal name. If supported by the KDC, the principal (but not realm) will be replaced by the anonymous principal. As of release 1.8, the MIT Kerberos KDC supports only fully anonymous operation.

-p *principal*

Authenticate *principal* to the kadmin/*fqdn* service. Otherwise, kadmin will append /admin to the primary principal name of the default credentials cache, the value of the USER environment variable, or the username as obtained with getpwuid, in that order of preference.

-q *query*

Pass *query* directly to kadmin, which will perform *query* and then exit. This can be useful for writing scripts.

-r *realm*

Use *realm* as the default database realm.

-s *admin_server*[:*port*]

Administer the specified *admin* server at the specified port number (*port*). This can be useful in administering a realm not known to your client.

-w *password*

Use *password* instead of prompting for one. Note that placing the password for a Kerberos principal with administration access into a shell script can be dangerous if unauthorized users gain read access to the script or can read arguments of this command through ps(1).

-x *db_args*

Pass database-specific arguments to kadmin. Supported arguments are for LDAP and the Berkeley-db2 plug-in. These arguments are:

binddn=*binddn*
LDAP simple bind DN for authorization on the directory server. Overrides the
ldap_kadmind_dn parameter setting in krb5.conf(4).

bindpwd=*bindpwd*
Bind password.

dbname=*name*
For the Berkeley-db2 plug-in, specifies a name for the Kerberos database.

nconns=*num*
Maximum number of server connections.

port=*num*
Directory server connection port.

Commands list_requests
Lists all the commands available for kadmin. Aliased by lr and ?.

get_privs
Lists the current Kerberos administration privileges (ACLs) for the principal that is
currently running kadmin. The privileges are based on the /etc/krb5/kadm5.acl file on
the master KDC. Aliased by getprivs.

add_principal [*options*] *newprinc*
Creates a new principal, *newprinc*, prompting twice for a password. If the -policy option is
not specified and a policy named default exists, then the default policy is assigned to the
principal; note that the assignment of the default policy occurs automatically only when a
principal is first created, so the default policy must already exist for the assignment to
occur. The automatic assignment of the default policy can be suppressed with the
-clearpolicy option. This command requires the add privilege. Aliased by addprinc and
ank. The options are:

-expire *expdate*
Expiration date of the principal. See the Time Formats section for the valid absolute time
formats that you can specify for *expdate*.

-pwexpire *pwexpdate*
Password expiration date. See the Time Formats section for the valid absolute time
formats that you can specify for *pwexpdate*.

-maxlife *maxlife*
Maximum ticket life for the principal. See the Time Formats section for the valid time
duration formats that you can specify for *maxlife*.

-maxrenewlife *maxrenewlife*
Maximum renewable life of tickets for the principal. See the Time Formats section for
the valid time duration formats that you can specify for *maxrenewlife*.

-kvno *kvno*
Explicitly set the key version number.

-policy *policy*

Policy used by the principal. If both the -policy and -clearpolicy options are not specified, the default policy is used if it exists; otherwise, the principal will have no policy. Also note that the password and principal name must be different when you add a new principal with a specific policy or the default policy.

-clearpolicy

-clearpolicy prevents the default policy from being assigned when -policy is not specified. This option has no effect if the default policy does not exist.

{−|+}allow_postdated

-allow_postdated prohibits the principal from obtaining postdated tickets. (Sets the KRB5_KDB_DISALLOW_POSTDATED flag.) +allow_postdated clears this flag.

{−|+}allow_forwardable

-allow_forwardable prohibits the principal from obtaining forwardable tickets. (Sets the KRB5_KDB_DISALLOW_FORWARDABLE flag.) +allow_forwardable clears this flag.

{−|+}allow_renewable

-allow_renewable prohibits the principal from obtaining renewable tickets. (Sets the KRB5_KDB_DISALLOW_RENEWABLE flag.) +allow_renewable clears this flag.

{−|+}allow_proxiable

-allow_proxiable prohibits the principal from obtaining proxiable tickets. (Sets the KRB5_KDB_DISALLOW_PROXIABLE flag.) +allow_proxiable clears this flag.

{−|+}allow_dup_skey

-allow_dup_skey disables user-to-user authentication for the principal by prohibiting this principal from obtaining a session key for another user. (Sets the KRB5_KDB_DISALLOW_DUP_SKEY flag.) +allow_dup_skey clears this flag.

{−|+}requires_preauth

+requires_preauth requires the principal to preauthenticate before being allowed to kinit. (Sets the KRB5_KDB_REQUIRES_PRE_AUTH flag.) -requires_preauth clears this flag.

{−|+}requires_hwauth

+requires_hwauth requires the principal to preauthenticate using a hardware device before being allowed to kinit. (Sets the KRB5_KDB_REQUIRES_HW_AUTH flag.) -requires_hwauth clears this flag.

{−|+}allow_svr

-allow_svr prohibits the issuance of service tickets for the principal. (Sets the KRB5_KDB_DISALLOW_SVR flag.) +allow_svr clears this flag.

{−|+}allow_tgs_req

−allow_tgs_req specifies that a Ticket-Granting Service (TGS) request for a service ticket for the principal is not permitted. This option is useless for most things.

+allow_tgs_req clears this flag. The default is +allow_tgs_req. In effect,
−allow_tgs_req sets the KRB5_KDB_DISALLOW_TGT_BASED flag on the principal in the
database.

{−|+}allow_tix

−allow_tix forbids the issuance of any tickets for the principal. +allow_tix clears this
flag. The default is +allow_tix. In effect, −allow_tix sets the
KRB5_KDB_DISALLOW_ALL_TIX flag on the principal in the database.

{−|+}needchange

+needchange sets a flag in attributes field to force a password change; −needchange
clears it. The default is −needchange. In effect, +needchange sets the
KRB5_KDB_REQUIRES_PWCHANGE flag on the principal in the database.

{−|+}password_changing_service

+password_changing_service sets a flag in the attributes field marking this as a
password change service principal (useless for most things).
−password_changing_service clears the flag. This flag intentionally has a long name.
The default is −password_changing_service. In effect, +password_changing_service
sets the KRB5_KDB_PWCHANGE_SERVICE flag on the principal in the database.

{-|+}ok_as_delegate

+ok_as_delegate sets the OK-AS-DELEGATE flag on tickets issued for use with this
principal as the service, which clients may use as a hint that credentials can and should
be delegated when authenticating to the service. (Sets the KRB5_KDB_OK_AS_DELEGATE
flag.) -ok_as_delegate clears this flag.

{-|+}ok_to_auth_as_delegate

+ok_to_auth_as_delegate sets the service to allow the use of S4U2Self.
-ok_to_auth_as_delegate clears this flag.

-randkey

Sets the key of the principal to a random value.

-pw *password*

Sets the key of the principal to the specified string and does not prompt for a password.
Note that using this option in a shell script can be dangerous if unauthorized users gain
read access to the script.

-e "enc:salt ..."

Override the list of enctype:salttype pairs given in kdc.conf(4) for setting the key of the
principal. The quotes are necessary if there are multiple enctype:salttype pairs. One key
for each similar enctype and same salttype will be created and the first one listed will be
used. For example, in a list of two similar enctypes with the same salt,
"des-cbc-crc:normal des-cbc-md5:normal", one key will be created and it will be of type
des-cbc-crc:normal.

-unlock

Unlocks the principal so that it can successfully authenticate. If the principal had previously been locked due to reaching maxfailure in failurecountinterval time then the principal will be locked for lockoutduration time.

Example:

```
kadmin: addprinc tlyu/admin
WARNING: no policy specified for "tlyu/admin@ACME.COM";
defaulting to no policy.
Enter password for principal tlyu/admin@ACME.COM:
Re-enter password for principal tlyu/admin@ACME.COM:
Principal "tlyu/admin@ACME.COM" created.
kadmin:
```

Errors:

KADM5_AUTH_ADD (requires add privilege)

KADM5_BAD_MASK (should not happen)

KADM5_DUP (principal exists already)

KADM5_UNK_POLICY (policy does not exist)

KADM5_PASS_Q_* (password quality violations)

delete_principal [-force] *principal*

Deletes the specified principal from the database. This command prompts for deletion, unless the -force option is given. This command requires the delete privilege. Aliased by delprinc.

Example:

```
kadmin: delprinc mwm_user
Are you sure you want to delete the principal
"mwm_user@ACME.COM"? (yes/no): yes
Principal "mwm_user@ACME.COM" deleted.
Make sure that you have removed this principal from
all kadmind ACLs before reusing.
kadmin:
```

Errors:

KADM5_AUTH_DELETE (requires delete privilege)

KADM5_UNK_PRINC (principal does not exist)

modify_principal [*options*] *principal*

Modifies the specified principal, changing the fields as specified. The options are as above for add_principal, except that password changing is forbidden by this command. In addition, the option -clearpolicy will clear the current policy of a principal. This command requires the modify privilege. Aliased by modprinc.

Errors:
    KADM5_AUTH_MODIFY (requires `modify` privilege)

    KADM5_UNK_PRINC (principal does not exist)

    KADM5_UNK_POLICY (policy does not exist)

    KADM5_BAD_MASK (should not happen)

change_password [*options*] *principal*
> Changes the password of *principal*. Prompts for a new password if neither `-randkey` or `-pw` is specified. Requires the `changepw` privilege, or that the principal that is running the program to be the same as the one changed. Aliased by `cpw`. The following options are available:

> `-randkey`
>> Sets the key of the principal to a random value.

> `-pw` *password*
>> Sets the password to the specified string. Not recommended.

> `-e` "enc:salt ..."
>> Override the list of enctype:salttype pairs given in `kdc.conf(4)` for setting the key of the principal. The quotes are necessary if there are multiple enctype:salttype pairs. For each key, the first matching similar enctype and same salttype in the list will be used to set the new key(s).

> `-keepold`
>> Keeps the previous kvno's keys around. There is no easy way to delete the old keys, and this flag is usually not necessary except perhaps for TGS keys as it will allow existing valid TGTs to continue to work.

> Example:

> ```
> kadmin: cpw systest
> Enter password for principal systest@ACME.COM:
> Re-enter password for principal systest@ACME.COM:
> Password for systest@ACME.COM changed.
> kadmin:
> ```

> Errors:
>> KADM5_AUTH_MODIFY (requires the `modify` privilege)

>> KADM5_UNK_PRINC (principal does not exist)

>> KADM5_PASS_Q_* (password policy violation errors)

>> KADM5_PASS_REUSE (password is in principal's password history)

>> KADM5_PASS_TOOSOON (current password minimum life not expired)

get_principal [-terse] *principal*

>   Gets the attributes of *principal*. Requires the inquire privilege, or that the principal that is
>   running the program to be the same as the one being listed. With the -terse option,
>   outputs fields as quoted tab-separated strings. Aliased by getprinc.

>   Examples:

```
kadmin: getprinc tlyu/admin
Principal: tlyu/admin@ACME.COM
Expiration date: [never]
Last password change: Thu Jan 03 12:17:46 CET 2008
Password expiration date: [none]
Maximum ticket life: 24855 days 03:14:07
Maximum renewable life: 24855 days 03:14:07
Last modified: Thu Jan 03 12:17:46 CET 2008 (root/admin@ACME.COM)
Last successful authentication: [never]
Last failed authentication: [never]
Failed password attempts: 0
Number of keys: 5
Key: vno 2, AES-256 CTS mode with 96-bit SHA-1 HMAC, no salt
Key: vno 2, AES-128 CTS mode with 96-bit SHA-1 HMAC, no salt
Key: vno 2, Triple DES cbc mode with HMAC/sha1, no salt
Key: vno 2, ArcFour with HMAC/md5, no salt
Key: vno 2, DES cbc mode with RSA-MD5, no salt
Attributes: REQUIRES_PRE_AUTH
Policy: [none]
kadmin: getprinc -terse tlyu/admin
"tlyu/admin@ACME.COM"   0        1199359066      0        2147483647
"root/admin@ACME.COM"   1199359066      128     2        0        "[none]"       21474836
47      0       0       0       5       1       2       18      0       1       2
17      0       1       2       16      0       1       2       23      0       12
        3       0
kadmin:
```

>   Errors:
>   KADM5_AUTH_GET (requires the get [inquire] privilege)

>   KADM5_UNK_PRINC (principal does not exist)

list_principals [*expression*]

>   Retrieves all or some principal names. *expression* is a shell-style glob expression that can
>   contain the wild-card characters ?, *, and []'s. All principal names matching the expression
>   are printed. If no expression is provided, all principal names are printed. If the expression
>   does not contain an "@" character, an "@" character followed by the local realm is
>   appended to the expression. Requires the list privilege. Aliased by listprincs,
>   get_principals, and getprincs.

Examples:

```
kadmin: listprincs test*
test3@ACME.COM
test2@ACME.COM
test1@ACME.COM
testuser@ACME.COM
kadmin:
```

add_policy [*options*] *policy*
> Adds the named policy to the policy database. Requires the add privilege. Aliased by addpol. The following options are available:

-maxfailure *maxnumber*
> sets the maximum number of failures before the principal is locked after authentication failures in *failurecountinterval* time.

-failurecountinterval *failuretime*
> sets the time after which the authentication failure count is reset 0. See the "Time Formats" section, below, for the valid time duration formats that you can specify for *failuretime*.

-lockoutduration *lockouttime*
> sets the time in which the principal is locked from authenticating if *maxfailure* authentication failures occur within *failurecountinterval* time. See the "Time Formats" section, below, for the valid time duration formats that you can specify for *lockouttime*.

-maxlife *maxlife*
> sets the maximum lifetime of a password. See the Time Formats section for the valid time duration formats that you can specify for *maxlife*.

-minlife *minlife*
> sets the minimum lifetime of a password. See the Time Formats section for the valid time duration formats that you can specify for *minlife*.

-minlength *length*
> sets the minimum length of a password.

-minclasses *number*
> sets the minimum number of character classes allowed in a password. The valid values are:

1
> only letters (himom)

2
> both letters and numbers (hi2mom)

3
> letters, numbers, and punctuation (hi2mom!)

-history *number*
    sets the number of past keys kept for a principal.

Errors:
    KADM5_AUTH_ADD (requires the add privilege)

    KADM5_DUP (policy already exists)

delete_policy [-force] *policy*
    Deletes the named policy. Unless the -force option is specified, prompts for confirmation
    before deletion. The command will fail if the policy is in use by any principals. Requires the
    delete privilege. Aliased by delpol.

Example:

```
kadmin: del_policy guests
Are you sure you want to delete the
policy "guests"? (yes/no): yes
Policy "guests" deleted.
kadmin:
```

Errors:
    KADM5_AUTH_DELETE (requires the delete privilege)

    KADM5_UNK_POLICY (policy does not exist)

    KADM5_POLICY_REF (reference count on policy is not zero)

modify_policy [*options*] *policy*
    Modifies the named policy. Options are as above for add_policy. Requires the modify
    privilege. Aliased by modpol.

Errors:
    KADM5_AUTH_MODIFY (requires the modify privilege)

    KADM5_UNK_POLICY (policy does not exist)

get_policy [-terse] *policy*
    Displays the values of the named policy. Requires the inquire privilege. With the -terse
    flag, outputs the fields as quoted strings separated by tabs. Aliased by getpol.

Examples:

```
kadmin: get_policy admin
Policy: admin
Maximum password life: 180 days 00:00:00
Minimum password life: 00:00:00
Minimum password length: 6
Minimum number of password character classes: 2
Number of old keys kept: 5
Reference count: 17
```

```
                    Maximum password failures before lockout: 3
                    Password failure count reset interval: 180
                    Password lockout duration: 60
                    kadmin: get_policy -terse admin
                    admin admin    15552000    0    6    2    5    17 3 180 60
                    kadmin:
```

Errors:

> KADM5_AUTH_GET (requires the get privilege)
>
> KADM5_UNK_POLICY (policy does not exist)

list_policies [*expression*]

> Retrieves all or some policy names. *expression* is a shell-style glob expression that can
> contain the wild-card characters ?, *, and []'s. All policy names matching the expression are
> printed. If no expression is provided, all existing policy names are printed. Requires the
> list privilege. Aliased by listpols, get_policies, and getpols.

Examples:

```
        kadmin: listpols
        test-pol dict-only once-a-min test-pol-nopw
        kadmin: listpols t*
        test-pol test-pol-nopw kadmin:
```

ktadd [-k *keytab*] [-q] [-e *keysaltlist*] [-norandkey] [[*principal* | -glob *princ-exp*]] [...]

> Adds a principal or all principals matching *princ-exp* to a keytab. It randomizes each
> principal's key in the process, to prevent a compromised admin account from reading out
> all of the keys from the database. However, kadmin.local has the -norandkey option,
> which leaves the keys and their version numbers unchanged, similar to the Kerberos V4
> ext_srvtab command. That allows users to continue to use the passwords they know to
> login normally, while simultaneously allowing scripts to login to the same account using a
> keytab. There is no significant security risk added since kadmin.local must be run by root
> on the KDC anyway.
>
> ktadd requires the inquire and changepw privileges. An entry for each of the principal's
> unique encryption types is added, ignoring multiple keys with the same encryption type
> but different salt types. If the -k argument is not specified, the default keytab file,
> /etc/krb5/krb5.keytab, is used.
>
> The "-e *enctype*:salt" option overrides the list of *enctypes* given in krb5.conf(4), in the
> permitted_enctypes parameter. If "-e *enctype*:salt" is not used and
> permitted_enctypes is not defined in krb5.conf(4), a key for each *enctype* supported by
> the system on which kadmin is run will be created and added to the keytab. Restricting the
> *enctypes* of keys in the keytab is useful when the system for which keys are being created
> does not support the same set of *enctypes* as the KDC. Note that ktadd modifies the *enctype*
> of the keys in the principal database as well.

If the -q option is specified, less status information is displayed. Aliased by xst. The -glob option requires the list privilege. Also, note that if you use -glob to create a keytab, you need to remove /etc/krb5/kadm5.keytab and create it again if you want to use -p */admin with kadmin.

princ-exp

princ-exp follows the same rules described for the list_principals command.

Example:

```
kadmin: ktadd -k /tmp/new-keytab nfs/chicago
Entry for principal nfs/chicago with kvno 2,
encryption type DES-CBC-CRC added to keytab
WRFILE:/tmp/new-keytab.
kadmin:
```

ktremove [-k *keytab*] [-q] *principal* [*kvno* | all | old]

Removes entries for the specified principal from a keytab. Requires no privileges, since this does not require database access. If all is specified, all entries for that principal are removed; if old is specified, all entries for that principal except those with the highest kvno are removed. Otherwise, the value specified is parsed as an integer, and all entries whose kvno match that integer are removed. If the -k argument is not specified, the default keytab file, /etc/krb5/krb5.keytab, is used. If the -q option is specified, less status information is displayed. Aliased by ktrem.

Example:

```
kadmin: ktremove -k /tmp/new-keytab nfs/chicago
Entry for principal nfs/chicago with kvno 2
removed from keytab
WRFILE:/tmp/new-keytab.
kadmin:
```

quit

Quits kadmin. Aliased by exit and q.

Time Formats   Various commands in kadmin can take a variety of time formats, specifying time durations or absolute times. The kadmin option variables *maxrenewlife*, *maxlife*, and *minlife* are time durations, whereas *expdate* and *pwexpdate* are absolute times.

Examples:

```
kadmin: modprinc -expire "12/31 7pm" jdb
kadmin: modprinc -maxrenewlife "2 fortnight" jdb
kadmin: modprinc -pwexpire "this sunday" jdb
kadmin: modprinc -expire never jdb
kadmin: modprinc -maxlife "7:00:00pm tomorrow" jdb
```

Note that times which do not have the "ago" specifier default to being absolute times, unless they appear in a field where a duration is expected. In that case, the time specifier will be interpreted as relative. Specifying "ago" in a duration can result in unexpected behavior.

The following time formats and units can be combined to specify a time. The time and date format examples are based on the date and time of July 2, 1999, 1:35:30 p.m.

Time Format	Examples
hh[:mm][:ss][am/pm/a.m./p.m.]	1p.m., 1:35, 1:35:30pm

Variable	Description
hh	hour (12-hour clock, leading zero permitted but not required)
mm	minutes
ss	seconds

Date Format	Examples
mm/dd[/yy]	07/02, 07/02/99
$yyyy$-mm-dd	1999-07-02
dd-$month$-$yyyy$	02-July-1999
$month$ [,$yyyy$]	Jul 02, July 02,1999
dd $month$[$yyyy$]	02 JULY, 02 july 1999

Variable	Description
dd	day
mm	month
yy	year within century (00-38 is 2000 to 2038; 70-99 is 1970 to 1999)
$yyyy$	year including century
$month$	locale's full or abbreviated month name

Time Units	Examples
[+|- #] year	"-2 year"
[+|- #] month	"2 months"
[+|- #] fortnight	

[+|- #] week	
[+|- #] day	
[+|- #] hour	
[+|- #] minute	
[+|- #] min	
[+|- #] second	
[+|- #] sec	
tomorrow	
yesterday	
today	
now	
this	"this year"
last	"last saturday"
next	"next month"
sunday	
monday	
tuesday	
wednesday	
thursday	
friday	
saturday	
never	

You can also use the following time modifiers: first, second, third, fourth, fifth, sixth, seventh, eighth, ninth, tenth, eleventh, twelfth, and ago.

Environment Variables See environ(5) for descriptions of the following environment variables that affect the execution of kadmin:

PAGER
   The command to use as a filter for paging output. This can also be used to specify options. The default is more(1).

Files /var/krb5/principal
Kerberos principal database.

/var/krb5/principal.ulog
The update log file for incremental propagation.

/var/krb5/principal.kadm5
Kerberos administrative database. Contains policy information.

/var/krb5/principal.kadm5.lock
Lock file for the Kerberos administrative database. This file works backwards from most other lock files (that is, kadmin will exit with an error if this file does *not* exist).

/var/krb5/kadm5.dict
Dictionary of strings explicitly disallowed as passwords.

/etc/krb5/kadm5.acl
List of principals and their kadmin administrative privileges.

/etc/krb5/kadm5.keytab
Keytab for kadmind principals: kadmin/*fqdn*, changepw/*fqdn*, and kadmin/changepw.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/security/kerberos-5
Interface Stability	Committed

See Also kpasswd(1), more(1), gkadmin(1M), kadmind(1M), kdb5_util(1M), kdb5_ldap_util(1M), kproplog(1M), kadm5.acl(4), kdc.conf(4), krb5.conf(4), attributes(5), environ(5), kerberos(5), krb5envvar(5)

History The kadmin program was originally written by Tom Yu at MIT, as an interface to the OpenVision Kerberos administration program.

Diagnostics The kadmin command is currently incompatible with the MIT kadmind daemon interface, so you cannot use this command to administer an MIT-based Kerberos database. However, clients running the Solaris implementation of Kerberos can still use an MIT-based KDC.

Name   kadmind – Kerberos administration daemon

Synopsis   /usr/lib/krb5/kadmind [-nofork] [-m] [-port *port-number*] [-r *realm*]
          [-x *db_args*] [-P *pid_file*]

Description   kadmind runs on the master key distribution center (KDC), which stores the principal and policy databases. kadmind accepts remote requests to administer the information in these databases. Remote requests are sent, for example, by kpasswd(1), gkadmin(1M), and kadmin(1M) commands, all of which are clients of kadmind. When you install a KDC, kadmind is set up in the init scripts to start automatically when the KDC is rebooted.

kadmind requires a number of configuration files to be set up for it to work:

/etc/krb5/kdc.conf
    The KDC configuration file contains configuration information for the KDC and the Kerberos administration system. kadmind understands a number of configuration variables (called relations) in this file, some of which are mandatory and some of which are optional. In particular, kadmind uses the acl_file, dict_file, admin_keytab, and kadmind_port relations in the [*realms*] section. Refer to the kdc.conf(4) man page for information regarding the format of the KDC configuration file.

/etc/krb5/kadm5.keytab
    kadmind requires a keytab (key table) containing correct entries for the kadmin/*fqdn*, kadmin/changepw and kadmin/changepw principals for every realm that kadmind answers requests. The keytab can be created with the kadmin(1M) or kdb5_util(1M) command. The location of the keytab is determined by the admin_keytab relation in the kdc.conf(4) file.

/etc/krb5/kadm5.acl
    kadmind uses an ACL (access control list) to determine which principals are allowed to perform Kerberos administration actions. The path of the ACL file is determined by the acl_file relation in the kdc.conf file. See kdc.conf(4). For information regarding the format of the ACL file, refer to kadm5.acl(4).

    The kadmind daemon will need to be restarted to reread the kadm5.acl file after it has been modified. You can do this, as root, with the following command:

    # svcadm restart svc:/network/security/kadmin:default

After kadmind begins running, it puts itself in the background and disassociates itself from its controlling terminal.

kadmind can be configured for incremental database propagation. Incremental propagation allows slave KDC servers to receive principal and policy updates incrementally instead of receiving full dumps of the database. These settings can be changed in the kdc.conf(4) file:

sunw_dbprop_enable = [true | false]
    Enable or disable incremental database propagation. Default is false.

sunw_dbprop_master_ulogsize = N
>   Specifies the maximum amount of log entries available for incremental propagation to the slave KDC servers. The maximum value that this can be is 2500 entries. Default value is 1000 entries.

The kiprop/<*hostname*>@<*REALM*> principal must exist in the master's kadm5.keytab file to enable the slave to authenticate incremental propagation from the master. In the principal syntax above, <*hostname*> is the master KDC's host name and <*REALM*> is the realm in which the master KDC resides.

Kerberos client machines can automatically migrate Unix users to the default Kerberos realm specified in the local krb5.conf(4), if the user does not have a valid kerberos account already. You achieve this by using the pam_krb5_migrate(5) service module for the service in question. The Kerberos service principal used by the client machine attempting the migration needs to be validated using the u privilege in kadm5.acl(4). When using the u privilege, kadmind validates user passwords using PAM, specifically using a PAM_SERVICE name of k5migrate by calling pam_authenticate(3PAM) and pam_acct_mgmt(3PAM).

A suitable PAM stack configuration example for k5migrate would look like:

```
k5migrate          auth     required      pam_unix_auth.so.1
k5migrate          account required       pam_unix_account.so.1
```

Options   The following options are supported:

-nofork
>   Specifies that kadmind does not put itself in the background and does not disassociate itself from the terminal. In normal operation, you should use the default behavior, which is to allow the daemon to put itself in the background.

-m
>   Specifies that the master database password should be retrieved from the keyboard rather than from the stash file. When using -m, the kadmind daemon receives the password prior to putting itself in the background. If used in combination with the -d option, you must explicitly place the daemon in the background.

-port *port-number*
>   Specifies the port on which the kadmind daemon listens for connections. The default is controlled by the kadmind_port relation in the kdc.conf(4) file.

-P *pid_file*
>   Specifies the file to which the PID of kadmind process should be written to after it starts up. This can be used to identify whether kadmind is still running and to allow init scripts to stop the correct process.

-r *realm*
>   Specifies the default realm that kadmind serves. If *realm* is not specified, the default *realm* of the host is used. kadmind answers requests for any realm that exists in the local KDC database and for which the appropriate principals are in its keytab.

-x *db_args*
　Pass database-specific arguments to kadmind. Supported arguments are for LDAP and the
　Berkeley-db2 plug-in. These arguments are:

binddn=*binddn*
　LDAP simple bind DN for authorization on the directory server. Overrides the
　ldap_kadmind_dn parameter setting in krb5.conf(4).

bindpwd=*bindpwd*
　Bind password.

dbname=*name*
　For the Berkeley-db2 plug-in, specifies a name for the Kerberos database.

nconns=*num*
　Maximum number of server connections.

port=*num*
　Directory server connection port.

Files /var/krb5/principal
　Kerberos principal database.

/var/krb5/principal.ulog
　The update log file for incremental propagation.

/var/krb5/principal.kadm5
　Kerberos administrative database containing policy information.

/var/krb5/principal.kadm5.lock
　Kerberos administrative database lock file. This file works backwards from most other lock
　files (that is, kadmin exits with an error if this file does not exist).

/var/krb5/kadm5.dict
　Dictionary of strings explicitly disallowed as passwords.

/etc/krb5/kadm5.acl
　List of principals and their kadmin administrative privileges.

/etc/krb5/kadm5.keytab
　Keytab for kadmin principals: kadmin/*fqdn*, changepw/*fqdn*, and kadmin/changepw.

/etc/krb5/kdc.conf
　KDC configuration information.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/security/kerberos-5

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Committed

See Also kpasswd(1), svcs(1), gkadmin(1M), kadmin(1M), kadmin(1M), kdb5_util(1M), kdb5_ldap_util(1M), kproplog(1M), svcadm(1M), pam_acct_mgmt(3PAM), pam_authenticate(3PAM), kadm5.acl(4), kdc.conf(4), krb5.conf(4), attributes(5), kerberos(5), krb5envvar(5), pam_krb5_migrate(5), smf(5)

Notes The Kerberos administration daemon (kadmind) is now compliant with the change-password standard mentioned in RFC 3244, which means it can now handle change-password requests from non-Solaris Kerberos clients.

The kadmind service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/network/security/kadmin
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

The -d and -p arguments are made obsolete with the -nofork and -port arguments, respectively. The -d and -p arguments might be removed in a future release of the Solaris operating system.

Name kcfd – kernel-level cryptographic framework daemon

Synopsis kcfd

Description The kcfd daemon helps in managing CPU usage by cryptographic operations performed in software by kernel threads. The system utilization associated with these threads is charged to the kcfd process. It also does module verification for kernel cryptographic modules.

Only a privileged user can run this daemon.

The kcfd daemon is automatically invoked in run level 1, after /usr is mounted. A previously invoked kcfd daemon that is still running must be stopped before invoking another kcfd command.

Manually starting and restarting kcfd is not recommended. If it is necessary to do so, use the cryptoadm(1M) start and stop subcommands.

Exit Status The following exit values are returned:

0   Daemon started successfully.

> 1   Daemon failed to start.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

Name kclient – set up a machine as a Kerberos client

Synopsis /usr/sbin/kclient [-n] [-R *realm*] [-k *kdc*] [-a *adminuser*]
          [-c *filepath*] [-d *dnsarg*] [-f *fqdn_list*] [-h *logical_host_name*]
          [-k *kdc_list*] [-m *master_kdc*] [-p *profile*] [-s *pam_service*]
          [-T *kdc_vendor*]

Description By specifying the various command options, you can use the kclient utility to:

- Configure a machine as a Kerberos client for a specified realm and for KDC by setting up krb5.conf(4).

- Add the Kerberos host principal to the local host's keytab file (/etc/krb5/krb5.keytab).

- Set up the machine to do kerberized NFS.

- Bring over a master krb5.conf copy from a specified pathname.

- Setup a machine to do server and/or host/domain name-to-realm mapping lookups by means of DNS.

- Configure a Kerberos client to use an MS Active Directory server. This generates a keytab file with the Kerberos client's service keys populated.

- Setup a Kerberos client that has no service keys. This is useful when the client does not require service keys, because the client does not wish to host a service that uses Kerberos for security.

- Configure a Kerberos client that is part of a cluster. This option requires the logical host name of the cluster so that the proper service keys are created and populated in the client's keytab file.

- Setup a Kerberos client to join an environment that consists of Kerberos servers that are non-Solaris and non-MS Active Directory servers.

- Configure pam.conf(4) to use Kerberos authentication for specified services.

- Configure the client as a simple NTP broadcast/multicast client.

- Specify custom domain/host name-to-realm name mappings.

- Setup the Kerberos client to use multiple KDC servers.

The kclient utility needs to be run on the client machine with root permission and can be run either interactively or non-interactively. In the non-interactive mode, the user feeds in the required inputs by means of a profile, command-line options, or a combination of profile and command-line options. The user is prompted for "required" parameter values (realm and adminuser), if found missing in the non-interactive run. The interactive mode is invoked when the utility is run without any command-line arguments.

Both the interactive and non-interactive forms of kclient can add the host/fqdn entry to the local host's keytab file. They also can require the user to enter the password for the administrative user requested, to obtain the Kerberos Ticket Granting Ticket (TGT) for adminuser. The host/fqdn, nfs/fqdn, and root/fqdn principals can be added to the KDC database (if not already present) before their possible addition to the local host's keytab.

The kclient utility assumes that the local host has been setup for DNS and requires the presence of a valid resolv.conf(4). Also, kclient can fail if the localhost time is not synchronized with that of the KDC. For Kerberos to function the localhost time must be within five minutes of that of the KDC. It is advised that both systems run some form of time synchronization protocol, such as the Network Time Protocol (NTP). See the ntpd man page, delivered in the SUNWntpu package (not a SunOS man page).

Options   The non-interactive mode supports the following options:

-n

   Set up the machine for kerberized NFS. This involves making changes to krb5* security flavors in nfssec.conf(4). This option will also add nfs/fqdn and root/fqdn entries to the local host's keytab file if the -K option has not been specified.

-R [*realm*]
   Specifies the Kerberos realm.

-k *kdc_list*
   The -k option specifies the KDC host names for the Kerberos client. *kdc_list* is a comma-separated list of KDCs. If the -m option is not used, it is assumed that the first (or only) host in *kdc_list* is the master KDC host name. Note that the list specified is used verbatim. This is helpful when specifying non-fully qualified KDC host names that can be canonicalized by DNS.

-a [*adminuser*]
   Specifies the Kerberos administrative user.

-T *kdc_vendor*
   Configure the Kerberos client to associate with a third party server. Valid *kdc_vendor* currently supported are:

   ms_ad
      Microsoft Active Directory

   mit
      MIT KDC server

   heimdal
      Heimdal KDC server

   shishi
      Shishi KDC server

   Knowing the administrative password will be required to associate the client with the server if the ms_ad option is specified.

-c [*filepath*]
   Specifies the pathname to the krb5.conf(4) master file, to be copied over to the local host. The path specified normally points to a master copy on a remote host and brought over to the local host by means of NFS.

-d [*dnsarg*]

Specifies the DNS lookup option to be used and specified in the `krb5.conf(4)` file. Valid *dnsarg* entries are: `none`, `dns_lookup_kdc`, `dns_lookup_realm` and `dns_fallback`. Any other entry is considered invalid. The latter three *dnsarg* values assume the same meaning as those described in `krb5.conf`. `dns_lookup_kdc` implies DNS lookups for the KDC and the other servers. `dns_lookup_realm` is for host/domain name-to-realm mapping by means of DNS. `dns_fallback` is a superset and does DNS lookups for both the servers and the host/domain name-to-realm mapping. A lookup option of `none` specifies that DNS is not be used for any kind of mapping lookup.

-D *domain_list*

Specifies the host and/or domain names to be mapped to the Kerberos client's default realm name. *domain_list* is a comma–separated list, for example "`example.com,host1.example.com`". If the `-D` option is not used, then only the client's domain is used for this mapping. For example, if the client is `host1.eng.example.com`, then the domain that is mapped to the `EXAMPLE.COM` realm is `example.com`.

-K

Configure the Kerberos client without service keys, which are usually stored in `/etc/krb5/krb5.keytab`. This is useful in the following scenarios:

- The client IP address is dynamically assigned and therefore does not host Kerberized services.

- Client has a static IP address, but does not want to host any Kerberized services.

- Client has a static IP address, but the local administrator does not currently have service keys available for the machine. It is expected that, at a later time, these keys will be installed on the machine.

-f [*fqdn_list*]

This option creates a service principal entry (host/nfs/root) associated with each of the listed fqdn's, if required, and subsequently adds the entries to the local host's keytab.

fqdn_list is a comma-separated list of one or more fully qualified DNS domain names.

This option is especially useful in Kerberos realms having systems offering kerberized services, but situated in multiple different DNS domains.

-h *logical_host_name*

Specifies that the Kerberos client is a node in a cluster. The *logical_host_name* is the logical host name given to the cluster. The resulting `/etc/krb5/krb5.conf` and `/etc/krb5/krb5.keytab` files must be manually copied over to the other members of the cluster.

-m *master_kdc*

This option specifies the master KDC to be used by the Kerberos client. *master_kdc* is the host name of the master KDC for the client. If the `-m` option is not used, then it is assumed that the first KDC host name listed with the `-k` option is the master KDC.

-p [*profile*]

> Specifies the profile to be used to enable the reading in of the values of all the parameters required for setup of the machine as a Kerberos client.

> The profile should have entries in the format:

> *PARAM <value>*

> Valid *PARAM* entries are: REALM, KDC, ADMIN, FILEPATH, NFS, DNSLOOKUP, FQDN, NOKEY, NOSOL, LHN, KDCVENDOR, RMAP, MAS, and PAM.

> These profile entries correspond to the -R [*realm*], -k [*kdc*], -a [*adminuser*], -c [*filepath*], -n, -d [*dnsarg*], -f [*fqdn_list*], -K, -h [*logical_host_name*], -T [*kdc_vendor*], -D [*domain_list*], -m [*master_kdc*], and -s [*pam_service*] command-line options, respectively. Any other *PARAM* entry is considered invalid and is ignored.

> The NFS profile entry can have a value of 0 (do nothing) or 1 (operation is requested). Any other value is considered invalid and is ignored.

> Keep in mind that the command line options override the *PARAM* values listed in the profile.

-s *pam_service*:*auth_type*[,...]

> Specifies that the PAM service names, listed in *pam_service*, are authenticated through Kerberos. Using this option updates pam.conf(4) to include a separate authentication stack with pam_krb5(5). Examples of *pam_service* names are sshd-kbdint, xscreensaver, and so forth.

> *auth_type* can be one of the following keywords:

> first

>> Try authenticating through Kerberos first. If this fails try to authenticate through Unix.

> only

>> Try to authenticate only through Kerberos.

> optional

>> Try authenticating through Unix first. If this is successful try to authenticate through Kerberos.

Examples EXAMPLE 1 Setting Up a Kerberos Client Using Command-Line Options

To setup a Kerberos client using the clntconfig/admin administrative principal for realm 'ABC.COM', kdc 'example1.com' and that also does kerberized NFS, enter:

```
# /usr/sbin/kclient -n -R ABC.COM -k example1.com -a clntconfig
```

Alternatively, to set up a Kerberos client using the clntconfig/admin administrative principal for the realm 'EAST.ABC.COM', kdc 'example2.east.abc.com' and that also needs service principal(s) created and/or added to the local keytab for multiple DNS domains, enter:

EXAMPLE 1   Setting Up a Kerberos Client Using Command-Line Options   *(Continued)*

```
# /usr/sbin/kclient -n -R EAST.ABC.COM -k example2.east.abc.com \
-f west.abc.com,central.abc.com -a clntconfig
```

Note that the `krb5` administrative principal used by the administrator needs to have only `add`, `inquire`, `change-pwd` and `modify` privileges (for the principals in the KDC database) in order for the `kclient` utility to run. A sample `kadm5.acl(4)` entry is:

```
clntconfig/admin@ABC.COM acmi
```

EXAMPLE 2   Setting Up a Kerberos Client Using the Profile Option

To setup a Kerberos client using the `clntconfig/admin` administrative principal for realm 'ABC.COM', kdc 'example1.com' and that also copies over the master `krb5.conf` from a specified location, enter:

```
# /usr/sbin/kclient -p /net/example1.com/export/profile.krb5
```

The contents of `profile.krb5`:

```
REALM ABC.COM
KDC example1
ADMIN clntconfig
FILEPATH /net/example1.com/export/krb5.conf
NFS 0
DNSLOOKUP none
```

EXAMPLE 3   Setting Up a Kerberos Client That Has a Dynamic IP Address

In this example a Kerberos client is a DHCP client that has a dynamic IP address. This client does not wish to host any Kerberized services and therefore does not require a `keytab` (`/etc/krb5/krb5.keytab`) file.

For this type of client the administrator would issue the following command to configure this machine to be a Kerberos client of the `ABC.COM` realm with the KDC server `kdc1.example.com`:

```
# /usr/sbin/kclient -K -R EXAMPLE.COM -k kdc1.example.com
```

Files   /etc/krb5/kadm5.acl
>   Kerberos access control list (ACL) file.

/etc/krb5/krb5.conf
>   Default location for the local host's configuration file.

/etc/krb5/krb5.keytab
>   Default location for the local host's `keytab` file.

/etc/nfssec.conf
>   File listing NFS security modes.

/etc/resolv.conf
    DNS resolver configuration file.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/security/kerberos-5
Interface Stability	Committed

See Also encrypt(1), ksh(1), ldapdelete(1), ldapmodify(1), ldapsearch(1), dd(1M), smbadm(1M), kadm5.acl(4), krb5.conf(4), nfssec.conf(4), pam.conf(4), resolv.conf(4), attributes(5), pam_krb5(5)

Notes fqdn stands for the Fully Qualified Domain Name of the local host. The kclient utility saves copies of both the krb5.conf(4) and nfssec.conf(4) files to files with corresponding names and .sav extensions. The optional copy of the krb5.conf(4) master file is neither encrypted nor integrity-protected and it takes place over regular NFS.

Name kdb5_ldap_util – Kerberos configuration utility

Synopsis kdb5_ldap_util [-D *user_dn* [-w *passwd*]] [-H *ldap_uri*] *command*
[*command_options*]

Description The kdb5_ldap_util utility allows an administrator to manage realms, Kerberos services, and ticket policies. The utility offers a set of general options, described under OPTIONS, and a set of commands, which, in turn, have their own options. Commands and their options are described in their own subsections, below.

Options kdb5_ldap_util has a small set of general options that apply to the kdb5_ldap_util utility itself and a larger number of options that apply to specific commands. A number of these command-specific options apply to multiple commands and are described in their own section, below.

General Options The following general options are supported:

-D *user_dn*
   Specifies the distinguished name (DN) of a user who has sufficient rights to perform the operation on the LDAP server.

-H *ldap_uri*
   Specifies the URI of the LDAP server.

-w *passwd*
   Specifies the password of *user_dn*. This option is not recommended.

Common Command-specific Options The following options apply to a number of kdb5_ldap_util commands.

-subtrees *subtree_dn_list*
   Specifies the list of subtrees containing the principals of a realm. The list contains the DNs of the subtree objects separated by a colon.

-sscope *search_scope*
   Specifies the scope for searching the principals under a subtree. The possible values are 1 or one (one level), 2 or sub (subtrees).

-containerref *container_reference_dn*
   Specifies the DN of the container object in which the principals of a realm will be created. If the container reference is not configured for a realm, the principals will be created in the realm container.

-maxtktlife *max_ticket_life*
   Specifies maximum ticket life for principals in this realm.

-maxrenewlife *max_renewable_ticket_life*
   Specifies maximum renewable life of tickets for principals in this realm.

-r *realm*
   Specifies the Kerberos realm of the database; by default the realm returned by krb5_default_local_realm(3) is used.

kdb5_ldap_util Commands The kdb5_ldap_util utility comprises a set of commands, each with its own set of options. These commands are described in the following subsections.

The create Command The create command creates a realm in a directory. The command has the following syntax:

```
create \
[-subtrees subtree_dn_list]
[-sscope search_scope]
[-containerref container_reference_dn]
[-k mkeytype]
[-m|-P password| -sf stashfilename]
[-s]
[-r realm]
[-maxtktlife max_ticket_life]
[-kdcdn kdc_service_list]
[-admindn admin_service_list]
[-maxrenewlife max_renewable_ticket_life]
[ticket_flags]
```

The create command has the following options:

-subtree *subtree_dn_list*
　　See "Common Command-specific Options," above.

-sscope *search_scope*
　　See "Common Command-specific Options," above.

-containerref *container_reference_dn*
　　See "Common Command-specific Options," above.

-k *mkeytype*
　　Specifies the key type of the master key in the database; the default is that given in
　　kdc.conf(4).

-m
　　Specifies that the master database password should be read from the TTY rather than
　　fetched from a file on the disk.

-P *password*
　　Specifies the master database password. This option is not recommended.

-sf *stashfilename*
　　Specifies the stash file of the master database password.

-s
　　Specifies that the stash file is to be created.

-maxtktlife *max_ticket_life*
　　See "Common Command-specific Options," above.

-maxrenewlife *max_renewable_ticket_life*
　　See "Common Command-specific Options," above.

-r *realm*
   See "Common Command-specific Options," above.

ticket_flags
   Specifies the ticket flags. If this option is not specified, by default, none of the flags are set. This means all the ticket options will be allowed and no restriction will be set. See "Ticket Flags" for a list and descriptions of these flags.

The modify Command
The modify command modifies the attributes of a realm. The command has the following syntax:

```
modify \
[-subtrees subtree_dn_list]
[-sscope search_scope]
[-containerref container_reference_dn]
[-r realm]
[-maxtktlife max_ticket_life]
[-maxrenewlife max_renewable_ticket_life]
[ticket_flags]
```

The modify command has the following options:

-subtree *subtree_dn_list*
   See "Common Command-specific Options," above.

-sscope *search_scope*
   See "Common Command-specific Options," above.

-containerref *container_reference_dn*
   See "Common Command-specific Options," above.

-maxtktlife *max_ticket_life*
   See "Common Command-specific Options," above.

-maxrenewlife *max_renewable_ticket_life*
   See "Common Command-specific Options," above.

-r *realm*
   See "Common Command-specific Options," above.

ticket_flags
   Specifies the ticket flags. If this option is not specified, by default, none of the flags are set. This means all the ticket options will be allowed and no restriction will be set. See "Ticket Flags" for a list and descriptions of these flags.

The view Command
The view command displays the attributes of a realm. The command has the following syntax:

```
view [-r realm]
```

The view command has the following option:

-r *realm*
   See "Common Command-specific Options," above.

The destroy
Command
The destroy command destroys a realm, including the master key stash file. The command has the following syntax:

destroy [-f] [-r *realm*]

The destroy command has the following options:

-f
   If specified, destroy does not prompt you for confirmation.

-r *realm*
   See "Common Command-specific Options," above.

The list Command
The list command displays the names of realms. The command has the following syntax:

list

The list command has no options.

The stashsrvpw
Command
The stashsrvpw command enables you to store the password for service object in a file so that a KDC and Administration server can use it to authenticate to the LDAP server. The command has the following syntax:

stashsrvpw [-f *filename*] *servicedn*

The stashsrvpw command has the following option and argument:

-f *filename*
   Specifies the complete path of the service password file. The default is:

   /var/krb5/service_passwd

servicedn
   Specifies the distinguished name (DN) of the service object whose password is to be stored in file.

The create_policy
Command
The create_policy command creates a ticket policy in a directory. The command has the following syntax:

create_policy \
[-r *realm*]
[-maxtktlife *max_ticket_life*]
[-maxrenewlife *max_renewable_ticket_life*]
[*ticket_flags*]
policy_name

The create_policy command has the following options:

-r *realm*
   See "Common Command-specific Options," above.

-maxktlife *max_ticket_life*
    See "Common Command-specific Options," above.

-maxrenewlife *max_renewable_ticket_life*
    See "Common Command-specific Options," above.

ticket_flags
    Specifies the ticket flags. If this option is not specified, by default, none of the flags are set.
    This means all the ticket options will be allowed and no restriction will be set. See "Ticket
    Flags" for a list and descriptions of these flags.

policy_name
    Specifies the name of the ticket policy.

The modify_policy
Command

The modify_policy command modifies the attributes of a ticket policy. The command has
the following syntax:

```
modify_policy \
[-r realm]
[-maxktlife max_ticket_life]
[-maxrenewlife max_renewable_ticket_life]
[ticket_flags]
policy_name
```

The modify_policy command has the same options and argument as those for the
create_policy command.

The view_policy
Command

The view_policy command displays the attributes of a ticket policy. The command has the
following syntax:

```
view_policy [-r realm] policy_name
```

The view_policy command has the following options:

-r *realm*
    See "Common Command-specific Options," above.

policy_name
    Specifies the name of the ticket policy.

The destroy_policy
Command

The destroy_policy command destroys an existing ticket policy. The command has the
following syntax:

```
destroy_policy [-r realm] [-force] policy_name
```

The destroy_policy command has the following options:

-r *realm*
    See "Common Command-specific Options," above.

-force
    Forces the deletion of the policy object. If not specified, you will be prompted for
    confirmation before the policy is deleted. Enter yes to confirm the deletion.

policy_name
    Specifies the name of the ticket policy.

The list_policy
Command

The list_policy command lists the ticket policies in the default or a specified realm. The
command has the following syntax:

list_policy [-r *realm*]

The list_policy command has the following option:

-r *realm*
    See "Common Command-specific Options," above.

Ticket Flags   A number of kdb5_ldap_util commands have ticket_flag options. These flags are
described as follows:

{-|+}allow_dup_skey
    -allow_dup_skey disables user-to-user authentication for principals by prohibiting
    principals from obtaining a session key for another user. This setting sets the
    KRB5_KDB_DISALLOW_DUP_SKEY flag. +allow_dup_skey clears this flag.

{-|+}allow_forwardable
    -allow_forwardable prohibits principals from obtaining forwardable tickets. This setting
    sets the KRB5_KDB_DISALLOW_FORWARDABLE flag. +allow_forwardable clears this flag.

{-|+}allow_postdated
    -allow_postdated prohibits principals from obtaining postdated tickets. This setting sets
    the KRB5_KDB_DISALLOW_POSTDATED flag. +allow_postdated clears this flag.

{-|+}allow_proxiable
    -allow_proxiable prohibits principals from obtaining proxiable tickets. This setting sets
    the KRB5_KDB_DISALLOW_PROXIABLE flag. +allow_proxiable clears this flag.

{-|+}allow_renewable
    -allow_renewable prohibits principals from obtaining renewable tickets. This setting sets
    the KRB5_KDB_DISALLOW_RENEWABLE flag. +allow_renewable clears this flag.

{-|+}allow_svr
    -allow_svr prohibits the issuance of service tickets for principals. This setting sets the
    KRB5_KDB_DISALLOW_SVR flag. +allow_svr clears this flag.

{-|+}allow_tgs_req
    -allow_tgs_req specifies that a Ticket-Granting Service (TGS) request for a service ticket
    for principals is not permitted. This option is useless for most purposes. +allow_tgs_req
    clears this flag. The default is +allow_tgs_req. In effect, -allow_tgs_req sets the
    KRB5_KDB_DISALLOW_TGT_BASED flag on principals in the database.

{-|+}allow_tix

-allow_tix forbids the issuance of any tickets for principals. +allow_tix clears this flag. The default is +allow_tix. In effect, -allow_tix sets the KRB5_KDB_DISALLOW_ALL_TIX flag on principals in the database.

{-|+}needchange

+needchange sets a flag in the attributes field to force a password change; -needchange clears that flag. The default is -needchange. In effect, +needchange sets the KRB5_KDB_REQUIRES_PWCHANGE flag on principals in the database.

{-|+}password_changing_service

+password_changing_service sets a flag in the attributes field marking a principal as a password-change-service principal (a designation that is most often not useful). -password_changing_service clears the flag. That this flag has a long name is intentional. The default is -password_changing_service. In effect, +password_changing_service sets the KRB5_KDB_PWCHANGE_SERVICE flag on principals in the database.

{-|+}requires_hwauth

+requires_hwauth requires principals to preauthenticate using a hardware device before being allowed to kinit(1). This setting sets the KRB5_KDB_REQUIRES_HW_AUTH flag. -requires_hwauth clears this flag.

{-|+}requires_preauth

+requires_preauth requires principals to preauthenticate before being allowed to kinit(1). This setting sets the KRB5_KDB_REQUIRES_PRE_AUTH flag. -requires_preauth clears this flag.

Examples   **EXAMPLE 1**   Using create

The following is an example of the use of the create command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
create -subtrees o=org -sscope SUB -r ATHENA.MIT.EDU
Password for "cn=admin,o=org":  password entered
Initializing database for realm 'ATHENA.MIT.EDU'
You will be prompted for the database Master Password.
It is important that you NOT FORGET this password.
Enter KDC database master key: master key entered
Re-enter KDC database master key to verify: master key re-enteredjjjjjj
```

EXAMPLE 2   Using modify

The following is an example of the use of the modify command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
modify +requires_preauth -r ATHENA.MIT.EDU
Password for "cn=admin,o=org":  password entered
Password for "cn=admin,o=org":  password entered
```

EXAMPLE 3 Using view

The following is an example of the use of the view command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
view -r ATHENA.MIT.EDU
            Password for "cn=admin,o=org":
                                Realm Name: ATHENA.MIT.EDU
                                   Subtree: ou=users,o=org
                                   Subtree: ou=servers,o=org
                               SearchScope: ONE
                       Maximum ticket life: 0 days 01:00:00
                    Maximum renewable life: 0 days 10:00:00
                              Ticket flags: DISALLOW_FORWARDABLE REQUIRES_PWCHANGE
```

EXAMPLE 4 Using destroy

The following is an example of the use of the destroy command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
destroy -r ATHENA.MIT.EDU
Password for "cn=admin,o=org": password entered
Deleting KDC database of 'ATHENA.MIT.EDU', are you sure?
(type 'yes' to confirm)? yes
OK, deleting database of 'ATHENA.MIT.EDU'...
```

EXAMPLE 5 Using list

The following is an example of the use of the list command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu list
Password for "cn=admin,o=org": password entered
Re-enter Password for "cn=admin,o=org": password re-entered
ATHENA.MIT.EDU
OPENLDAP.MIT.EDU
MEDIA-LAB.MIT.EDU
```

EXAMPLE 6 Using stashsrvpw

The following is an example of the use of the stashsrvpw command.

```
# kdb5_ldap_util stashsrvpw -f \
/home/andrew/conf_keyfile cn=service-kdc,o=org
Password for "cn=service-kdc,o=org": password entered
Re-enter password for "cn=service-kdc,o=org": password re-entered
```

EXAMPLE 7 Using create_policy

The following is an example of the use of the create_policy command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
create_policy -r ATHENA.MIT.EDU \
-maxtktlife "1  day" -maxrenewlife "1 week" \
```

EXAMPLE 7 Using create_policy   *(Continued)*

-allow_postdated +needchange -allow_forwardable *tktpolicy*
Password for "cn=admin,o=org": *password entered*

EXAMPLE 8 Using modify_policy

The following is an example of the use of the modify_policy command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
modify_policy -r ATHENA.MIT.EDU \
-maxtktlife "60 minutes" -maxrenewlife "10 hours" \
+allow_postdated -requires_preauth tktpolicy
```
Password for "cn=admin,o=org": *password entered*

EXAMPLE 9 Using view_policy

The following is an example of the use of the view_policy command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
view_policy -r ATHENA.MIT.EDU tktpolicy
```
Password for "cn=admin,o=org": *password entered*
```
          Ticket policy: tktpolicy
    Maximum ticket life: 0 days 01:00:00
 Maximum renewable life: 0 days 10:00:00
           Ticket flags: DISALLOW_FORWARDABLE REQUIRES_PWCHANGE
```

EXAMPLE 10 Using destroy_policy

The following is an example of the use of the destroy_policy command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
destroy_policy -r ATHENA.MIT.EDU tktpolicy
```
Password for "cn=admin,o=org": *password entered*
```
This will delete the policy object 'tktpolicy', are you sure?
(type 'yes' to confirm)? yes
** policy object 'tktpolicy' deleted.
```

EXAMPLE 11 Using list_policy

The following is an example of the use of the list_policy command.

```
# kdb5_ldap_util -D cn=admin,o=org -H ldaps://ldap-server1.mit.edu \
list_policy -r ATHENA.MIT.EDU
```
Password for "cn=admin,o=org": *password entered*
```
tktpolicy
tmppolicy
userpolicy
```

EXAMPLE 12 Using setsrvpw

The following is an example of the use of the setsrvpw command.

EXAMPLE 12 Using setsrvpw   *(Continued)*

```
# kdb5_ldap_util setsrvpw -D cn=admin,o=org setsrvpw \
-fileonly -f /home/andrew/conf_keyfile cn=service-kdc,o=org
Password for "cn=admin,o=org": password entered
Password for "cn=service-kdc,o=org": password entered
Re-enter password for "cn=service-kdc,o=org": password re-entered
```

EXAMPLE 13 Using create_service

The following is an example of the use of the create_service command.

```
# kdb5_ldap_util -D cn=admin,o=org create_service \
-kdc -randpw -f /home/andrew/conf_keyfile cn=service-kdc,o=org
Password for "cn=admin,o=org": password entered
File does not exist. Creating the file /home/andrew/conf_keyfile...
```

EXAMPLE 14 Using modify_service

The following is an example of the use of the modify_service command.

```
# kdb5_ldap_util -D cn=admin,o=org modify_service \
-realm ATHENA.MIT.EDU cn=service-kdc,o=org
Password for "cn=admin,o=org": password entered
Changing rights for the service object. Please wait ... done
```

EXAMPLE 15 Using view_service

The following is an example of the use of the view_service command.

```
# kdb5_ldap_util -D cn=admin,o=org view_service \
cn=service-kdc,o=org
Password for "cn=admin,o=org": password entered
                        Service dn: cn=service-kdc,o=org
                      Service type: kdc
                 Service host list:
                     Realm DN list: cn=ATHENA.MIT.EDU,cn=Kerberos,cn=Security
```

EXAMPLE 16 Using destroy_service

The following is an example of the use of the destroy_service command.

```
# kdb5_ldap_util -D cn=admin,o=org destroy_service \
cn=service-kdc,o=org
Password for "cn=admin,o=org": password entered
This will delete the service object 'cn=service-kdc,o=org', are you sure?
(type 'yes' to confirm)? yes
** service object 'cn=service-kdc,o=org' deleted.
```

EXAMPLE 17 Using list_service

The following is an example of the use of the list_service command.

kdb5_ldap_util(1M)

EXAMPLE 17 Using `list_service` *(Continued)*

```
# kdb5_ldap_util -D cn=admin,o=org list_service
Password for "cn=admin,o=org": password entered
cn=service-kdc,o=org
cn=service-adm,o=org
cn=service-pwd,o=org
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/security/kerberos-5
Interface Stability	Volatile

See Also kinit(1), kadmin(1M), kdc.conf(4), attributes(5)

Name kdb5_util – Kerberos Database maintenance utility

Synopsis /usr/sbin/kdb5_util [-d *dbname*] [-k *mkeytype*] [-kv *mkeyVNO*] [-m]
            [-M *mkeyname*] [-P *password*] [-r *realm*] [-sf *stashfilename*]
            [-x *db_args*]... *cmd*

Description The kdb5_util utility enables you to create, dump, load, and destroy the Kerberos V5
            database. You can also use kdb5_util to create a stash file containing the Kerberos database
            master key.

Options The following options are supported:

   -d *dbname*
      Specify the database name. .db is appended to whatever name is specified. You can specify
      an absolute path. If you do not specify the -d option, the default database name is
      /var/krb5/principal.

   -k *mkeytype*
      Specify the master key type. Valid values are des3-cbc-sha1, des-cbc-crc, des-cbc-md5,
      des-cbc-raw, arcfour-hmac-md5, arcfour-hmac-md5-exp, aes128-cts-hmac-sha1-96,
      and aes256-cts-hmac-sha1-96.

   -m
      Enter the master key manually.

   -M *mkeyname*
      Specify the master key name.

   -P *password*
      Use the specified *password* instead of the stash file.

   -r *realm*
      Use *realm* as the default database realm.

   -sf *stashfile_name*
      Specifies the stash file of the master database password.

   -x *db_args*
      Pass database-specific arguments to kadmin. Supported arguments are for LDAP and the
      Berkeley-db2 plug-in. These arguments are:

      binddn=*binddn*
         LDAP simple bind DN for authorization on the directory server. Overrides the
         ldap_kadmind_dn parameter setting in krb5.conf(4).

      bindpwd=*bindpwd*
         Bind password.

      dbname=*name*
         For the Berkeley-db2 plug-in, specifies a name for the Kerberos database.

nconns=*num*
> Maximum number of server connections.

port=*num*
> Directory server connection port.

Operands The following operands are supported:

cmd
> Specifies whether to create, destroy, dump, or load the database, or to create a stash file.

> You can specify the following commands:

create -s
> Creates the database specified by the -d option. You will be prompted for the database master password. If you specify -s, a stash file is created as specified by the -f option. If you did not specify -f, the default stash file name is /var/krb5/.k5.realm. If you use the -f, -k, or -M options when you create a database, then you must use the same options when modifying or destroying the database.

destroy
> Destroys the database specified by the -d option.

stash
> Creates a stash file. If -f was not specified, the default stash file name is /var/krb5/.k5.realm. You will be prompted for the master database password. This command is useful when you want to generate the stash file from the password.

dump [-old] [-b6] [-b7] [-ov] [-r13] [-verbose] [-mkey_convert] [-new_mkey_file *mkey_file*] [-rev] [-recurse] [*filename* [*principals*...]]
> Dumps the current Kerberos and KADM5 database into an ASCII file. By default, the database is dumped in current format, "kdb5_util load_dumpversion 6". If *filename* is not specified or is the string "-", the dump is sent to standard output. Options are as follows:

> -old
> > Causes the dump to be in the Kerberos 5 Beta 5 and earlier dump format ("kdb5_edit load_dump version 2.0").

> -b6
> > Causes the dump to be in the Kerberos 5 Beta 6 format ("kdb5_edit load_dump version 3.0").

> -b7
> > Causes the dump to be in the Kerberos 5 Beta 7 format ("kdb5_util load_dump version 4"). This was the dump format produced on releases prior to 1.2.2.

> -ov
> > Causes the dump to be in ovsec_adm_export format.

-r13

    Causes the dump to be in the Kerberos 5 1.3 format ("`kdb5_util load_dump`
    `version 5`"). This was the dump format produced on releases prior to 1.8.

-verbose

    Causes the name of each principal and policy to be displayed as it is dumped.

-mkey_convert

    Prompts for a new master key. This new master key will be used to re-encrypt the key
    data in the dumpfile. The key data in the database will not be changed.

-new_mkey_file *mkey_file*

    The filename of a stash file. The master key in this stash file will be used to re-encrypt
    the key data in the dumpfile. The key data in the database will not be changed.

-rev

    Dumps in reverse order. This might recover principals that do not dump normally,
    in cases where database corruption has occured.

-recurse

    Causes the dump to walk the database recursively (`btree` only). This might recover
    principals that do not dump normally, in cases where database corruption has
    occurred. In cases of such corruption, this option will probably retrieve more
    principals than will the -rev option.

load [-old] [-b6] [-b7] [-ov] [-r13] [-hash] [-verbose] [-update] *filename dbname*
[*admin_dbname*]

    Loads a database dump from *filename* into *dbname*. Unless the -old or -b6 option is
    specified, the format of the dump file is detected automatically and handled
    appropriately. Unless the -update option is specified, load creates a new database
    containing only the principals in the dump file, overwriting the contents of any existing
    database. The -old option requires the database to be in the Kerberos 5 Beta 5 or earlier
    format ("kdb5_edit load_dump version 2.0").

-b6

    Requires the database to be in the Kerberos 5 Beta 6 format ("`kdb5_edit load_dump`
    `version 3.0`").

-b7

    Requires the database to be in the Kerberos 5 Beta 7 format ("`kdb5_util load_dump`
    `version 4`").

-ov

    Requires the database to be in `ovsec_adm_import` format. Must be used with the
    -update option.

-hash

    Requires the database to be stored as a hash. If this option is not specified, the
    database will be stored as a `btree`. This option is not recommended, as databases
    stored in hash format are known to corrupt data and lose principals.

-r13

    Causes the dump to be in the Kerberos 5 1.3 format ("kdb5_util load_dump version 5"). This was the dump format produced on releases prior to 1.8.

-verbose

    Causes the name of each principal and policy to be displayed as it is dumped.

-update

    Records from the dump file are added to or updated in the existing database. Otherwise, a new database is created containing only what is in the dump file and the old one is destroyed upon successful completion.

filename

    Required argument that specifies a path to a file containing database dump.

dbname

    Required argument that overrides the value specified on the command line or overrides the default.

admin_dbname

    Optional argument that is derived from *dbname* if not specified.

add_mkey [-e *etype*] [-s]

    Adds a new master key to the K/M (master key) principal. Existing master keys will remain. The -e *etype* option allows specification of the enctype of the new master key. The -s option stashes the new master key in a local stash file which will be created if it does not already exist.

use_mkey *mkeyVNO* [*time*]

    Sets the activation time of the master key specified by *mkeyVNO*. Once a master key is active (that is, its activation time has been reached) it will then be used to encrypt principal keys either when the principal keys change, are newly created, or when the update_princ_encryption command is run. If the *time* argument is provided, that will be the activation time; otherwise the current time is used by default. The format of the optional time argument is that specified in the Time Formats section of the kadmin(1M) man page.

list_mkeys

    List all master keys from most recent to earliest in K/M principal. The output will show the KVNO, enctype and salt for each mkey, similar to kadmin getprinc output. An asterisk (*) following an mkey denotes the currently active master key.

purge_mkeys [-f] [-n] [-v]

    Delete master keys from the K/M principal that are not used to protect any principals. This command can be used to remove old master keys from a K/M principal once all principal keys are protected by a newer master key.

    -f

        Does not prompt user.

-n

 Does a dry run, shows master keys that would be purged, but does not actually purge any keys.

-v

 Verbose output.

update_princ_encryption [-f] [-n] [-v] [*princ-pattern*]

 Update all principal records (or only those matching the *princ-pattern* glob pattern) to re-encrypt the key data using the active database master key, if they are encrypted using older versions, and give a count at the end of the number of principals updated. If the -f option is not given, ask for confirmation before starting to make changes. The -v option causes each principal processed (each one matching the pattern) to be listed, and an indication given as to whether it needed updating or not. The -n option causes the actions not to be taken, only the normal or verbose status messages displayed; this implies -f, since no database changes will be performed and thus there is little reason to seek confirmation.

Examples   EXAMPLE 1   Creating File that Contains Information about Two Principals

The following example creates a file named slavedata that contains the information about two principals, jdb@ACME.COM and pak@ACME.COM.

```
# /usr/krb5/bin/kdb5_util dump -verbose slavedata
jdb@ACME.COM pak@ACME.COM
```

Files   /var/krb5/principal
 Kerberos principal database.

/var/krb5/principal.kadm5
 Kerberos administrative database. Contains policy information.

/var/krb5/principal.kadm5.lock
 Lock file for the Kerberos administrative database. This file works backwards from most other lock files (that is, kadmin exits with an error if this file does not exist).

/var/krb5/principal.ulog
 The update log file for incremental propagation.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/security/kerberos-5
Interface Stability	Committed

See Also   kpasswd(1), gkadmin(1M), kadmin(1M), kadmind(1M), kadmin.local(1M), kdb5_ldap_util(1M), kproplog(1M), kadm5.acl(4), kdc.conf(4), attributes(5), kerberos(5)

Notes The global `-f` is made obsolete with the `-sf` argument for specifying a non-default stash file location. The global `-f` argument might be removed in a future release of the Solaris operating system. Use caution in specifying `-f` as it has different semantics in subcommands as distinguished from its use as a global argument.

Name kdcmgr – set up a Kerberos Key Distribution Center (KDC)

Synopsis /usr/sbin/kdcmgr [-a *admprincipal*] [-e *enctype*]
                    [-h] [-p *pwfile*] [-r *realm*] *subcommand*

Description Use the kdcmgr utility to do the following:

- Configure a master Key Distribution Center (KDC) server.

- Configure a slave KDC. This assumes that a master KDC has already been configured. The default propagation method configured is incremental propagation. See kpropd(1M).

- Specify a list of slave KDCs to configure service principals and create access control list for those slaves on the master KDC.

If you specify no options, kdcmgr prompts you for required information, including a password to generate the master key and a password for the administrative principal. When you specify sufficient options, you are still prompted for these passwords, unless you specified the -p *pwfile* option.

The kdcmgr utility must be run as superuser or by someone who has the Primary Administrator role. The command must be run on the server from which it is invoked.

Note that kdcmgr requires the user to enter sensitive information, such as the password used to generate the database's master key and the password for the administrative principal. Great care must be taken to ensure that the connection to the server is secured over the network, by using a protocol such as ssh(1).

You must also exercise great care when selecting the administrative and master key passwords. They should be derived from non-dictionary words and a long string of characters consisting of all of the following character classes:

- special characters (for example, !@#$%^&*)
- numerals (0-9)
- uppercase letters
- lowercase letters

Options The following options are supported:

-a *admprincipal*
  When creating a master KDC, specifies the administrative principal, *admprincipal*, that will be created.

  When creating a slave KDC, *admprincipal* is used to authenticate as the administrative principal.

  If you omit -a, the suggested default administrative principal name is the output of logname(1) appended by /admin.

-e *enctype*

Specifies the encryption type to be used when creating the key for the master key, which is used to encrypt all principal keys in the database. The set of valid encryption types used here are described in `krb5.conf(4)` under the `permitted_enctypes` option. Note that the encryption type specified here must be supported on all KDCs or else they will not be able to decrypt any of the principal keys. Solaris 9 and earlier releases support only the `des-cbc-crc` encryption type for the master key. Therefore, if any of the master or slave KDCs are of these older releases, then `-e des-cbc-crc` would need to be specified on all KDCs configured with `kdcmgr`.

The default encryption type is `aes256-cts-hmac-sha1-96`.

-h

Displays usage information for `kdcmgr`.

-p *pwfile*

Provides the location of the password file that contains the password used to create the administrative principal and/or master key.

Warning: This option should be used with great care. Make sure that this *pwfile* is accessible only by a privileged user and on a local file system. Once the KDC has been configured, you should remove *pwfile*.

-r *realm*

Set the default realm for this server.

If the `-r` option is not specified, `kdcmgr` attempts to obtain the machine's local domain name by submitting the canonical form of the machine's host name to DNS and using the return value to derive the domain name. If successful, the domain name is converted to uppercase and proposed as the default realm name.

Subcommands The following subcommands are supported:

create [*master*]
create [-m *masterkdc*] slave

Creates a KDC. If no option is specified, an attempt to create a master KDC is made.

create [*master*]

Create a master KDC. Upon successful configuration the `krb5kdc(1M)` and `kadmind(1M)` are enabled on the machine.

create [-m *masterkdc*] slave

Configures a slave KDC. After configuration, the `krb5kdc(1M)` and `kpropd(1M)` services are enabled on the machine.

masterkdc specifies the master KDC to authenticate and with which to perform administrative tasks. If the `-m` option is not specified, you are prompted for a master KDC host name.

destroy

Remove all Kerberos configuration and database files associated with the KDC server. A confirmation is required before these files are deleted.

status

Determines the role of the KDC, master or slave, and outputs this and the state of such associated processes as:

- krb5kdc(1M)
- kadmind(1M)
- kpropd(1M)

The subcommand also displays information on incremental propagation if the configuration has this feature enabled, as well as any issues with dependent files.

Examples EXAMPLE 1 Setting up a Master KDC

The following command configures a master KDC with the administrative principal user1/admin and with the realm name EXAMPLE.COM:

$ **kdcmgr -a user1/admin -r EXAMPLE.COM create**

Note that a password will be required to assign to the newly created **user1/admin** principal. The password for the master key will also need to be provided.

EXAMPLE 2 Setting up a Slave KDC

The following command configures a slave KDC, authenticates with the administrative principal user1/admin, specifies kdc1 as the master, and uses the EXAMPLE.COM realm name:

$ **kdcmgr -a user1/admin -r EXAMPLE.COM create -m kdc1 slave**

Note that you must enter the correct password for user1/admin and that the master KDC must already have been created before entering this command. The correct password for the master key is also required.

Files /etc/krb5/krb5.conf
    Main Kerberos configuration file.

/etc/krb5/kdc.conf
    KDC configuration, used by both master and slave servers.

/etc/krb5/krb5.keytab
    Default location of the local host's service keys.

/etc/krb5/kadm5.acl
    Kerberos administrative access control list (ACL).

/etc/krb5/kadm5.keytab
    Service keys specific to kadmind(1M).

/var/krb5/principal
   Kerberos principal database.

/var/krb5/principal.kadm5
   Kerberos policy database.

/etc/krb5/kpropd.acl
   Used by slaves to indicate from which server to receive updates.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/security/kerberos-5
Interface Stability	See below

The command line interface (CLI) is Uncommitted. The CLI output is Not an Interface.

See Also logname(1), ssh(1), kadmin(1M), kadmind(1M), kdb5_util(1M), kdb5_ldap_util(1M), kpropd(1M), krb5kdc(1M), ping(1M), svcadm(1M), kdc.conf(4), krb5.conf(4), attributes(5)

Name kernel – UNIX system executable file containing basic operating system services

Synopsis kernel-name [-asrvx] [-m *smf_options*] [-i *altinit*]

Description The operating system image, or kernel, is the collection of software comprising the image files (unix and genunix) and the modules loaded at any instant in time. The system will not function without a kernel to control it.

The kernel is loaded by the boot(1M) command in a machine-specific way. The kernel may be loaded from disk, CD-ROM, or DVD (diskfull boot) or over the network (diskless boot). In either case, the directories under /platform and /kernel must be readable and must contain executable code which is able to perform the required kernel service. If the -a flag is given, the user is able to supply different pathnames for the default locations of the kernel and modules. See boot(1M) for more information on loading a specific kernel.

The moddir variable contains a list of module directories separated by whitespace. moddir can be set in the /etc/system file. The minimal default is:

/platform/platform-name/kernel /kernel /usr/kernel

This default can be supplemented by a specific platform. It is common for many SPARC systems to override the default path with:

/platform/*platform-name*/kernel:/platform/*hardware-class-name*\
    /kernel:/kernel:/usr/kernel

where *platform-name* can be found using the -i option of uname(1), and *hardware-class-name* can be found using the -m option of uname(1).

The kernel configuration can be controlled using the /etc/system file (see system(4)).

genunix is the platform-independent component of the base kernel.

Options The following options are supported:

-a

Asks the user for configuration information, such as where to find the system file, where to mount root, and even override the name of the kernel itself. Default responses will be contained in square brackets ([ ]), and the user may simply enter RETURN to use the default response (note that RETURN is labeled ENTER on some keyboards). To help repair a damaged /etc/system file, enter **/dev/null** at the prompt that asks for the pathname of the system configuration file. See system(4).

-i *altinit*

Select an alternative executable to be the primordial process. *altinit* must be a valid path to an executable. The default primordial process is init(1M).

-m *smf_options*

The *smf_options* include two categories of options to control booting behavior of the service management facility: recovery options and messages options.

Message options determine the type and amount of messages that smf(5) displays during boot. Service options determine the services which are used to boot the system.

Recovery options

debug

Prints standard per-service output and all svc.startd messages to log.

milestone=[milestone]

Boot with some SMF services temporarily disabled, as indicated by *milestone*. *milestone* can be "none", "single-user", "multi-user", "multi-user-server", or "all". See the milestone subcommand of svcadm(1M).

Messages options

quiet

Prints standard per-service output and error messages requiring administrative intervention.

verbose

Prints standard per-service output with more informational messages.

-r

Reconfiguration boot. The system will probe all attached hardware devices and configure the logical namespace in /dev. See add_drv(1M) and rem_drv(1M) for additional information about maintaining device drivers.

-s

Boots only to init level 's'. See init(1M).

-v

Boots with verbose messages enabled. If this flag is not given, the messages are still printed, but the output is directed to the system logfile. See syslogd(1M).

-x

Does not boot in clustered mode. This option only has an effect when a version of Sun Cluster software that supports this option has been installed.

Examples See boot(1M) for examples and instructions on how to boot.

Files /kernel

Contains kernel components common to all platforms within a particular instruction set that are needed for booting the system. of the core image file.

/platform/*platform-name*/kernel

The platform-specific kernel components.

/platform/*hardware-class-name*/kernel

The kernel components specific to this hardware class.

/usr/kernel

    Contains kernel components common to all platforms within a particular instruction set.

The directories in this section can potentially contain the following subdirectories:

drv

    Loadable device drivers

exec

    The modules that execute programs stored in various file formats.

fs

    File system modules

misc

    Miscellaneous system-related modules

sched

    Operating system schedulers

strmod

    System V STREAMS loadable modules

sys

    Loadable system calls

SPARC   cpu

    Processor specific modules

tod

    Time-Of-Day hardware interface modules

As only 64-bit SPARC platforms are supported, all SPARC executable modules are contained within sparcv9 directories in the directories listed above.

x86   mach

    x86 hardware support

Modules comprising the 32-bit x86 kernel are contained in the above directories, with the 64-bit x86 kernel components contained within amd64 subdirectories.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/library/processor, system/library/processorx

See Also kmdb(1), uname(1), isainfo(1), add_drv(1M), boot(1M), init(1M), rem_drv(1M), savecore(1M), svc.startd(1M), svcadm(1M), syslogd(1M), system(4), attributes(5), smf(5), devfs(7FS)

SPARC Only   monitor(1M)

Diagnostics   The kernel gives various warnings and error messages. If the kernel detects an unrecoverable fault, it will panic or halt.

Notes   Reconfiguration boot will, by design, not remove /dev entries for some classes of devices that have been physically removed from the system.

Name keyserv – server for storing private encryption keys

Synopsis `keyserv [-c] [-d | -e] [-D] [-n] [-s` *sizespec*`]`

Description keyserv is a daemon that is used for storing the private encryption keys of each user logged into the system. These encryption keys are used for accessing secure network services such as secure NFS.

Normally, root's key is read from the file /etc/.rootkey when the daemon is started. This is useful during power-fail reboots when no one is around to type a password.

keyserv does not start up if the system does not have a secure rpc domain configured. Set up the domain name by using the /usr/bin/domainname command. Usually the svc:/system/identity:domain service reads the domain from /etc/defaultdomain. Invoking the domainname command without arguments tells you if you have a domain set up.

The /etc/default/keyserv file contains the following default parameter settings. See Files.

ENABLE_NOBODY_KEYS   Specifies whether default keys for nobody are used. ENABLE_NOBODY_KEYS=NO is equivalent to the -d command-line option. The default value for ENABLE_NOBODY_KEYS is YES.

Options The following options are supported:

-c   Do not use disk caches. This option overrides any -s option.

-D   Run in debugging mode and log all requests to keyserv.

-d   Disable the use of default keys for nobody. See Files.

-e   Enable the use of default keys for nobody. This is the default behavior. See Files.

-n   Root's secret key is not read from /etc/.rootkey. Instead, keyserv prompts the user for the password to decrypt root's key stored in the publickey database and then stores the decrypted key in /etc/.rootkey for future use. This option is useful if the /etc/.rootkey file ever gets out of date or corrupted.

-s *sizespec*   Specify the size of the extended Diffie-Hellman common key disk caches. The *sizespec* can be one of the following forms:

        mechtype=size   size is an integer specifying the maximum number of entries in the cache, or an integer immediately followed by the letter *M*, denoting the maximum size in MB.

        size   This form of *sizespec* applies to all caches.

        Note that the des mechanism, AUTH_DES, does not use a disk cache.

Files /etc/.rootkey

/etc/default/keyserv Contains default settings. You can use command-line options to override these settings.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also keylogin(1), svcs(1), keylogout(1), svcadm(1M), publickey(4), attributes(5), smf(5)

Notes The keyserv service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rpc/keyserv:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name killall – kill all active processes

Synopsis /usr/sbin/killall [*signal*]

Description killall is used by shutdown(1M) to kill all active processes not directly related to the shutdown procedure.

killall terminates all processes with open files so that the mounted file systems will be unbusied and can be unmounted.

killall sends *signal* (see kill(1)) to the active processes. If no *signal* is specified, a default of 15 is used.

The killall command can be run only by the super-user.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also kill(1), ps(1), fuser(1M), shutdown(1M), signal(3C), attributes(5)

Name kmscfg – configure the PKCS#11 KMS provider

Synopsis kmscfg

kmscfg -p[rofile] *Profile_Name*

kmscfg -a[gent] *Agent_ID*

kmscfg -i[paddr] *Agent_Address*

kmscfg -t[imeout] *Transaction_Timeout*

kmscfg -f[ailover] *Failover_Limit*

kmscfg -d[iscovery] *Discovery_Freq*

Description The kmscfg command is used to initialize the PKCS#11 KMS provider (pkcs11_kms) for use with the Solaris Cryptographic Framework. In order for the KMS provider to communicate with the Oracle Key Manager (OKM), it must have some configuration information available. This configuration data contains information such as the name of the profile to be used, the name of the OKM Agent, the IP address of an OKM appliance (KMA) and some other parameters (see SYNOPSIS).

By default, kmscfg stores the configuration information in /var/user/kms/$USERNAME. This directory will be created if it is not already present. If the configuration is already detected, the user will be given the option to override the existing data. The default location can be overriden by using the KMSTOKEN_DIR environment variable, which must be set prior to invoking kmscfg.

Prior to running kmscfg, the OKM administrator must have performed the required initialization and configuration steps on the appliance itself to setup the individual Profiles and Agents that PKCS11 KMS consumers will use. The instructions for configuring these profiles are available in the *Oracle Key Manager Administration Guide* on the Oracle website (http://docs.oracle.com).

Once the administrator has configured the KMA, the necessary identification information (profile name, agent ID, IP address) must be provided to be able to run kmscfg and initialize the provider on the Oracle Solaris client.

Options The options listed below are supported. Note that, if the profile, agent id, or KMA address are not specified on the command line, kmscfg prompts you to provide these items.

-a *Agent_ID*
    The user agent ID as configured on the OKM to be used for the KMS token being configured. It is not unusual for the Profile and Agent ID to be the same, for example, MyAgent.

-d *Discovery_Freq*
    Frequency in seconds with which the client will try to discover the availability of other KMAs in an OKM cluster. If not specified, *Discovery_Freq* defaults to 10.

-f *Failover_Limit*
The number of times communications to the KMA can fail before the client gives up. If not specified, *Failover_Limit* defaults to 3.

-i *Agent_Addr*
Address of the KMA. This can be an IPv4 address (*xxx.xxx.xxx.xxx*) or an IPv6 address. A fully qualified host name can also be used, as long as that name can be resolved by the name service configured on the client. If an OKM cluster is being used, the address of any member of the cluster can be specified.

-p *Profile_Name*
A name for the profile to be used for the KMS token being configured. Typically, the profile name and the Agent ID will be the same, though they are not required to be.

-t *Transaction_Timeout*
Timeout period for individual KMS commands, in seconds. If not specified, this value defaults to 10.

Exit Status After completing the requested operation, kmscfg exits with one of the following status values.

0
Successful termination.

1
Failure. The requested operation could not be completed.

Files /var/kms/$USERNAME
Default KMS token configuration directory.

${KMSTOKEN_DIR}
Alternate KMS token configuration directory.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	/system/library/security/crypto/pkcs11_kms
Interface Stability	Volatile

See Also pktool(1), attributes(5), pkcs11_kms(5)

Oracle Key Manager Administration Guide (http://docs.oracle.com)

Notes PKCS#11 clients require Oracle Key Manager Software Version 2.4 be installed on the OKM.

If PKCS#11 clients will use the same Agent ID from multiple systems, that agent should be created without the "One Time Passphrase" flag set. This option will not be available in OKM clusters with some members running versions of the OKM software prior to 2.4. Please refer to the *OKM Administration Guide* for assistance in creating Agents.

OKM Agents must have a Default Key Group assigned prior to being used to create keys with a PKCS#11 client. If a Default Key Group is not assigned to the Agent, operations will fail with a CKR_PIN_INCORRECT error. Please refer to the *OKM Administration Guide* for assistance in assigning key groups to agents.

Name kprop – Kerberos database propagation program

Synopsis /usr/lib/krb5/kprop [-d] [-f *file*] [-p *port-number*]
[-r *realm*] [-s *keytab*] [*host*]

Description kprop is a command-line utility used for propagating a Kerberos database from a master KDC
to a slave KDC. This command must be run on the master KDC. See the *Solaris System
Administration Guide, Vol. 6* on how to set up periodic propagation between the master KDC
and slave KDCs.

To propagate a Kerberos database, the following conditions must be met:

- The slave KDCs must have an /etc/krb5/kpropd.acl file that contains the principals for
  the master KDC and all the slave KDCs.

- A keytab containing a host principal entry must exist on each slave KDC.

- The database to be propagated must be dumped to a file using kdb5_util(1M).

Options The following options are supported:

-d   Enable debug mode. Default is debug mode disabled.

-f *file*   File to be sent to the slave KDC. Default is the
                  /var/krb5/slave_datatrans file.

-p *port-number*   Propagate *port-number*. Default is port 754.

-r *realm*   Realm where propagation will occur. Default *realm* is the local realm.

-s *keytab*   Location of the keytab. Default location is /etc/krb5/krb5.keytab.

Operands The following operands are supported:

host   Name of the slave KDC.

Examples EXAMPLE 1   Propagating the Kerberos Database

The following example propagates the Kerberos database from the /tmp/slave_data file to
the slave KDC london. The machine london must have a host principal keytab entry and the
kpropd.acl file must contain an entry for the all the KDCs.

kprop -f /tmp/slave_data london

Files /etc/krb5/kpropd.acl   List of principals of all the KDCs; resides on each slave
                                KDC.

/etc/krb5/krb5.keytab   Keytab for Kerberos clients.

/var/krb5/slave_datatrans   Kerberos database propagated to the KDC slaves.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/security/kerberos-5

See Also kpasswd(1), svcs(1), gkadmin(1M), inetadm(1M), inetd(1M), kadmind(1M), kadmin.local(1M), kdb5_util(1M), svcadm(1M), kadm5.acl(4), kdc.conf(4), attributes(5), kerberos(5), smf(5)

Oracle Solaris Administration: Security Services

Name kpropd – Kerberos propagation daemon for slave KDCs

Synopsis /usr/lib/krb5/kpropd [-d] [-f *temp_dbfile*] [-F *dbfile*]
            [-p *kdb_util*] [-P *port_number*] [-r *realm*]
            [-s *srv_tabfile*] [-S] [-a *acl_file*]

Description The kpropd command runs on the slave KDC server. It listens for update requests made by
kprop(1M) from the master KDC and periodically requests incremental updates from the
master KDC.

When the slave receives a kprop request from the master, kpropd copies principal data to a
temporary text file. Next, kpropd invokes kdb5_util(1M) (unless a different database utility is
selected) to load the text file in database format.

When the slave periodically requests incremental updates, kpropd update its principal.ulog
file with any updates from the master. kproplog(1M) can be used to view a summary of the
update entry log on the slave KDC.

kpropd is not configured for incremental database propagation by default. These settings can
be changed in the kdc.conf(4) file:

sunw_dbprop_enable = [true | false]	Enables or disables incremental database propagation. Default is false.
sunw_dbprop_slave_poll = N[s, m, h]	Specifies how often the slave KDC polls for any updates that the master might have. Default is 2m (two minutes).

The kiprop/<*hostname*>@<*REALM*> principal must exist in the slave's keytab file to enable
the master to authenticate incremental propagation requests from the slave. In this syntax,
<*hostname*> is the slave KDC's host name and <*REALM*> is the realm in which the slave KDC
resides.

Options The following options are supported:

-d	Enable debug mode. Default is debug mode disabled.
-f *temp_dbfile*	The location of the slave's temporary principal database file. Default is /var/krb5/from_master.
-F *dbfile*	The location of the slave's principal database file. Default is /var/krb5/principal.
-p *kdb_util*	The location of the Kerberos database utility used for loading principal databases. Default is /usr/sbin/kdb5_util.
-P *port_number*	Specifies the port number on which kpropd will listen. Default is 754 (service name: krb5_prop).
-r *realm*	Specifies from which Kerberos realm kpropd will receive information. Default is specified in /etc/krb5/krb5.conf.

-s *srv_tabfile*		The location of the service table file used to authenticate the kpropd daemon.
-S		Run the daemon in standalone mode, instead of having inetd listen for requests. Default is non-standalone mode.
-a *acl_file*		The location of the kpropd's access control list to verify if this server can run the kpropd daemon. The file contains a list of principal name(s) that will be receiving updates. Default is /etc/krb5/kpropd.acl.

Files

/var/krb5/principal	Kerberos principal database.
/var/krb5/principal.ulog	The update log file.
/etc/krb5/kdc.conf	KDC configuration information.
/etc/krb5/kpropd.acl	List of principals of all the KDCs; resides on each slave KDC.
/var/krb5/from_master	Temporary file used by kpropd before loading this to the principal database.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/security/kerberos-5
Interface Stability	Committed

See Also kdb5_util(1M), kprop(1M), kproplog(1M), kdc.conf(4), krb5.conf(4), attributes(5), kerberos(5)

Notes The kprop service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/network/security/krb5_prop:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

Name   kproplog – display the contents of the Kerberos principal update log

Synopsis   /usr/sbin/kproplog [-h | -e *num*]

Description   The kproplog displays the contents of the Kerberos principal update log to standard output. This command can be used to keep track of the incremental updates to the principal database, which is enabled by default. The /var/krb5/principal.ulog file contains the update log maintained by the kadmind(1M) process on the master KDC server and the kpropd(1M) process on the slave KDC servers. When updates occur, they are logged to this file. Subsequently any KDC slave configured for incremental updates will request the current data from the master KDC and update their principal.ulog file with any updates returned.

The kproplog command can only be run on a KDC server by someone with privileges comparable to the superuser. It will display update entries for that server only.

If no options are specified, the summary of the update log is displayed. If invoked on the master, all of the update entries are also displayed. When invoked on a slave KDC server, only a summary of the updates are displayed, which includes the serial number of the last update received and the associated time stamp of the last update.

Options   The following options are supported:

-h   Display a summary of the update log. This information includes the database version number, state of the database, the number of updates in the log, the time stamp of the first and last update, and the version number of the first and last update entry.

-e *num*   Display the last *num* update entries in the log. This is useful when debugging synchronization between KDC servers.

-v   Display individual attributes per update. If more than one -v is specified then very verbose output is displayed. An example of the output generated for one entry:

```
Update Entry
    Update serial # : 4
    Update operation : Add
    Update principal : test@EXAMPLE.COM
    Update size : 424
    Update committed : True
    Update time stamp : Fri Feb 20 23:37:42 2004
    Attributes changed : 6
            Principal
            Key data
            Password last changed
            Modifying principal
            Modification time
            TL data
```

Files /var/krb5/principal.ulog   The update log file for incremental propagation.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/security/kerberos-5
Interface Stability	Committed

See Also kpasswd(1), gkadmin(1M), kadmin(1M), kadmind(1M), kdb5_util(1M), kprop(1M), kpropd(1M), kadm5.acl(4), kdc.conf(4), attributes(5), kerberos(5)

Name   krb5kdc – KDC daemon

Synopsis   /usr/lib/krb5/krb5kdc [-d *dbpath*] [-r *realm*] [-m]
                [-k *masterenctype*] [-M *masterkeyname*]
                [-p *port*] [-n] [-x *db_args*] [-P *pid_file*]

Description   krb5kdc is the daemon that runs on the master and slave KDCs to process the Kerberos
tickets. For Kerberos to function properly, krb5kdc must be running on at least one KDC that
the Kerberos clients can access. Prior to running krb5kdc, you must initialize the Kerberos
database using kdb5_util(1M). See the *Oracle Solaris Administration: Security Services* for
information regarding how to set up KDCs and initialize the Kerberos database.

Options   The following options are supported:

-d *dbpath*
    Specify the path to the database; default value is /var/krb5.

-k *masterenctype*
    Specify the encryption type for encrypting the database. The default value is des-cbc-crc.
    des3-cbc-sha1, arcfour-hmac-md5, arcfour-hmac-md5-exp,
    aes128-cts-hmac-sha1-96, and aes256-cts-hmac-sha1-96 are also valid.

-m
    Specify that the master key for the database is to be entered manually.

-M *masterkeyname*
    Specify the principal to retrieve the master Key for the database.

-n
    Specify that krb5kdc should not detach from the terminal.

-p *port*
    Specify the port that will be used by the KDC to listen for incoming requests.

-P *pid_file*
    Tells the KDC to write its PID (followed by a newline) into *pid_file* after it starts up. This
    can be used to identify whether the KDC is still running and to allow init scripts to stop
    the correct process.

-r *realm*
    Specify the realm name; default is the local realm name.

-x *db_args*
    Pass database-specific arguments to kadmin. Supported arguments are for the LDAP
    plug-in. These arguments are:

    binddn=*binddn*
        Specifies the DN of the object used by the KDC server to bind to the LDAP server. This
        object should have the rights to read the realm container, principal container and the
        subtree that is referenced by the realm. Overrides the ldap_kdc_dn parameter setting in
        krb5.conf(4).

bindpwd=*bindpwd*
> Specifies the password for the above-mentioned *binddn*. It is recommended not to use this option. Instead, the password can be stashed using the stashsrvpw command of kdb5_ldap_util(1M).

nconns=*num*
> Specifies the number of connections to be maintained per LDAP server.

host=*ldapuri*
> Specifies, by an LDAP URI, the LDAP server to which to connect.

Files /var/krb5/principal.db
> Kerberos principal database.

/var/krb5/principal.kadm5
> Kerberos administrative database. This file contains policy information.

/var/krb5/principal.kadm5.lock
> Kerberos administrative database lock file. This file works backwards from most other lock files (that is, kadmin will exit with an error if this file does *not* exist).

/etc/krb5/kdc.conf
> KDC configuration file. This file is read at startup.

/etc/krb5/kpropd.acl
> File that defines the access control list for propagating the Kerberos database using kprop.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/security/kerberos-5

See Also kill(1), kpasswd(1), gkadmin(1M), kadmind(1M), kadmin.local(1M), kdb5_util(1M), kdb5_ldap_util(1M), logadm(1M), krb5.conf(4), attributes(5), krb5envvar(5), kerberos(5),

Oracle Solaris Administration: Security Services

Notes The following signal has the specified effect when sent to the server process using the kill(1) command:

SIGHUP
> krb5kdc closes and re-opens log files that it directly opens. This can be useful for external log-rotation utilities such as logadm(1M). If this method is used for log file rotation, set the krb5.conf(4) kdc_rotate period relation to never.

Name ksslcfg – enable and configure SMF instance of Kernel SSL

Synopsis ksslcfg create -f pkcs11 -T *token_label* -C *certificate_label*
[-d *softtoken_directory*]
-p *password_file* [-u *username*]
[-h *ca_certchain_file*] [-c *ciphersuites*]
[-t *ssl_session_cache_timeout*]
[-z *ssl_session_cache_size*] [-v] -x *proxy_port* [*host*] *ssl_port*

ksslcfg create -f pkcs12 -i *cert_and_key_pk12file*
-p *password_file* [-u *username*]
[-c *ciphersuites*] [-t *ssl_session_cache_timeout*]
[-z *ssl_session_cache_size*] [-v] -x *proxy_port* [*host*] *ssl_port*

ksslcfg create -f pem -i *cert_and_key_pemfile*
-p *password_file* [-u *username*]
[-c *ciphersuites*] [-t *ssl_session_cache_timeout*]
[-z *ssl_session_cache_size*] [-v] -x *proxy_port* [*host*] *ssl_port*

ksslcfg delete [-v] [*host*] *ssl_port*

ksslcfg -V

ksslcfg -?

Description ksslcfg manages smf(5) instances for the Kernel SSL proxy module. An SSL-enabled web server can use the services of its Kernel SSL proxy to improve the performance of the HTTPS packets processing. It does so by creating an instance of the Kernel SSL service, specifying the SSL proxy port and parameters, and by listening on the proxy port.

The create subcommand creates an instance and enables the service for the given address and SSL port.

The delete subcommand disables the service for the given address and port, if it is enabled, and deletes the instance from the SMF repository.

ksslcfg can be run as root or by other users assigned to the Network Security profile. See rbac(5) and user_attr(4).

After ksslcfg successfully configures the service in the kernel, the proxy application must be started, or restarted if it is already running.

You must run ksslcfg to configure your Kernel SSL proxy before you start your application.

ksslcfg allows you to specify an *ssl_port* operand, described under OPERANDS, and, with the -x option, a *proxy_port* value. When specified for use with the Kernel SSL proxy, these values cannot also be configured for the Solaris Network Cache and Acceleration (NCA) feature.

The Fault Managed Resource Identifier (FMRI) for the kernel SSL proxy instances is svc://network/ssl/proxy. ksslcfg creates an instance of that service unique to the

combination of host and SSL port. Instance FMRIs for particular proxy entries can be found with svcs(1) and used for dependencies of other services. The state of the service instance tracks in-kernel configuration only. It does not reflect the presence or state of the application listening on the proxy port.

Options The following options are supported:

-c *ciphersuites*

   Set of ciphers a client is allowed to negotiate in a sorted order. The supported SSL version3 and TLS ciphers are listed below. Note that the names are case-insensitive.

   ```
   rsa_rc4_128_sha
   rsa_rc4_128_md5
   rsa_aes_256_cbc_sha
   rsa_aes_128_cbc_sha
   rsa_3des_ede_cbc_sha
   rsa_des_cbc_sha
   ```

-f *key_format*

   Uses the certificate/key format specified in *key_format*. The supported options are pkcs11, pkcs12, and pem.

-i *key_and_certificate_file*

   When pkcs12 or pem is specified with the -f option, reads a key and a certificate of the web server from *key_and_certificate_file*. This file can also contain any intermediate CA certificates that form the certificate chain to the root CA for the server certificate. These certificates must follow the server certificate in the file and the order must be bottom up: lowest level CA certificate followed by the next higher level CA certificate, and so on.

-C *certificate_label*

   PKCS#11 can store multiple certificates in single token. This option enables you to specify a single certificate, identified by *certificate_label*. This label must match the CKA_LABEL on the certificate object in the token specified by -T. This option is to be used only with -f pkcs11.

-d *softtoken_directory*

   This option is applicable only with the pkcs11 key format, when the token label is the Sun Software PKCS#11 softtoken. Use this option to override the default location of the PKCS#11 softtoken directory ($HOME/.sunw). See pkcs11_softtoken(5).

-h *ca_certchain_file*

   When pkcs11 is specified with the -f option, reads a set of intermediate CA certificates that form the certificate chain to the root CA for the server certificate (specified with the -C option), from *ca_certchain_file*. The file must be in PEM format.

-p *password_file*

   Obtains the password used to encrypt the private key from *password_file*. When using the pkcs11 option (see -f, above), the password is used to authenticate the user to the PKCS #11 token.

-t *ssl_session_cache_timeout*

The timeout value, in seconds, for an SSL session. It corresponds to SSL3SessionTimeout of the Sun ONE web server configuration or SSLSessionCacheTimeout of mod_ssl.

-T *token_label*

When pkcs11 is specified with -f, uses the PKCS#11 token specified in *token_label*. Use cryptoadm list -v to display all PKCS#11 tokens available.

-u *username*

The username of the user who owns the password file. If omitted, the system will try to read the password file as root.

-v

Verbose mode.

-V

Displays the version.

-x *proxy_port*

The SSL proxy port. The port number is designated exclusively for clear-text HTTP communication between the web server and the kernel SSL proxy module. No external HTTP packets are delivered to this port.

-z *ssl_session_cache_size*

The maximum number of SSL sessions that can be cached. It corresponds to SSLCacheEntries of the Sun ONE web server configuration. When this option is not specified, the default is 5000 entries.

-?

Displays the usage of the command.

Operands [*host*] [*ssl_port*]

The address and the port of the web server for which the kernel SSL entry is created. If *host* is omitted, the entry will be used for all requests that arrived at the *ssl_port*, regardless of the destination address. Both a host name and an IP address are acceptable forms for *host*. *ssl_port* is required. Typically, this has a value of 443.

Examples EXAMPLE 1 Create and Enable a Kernel SSL Instance

The following command creates and enables a Kernel SSL instance using a certificate and a key in PKCS#11 format.

```
# ksslcfg create -f pkcs11 -T "Sun Software PKCS#11 softtoken"  \
-C "Server-Cert" -p /some/directory/password -u webservd \
-x 8080 www.mysite.com 443

% svcs svc:/network/ssl/proxy
STATE          STIME    FMRI
online         Sep_27   svc:/network/ssl/proxy:kssl-www-mysite-com-443
```

EXAMPLE 2 Create and Enable a Default Instance for All Addresses

The following command creates and enables a default instance for all addresses from a certificate and key in a pkcs#12 file.

```
# ksslcfg create -x 8888 -f pkcs12 -i /some/directory/keypair.p12 \
    -p /some/directory/password -u webservd 443
```

EXAMPLE 3 Create and Enable an Instance with Specific Cipher Suites

The following command creates and enables an instance with specific cipher suites.

```
# ksslcfg create -x 8080 -f pem \
-i /some/directory/keypair.pem -p /some/directory/password \
-c "rsa_rc4_128_md5,rsa_rc4_128_sha" \
209.249.116.195 443
```

EXAMPLE 4 Disable and Delete an Instance

The following command disables and deletes an instance.

```
# ksslcfg delete www.mysite.com 443
```

EXAMPLE 5 Establishing Dependency of Proxy Application

The sequence of commands shown below establishes a dependency of a proxy application on a KSSL instance. Note that he proxy application should only be started after the SSL kernel proxy instance has been started.

The following commands establish the dependency of an Apache 2.2 web server. KSSL has been configured to listen on SSL port 443 and a wildcard address.

```
# svccfg -s svc:/network/http:apache22
svc:/network/http:apache22> addpg kssl dependency
svc:/network/http:apache22> setprop kssl/entities = fmri:svc:/network/\
ssl/proxy:kssl-INADDR_ANY-443
svc:/network/http:apache22> setprop kssl/grouping = astring: require_all
svc:/network/http:apache22> setprop kssl/restart_on = astring: refresh
svc:/network/http:apache22> setprop kssl/type = astring: service
svc:/network/http:apache22> end
```

Following these commands, enable the web server:

```
# svcadm enable svc:/network/http:apache22
```

If the web server was already running, restart it:

```
# svcadm refresh svc:/network/http:apache22
# svcadm restart svc:/network/http:apache22
```

Exit Status   **0**

Successful completion.

>0

An error occurred.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	See below.

Command line options and the utility name are Committed. The command output, the FMRI service name (svc://network/ssl/proxy), and the FMRI instance's name format are Uncommitted

See Also   svcprop(1), svcs(1), cryptoadm(1M), svcadm(1M), svccfg(1M), user_attr(4), attributes(5), kssl(5), pkcs11_softtoken(5), rbac(5), smf(5), nca(7d)

Chown, P., *Advanced Encryption Standard (AES) Ciphersuites for Transport Layer Security (TLS)*, RFC 3268, June 2002.

Notes   ksslcfg create without an host argument creates an INADDR_ANY smf instance. ksslcfg delete without an host argument deletes only the INADDR_ANY instance. ksslcfg delete needs a host argument to delete any non-INADDR_ANY instance.

On a system with zones(5) installed, the ksslcfg command can be used only in the global zone at this time.

Name   kstat – display kernel statistics

Synopsis   kstat [-lpq] [-T u | d] [-c *class*] [-m *module*]
           [-i *instance*] [-n *name*] [-s *statistic*]
           [interval [count]]

           kstat [-lpq] [-T u | d] [-c *class*]
           [*module*:*instance*:*name*:*statistic*]...
           [interval [count]]

Description   The kstat utility examines the available kernel statistics, or kstats, on the system and reports those statistics which match the criteria specified on the command line. Each matching statistic is printed with its module, instance, and name fields, as well as its actual value.

Kernel statistics may be published by various kernel subsystems, such as drivers or loadable modules; each kstat has a module field that denotes its publisher. Since each module might have countable entities (such as multiple disks associated with the sd(7D) driver) for which it wishes to report statistics, the kstat also has an instance field to index the statistics for each entity; kstat instances are numbered starting from zero. Finally, the kstat is given a name unique within its module.

Each kstat may be a special kstat type, an array of name-value pairs, or raw data. In the name-value case, each reported value is given a label, which we refer to as the statistic. Known raw and special kstats are given statistic labels for each of their values by kstat; thus, all published values can be referenced as *module*:*instance*:*name*:*statistic*.

When invoked without any module operands or options, kstat will match all defined statistics on the system. Example invocations are provided below. All times are displayed as fractional seconds since system boot.

Options   The tests specified by the following options are logically ANDed, and all matching kstats will be selected. A regular expression containing shell metacharacters must be protected from the shell by enclosing it with the appropriate quotes.

The argument for the -c, -i, -m, -n, and -s options may be specified as a shell glob pattern, or a Perl regular expression enclosed in '/' characters.

-c *class*   Displays only kstats that match the specified class. *class* is a kernel-defined string which classifies the "type" of the kstat.

-i *instance*   Displays only kstats that match the specified instance.

-l   Lists matching kstat names without displaying values.

-m *module*   Displays only kstats that match the specified module.

-n *name*   Displays only kstats that match the specified name.

-p   Displays output in parseable format. All example output in this document is given in this format. If this option is not specified, kstat produces output in a human-readable, table format.

-q   Displays no output, but return appropriate exit status for matches against
               given criteria.

-s *statistic*   Displays only kstats that match the specified statistic.

-T d | u   Displays a time stamp before each statistics block, either in date(1) format (d)
               or as an alphanumeric representation of the value returned by time(2) (u).

Operands The following operands are supported:

module:*instance*:*name*:*statistic*   Alternate method of specifying module, instance, name,
                                       and statistic as described above. Each of the module,
                                       instance, name, or statistic specifiers may be a shell glob
                                       pattern or a Perl regular expression enclosed by '/'
                                       characters. It is possible to use both specifier types within a
                                       single operand. Leaving a specifier empty is equivalent to
                                       using the '*' glob pattern for that specifier.

interval   The number of seconds between reports.

count   The number of reports to be printed.

Examples In the following examples, all the command lines in a block produce the same output, as
shown immediately below. The exact statistics and values will of course vary from machine to
machine.

EXAMPLE 1   Using the kstat Command

```
example$ kstat -p -m unix -i 0 -n system_misc -s 'avenrun*'
example$ kstat -p -s 'avenrun*'
example$ kstat -p 'unix:0:system_misc:avenrun*'
example$ kstat -p ':::avenrun*'
example$ kstat -p ':::/^avenrun_\d+min$/'

unix:0:system_misc:avenrun_15min        3
unix:0:system_misc:avenrun_1min 4
unix:0:system_misc:avenrun_5min 2
```

EXAMPLE 2   Using the kstat Command

```
example$ kstat -p -m cpu_stat -s 'intr*'
example$ kstat -p cpu_stat:::/^intr/

cpu_stat:0:cpu_stat0:intr       29682330
cpu_stat:0:cpu_stat0:intrblk    87
cpu_stat:0:cpu_stat0:intrthread 15054222
cpu_stat:1:cpu_stat1:intr       426073
cpu_stat:1:cpu_stat1:intrblk    51
cpu_stat:1:cpu_stat1:intrthread 289668
```

EXAMPLE 2 Using the kstat Command   *(Continued)*

```
cpu_stat:2:cpu_stat2:intr       134160
cpu_stat:2:cpu_stat2:intrblk    0
cpu_stat:2:cpu_stat2:intrthread 131
cpu_stat:3:cpu_stat3:intr       196566
cpu_stat:3:cpu_stat3:intrblk    30
cpu_stat:3:cpu_stat3:intrthread 59626
```

EXAMPLE 3 Using the kstat Command

```
example$ kstat -p :::state ':::avenrun*'
example$ kstat -p :::state :::/^avenrun/

cpu_info:0:cpu_info0:state       on-line
cpu_info:1:cpu_info1:state       on-line
cpu_info:2:cpu_info2:state       on-line
cpu_info:3:cpu_info3:state       on-line
unix:0:system_misc:avenrun_15min        4
unix:0:system_misc:avenrun_1min 10
unix:0:system_misc:avenrun_5min 3
```

EXAMPLE 4 Using the kstat Command

```
example$ kstat -p 'unix:0:system_misc:avenrun*' 1 3
unix:0:system_misc:avenrun_15min        15
unix:0:system_misc:avenrun_1min 11
unix:0:system_misc:avenrun_5min 21

unix:0:system_misc:avenrun_15min        15
unix:0:system_misc:avenrun_1min 11
unix:0:system_misc:avenrun_5min 21

unix:0:system_misc:avenrun_15min        15
unix:0:system_misc:avenrun_1min 11
unix:0:system_misc:avenrun_5min 21
```

EXAMPLE 5 Using the kstat Command

```
example$ kstat -p -T d 'unix:0:system_misc:avenrun*' 5 2
Thu Jul 22 19:39:50 1999
unix:0:system_misc:avenrun_15min        12
unix:0:system_misc:avenrun_1min 0
unix:0:system_misc:avenrun_5min 11

Thu Jul 22 19:39:55 1999
unix:0:system_misc:avenrun_15min        12
unix:0:system_misc:avenrun_1min 0
unix:0:system_misc:avenrun_5min 11
```

EXAMPLE 6 Using the kstat Command

```
example$ kstat -p -T u 'unix:0:system_misc:avenrun*'
932668656
unix:0:system_misc:avenrun_15min        14
unix:0:system_misc:avenrun_1min 5
unix:0:system_misc:avenrun_5min 18
```

Exit Status The following exit values are returned:

0   One or more statistics were matched.

1   No statistics were matched.

2   Invalid command line options were specified.

3   A fatal error occurred.

Files /dev/kstat   kernel statistics driver

Attributes See attributes(5) for descriptions of the following attributes:

Availability	system/core-os

See Also date(1), sh(1), time(2), gmatch(3GEN), kstat(3KSTAT), attributes(5), kstat(7D), sd(7D), kstat(9S)

Notes If the pattern argument contains glob or Perl RE metacharacters which are also shell metacharacters, it will be necessary to enclose the pattern with appropriate shell quotes.

Name ktkt_warnd – Kerberos warning daemon

Synopsis /usr/lib/krb5/ktkt_warnd

Description ktkt_warnd is a daemon on Kerberos clients that can warn users when their Kerberos tickets are about to expire or renew the tickets before they expire. It is invoked by inetd when a ticket-granting ticket (TGT) is obtained for the first time, such as after using the kinit command. ktkt_warnd can be configured through the /etc/krb5/warn.conf file on the client. In warn.conf, you can specify that you be supplied notice, through syslog or terminal or mail, of ticket expiration or to renew the TGT.

Files /etc/krb5/warn.conf   Kerberos warning configuration file

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Committed

See Also svcs(1), inetadm(1M), inetd(1M), svcadm(1M), warn.conf(4), attributes(5), kerberos(5), smf(5)

Notes The ktkt_warnd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/security/ktkt_warn:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

Name labeld – Trusted Extensions label daemon

Synopsis /usr/lib/labeld

Description The label daemon is a system daemon which is started at boot time when Trusted Extensions is enabled. This daemon is started automatically and should not be invoked directly. It does not constitute a programming interface.

To enable Trusted Extensions, enter the following at the command line:

% svcadm enable svc:/system/labeld

Because Trusted Extensions affects the initialization and operation of zones, all zones must be removed before enabling Trusted Extensions. After enabling, the system should be rebooted to allow Trusted Extensions to come up properly initialized.

Enabling or disabling Trusted Extensions can only be done by a user or role with the solaris.smf.manage.labels authorization. (For example, a user or role that has either the Information Security or Object Label Management Rights Profile, or superuser.)

Other configuration steps are needed before using Trusted Extensions functionality. For more information, see the *Solaris Trusted Extensions Installation and Configuration Guide*.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/trusted
Interface Stability	Uncommitted

See Also svcs(1), svcadm(1M), syslogd(1M), attributes(5), smf(5)

Solaris Trusted Extensions Administrator's Procedures

Notes The labels(5) service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/labeld:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name labelit – list or provide labels for file systems

Synopsis labelit [-F *FSType*] [-V] [-o *FSType-specific-options*] *special*
[*operands*]

Description The labelit utility is used to write or display labels on unmounted disk file systems.

Options The following options are supported:

-F *FSType* Specify the *FSType* on which to operate. The *FSType* should either be specified
here or be determinable from /etc/vfstab by matching the *special* with an
entry in the table. If no matching entry is found, the default file system type
specified in /etc/default/fs will be used.

-V Echo complete command line. This option may be used to verify and validate
the command line. Additional information obtained using a /etc/vfstab
lookup is included in the output. The command is not executed.

-o Specify *FSType*-specific options. See the manual page for the labelit module
specific to the file system type.

Operands The following operands are supported. If no operands are specified, labelit will display the
value of the labels.

special The disk partition (for example, /dev/rdsk/c0t3d0s6). The device may not be
on a remote machine.

operands *FSType*-specific operands. Consult the manual page of the *FSType*-specific
labelit command for detailed descriptions.

Usage See largefile(5) for the description of the behavior of labelit when encountering files
greater than or equal to 2 Gbyte (2^{31} bytes).

Exit Status The following exit values are returned:

0 Write or display of labels was successful.

non-zero An error occurred.

Files /etc/vfstab List of default parameters for each file system.

/etc/default/fs Default local file system type. Default values can be set for the following
flags in /etc/default/fs. For example:

LOCAL=ufs
LOCAL The default partition for a command if no *FSType* is
specified.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also labelit_hsfs(1M), labelit_udfs(1M), labelit_ufs(1M), volcopy(1M), vfstab(4), attributes(5), largefile(5)

Notes This utility may not be supported for all *FSTypes*.

Name labelit_hsfs – provide and print labels for hsfs file systems

Synopsis /usr/sbin/labelit -F hsfs [*generic_options*]
         [-o *specific_options*] *special*

Description labelit can be used to provide labels for unmounted CD-ROM images (CD-ROMs may not be labeled, as they are read-only media).

generic_options are options supported by the generic labelit command.

If no *specific_options* are specified, labelit prints the current value of all label fields.

The *special* name should be the physical disk section (for example, /dev/dsk/c0d0s6).

Options -o Use one or more of the following *name=value* pairs separated by commas (with no intervening spaces) to specify values for specific label fields. According to the ISO 9660 specification, only certain sets of characters may be used to fill in these labels. Thus, "d-characters" below refers to the characters 'A' through 'Z', the digits '0' through '9', and the '_' (underscore) character. "a-characters" below refers to 'A' through 'Z', '0' through '9', space, and the following characters: !"%&'()*+,-./:;<=>?_.

absfile= Abstract file identifier, d-characters, 37 characters maximum.

applid= Application identifier, d-characters, 128 characters maximum.

bibfile= Bibliographic file identifier, d-characters, 37 characters maximum.

copyfile= Copyright file identifier, d-characters, 128 maximum.

prepid= Data preparer identifier, d-characters, 128 maximum.

pubid= Publisher identifier, d-characters, 128 maximum.

sysid= System identifier, a-characters, 32 maximum.

volid= Volume identifier, d-characters, 32 maximum.

volsetid= Volume set identifier, d-characters, 128 maximum.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also labelit(1M), volcopy(1M), attributes(5)

Name labelit_udfs – provide and print labels for udf file systems

Synopsis labelit -F udfs [*generic_options*] [-o *specific_options*] *special*
[*fsname volume*]

Description The labelit command writes labels on an unmounted disk that contains a universal disk file
(udf) system. These labels can be used to identify volumes.

Options The following options are supported:

generic_options   Specify *generic_options* supported by the generic labelit command.
See labelit(1M) for descriptions of supported options.

-o *specific_options*   Specify udfs-file-system-specific options in a comma-separated list
with no intervening spaces. The following *specific_options* are
available:

lvinfo1=*string*   Specify information to be inserted in the LVInfo1
field of the Implementation Use Volume
Descriptor. Information in LVInfo1 is generally
used to identify the person creating the file system.
The maximum length of the string specified is 35
bytes.

lvinfo2=*string*   Specify information to be inserted into the
LVInfo2 field of the Implementation Use Volume
Descriptor. Information in LVInfo2 is generally
used to identify the organization responsible for
creating the file system. The maximum length of
the string specified is 35 bytes.

lvinfo3=*string*   Specify information to be inserted into the
LVInfo3 field of the Implementation Use Volume
Descriptor. Information in LVInfo3 is generally
used to identify the contact information for the
medium. The maximum length of the string
specified is 35 bytes.

Operands The following operands are supported:

special   Specify *special* as the physical disk slice, for example, /dev/rdsk/c0t0d0s6. The
device can not be on a remote machine.

fsname   Specify *fsname* as the mount point, (for example, root, u1, and so forth), of the file
system.

volume   Specify *volume* as the physical volume name.

If none of the options (*fsname, volume, specific_options*) is specified, labelit prints the
current values of *fsname*, *volume*, LVInfo1, LVInfo2 and LVInfo3.

Exit Status   The following exit values are returned:

0   Successful completion.

non-zero   An error occurred.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/udfs

See Also   labelit(1M), attributes(5)

Name labelit_ufs – provide and print labels for ufs file systems

Synopsis labelit -F ufs [*generic_options*] *special* [*fsname volume*]

Description labelit is used to write labels on unmounted disk file systems. Such labels may be used to uniquely identify volumes and are used by volume-oriented programs such as volcopy(1M).

Options The following option is supported:

generic_options options supported by the generic labelit command. See labelit(1M).

Operands The following operands are supported:

special name should be the physical disk section (for example, /dev/dsk/c0d0s6). The device may not be on a remote machine.

fsname represents the mount point (for example, root, u1, and so on) of the file system.

volume may be used to represent the physical volume name.

If *fsname* and *volume* are not specified, labelit prints the current values of these labels. Both *fsname* and *volume* are limited to six or fewer characters.

Exit Status The following exit values are returned:

0 Write or display of labels was successful.

non-zero An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

Name latencytop – report latency-related statistics in system and in applications

Synopsis latencytop [-t *interval*] [-o *log_file*] [-k *log_level*]
              [-f [no]*feature*,...] [-l *log_interval*] [-h]
              [-s pid=*PID* | pgid=*PGID*]

Description LatencyTOP is an observability tool that reports statistics about latencies in the system and in applications. The tool reports statistics about where and what kind of latencies are happening in the system and in the applications that are running on the system. The statistics then can be used to improve performance throughput of applications and system, as you remove the identified latencies.

The tool analyzes system activity periodically and displays the data in the output window. Two types of latencies are tracked: an LWP going in and out of sleep and an LWP spinning order to acquire a synchronization object. The tool uses the Solaris DTrace framework to collect the statistics corresponding to these two scenarios of inactivity of the system and application LWPs.

The output window is divided into two sections. An upper part displays the system-wide statistics, while the lower part displays statistics about individual processes. The user can navigate the list of processes (using the left- and right-arrow keys) and select the list they are interested in. The tool will then display statistics about that selected process in the lower part of the window. If the t or T key is pressed, the tool displays the LWP-specific view of that selected process. The t or T key can be used to toggle between the process-view and the thread-view.

During execution, a user can force a refresh of the analysis by pressing the r or R key. The interval time is restored to the default or to a specified value (if -t was used). To quit the application, the user must press the q or Q key.

Options The following options are supported:

-f, --feature [no]*feature1*,[no]*feature2*,...
    Enables/disables features in LatencyTOP. Features can be only one of the following:

    [no]filter
        Filter large interruptible latencies, for example, sleep. The default is off.

    [no]sched
        Monitors sched (PID=0). The default is off.

    [no]sobj
        Monitors synchronize objects. The default is on.

    [no]low
        Lower overhead by sampling small latencies. Enabling this feature will lower CPU utilization by estimating small latencies statistically. Use it for heavy workloads such as a very busy web server. The default is off.

-h
  Displays the command's usage.

-k *log_level*
  Specifies the level of logging in the log file. Valid values are:

  0   none (default)

  1   unknown

  2   all

-l [*log_interval*]
  Writes data to the log file every *log_interval* seconds; *log_interval* must be greater than 60.

-o *log_file*
  Specifies the log file where output will be written. The default log file is /var/log/latencytop.log.

-s pid=*PID* | pgid=*PGID*
  Tracks only the specified process or the specified process group and displays data related only to that process or the process group.

-t *interval*
  Specifies the interval, in seconds, at which the tool collects statistics from the system. The possible values are between 1 and 60; the default is 5 seconds.

Examples   EXAMPLE 1   Running the Tool

The following command launches the tool with default values for options.

% **latencytop**

EXAMPLE 2   Setting the Interval

The following command sets the sampling interval to two seconds.

% **latencytop -t 2**

EXAMPLE 3   Specifying the Log File

The following command sets the log file to /tmp/latencytop.log.

% **latencytop -o /tmp/latencytop.log**

EXAMPLE 4   Specifying the Log Level

The following command sets the log level to all.

% **latencytop -l 2**

EXAMPLE 5 Enabling Tracing of Latencies

The following command enables the tracing of latencies caused by synchronization objects.

```
% latencytop -f sobj
```

EXAMPLE 6 Displaying Data for a Process Group

The following command displays trace date for processes belonging to Process Group 630.

```
% latencytop -s pgid=630
```

Exit Status

0

    Successful operation.

1

    An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Architecture	x86, SPARC
Availability	diagnostic/latencytop
Interface Stability	Volatile

See Also dtrace(1M), kstat(1M), attributes(5)

Usage You must have DTrace privileges to run LatencyTOP.

Name ldapaddent – create LDAP entries from corresponding /etc files

Synopsis ldapaddent [-cpv] [-a *authenticationMethod*] [-b *baseDN*]
　　　　-D *bindDN* [-w *bind_password*] [-j *passwdFile*] [-f *filename*]
　　　　database

　　　　ldapaddent [-cpv] -a sasl/GSSAPI [-b *baseDN*] [-f *filename*]
　　　　database

　　　　ldapaddent -d [-v] [-a *authenticationMethod*] [-D *bindDN*]
　　　　[-w *bind_password*] [-j *passwdFile*] *database*

　　　　ldapaddent [-cpv] -h *LDAP_server*[:*serverPort*] [-M *domainName*]
　　　　[-N *profileName*] [-P *certifPath*] [-a *authenticationMethod*]
　　　　[-b *baseDN*] -D *bindDN* [-w *bind_password*] [-f *filename*]
　　　　[-j *passwdFile*] *database*

　　　　ldapaddent [-cpv] -h *LDAP_server*[:*serverPort*] [-M *domainName*]
　　　　[-N *profileName*] [-P *certifPath*] [-a *authenticationMethod*]
　　　　[-b *baseDN*] [-f *filename*] *database*

　　　　ldapaddent -d [-v] -h *LDAP_server*[:*serverPort*] [-M *domainName*]
　　　　[-N *profileName*] [-P *certifPath*] [-a *authenticationMethod*]
　　　　[-b *baseDN*] -D *bindDN* [-w *bind_password*] [-j *passwdFile*]
　　　　database

Description ldapaddent creates entries in LDAP containers from their corresponding /etc files. This
operation is customized for each of the standard containers that are used in the administration
of Solaris systems. The *database* argument specifies the type of the data being processed. Legal
values for this type are one of aliases, auto_*, bootparams, ethers, group, hosts (including
both IPv4 and IPv6 addresses), ipnodes (alias for hosts), netgroup, netmasks, networks,
passwd, shadow, protocols, publickey, rpc, and services. In addition to the preceding, the
database argument can be one of the RBAC-related files (see rbac(5)):

- /etc/user_attr
- /etc/security/auth_attr
- /etc/security/prof_attr
- /etc/security/exec_attr

By default, ldapaddent reads from the standard input and adds this data to the LDAP
container associated with the database specified on the command line. An input file from
which data can be read is specified using the -f option.

If you specify the -h option, ldapaddent establishes a connection to the server indicated by the
option in order to obtain a DUAProfile specified by the -N option. The entries will be stored in
the directory described by the configuration obtained.

By default (if the -h option is not specified), entries will be stored in the directory based on the
client's configuration. To use the utility in the default mode, the Solaris LDAP client must be
set up in advance.

The location where entries are to be written can be overridden by using the -b option.

If the entry to be added exists in the directory, the command displays an error and exits, unless the -c option is used.

Although, there is a shadow database type, there is no corresponding shadow container. Both the shadow and the passwd data is stored in the people container itself. Similarly, data from networks and netmasks databases are stored in the networks container.

The user_attr data is stored by default in the people container. The prof_attr and exec_attr data is stored by default in the SolarisProfAttr container.

You must add entries from the passwd database before you attempt to add entries from the shadow database. The addition of a shadow entry that does not have a corresponding passwd entry will fail.

The passwd database must precede the user_attr database.

For better performance, the recommended order in which the databases should be loaded is as follows:

- passwd database followed by shadow database
- networks database followed by netmasks database
- bootparams database followed by ethers database

Only the first entry of a given type that is encountered will be added to the LDAP server. The ldapaddent command skips any duplicate entries.

Options The ldapaddent command supports the following options:

-a *authenticationMethod*
Specify authentication method. The default value is what has been configured in the profile. The supported authentication methods are:

```
simple
sasl/CRAM-MD5
sasl/DIGEST-MD5
sasl/GSSAPI
tls:simple
tls:sasl/CRAM-MD5
tls:sasl/DIGEST-MD5
```

Selecting simple causes passwords to be sent over the network in clear text. Its use is strongly discouraged. Additionally, if the client is configured with a profile which uses no authentication, that is, either the credentialLevel attribute is set to anonymous or authenticationMethod is set to none, the user must use this option to provide an authentication method. If the authentication method is sasl/GSSAPI, *bindDN* and *bindPassword* is not required and the hosts and ipnodes fields of /etc/nsswitch.conf must be configured as:

```
hosts: dns files
ipnodes: dns files
```

See nsswitch.conf(4).

-b *baseDN*

Create entries in the *baseDN* directory. *baseDN* is not relative to the client's default search base, but rather. it is the actual location where the entries will be created. If this parameter is not specified, the first search descriptor defined for the service or the default container will be used.

-c

Continue adding entries to the directory even after an error. Entries will not be added if the directory server is not responding or if there is an authentication problem.

-D *bindDN*

Create an entry which has write permission to the *baseDN*. When used with -d option, this entry only needs read permission.

-d

Dump the LDAP container to the standard output in the appropriate format for the given database.

-f *filename*

Indicates input file to read in an /etc/ file format.

-h *LDAP_server*[:*serverPort*]

Specify an address (or a name) and an optional port of the LDAP server in which the entries will be stored. The current naming service specified in the nsswitch.conf file is used. The default value for the port is 389, except when TLS is specified as the authentication method. In this case, the default LDAP server port number is 636.

The format to specify the address and port number for an IPv6 address is:

[*ipv6_addr*]:*port*

To specify the address and port number for an IPv4 address, use the following format:

ipv4_addr:*port*

If the host name is specified, use the format:

host_name:*port*

-j *passwdFile*

Specify a file containing the password for the bind DN or the password for the SSL client's key database. To protect the password, use this option in scripts and place the password in a secure file. This option is mutually exclusive of the -w option.

-M *domainName*

The name of a domain served by the specified server. If not specified, the default domain name will be used.

-N *profileName*

Specify the `DUAProfile` name. A profile with such a name is supposed to exist on the server specified by `-h` option. Otherwise, a default `DUAProfile` will be used. The default value is `default`.

-P *certifPath*

The certificate path for the location of the certificate database. The value is the path where security database files reside. This is used for TLS support, which is specified in the `authenticationMethod` and `serviceAuthenticationMethod` attributes. The default is `/var/ldap`.

-p

Process the `password` field when loading password information from a file. By default, the `password` field is ignored because it is usually not valid, as the actual password appears in a `shadow` file.

-w *bindPassword*

Password to be used for authenticating the *bindDN*. If this parameter is missing, the command will prompt for a password. `NULL` passwords are not supported in LDAP.

When you use `-w` *bindPassword* to specify the password to be used for authentication, the password is visible to other users of the system by means of the `ps` command, in script files or in shell history.

If you supply "-" (hyphen) as a password, you will be prompted to enter a password.

-v

Verbose.

Operands The following operands are supported:

database

The name of the database or service name. Supported values are: `aliases`, `auto_*`, `bootparams`, `ethers`, `group`, `hosts` (including IPv6 addresses), `netgroup`, `netmasks`, `networks`, `passwd`, `shadow`, `protocols`, `publickey`, `rpc`, and `services`. Also supported are `auth_attr`, `prof_attr`, `exec_attr`, `user_attr`, and `projects`.

Examples EXAMPLE 1   Adding Password Entries to the Directory Server

The following example shows how to add password entries to the directory server:

```
example# ldapaddent -D "cn=directory manager" -w secret \
      -f /etc/passwd passwd
```

EXAMPLE 2   Adding Group Entries

The following example shows how to add `group` entries to the directory server using `sasl/CRAM-MD5` as the authentication method:

```
example# ldapaddent -D "cn=directory manager" -w secret \
      -a "sasl/CRAM-MD5" -f /etc/group group
```

EXAMPLE 3 Adding auto_master Entries

The following example shows how to add auto_master entries to the directory server:

```
example# ldapaddent -D "cn=directory manager" -w secret \
    -f /etc/auto_master auto_master
```

EXAMPLE 4 Dumping passwd Entries from the Directory to File

The following example shows how to dump password entries from the directory to a file foo:

```
example# ldapaddent -d passwd > foo
```

EXAMPLE 5 Adding Password Entries to a Specific Directory Server

The following example shows how to add password entries to a directory server that you specify:

```
example# ldapaddent -h 10.10.10.10:3890 \
-M another.domain.name -N special_duaprofile \
-D "cn=directory manager" -w secret \
-f /etc/passwd passwd
```

Exit Status The following exit values are returned:

0
   Successful completion.

>0
   An error occurred.

Files /var/ldap/ldap_client_file
/var/ldap/ldap_client_cred
   Files containing the LDAP configuration of the client. These files are not to be modified manually. Their content is not guaranteed to be human readable. Use ldapclient(1M) to update these files.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/nis
Interface Stability	Committed

See Also ldaplist(1), ldapmodify(1), ldapmodrdn(1), ldapsearch(1), idsconfig(1M), ldapclient(1M), nsswitch.conf(4), attributes(5)

Oracle Solaris Administration: Security Services

Caution Currently StartTLS is not supported by `libldap.so.5`, therefore the port number provided refers to the port used during a TLS open, rather than the port used as part of a StartTLS sequence. For example:

```
-h foo:1000 -a tls:simple
```

The preceding refers to a raw TLS open on host `foo` port 1000, not an open, StartTLS sequence on an unsecured port 1000. If port 1000 is unsecured the connection will not be made.

Name ldap_cachemgr – LDAP daemon to manage client configuration for LDAP based Network Information Service lookups

Synopsis /usr/lib/ldap/ldap_cachemgr [-l *log-file*] [-g]

Description The ldap_cachemgr daemon is a process that provides an up-to-date configuration cache for LDAP naming services. It is started during multi-user boot.

The ldap_cachemgr utility provides caching for all parameters as specified and used by the LDAP naming service clients. The ldap_cachemgr utility uses the cache files which are originally created by executing the ldapclient(1M) utility, as cold start files. Updates to the cache files take place dynamically if profiles are used to configure the client. See the init option to ldapclient(1M).

The ldap_cachemgr utility helps improve the performance of the clients that are using LDAP as the Naming service repository. In order for the LDAP naming services to function properly, the ldap_cachemgr daemon must be running. ldap_cachemgr also improves system security by making the configuration files readable by superuser only.

The cache maintained by this daemon is shared by all the processes that access LDAP Naming information. All processes access this cache through a door call. On startup, ldap_cachemgr initializes the cache from the cache files. See ldapclient(1M). Thus, the cache survives machine reboots.

The ldap_cachemgr daemon also acts as its own administration tool. If an instance of ldap_cachemgr is already running, commands are passed transparently to the running version.

Options The following options are supported:

-g

Print current configuration and statistics to standard output. This is the only option executable without superuser privileges.

-l *log-file*

Cause ldap_cachemgr to use a log file other than the default /var/ldap/cachemgr.log.

Examples EXAMPLE 1 Stopping and Restarting the ldap_cachemgr Daemon

The following example shows how to stop and to restart the ldap_cachemgr daemon.

```
example# svcadm disable network/ldap/client
example# svcadm enable network/ldap/client
```

EXAMPLE 2 Forcing ldap_cachemgr to Reread Configuration Files

The following example shows how to force ldap_cachemgr to reread the /var/ldap/ldap_client_file and /var/ldap/ldap_client_cred files

```
example# pkill -HUP ldap_cachemgr
```

Files /var/ldap/cachemgr.log
        Default log file.

/var/ldap/ldap_client_file
/var/ldap/ldap_client_cred
        Files containing the LDAP configuration of the client. These files are not to be modified
        manually. Their content is not guaranteed to be human readable. Use ldapclient(1M) to
        update these files.

Warnings The ldap_cachemgr utility is included in the current Solaris release on an uncommitted basis
        only. It is subject to change or removal in a future minor release.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/nis

See Also ldapadd(1), ldapdelete(1), ldaplist(1), ldapmodify(1), ldapmodrdn(1), ldapsearch(1),
        pkill(1), svcs(1), idsconfig(1M), ldapaddent(1M), ldapclient(1M), svcadm(1M),
        signal.h(3HEAD), resolv.conf(4), attributes(5), ldap(5), smf(5)

Notes The ldap_cachemgr service is managed by the service management facility, smf(5), under the
        service identifier:

        svc:/network/ldap/client

        Administrative actions on this service, such as enabling, disabling, or requesting restart, can
        be performed using svcadm(1M). The service's status can be queried using the svcs(1)
        command.

Name ldapclient – initialize LDAP client machine or output an LDAP client profile in LDIF format

Synopsis /usr/sbin/ldapclient [-v | -q] init [-a profileName=*profileName*]
       [-a domainName=*domain*] [-a proxyDN=*proxyDN*]
       [-a proxyPassword=*password*]
       [-a authenticationMethod=*authenticationMethod*]
       [-a enableShadowUpdate=true | false]
       [-a adminDN=*adminDN*]
       [-a adminPassword=*adminPassword*]
       [-a certificatePath=*path*] [-d *bindDN*] [-w *bindPassword*]
       [-j *passwdFile*] [-y *passwdFile*]
       [-z *adminrPasswdFile*] *LDAP_server*[:*port_number*]

/usr/sbin/ldapclient [-v | -q] manual [-a attrName=*attrVal*]

/usr/sbin/ldapclient [-v | -q] mod [-a attrName=*attrVal*]

/usr/sbin/ldapclient [-v | -q] list

/usr/sbin/ldapclient [-v | -q] uninit

/usr/sbin/ldapclient [-v | -q] genprofile -a profileName=*profileName*
      [-a attrName=*attrVal*]

Description The ldapclient utility can be used to:

- initialize LDAP client machines
- restore the network service environment on LDAP clients
- list the contents of the LDAP client cache in human readable format.

The init form of the ldapclient utility is used to initialize an LDAP client machine, using a profile stored on an LDAP server specified by LDAP_server. The LDAP client will use the attributes in the specified profile to determine the configuration of the LDAP client. Using a configuration profile allows for easy installation of LDAP client and propagation of configuration changes to LDAP clients. The ldap_cachemgr(1M) utility will update the LDAP client configuration when its cache expires by reading the profile. For more information on the configuration profile refer to IETF document *A Configuration Schema for LDAP Based Directory User Agents*.

The manual form of the ldapclient utility is used to initialize an LDAP client machine manually. The LDAP client will use the attributes specified on the command line. Any unspecified attributes will be assigned their default values. At least one server must be specified in the defaultServerList or the preferredServerList attributes.The domainName attribute must be specified if the client's domainName is not set.

The mod form of the ldapclient utility is used to modify the configuration of an LDAP client machine that was setup manually. This option modifies only those LDAP client configuration attributes specified on the command line. The mod option should only be used on LDAP clients that were initialized using the manual option.

Regardless of which method is used for initialization, if a client is to be configured to use a proxy credentialLevel, proxy credentials must be provided using -a proxyDN=*proxyDN* and -a proxyPassword=*proxyPassword* options. However, if -a proxyPassword=*proxyPassword* is not specified, ldapclient will prompt for it. Note that NULL passwords are not allowed in LDAP. If a self credentialLevel is configured, authenticationMethod must be sasl/GSSAPI.

Similarly, if a client is to be configured to enable shadow information update and use a proxy credentialLevel, administrator credentials must be provided using -a adminDN=*adminDN* and -a adminPassword=*adminPassword*. However, the shadow information update does not need the administrator credentials if a self credentialLevel is configured.

The naming service-specific configuration properties are stored in the svc:/network/ldap/client SMF service. Modifying the SMF properties directly is not advised. Use this tool instead.

Other configuration might be modified during installation. It will be backed up to /var/ldap/restore. The files that are typically modified during initialization are:

- /etc/nsswitch.conf
- /etc/defaultdomain (if it exists)
- /var/yp/binding/'domainname' (for a NIS [YP] client)

ldapclient does not set up a client to resolve hostnames using DNS. It simply copies /etc/nsswitch.ldap to /etc/nsswitch.conf. If you prefer to use DNS for host resolution, please refer to the DNS documentation for information on setting up DNS. See resolv.conf(4). If you want to use sasl/GSSAPI as the authentication method, you have to use DNS for hosts and ipnodes resolution.

The list form of the ldapclient utility is used to list the LDAP client configuration. The output will be human readable. LDAP configuration files are not guaranteed to be human readable. Note that for security reason, the values for adminDN and adminPassword will not be displayed.

The uninit form of the ldapclient utility is used to uninitialize the network service environment, restoring it to the state it was in prior to the last execution of ldapclient using init or manual. The restoration will succeed only if the machine was initialized with the init or manual form of ldapclient, as it uses the backup files created by these options.

The genprofile option is used to write an LDIF formatted configuration profile based on the attributes specified on the command line to standard output. This profile can then be loaded into an LDAP server to be used as the client profile, which can be downloaded by means of the ldapclient init command. Loading the LDIF formatted profile to the directory server can be done through ldapadd(1), or through any server specific import tool. Note that the attributes proxyDN, proxyPassword, certificatePath, domainName, enableShadowUpdate, adminDN, and adminPassword are not part of the configuration profile and thus are not permitted.

You must have superuser privileges to run the ldapclient command, except with the genprofile option.

To access the information stored in the directory, clients can either authenticate to the directory, or use an unauthenticated connection. The LDAP client is configured to have a credential level of either anonymous or proxy. In the first case, the client does not authenticate to the directory. In the second case, client authenticates to the directory using a proxy identity for read access, and using a administrator identity for write access if enableShadowUpdate is configured. In the third case, client authenticates to the directory using a Kerberos principal that is mapped to an LDAP identity by the LDAP server. Refer to the chapter on implementing security in the *Oracle Solaris Administration: Naming and Directory Services* or your appropriate directory server documentation for identity mapping details.

If a client is configured to use an identity, you can configure which authentication method the client will use. The LDAP client supports the following authentication methods:

```
none
simple
sasl/CRAM-MD5
sasl/DIGEST-MD5
sasl/GSSAPI
tls:simple
tls:sasl/CRAM-MD5
tls:sasl/DIGEST-MD5
```

Note that some directory servers may not support all of these authentication methods. For simple, be aware that the bind password will be sent in the clear to the LDAP server. For those authentication methods using TLS (transport layer security), the entire session is encrypted. You will need to install the appropriate certificate databases to use TLS.

Commands The following commands are supported:

init
    Initialize client from a profile on a server.

manual
    Manually initialize client with the specified attribute values.

mod
    Modify attribute values in the configuration file after a manual initialization of the client.

list
    Write the contents of the LDAP client cache to standard output in human readable form.

uninit
    Uninitialize an LDAP client, assuming that ldapclient was used to initialize the client.

genprofile

Generate a configuration profile in LDIF format that can then be stored in the directory for clients to use, with the init form of this command.

Attributes   The following attributes are supported:

adminDN

Specify the Bind Distinguished Name for the administrator identity that is used for shadow information update. This option is required if the credential level is proxy, and enableShadowUpdate is set to true. There is no default value.

adminPassword

Specify the administrator password. This option is required if the credential level is proxy, and enableShadowUpdate is set to true. There is no default value.

attributeMap

Specify a mapping from an attribute defined by a service to an attribute in an alternative schema. This can be used to change the default schema used for a given service. The syntax of attributeMap is defined in the profile IETF draft. This option can be specified multiple times. The default value for all services is NULL. In the example,

```
attributeMap: passwd:uid=employeeNumber
```

the LDAP client would use the LDAP attribute employeeNumber rather than uid for the passwd service. This is a multivalued attribute.

authenticationMethod

Specify the default authentication method used by all services unless overridden by the serviceAuthenticationMethod attribute. Multiple values can be specified by using a semicolon-separated list. The default value is none. For those services that use credentialLevel and credentialLevel is anonymous, this attribute is ignored. Services such as pam_ldap will use this attribute, even if credentialLevel is anonymous. The supported authentication methods are described above. If the authenticationMethod is sasl/GSSAPI, the hosts and ipnodes of /etc/nsswitch.conf must be configured with DNS support, for example:

```
hosts: dns files
ipnodes: dns files
```

bindTimeLimit

The maximum time in seconds that a client should spend performing a bind operation. Set this to a positive integer. The default value is 30.

certificatePath

The certificate path for the location of the certificate database. The value is the path where security database files reside. This is used for TLS support, which is specified in the authenticationMethod and serviceAuthenticationMethod attributes. The default is /var/ldap.

credentialLevel

Specify the credential level the client should use to contact the directory. The credential levels supported are either anonymous or proxy. If a proxy credential level is specified, then the authenticationMethod attribute must be specified to determine the authentication mechanism. Also, if the credential level is proxy and at least one of the authentication methods require a bind DN, the proxyDN and proxyPassword attribute values must be set. In addition, if enableShadowUpdate is set to true, the adminDN and adminPassword values must be set. If a self credential level is specified, the authenticationMethod must be sasl/GSSAPI.

defaultSearchBase

Specify the default search base DN. There is no default. The serviceSearchDescriptor attribute can be used to override the defaultSearchBase for given services.

defaultSearchScope=one | sub

Specify the default search scope for the client's search operations. This default can be overridden for a given service by specifying a serviceSearchDescriptor. The default is one level search.

defaultServerList

A space separated list of server names or server addresses, either IPv4 or IPv6. If you specify server names, be sure that the LDAP client can resolve the name without the LDAP name service. You must resolve the LDAP servers' names by using either files or dns. If the LDAP server name cannot be resolved, your naming service will fail.

The port number is optional. If not specified, the default LDAP server port number 389 is used, except when TLS is specified in the authentication method. In this case, the default LDAP server port number is 636.

The format to specify the port number for an IPv6 address is:

[ipv6_addr]:port

To specify the port number for an IPv4 address, use the following format:

ipv4_addr:port

If the host name is specified, use the format:

host_name:port

If you use TLS, the LDAP server's hostname must match the hostname in the TLS certificate. Typically, the hostname in the TLS certificate is a fully qualified domain name. With TLS, the LDAP server host addresses must resolve to the hostnames in the TLS certificate. You must use files or dns to resolve the host address.

domainName

Specify the DNS domain name. This becomes the default domain for the machine. The default is the current domain name. This attribute is only used in client initialization.

enableShadowUpdate=true | false

Specify whether the client is allowed to update shadow information. If set to `true` and the credential level is `proxy`, `adminDN` and `adminPassword` must be specified.

followReferrals=true | false

Specify the referral setting. A setting of true implies that referrals will be automatically followed and false would result in referrals not being followed. The default is true.

objectclassMap

Specify a mapping from an `objectclass` defined by a service to an `objectclass` in an alternative schema. This can be used to change the default schema used for a given service. The syntax of `objectclassMap` is defined in the profile IETF draft. This option can be specified multiple times. The default value for all services is NULL. In the example,

`objectclassMap=passwd:posixAccount=unixAccount`

the LDAP client would use the LDAP `objectclass` of `unixAccount` rather than the `posixAccount` for the `passwd` service. This is a multivalued attribute.

preferredServerList

Specify the space separated list of server names or server addresses, either IPv4 or IPv6, to be contacted before servers specified by the `defaultServerList` attribute. If you specify server names, be sure that the LDAP client can resolve the name without the LDAP name service. You must resolve the LDAP servers' names by using either `files` or `dns`. If the LDAP server name cannot be resolved, your naming service will fail.

The port number is optional. If not specified, the default LDAP server port number 389 is used, except when TLS is specified in the authentication method. In this case, the default LDAP server port number is 636.

The format to specify the port number for an IPv6 address is:

`[ipv6_addr]:port`

To specify the port number for an IPv4 address, use the following format:

`ipv4_addr:port`

If the host name is specified, use the format:

`host_name:port`

If you use TLS, the LDAP server's hostname must match the hostname in the TLS certificate. Typically, the hostname in the TLS certificate is a fully qualified domain name. With TLS, the LDAP server host addresses must resolve to the hostnames in the TLS certificate. You must use `files` or `dns` to resolve the host address.

profileName

Specify the profile name. For `ldapclient init`, this attribute is the name of an existing profile which may be downloaded periodically depending on the value of the `profileTTL` attribute. For `ldapclient genprofile`, this is the name of the profile to be generated. The default value is `default`.

profileTTL

Specify the TTL value in seconds for the client information. This is only relevant if the machine was initialized with a client profile. If you do not want ldap_cachemgr(1M) to attempt to refresh the LDAP client configuration from the LDAP server, set profileTTL to 0 (zero). Valid values are either zero 0 (for no expiration) or a positive integer in seconds. The default value is 12 hours.

proxyDN

Specify the Bind Distinguished Name for the proxy identity. This option is required if the credential level is proxy, and at least one of the authentication methods requires a bind DN. There is no default value.

proxyPassword

Specify client proxy password. This option is required if the credential level is proxy, and at least one of the authentication methods requires a bind DN. There is no default.

searchTimeLimit

Specify maximum number of seconds allowed for an LDAP search operation. The default is 30 seconds. The server may have its own search time limit.

serviceAuthenticationMethod

Specify authentication methods to be used by a service in the form *servicename*:authenticationmethod, for example:

pam_ldap:tls:simple

For multiple authentication methods, use a semicolon-separated list. The default value is no service authentication methods, in which case, each service would default to the authenticationMethod value. The supported authentications are described above.

Three services support this feature: passwd-cmd, keyserv, and pam_ldap. The passwd-cmd service is used to define the authentication method to be used by passwd(1) to change the user's password and other attributes. The keyserv service is used to identify the authentication method to be used by the chkey(1) and newkey(1M) utilities. The pam_ldap service defines the authentication method to be used for authenticating users when pam_ldap(5) is configured. If this attribute is not set for any of these services, the authenticationMethod attribute is used to define the authentication method. This is a multivalued attribute.

serviceCredentialLevel

Specify credential level to be used by a service. Multiple values can be specified in a space-separated list. The default value for all services is NULL. The supported credential levels are: anonymous or proxy. At present, no service uses this attribute. This is a multivalued attribute.

serviceSearchDescriptor

Override the default base DN for LDAP searches for a given service. The format of the descriptors also allow overriding the default search scope and search filter for each service.

The syntax of `serviceSearchDescriptor` is defined in the profile IETF draft. The default value for all services is `NULL`. This is a multivalued attribute. In the example,

`serviceSearchDescriptor=passwd:ou=people,dc=a1,dc=acme,dc=com?one`

the LDAP client would do a one level search in `ou=people,dc=a1,dc=acme,dc=com` rather than `ou=people,` *defaultSearchBase* for the `passwd` service.

Options The following options are supported:

-a attrName=*attrValue*
Specify `attrName` and its value. See SYNOPSIS for a complete list of possible attribute names and values.

-D *bindDN*
Specifies an entry that has read permission for the requested database.

-j *passwdFile*
Specify a file containing the password for the bind DN or the password for the SSL client's key database. To protect the password, use this option in scripts and place the password in a secure file. This option is mutually exclusive of the -w option.

-q
Quiet mode. No output is generated.

-v
Verbose output.

-w *bindPassword*
Password to be used for authenticating the bind DN. If this parameter is missing, the command will prompt for a password. `NULL` passwords are not supported in LDAP.

When you use -w *bindPassword* to specify the password to be used for authentication, the password is visible to other users of the system by means of the `ps` command, in script files, or in shell history.

If you supply "-" (hyphen) as a password, the command will prompt for a password.

-y *passwdFile*
Specify a file containing the password for the proxy DN. To protect the password, use this option in scripts and place the password in a secure file. This option is mutually exclusive of the -a *proxyPassword* option.

-z *adminrPasswdFile*
Specify a file containing the password for the `adminDN`. To protect the password, use this option in scripts and place the password in a secure file. This option is mutually exclusive of the -a *adminPassword* option.

Operands The following operand is supported:

LDAP_server
   An address or a name for the LDAP server from which the profile will be loaded. The
   current naming service specified in the nsswitch.conf file is used. Once the profile is
   loaded, the preferredServerList and defaultServerList specified in the profile are
   used.

Examples **EXAMPLE 1** Setting Up a Client By Using the Default Profile Stored on a Specified LDAP Server

The following example shows how to set up a client using the default profile stored on the
specified LDAP server. This command will only be successful if either the credential level in
the profile is set to anonymous or the authentication method is set to none.

```
example# ldapclient init 172.16.100.1
```

EXAMPLE 2 Setting Up a Client By Using the simple Profile Stored on a Specified LDAP Server

The following example shows how to set up a client using the simple profile stored on the
specified LDAP server. The domainname is set to xyz.mycompany.com and the proxyPassword
is secret.

```
example# ldapclient init -a profileName=simple \
-a domainName=xyz.mycompany.com \
-a proxyDN=cn=proxyagent,ou=profile,dc=xyz,dc=mycompany,dc=com \
-a proxyPassword=secret '['fe80::a00:20ff:fea3:388']':386
```

EXAMPLE 3 Setting Up a Client Using Only One Server

The following example shows how to set up a client using only one server. The authentication
method is set to none, and the search base is dc=mycompany,dc=com.

```
example# ldapclient manual -a authenticationMethod=none \
-a defaultSearchBase=dc=mycompany,dc=com \
-a defaultServerList=172.16.100.1
```

EXAMPLE 4 Setting Up a Client Using Only One Server That Does Not Follow Referrals

The following example shows how to set up a client using only one server. The credential level
is set to proxy. The authentication method of is sasl/CRAM-MD5, with the option not to follow
referrals. The domain name is xyz.mycompany.com, and the LDAP server is running on port
number 386 at IP address 172.16.100.1.

```
example# ldapclient manual \
-a credentialLevel=proxy \
-a authenticationMethod=sasl/CRAM-MD5 \
-a proxyPassword=secret \
-a proxyDN=cn=proxyagent,ou=profile,dc=xyz,dc=mycompany,dc=com \
-a defaultSearchBase=dc=xyz,dc=mycompany,dc=com \
-a domainName=xyz.mycompany.com \
-a followReferrals=false \
```

EXAMPLE 4 Setting Up a Client Using Only One Server That Does Not Follow Referrals   *(Continued)*

```
-a defaultServerList=172.16.100.1:386
```

EXAMPLE 5 Using genprofile to Set Only the defaultSearchBase and the Server Addresses

The following example shows how to use the genprofile command to set the defaultSearchBase and the server addresses.

```
example# ldapclient genprofile -a profileName=myprofile \
-a defaultSearchBase=dc=eng,dc=sun,dc=com \
-a "defaultServerList=172.16.100.1 172.16.234.15:386" \
> myprofile.ldif
```

EXAMPLE 6 Creating a Profile on IPv6 servers

The following example creates a profile on IPv6 servers

```
example# ldapclient genprofile -a profileName=eng \
-a credentialLevel=proxy \
-a authenticationMethod=sasl/DIGEST-MD5 \
-a defaultSearchBase=dc=eng,dc=acme,dc=com \
-a "serviceSearchDescriptor=passwd:ou=people,dc=a1,dc=acme,dc=com?one"\
-a preferredServerList= '['fe80::a00:20ff:fea3:388']' \
-a "defaultServerList='['fec0::111:a00:20ff:fea3:edcf']' \
    '['fec0::111:a00:20ff:feb5:e41']'" > eng.ldif
```

EXAMPLE 7 Creating a Profile That Overrides Every Default Value

The following example shows a profile that overrides every default value.

```
example# ldapclient genprofile -a profileName=eng \
-a credentialLevel=proxy -a authenticationMethod=sasl/DIGEST-MD5 \
-a bindTimeLimit=20 \
-a defaultSearchBase=dc=eng,dc=acme,dc=com \
-a "serviceSearchDescriptor=passwd:ou=people,dc=a1,dc=acme,dc=com?one"\
-a serviceAuthenticationMethod=pam_ldap:tls:simple \
-a defaultSearchScope=sub \
-a attributeMap=passwd:uid=employeeNumber \
-a objectclassMap=passwd:posixAccount=unixAccount \
-a followReferrals=false -a profileTTL=6000 \
-a preferredServerList=172.16.100.30 -a searchTimeLimit=30 \
-a "defaultServerList=172.16.200.1 172.16.100.1 192.168.5.6" > eng.ldif
```

Exit Status   The following exit values are returned:

0   The command successfully executed.

1   An error occurred. An error message is output.

2   proxyDN and proxyPassword attributes are required, but they are not provided.

Files /var/ldap/ldap_client_cred
/var/ldap/ldap_client_file
Contain the LDAP configuration of the client. These files are not to be modified manually.
Their content is not guaranteed to be human readable. Use ldapclient to update them.

/etc/defaultdomain
System default domain name, matching the domain name of the data in the LDAP servers.
See defaultdomain(4).

/etc/nsswitch.conf
Configuration file for the name-service switch. See nsswitch.conf(4).

/etc/nsswitch.ldap
Sample configuration file for the name-service switch configured with LDAP and files.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/nis
Interface Stability	Committed

See Also chkey(1), ldapadd(1), ldapdelete(1), ldaplist(1), ldapmodify(1), ldapmodrdn(1),
ldapsearch(1), idsconfig(1M), ldapaddent(1M), ldap_cachemgr(1M), defaultdomain(4),
nsswitch.conf(4), resolv.conf(4), attributes(5)

Caution Currently StartTLS is not supported by libldap.so.5, therefore the port number provided
refers to the port used during a TLS open, rather than the port used as part of a StartTLS
sequence. To avoid timeout delays, mixed use of TLS and non-TLS authentication
mechanisms is not recommended.

For example:

```
-h foo:1000 -a authenticationMethod=tls:simple
```

...or:

```
defaultServerList= foo:1000
authenticationMethod= tls:simple
```

The preceding refers to a raw TLS open on host foo port 1000, not an open, StartTLS sequence
on an unsecured port 1000. If port 1000 is unsecured the connection will not be made.

As a second example, the following will incur a significant timeout delay while attempting the
connection to foo:636 with an unsecured bind.

```
defaultServerList= foo:636 foo:389
authenticationMethod= simple
```

Name   ldmad – Logical Domains Agents daemon

Synopsis   /usr/lib/ldoms/ldmad

Description   The ldmad daemon is part of the framework that enables Logical Domain agents to run on a Logical Domain. A Logical Domain agent is a component that interacts with the control domain to provide features or information.

ldmad is responsible for running agents on a Logical Domain. ldmad must be enabled to ensure the proper functionality of all features provided by the domain manager on the control domain. The daemon is started at boot time and has no configuration options.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/ldoms
Interface Stability	Unstable

See Also   svcs(1), svcadm(1M), syslog(3C), syslog.conf(4), attributes(5), smf(5)

Logical Domains 1.2 Administration Guide

Errors   ldmad uses syslog(3C) to report status and error messages. Error messages are logged with the LOG_ERR and LOG_NOTICE priorities. Informational messages are logged with the LOG_INFO priority. The default entries in the /etc/syslog.conf file specify that all ldmad error messages are written to the /var/adm/messages log.

Notes   The ldmad service is managed by the service management facility, smf(5), under the service identifier:

svc:/ldoms/agents:default

Administrative actions on this service, such as enabling, disabling, or requesting restart can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name link, unlink – link and unlink files and directories

Synopsis /usr/sbin/link *existing-file* *new-file*

/usr/xpg4/bin/link *existing-file* *new-file*

/usr/sbin/unlink *file*

Description The link and unlink commands link and unlink files and directories. Only super-users can use these commands on directories.

Use link to create a new file that points to an existing file. The *existing-file* and *new-file* operands specify the existing file and newly-created files. See OPERANDS.

Note that the ZFS file system does not support links between directories.

link and unlink directly invoke the link(2) and unlink(2) system calls, performing exactly what they are told to do and abandoning all error checking. This differs from the ln(1) command. See ln(1).

While linked files and directories can be removed using unlink, it is safer to use rm(1) and rmdir(1) instead. See rm(1) and rmdir(1).

/usr/xpg4/bin/link If the existing file being hard linked is itself a symbolic link, then the newly created file (*new-file*) will be a hard link to the file referenced by the symbolic link, not to the symbolic link object itself (*existing-file*).

Operands The following operands are supported:

existing-file   Specifies the name of the existing file to be linked.

file   Specifies the name of the file to be unlinked.

new-file   Specifies the name of newly created (linked) file.

Environment Variables See environ(5) for descriptions of the following environment variables that affect the execution of link: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

/usr/xpg4/bin/link

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/xopen/xcu4
Interface Stability	Committed
Standard	See standards(5).

Name llc2_loop – loopback diagnostics to test the driver, adapter and network.

Synopsis /usr/lib/llc2/llc2_loop2 [-v] *ppa*

/usr/lib/llc2/llc2_loop3 *ppa sap frames*

/usr/lib/llc2/llc2_loop3 *ppa type frames*

/usr/lib/llc2/llc2_loop4 [-v] *ppa*

Description

Loop 2 The loop2 test sends a NULL XID frame to the broadcast (all 1's) destination MAC address. The source SAP (Service Access Point) value used is 0x04 (SNA's SAP). Therefore, if SNA is running on the system, the loop2 test will fail. The destination SAP value is the NULL SAP (0x00). This test finds out who is listening and can receive frames sent out from a node. The verbose (-v) option displays the MAC address of responding nodes. All possible responders may not be displayed, since the loop2 test only waits for responses for 2 seconds, but during this time 50-200 nodes may be displayed. The most likely error is:

```
Unexpected DLPI primitive x, expected y.
```

where $x = 5$ and $y = 6$. From /usr/include/sys/dlpi.h, the expected return value from one of the DLPI primitives is 6 (DL_OK_ACK), but instead a 5 (DL_ERROR_ACK) was received. This can occur for two reasons:

- The loop2 command was issued to a non-existent PPA (Physical Point of Attachment).
- The SAP (0x04) is already in use (for example, the SNA subsystem is up).

Loop 3 The loop3 test sends 1,495 byte Unnumbered Information (UI) frames to the NULL (all 0's) destination MAC address. This should be used along with data capture either on the local node or another node on the same LAN to verify the transmission of data. The *ppa* argument specifies the adapter on which to run the test. The *ppa* is the relative physical position of the adapter and may be ascertained by viewing the adapter configuration (see llc2_config(1)). For Token Ring or Ethernet, specify an even *sap* value from 2 through 254, or, for Ethernet only, any *type* value from 1519 (0x05ef) through 65535 (0xffff). It is advised to pick a value that is easily recognized when the data capture output is viewed. *frames* is the decimal number of 1,495 bytes packets to transmit. The test will only display a message if a failure occurs.

Loop 4 The loop4 test sends a TEST frame (no information field) to the broadcast (all 1's) destination MAC address. The source SAP value used is 0x04 (SNA's SAP). Therefore, if SNA is running on the system, the loop4 test will fail. The destination SAP value is the NULL SAP (0x00). This test finds out who is listening and can receive frames sent out from a node. The verbose (-v) option displays the MAC address of responding nodes. All possible responders may not be displayed since the loop4 test only waits for responses for 2 seconds, but during this time 50-200 nodes may be displayed. The loop4 test displays information similar to the following example if other nodes are listening and respond (verbose mode):

```
-Attaching
   -Binding
```

```
                    -Sending TEST
                    -Responders
                       1-0000c0c12449
                       2-08000e142990
                       3-08000e142a51
                       4-0000c0450044
                       5-0000c0199e46
                    -Unbinding
                 -Detaching
                 5 nodes responding
```

The errors displayed are the same as for loop2.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/llc2

See Also llc2_config(1), llc2(4), attributes(5), llc2(7D)

Notes For information about how to start the service, see llc2(7D)

Name lldpadm – Link Layer Discovery Protocol administration tool

Synopsis lldpadm set-agentprop -p *prop*[+|-]=*value*[,...] *lldp_agent*
lldpadm reset-agentprop -p *prop*[,...] *lldp_agent*
lldpadm show-agentprop [[-c] -o *field*,...] -p *prop*[,...] [*lldp_agent*]

lldpadm set-tlvprop -p *prop*[+|-]=*value*[,...] *tlv_name*
lldpadm reset-tlvprop -p *prop*[,...] *tlv_name*
lldpadm show-tlvprop [[-c] -o *field*,...] -p *prop*[,...] [*tlv_name*]

lldpadm set-agenttlvprop -p *prop*[+|-]=*value*[,...] -a *lldp_agent*
    tlv_name
lldpadm reset-agenttlvprop -p *prop*[,...] -a *lldp_agent* *tlv_name*
lldpadm show-agenttlvprop [[-c] -o *field*,...] -p *prop*[,...]
    [-a *lldp_agent*] [*tlv_name*]

lldpadm show-agent [-c] [-s] [-v] -o *field*,... [-l|-r] [*lldp_agent*]

Description The lldpadm command is used to enable or disable a Link Layer Discovery Protocol (LLDP) agent on a physical datalink. lldpadm is also used to configure the behavior of an LLDP agent. The LLDP agent implements the LLDP protocol for a given physical datalink. LLDP is a one-way link layer protocol that allows an IEEE 802 LAN station to advertise the capabilities and current status of the system to other stations attached to the same LAN. The LLDP agent can also receive information about the capabilities and current status of the system associated with a remote station. LLDP agent can either be enabled for transmission only, for reception only, or for both.

Information to be exchanged is packed as a sequence of type, length, and value (TLVs), wherein the type field identifies the type of information, the length field indicates the length of the information field in octets, and the value field contains the information itself.

Operands Each lldpadm subcommand operates on one of the following objects:

lldp_agent
An LLDP agent implements the LLDP protocol for a given physical datalink that is connected to IEEE 802 LAN. The only supported physical links are the ones of media type Ethernet. Thus, LLDP can be enabled on all the links displayed in dladm show-phys output that are of media type Ethernet. The name of the *lldp_agent* is the name of the datalink itself.

tlv_name
Name of the TLV whose value can be modified. The supported modifiable TLVs are:

- syscapab and mgmtaddr. These form Global TLVs that are common to all the LLDP agents on the system.

- pfc and appln. Per-LLDP agent TLVs.

Sub-commands   lldpadm supports the following subcommands.

lldpadm set-agentprop|set-ap -p *prop*[+|-]=*value*[,...] *lldp_agent*
> Sets the value of one or more LLDP agent properties to the value specified. If the property takes multiple values then the value should be specified with a comma as the delimiter. The value is always made persistent and thus will be reapplied on system reboot or lldpd(1M) daemon restart. The list of properties supported and each property's possible values can be retrieved using show-agentprop subcommand.

> -p *prop*[+|-]=*value*[,...], --prop *prop*[+|-]=*value*[,...]
> > A comma-separated list of properties to be set to the specified values. It also provides the following qualifiers to perform add and delete operations in addition to assignment.

> > +   Adds the given value to the current list of value(s).

> > -   Removes the given value from the current list of value(s).

> > =   Makes a new assignment and removes all the current value(s).

> > See EXAMPLES for more information on how to use the qualifiers.

lldpadm reset-agentprop|reset-ap -p *prop*[,...] *lldp_agent*
> Resets one or more properties to their default values. The default values for properties can be retrieved using show-agentprop subcommand.

> -p *prop*[,...], --prop *prop*[,...]
> > A comma-separated list of properties to reset.

lldpadm show-agentprop|show-ap [[-c] -o *field*,...] -p *prop*[,...] [*lldp_agent*]
> Show the current value of one or more properties, either for all of the LLDP agents or for the specified LLDP agent. Several properties of interest can be retrieved at a time by providing comma-separated property names to -p option. If the -p option is not specified, all available properties are displayed.

> -o *field*[,...], --output *field*[,...]
> > A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value all to display all fields. For each LLDP agent, the following fields can be displayed:

> > AGENT
> > > The name of the LLDP agent.

> > PROPERTY
> > > The name of the property.

> > PERM
> > > The read/write permissions of the property. The value shown will be r (read only), w (write only) or rw (read/write).

VALUE
: The current value of the property. If the value is not set, it is shown as - -. If it is unknown, the value is shown as ?.

DEFAULT
: The default value of the property. If the property has no default value, - - is shown.

POSSIBLE
: A comma-separated list of the values the property can have. If the values span a numeric range, *min* - *max* might be shown as shorthand. If the possible values are unknown or unbounded, - - is shown.

-c, --parsable
: Display using a stable machine-parsable format. The -o option is required with this option. See "Parsable Output Format", below.

-p *prop*[,...], --prop *prop*[,...]
: A comma-separated list of properties to display.

For the supported list of agent properties, see "Agent Properties" section below.

lldpadm set-tlvprop|set-tp -p *prop*[+|-]=*value*[,...] *tlv_name*
: Sets the value of one or more TLV properties to the value specified. If the property takes multiple values, the value should be specified with a comma as the delimiter. The value is always persisted and will be reapplied on system reboot or lldpd(1M) daemon restart. The list of properties supported and each property's possible values can be retrieved using show-tlvprop subcommand.

Note – The TLVs modified using this subcommand apply to all the LLDP agents running on the system.

-p *prop*[+|-]=*value*[,...], --prop *prop*[+|-]=*value*[,...]
: See the description of this option under the set-agentprop subcommand, above.

lldpadm reset-tlvprop|reset-tp -p *prop*[,...] *tlv_name*
: Resets one or more properties to their default values. The default values for properties can be retrieved using show-tlvprop subcommand.

-p *prop*[,...], --prop *prop*[,...]
: A comma-separated list of properties to reset.

lldpadm show-tlvprop|show-tp [[-c] -o *field*,...] -p *prop*[,...] [*lldp_agent*]
: Show the current value of one or more properties, either for all the TLVs or for a specified TLV. Several properties of interest can be retrieved at a time by providing comma-separated property names to -p option. If the -p option is not specified, all available properties are displayed.

-o *field*[,...], --output *field*[,...]

A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value all to display all fields. For each TLV, the following fields can be displayed:

TLVNAME

The name of the TLV.

PROPERTY

The name of the property.

PERM

The read/write permissions of the property. The value shown will be r (read only), w (write only) or rw (read/write).

VALUE

The current value of the property. If the value is not set, it is shown as --. If it is unknown, the value is shown as ?.

DEFAULT

The default value of the property. If the property has no default value, -- is shown.

POSSIBLE

A comma-separated list of the values the property can have. If the values span a numeric range, *min - max* might be shown as shorthand. If the possible values are unknown or unbounded, -- is shown.

-c, --parsable

Display using a stable machine-parsable format. The -o option is required with this option. See "Parsable Output Format", below.

-p *prop*[,...], --prop *prop*[,...]

A comma-separated list of properties to display.

lldpadm set-agenttlvprop|set-atp -p *prop*[+|-]=*value*[,...] -a *lldp_agent tlv_name*

Sets the value of one or more TLV properties to the value specified. The -a option is mandatory and identifies the name of the agent for which the TLV property needs to be set. In this way, the TLV property modification is reflected only on the specified agent. If the property takes multiple values then the value should be specified with a comma as the delimiter. The value is always made persistent and will be reapplied on system reboot or lldpd(1M) daemon restart. The list of properties supported and each property's possible values can be retrieved using show-agenttlvprop subcommand.

-p *prop*[+|-]=*value*[,...], --prop *prop*[+|-]=*value*[,...]

See the description of this option under the set-agentprop subcommand, above.

-a *lldp_agent*, --agent=*lldp_agent*

The name of the LLDP agent for which TLV properties need to be displayed.

lldpadm reset-agenttlvprop|reset-atp -p *prop*[,...]=*value*[,...] -a *lldp_agent tlv_name*
Resets one or more properties to their default values. The -a option is mandatory and identifies the name of the agent for which the TLV property needs to be reset. The default values for properties can be retrieved using show-agenttlvprop subcommand.

-p *prop*[,...], --prop *prop*[,...]
A comma-separated list of properties to display.

-a *lldp_agent*, --agent=*lldp_agent*
The name of the LLDP agent for which TLV properties need to be displayed.

lldpadm show-agenttlvprop|show-atp [[-c] -o *field*,...] -p *prop*[,...] [-a *lldp_agent*]
[*tlv_name*]
Show the current value of one or more properties, either for all of the TLVs or for a specified TLV. If a single LLDP agent is not specified (using -a), TLV properties for all LLDP agents are displayed. Several properties of interest can be retrieved at a time by providing comma-separated property names to the -p option. If the -p option is not specified, all available properties are displayed.

-o *field*[,...], --output *field*[,...]
A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value all to display all fields. For each LLDP agent, the following fields can be displayed:

AGENT
The name of the LLDP agent.

TLVNAME
The name of the TLV.

PROPERTY
The name of the property.

PERM
The read/write permissions of the property. The value shown will be r (read only), w (write only) or rw (read/write).

VALUE
The current value of the property. If the value is not set, it is shown as --. If it is unknown, the value is shown as ?.

DEFAULT
The default value of the property. If the property has no default value, -- is shown.

POSSIBLE
A comma-separated list of the values the property can have. If the values span a numeric range, *min - max* might be shown as shorthand. If the possible values are unknown or unbounded, -- is shown.

-c, --parsable

Display using a stable machine-parsable format. The -o option is required with this
option. See "Parsable Output Format", below.

-p *prop*[,...], --prop *prop*[,...]

A comma-separated list of properties to display.

-a *lldp_agent*, --agent=*lldp_agent*

The name of the LLDP agent for which TLV properties need to be displayed.

For the supported list of TLV properties that apply on a per-LLDP agent basis, see the
"Per-LLDP agent TLV properties" section, below.

lldpadm show-agent [-c] [-s] [-v] -o *field*,...] [-l | -r] [*lldp_agent*]

Show the information advertised by the specified LLDP agent or information advertised by
the adjacent neighbors to the specified LLDP agent. If no LLDP agent is specified, then the
local or remote information will be displayed for all the LLDP agents. The information is
displayed as a multi-line output, with each line containing information about a single TLV
in the following format:

<Name of the TLV> : *<TLV Information expressed as a string>*

The following lines can be displayed:

```
                        Agent:
            Chassis ID Subtype:
                    Chassis ID:
               Port ID Subtype:
                       Port ID:
              Port Description:
                  Time to Live:
                   System Name:
            System Description:
         Supported Capabilities:
           Enabled Capabilities:
             Management Address:
             Maximum Frame Size:
                   Port VLAN ID:
                   VLAN Name/ID:
            VNIC PortID/VLAN ID:
        Aggregation Information:
                    PFC Willing:
                       PFC Cap:
                       PFC MBC:
                    PFC Enable:
      Application(s)(ID/Sel/Pri):
       Next Packet Transmission:  [displayed only when -l is used]
         Information Valid Until:  [displayed only when -r is used]
```

-c, --parsable

Display using a stable machine-parsable format. The -o option is required with this option. See "Parsable Output Format", below.

-l, --local

Displays information advertised by the local LLDP agent. This option is mutually exclusive of the -r option.

-r, --remote

Displays information advertised by the adjacent neighbors. This option is mutually exclusive of the -l option.

-s

Show the statistics for the specified LLDP agents or for all the LLDP agents on the system. Every LLDP agent maintains statistical counters that are used to count significant events in the transmit and receive state machines. These counters are defined to be 32-bit unsigned integers.

-o *field*[,...], --output *field*[,...]

A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value all to display all fields. For each TLV, the following fields can be displayed:

AGENT

The name of the LLDP agent.

IFRAMES

Count of all LLDP frames received by AGENT.

IERR

Count of all LLDPDUs received with one or more detectable errors.

IDISCARD

Count of all LLDPDUs received and then discarded for any of the following reasons:

- incorrectly formed LLDPDUs with respect to the first three mandatory TLVs
- insufficient space to store the incoming LLDPDU

OFRAMES

Count of all LLDP frames transmitted by AGENT.

OLENERR

Count of times the outgoing LLDPDU exceeded the length restrictions of 1500 bytes.

TLVDISCARD

Count of all TLVs received and then discarded because the TLVs did not adhere to the TLV usage rules as specified by the standard.

TLVUNRECOG

Count of all TLVs received that are not recognized by the LLDP agent.

AGEOUT

Count of the times that a neighbor's information has been deleted because of aging.

-v, --verbose

Displays detailed information.

Parsable Output Format
The `lldpadm show` subcommands have a `-c` option that displays output in a machine-parsable format. The output format is one or more lines of colon (:)-delimited fields. The fields displayed are specific to the subcommand used and are listed under the entry for the `-o` option for a given subcommand. Output includes only those fields requested by means of the `--o` option, in the order requested. Note that the `-o all` option, which displays all the fields for a given subcommand, cannot be used with the parsable output option.

When you request multiple fields, any literal colon characters are escaped by a backslash (\) before being output. Similarly, literal backslash characters are also escaped with a backslash. This escape format is parsable by using shell read(1) functions with the environment variable set as IFS=: Note that escaping is not done when you request only a single field.

Agent Properties
The following LLDP agent properties are supported:

mode

Configures the operation mode of the LLDP agent. Possible values are:

txonly

Enables LLDP for transmission only.

rxonly

Enables LLDP for receiving only.

both

Enables LLDP for both transmission and receiving.

disable

Disables LLDP on the LLDP agent.

Every LLDP packet (LLDPDU) transmitted by an LLDP agent contains multiple TLVs. The following four TLVs are mandatory and therefore included in all the LLDPDUs transmitted by an agent configured in the txonly or both mode:

CHASSIS ID

The value transmitted in the Chassis ID TLV is:

- subtype = 7 (locally assigned)
- Chassis ID = hostid(1)

PORT ID

The value transmitted in the Port ID TLV is:

- subtype = 3 (MAC address)
- Port ID = primary MAC address of the agent

TTL
:   The duration for which this packet is valid. The default value is 30 seconds.

End of PDU TLV
:   End of PDU indicator.

Optional TLVs that can be advertised are configured using the following properties:

basic-tlv
:   Configures the Basic Management TLVs that should be advertised by the LLDP agent. The possible values are:

    portdesc
    :   Alphanumeric string that identifies the datalink. Value set to the linkname.

    sysname
    :   Alphanumeric string that identifies the system. Value set to the output of 'uname -n'.

    sysdesc
    :   Alphanumeric string that describes the system. Value set to the output of 'uname -a'.

    syscapab
    :   Indicates the systems supported and enabled capabilities.

    mgmtaddr
    :   Indicates the IP address of the system that can be used by network management.

dot1-tlv
:   Configures the IEEE 802.1 Organizationally Specific TLVs that should be advertised by the LLDP agent. The possible values are:

    vlanname
    :   Indicates the names and IDs of all the VLANS configured on the datalink.

    pvid
    :   Indicates the default VLAN ID associated with the given datalink. It corresponds to the default_tag datalink property that is managed by means of the dladm(1M) utility.

    linkaggr
    :   Indicates whether underlying datalink is in an aggregation or is capable of being part of an aggregation.

    pfc
    :   Indicates whether underlying datalink supports PFC (Priority Flow Control) and the priorities for which the PFC pause frame is enabled. Also indicates whether the local endpoint is willing to negotiate the PFC configuration.

    appln
    :   Indicates the priority that will be used by an application.

dot3-tlv

Configures the IEEE 802.3 Organizationally Specific TLVs that should be advertised by the LLDP agent. The possible values are:

max-framesize

Indicates the maximum supported frame size for the underlying datalink.

virt-tlv

Configures the Solaris's Virtualization Specific TLVs that should be advertised by the LLDP agent. The possible values are:

vnic

Indicates the MAC address of the Virtual NIC created on top of the underlying physical link. Also indicates any VLAN id associated with the VNIC. See dladm(1M) for more information on VNIC.

Global TLVs and Their Properties

The following Global TLV properties are supported:

syscapab (TLV name)

This property can one of the following values:

supported

Indicates the supported capabilities on the system. The default supported capabilities are: bridge, router, and station.

enabled

Indicates the enabled capabilities on the system. The enabled capabilities must be a subset of the supported capabilities.

mgmtaddr (TLV name)

This property can have the following value:

ipaddr

The IP address(es), either IPv4 or IPv6, associated with the local LLDP agent that will be used to reach higher layer entities to assist discovery by network management.

Per-Agent TLVs and Their Properties

The following Agent TLV properties are supported:

appln (TLV name)

This property can have the following value:

apt

Configures the Application Priority Table for an Application TLV. One can add or remove entries from this table using the + and - qualifiers. Each entry in the table indicates the application and the priority that will be used for that application. Its value is of the form:

id/*selector*/*priority*

The meaning of the *id* is determined by the *selector* field. The *selector* field can be any one of the following:

- 1 — *id* indicates an Ethertype (an L2 protocol), therefore *id*'s value should be greater than 1536
- 2 — *id* indicates a port number over TCP or SCTP
- 3 — *id* indicates a port number over UDP or DCCP
- 4 — *id* indicates a port number over TCP, SCTP, UDP, or DCCP

The *priority* indicates the priority value (0-7) that will be used for given application.

Authorizations The following subcommands require solaris.network.lldp authorization:

- `set-agentprop`
- `reset-agentprop`
- `set-tlvprop`
- `reset-tlvprop`
- `set-agenttlvprop`
- `reset-agenttlvprop`

The various show-* subcommands do not need any authorization.

Examples **EXAMPLE 1** Enabling LLDP Protocol on an LLDP Agent

The following command enables the LLDP protocol on an LLDP agent for both transmission and reception of LLDPDUs.

```
# lldpadm set-agentprop -p mode=both net0
```

EXAMPLE 2 Disabling LLDP Protocol on an LLDP Agent

The following command disables the LLDP protocol on an LLDP agent.

```
# lldpadm set-agentprop -p mode=disable net0
```

EXAMPLE 3 Configuring TLVs

The following command configures transmission of the Port Description and System Name TLV.

```
# lldpadm set-agentprop -p basic-tlv=portdesc,sysname net0
```

The following command configures transmission of a VLAN Name TLV and a Link Aggregation TLV.

```
# lldpadm set-agentprop -p dot1-tlv=vlanname net0
# lldpadm set-agentprop -p dot1-tlv+=linkaggr net0
```

The following command configures transmission of all dot3-tlvs.

```
# lldpadm set-agentprop -p dot3-tlv=all net0
```

All the above lldpadm invocations can be combined into the following, single invocation.

EXAMPLE 3 Configuring TLVs   *(Continued)*

```
# lldpadm set-agentprop -p basic-tlv=portdesc,sysname,\
dot1-tlv=vlanname,linkaggr,dot3-tlv=all net0
```

EXAMPLE 4 Disabling Transmission

The following command disables the transmission of all `dot1-tlv`s out of an LLDP agent.

```
# lldpadm set-agentprop -p dot1-tlv=none net0
```

The following command is equivalent to the preceding.

```
# lldpadm reset-agentprop -p dot1-tlv net0
```

EXAMPLE 5 Configuring Enabled Capabilities

The following command configures the enabled capabilities on a system.

```
# lldpadm set-tlvprop -p enabled=router syscapab
```

With this configuration, when an LLDP agent is enabled for advertising a System Capabilities TLV, the adjacent neighbors would learn of the local system's capabilities.

EXAMPLE 6 Configuring a Management Address for Subsequent Advertising

The following command configures the management address that will be advertised by means of the Management Address TLV.

```
# lldpadm set-tlvprop -p ipaddr=192.168.1.2 mgmtaddr
```

Note that this address would be identified as an address associated with the local LLDP agent that will be used to reach higher layer entities to assist discovery by network management.

EXAMPLE 7 Configuring an Application TLV

The following sequence of commands configures the application TLV to advertise the priority that will be used by FCoE.

```
# lldpadm set-agenttlvprop -p apt=8906/1/4 -a net0 appln
# lldpadm show-agenttlvprop -a net0 appln
AGENT     TLVNAME PROPERTY  PERM VALUE      DEFAULT     POSSIBLE
net0      appln   apt       rw   8906/1/4   --          --
```

EXAMPLE 8 Show Local Information Advertised by LLDP Agent

The following commands show, respectively, brief and detailed local information advertised by an LLDP agent.

Brief information:

```
# lldpadm show-agent -l net0
AGENT             CHASSISID         PORTID
```

EXAMPLE 8 Show Local Information Advertised by LLDP Agent *(Continued)*

```
net0                   004bb87f                 00:14:4f:01:77:5d
```

Detailed information:

```
# lldpadm show-agent -lv net0
                    Agent: net0
       Chassis ID Subtype: Local(7)
               Chassis ID: 004bb87f
          Port ID Subtype: MacAddress(3)
                  Port ID: 00:14:4f:01:77:5d
         Port Description: net0
             Time to Live: 81 (seconds)
              System Name: hosta.example.com
       System Description: SunOS 5.11 dcb-clone-x-01-19-11 i86pc
    Supported Capabilities: bridge, router, station
      Enabled Capabilities: router
        Management Address: 192.168.1.2
        Maximum Frame Size: 3000
             Port VLAN ID: --
             VLAN Name/ID: vlan25/25
     VNIC PortID/VLAN ID : --
   Aggregation Information: Capable, Not Aggregated
              PFC Willing: --
                  PFC Cap: --
                  PFC MBC: --
               PFC Enable: --
Application(s)(ID/Sel/Pri): --
  Next Packet Transmission: 18 (seconds)
```

EXAMPLE 9 Show Remote Information about Adjacent Devices for an LLDP Agent

The following commands show, respectively, brief and detailed remote information about adjacent devices for a given LLDP agent.

Brief information:

```
# lldpadm show-agent -r net0
AGENT     SYSNAME     CHASSISID     PORTID
net0      hostb       0083b390      00:14:4f:01:59:ab
```

Detailed information:

```
# lldpadm show-agent -rv net0
                    Agent: net0
       Chassis ID Subtype: Local(7)
               Chassis ID: 0083b390
          Port ID Subtype: MacAddress(3)
                  Port ID: 00:14:4f:01:59:ab
```

EXAMPLE 9   Show Remote Information about Adjacent Devices for an LLDP Agent   *(Continued)*

```
          Port Description: net0
               Time to Live: 121 (seconds)
                System Name: hostb.example.com
         System Description: SunOS 5.11 dcb-clone-x-01-19-11 i86pc
      Supported Capabilities: bridge, router, station
        Enabled Capabilities: router
          Management Address: 192.168.1.3
          Maximum Frame Size: 3000
                Port VLAN ID: --
                VLAN Name/ID: vlan25/25
       VNIC PortID/VLAN ID : 02:08:20:72:71:31
     Aggregation Information: Capable, Not Aggregated
                  PFC Willing: --
                       PFC Cap: --
                       PFC MBC: --
                   PFC Enable: --
Application(s)(ID/Sel/Pri): --
     Information Valid Until: 117 (seconds)
```

EXAMPLE 10   Show LLDP Agent Statistics

The following command displays LLDP agent statistics.

```
# lldpadm show-agent -s net0
AGENT IFRAMES IERR IDISCARD OFRAMES OLENERR TLVDISCARD TLVUNRECOG AGEOUT
net0      44    0        0      57       0          0          0      0
```

Notes The lldpd(1M) daemon that implements the LLDP protocol must be first enabled before using the lldpadm command. The lldpd daemon is controlled through the service management facility (SMF) service instance:

```
svc:/network/lldp:default
```

Use svcadm(1M) to enable this service.

Name lldpd – Link Layer Discovery Protocol daemon

Synopsis /usr/lib/lldpd

svc:/network/lldp:default

Description lldpd is a system daemon that implements the Link Layer Discovery Protocol as specified in IEEE Std. 802.1AB. The daemon also manages LLDP agents on physical datalinks. Please see lldpadm(1M) for more information on administering LLDP on LLDP agents.

The lldpd daemon is controlled through the service management facility (SMF) service instance:

svc:/network/lldp:default

This means, svcadm(1M) must be used to start, stop, restart, and refresh this daemon. This daemon is disabled by default. To enable LLDP on any of the physical datalinks, this daemon should be running.

The lldpd daemon is a project private interface and has no user-accessible options.

Examples EXAMPLE 1 Enabling the Daemon

The following command enables the lldpd daemon.

```
# svcadm enable network/lldp
# svcs network/lldp
STATE          STIME    FMRI
online         Jan_26   svc:/network/lldp:default
```

EXAMPLE 2 Disabling the Daemon

The following command disables the lldpd daemon.

```
# svcadm disable network/lldp
# svcs network/lldp
STATE          STIME    FMRI
disabled       5:11:35  svc:/network/lldp:default
```

IEEE Std 802.1AB-2009, *IEEE Standard for Local and Metropolitan Area Networks: Station and Media Access Control Connectivity Discovery*

Name lms – allow applications to access the Intel Active Management Technology

Synopsis `lms`

Description The Local Manageability Service, `lms`, allows applications to access the Intel Active Management Technology (Intel AMT) ME (Management Engine) using the local HECI interface. LMS is dependent on the HECI driver.

To use `lms`, ensure that the Intel AMT Manageability Interface driver is installed and connected to the ME.

`lms` is intended to be run as a daemon. Messages from the service are sent to the `syslog`. LMS messages are marked with a source of `"LMS"`.

For an example of how to enable the LMS service using SMF, see EXAMPLES.

Examples EXAMPLE 1 Enabling the LMS service using SMF

The following example enables the LMS service using SMF:

```
svcadm enable network/lms
```

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Name localectr – customize and build new locales

Synopsis /usr/bin/localectr

/usr/bin/localectr -l *locale1,locale2*... [-d *destination_path*]
    [-c *compiler_path*] [-r 0 | 1 | 2] [-i *pkginfo_template*]
    [-p *pkgname_prefix*]

/usr/bin/localectr -h

/usr/bin/localectr -q

/usr/bin/localectr -V

Description The localectr utility allows new locales to be customized and built. The output of localectr is an installable package containing the compiled shared object binary which contains the locale data information as well as a number of other supporting files that are required to have a fully working locale on the system.

Once generated, the package can be added to the system by using the pkgadd(1M) command and removed with pkgrm(1M).

Depending on your default system login, you might have to reset your user environment after you add a locale. If dtlogin(1X) (for the CDE user environment) is the default system login, you need to restart dtlogin. No action is required if gdm(1) (for the Gnome user environment) is the default login.

There are two interfaces to localectr, command line (CLI) and graphical user interface (GUI). To customize the locale data, you must use the GUI. To create locales with standard locale data according to Unicode's Common Locale Data Repository (CLDR), the CLI is sufficient.

With the CLI it is also possible to generate several locales in a single step, with a separate package being generated for each locale. With the GUI, a single locale is processed at a time.

To launch the GUI, run the localectr command with no options. To run from the CLI, use the appropriate options as described below.

localectr uses the localedef(1) utility to build the locale data binary shared object. Therefore, access to a C compiler is required in order to run localectr successfully, as this is also required by localedef.

localectr is mainly concerned with locale data. However, in order to create a fully working locale on the system with localectr, many features, such as fonts, translations and input methods, are also required. Depending on what locales are already installed on the system, the relevant features might or might not be present on the system. localectr bundles locale data for the latest set of locales available in Unicode's CLDR. A user can also create a locale not available in CLDR by supplying her own data in the localectr GUI.

Options The following options are supported:

-c *compiler_path*

Specify the path to the C compiler that is used to compile the locale data into a shared object binary. Not required if the compiler is already in the user's PATH.

-d *destination_path*

Specify the path to the directory where the created package is to be stored.

-h

Displays the usage message.

-i *template_file*

The full path to user defined pkginfo(4) template file.

-l *locale1,locale2...*

Specify a comma-separated list of locale(s) to generate. Locale names are in the form: *locale.codeset@variant*, where *codeset* and *variant* are optional. The default and only allowed *codeset* is UTF-8. The default *variant* is localectr.

-p

The package name prefix

-q

Queries localectr for a complete list of locales for which locale data is defined in localectr. When localectr is run from the CLI, the locale(s) specified with the -l option must be on this list in order for an installable locale package to be generated.

-r

Specify the range of Unicode characters for which locale data rules in the LC_CTYPE and LC_COLLATE categories are to be generated. There are three valid options:

0

Locale data rules are restricted to the exemplar or to commonly used characters of the locale in question.

1

Locale data rules are restricted to the Unicode plane 0 characters, whose codepoints fall in the range u0000-uFFFF.

2

Locale data rules are generated for all codepoints defined in the latest version of Unicode that is supported by the system on which localectr is being run.

-V

Shows the version of this software.

Examples EXAMPLE 1 Launching the GUI

The following example launches the localectr GUI.

example% **localectr**

EXAMPLE 2   Generating Locale for Afrikaans (South Africa) with Default Locale Data

The following example generates a package in the specified destination directory, which can be used to install the Afrikaans (af_ZA.UTF-8) locale on the system. The package name is composed of a prefix followed by the hyphen separated ISO-639 language code, the ISO-3166 country code, the locale encoding and an optional user-defined tag. The resulting package can then be added to the system using pkgadd(1M).

```
example% localectr -l af_ZA -d /tmp
```

EXAMPLE 3   Generating Several South Africa Locales with Full Unicode Range of Characters

The following example generates an installable package for each of the specified locales.

```
example% localectr -l af_ZA,en_ZA,xh_ZA,zu_ZA -d /tmp -r 2
```

EXAMPLE 4   Generating the Irish Locale with a User-Specified Tag

The following example will generate a locale whose full name is ga_IE.UTF-8@mycompanyname.

```
example% localectr -l ga_IE@mycompanyname -d /tmp
```

Exit Status   The following exit codes are returned:

0
   Successful completion

>0
   An error occurred.

Files   /usr/bin/localectr
   Wrapper script that launches locale creator.

/usr/lib/localectr
   Jar files, scripts, and locale data repository needed to run the application.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWlocalecreator
Interface Stability	See below.

Interface stability is Committed for command-line options and is Uncommitted for other interfaces.

International Language Environments Guide

Name locator – location indicator control

Synopsis /usr/sbin/locator [-f | -n]

Description The locator command sets or queries the state of the system locator if such a device exists.

Without options, the locator command reports the current state of the system.

The privileges required to use this command are hardware dependent. Typically, only the super user can get or set a locator.

Options The following options are supported:

-f   Turns the locator off.

-n   Turns the locator on.

Examples EXAMPLE 1   Using the locator Command on a Platform Which Has a System Locator LED

When issued on a platform which has a system locator LED, the following command turns the locator on:

```
# locator -n
# locator
The 'system' locator is on
```

EXAMPLE 2   Using the locator Command on a Platform Which Does Not Have a System Locator LED

When issued on a platform which does not have a system locator LED, the following command attempts to turn the locator on. The command returns an error message.

```
# locator -n
'system' locator not found
```

Exit Status The following exit values are returned:

0   Successful completion.

1   Invalid command line input.

2   The requested operation failed.

Attributes See attributes(5) for descriptions of the following attributes:

Name lockd – network lock daemon

Synopsis /usr/lib/nfs/lockd [-g *graceperiod*] [-l *listen_min_backlog*]
              [-t *timeout*] [*nthreads*]

Description The lockd utility is part of the NFS lock manager, which supports record locking operations
on NFS files. See fcntl(2) and lockf(3C). The lock manager provides the following two
functions:

- It forwards fcntl(2) locking requests for NFS mounted file systems to the lock manager on
  the NFS server.

- It generates local file locking operations in response to requests forwarded from lock
  managers running on NFS client machines.

State information kept by the lock manager about these locking requests can be lost if the
lockd is killed or the operating system is rebooted. Some of this information can be recovered
as follows. When the server lock manager restarts, it waits for a grace period for all client-site
lock managers to submit reclaim requests. Client-site lock managers, on the other hand, are
notified by the status monitor daemon, statd(1M), of the restart and promptly resubmit
previously granted lock requests. If the lock daemon fails to secure a previously granted lock at
the server site, then it sends SIGLOST to a process.

Administrators can make changes to the startup parameters for lockd by logging in as root
and using the sharectl(1M) command.

SMF Management The lockd service is managed by the service management facility, smf(5), under the service
identifier:

svc:/network/nfs/nlockmgr

Administrative actions on this service, such as enabling, disabling, or requesting restart, can
be performed using svcadm(1M). The service's status can be queried using the svcs(1)
command.

If it is disabled, it will be enabled by mount_nfs(1M), share_nfs(1M), and automountd(1M)
unless its application/auto_enable property is set to false.

The sharectl(1M) command is used to manipulate the startup SMF parameters for lockd.
Currently supported parameters are as follows:

lockd_listen_backlog=*num*
  Set connection queue length for lockd over a connection-oriented transport. The default
  and minimum value is 32. Equivalent to -l option.

lockd_servers=*num*
  Maximum number of concurrent lockd requests. The default is 1024. Equivalent to the
  nthreads operand.

lockd_retransmit_timeout=*num*
> Retransmit timeout, in seconds, before lockd retries. The default is 5. Equivalent to -t option.

grace_period=*num*
> Grace period, in seconds, that all clients (both NLM and NFSv4) have to reclaim locks after a server reboot. This parameter also controls the NFSv4 lease interval. The default is 90. Equivalent to -g option.

See EXAMPLES, below.

Options The following options are supported:

-g *graceperiod*
> Deprecated in favor of grace_period. Specify the number of seconds that all clients (both NLM and NFSv4) have to reclaim locks after the server reboots. It also controls the NFSv4 lease interval. This option is equivalent to the grace_period property described above.

-l *listen_min_backlog*
> Specify the listener backlog (*listen_min_backlog*). *listen_min_backlog* is the number connect requests that are queued and waiting to be processed before new connect requests start to get dropped. Equivalent of the lockd_listen_backlog property described above.

-t *timeout*
> Specify the number of seconds to wait before retransmitting a lock request to the remote server. The default value is 5 seconds. Equivalent of the lockd_retransmit_timeout property described above.

Operands *nthreads*
> Specify the maximum number of concurrent threads that the server can handle. This concurrency is achieved by up to *nthreads* threads created as needed in the kernel. *nthreads* should be based on the load expected on this server. If *nthreads* is not specified, the maximum number of concurrent threads will default to 1024. Equivalent of the lockd_servers property described above.

Examples **EXAMPLE 1** Setting a lockd Property

The following command sets lockd_listen_backlog to a new value:

```
# sharectl set -p lockd_listen_backlog=40 nfs
```

The lockd_listen_backlog and other lockd properties are described under NOTES, below.

EXAMPLE 2 Getting a lockd Property Value

The following command retrieves the value of the lockd_listen_backlog property.

```
% sharectl get -p lockd_listen_backlog nfs
lockd_listen_backlog=40
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/nfs

Notes The lockd daemon might not exist in a future release of Solaris.

Name   lockfs – change or report file system locks

Synopsis   /usr/sbin/lockfs [-adefhnuw] [-c *string*] [*file-system*]...

Description   lockfs is used to change and report the status of file system locks. lockfs reports the lock status and unlocks the file systems that were improperly left locked.

Using lockfs to lock a file system is discouraged because this requires extensive knowledge of SunOS internals to be used effectively and correctly.

When invoked with no arguments, lockfs lists the UFS file systems that are locked. If *file-system* is not specified, and -a is specified, lockfs is run on all mounted, UFS type file systems.

Options   The options are mutually exclusive: wndheuf. If you do specify more than one of these options on a lockfs command line, the utility does not protest and invokes only the last option specified. In particular, you cannot specify a flush (-f) and a lock (for example, -w) on the same command line. However, all locking operations implicitly perform a flush, so the -f is superfluous when specifying a lock.

You must be super-user to use any of the following options, with the exception of -a, -f and -v.

The following options are supported.

-a
   Apply command to all mounted, UFS type file systems. *file-system* is ignored when -a is specified.

-c *string*
   Accept a string that is passed as the comment field. The -c only takes affect when the lock is being set using the -d, -h, -n, -u, or -w options.

-d
   Delete-lock (dlock) the specified *file-system*. dlock suspends access that could remove directory entries.

-e
   Error-lock (elock) the specified *file-system*. elock blocks all local access to the locked file system and returns EWOULDBLOCK on all remote access. File systems are elocked by UFS on detection of internal inconsistency. They may only be unlocked after successful repair by fsck, which is usually done automatically (see mount_ufs(1M)). elocked file systems can be unmounted.

-f
   Force a synchronous flush of all data that is dirty at the time fsflush is run to its backing store for the named file system (or for all file systems.)

It is a more reliable method than using sync(1M) because it does not return until all possible data has been pushed. In the case of UFS filesystems with logging enabled, the log is also rolled before returning. Additional data can be modified by the time fsflush exits, so using one of the locking options is more likely to be of general use.

-h

Hard-lock (hlock) the specified *file-system*. hlock returns an error on every access to the locked file system, and cannot be unlocked. hlocked file systems can be unmounted.

-n

Name-lock (nlock) the specified *file-system*. nlock suspends accesses that could change or remove existing directories entries.

-u

Unlock (ulock) the specified *file-system*. ulock awakens suspended accesses.

-v

Enable verbose output.

-w

Write-lock (wlock) the specified *file-system*. wlock suspends writes that would modify the file system. Access times are not kept while a file system is write-locked.

Operands The following operands are supported.

file-system

A list of path names separated by whitespace. Note that *file-system* can be a directory rather than the specific name of a file system, such as / or /usr. For example, if you specify /export/home as an argument to a lockfs command and /export/home is mounted on the root (/) file system, the lockfs command will take effect on the root file system.

Usage See largefile(5) for the description of the behavior of lockfs when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples EXAMPLE 1 Using lockfs -a

In the following examples, *filesystem* is the pathname of the mounted-on directory (mount point). Locktype is one of "write," "*name*," "*delete*," "*hard*," or "*unlock*". When enclosed in parenthesis, the lock is being set. Comment is a string set by the process that last issued a lock command.

The following example shows the lockfs output when only the -a option is specified.

```
example#   /usr/sbin/lockfs -a
```

Filesystem	Locktype	Comment
/	unlock	

EXAMPLE 1 Using lockfs -a   *(Continued)*

/var	unlock

example#

EXAMPLE 2 Using lockfs -w

The following example shows the lockfs output when the -w option is used to write lock the /var file system and the comment string is set using the -c option. The -a option is then specified on a separate command line.

```
example#  /usr/sbin/lockfs -w -c "lockfs: write lock example" /var
example#  /usr/sbin/lockfs -a
```

Filesystem	Locktype	Comment
/	unlock	
/var	write	lockfs: write lock example

example#

EXAMPLE 3 Using lockfs -u

The following example shows the lockfs output when the -u option is used to unlock the /var file system and the comment string is set using the -c option.

```
example#  /usr/sbin/lockfs -uc "lockfs: unlock example" /var
example#  /usr/sbin/lockfs /var
```

Filesystem	Locktype	Comment
/var	unlock	lockfs: unlock example

example#

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Oracle Solaris Administration: Common Tasks

Diagnostics *file system*: Not owner
You must be root to use this command.

file system :Deadlock condition detected/avoided
A file is enabled for accounting or swapping, on *file system*.

file system: Device busy
Another process is setting the lock on *file system*.

Name lockstat – report kernel lock and profiling statistics

Synopsis lockstat [-ACEHI] [-e *event_list*] [-i *rate*]
        [-b | -t | -h | -s *depth*] [-n *nrecords*]
        [-l *lock* [, *size*]] [-d *duration*]
        [-f *function* [, *size*]] [-T] [-ckgwWRpP] [-D *count*]
        [-o *filename*] [-x *opt* [=val]] *command* [*args*]

Description The lockstat utility gathers and displays kernel locking and profiling statistics. lockstat
allows you to specify which events to watch (for example, spin on adaptive mutex, block on
read access to rwlock due to waiting writers, and so forth) how much data to gather for each
event, and how to display the data. By default, lockstat monitors all lock contention events,
gathers frequency and timing data about those events, and displays the data in decreasing
frequency order, so that the most common events appear first.

lockstat gathers data until the specified command completes. For example, to gather
statistics for a fixed-time interval, use sleep(1) as the command, as follows:

example# lockstat sleep 5

When the -I option is specified, lockstat establishes a per-processor high-level periodic
interrupt source to gather profiling data. The interrupt handler simply generates a lockstat
event whose caller is the interrupted PC (program counter). The profiling event is just like any
other lockstat event, so all of the normal lockstat options are applicable.

lockstat relies on DTrace to modify the running kernel's text to intercept events of interest.
This imposes a small but measurable overhead on all system activity, so access to lockstat is
restricted to super-user by default. The system administrator can permit other users to use
lockstat by granting them additional DTrace privileges. Refer to the *Solaris Dynamic Tracing
Guide* for more information about DTrace security features.

Options The following options are supported:

Event Selection If no event selection options are specified, the default is -C.

-A
    Watch all lock events. -A is equivalent to -CH.

-C
    Watch contention events.

-E
    Watch error events.

-e *event_list*
    Only watch the specified events. *event list* is a comma-separated list of events or ranges of
    events such as 1,4-7,35. Run lockstat with no arguments to get a brief description of all
    events.

-H

    Watch hold events.

-I

    Watch profiling interrupt events.

-i *rate*

    Interrupt rate (per second) for -I. The default is 97 Hz, so that profiling doesn't run in lockstep with the clock interrupt (which runs at 100 Hz).

Data Gathering   -x *arg*[=*val*]

    Enable or modify a DTrace runtime option or D compiler option. The list of options is found in dtrace(1M). Boolean options are enabled by specifying their name. Options with values are set by separating the option name and value with an equals sign (=).

Data Gathering   -b
(Mutually Exclusive)

    Basic statistics: lock, caller, number of events.

-h

    Histogram: Timing plus time-distribution histograms.

-s *depth*

    Stack trace: Histogram plus stack traces up to *depth* frames deep.

-t

    Timing: Basic plus timing for all events [default].

Data Filtering   -d *duration*

    Only watch events longer than *duration*.

-f *func[,size]*

    Only watch events generated by *func*, which can be specified as a symbolic name or hex address. *size* defaults to the ELF symbol size if available, or 1 if not.

-l *lock[,size]*

    Only watch *lock*, which can be specified as a symbolic name or hex address. size defaults to the ELF symbol size or 1 if the symbol size is not available.

-n *nrecords*

    Maximum number of data records.

-T

    Trace (rather than sample) events [off by default].

Data Reporting   -c

    Coalesce lock data for lock arrays (for example, pse_mutex[]).

-D *count*

    Only display the top *count* events of each type.

-g

Show total events generated by function. For example, if `foo()` calls `bar()` in a loop, the work done by `bar()` counts as work generated by `foo()` (along with any work done by `foo()` itself). The `-g` option works by counting the total number of stack frames in which each function appears. This implies two things: (1) the data reported by `-g` can be misleading if the stack traces are not deep enough, and (2) functions that are called recursively might show greater than 100% activity. In light of issue (1), the default data gathering mode when using `-g` is `-s 50`.

-k

Coalesce PCs within functions.

-o *filename*

Direct output to *filename*.

-P

Sort data by (*count * time*) product.

-p

Parsable output format.

-R

Display rates (events per second) rather than counts.

-W

Whichever: distinguish events only by caller, not by lock.

-w

Wherever: distinguish events only by lock, not by caller.

Display Formats   The following headers appear over various columns of data.

Count or ops/s

Number of times this event occurred, or the rate (times per second) if `-R` was specified.

indv

Percentage of all events represented by this individual event.

genr

Percentage of all events generated by this function.

cuml

Cumulative percentage; a running total of the individuals.

rcnt

Average reference count. This will always be 1 for exclusive locks (mutexes, spin locks, rwlocks held as writer) but can be greater than 1 for shared locks (rwlocks held as reader).

nsec

Average duration of the events in nanoseconds, as appropriate for the event. For the profiling event, duration means interrupt latency.

Lock
    Address of the lock; displayed symbolically if possible.

CPU+PIL
    CPU plus processor interrupt level (PIL). For example, if CPU 4 is interrupted while at PIL
    6, this will be reported as cpu[4]+6.

Caller
    Address of the caller; displayed symbolically if possible.

Examples   EXAMPLE 1   Measuring Kernel Lock Contention

```
example# lockstat sleep 5
Adaptive mutex spin: 2210 events in 5.055 seconds (437 events/sec)

EXAMPLE 4   Basic Kernel Profiling

For basic profiling, we don't care whether the profiling interrupt sampled foo()+0x4c or foo()+0x78; we care only that it sampled somewhere in foo(), so we use -k. The CPU and PIL aren't relevant to basic profiling because we are measuring the system as a whole, not a particular CPU or interrupt level, so we use -W.

```
example# lockstat -kIW -D 20 ./polltest
Profiling interrupt: 82 events in 0.424 seconds (194
events/sec)

Count indv cuml rcnt     nsec Hottest CPU+PIL    Caller
-------------------------------------------------------------------------

```

EXAMPLE 5 Generated-load Profiling

In the example above, 5% of the samples were in poll(). This tells us how much time was spent inside poll() itself, but tells us nothing about how much work was *generated* by poll(); that is, how much time we spent in functions called by poll(). To determine that, we use the -g option. The example below shows that although polltest spends only 5% of its time in poll() itself, poll()-induced work accounts for 34% of the load.

Note that the functions that generate the profiling interrupt (lockstat_intr(), cyclic_fire(), and so forth) appear in every stack trace, and therefore are considered to have generated 100% of the load. This illustrates an important point: the generated load percentages do *not* add up to 100% because they are not independent. If 72% of all stack traces contain both foo() and bar(), then both foo() and bar() are 72% load generators.

```
example# lockstat -kgIW -D 20 ./polltest
Profiling interrupt: 80 events in 0.412 seconds (194 events/sec)

Count genr cuml rcnt     nsec Hottest CPU+PIL    Caller

```

EXAMPLE 6 Gathering Lock Contention and Profiling Data for a Specific Module

In this example we use the -f option not to specify a single function, but rather to specify the entire text space of the sbus module. We gather both lock contention and profiling statistics so that contention can be correlated with overall load on the module.

```
example# modinfo | grep sbus
 24 102a8b6f   b8b4 59   1  sbus (SBus (sysio) nexus driver)

example# lockstat -kICE -f 0x102a8b6f,0xb8b4 sleep 10

Solaris Dynamic Tracing Guide

Notes   The profiling support provided by lockstat -I replaces the old (and undocumented) /usr/bin/kgmon and /dev/profile.

Tail-call elimination can affect call sites. For example, if foo()+0x50 calls bar() and the last thing bar() does is call mutex_exit(), the compiler can arrange for bar() to branch to mutex_exit() with a return address of foo()+0x58. Thus, the mutex_exit() in bar() will appear as though it occurred at foo()+0x58.

The PC in the stack frame in which an interrupt occurs can be bogus because, between function calls, the compiler is free to use the return address register for local storage.

When using the -I and -s options together, the interrupted PC will usually not appear anywhere in the stack since the interrupt handler is entered asynchronously, not by a function call from that PC.

The lockstat technology is provided on an as-is basis. The format and content of lockstat output reflect the current Solaris kernel implementation and are therefore subject to change in future releases.

Name   lofiadm – administer files available as block devices through lofi

Synopsis   /usr/sbin/lofiadm -a *file* [*device*]

/usr/sbin/lofiadm -c *crypto_algorithm* -a *file* [*device*]

/usr/sbin/lofiadm -c *crypto_algorithm* -k *raw_key_file* -a *file* [*device*]

/usr/sbin/lofiadm -c *crypto_algorithm* -T *token_key* -a *file* [*device*]

/usr/sbin/lofiadm -c *crypto_algorithm* -T *token_key*
        -k *wrapped_key_file* -a *file* [*device*]

/usr/sbin/lofiadm -c *crypto_algorithm* -e -a *file* [*device*]

/usr/sbin/lofiadm -C *algorithm* [-s *segment_size*] *file*

/usr/sbin/lofiadm -d *file* | *device*

/usr/sbin/lofiadm -U *file*

/usr/sbin/lofiadm [*file* | *device*]

Description   lofiadm administers lofi, the loopback file driver. lofi allows a file to be associated with a
block device. That file can then be accessed through the block device. This is useful when the
file contains an image of some filesystem (such as a CD-ROM image), because the block device
can then be used with the normal system utilities for mounting, checking or repairing file
systems. See fsck(1M) and mount(1M).

Use lofiadm to add a file as a loopback device, remove such an association, or display
information about the current associations.

The number of potential lofi devices is limited by the zone.max-lofi rctl, which can be set
by means of zonecfg(1M) in the global zone. See resource_controls(5) for a description of
zone.max-lofi.

Encryption and compression options are mutually exclusive on the command line. Further,
an encrypted file cannot be compressed later, nor can a compressed file be encrypted later.

In the global zone, lofiadm can be used on both the global zone devices and all devices owned
by other non-global zones on the system.

Options   The following options are supported:

-a *file* [*device*]
    Add *file* as a block device.

    If *device* is not specified, an available device is picked.

    If *device* is specified, lofiadm attempts to assign it to *file*. *device* must be available or
    lofiadm will fail. The ability to specify a device is provided for use in scripts that wish to
    reestablish a particular set of associations.

-C {*gzip* | *gzip-N* | *lzma*}
    Compress the file with the specified compression algorithm.

    The gzip compression algorithm uses the same compression as the open-source gzip
    command. You can specify the gzip level by using the value gzip-*N* where *N* is 6 (fast) or 9
    (best compression ratio). Currently, gzip, without a number, is equivalent to gzip-6
    (which is also the default for the gzip command).

    lzma stands for the LZMA (Lempel-Ziv-Markov) compression algorithm.

    Note that you cannot write to a compressed file, nor can you mount a compressed file
    read/write.

-d *file* | *device*
    Remove an association by *file* or *device* name, if the associated block device is not busy, and
    deallocates the block device.

-s *segment_size*
    The segment size to use to divide the file being compressed. *segment_size* can be an integer
    multiple of 512.

-U *file*
    Uncompress a compressed file.

The following options are used when the file is encrypted:

-c *crypto_algorithm*
    Select the encryption algorithm. The algorithm must be specified when encryption is
    enabled because the algorithm is not stored in the disk image.

    If none of -e, -k, or -T is specified, lofiadm prompts for a passphrase, with a minimum
    length of eight characters, to be entered . The passphrase is used to derive a symmetric
    encryption key using PKCS#5 PBKD2.

-k *raw_key_file* | *wrapped_key_file*
    Path to raw or wrapped symmetric encryption key. If a PKCS#11 object is also given with
    the -T option, then the key is wrapped by that object. If -T is not specified, the key is used
    raw.

-T *token_key*
    The key in a PKCS#11 token to use for the encryption or for unwrapping the key file.

    If -k is also specified, -T identifies the unwrapping key, which must be an RSA private key.

-e
    Generate an ephemeral symmetric encryption key.

Operands   The following operands are supported:

crypto_algorithm
    One of: aes-128-cbc, aes-192-cbc, aes-256-cbc, des3-cbc, blowfish-cbc.

device
    Display the file name associated with the block device *device*.

    Without arguments, print a list of the current associations. Filenames must be valid absolute pathnames.

    When a file is added, it is opened for reading or writing by root. Any restrictions apply (such as restricted root access over NFS). The file is held open until the association is removed. It is not actually accessed until the block device is used, so it will never be written to if the block device is only opened read-only.

    Note that the filename might appear as a question mark (?) if it is not possible to resolve the path in the current context (for example, if it is an NFS path in a non-global zone).

file
    Display the block device associated with *file*.

raw_key_file
    Path to a file of the appropriate length, in bits, to use as a raw symmetric encryption key.

token_key
    PKCS#11 token object in the format:

    token_name:*manufacturer_id*:*serial_number*:*key_label*

    All but the key label are optional and can be empty. For example, to specify a token object with only its key label MylofiKey, use:

    -T :::MylofiKey

wrapped_key_file
    Path to file containing a symmetric encryption key wrapped by the RSA private key specified by -T.

Examples   **EXAMPLE 1**   Mounting an Existing CD-ROM Image

You should ensure that Solaris understands the image before creating the CD. lofi allows you to mount the image and see if it works.

This example mounts an existing CD-ROM image (sparc.iso), of the Red Hat 6.0 CD which was downloaded from the Internet. It was created with the mkisofs utility from the Internet.

Use lofiadm to attach a block device to it:

```
# lofiadm -a /home/mike_s/RH6.0/sparc.iso
/dev/lofi/1
```

EXAMPLE 1 Mounting an Existing CD-ROM Image   *(Continued)*

lofiadm picks the device and prints the device name to the standard output. You can run
lofiadm again by issuing the following command:

```
# lofiadm
Block Device     File                          Options
/dev/lofi/1      /home/mike_s/RH6.0/sparc.iso  -
```

Or, you can give it one name and ask for the other, by issuing the following command:

```
# lofiadm /dev/lofi/1
/home/mike_s/RH6.0/sparc.iso
```

Use the mount command to mount the image:

```
# mount -F hsfs -o ro /dev/lofi/1 /mnt
```

Check to ensure that Solaris understands the image:

```
# df -k /mnt
Filesystem         kbytes    used    avail capacity  Mounted on
/dev/lofi/1        512418  512418       0   100%     /mnt
# ls /mnt
./           RedHat/     doc/         ls-lR        rr_moved/
../          TRANS.TBL   dosutils/    ls-lR.gz     sbin@
.buildlog    bin@        etc@         misc/        tmp/
COPYING      boot/       images/      mnt/         usr@
README       boot.cat*   kernels/     modules/
RPM-PGP-KEY  dev@        lib@         proc/
```

Solaris can mount the CD-ROM image, and understand the filenames. The image was created
properly, and you can now create the CD-ROM with confidence.

As a final step, unmount and detach the images:

```
# umount /mnt
# lofiadm -d /dev/lofi/1
# lofiadm
Block Device          File          Options
```

EXAMPLE 2 Making a UFS Filesystem on a File

Making a UFS filesystem on a file can be useful, particularly if a test suite requires a scratch
filesystem. It can be painful (or annoying) to have to repartition a disk just for the test suite,
but you do not have to. You can newfs a file with lofi

Create the file:

```
# mkfile 35m /export/home/test
```

Attach it to a block device. You also get the character device that newfs requires, so newfs that:

EXAMPLE 2   Making a UFS Filesystem on a File   *(Continued)*

```
# lofiadm -a /export/home/test
/dev/lofi/1
# newfs /dev/rlofi/1
newfs: construct a new file system /dev/rlofi/1: (y/n)? y
/dev/rlofi/1:   71638 sectors in 119 cylinders of 1 tracks, 602 sectors
        35.0MB in 8 cyl groups (16 c/g, 4.70MB/g, 2240 i/g)
super-block backups (for fsck -F ufs -o b=#) at:
 32, 9664, 19296, 28928, 38560, 48192, 57824, 67456,
```

Note that ufs might not be able to use the entire file. Mount and use the filesystem:

```
# mount /dev/lofi/1 /mnt
# df -k /mnt
Filesystem            kbytes     used   avail capacity  Mounted on
/dev/lofi/1            33455        9   30101     1%    /mnt
# ls /mnt
./          ../         lost+found/
# umount /mnt
# lofiadm -d /dev/lofi/1
```

EXAMPLE 3   Creating a PC (FAT) File System on a Unix File

The following series of commands creates a FAT file system on a Unix file. The file is associated with a block device created by lofiadm.

```
# mkfile 10M /export/test/testfs
# lofiadm -a /export/test/testfs
/dev/lofi/1
Note use of rlofi, not lofi, in following command.
# mkfs -F pcfs -o nofdisk,size=20480 /dev/rlofi/1
Construct a new FAT file system on /dev/rlofi/1: (y/n)? y
# mount -F pcfs /dev/lofi/1 /mnt
# cd /mnt
# df -k .
Filesystem            kbytes     used   avail capacity  Mounted on
/dev/lofi/1            10142        0   10142     0%    /mnt
```

EXAMPLE 4   Compressing an Existing CD-ROM Image

The following example illustrates compressing an existing CD-ROM image (solaris.iso), verifying that the image is compressed, and then uncompressing it.

```
# lofiadm -C gzip /export/home/solaris.iso
```

Use lofiadm to attach a block device to it:

```
# lofiadm -a /export/home/solaris.iso
  /dev/lofi/1
```

EXAMPLE 4 Compressing an Existing CD-ROM Image   *(Continued)*

Check if the mapped image is compressed:

```
# lofiadm
Block Device      File                      Options
/dev/lofi/1       /export/home/solaris.iso  Compressed(gzip)
/dev/lofi/2       /export/home/regular.iso  -
```

Unmap the compressed image and uncompress it:

```
# lofiadm -d /dev/lofi/1
# lofiadm -U /export/home/solaris.iso
```

EXAMPLE 5 Creating an Encrypted UFS File System on a File

This example is similar to the example of making a UFS filesystem on a file, above.

Create the file:

```
# mkfile 35m /export/home/test
```

Attach the file to a block device and specify that the file image is encrypted. As a result of this command, you obtain the character device, which is subsequently used by newfs:

```
# lofiadm -c aes-256-cbc -a /export/home/secrets
Enter passphrase: My-M0th3r;l0v3s_m3+4lw4ys!         (not echoed)
Re-enter passphrase: My-M0th3r;l0v3s_m3+4lw4ys!      (not echoed)
/dev/lofi/1

# newfs /dev/rlofi/1
newfs: construct a new file system /dev/rlofi/1: (y/n)? y
/dev/rlofi/1:   71638 sectors in 119 cylinders of 1 tracks, 602 sectors
        35.0MB in 8 cyl groups (16 c/g, 4.70MB/g, 2240 i/g)
super-block backups (for fsck -F ufs -o b=#) at:
32, 9664, 19296, 28928, 38560, 48192, 57824, 67456,
```

The mapped file system shows that encryption is enabled:

```
# lofiadm
Block Device    File                   Options
/dev/lofi/1     /export/home/secrets   Encrypted
```

Mount and use the filesystem:

```
# mount /dev/lofi/1 /mnt
# cp moms_secret_*_recipe /mnt
# ls /mnt
./           moms_secret_cookie_recipe    moms_secret_soup_recipe
../          moms_secret_fudge_recipe     moms_secret_stuffing_recipe
lost+found/  moms_secret_meatloaf_recipe  moms_secret_waffle_recipe
```

EXAMPLE 5   Creating an Encrypted UFS File System on a File   *(Continued)*

```
# umount /mnt
# lofiadm -d /dev/lofi/1
```

Subsequent attempts to map the filesystem with the wrong key or the wrong encryption
algorithm will fail:

```
# lofiadm -c blowfish-cbc -a /export/home/secrets
Enter passphrase: mommy                                    (not echoed)
Re-enter passphrase: mommy                                 (not echoed)
lofiadm: could not map file /root/lofi: Invalid argument
# lofiadm
Block Device    File                  Options
#
```

Attempts to map the filesystem without encryption will succeed, however attempts to mount
and use the filesystem will fail:

```
# lofiadm -a /export/home/secrets
/dev/lofi/1
# lofiadm
Block Device    File                  Options

#
```

Environment Variables See environ(5) for descriptions of the following environment variables that affect the
execution of lofiadm: LC_CTYPE, LC_MESSAGES and NLSPATH.

Exit Status The following exit values are returned:

0
   Successful completion.

>0
   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also fsck(1M), mount(1M), mount_ufs(1M), newfs(1M), zonecfg(1M), attributes(5),
resource_controls(5), lofi(7D), lofs(7FS)

Notes Just as you would not directly access a disk device that has mounted file systems, you should not access a file associated with a block device except through the `lofi` file driver. It might also be appropriate to ensure that the file has appropriate permissions to prevent such access.

The abilities of `lofiadm`, and who can use them, are controlled by the permissions of `/dev/lofictl`. Read-access allows query operations, such as listing all the associations. Write-access is required to do any state-changing operations, like adding an association. As shipped, `/dev/lofictl` is owned by `root`, in group `sys`, and mode `0644`, so all users can do query operations but only root can change anything. The administrator can give users write-access, allowing them to add or delete associations, but that is very likely a security hole and should probably only be given to a trusted group.

When mounting a filesystem image, take care to use appropriate mount options. In particular, the `nosuid` mount option might be appropriate for UFS images whose origin is unknown. Also, some options might not be useful or appropriate, like `logging` or `forcedirectio` for UFS. For compatibility purposes, a raw device is also exported along with the block device. For example, newfs(1M) requires one.

The output of `lofiadm` (without arguments) might change in future releases.

Name logadm – manage endlessly growing log files

Synopsis `logadm`

`logadm [`-*options*`]` *logname*`...`

Description `logadm` is a general log rotation tool that is suitable for running from cron(1M).

Without arguments, `logadm` reads the `/etc/logadm.conf` file, and for every entry found in that file checks the corresponding log file to see if it should be rotated. Typically this check is done each morning by an entry in the root's `crontab`.

If the *logname* argument is specified, `logadm` renames the corresponding log file by adding a suffix so that the most recent log file ends with `.0` (that is, *logfile*`.0`), the next most recent ends with `.1` (that is, *logfile*`.1`), and so forth. By default, ten versions of old log files are kept (that is, *logfile*`.0` through *logfile*`.9`). At the point when what would be the eleventh file is logged, `logadm` automatically deletes the oldest version to keep the count of files at ten.

`logadm` takes a number of *options*. You can specify these options on the command line or in the `/etc/logadm.conf` file. The `logadm` command searches `/etc/logadm.conf` for lines of the form *logname options*

logname
> Identifies an entry in `/etc/logadm.conf`. This can be a name or the pathname of the log file. If you specify a log file, rather than a name, for this field, it must be a fully qualified pathname.

options
> Identifies command line options exactly as they would be entered on the command line. This allows commonly used log rotation policies to be stored in the `/etc/logadm.conf` file. See EXAMPLES.
>
> If *options* are specified both in `/etc/logadm.conf` and on the command line, those in the `/etc/logadm.conf` file are applied first. Therefore, the command line options override those in `/etc/logadm.conf`.
>
> Log file names specified in `/etc/logadm.conf` may contain filename substitution characters such as `*` and `?`, that are supported by csh(1).

Two options control when a log file is rotated. They are: `-s` size `-p` period.

When using more than one of these options at a time, there is an implied *and* between them. This means that all conditions must be met before the log is rotated.

If neither of these two options are specified, the default conditions for rotating a log file are: `-s 1b -p 1w`, which means the log file is only rotated if the size is non-zero and if at least 1 week has passed since the last time it was rotated.

By specifying -p never as a rotation condition, any other rotation conditions are ignored and logadm moves on to the expiration of old log files. By specifying -p now as a rotation condition, a log rotation is forced.

Unless specified by the -o, -g, or -m options, logadm replaces the log file (after renaming it) by creating an empty file whose owner, group ID, and permissions match the original file.

Three options control when old log files are expired: -A age -C count -S size. These options expire the oldest log files until a particular condition or conditions are met. For example, the combination -C 5 and the -S 10m options expires old log files until there are no more than 5 of the *and* their combined disk usage is no more than 10 megabytes. If none of these options are specified, the default expiration is -C 10 which keeps ten old log files. If no files are to be expired, use -C 0 to prevent expiration by default.

logadm stores timestamps in the file /var/logadm/timestamps. For users of previous versions of logadm, the utility automatically moves timestamps from /etc/logadm.conf, their previous repository, to /var/logadm/timestamps.

Options   The following options are supported:

-a *post_command*
    Execute the *post_command* after renaming the log file. *post_command* is passed to sh -c.

    Specify *post_command* as a valid shell command. Use quotes to protect spaces or shell metacharacters in *post_command*.

    This option can be used to restart a daemon that is writing to the file. When rotating multiple logs with one logadm command, *post_command* is executed only once after all the logs are rotated, not once per rotated log.

-A *age*
    Delete any versions that have not been modified for the amount of time specified by *age*.

    Specify *age* as a number followed by an h (hours), d (days), w(weeks), m (months), or y (years).

-b *pre_command*
    Execute *pre_command* before renaming the log file. *pre_command* is passed to sh -c.

    Specify *pre_command* as a valid shell command. Use quotes to protect spaces or shell metacharacters in the *pre_command*.

    This option can be used to stop a daemon that is writing to the file. When rotating multiple logs with one logadm command, *pre_command* is executed only once before all the logs are rotated, not once per rotated log.

-c
    Rotate the log file by copying it and truncating the original logfile to zero length, rather than renaming the file.

-C *count*
　　Delete the oldest versions until there are not more than *count* files left.

　　If no expire options (-A, -C, or -S) are specified, -C 10 is the default. To prevent the default expire rule from being added automatically, specify -C 0 .

-e *mail_addr*
　　Send error messages by email to *mail_addr*.

　　As logadm is typically run from cron(1M), error messages are captured by cron and mailed to the owner of the crontab.

　　This option is useful if you want the mail regarding error messages to go to another address instead. If no errors are encountered, no mail message is generated.

-E *cmd*
　　Execute *cmd* to expire the file, rather than deleting the old log file to expire it.

　　cmd is passed it to sh -c. The file is considered expired after *cmd* completes. If the old log file is not removed or renamed by the *cmd*, logadm considers it for expiration the next time that it runs on the specified log file. If present, the keyword $file is expanded in the specified *cmd* to the name of the file being expired.

　　This option is useful for tasks such as mailing old log files to administrators, or copying old log files to long term storage.

-f *conf_file*
　　Use *conf_file* instead of /etc/logadm.conf.

　　This option allows non-root users to keep their own logadm configuration files.

-F *timestamp_file*
　　Use *timestamp_file* instead of /var/logadm/timestamps to store logadm timestamps.

-g *group*
　　Create a new empty file with the ID specified by *group*, instead of preserving the group ID of the log file.

　　Specify *group* by name or by numeric group ID, as accepted by chgrp(1).

　　This option requires the ability to change file group ownership using the chgrp(1) command.

-h
　　Print a help message that describes logadm's options.

-l
　　Use local time rather than the Coordinated Universal Time (UTC) when naming rotated log files (see the discussion of percent sequences in the templates supplied with the -t option).

-m *mode*

   Create a new empty file with the mode specified by *mode*, instead of preserving the mode of the log file.

   Specify *mode* in any form that is accepted by the chmod(1) command.

-M *cmd*

   Use *cmd* to rename the log file. If the keyword $file is specified, it is expanded to the name of the log file. Similarly, the keyword $nfile is expanded to the new name of the log file. The $nfile keyword is only available with commands provided with the -M option. After the command completes, the log file is replaced by the rotate file. The default *cmd* is "/bin/mv $file $nfile".

-n

   Print the actions that the logadm command will perform without actually performing them.

   This option is useful for checking arguments before making any changes to the system.

   It is important to remember, however, that since log rotating actions are only printed with this option, logadm might not find files that need expiring, but if run without the -n logadm might create a file that needs expiring by performing the log rotating actions. Therefore, if you see no files being expired with the -n option, files still might be expired without it.

-N

   Prevent an error message if the specified logfile does not exist. Normally, logadm produces an error message if the log file is not found. With -N, if the log file doesn't exist logadm moves on to the expire rules (if any) and then to the next log file (if any), without creating the empty replacement log file.

-o *owner*

   Create the new empty file with *owner*, instead of preserving the owner of the log file.

   Specify *owner* in any form that is accepted by the chown(1) command.

-p *period*

   Rotate a log file after the specified time period (*period*).

   Specify *period* as a number followed by d for days, h for hours, w for weeks, m for months (30 days) or y for years. There are also two special values for period: now and never. "-p now" forces log rotation. "-p never" forces no log rotation.

-P *timestamp*

   Used by logadm to record the last time the log was rotated in /var/logadm/timestamps.

   This option uses *timestamp* to determine if the log rotation period has passed. The format of *timestamp* matches the format generated by ctime(3C), with quotes around it to protect embedded spaces. *timestamp* is always recorded in the Coordinated Universal Time (UTC) timezone.

-r

    Remove any entries corresponding to the specified *logname* from the /etc/logadm.conf.

-R *cmd*

    Run the *cmd* when an old log file is created by a log rotation. If the keyword $file is embedded in the specified command, it is expanded to the name of the old log file just created by log rotation.

    This option is useful for processing log file contents after rotating the log. *cmd* is executed by passing it to sh -c. When rotating multiple logs with one logadm command, the command supplied with -R is executed once every time a log is rotated. This is useful for post-processing a log file (that is, sorting it, removing uninteresting lines, etc.). The -a option is a better choice for restarting daemons after log rotation.

-s *size*

    Rotate the log file only if its size is greater than or equal to *size*.

    Specify *size* as a number followed by the letter b for bytes, k for kilobytes, m for megabytes, or g for gigabytes.

-S *size*

    Delete the oldest versions until the total disk space used by the old log files is less than the specified size.

    Specify *size* as a number followed by the letter b for bytes, k for kilobytes, m for megabytes, or g for gigabytes.

-t *template*

    Specify the template to use when renaming log files.

    template can be a simple name, such as /var/adm/oldfile, or it can contain special keywords which are expanded by logadm and are in the form $*word*. Allowed sequences are:

    $*basename*

        The log file name, without the directory name

    $*dirname*

        The directory of the file to be rotated

    $*domain*

        Expands to the output of domainname

    $*file*

        The full path name of the file to be rotated

    $*isa*

        Expands to the output of uname -p

    $*machine*

        Expands to the output of uname -m

$*n*

    The version number, `0` is most recent, `1` is next most recent, and so forth

$*N*

    The same as $*n*, but starts at `1` instead of zero

$*nodename*

    Expands to the output of `uname -n`

$*platform*

    Expands to the output of `uname -i`

$*release*

    Expands to the output of `uname -r`

$*secs*

    The number of seconds since `00:00:00` UTC, January 1,1970

$*zonename*

    Expands to the output of `zonename(1)`.

To actually have the dollar sign character in the file name, use `$$`. Any percent sequences allowed by `strftime(3C)` are also allowed, for example, `%d` expands to the day of the month. To actually have a percent sign character in the file name, use `%%`. Both dollar-sign keywords and percent sequences can appear anywhere in the template. If the template results in a pathname with non-existent directories, they are created as necessary when rotating the log file.

If no `-t` option is specified, the default template is `$file.$n`. Actual *rotation* of log files, where each version is shifted up until it expires is done using the `$n` keyword. If the template does not contain the `$n` keyword, the log file is simply renamed to the new name and then the expire rules, if any, are applied.

`-T` *pattern*

    Normally `logadm` looks for a list of old log files by turning the template (specified with the `-t` option) into a pattern and finding existing files whose names match that pattern. The `-T` option causes the given pattern to be used instead.

    This option is useful if another program fiddles with the old log file names, like a `cron` job to compress them over time. The pattern is in the form of a pathname with special characters such as `*` and `?` as supported by `csh(1)` filename substitution.

`-v`

    Print information about the actions being executed in verbose mode.

`-V`

    Validate the configuration file.

    This option validates that an entry for the specified *logname* exists in the `/etc/logadm.conf` file and is syntactically correct. If *logname* is not specified, all entries in

the configuration file are validated. If a logname argument is specified, the command validates the syntax of that entry. If the entry is found, it is printed and the exit value of the command is true. Otherwise the exit value is false.

-w *entryname*

Write an entry into the config file (that is, /etc/logadm.conf) that corresponds to the current command line arguments. If an entry already existed for the specified *entryname*, it is removed first. This is the preferred method for updating /etc/logadm.conf, because it prevents syntax errors. The *entryname* is an argument to an invocation of logadm. *entryname* might be chosen as something easy to remember or it can be the pathname of the log file. If a pathname, rather than a name is used, it must be a fully qualified pathname.

If no log file name is provided on a logadm command line, the entry name is assumed to be the same as the log file name. For example, the following two lines achieve the same thing, keeping two copies of rotated log files:

```
% logadm -C2 -w mylog /my/really/long/log/file/name
% logadm -C2 -w /my/really/long/log/file/name
```

-z *count*

Compress old log files after all other commands have been executed. *count* of the most recent log files are left uncompressed, therefore making the *count* most recent files easier to peruse. Use *count* of zero to compress all old logs.

The compression is done with gzip(1) and the resulting log file has the suffix of .gz.

Operands   The following operands are supported:

logname

Identifies the name of the entry in /etc/logadm.conf. If the log file name is specified in the *logname* field, it is assumed that *logname* is the same as the actual log file name.

Examples   EXAMPLE 1   Rotating a File and Keeping Previous Versions

The following example rotates the /var/adm/exacct/proc file, keeping ten previous versions in /var/adm/exacct/proc.0 through /var/adm/exacct/proc.9.

Tell logadm to copy the file and truncate it.

```
% logadm -c /var/adm/exacct/proc
```

EXAMPLE 2   Rotating syslog

The following example rotates syslog and keeps eight log files. Old log files are put in the directory /var/oldlogs instead of /var/log:

```
% logadm -C8 -t'/var/oldlogs/syslog.$n' /var/log/syslog
```

EXAMPLE 3 Rotating /var/adm/sulog and Expiring Based on Age

The following entry in the `/etc/logadm.conf` file rotates the `/var/adm/sulog` file and expires any copies older than 30 days.

```
/var/adm/sulog -A 30d
```

EXAMPLE 4 Rotating Files and Expiring Based on Disk Usage

The following entry in the `/etc/logadm.conf` file rotates the `/var/adm/sulog` file and expires old log files when more than 100 megabytes are used by the sum of all the rotated log files.

```
/var/adm/sulog -S 100m
```

EXAMPLE 5 Creating an Entry that Stores the Logfile Name

This example creates an entry storing the log file name and the fact that we want to keep 20 copies in `/etc/logadm.conf`, but the `-p never` means the entry is ignored by the normal `logadm` run from root's crontab every morning.

```
% logadm -w locallog /usr/local/logfile -C20 -p never
```

Use the following entry on the command line to override the `-p never` option:

```
 % logadm -p now locallog
```

EXAMPLE 6 Rotating the apache Error and Access Logs

The following example rotates the apache error and access logs monthly to filenames based on current year and month. It keeps the 24 most recent copies and tells apache to restart after renaming the logs.

This command is run once, and since the `-w` option is specified, an entry is made in `/etc/logadm.conf` so the apache logs are rotated from now on.

```
 % logadm -w apache -p 1m -C 24\
     -t '/var/apache/old-logs/$basename.%Y-%m'\
     -a '/usr/apache/bin/apachectl graceful'\
     '/var/apache/logs/*{access,error}_log'
```

This example also illustrates that the entry name supplied with the `-w` option doesn't have to match the log file name. In this example, the entry name is apache and once the line has been run, the entry in `/etc/logadm.conf` can be forced to run by executing the following command:

```
% logadm -p now apache
```

Because the expression matching the apache log file names was enclosed in quotes, the expression is stored in `/etc/logadm.conf`, rather than the list of files that it expands to. This means that each time `logadm` runs from `cron` it expands that expression and checks all the log files in the resulting list to see if they need rotating.

EXAMPLE 6 Rotating the apache Error and Access Logs   *(Continued)*

The following command is an example without the quotes around the log name expression. The shell expands the last argument into a list of log files that exist at the time the command is entered, and writes an entry to /etc/logadm.conf that rotates the files.

```
logadm -w apache /var/apache/logs/*_log
```

Files /etc/logadm.conf
   configuration file for logadm command

/var/logadm/timestamps
   repository for logging timestamps

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also chgrp(1), chmod(1), chown(1), csh(1), gzip(1), cron(1M), ctime(3C), strftime(3C), logadm.conf(4), attributes(5)

Notes When logadm applies expire conditions (supplied by the -A, -C, and -S options), it deletes files, the oldest first, until the conditions are satisfied. If the template used for naming the old logs contained $n or $N, logadm picks the highest value of $n or $N found in the old log file names first. If the template used is something else, logadm uses the modification time to determine which files to expire first. This may not be the expected behavior if an old log file has been modified since it was rotated.

Depending on log file sizes and number of log files, log file rotations can be very time-consuming.

By default, logadm works in UTC. Therefore, all entries written to the /etc/logadm.conf file (see logadm.conf(4)) will have a UTC timestamp. Users can use the -l option to set logadm to local time.

The -f and -F options can specify the same file, in which case logadm reverts to the same behavior as in prior releases. That is, timestamps are written to the configuration file.

Name logins – list user and system login information

Synopsis /usr/bin/logins [-admopstux] [-g *group*...]
[-l *login_name*...]

Description This command displays information on user and system logins known to the system.
Contents of the output is controlled by the command options and can include the following:
user or system login, user id number, passwd account field value (user name or other
information), primary group name, primary group id, multiple group names, multiple group
ids, home directory, login shell, and four password aging parameters. The default information
is the following: login id, user id, primary group name, primary group id and the account field
value. Output is sorted by user id, system logins, followed by user logins.

Options Options may be used together. If so, any login that matches any criteria are displayed.

The following options are supported:

-a

Add two password expiration fields to the display. The fields show how many days a
password can remain unused before it automatically becomes inactive, and the date that
the password expires.

-d

Selects logins with duplicate uids.

-g *group*

Selects all users belonging to group, sorted by login. Multiple groups can be specified as a
comma-separated list. When the -l and -g options are combined, a user is only listed once,
even if the user belongs to more than one of the selected groups.

-l *login_name*...

Selects the requested login. Multiple logins can be specified as a comma-separated list.
Depending on the nameservice lookup types set in /etc/nsswitch.conf, the information
can come from the /etc/passwd and /etc/shadow files and other nameservices. When the
-l and -g options are combined, a user is only listed once, even if the user belongs to more
than one of the selected groups.

-m

Displays multiple group membership information.

-o

Formats output into one line of colon-separated fields.

-p

Selects logins with no passwords.

-s

Selects all system logins.

-t

Sorts output by login instead of by uid.

-u

Selects all user logins.

-x

Prints an extended set of information about each selected user. The extended information includes home directory, login shell and password aging information, each displayed on a separate line. The password information currently consists of password status:

NP

Account has no password

LK

Account is locked for UNIX authentication

NL

Account is a no login account

UP

This account has not yet been activated by the administrator and cannot be used.

PS

Account probably has a valid password

UN

Account password status is unknown. That is, it is not a recognizable hashed password or any of the above entries. See crypt(3C) for valid password hashes.

If the login is passworded, status is followed by the date the password was last changed, the number of days required between changes, and the number of days allowed before a change is required. The password aging information shows the time interval that the user receives a password expiration warning message (when logging on) before the password expires.

Name   lpget – get printing configuration

Synopsis   lpget [-k *key*] [*destination*... | list]

Description   The lpget utility reads printing configuration information from the configuration databases in $HOME/.printers and printers.org_dir printer. This information, called a *configuration report*, is displayed to the standard output.

lpget displays a configuration report for all keys for the specified destination or destinations by default. Use the -k option to display a configuration report for specific keys. Use the list operand to display a configuration report for all configured destinations.

Options   The following option is supported:

-k *key*   Displays a configuration report for *key*.

Operands   The following operands are supported:

destination   Displays a configuration report for *destination*. Destination can be either a printer of a class of printers. Specify *destination* using atomic or POSIX-style (*server*:*destination*) names. See standards(5) for information concerning POSIX.

list   Displays a configuration report for all configured destinations.

Examples   EXAMPLE 1   Displaying a Configuration Report for the bsdaddr Key

The following example displays a configuration report for the bsdaddr key for printer catalpa.

example% **lpget -k bsdaddr catalpa**

EXAMPLE 2   A Configuration Report for all Keys for all Configured Destinations

The following example displays a configuration report for all keys for all configured destinations.

example% **lpget list**

Exit Status   The following exit values are returned:

0   Successful completion.

non-zero   An error occurred.

Files $HOME/.printers   User-configurable printer database.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	print/lp/print-client-commands
Interface Stability	Committed

See Also lpset(1M), attributes(5), standards(5), ldap(5)

Oracle Solaris Administration: Naming and Directory Services

Notes If the LDAP database is used as the name service. If the ldapclient(1M) server is a replica LDAP server, LDAP printer database updates may not appear immediately, as the replica server may not have been updated by the master server and can be out of sync. For example, a printer that you deleted by using lpset(1M) may still appear in the printer list you display with lpget until the replica is updated from the master. Replica servers vary as to how often they are updated from the master. Refer to the *Oracle Solaris Administration: Naming and Directory Services* for more information on LDAP replication.

Name lpset – set printing configuration in supported databases

Synopsis lpset [-n system | fnsldap] [-x]
　　　[[-D binddn] [-w passwd] [-h ldaphost]]
　　　[-a *key*=*value*] [-d *key*] *destination*

Description The lpset utility sets printing configuration information in the system configuration databases. See nsswitch.conf(4).

Only a superuser or a member of Group 14 may execute lpset.

Options The following options are supported:

-n ldap　　　Create or update the configuration information for the *destination* entry in LDAP printer contexts. ldap specifies that the information is written to an LDAP server. See NOTES.

-x　　　　　Remove all configuration for the *destination* entry from the database specified by the -n option.

-a *key*=*value*　Configure the specified *key*=*value* pair for the *destination*.

-d *key*　　　Delete the configuration option specified by *key* for the *destination* entry.

-D binddn　　Use the distinguished name (DN) binddn to bind to the LDAP directory server.

-w passwd　　Use passwd as the password for authentication to the LDAP directory server.

-h ldaphost　Specify an alternate host on which the LDAP server is running. This option is only used when ldap is specified as the naming service. If this option is not specified, the default is the current host system.

Operands The following operand is supported:

destination　Specifies the entry in LDAP, in which to create or modify information. *destination* names a printer of class of printers. Specify *destination* using atomic names. POSIX-style destination names are not acceptable. See standards(5) for information regarding POSIX.

Examples EXAMPLE 1　Setting a key=value Pair

The following example sets the user-equivalence =true *key*=*value* pair for destination tabloid in the NIS context:

example% **lpset -n nis -a user-equivalence=true tabloid**

EXAMPLE 2　Setting a key=value Pair in LDAP

example% **lpset -n ldap -h ldapl.xyz.com -D "cn=Directory Manager" \
　-w passwd -a key1=value1 printer1**

Exit Status   The following exit values are returned:

    0   Successful completion.

    non-zero   An error occurred.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Interface Stability	Committed

See Also   ldapclient(1M), lpget(1M), nsswitch.conf(4), attributes(5), ldap(5), standards(5)

Oracle Solaris Administration: Naming and Directory Services

Notes   If the ldap database is used, the printer administrator should be mindful of the following when updating printer information.

1. Because the domain information for the printer being updated is extracted from the ldapclient(1M) configuration, the LDAP server being updated must host the same domain that is used by the current ldapclient(1M) server.

2. If the LDAP server being updated is a replica LDAP server, the updates will be referred to the master LDAP server and completed there. The updates might be out of sync and not appear immediately, as the replica server may not have been updated by the master server. For example, a printer that you deleted by using lpset may still appear in the printer list you display with lpget until the replica is updated from the master. Replica servers vary as to how often they are updated from the master.

3. Although users can use the LDAP command line utilities ldapadd(1) and ldapmodify(1) to update printer entries in the directory, the preferred method is to use lpset. Otherwise, if the ldapadd and ldapmodify utilities are used, the administrator must ensure that the printer-name attribute value is unique within the ou=printers container on the LDAP server. If the value is not unique, the result of modifications done using lpset might be unpredictable.

Name luxadm – administer Sun Fire 880 storage subsystem and FC_AL devices

Synopsis luxadm [*options*]... *subcommand* [*options*]... *enclosure*
[,*dev*] | *pathname*...

Description The luxadm program is an administrative command that manages the SENA, Sun Fire 880 internal storage subsystem, and individual Fiber Channel Arbitrated Loop (FC_AL) devices. luxadm performs a variety of control and query tasks depending on the command line arguments and options used.

The command line must contain a subcommand. The command line may also contain options, usually at least one enclosure name or pathname, and other parameters depending on the subcommand. You need specify only as many characters as are required to uniquely identify a subcommand.

Specify the device that a subcommand interacts with by entering a pathname. For the SENA subsystem, a disk device or enclosure services controller may instead be specified by entering the World Wide Name (WWN) for the device or a port to the device. The device may also be specified by entering the name of the SENA enclosure, and an optional identifier for the particular device in the enclosure. The individual FC_AL devices may be specified by entering the WWN for the device or a port to the device.

Pathname Specify the device or controller by either a complete physical pathname or a complete logical pathname.

For SENA, a typical physical pathname for a device is:

```
/devices/sbus@1f,0/SUNW,socal@1,0/sf@0,0/ssd@w2200002037000f96,
        0:a,raw
```

For all SENA IBs (Interface Boards) and Sun Fire 880 SES device controllers on the system, a logical link to the physical paths is kept in the directory /dev/es. An example of a logical link is /dev/es/ses0.

The WWN may be used in place of the pathname to select an FC_AL device, SENA subsystem IB, or Sun Fire 880 internal storage subsystem. The WWN is a unique 16 hexadecimal digit value that specifies either the port used to access the device or the device itself. A typical WWN value is:

```
2200002037000f96
```

See NOTES for more information on the WWN formats.

For a disk in a Sun Fire 880 internal storage subsystem, a typical physical pathname is:

```
/devices/pci@8,600000/SUNW,qlc@2/fp@0,0/ssd@w2100002037a6303c,0:a
```

and a typical logical pathname is:

```
/dev/rdsk/c2t8d0s2
```

For individual FC_AL devices, a typical physical pathname is:

/devices/sbus@3.0/SUNW,socal@d,10000/sf@0,0/ssd@w2200002037049fc3,0:a,raw

and a typical logical pathname is:

/dev/rdsk/c1t0d0s2

Enclosure   For SENA, a device may be identified by its enclosure name and slotname:

box_name[,f*slot_number*]
box_name[,r*slot_number*]

box_name is the name of the SENA enclosure, as specified by the enclosure_name
subcommand. When used without the optional *slot_number* parameter, the *box_name*
identifies the SENA subsystem IB.

f or r specifies the front or rear slots in the SENA enclosure.

slot_number specifies the slot number of the device in the SENA enclosure, 0-6 or 0-10.

For a Sun Fire 880 internal storage subsystem, a device may also be identified by its enclosure
name and slot name. However, there is only one set of disks:

box_name[,s*slot_number*]

box_name is the name of the Sun Fire 880 enclosure, as specified by the enclosure_name
subcommand. When used without the optional *slot_number* parameter, *box_name* identifies
the Sun Fire 880 internal storage subsystem enclosure services device. Use *s* to specify the disk
slot number in the Sun Fire 880 internal storage subsystem, 0 - 11.

See disks(1M) and devlinks(1M) for additional information on logical names for disks and
subsystems.

Options   The following options are supported by all subcommands:

-e   Expert mode. This option is not recommended for the novice user.

-v   Verbose mode.

Options that are specific to particular subcommands are described with the subcommand in
the USAGE section.

Operands   The following operands are supported:

enclosure
    The *box_name* of the SENA or Sun Fire 880 internal storage subsystem.

fibre_channel_HBA_port
    The path to the host controller port. A typical path is:

    /devices/pci@8,600000/pci@1/SUNW,qlc@4/fp@0,0:devctl

pathname
>   The logical or physical path of a SENA IB, Sun Fire 880 internal storage subsystem, or disk
>   device. *pathname* can also be the WWN of a SENA IB, SENA disk, or individual FC_AL
>   device.

Usage

Subcommands `display` *enclosure*[,*dev*] . . . | *pathname* . . .
`display` -p *pathname* . . .
`display` -r *enclosure*[,*dev*] . . . | *pathname* . . .
`display` -v *enclosure*[,*dev*] . . . | *pathname* . . .
>   Displays enclosure or device specific data.

>   Subsystem data consists of enclosure environmental sense information and status for all
>   subsystem devices, including disks.

>   Disk data consists of inquiry, capacity, and configuration information.

>   -p   Displays performance information for the device or subsystem specified by
>   *pathname*. This option only applies to subsystems that accumulate performance
>   information.

>   -r   Displays error information for the FC_AL device specified by the pathname, or, if
>   the path is a SENA, for all devices on the loop. The -r option only applies to SENA
>   subsystems and individual FC_AL devices.

>   -v   Displays in verbose mode, including mode sense data.

`download` [-s] [-f *filename_path*] *enclosure*. . .
>   Download the prom image pointed to the SENA subsystem Interface Board unit or the Sun
>   Fire 880 internal storage subsystem specified by the enclosure or pathname.

>   When the SENA's download is complete, the SENA will be reset and the downloaded code
>   executed. If no filename is specified, the default prom image will be used. The default prom
>   image for the SENA is in the directory `usr/lib/locale/C/LC_MESSAGES` and is named
>   `ibfirmware`

>   When the Sun Fire 880 internal storage subsystem's download is complete, the subsystem
>   resets and the downloaded code begins execution. The default firmware image for the Sun
>   Fire 880 internal storage subsystem is in:
>   `/usr/platform/SUNW,Sun-Fire-880/lib/images/int_fcbpl_fw`.

>   -s   Save. The -s option is used to save the downloaded firmware in the FEPROM. If -s
>   is not specified, the downloaded firmware will not be saved across power cycles.

>   The -s option does not apply to the Sun Fire 880 internal storage subsystem as it
>   always stores downloaded firmware in the flash memory.

When using the -s option, the download subcommand modifies the FEPROM on the subsystem and should be used with *caution*.

enclosure_name *new_name enclosure* | *pathname*
Change the enclosure name of the enclosure or enclosures specified by the enclosure or pathname. The new name (*new_name*) must be 16 or less characters. Only alphabetic or numeric characters are acceptable. This subcommand applies only to the SENA and the Sun Fire 880 internal storage subsystem.

failover primary | secondary *pathname*
Select which Sun Storage T3 storage array partner group controller accesses a given logical volume. If primary is specified, the logical volume is accessed through the primary controller. If secondary is specified, the logical volume is accessed through the secondary controller specified by *pathname*.

fcal_s_download [-f *fcode-file*]
Download the fcode contained in the file *fcode-file* into *all* the FC100/S Sbus Cards. This command is interactive and expects user confirmation before downloading the fcode.

Use fcal_s_download *only* in single-user mode. Using fcal_s_download to update a host adapter while there is I/O activity through that adapter *will* cause the adapter to reset. Newly updated FCode will not be executed or visible until a system reboot.

-f *fcode-file*   When invoked without the -f option, the current version of the fcode in each FC100/S Sbus card is printed.

fcode_download -p
fcode_download -d *dir-name*
Locate the installed FC/S, FC100/S, FC100/P, or FC100/2P host bus adapter cards and download the FCode files in *dir-name* to the appropriate cards. The command determines the correct card for each type of file, and is interactive. User confirmation is required before downloading the FCode to each device.

Use fcode_download to load FCode only in single-user mode. Using fcode_download to update a host adapter while there is I/O activity through that adapter causes the adapter to reset. Newly updated FCode will not be executed or visible until a system reboot.

-d *dir-name*   Download the FCode files contained in the directory *dir-name* to the appropriate adapter cards.

-p   Prints the current version of FCode loaded on each card. No download is performed.

inquiry *enclosure*[,*dev*] . . . | *pathname* . . .
Display the inquiry information for the selected device specified by the enclosure or pathname.

insert_device [*enclosure*,*dev* ...]
> Assist the user in the hot insertion of a new device or a chain of new devices. Refer to NOTES for limitations on hotplug operations. This subcommand applies only to the SENA, Sun Fire 880 internal storage subsystem, and individual FC_AL drives. For the SENA, if more than one enclosure has been specified, concurrent hot insertions on multiple busses can be performed. With no arguments to the subcommand, entire enclosures or individual FC_AL drives can be inserted. For the SENA or the Sun Fire 880 internal storage subsystem, this subcommand guides the user interactively through the hot insertion steps of a new device or chain of devices. If a list of disks was entered it will ask the user to verify the list of devices to be inserted is correct, at which point the user can continue or quit. It then interactively asks the user to insert the disk(s) or enclosure(s) and then creates and displays the logical pathnames for the devices.

led *enclosure*,*dev* ... | *pathname*...
> Display the current state of the LED associated with the disk specified by the enclosure or pathname. This subcommand only applies to subsystems that support this functionality.

led_blink *enclosure*,*dev* ... | *pathname* ...
> Requests the subsystem to start blinking the LED associated with the disk specified by the enclosure or pathname. This subcommand only applies to subsystems that support this functionality.

led_off *enclosure*,*dev* ... | *pathname* ...
> Requests the subsystem to disable (turn off) the LED associated with the disk specified by the enclosure or pathname. On a SENA subsystem, this may or may not cause the LED to turn off or stop blinking depending on the state of the SENA subsystem. Refer to the SENA Array Installation and Service Manual (p/n 802-7573). This subcommand only applies to subsystems that support this functionality.

led_on *pathname* ...
> Requests the subsystem to enable (turn on) the LED associated with the disk specified by the pathname. This subcommand only applies to subsystems that support this functionality.

power_off [-F] *enclosure*[,*dev*] ... | *pathname* ...
> When a SENA is addressed, this subcommand causes the SENA subsystem to go into the power-save mode. The SENA drives are not available when in the power-save mode. When a drive in a SENA is addressed the drive is set to the drive off/unmated state. In the drive off/unmated state, the drive is spun down (stopped) and in bypass mode. This command does not apply to the Sun Fire 880 internal storage subsystem.

> -F   The force option only applies to the SENA. Instructs luxadm to attempt to power off one or more devices even if those devices are being used by this host (and are, therefore, busy).

> *Warning*: Powering off a device which has data that is currently being used will cause unpredictable results. Users should attempt to power off the device normally (without -F) first, only resorting to this option when sure of the consequences of

overriding normal checks.

power_on *enclosure*[, *dev*] . .

Causes the SENA subsystem to go out of the power-save mode, when this subcommand is addressed to a SENA.. When this subcommand is addressed to a drive the drive is set to its normal start-up state. This command does not apply to the Sun Fire 880 internal storage subsystem.

probe [-p]

Finds and displays information about all attached SENA subsystems, Sun Fire 880 internal storage subsystems, and individual FC_AL devices, including the logical pathname, the WWNs, and enclosure names. This subcommand warns the user if it finds different SENAs with the same enclosure names.

-p   Includes the physical pathname in the display.

qlgc_s_download [-f *fcode-file*]

Download the FCode contained in the file *fcode-file* into all the FC100/P, FC100/2P PCI host adapter cards. This command is interactive and expects user confirmation before downloading the FCode to each device. Only use qlgc_s_download in single-user mode. Using qlgc_s_download to update a host adapter while there is I/O activity through that adapter will cause the adapter to reset. Newly updated FCode will not be executed or visible until a system reboot.

-f *fcode-file*   When invoked without the -f option, the current version of the FCode in each FC100/P, FC100/2P PCI card is printed.

release *pathname*

Release a reservation held on the specified disk. The pathname should be the physical or logical pathname for the disk.

This subcommand is included for historical and diagnostic purposes only.

remove_device [-F] *enclosure*[,*dev*] . . . | *pathname* . . .

Assists the user in hot removing a device or a chain of devices. This subcommand can also be used to remove entire enclosures. This subcommand applies to the SENA, Sun Fire 880 internal storage subsystem, and individual FC_AL drives. Refer to NOTES for limitations on hotplug operations. For the SENA, Sun Fire 880 internal storage subsystem, and individual FC_AL devices, this subcommand guides the user through the hot removal of a device or devices. During execution it will ask the user to verify the list of devices to be removed is correct, at which point the user can continue or quit. It then prepares the disk(s) or enclosure(s) for removal and interactively asks the user to remove the disk(s) or enclosure(s).

For Multi-Hosted disk, the steps taken are:

- Issue the luxadm remove_device command on the first host. When prompted to continue, wait.

- Issue the luxadm remove_device command on the secondary hosts. When prompted to continue, wait.

- Continue with the remove_device command on the first host. Remove the device when prompted to do so.

- Complete the luxadm remove_device command on the additional hosts.

-F Instructs luxadm to attempt to hot plug one or more devices even if those devices are being used by this host (and are, therefore, *busy* or *reserved*), to *force* the hotplugging operation.

   Warning: Removal of a device which has data that is currently being used will cause unpredictable results. Users should attempt to hotplug normally (without -F) first, only resorting to this option when sure of the consequences of overriding normal hotplugging checks.

reserve *pathname*   Reserve the specified disk for exclusive use by the issuing host. The pathname used should be the physical or logical pathname for the disk.

            This subcommand is included for historical and diagnostic purposes only.

set_boot_dev [-y] *pathname*   Set the boot-device variable in the system PROM to the physical device name specified by *pathname*, which can be a block special device or the pathname of the directory on which the boot file system is mounted. The command normally runs interactively requesting confirmation for setting the default boot-device in the PROM. The -y option can be used to run it non-interactively, in which case no confirmation is requested or required.

start *pathname*   Spin up the specified disk(s) in a SENA.

stop *pathname*...   Spin down the specified disks in a SENA.

SENA, Sun Fire 880 Internal Storage Subsystem, and Individual FC_AL Drive Expert Mode Subcommands

The following subcommands are for expert use only, and are applicable only to the SENA, Sun Fire 880 internal storage subsystem, and fiber channel loops. They should only be used by users that are knowledgeable about the SENA subsystem and fiber channel loops.

If you specify a disk to an expert subcommand that operates on a bus, the subcommand operates on the bus to which the specified disk is attached.

-e bypass [-ab] *enclosure*,*dev*
-e bypass -f *enclosure*   Request the enclosure services controller to set the LRC (Loop Redundancy Circuit) to the bypassed state for the port and device specified.

	This subcommand supports the following options:
	-a Bypass port a of the device specified.
	-b Bypass port b of the device specified.

-e dump_map *fibre_channel_HBA_port* — Display WWN data for a target device or host bus adapter on the specified fibre channel port. If there are no target devices on the specified port, an error is returned.

-e enable [-ab] *enclosure,dev*
-e enable -f *enclosure* — Request the enclosure services controller to set the LRC (Loop Redundancy Circuit) to the enabled state for the port and device specified.

This subcommand supports the following options:

-a   Enable port a of the device specified.

-b   Enable port b of the device specified.

-e forcelip *enclosure*[,*dev*] . . . | *pathname* . . . — Force the link to reinitialize, using the Loop Initialization Primitive (LIP) sequence. The enclosure or pathname can specify any device on the loop. Use the pathname to specify a specific path for multiple loop configurations.

This is an expert only command and should be used with caution. It will reset all ports on the loop.

-e rdls *enclosure*[,*dev*] . . . | *pathname* . . . — Read and display the link error status information for all available devices on the loop that contains the device specified by the enclosure or pathname.

Other Expert Mode Subcommands   See NOTES for limitations of these subcommands. They should only be used by users that are knowledgeable about the systems they are managing.

These commands do not apply to the Sun Fire 880 internal storage subsystem.

-e bus_getstate *pathname*	Get and display the state of the specified bus.
-e bus_quiesce *pathname*	Quiesce the specified bus.
-e bus_reset *pathname*	Reset the specified bus only.
-e bus_resetall *pathname*	Reset the specified bus and all devices.
-e bus_unquiesce *pathname*	Unquiesce the specified bus. the specified device.
-e dev_getstate *pathname*	Get and display the state of the specified device.
-e dev_reset *pathname*	Reset the specified device.
-e offline *pathname*	Take the specified device offline.
-e online *pathname*	Put the specified device online.

Examples **EXAMPLE 1** Displaying the SENAs and Individual FC_AL Devices on a System

The following example finds and displays all of the SENAs and individual FC_AL devices on a system:

```
example% luxadm probe
```

EXAMPLE 2 Displaying a SENA or Sun Fire 880 Internal Storage Subsystem

The following example displays a SENA or Sun Fire 880 internal storage subsystem:

```
example% luxadm display /dev/es/ses0
```

EXAMPLE 3 Displaying Two Subsystems

The following example displays two subsystems using the enclosure names:

```
example% luxadm display BOB system1
```

EXAMPLE 4 Displaying Information about the First Disk

The following example displays information about the first disk in the front of the enclosure named BOB. Use f to specify the front disks. Use r to specify the rear disks.

```
example% luxadm display BOB,f0
```

EXAMPLE 5 Displaying Information on a Sun Fire 880 Internal Storage Subsystem

The Sun Fire 880 internal storage subsystem has only one set of disks. In this case, use *s* to specify the slot:

```
example% luxadm display BOB,s0
```

EXAMPLE 6   Displaying Information about a SENA disk, an Enclosure, or an Individual FC_AL Drive

The following example displays information about a SENA disk, an enclosure, or an individual FC_AL drive with the port WWN of 2200002037001246:

```
example% luxadm display 2200002037001246
```

EXAMPLE 7   Using Unique Characters to Issue a Subcommand

The following example uses only as many characters as are required to uniquely identify a subcommand:

```
example% luxadm disp BOB
```

EXAMPLE 8   Displaying Error Information

The following example displays error information about the loop that the enclosure BOB is on:

```
example% luxadm display -r BOB
```

EXAMPLE 9   Downloading New Firmware into the Interface Board

The following example downloads new firmware into the Interface Board in the enclosure named BOB (using the default path for the file to download):

```
example% luxadm download -s BOB
```

EXAMPLE 10   Displaying Information from the SCSI Inquiry Command

The following example displays information from the SCSI inquiry command from all individual disks on the system, using only as many characters as necessary to uniquely identify the inquiry subcommand:

```
example% luxadm inq /dev/rdsk/c?t?d?s2
```

EXAMPLE 11   Hotplugging

The following example hotplugs a new drive into the first slot in the front of the enclosure named BOB:

```
example% luxadm insert_device BOB,f0
```

The following example hotplugs a new drive into the first slot in the Sun Fire 880 internal storage subsystem named SF880-1:

```
example% luxadm insert_device SF880-1,s0
```

EXAMPLE 12   Running an Expert Subcommand

The following example runs an expert subcommand. The subcommand forces a loop initialization on the loop that the enclosure BOB is on:

```
example% luxadm -e forcelip BOB
```

EXAMPLE 13 Using the Expert Mode Hot Plugging Subcommands

An example of using the expert mode hot plugging subcommands to hot remove a disk follows. See NOTES for hot plugging limitations.

The first step reserves the SCSI device so that it can't be accessed by way of its second SCSI bus:

```
example# luxadm reserve /dev/rdsk/c1t8d0s2
```

EXAMPLE 14 Taking the Disk to be Removed Offline

The next two steps take the disk to be removed offline then quiesce the bus:

```
example# luxadm -e offline /dev/rdsk/c1t8d0s2
example# luxadm -e bus_quiesce /dev/rdsk/c1t8d0s2
```

EXAMPLE 15 Unquiescing the Bus

The user then removes the disk and continues by unquiescing the bus, putting the disk back online, then unreserving it:

```
example# luxadm -e bus_unquiesce /dev/rdsk/c1t8d0s2
example# luxadm -e online /dev/rdsk/c1t8d0s2
example# luxadm release /dev/rdsk/c1t8d0s2
```

Environment Variables See environ(5) for a description of the LANG environment variable that affects the execution of luxadm.

Exit Status The following exit values are returned:

0 Successful completion.

−1 An error occurred.

Files
- usr/lib/firmware/fc_s/fc_s_fcode
- usr/lib/locale/C/LC_MESSAGES/ibfirmware

Attributes See attributes(5) for descriptions of the following attributes:

usr/sbin

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/storage/fc-utilities

See Also devlinks(1M), disks(1M), attributes(5), environ(5), ses(7D)

SAN Configuration and Multipathing Guide

Oracle Solaris Cluster 3.3 with Fibre Channel JBOD Storage Device Manual

Notes   Refer to *Tutorial for SCSI use of IEEE Company_ID*, R. Snively, for additional information regarding the IEEE extended WWN. Currently, only some device drivers support hot plugging. If hot plugging is attempted on a disk or bus where it is not supported, an error message of the form:

```
luxadm: can't acquire "PATHNAME": No such file or directory
```

...will be displayed.

You must be careful not to quiesce a bus that contains the root or the /usr filesystems or any swap data. If you do quiesce such a bus a deadlock can result, requiring a system reboot.

System Administration Commands – Part 2

Name mail.local – store mail in a mailbox

Synopsis `/usr/lib/mail.local` [-f *sender*] [-d] *recipient*

Description `mail.local` reads the standard input up to an end-of-file and appends it to each user's mail file (mailbox). This program is intended to be used by sendmail(1M) as a mail delivery agent for local mail. It is not a user interface agent.

Messages are appended to the user's mail file in the /var/mail directory. The user must be a valid user name.

Each delivered mail message in the mailbox is preceded by a "Unix From line" with the following format:

From *sender_address time_stamp*

The *sender_address* is extracted from the SMTP envelope address (the envelope address is specified with the -f option).

A trailing blank line is also added to the end of each message.

The mail files are locked with a .lock file while mail is appended.

The mail files are created with mode 660, owner is set to *recipient*, and group is set to mail. If the "biff" service is returned by getservbyname(3SOCKET), the biff server is notified of delivered mail. This program also computes the Content-Length: header which will be used by the mailbox reader to mark the message boundary.

Options The following options are supported:

- -f *sender* Specifies the "envelope from address" of the message. This flag is technically optional, but should be used.

- -d Specifies the recipient of the message. This flag is also optional and is supported here for backward compatibility. That is, mail.local *recipient* is the same as mail.local -d *recipient*.

- -l Turn on LMTP mode.

- -r *from* Specify the sender's name (for backward compatibility).

- -7 Do not advertise 8BITMIME support in LMTP mode.

- -b Return a permanent error instead of a temporary error if a mailbox exceeds quota.

Operands The following operand is supported:

recipient The recipient of the mail message.

Environment Variables TZ Used to set the appropriate time zone on the timestamp.

Exit Status The following exit values are returned:

    0 Successful operation.

    >0 An error occurred.

Files /tmp/local.*XXXXXX* temporary files

    /tmp/lochd.*XXXXXX* temporary files

    /var/mail/*user_name* user's mail file

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

See Also mail(1), comsat(1M), sendmail(1M), getservbyname(3SOCKET), attributes(5)

Name makedbm – make a dbm file, or get a text file from a dbm file

Synopsis
```
makedbm [-b] [-l] [-s] [-E] [-i yp_input_file]
        [-o yp_output_name] [-d yp_domain_name]
        [-m yp_master_name] [-S delimiter]
        [-D number_of_delimiters] infile outfile

makedbm [-u dbmfilename]
```

Description The makedbm utility takes the *infile* and converts it to a pair of files in ndbm format (see ndbm(3C)), namely *outfile*.pag and *outfile*.dir. Each line of the input file is converted to a single dbm record. All characters up to the first TAB or SPACE form the key, and the rest of the line is the data. If a line ends with '\' (backslash), the data for that record is continued on to the next line. makedbm does not treat '#' (pound-sign) as a special character.

Because makedbm is mainly used in generating dbm files for the NIS name service, it generates a special entry with the key *yp_last_modified*, which is the date of *infile* (or the current time, if *infile* is '−'). The entries that have keys with the prefix *yp_* are interpreted by NIS server utilities.

Options The following options are supported:

-b	Insert the YP_INTERDOMAIN into the output. This key causes ypserv(1M) to use DNS for host name and address lookups for hosts not found in the maps.
-d *yp_domain_name*	Create a special entry with the key *yp_domain_name*.
-D *number_of delimiters*	Specify *number_of_delimiters* to skip before forming the key.
-E	Delimiters are escaped.
-i *yp_input_file*	Create a special entry with the key *yp_input_file*.
-l	Lower case. Convert the keys of the given map to lower case, so that, for example, host name matches succeed independent of upper or lower case distinctions.
-m *yp_master_name*	Create a special entry with the key *yp_master_name*. If no master host name is specified, *yp_master_name* is set to the local host name.
-o *yp_output_name*	Create a special entry with the key *yp_output_name*.
-s	Secure map. Accept connections from secure NIS networks only.
-S *delimiter*	Specify the *delimiter* to use instead of the default delimiter for forming the key.
-u *dbmfilename*	Undo a dbm file. Prints out the file in text format, one entry per line, with a single space separating keys from values.

Operands The following operands are supported:

    infile   Input file for makedbm. If *infile* is '−' (dash), the standard input is read.

    outfile   One of two output files in ndbm format: *outfile*.pag and *outfile*.dir.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also ypserv(1M), ndbm(3C), attributes(5)

Name makemap – create database maps for sendmail

Synopsis makemap [-N] [-d] [-f] [-o] [-r] [-s] [-v] [-C *file*]
        [-c *cachesize*] [-D *commentchar*] [-e] [-l] [-t *delim*]
        [-u] *mantype mapname*

Description makemap creates the database maps used by the keyed map lookups in sendmail(1M). makemap
reads from the standard input and outputs to the specified *mapname*.

In all cases, makemap reads lines from the standard input consisting of two words separated by
whitespace. The first is the database key, the second is the value. The value may contain %*n*
strings to indicated parameter substitution. Literal percents should be doubled (%%). Blank
lines and lines beginning with # are ignored.

makemap handles three different database formats. Database format is selected using the
maptype parameter. See OPERANDS.

Options The following options are supported:

-c *cachesize*	Use the specified hash and B-Tree cache size (*cachesize*).
-C *file*	Use the specified sendmail configuration file (*file*) for looking up the TrustedUser option.
-d	Allow duplicate keys in the map. This is only allowed on B-Tree format maps. If two identical keys are read, both be inserted into the map.
-D *commentchar*	Use the specified character to indicate a comment (which is ignored) instead of the default of '#'.
-e	Allow empty value (right hand side).
-f	Normally, all upper case letters in the key are folded to lower case. This flag disables that behavior. This is intended to mesh with the -f flag in the K line in sendmail.cf. The value is never case folded.
-l	List supported map types.
-N	Include the null byte that terminates strings in the map. This must match the -N flag in the K line in sendmail.cf
-o	Append to an old file. This allows you to augment an existing file.
-r	Allow replacement of existing keys. Normally makemap complains if you repeat a key, and does not do the insert.
-s	Ignore safety checks on maps being created. This includes checking for hard or symbolic links in world writable directories.
-t *delim*	Use the specified delimiter (*delim*) instead of whitespace.

-u
Dump (unmap) the content of the database to standard output. Note that, if the -t option is also provided, the specified delimiter is used when the content is dumped instead of whitespace.

-v
Verbosely print what it is doing.

Operands The following operands are supported:

mapname File name of the database map being created.

maptype Specifies the database format. The following *maptype* parameters are available:

dbm Specifies DBM format maps.

btree Specifies B-Tree format maps.

hash Specifies hash format maps.

Attributes See attributes(5) for descriptions of the following attributes:

Name makeuuid – generate Universal Unique Identifiers

Synopsis `makeuuid [-e *ether*] [-n *count*] [-R *root*]`

Description The `makeuuid` command generates UUIDs (Universal Unique Identifiers) conforming to the OSF DCE specification for UUIDs. The specification states:

"A UUID is an identifier that is unique across both space and time, with respect to the space of all UUIDs. A UUID can be used for multiple purposes, from tagging objects with an extremely short lifetime, to reliably identifying very persistent objects across a network.

"The generation of UUIDs does not require a registration authority for each single identifier. Instead, it requires a unique value over space for each UUID generator. This spatially unique value is [normally] specified as an IEEE 802 address, which is usually already applied to network-connected systems."

The `makeuuid` command generates one or more UUIDs on the standard output.

Options The `makeuuid` command supports the following options:

-e *ether*   Supplies an alternate address to be used in the generation of the UUIDs. Normally, the system's Ethernet address is acquired and used during the generation of a UUID. However, this requires root privileges to open and read the network devices. If this is not possible, you must supply an alternate Ethernet address.

-n *count*   Generate multiple UUIDs. This option generates the specified number of UUIDs, one per line. Using this form is more efficient than, and functionally equivalent to, calling the `makeuuid` command multiple times. This can be used, for example, when a large number of UUIDs need to be generated for a given application.

-R *root*   Use *root* as the root filesystem path when updating the shared state file (see FILES). The shared state file must be writable by the user running `makeuuid`, otherwise no UUIDs will be generated and the command will return in failure.

    Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

Usage Normally, you run the `makeuuid` command with root privileges, as the Ethernet address and state files can be easily accessed and updated. If this is not possible, you must use the -R and -e options to specify an alternate root and Ethernet address to use when calculating the UUIDs.

Examples EXAMPLE 1 Generating Multiple UUIDs

The following command generates 3000 UUIDs:

```
example# makeuuid -n 3000
```

EXAMPLE 2 Invoking Without Root Privileges

If you cannot obtain root privileges, you must specify an alternate Ethernet address and state file location:

```
example% makeuuid -e 11:22:33:44:55:66 -R /export/root/example2
```

See the caveat on the use of the -R option in the description of that option, above.

Exit Status The following exit values are returned:

0   Successful completion.

1   Out of memory.

−1   Invalid Ethernet address given or access denied.

Files /var/sadm/system/uuid_state   UUID state file. Use of time values is one way that UUID generators, such as makeuuid, guarantee uniqueness. A state file is a mechanism that allows makeuuid to "remember" the last time value it used so it can increment that value for use in a new UUID. See the Internet Draft *UUIDs and GUIDs*, dated February 4, 1998, for details on the state file mechanism.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/management/product-registry

See Also Intro(3), libwsreg(3LIB), attributes(5)

Notes The formal UUID specification is in the OSF DCE specification, available at www.opengroup.org. As of the date of publication of this man page, a copy of the specification is available at:

```
http://www.opengroup.org/onlinepubs/9629399/apdxa.htm
```

Sun has no control over the availability of documents on the www.opengroup.org web site.

Name   masfcnv – SNMP configuration migration script

Synopsis   /usr/lib/sma_snmp/masfcnv [-cimnrs] [-l *agentmaster*]
        [-p *enabledisableerror*] [-t *noneadd*]
        [-u *agentmastererror*] [-y *agentmastererror*]

masfcnv [-V]

masfcnv [-?]

Description   The masfcnv script is used to assist the system administrator in migrating an existing set of configuration files for the Sun SNMP Management Agent for Sun Fire and Netra Systems (MASF) to the Systems Management Agent (SMA).

The script accepts as input the currently installed set of MASF and SMA configuration files and outputs a new set of SMA configuration files. Existing SMA configuration files are backed up by appending .bak to the filename. The administrator can choose to output the new configuration to standard output, instead of replacing the current configuration, by specifying the -n option.

The migration script must be run as the superuser. Failure to do so causes the script to exit with an error message. Before running the script you should ensure that both the SMA and MASF agents are not running. If the agents are running they will be shut down by the script.

The migration script installs a new startup script for the MASF agent in /etc/init.d, as well as a backup of the old script. During migration, MASF will be configured as an AgentX subagent of SMA. All migration settings will be migrated to the SMA configuration file.

The migration script aborts if any unrecognized directives are found in either the MASF configuration files or the SMA configuration files. This can be overridden with the -i option. If this option is selected, the behavior is to retain unrecognized directives that were present in the SMA configuration, but remove those present in the MASF configuration.

The migration script then proceeds to migrate access control and trap configuration. As a side effect of running the migration script, the following directives might be expanded by the script into multiple directives with an equivalent interpretation:

- rwcommunity
- rocommunity
- rwuser
- rouser
- trapcommunity
- trapsink
- trap2sink
- informsink

Access Control Migration

Access control directives are expanded into the equivalent com2sec, group, access and view directives. Existing group names are renamed by prepending a prefix to avoid conflict with any which may already be defined in SMA.

When migrating SNMPv1 or v2c access control, a conflict can occur if both MASF and SMA configuration files have defined access permissions for the same community and source address. The default behavior is to abort with a message, unless a use of the -y option specifies otherwise. If -y agent is specified then the MASF configuration takes precedence. If -y master is specified then the SMA configuration is retained.

When migrating USM configuration (SNMPv3), a conflict can occur if both SMA and MASF configurations define a user with the same securityName. If this occurs, the behavior of the script is determined by the -u option. If -u agent is specified, the configuration of the user defined in the MASF configuration files is the one that is retained. Otherwise, if the -u master option is specified, the use defined in the SMA configuration files is retained.

By default, the migration script attempts to migrate USM users from MASF to SMA. The script determines whether there are any SNMPv3 users present in the SMA configuration and whether the default engineID has been overridden in the SMA configuration files. If neither of these conditions obtain, then the any usmUser statements containing localized authentication keys can be migrated to SMA, along with the MASF engineID. This results in the engineID of the SMA master agent changing.

If the script determines that there are existing SNMPv3 users or a manually configured engineID present in the SMA configuration, only those users defined in createUser statements are transferred. Those users that were defined in usmUser statements are transferred but will have their passwords reset to a random value. You should notify your users of their new password or reset the password yourself by editing the newly-generated configuration file.

Trap/Inform Migration

The migration script performs a check to determine whether a trap destination defined for MASF is already specified in an existing SMA trapsink, trap2sink or informsink directive. If this is the case, then the directive in the MASF configuration will be discarded to avoid duplicate traps/informs being received.

trapsink, trap2sink and informsink directives specified in the existing SMA configuration are considered valid destinations for MASF traps/informs and will receive them from the MASF subagent after migration.

If the -t none option was specified on the command line, the migration script carries over any remaining MASF trap/inform directives without modification.

If the -t add option was specified (the default), the migration script expands any trapsink, trap2sink, or informsink directives to use the TARGET-MIB and NOTIFICATION-MIB. The TARGET-MIB specifies targets using IP addresses, so it might be desirable to use the -t none option if, for example, the network allocates IP addresses to hostnames dynamically by means of DHCP.

The expanded directives defines filters specific to the MASF agent so that traps from other subagents will not be received by migrated trap destinations. Existing filters present in the SMA configuration are, by default, not modified and might or might not receive MASF traps, depending upon the filters that were originally defined for them.

If the -l option is specified, any filters already defined in the TARGET-MIB and the NOTIFICATION-MIB for SMA are extended to include traps from MASF. In the event that a trap destination is already configured in the TARGET-MIB with the same target address and community as an existing MASF trap/inform sink, a conflict will arise.

If -l agent was specified and a conflict arises, the migration script uses the target SNMP parameters (that is, the SNMP version and choice of trap/inform) defined by the MASF trap/informsink directive to send traps to this destination. Otherwise, if the -l master option was specified, the conflict will be resolved using the target SNMP parameters specified in the SMA configuration.

Miscellaneous   If the migration script encounters in the MASF configuration file any of the directives listed below and the directives are either not present or differ from the SMA configuration, the script will log a warning message.

- syslocation
- syscontact
- sysname
- sysservices
- agentgroup
- agentuser
- authtrapenable

Options   The following options are supported:

-? --help	Displays usage information.
-c --no-community	Do not transfer v1/v2c communities.
-i --ignore-unrecognized-directives	Continue processing if unrecognized directives are present.
-l agent | master --master-trap-target=agent | master	If agent is specified, the existing SMA trap targets will be configured to receive traps that were previously sent to destinations for the Sun Fire SNMP agent. If master is specified, the targets will be configured to receive Sun Fire SNMP traps, but existing SNMP target parameters will be used.

-m	
--no-usmuser	Do not transfer usm (v3) users.
-n	
--dry-run	Run the migration without modifying any files. If an error arises, continue processing. This can be used to determine the likely migration issues.
-p enable | disable | error	
--use-agent-port=enable | disable | error	Indicates whether the port originally used by the Sun Fire SNMP agent should be used by the SMA agent after migration (if the two agents are using different ports). If enable is specified, then the port used by the Sun Fire SNMP agent will also be used by the SMA agent after migration. If disable is specified, the ports used by SMA will not be updated by the migration tool. If the error option is specified and the SMA agent is not already using the same ports as those used by the original Sun Fire SNMP agent, an error is reported and the migration process is terminated. If no option is specified the default behavior is equivalent to the error flag.
-r	
--no-trap	Do not transfer trap destinations.
-s	
--skip-user	If a user is found in the MASF configuration file that cannot be created in the new configuration because of a change in the engine ID, then output a message indicating that the user could not be migrated (needs to be manually recreated) and continue processing. If this option is not present, the migration tool will consider such a situation as an error and abort.
-t none | add	
--trap-filter=none | add	If none is specified then the script will copy trap directives directly. The administrator might need to manually update the

configuration file to ensure traps are only delivered to their intended destinations. If add is specifed, trap filters will be constructed so that traps originating from the original Sun Fire SNMP agent are delivered only to the destinations that originally received them. The default behavior is add.

-u agent | master | error
--select-user=agent | master | error

Specifies that if a user with the same name is found in both configuration files that the conflict is to be resolved using the specified configuration file as input. Selecting a user from a particular file will also cause the group declaration for that user to be taken from the same file. If agent is specified then the user will be taken from the configuration file for the Sun Fire SNMP Agent. If master is specified, the user will be taken from the SMA configuration. Otherwise, if error is given, the script will terminate. If this option is not present, the default behavior is equivalent to the error flag.

-V
--version

Display the version of this script.

-y agent | master | error
--select-community=agent | master | error

Specifies that if a community with the same name is found in both configuration files that the conflict is to be resolved using the specified configuration file as input. If agent is specified then the community will be taken from the configuration file for the Sun Fire SNMP Agent. If master is specified, the community will be taken from the SMA configuration. Otherwise, if error is given, the script will terminate. If this option is not present, the default behavior is equivalent to the error flag.

Examples EXAMPLE 1   Simplest Case

The command shown below is appropriate for a simple migration. The migration fails if there are any potential conflicts.

```
# masfcnv
```

EXAMPLE 2   Migrating Such That MASF Settings Override

To migrate the MASF configuration such that it will always succeed, that MASF settings will override in the event of a conflict with SMA, and that access will still be provided on the original MASF port, enter:

```
# masfcnv -is -l agent -p enable -u agent -y agent
```

EXAMPLE 3   Dry Run, Retaining SMA Settings

To attempt a dry run and migrate the configuration such that any conflicts will be resolved by retaining existing SMA settings, enter:

```
masfcnv -l master -u master -y master
```

Exit Status 0   Success.

non-zero   A problem occurred during migration.

Files /etc/sma/snmp/snmpd.conf
/var/sma_snmp/snmpd.conf   SMA configuration files

/etc/opt/SUNWmasf/conf/snmpd.conf
/var/opt/SUNWmasf/snmpd.dat   MASF configuration files

/tmp/sma_migration.log   masfcnv log file

Notes The former path to this utility, /usr/sfw/lib, is now a link to /usr/lib.

Name mdlogd – Solaris Volume Manager daemon

Synopsis mdlogd

Description mdlogd implements a simple daemon that watches the system console looking for messages written by the Solaris Volume Manger. When a Solaris Volume Manager message is detected, mdlogd sends a generic SNMP trap.

To enable traps, you must configure mdlogd into the SNMP framework. See *Solaris Volume Manager Administration Guide*.

Usage mdlogd implements the following SNMP MIB:

```
SOLARIS-VOLUME-MGR-MIB DEFINITIONS ::= BEGIN
        IMPORTS
                enterprises FROM RFC1155-SMI
                DisplayString FROM SNMPv2-TC;

        -- Sun Private MIB for Solaris Volume Manager

        sun       OBJECT IDENTIFIER ::= { enterprises 42 }
        sunSVM      OBJECT IDENTIFIER ::= { sun 104 }

        -- this is actually just the string from /dev/log that
        -- matches the md: regular expressions.
        -- This is an interim SNMP trap generator to provide
        -- information until a more complete version is available.

        -- this definition is a formalization of the old
        -- Solaris DiskSuite mdlogd trap mib.

        svmOldTrapString OBJECT-TYPE
                        SYNTAX DisplayString (SIZE (0..255))
                        ACCESS read-only
                        STATUS mandatory
                        DESCRIPTION
                        "This is the matched string that
                         was obtained from /dev/log."
        ::= { sunSVM 1 }

        -- SVM Compatibility ( error trap )

        svmNotice       TrapTRAP-TYPE
                        ENTERPRISE sunSVM
                        VARIABLES { svmOldTrapString }
                        DESCRIPTION
                              "SVM error log trap for NOTICE.
                               This matches 'NOTICE: md:'"
```

```
                  ::= 1

Solaris Volume Manager Administration Guide

Name mdmonitord – daemon to monitor metadevices

Synopsis /usr/sbin/mdmonitord [-t *time_interval*]

Description The mdmonitord utility is part of Solaris Volume Manager. It monitors and checks RAID1 (mirrors), RAID5 and hot spares.

There are two methods for checking:

- At fixed time intervals.
- When a RAID-1 (mirror), RAID-5, or hot spare fails. A failure generates an error event which triggers a check of these metadevices.

Options The following options are supported:

-t   Time interval in seconds. The default value is 0, which causes probes to occur only upon an error. If you want to run mdmonitord at a regular interval, a value of 1800 (seconds, every half hour) is recommended as a starting point.

Exit Status The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm

See Also svcs(1), metaclear(1M), metadb(1M), metadetach(1M), metahs(1M), metainit(1M), metaoffline(1M), metaonline(1M), metaparam(1M), metarecover(1M), metarename(1M), metareplace(1M), metaset(1M), metassist(1M), metastat(1M), metasync(1M), metattach(1M), svcadm(1M), md.tab(4), md.cf(4), mddb.cf(4), md.tab(4), attributes(5), smf(5), md(7D)

Solaris Volume Manager Administration Guide

Notes Since frequent probes can affect performance, it is recommended that the intervals between probes be limited.

The mdmonitord service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/mdmonitor

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name mdnsd – Multicast DNS daemon

Synopsis mdnsd [-debug]

Description mdnsd is the daemon program for Multicast DNS and DNS Service Discovery.

The mdnsd daemon listens on UDP port 5353 for Multicast DNS Query packets. When it receives a query for which it knows an answer, mdnsd issues the appropriate Multicast DNS Reply packet.

The mdnsd daemon also performs Multicast DNS Queries on behalf of client processes, and maintains a cache of the replies.

The mdnsd daemon has no user-specifiable command-line argument, and users should not run mdnsd manually. The mdnsd daemon should be managed by the Solaris Management Facility (SMF) and should be administered by the svcadm(1M) command using the following fault management resource identifier (FMRI):

svc:/network/dns/multicast:default

To examine mdnsd's internal state for debugging and diagnostic purposes, send it a SIGUSR1 signal, and it will then log a snapshot summary of its internal state using the syslog(3C) facility. mdnsd uses the syslog facility code daemon and info priority level.

Options The mdnsd daemon recognizes the following option:

-debug   Debug mode. The mdnsd daemon sends output to the standard error, and does not run in the background. This option is only intended for debugging the daemon.

CONFIGURATION Multicast DNS can be used to look up host names and host addresses by specifying mdns as a source for hosts and ipnodes in the name service switch configuration file nsswitch.conf(4). The configuration options for host name and host address queries using Multicast DNS are stored in the SMF repository. This configuration can be modified by the svccfg(1M) command using the following fault management resouce identfier (FMRI):

svc:/network/dns/multicast:default

The configuration options for host name and host address queries using Multicast DNS are stored in a property group named "nss_mdns_config". The properties that make up the configuration options are as follows:

search   A list of search domains for host name look up. By default, no search domains are included in the configuration. The search list is currently limited to six domains.

valid   A list of valid domains checked before Multicast DNS is used to look up the host name or host address for a domain. Domains specified in the search list are always included in the valid list. The valid domain list is currently limited to ten domains.

Please note the above configuration options are Volatile and may change in a future release.

Files /usr/lib/inet/mdnsd

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/dns/mdns
Interface Stability	Volatile

See Also dns-sd(1M), svcadm(1M), svccfg(1M), syslog(3C),nsswitch.conf(4), attributes(5)

For information on Multicast DNS, see http://www.multicastdns.org/

For information on DNS Service Discovery, see http://www.dns-sd.org/.

Name medstat – check the status of mediator hosts for a given diskset

Synopsis /usr/sbin/medstat [-q] -s *setname*

Description If a specified diskset has been configured for mediators, medstat attempts to contact these hosts to see if they are accessible and returns the results of the communication.

Options
-q This optional argument disables the printing of informative text. When used with -q, medstat still prints error messages and returns a result code.

-s *setname* Specifies the name of a diskset on which medstat will work.

Examples EXAMPLE 1 Checking diskset

This example checks the mediator hosts for the selected diskset.

```
# medstat -s relo-red
```

The name of the diskset is relo-red. The medstat command prints the status for each mediator host. Additionally, if the mediator quorum is met, either through a "golden" mediator host or because half+1 of the mediator hosts respond, the exit code is 0. If the quorum is not met, then the exit code is 1. If no mediator hosts have been configured for the named diskset, the exit code is 2. The status field will contain one of the following values: Unreachable, Bad, Fatal, or Ok, where Unreachable indicates an RPC/communication problem, Bad indicates an error in the mediator data, Fatal indicates any other error condition, and Ok indicates no error conditions.

Files /etc/lvm/meddb Contains the mediator data for a host that has been selected as a mediator host.

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm
Interface Stability	Committed

See Also metaclear(1M), metadb(1M), metadetach(1M), metahs(1M), metainit(1M), metaoffline(1M), metaonline(1M), metaparam(1M), metareplace(1M), metaset(1M), metastat(1M), metasync(1M), metattach(1M), md.cf(4), md.tab(4), mddb.cf(4), meddb(4), mediator(7D)

Sun Cluster documentation, *Solaris Volume Manager Administration Guide*

Notes   This command is designed for use in the high availability product.

Name metaclear – delete active metadevices and hot spare pools

Synopsis /usr/sbin/metaclear -h

/usr/sbin/metaclear [-s *setname*] -a [-f]

/usr/sbin/metaclear *component*

/usr/sbin/metaclear [-s *setname*] [-f] *metadevice... hot_spare_pool...*

/usr/sbin/metaclear [-s *setname*] -r [-f] *metadevice... hot_spare_pool...*

/usr/sbin/metaclear [-s *setname*] -p *component*

/usr/sbin/metaclear [-s *setname*] -p *metadevice*

Description The metaclear command deletes the specified metadevice or *hot_spare_pool*, or purges all soft partitions from the designated component. Once a metadevice or hot spare pool is deleted, it must be re-created using metainit before it can be used again.

Any metadevice currently in use (open) cannot be deleted.

Options Root privileges are required for all of the following options except -h.

-a   Deletes all metadevices and configured hot spare pools in the set named by -s, or the local set by default.

-f   Deletes (forcibly) a metadevice that contains a subcomponent in an error state.

-h   Displays usage message.

-p   Deletes (purges) all soft partitions from the specified metadevice or component.

-r   Recursively deletes specified metadevices and hot spare pools, but does not delete metadevices on which others depend.

-s *setname*   Specifies the name of the diskset on which metaclear will work. Using the -s option causes the command to perform its administrative function within the specified diskset. Without this option, the command performs its function on local metadevices and/or hot spare pools.

Operands *metadevice ...*   Specifies the name(s) of the metadevice(s) to be deleted.

component   Specifies the c*d*t*s* name(s) of the components containing soft partitions to be deleted.

hot_spare_pool ...   Specifies the name(s) of the hot spare pools to be deleted. Names for hot spare pools can be any legal file name that is composed of alphanumeric characters, a dash ("-"), an underscore ("_"), or a period ("."). Names must begin with a letter. The words "all" and "none" are reserved and cannot be used.

Examples EXAMPLE 1 Deleting Various Devices

The following example deletes a metadevice named d10.

```
# metaclear /dev/md/dsk/d10
```

The following example deletes all local metadevices and hot spare pools on the system.

```
# metaclear -a
```

The following example deletes a mirror, mymirror, with a submirror in an error state.

```
# metaclear -f mymirror
```

The following example deletes a hot spare pool, hsp001.

```
# metaclear hsp001
```

The following example deletes a soft partition, d23.

```
# metaclear d23
```

The following example purges all soft partitions on the slice c2t3d5s2 if those partitions are not being used by other metadevices or are not open.

```
# metaclear -p c2t3d5s2
```

The following example purges soft partitions from a metadevice.

```
# metaclear -p d2
d3: Soft Partition is cleared
d4: Soft Partition is cleared
d5: Soft Partition is cleared
```

Exit Status The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Solaris Volume Manager Administration Guide

Name metadb – create and delete replicas of the metadevice state database

Synopsis /usr/sbin/metadb -h

/usr/sbin/metadb [-s *setname*]

/usr/sbin/metadb [-s *setname*] -a [-f] [-k *system-file*] mddb*nn*

/usr/sbin/metadb [-s *setname*] -a [-f] [-k *system-file*]
    [-c *number*] [-l *length*] *slice*...

/usr/sbin/metadb [-s *setname*] -d [-f] [-k *system-file*] mddb*nn*

/usr/sbin/metadb [-s *setname*] -d [-f] [-k *system-file*] *slice*...

/usr/sbin/metadb [-s *setname*] -i

/usr/sbin/metadb [-s *setname*] -p [-k *system-file*]
    [*mddb.cf-file*]

Description The metadb command creates and deletes replicas of the metadevice state database. State database replicas can be created on dedicated slices, or on slices that will later become part of a simple metadevice (concatenation or stripe) or RAID5 metadevice. Do not place state database replicas on fabric-attached storage, SANs, or other storage that is not directly attached to the system and available at the same point in the boot process as traditional SCSI or IDE drives. See NOTES.

The metadevice state database contains the configuration of all metadevices and hot spare pools in the system. Additionally, the metadevice state database keeps track of the current state of metadevices and hot spare pools, and their components. Solaris Volume Manager automatically updates the metadevice state database when a configuration or state change occurs. A submirror failure is an example of a state change. Creating a new metadevice is an example of a configuration change.

The metadevice state database is actually a collection of multiple, replicated database copies. Each copy, referred to as a replica, is subject to strict consistency checking to ensure correctness.

Replicated databases have an inherent problem in determining which database has valid and correct data. To solve this problem, Volume Manager uses a *majority consensus algorithm*. This algorithm requires that a majority of the database replicas be available before any of them are declared valid. This algorithm strongly encourages the presence of at least three initial replicas, which you create. A consensus can then be reached as long as at least two of the three replicas are available. If there is only one replica and the system crashes, it is possible that all metadevice configuration data can be lost.

The majority consensus algorithm is conservative in the sense that it will fail if a majority consensus cannot be reached, even if one replica actually does contain the most up-to-date data. This approach guarantees that stale data will not be accidentally used, regardless of the failure scenario. The majority consensus algorithm accounts for the following: the system will

stay running with exactly half or more replicas; the system will panic when less than half the replicas are available; the system will not reboot without one more than half the total replicas.

When used with no options, the metadb command gives a short form of the status of the metadevice state database. Use metadb -i for an explanation of the flags field in the output.

The initial state database is created using the metadb command with both the -a and -f options, followed by the slice where the replica is to reside. The -a option specifies that a replica (in this case, the initial) state database should be created. The -f option forces the creation to occur, even though a state database does not exist. (The -a and -f options should be used together only when no state databases exist.)

Additional replicas beyond those initially created can be added to the system. They contain the same information as the existing replicas, and help to prevent the loss of the configuration information. Loss of the configuration makes operation of the metadevices impossible. To create additional replicas, use the metadb -a command, followed by the name of the new slice(s) where the replicas will reside. All replicas that are located on the same slice must be created at the same time.

To delete all replicas that are located on the same slice, the metadb -d command is used, followed by the slice name.

When used with the -i option, metadb displays the status of the metadevice state databases. The status can change if a hardware failure occurs or when state databases have been added or deleted.

To fix a replica in an error state, delete the replica and add it back again.

The metadevice state database (mddb) also contains a list of the replica locations for this set (local or shared diskset).

The local set mddb can also contain host and drive information for each of the shared disksets of which this node is a member. Other than the diskset host and drive information stored in the local set mddb, the local and shared diskset mddbs are functionality identical.

The mddbs are written to during the resync of a mirror or during a component failure or configuration change. A configuration change or failure can also occur on a single replica (removal of a mddb or a failed disk) and this causes the other replicas to be updated with this failure information.

Options Root privileges are required for all of the following options except -h and -i.

The following options can be used with the metadb command. Not all the options are compatible on the same command line. Refer to the SYNOPSIS to see the supported use of the options.

-a

Attach a new database device. The /kernel/drv/md.conf file is automatically updated
with the new information and the /etc/lvm/mddb.cf file is updated as well. An alternate
way to create replicas is by defining them in the /etc/lvm/md.tab file and specifying the
assigned name at the command line in the form, mddb*nn*, where *nn* is a two-digit number
given to the replica definitions. Refer to the md.tab(4) man page for instructions on setting
up replicas in that file.

-c *number*

Specifies the number of replicas to be placed on each device. The default number of replicas
is 1.

-d

Deletes all replicas that are located on the specified *slice*. The /kernel/drv/md.conf file is
automatically updated with the new information and the /etc/lvm/mddb.cf file is updated
as well.

-f

The -f option is used to create the initial state database. It is also used to force the deletion
of replicas below the minimum of one. (The -a and -f options should be used together
only when no state databases exist.)

-h

Displays a usage message.

-i

Inquire about the status of the replicas. The output of the -i option includes characters in
front of the device name that represent the status of the state database. Explanations of the
characters are displayed following the replica status and are as follows:

d

replica does not have an associated device ID.

o

replica active prior to last mddb configuration change

u

replica is up to date

l

locator for this replica was read successfully

c

replica's location was in /etc/lvm/mddb.cf

p

replica's location was patched in kernel

m

replica is master, this is replica selected as input

r

replica does not have device relocation information

t

tagged data is associated with the replica

W

replica has device write errors

a

replica is active, commits are occurring to this

M

replica had problem with master blocks

D

replica had problem with data blocks

F

replica had format problems

S

replica is too small to hold current database

R

replica had device read errors

B

tagged data associated with the replica is not valid

-k *system-file*

Specifies the name of the kernel file where the replica information should be written. The default *system-file* is /kernel/drv/md.conf. This option is for use with the local diskset only.

-l *length*

Specifies the size of each replica. The default *length* is 8192 blocks, which should be appropriate for most configurations. "Replica" sizes of less than 128 blocks are not recommended.

-p

Specifies updating the system file (md.conf) in the current working directory with entries from the /etc/lvm/mddb.cf file. This option is normally used to update a newly built system before it is booted for the first time. If the system has been built on a system other than the one where it will run, the location of the mddb.cf on the local machine can be passed as an argument. The system file to be updated can be changed using the -k option. This option is for use with the local diskset only.

-s *setname*

Specifies the name of the diskset on which the metadb command will work. Using the -s option will cause the command to perform its administrative function within the specified diskset. Without this option, the command will perform its function on local database replicas.

slice

Specifies the logical name of the physical slice (partition), such as /dev/dsk/c0t0d0s3.

Examples   EXAMPLE 1   Creating Initial State Database Replicas

The following example creates the initial state database replicas on a new system.

```
# metadb -a -f c0t0d0s7 c0t1d0s3 c1t0d0s7 c1t1d0s3
```

The -a and -f options force the creation of the initial database and replicas. You could then create metadevices with these same slices, making efficient use of the system.

EXAMPLE 2   Adding Two Replicas on Two New Disks

This example shows how to add two replicas on two new disks that have been connected to a system currently running Volume Manager.

```
# metadb -a c0t2d0s3 c1t1d0s3
```

EXAMPLE 3   Deleting Two Replicas

This example shows how to delete two replicas from the system. Assume that replicas have been set up on /dev/dsk/c0t2d0s3 and /dev/dsk/c1t1d0s3.

```
# metadb -d c0t2d0s3 c1t1d0s3
```

Although you can delete all replicas, you should never do so while metadevices still exist. Removing all replicas causes existing metadevices to become inoperable.

Files   /etc/lvm/mddb.cf

Contains the location of each copy of the metadevice state database.

/etc/lvm/md.tab

Workspace file for metadevice database configuration.

/kernel/drv/md.conf

Contains database replica information for all metadevices on a system. Also contains Solaris Volume Manager configuration information.

Exit Status   The following exit values are returned:

0

successful completion

>0

an error occurred

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm
Interface Stability	Committed

See Also mdmonitord(1M), metaclear(1M), metadetach(1M), metahs(1M), metainit(1M), metaoffline(1M), metaonline(1M), metaparam(1M), metarecover(1M), metarename(1M), metareplace(1M), metaset(1M), metassist(1M), metastat(1M), metasync(1M), metattach(1M), md.tab(4), md.cf(4), mddb.cf(4), md.tab(4), attributes(5), md(7D)

Solaris Volume Manager Administration Guide

Notes Replicas cannot be stored on fabric-attached storage, SANs, or other storage that is not directly attached to the system. Replicas must be on storage that is available at the same point in the boot process as traditional SCSI or IDE drives. A replica can be stored on a:

- Dedicated local disk partition
- Local partition that will be part of a volume
- Local partition that will be part of a UFS logging device

Name metadevadm – update metadevice information

Synopsis /usr/sbin/metadevadm [-h] [-n] [[-l]-r] [-s *setname*]
        [-u *disk_specifier*] [-v]

Description The metadevadm command facilitates the administration of device ID entries in Solaris
Volume Manager. Use this command when the pathname stored in the metadevice state
database no longer correctly addresses the device or when a disk drive has had its device ID
changed.

This command requires root privileges.

Options The following options are supported.

-h	Provide a help display.
-l	Specify that metadevadm log to syslog(3C). metadevadm logs to the DAEMON facility at the ERR level by default. See syslog.conf(4) for additional information on changing logging levels.
	Use this option anytime. It is most useful in startup scripts and less useful interactively.
-n	Emulate the effect of a command, without making any changes to the system.
-r	Recompute the pathname and disk specifier (including slice) associated with all devices in the metadevice state database if the device supports device IDs. If a device does not support device IDs or the device is not available, then no action is taken for that device.
	Use this option when the disk has been moved or readdressed.
	This option is run automatically at boot time to detect device ID changes and update the state database.
-s *setname*	Specify the name of the disk set on which metadevadm works. This option causes the command to perform its administrative function within the specified disk set. Without this option, the command performs its function on devices in the local disk set.
-u *disk_specifier*	Obtain the device ID associated with the *disk_specifier* (for example, c1t2d0) of a device and update the metadevice state database. If the device ID has not changed this option does nothing. Use this option when a disk drive has had its device ID changed during a firmware upgrade or due to changing the controller of a storage subsystem.
-v	Execute in verbose mode. This option has no effect when used with -u. Verbose is the default.

Examples   EXAMPLE 1   Updating Device ID of Disk

The following example updates the device c2t3d0:

```
# metadevadm -u c2t3d0
Updating SLVM device relocation information for c2t3d0.
Old device reloc information: id1928019239129312301201202010012012091398
New device reloc information: id1938019239129312301201202010012012091398
```

The following example is a variation of the preceding, using the full pathname.

```
# metadevadm -u /dev/dsk/c2t3d0
```

The following example uses the -n option, which means that the command is emulated, but does not take effect. Note that when the -v option is used with -u, -v has no effect (verbose is the default).

```
# metadevadm -u -v -n c2t3d0
Updating SLVM device relocation information for c2t3d0.
Old device reloc information: id1928019239129312301201202010012012091398
New device reloc information: id1938019239129312301201202010012012091398
```

EXAMPLE 2   Recomputing Pathnames

In the following example, all device names are valid.

```
# metadevadm -r
Disk movement detected.
Updating device names in SLVM.
```

In the following example, once again device names are valid.

```
# metadevadm -r -v
Disk movement detected.
Updating device names in SLVM.
c0t0d0s0 changed to c0t0d1s0 from device relocation information
id12098123lkmklsdjaasdkfjadfjakds
```

In the following example, metadevadm detects an invalid device name.

```
# metadevadm -r
Invalid device relocation information detected in SLVM.
Please check status of following disk(s):
c3t0d0
```

Return Values   The following exit values are returned:

0   Command was successful.

1   metadevadm encountered an error condition.

2   An invalid device ID was detected when using the `-r` option. This is for use in the `rc2.d` script. See `init.d(4)`.

Attributes   See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm
Interface Stability	Committed

Solaris Volume Manager Administration Guide

Name metahs – manage hot spares and hot spare pools

Synopsis /usr/sbin/metahs [-s *setname*] -a all *component*

/usr/sbin/metahs [-s *setname*] -a *hot_spare_pool* [*component*]

/usr/sbin/metahs [-s *setname*] -d *hot_spare_pool* [*component*]

/usr/sbin/metahs [-s *setname*] -d all *component*

/usr/sbin/metahs [-s *setname*] -e *component*

/usr/sbin/metahs [-s *setname*] -r *hot_spare_pool component-old*

/usr/sbin/metahs [-s *setname*] -r all *component-old component-new*

/usr/sbin/metahs [-s *setname*] -i [*hot_spare_pool*]...

Description The metahs command manages existing hot spares and hot spare pools. It is used to add, delete, enable, and replace components (slices) in hot spare pools. Like the metainit command, the metahs command can also create an initial hot spare pool. The metahs command does not replace a component of a metadevice. This function is performed by the metareplace command.

Hot spares are always in one of three states: available, in-use, or broken. Available hot spares are running and ready to accept data, but are not currently being written to or read from. In-use hot spares are currently being written to and read from. Broken hot spares are out of service and should be repaired. The status of hot spares is displayed when metahs is invoked with the -i option.

Solaris Volume Manager supports storage devices and logical volumes, including hot spares, greater than 1 terabyte (TB) when Solaris 10 is running a 64-bit kernel.

If a system with large volumes or hot spares is rebooted under a 32-bit Solaris 10 kernel, the large volumes are visible through metastat output, but they cannot be accessed, modified or deleted, and no new large volumes can be created. Any volumes or file systems on a large volume in this situation are also unavailable. If a system with large volumes is rebooted under a version of Solaris prior to Solaris 10, Solaris Volume Manager will not start. All large volumes must be removed before Solaris Volume Manager runs under another version of the Solaris Operating Environment.

Options Root privileges are required for any of the following options except -i.

The following options are supported:

-a all *component*	Add *component* to all hot spare pools. all is not case sensitive.
-a *hot_spare_pool* [*component*]	Add the *component* to the specified *hot_spare_pool*. *hot_spare_pool* is created if it does not already exist.

-d all *component*	Delete *component* from all the hot spare pools. The *component* cannot be deleted if it is in the in-use state.
-d *hot_spare_pool* [*component*]	Delete *hot_spare_pool*, if the *hot_spare_pool* is both empty and not referenced by a metadevice. If *component* is specified, it is deleted from the *hot_spare_pool*. Hot spares in the in-use state cannot be deleted.
-e *component*	Enable *component* to be available for use as a hot spare. The *component* can be enabled if it is in the broken state and has been repaired.
-i [*hot_spare_pool* . . .]	Display the status of the specified *hot_spare_pool* or for all hot spare pools if one is not specified.
-r all *component-old component-new*	Replace *component-old* with *component-new* in all hot spare pools which have the component associated. Components cannot be replaced from any hot spare pool if the old hot spare is in the in-use state.
-r *hot_spare_pool component-old component-new*	Replace *component-old* with *component-new* in the specified *hot_spare_pool*. Components cannot be replaced from a hot spare pool if the old hot spare is in the in-use state.
-s *setname*	Specify the name of the diskset on which metahs works. Using the -s option causes the command to perform its administrative function within the specified diskset. Without this option, the command performs its function on local hot spare pools.

Operands The following operands are supported:

component	The logical name for the physical slice (partition) on a disk drive, such as /dev/dsk/c0t0d0s2.
hot_spare_pool	Names for hot spare pools can be any legal file name that is composed of alphanumeric characters, a dash ("-"), an underscore ("_"), or a period

("."). Names must begin with a letter. The words "all" and "none" are reserved and cannot be used.

Examples   **EXAMPLE 1**   Adding a Hot Spare to a Hot Spare Pool

The following example adds a hot spare /dev/dsk/c0t0d0s7 to a hot spare pool mirror1_pool:

```
# metahs -a mirror1_pool c0t0d0s7
```

When the hot spare is added to the pool, the existing order of the hot spares already in the pool is preserved. The new hot spare is added at the end of the list of hot spares in the hot spare pool specified.

EXAMPLE 2   Adding a Hot Spare to All Currently Defined Pools

This example adds a hot spare to the hot spare pools that are currently defined:

```
# metahs -a all c0t0d0s7
```

The keyword all in this example specifies adding the hot spare, /dev/dsk/c0t0d0s7, to all the hot spare pools.

EXAMPLE 3   Deleting a Hot Spare

This example deletes a hot spare, /dev/dsk/c0t0d0s7, from a hot spare pool, hsp003:

```
# metahs -d hsp003 c0t0d0s7
```

When you delete a hot spare, the position of the remaining hot spares in the pool changes to reflect the new order. For instance, if in this example /dev/dsk/c0t0d0s7 were the second of three hot spares, after deletion the third hot spare would move to the second position.

EXAMPLE 4   Replacing a Hot Spare

This example replaces a hot spare that was previously defined:

```
# metahs -r hsp001 c0t1d0s0 c0t3d0s0
```

In this example, the hot spare /dev/dsk/c0t1d0s0 is replaced by /dev/dsk/c0t3d0s0. The order of the hot spares does not change.

Exit Status   The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm

Solaris Volume Manager Administration Guide

Warnings Do not create large (>1 TB) volumes if you expect to run the Solaris Operating Environment with a 32-bit kernel or if you expect to use a version of the Solaris Operating Environment prior to Solaris 10.

Name metaimport – imports disk sets into existing Solaris Volume Manager configurations

Synopsis metaimport -s *setname* [-n] [-f] [-v] [*disks*]...

metaimport -r [-v] [*disks*]...

metaimport -V

metaimport -?

Description The metaimport command allows the importing of disk sets, including replicated disk sets, into an existing Solaris Volume Manager configuration. Replicated disk sets are disk sets created using remote replication software.

The default Solaris Volume Manager configuration specifies a maximum number of disk sets that can be configured. The metaimport command fails if importing the disk set would result in exceeding the number of disk sets configured on the system. To increase the number of disk sets allowed on a system, see the *Solaris Volume Manager Administration Guide*.

Use metaset(1M) or metastat(1M) to view the configuration of the imported set.

You must run metaimport as root.

metaimport requires a functional Solaris Volume Manager configuration before it runs.

Options The following options are supported:

-f   Force the import, even if a quorum of replicas from the imported disk set is not available. This option could result in corrupt configurations and should only be used when metaimport fails with the "Insufficient quorum detected; exiting" error. If only a partial disk set is available, this option might be necessary to successfully import. Some or all data could be corrupted or unavailable when importing a partial set or a set lacking a replica quorum.

-n   Does not actually perform the operation, but shows the output or errors that would have resulted from the operation, had it been run.

-r   Report on the non-configured disk sets found on the system. If no disk device or LUN is specified, metaimport reports on all non-configured disk sets attached to the system. When the name of one disk is specified, metaimport reports on the disk set (or virtual LUN) containing the specified disk. If two or more disks are specified, metaimport reports on the set (or sets, if they belong to different disk sets) containing the specified disks. If two or more disks are specified, metaimport reports on the set (or sets, if they belong to different disk sets) containing the specified disks.

      This option can be used in conjunction with the -v option to give verbose output on each disk set reported.

-s *setname*		Specify the disk set name to use when importing. The imported disk set will be called *setname*, without regard to the name it may have had on a different system.
-v		Verbose. Provides detailed information about the metadb replica location and status. It also provides detailed information about the disk set configuration and status similar to the "metastat –c" output.
-V		Version information.
-?		Display a help message.

Examples   **EXAMPLE 1**   Importing a Disk Set

The following example creates a disk set called blue and identifies c1t5d0 as a disk containing a state database replica from the disk set being imported.

```
# metaimport -s blue c1t5d0
```

EXAMPLE 2   Reporting Disk Sets to Import

The following example scans all disks and LUNs attached to the system and configured as part of the system. It scans for disks that could be part of a disk set to be imported. Components that are already part of the Solaris Volume Manager configuration are ignored.

This use of metaimport provides suggested forms of the metaimport command to use to actually import the disk sets that have been found. You can specify a component on the command line to reduce the scope of the scan and generate results more quickly.

```
# metaimport -r
```

Exit Status   0   Successful completion.

>0   An error occurred.

Attributes   See attributes(5) for descriptions of the following attributes:

Solaris Volume Manager Administration Guide

Name metainit – configure metadevices

Synopsis /usr/sbin/metainit -h

/usr/sbin/metainit [*generic options*] *concat/stripe numstripes width*
      component... [-i *interlace*]

/usr/sbin/metainit [*width component...* [-i *interlace*]]
      [-h *hot_spare_pool*]

/usr/sbin/metainit [*generic options*] *mirror* -m *submirror*
      [*read_options*] [*write_options*]
      [*pass_num*]

/usr/sbin/metainit [*generic options*] *RAID* -r *component...*
      [-i *interlace*]
      [-h *hot_spare_pool*] [-k] [-o *original_column_count*]

/usr/sbin/metainit [*generic options*] *hot_spare_pool*
      [*hotspare...*]

/usr/sbin/metainit [*generic options*] *metadevice-name*

/usr/sbin/metainit [*generic options*] -a

/usr/sbin/metainit [*generic options*] *softpart* -p [-e] *component*
      [-A *alignment*] *size*

/usr/sbin/metainit -r

Description The metainit command configures metadevices and hot spares according to the information
specified on the command line. Alternatively, you can run metainit so that it uses
configuration entries you specify in the /etc/lvm/md.tab file (see md.tab(4)). All metadevices
must be set up by the metainit command before they can be used.

Solaris Volume Manager supports storage devices and logical volumes greater than 1 terabyte
(TB) when a system runs a 64-bit Solaris kernel. Support for large volumes is automatic. If a
device greater than 1 TB is created, Solaris Volume Manager configures it appropriately and
without user intervention.

If a system with large volumes is rebooted under a 32–bit Solaris kernel, the large volumes are
visible through metastat output. Large volumes cannot be accessed, modified or deleted, and
no new large volumes can be created. Any volumes or file systems on a large volume in this
situation are unavailable. If a system with large volumes is rebooted under a version of Solaris
prior to the Solaris 9 4/03 release, Solaris Volume Manager does not start. You must remove
all large volumes before Solaris Volume Manager runs under an earlier version of the Solaris
Operating System.

If you edit the /etc/lvm/md.tab file to configure metadevices, specify one complete
configuration entry per line. You then run the metainit command with either the -a option,
to activate all metadevices you entered in the /etc/lvm/md.tab file, or with the metadevice
name corresponding to a specific configuration entry.

metainit does not maintain the state of the volumes that would have been created when metainit is run with both the -a and -n flags. Any volumes in md.tab that have dependencies on other volumes in md.tab are reported as errors when metainit -a -n is run, although the operations might succeed when metainit -a is run. See md.tab(4).

Solaris Volume Manager never updates the /etc/lvm/md.tab file. Complete configuration information is stored in the metadevice state database, not md.tab. The only way information appears in md.tab is through editing it by hand.

When setting up a disk mirror, the *first* step is to use metainit create a one-on-one concatenation for the named slice. See EXAMPLES.

Options   The following options are supported:

Generic Options   Root privileges are required for all of the following options except -h.

The following generic options are supported:

-f
    Forces the metainit command to continue even if one of the slices contains a mounted file system or is being used as swap, or if the stripe being created is smaller in size than the underlying soft partition. This option is required when configuring mirrors on swap.

-h
    Displays usage message.

-n
    Checks the syntax of your command line or md.tab entry without actually setting up the metadevice. If used with -a, all devices are checked but not initialized.

-r
    Only used in a shell script at boot time. Sets up all metadevices that were configured before the system crashed or was shut down. The information about previously configured metadevices is stored in the metadevice state database (see metadb(1M)).

-s *setname*
    Specifies the name of the diskset on which metainit works. Without the -s option, the metainit command operates on your local metadevices and/or hotspares.

Concat/Stripe Options   The following concat/stripe options are supported:

concat/stripe
    Specifies the metadevice name of the concatenation, stripe, or concatenation of stripes being defined.

numstripes
    Specifies the number of individual stripes in the metadevice. For a simple stripe, *numstripes* is always 1. For a concatenation, *numstripes* is equal to the number of slices. For a concatenation of stripes, *numstripes* varies according to the number of stripes.

width
Specifies the number of slices that make up a stripe. When *width* is greater than 1, the slices are striped.

component
The logical name for the physical slice (partition) on a disk drive, such as /dev/dsk/c0t0d0s0. For RAID level 5 metadevices, a minimum of three slices is necessary to enable striping of the parity information across slices.

-i *interlace*
Specifies the interlace size. This value tells Solaris Volume Manager how much data to place on a slice of a striped or RAID level 5 metadevice before moving on to the next slice. *interlace* is a specified value, followed by either 'k' for kilobytes, 'm' for megabytes, or 'b' for blocks. The characters can be either uppercase or lowercase. The *interlace* specified cannot be less than 16 blocks, or greater than 100 megabytes. If *interlace* is not specified, it defaults to 512 kilobytes.

-h *hot_spare_pool*
Specifies the *hot_spare_pool* to be associated with the metadevice. If you use the command line, the hot spare pool must have been previously created by the metainit command before it can be associated with a metadevice. Use /-h hsp*nnn* when the concat/stripe being created is to be used as a submirror.

Names for hot spare pools can be any legal file name that is composed of alphanumeric characters, a dash ("-"), an underscore ("_"), or a period ("."). Names must begin with a letter. The words "all" and "none" are reserved and cannot be used.

Mirror Options   The following mirror options are supported:

mirror -m *submirror*
Specifies the metadevice name of the mirror. The -m indicates that the configuration is a mirror. *submirror* is a metadevice (stripe or concatentation) that makes up the initial one-way mirror. Solaris Volume Manager supports a maximum of four-way mirroring. When defining mirrors, first create the mirror with the metainit command as a one-way mirror. Then attach subsequent submirrors using the metattach command. This method ensures that Solaris Volume Manager properly syncs the mirrors. (The second and any subsequent submirrors are first created using the metainit command.)

read_options
The following read options for mirrors are supported:

-g
Enables the geometric read option, which results in faster performance on sequential reads.

-r
Directs all reads to the first submirror. This should only be used when the devices comprising the first submirror are substantially faster than those of the second mirror. This flag cannot be used with the -g flag.

If neither the -g nor -r flags are specified, reads are made in a round-robin order from all submirrors in the mirror. This enables load balancing across the submirrors.

write_options
The following write options for mirrors are supported:

-S

Performs serial writes to mirrors. The first submirror write completes before the second is started. This can be useful if hardware is susceptible to partial sector failures. If -S is not specified, writes are replicated and dispatched to all mirrors simultaneously.

pass_num
A number in the range 0-9 at the end of an entry defining a mirror that determines the order in which that mirror is resynced during a reboot. The default is 1. Smaller pass numbers are resynced first. Equal pass numbers are run concurrently. If 0 is used, the resync is skipped. 0 should be used only for mirrors mounted as read-only, or as swap.

RAID Level 5 Options   The following RAID level 5 options are available:

RAID -r
Specifies the name of the RAID level 5 metadevice. The -r specifies that the configuration is RAID level 5.

-k

For RAID level 5 metadevices, informs the driver that it is not to initialize (zero the disk blocks) due to existing data. Only use this option to recreate a previously created RAID level 5 device.

Use the -k option with extreme caution. This option sets the disk blocks to the OK state. If any errors exist on disk blocks within the metadevice, Solaris Volume Manager might begin fabricating data. Instead of using the -k option, you might want to initialize the device and restore data from tape.

-o *original_column_count*
For RAID level 5 metadevices, used with the -k option to define the number of original slices in the event the originally defined metadevice was grown. This is necessary since the parity segments are not striped across concatenated devices.

Use the -o option with extreme caution. This option sets the disk blocks to the OK state. If any errors exist on disk blocks within the metadevice, Solaris Volume Manager might begin fabricating data. Instead of using the -o option, you might want to initialize the device and restore data from tape.

Soft Partition Options   The following soft partition options are supported:

softpart -p [-e] *component* [-A *alignment*] *size*
The *softpart* argument specifies the name of the soft partition. The -p specifies that the configuration is a soft partition.

The -e specifies that the entire disk specified by *component* as c*t*d* should be repartitioned and reserved for soft partitions. The specified component is repartitioned such that slice 7 reserves space for system (state database replica) usage and slice 0 contains all remaining space on the disk. Slice 7 is a minimum of 4MB, but can be larger, depending on the disk geometry. The newly created soft partition is placed on slice 0 of the device.

The *component* argument specifies the disk (c*t*d*), slice (c*t*d*s*), or meta device (d*) from which to create the soft partition. The *size* argument determines the space to use for the soft partition and can be specified in K or k for kilobytes, M or m for megabytes, G or g for gigabytes, T or t for terabyte (one terabyte is the maximum size), and B or b for blocks (sectors). All values represent powers of 2, and upper and lower case options are equivalent. Only integer values are permitted.

The -A alignment option sets the value of the soft partition extent alignment. This option used when it is important specify a starting offset for the soft partition. It preserves the data alignment between the metadevice address space and the address space of the underlying physical device. For example, a hardware device that does checksumming should not have its I/O requests divided by Solaris Volume Manager. In this case, use a value from the hardware configuration as the value for the alignment. When you use this option in conjunction with a software I/O load, the alignment value corresponds to the I/O load of the application. This prevents I/O from being divided unnecessarily and affecting performance.

The literal all, used instead of specifying size, specifies that the soft partition should occupy all available space on the device.

Hot Spare Pool Options   The following hot spare pool options are supported:

hot_spare_pool [*hotspare...*]
When used as arguments to the metainit command, *hot_spare_pool* defines the name for a hot spare pool, and *hotspare...* is the logical name for the physical slice(s) for availability in that pool. Names for hot spare pools can be any legal file name that is composed of alphanumeric characters, a dash ("-"), an underscore ("_"), or a period ("."). Names must begin with a letter. The words "all" and "none" are reserved and cannot be used.

md.tab File Options   The following md.tab file options are supported:

metadevice-name
When the metainit command is run with a *metadevice-name* as its only argument, it searches the /etc/lvm/md.tab file to find that name and its corresponding entry. The order in which entries appear in the md.tab file is unimportant. For example, consider the following md.tab entry:

```
d0 2 1 c1t0d0s0 1 c2t1d0s0
```

When you run the command metainit d0, it configures metadevice d0 based on the configuration information found in the md.tab file.

-a

Activates all metadevices defined in the `md.tab` file.

`metainit` does not maintain the state of the volumes that would have been created when `metainit` is run with both the `-a` and `-n` flags. If a device `d0` is created in the first line of the `md.tab` file, and a later line in `md.tab` assumes the existence of `d0`, the later line fails when `metainit -an` runs (even if it would succeed with `metainit -a`).

Examples   **EXAMPLE 1**   Creating a One-on-One Concatenation

The following command creates a one-on-one concatenation for the root slice. This is the first step you take when setting up a mirror for any other slice that cannot be unmounted. The `-f` option is required to create a volume with an existing file system.

```
# metainit -f dl 1 1 c0t0d0s0
```

The preceding command makes `d1` a one-on-one concatenation, using the named slice. You can then enter:

```
# metainit d0 -m d1
```

...to make a one-way mirror of the named slice.

EXAMPLE 2   Concatenation

All drives in the following examples have the same size of 525 Mbytes.

This example shows a metadevice, `/dev/md/dsk/d7`, consisting of a concatenation of four slices.

```
# metainit d7 4 1 c0t1d0s0 1 c0t2d0s0 1 c0t3d0s0 1 /dev/dsk/c0t4d0s0
```

The number 4 indicates there are four individual stripes in the concatenation. Each stripe is made of one slice, hence the number 1 appears in front of each slice. The first disk sector in all of these devices contains a disk label. To preserve the labels on devices `/dev/dsk/c0t2d0s0`, `/dev/dsk/c0t3d0s0`, and `/dev/dsk/c0t4d0s0`, the metadisk driver must skip at least the first sector of those disks when mapping accesses across the concatenation boundaries. Because skipping only the first sector would create an irregular disk geometry, the entire first cylinder of these disks is skipped. This allows higher level file system software to optimize block allocations correctly.

EXAMPLE 3   Stripe

This example shows a metadevice, `/dev/md/dsk/d15`, consisting of two slices.

```
# metainit d15 1 2 c0t1d0s0 c0t2d0s0 -i 32k
```

The number 1 indicates that one stripe is being created. Because the stripe is made of two slices, the number 2 follows next. The optional `-i` followed by `32k` specifies the interlace size as 32 Kbytes. If the interlace size were not specified, the stripe would use the default value of 16

EXAMPLE 3 Stripe   *(Continued)*

Kbytes.

EXAMPLE 4 Concatentation of Stripes

This example shows a metadevice, `/dev/md/dsk/d75`, consisting of a concatenation of two stripes of three disks.

```
# metainit d75 2 3 c0t1d0s0 c0t2d0s0 \
      c0t3d0s0 -i 16k \
      3 c1t1d0s0 c1t2d0s0 c1t3d0s0 -i 32k
```

On the first line, the `-i` followed by 16k specifies that the stripe interlace size is 16 Kbytes. The second set specifies the stripe interlace size as 32 Kbytes. If the second set did not specify 32 Kbytes, the set would use the default interlace value of 16 Kbytes. The blocks of each set of three disks are interlaced across three disks.

EXAMPLE 5 Mirroring

This example shows a two-way mirror, `/dev/md/dsk/d50`, consisting of two submirrors. This mirror does not contain any existing data.

```
# metainit d51 1 1 c0t1d0s0
# metainit d52 1 1 c0t2d0s0
# metainit d50 -m d51
# metattach d50 d52
```

In this example, two submirrors, d51 and d52, are created with the `metainit` command. These two submirrors are simple concatenations. Next, a one-way mirror, d50, is created using the `-m` option with d51. The second submirror is attached later using the `metattach` command. When creating a mirror, any combination of stripes and concatenations can be used. The default read and write options in this example are a round-robin read algorithm and parallel writes to all submirrors.

EXAMPLE 6 Creating a metadevice in a diskset

This example shows a metadevice, `/dev/md/dsk/d75`, consisting of a concatenation of two stripes within a diskset called `set1`.

```
# metainit -s set1 d75 2 3 c2t1d0s0 c2t2d0s0 \
      c2t3d0s0 -i 32k
# metainit -s set1 d51 1 1 c2t1d0s0
# metainit -s set1 d52 1 1 c3t1d0s0
# metainit -s set1 d50 -m d51
# metattach -s set1 d50 d52
```

In this example, a diskset is created using the `metaset` command. Metadevices are then created within the diskset using the `metainit` command. The two submirrors, d51 and d52, are simple concatenations. Next, a one-way mirror, d50, is created using the `-m` option with

EXAMPLE 6 Creating a metadevice in a diskset *(Continued)*

d51. The second submirror is attached later using the metattach command. When creating a mirror, any combination of stripes and concatenations can be used. The default read and write options in this example are a round-robin read algorithm and parallel writes to all submirrors.

EXAMPLE 7 RAID Level 5

This example shows a RAID level 5 device, d80, consisting of three slices:

```
# metainit d80 -r c1t0d0s0 c1t1d0s0 c1t3d0s0 -i 20k
```

In this example, a RAID level 5 metadevice is defined using the -r option with an interlace size of 20 Kbytes. The data and parity segments are striped across the slices, c1t0d0s0, c1t2d0s0, and c1t3d0s0.

EXAMPLE 8 Soft Partition

The following example shows a soft partition device, d1, built on metadevice d100 and 100 Mbytes (indicated by 100M) in size:

```
# metainit d1 -p d100 100M
```

The preceding command creates a 100 Mbyte soft partition on the d100 metadevice. This metadevice could be a RAID level 5, stripe, concatenation, or mirror.

EXAMPLE 9 Soft Partition on Full Disk

The following example shows a soft partition device, d1, built on disk c3t4d0:

```
# metainit d1 -p -e c3t4d0 9G
```

In this example, the disk is repartitioned and a soft partition is defined to occupy all 9 Gbytes of disk c3t4d0s0.

EXAMPLE 10 Soft Partition Taking All Available Space

The following example shows a soft partition device, d1, built on disk c3t4d0:

```
# metainit d1 -p -e c3t4d0 all
```

In this example, the disk is repartitioned and a soft partition is defined to occupy all available disk space on slice c3t4d0s0.

EXAMPLE 11 Hot Spare

This example shows a two-way mirror, /dev/md/dsk/d10, and a hot spare pool with three hot spare components. The mirror does not contain any existing data.

```
# metainit hsp001 c2t2d0s0 c3t2d0s0 c1t2d0s0
# metainit d41 1 1 c1t0d0s0 -h hsp001
# metainit d42 1 1 c3t0d0s0 -h hsp001
```

EXAMPLE 11 Hot Spare   *(Continued)*

```
# metainit d40 -m d41
# metattach d40 d42
```

In this example, a hot spare pool, hsp001, is created with three slices from three different disks used as hot spares. Next, two submirrors are created, d41 and d42. These are simple concatenations. The metainit command uses the -h option to associate the hot spare pool hsp001 with each submirror. A one-way mirror is then defined using the -m option. The second submirror is attached using the metattach command.

EXAMPLE 12 Setting the Value of the Soft Partition Extent Alignment

This example shows how to set the alignment of the soft partition to 1 megabyte.

```
# metainit -s red d13 -p c1t3d0s4 -A 1m 4m
```

In this example the soft partition, d13, is created with an extent alignment of 1 megabyte. The metainit command uses the -A option with an alignment of 1m to define the soft partition extent alignment.

Files /etc/lvm/md.tab
        Contains list of metadevice and hot spare configurations for batch-like creation.

Warnings This section contains information on different types of warnings.

Devices and Volumes Greater Than 1 TB Do not create large (>1 TB) volumes if you expect to run the Solaris Operating Environment with a 32–bit kernel or if you expect to use a version of the Solaris Operating Environment prior to Solaris 10.

Multi-Way Mirror Do not use the metainit command to create a multi-way mirror. Rather, create a one-way mirror with metainit then attach additional submirrors with metattach. When the metattach command is not used, no resync operations occur and data could become corrupted.

If you use metainit to create a mirror with multiple submirrors, the following message is displayed:

```
WARNING: This form of metainit is not recommended.
The submirrors may not have the same data.
Please see ERRORS in metainit(1M) for additional information.
```

Truncation of Soft Partitions When creating stripes on top of soft partitions it is possible for the size of the new stripe to be less than the size of the underlying soft partition. If this occurs, metainit fails with an error indicating the actions required to overcome the failure.

If you use the -f option to override this behavior, the following message is displayed:

```
WARNING: This form of metainit is not recommended.
The stripe is truncating the size of the underlying device.
Please see ERRORS in metainit(1M) for additional information.
```

Write-On-Write Problem When mirroring data in Solaris Volume Manager, transfers from memory to the disks do not all occur at exactly the same time for all sides of the mirror. If the contents of buffers are changed while the data is in-flight to the disk (called write-on-write), then different data can end up being stored on each side of a mirror.

This problem can be addressed by making a private copy of the data for mirror writes, however, doing this copy is expensive. Another approach is to detect when memory has been modified across a write by looking at the dirty-bit associated with the memory page. Solaris Volume Manager uses this dirty-bit technique when it can. Unfortunately, this technique does not work for raw I/O or direct I/O. By default, Solaris Volume Manager is tuned for performance with the liability that mirrored data might be out of sync if an application does a "write-on-write" to buffers associated with raw I/O or direct I/O. Without mirroring, you were not guaranteed what data would actually end up on media, but multiple reads would return the same data. With mirroring, multiple reads can return different data. The following line can be added to /etc/system to cause a stable copy of the buffers to be used for all raw I/O and direct I/O write operations.

```
set md_mirror:md_mirror_wow_flg=0x20
```

Setting this flag degrades performance.

Exit Status The following exit values are returned:

0
    Successful completion.

>0
    An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm
Interface Stability	Committed

See Also mdmonitord(1M), metaclear(1M), metadb(1M), metadetach(1M), metahs(1M), metaoffline(1M), metaonline(1M), metaparam(1M), metarecover(1M), metarename(1M), metareplace(1M), metaset(1M), metassist(1M), metastat(1M), metasync(1M), metattach(1M), md.tab(4), md.cf(4), mddb.cf(4), md.tab(4), attributes(5), md(7D)

Limitations Recursive mirroring is not allowed; that is, a mirror cannot appear in the definition of another mirror.

Recursive logging is not allowed; that is, a trans metadevice cannot appear in the definition of another metadevice.

Stripes, concatenations, and RAID level 5 metadevices must consist of slices only.

Mirroring of RAID level 5 metadevices is not allowed.

Soft partitions can be built on raw devices, or on stripes, RAID level 5, or mirrors.

RAID level 5 or stripe metadevices can be built directly on soft partitions.

Notes Trans metadevices have been replaced by UFS logging. Existing trans devices are *not* logging--they pass data directly through to the underlying device. See mount_ufs(1M) for more information about UFS logging.

Name metaoffline, metaonline – place submirrors offline and online

Synopsis /usr/sbin/metaoffline -h

/usr/sbin/metaoffline [-s *setname*] [-f] *mirror submirror*

/usr/sbin/metaonline -h

/usr/sbin/metaonline [-s *setname*] *mirror submirror*

Description The metaoffline command prevents Solaris Volume Manager from reading and writing to the submirror that has been taken offline. While the submirror is offline, all writes to the mirror will be kept track of (by region) and will be written when the submirror is brought back online. The metaoffline command can also be used to perform online backups: one submirror is taken offline and backed up while the mirror remains accessible. (However, if this is a two-way mirror, data redundancy is lost while one submirror is offline.) The metaoffline command differs from the metadetach command because it does not sever the logical association between the submirror and the mirror. To completely remove a submirror from a mirror, use the metadetach command.

A submirror that has been taken offline will only remain offline until the metaonline command is invoked or the system is rebooted.

When the metaonline command is used, reading from and writing to the submirror resumes. A resync is automatically invoked to resync the regions written while the submirror was offline. Writes are directed to the submirror during resync. Reads, however, will come from a different submirror. Once the resync operation completes, reads and writes are performed on that submirror. The metaonline command is only effective on a submirror of a mirror that has been taken offline.

The metaoffline and metaonline commands can not be used on RAID 1 volumes in application-based recovery (ABR) mode.

A submirror that has been taken offline with the metaoffline command can only be mounted as read-only.

Options Root privileges are required for all of the following options except -h.

-f   Forces offlining of submirrors that have slices requiring maintenance.

-h   Displays usage message.

-s *setname*   Specifies the name of the diskset on which metaoffline and metaonline will work. Using the -s option will cause the command to perform its administrative function within the specified diskset. Without this option, the command will perform its function on local metadevices.

mirror   Specifies the metadevice name of the mirror from which the submirror will be either taken offline or put online.

submirror   Specifies the metadevice name of the submirror to be either taken offline or put online.

Examples   EXAMPLE 1   Taking a Submirror Offline

This example takes one submirror, mymirror_sub1, offline from mirror mymirror.

```
# metaoffline mymirror mymirror_sub1
```

Exit Status   The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm
Interface Stability	Committed

Solaris Volume Manager Administration Guide

Notes   The metaonline and metaoffline commands are not applicable to mirrors in application-based recovery (ABR) mode.

Name metaparam – modify parameters of metadevices

Synopsis /usr/sbin/metaparam -h

/usr/sbin/metaparam [-s *setname*]
    [*concat/stripe or RAID5 options*] *concat/stripe RAID*

/usr/sbin/metaparam [-s *setname*] [*mirror options*] *mirror*

Description The metaparam command is used to display or modify current parameters of metadevices.

If just the metadevice is specified as an argument to the metaparam command, the current settings are displayed.

The metaparam command enables most metadevice (volume) parameters to be changed. Only the interlace value cannot be changed by metaparam, because it is established when the metadevice is created and cannot be changed thereafter.

Options Root privileges are required for all of the options.

The following options are supported:

-h
  Displays usage message.

-s *setname*
  Specify the name of the diskset on which metaparam works. Using the -s option causes the command to perform its administrative function within the specified diskset. Without this option, the command performs its function on local metadevices.

Concat/STRIPE Or Raid5 Options –h*hot_spare_pool* | none
  Specifies the hot spare pool to be used by a metadevice. If none is specified, the metadevice is disassociated with the hot spare pool assigned to it. If the metadevice is currently using a hot spare, then metaparam cannot replace the hot spare pool.

concat/stripe | RAID
  Specifies the metadevice name of the concatenation, stripe, or concatenation of stripes, or of the RAID5 metadevice.

Mirror Options –r roundrobin | geometric | first
  Modifies the read option for a mirror. The -r option must be followed by either roundrobin, geometric, or first. roundrobin, which is the default action under the metainit command, specifies reading the disks in a round-robin (load balancing) method. geometric allows for faster performance on sequential reads. first specifies reading only from the first submirror.

–w parallel | serial
  Modifies the write option for a mirror. The -w option must be followed by either parallel or serial. parallel, the default action under the metainit command, specifies that all writes are parallel. serial specifies that all writes are serial.

-p *pass_number*

A number from 0-to-9 that specifies the order in which a mirror is resynced during reboot. The default is 1. Smaller pass numbers are resynced first. Equal pass numbers are run concurrently. If 0 is used, the mirror resync is skipped. 0 should only be used for mirrors mounted as read-only, or as swap.

mirror

Specifies the metadevice name of the mirror.

Examples EXAMPLE 1 Associating Hot Spare Pool with RAID5 Metadevice

This example associates a hot spare pool, user_pool, with a RAID5 metadevice, user_raid.

```
# metaparam -h user_pool user_raid
```

EXAMPLE 2 Changing Read Option to Geometric

This example changes the read option on a mirror d50 from the default of roundrobin to geometric.

```
# metaparam -r geometric d50
```

Exit Status The following exit values are returned:

0

Successful completion.

>0

An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm
Interface Stability	Committed

See Also mdmonitord(1M), metaclear(1M), metadb(1M), metadetach(1M), metahs(1M), metainit(1M), metaoffline(1M), metaonline(1M), metarecover(1M), metarename(1M), metareplace(1M), metaset(1M), metassist(1M), metastat(1M), metasync(1M), metattach(1M), md.tab(4), md.cf(4), mddb.cf(4), md.tab(4), attributes(5), md(7D)

Solaris Volume Manager Administration Guide

Name metarecover – recover soft partition information

Synopsis /usr/sbin/metarecover [-n] [-v] [-s *setname*] *component* -p

/usr/sbin/metarecover [-n] [-v] [-s *setname*] *component* -p {-d}

/usr/sbin/metarecover [-n] [-v] [-s *setname*] *component* -p {-m}

Description The metarecover command scans a specified component to look for soft partition configuration information and to regenerate the configuration.

Options The following options are supported:

-d Recover soft partitions in the metadevice state database from the extent headers on the device. Options -d and -m are mutually exclusive.

-m Regenerate the extent headers and reapplies them to the underlying device based on the soft partitions listed in metadevice state database. Options -d and -m are mutually exclusive.

-n Do not actually perform the operation. Show the output or errors that would have resulted from the operation, had it been run.

-p Regenerate soft partitions based on the metadevice state database or extent headers on the underlying device. If neither -d nor -m are specified, this option compares the soft partition information in the metadevice state database to the extent headers.

-s *setname* Specify the name of the diskset on which metarecover works. Using the s option causes the command to perform its function within the specified diskset. Without the -s option, the metarecover command operates on the metadevices and/or hot spare pools in the local diskset.

This option is required to recover former sps from a diskset component or raw-device. *setname* must be identical to the former *setname* in which the sps were created. The set numbers, however, seem irrelevant.

-v Verbose mode, displaying the changes being made.

Operands The following operand is supported:

component Specifies the c*t*d*s* number of the disk or slice containing the partitions, or the device name (for example, d10) of the metadevice containing the partitions.

component can be a slice name, component name, /dev/dsk path, or /dev/rdsk path.

Examples   **EXAMPLE 1**   Updating Metadevice State Database Based on Disk Extent Headers

A disk containing soft partitions is moved from one system to another. The system administrator would like to use the existing soft partitions. metarecover updates the metadevice state database based on the extent headers on the disk.

```
# metarecover -v c0t3d0s2 -p -d
```

EXAMPLE 2   Updating Metadevice State Database Based on Incomplete Soft Partition Creation

A system crashes in the middle of creating a new soft partition. The soft partition is in the creating state and the driver does not let that device be opened. metarecover rewrites the extent headers for the partially created soft partition and mark it as Okay.

```
# metarecover -v c0t3d0s2 -p -m
```

EXAMPLE 3   Updating Extent Headers Based on Metadevice State Database

Someone accidentally overwrote a portion of a disk leaving extent headers destroyed. metarecover rewrites the extent headers to ensure a valid soft partition configuration, though user data is not recovered.

```
# metarecover -v d5 -m
```

The following example implements the same command using a descriptive name.

```
# metarecover -v myvolume -m
```

EXAMPLE 4   Validating Soft Partition Configuration

To validate the existing soft partition configuration, use metarecover with only the -p flag.

```
# metarecover c0t3d0s2 -p
```

Exit Status   The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Solaris Volume Manager Administration Guide

Name metarename – rename metadevice or switch layered metadevice names

Synopsis /usr/sbin/metarename [-s *setname*] *metadevice1* *metadevice2*

/usr/sbin/metarename [-s *setname*] [-f] -x *metadevice1* *metadevice2*

/usr/sbin/metarename -h

Description There are two ways to use metarename, one with and one without the -x option. The first method (without -x) renames an existing metadevice to a new name. This makes managing the metadevice namespace easier. The metadevice being renamed cannot be mounted or open, nor can the new name already exist. For example, to rename a metadevice that contains a mounted file system, you would first need to unmount the file system.

With the second way to use metarename, using the -x option, metarename switches (exchanges) the names of an existing layered metadevice and one of its subdevices. In Solaris Volume Manager terms, a layered metadevice can be either a mirror or a trans metadevice. The -x option enables you to switch the metadevice names of a mirror and one of its submirrors, or a trans metadevice and its master device.

metarename -x makes it easier to mirror or unmirror an existing stripe or concatenation, and to remove a trans device.

When used to mirror an existing stripe or concatenatation, you must stop access to the device. For example, if the device contains a mounted file system, you must first unmount the file system before doing the rename.

You can also use the metarename -x command to untrans a trans metadevice from an existing device. This applies only to the master device. You cannot remove a logging device with metarename. Before you can rename a trans device, you must detach the logging device. Then you must stop access to the trans metadevice itself.

You cannot rename or switch metadevices that are in an error state or that have subcomponents in an error state, or metadevices actively using a hot spare replacement.

You can only switch metadevices that have a direct child/parent relationship. You could not, for example, directly exchange a stripe in a mirror that is a master device with the trans metadevice.

You must use the -f flag when switching members of a trans metadevice.

Only metadevices can be switched, not slices.

Options The following options are supported:

-f   Force the switching of trans metadevice members.

-h   Display a help message.

-s *setname*	Specifies the name of the diskset on which metarename will work. Using the -s option will cause the command to perform its administrative function within the specified diskset. Without this option, the command will perform its function on the local metadevices.
-x	Exchange the metadevice names *metadevice1* and *metadevice2*.
metadevice1	Specifies the metadevice to be renamed or switched.
metadevice2	Specifies the target metadevice name for the rename or switch operation.

Examples **EXAMPLE 1** Renaming a Metadevice

This example renames a metadevice named d10 to account_records. Note that account_records must not exist for the rename to succeed.

```
# metarename d10 account_records
```

EXAMPLE 2 Creating a Two-Way Mirror

This example creates a two-way mirror from an existing stripe named d1 with a mounted file system, /home2.

```
# metainit d2 1 1 c13d0s1
# metainit -f d20 -m d1
# umount /home2
# metarename -x d20 d1
# metattach d1 d2
# mount /home2
```

First, a second concatenation d2, is created. (d1 already exists.) The metainit command creates a one-way mirror, d20, from d1. Next, you umount the file system and switch d1 for d20, making d1 the top-level device (mirror). You attach the second submirror, d2, to create a two-way mirror. Lastly, you remount the file system.

EXAMPLE 3 Mounting a Mirrored File System on Stripe

This example takes an existing mirror named d1 with a mounted file system, and ends up with the file system mounted on a stripe d1.

```
# umount /fs2
# metarename -x d1 d20
# metadetach d20 d1
# metaclear -r d20
# mount /fs2
```

First, you unmount the file system, then switch the mirror d1 and its submirror d20. This makes the mirror into d20. Next, you detach d1 from d20, then delete the mirror d20 and its other submirror. You then remount the file system.

EXAMPLE 4 Deleting a Trans Metadevice

This example deletes a trans metadevice named d10 while its mount point is /myhome. The master device, which is a stripe, is named d2. The logging device, also a stripe, is named d5.

```
# umount /myhome
# metadetach d10
# metarename -f -x d10 d2
# metaclear d2
# metaclear d5
# fsck /dev/md/dsk/d10
# mount /myhome
```

You umount the file system first, then detach the trans metadevice's logging device. The trans metadevice is switched with the master device, making the trans metadevice d2 and the underlying stripe d10. You clear the trans metadevice d2 and the logging device d5. d10 must be fsck'd, and then the file system is remounted.

Exit Status The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Solaris Volume Manager Administration Guide

Limitations Renaming and exchanging metadevice names can only be used for metadevices. A physical slice cannot be renamed to a metadevice, nor can a metadevice be exchanged with a physical slice name.

Metadevice names are strings of the pattern *d<xyz>* where *xyz* is a value between 0 and 8192. You cannot use logical names for metadevices.

Notes Trans metadevices have been replaced by UFS logging. Existing trans devices are *not* logging—they pass data directly through to the underlying device. See mount_ufs(1M) for more information about UFS logging.

Name metareplace – enable or replace components of submirrors or RAID5 metadevices

Synopsis `/usr/sbin/metareplace -h`

`/usr/sbin/metareplace [-s` *setname*`] -e` *mirror component*

`/usr/sbin/metareplace [-s` *setname*`]` *mirror component-old component-new*

`/usr/sbin/metareplace [-s` *setname*`] -e` *RAID component*

`/usr/sbin/metareplace [-s` *setname*`] [-f]` *RAID component-old component-new*

Description The `metareplace` command is used to enable or replace components (slices) within a submirror or a RAID5 metadevice.

When you replace a component, the `metareplace` command automatically starts resyncing the new component with the rest of the metadevice. When the resync completes, the replaced component becomes readable and writable. If the failed component has been hot spare replaced, the hot spare is placed in the available state and made available for other hot spare replacements.

Note that the new component must be large enough to replace the old component.

A component may be in one of several states. The `Last Erred` and the `Maintenance` states require action. Always replace components in the `Maintenance` state first, followed by a resync and validation of data. After components requiring maintenance are fixed, validated, and resynced, components in the `Last Erred` state should be replaced. To avoid data loss, it is always best to back up all data before replacing `Last Erred` devices.

Options Root privileges are required for all of the following options except `-h`.

> `-e`   Transitions the state of *component* to the available state and resyncs the failed component. If the failed component has been hot spare replaced, the hot spare is placed in the available state and made available for other hot spare replacements. This command is useful when a component fails due to human error (for example, accidentally turning off a disk), or because the component was physically replaced. In this case, the replacement component must be partitioned to match the disk being replaced before running the `metareplace` command.

> `-f`   Forces the replacement of an errored component of a metadevice in which multiple components are in error. The component determined by the `metastat` display to be in the "Maintenance" state must be replaced first. This option may cause data to be fabricated since multiple components are in error.

> `-h`   Display help message.

> `-s` *setname*   Specifies the name of the diskset on which `metareplace` will work. Using the `-s` option will cause the command to perform its administrative

function within the specified diskset. Without this option, the command
will perform its function on local metadevices.

mirror   The metadevice name of the mirror.

component   The logical name for the physical slice (partition) on a disk drive, such as
                      /dev/dsk/c0t0d0s2.

component-old   The physical slice that is being replaced.

component-new   The physical slice that is replacing *component-old*.

RAID   The metadevice name of the RAID5 device.

Examples   **EXAMPLE 1** Recovering from Error Condition in RAID5 Metadevice

This example shows how to recover when a single component in a RAID5 metadevice is
errored.

```
# metareplace d10 c3t0d0s2 c5t0d0s2
```

In this example, a RAID5 metadevice d10 has an errored component, c3t0d0s2, replaced by a
new component, c5t0d0s2.

EXAMPLE 2 Use of -e After Physical Disk Replacement

This example shows the use of the -e option after a physical disk in a submirror (a submirror
of mirror mymirror1, in this case) has been replaced.

```
# metareplace -e mymirror1 c1t4d0s2
```

Note: The replacement disk must be partitioned to match the disk it is replacing before
running the metareplace command.

Exit Status   The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Solaris Volume Manager Administration Guide

Name   metaset – configure disk sets

Synopsis   /usr/sbin/metaset -s *setname* [-M-a -h *hostname*]

/usr/sbin/metaset -s *setname* -A {enable | disable}

/usr/sbin/metaset -s *setname* [-A {enable | disable}] -a -h *hostname*...

/usr/sbin/metaset -s *setname* -a [-l *length*] [-L] *drivename*...

/usr/sbin/metaset -s *setname* -C {take | release | purge}

/usr/sbin/metaset -s *setname* -d [-f] -h *hostname*...

/usr/sbin/metaset -s *setname* -d [-f] *drivename*...

/usr/sbin/metaset -s *setname* -j

/usr/sbin/metaset -s *setname* -r

/usr/sbin/metaset -s *setname* -w

/usr/sbin/metaset -s *setname* -t [-f] [-u *tagnumber*] [y]

/usr/sbin/metaset -s *setname* -b

/usr/sbin/metaset -s *setname* -P

/usr/sbin/metaset -s *setname* -q

/usr/sbin/metaset -s *setname* -o [-h *hostname*]

/usr/sbin/metaset [-s *setname*]

/usr/sbin/metaset [-s *setname*] -a | -d
        [[m] *mediator_host_list*]

Description   The metaset command administers sets of disks in named disk sets. Named disk sets include any disk set that is not in the local set. While disk sets enable a high-availability configuration, Solaris Volume Manager itself does not actually provide a high-availability environment.

A single-owner disk set configuration manages storage on a SAN or fabric-attached storage, or provides namespace control and state database replica management for a specified set of disks.

In a shared disk set configuration, multiple hosts are physically connected to the same set of disks. When one host fails, another host has exclusive access to the disks. Each host can control a shared disk set, but only one host can control it at a time.

When you add a new disk to any disk set, Solaris Volume Manager checks the disk format. If necessary, it repartitions the disk to ensure that the disk has an appropriately configured reserved slice 7 (or slice 6 on an EFI labelled device) with adequate space for a state database replica. The precise size of slice 7 (or slice 6 on an EFI labelled device) depends on the disk geometry. For tradtional disk sets, the slice is no less than 4 Mbytes, and probably closer to 6 Mbytes, depending on where the cylinder boundaries lie. For multi-owner disk sets, the slice is

a minimum of 256 Mbytes. The minimal size for slice 7 might change in the future. This change is based on a variety of factors, including the size of the state database replica and information to be stored in the state database replica.

For use in disk sets, disks must have a dedicated slice (six or seven) that meets specific criteria:

- The slice must start at sector 0
- The slice must include enough space for disk label
- The state database replicas cannot be mounted
- The slice does not overlap with any other slices, including slice 2

If the existing partition table does not meet these criteria, or if the -L flag is specified, Solaris Volume Manager repartitions the disk. A small portion of each drive is reserved in slice 7 (or slice 6 on an EFI labelled device) for use by Solaris Volume Manager. The remainder of the space on each drive is placed into slice 0. Any existing data on the disks is lost by repartitioning.

After you add a drive to a disk set, it can be repartitioned as necessary, with the exception that slice 7 (or slice 6 on an EFI labelled device) is not altered in any way.

After a disk set is created and metadevices are set up within the set, the metadevice name is in the following form:

/dev/md/*setname*/{dsk,rdsk}/d*number*

where *setname* is the name of the disk set, and *number* is the number of the metadevice (0-127).

If you have disk sets that you upgraded from Solstice DiskSuite software, the default state database replica size on those sets is 1034 blocks, not the 8192 block size from Solaris Volume Manager. Also, slice 7 on the disks that were added under Solstice DiskSuite are correspondingly smaller than slice 7 on disks that were added under Solaris Volume Manager.

If disks you add to a disk set have acceptable slice 7s (that start at cylinder 0 and that have sufficient space for the state database replica), they are not reformatted.

Hot spare pools within local disk sets use standard Solaris Volume Manager naming conventions. Hot spare pools with shared disk sets use the following convention:

setname/*hot_spare_pool*

where *setname* is the name of the disk set, and *hot_spare_pool* is the name of the hot spare pool associated with the disk set.

Multi–node Environment

To create and work with a disk set in a multi—node environment, root must be a member of Group 14 on all hosts, or the /.rhosts file must contain an entry for all other host names. This is not required in a SunCluster 3.x enviroment.

Tagged data Tagged data occurs when there are different versions of a disk set's replicas. This tagged data consists of the set owner's nodename, the hardware serial number of the owner, and the time it was written out to the available replicas. The system administer can use this information to determine which replica contains the correct data.

When a disk set is configured with an even number of storage enclosures and has replicas balanced across them evenly, it is possible that up to half of the replicas can be lost (for example, through a power failure of half of the storage enclosures). After the enclosure that went down is rebooted, half of the replicas are not recognized by SVM. When the set is retaken, the metaset command returns an error of "stale databases", and all of the metadevices are in a read-only state.

Some of the replicas that are not recognized need to be deleted. The action of deleting the replicas also causes updates to the replicas that are not being deleted. In a dual hosted disk set environment, the second node can access the deleted replicas instead of the existing replicas when it takes the set. This leads to the possibility of getting the wrong replica record on a disk set take. An error message is displayed, and user intervention is required.

Use the -q to query the disk set and the -t, -u, and -y, options to select the tag and take the disk set. See OPTIONS.

Mediator Configuration SVM provides support for a low-end HA solution consisting of two hosts that share only two strings of drives. The hosts in this type of configuration, referred to as *mediators* or mediator hosts, run a special daemon, rpc.metamedd(1M). The mediator hosts take on additional responsibilities to ensure that data is available in the case of host or drive failures.

A mediator configuration can survive the failure of a single host or a single string of drives, without administrative intervention. If both a host and a string of drives fail (multiple failures), the integrity of the data cannot be guaranteed. At this point, administrative intervention is required to make the data accessible. See mediator(7D) for further details.

Use the -m option to add or delete a mediator host. See OPTIONS.

Options The following options are supported:

-a *drivename*
  Add drives or hosts to the named set. For a drive to be accepted into a set, the drive must not be in use within another metadevice or disk set, mounted on, or swapped on. When the drive is accepted into the set, it is repartitioned and the metadevice state database replica (for the set) can be placed on it. However, if a slice 7 (or slice 6 on an EFI labelled device), starts at cylinder 0, and is large enough to hold a state database replica, then the disk is not repartitioned. Also, a drive is not accepted if it cannot be found on all hosts specified as part of the set. This means that if a host within the specified set is unreachable due to network problems, or is administratively down, the add fails.

  Specify a drive name in the form c*num*t*num*d*num*. Do not specify a slice number (s*num*). For drives in a Sun Cluster, you must specify a complete pathname for each drive. Such a name has the form:

/dev/did/[r]dsk/d*num*

-a | -d | -m *mediator_host_list*

Add (-a) or delete (-d) mediator hosts to the specified disk set. A *mediator_host_list* is the nodename (established by svc:/system/identity:node smf(5) service) of the mediator host to be added and (for adding) up to two other aliases for the mediator host. The nodename and aliases for each mediator host are separated only by commas. Up to three mediator hosts can be specified for the named disk set. Specify only the nodename of that host as the argument to -m to delete a mediator host.

In a single metaset command you can add or delete up to three mediator hosts. See EXAMPLES.

-A {enable | disable}

Specify auto-take status for a disk set. If auto-take is enabled for a set, the disk set is automatically taken at boot, and file systems on volumes within the disk set can be mounted through /etc/vfstab entries. Only a single host can be associated with an auto-take set, so attempts to add a second host to an auto-take set or attempts to configure a disk set with multiple hosts as auto-take fails with an error message. Disabling auto-take status for a specific disk set causes the disk set to revert to normal behavior. That is, the disk set is potentially shared (non-concurrently) among hosts, and unavailable for mounting through /etc/vfstab.

-b

Insure that the replicas are distributed according to the replica layout algorithm. This can be invoked at any time, and does nothing if the replicas are correctly distributed. In cases where the user has used the metadb command to manually remove or add replicas, this command can be used to insure that the distribution of replicas matches the replica layout algorithm.

-C {take | release | purge}

Do not interact with the Cluster Framework when used in a Sun Cluster 3 environment. In effect, this means do not modify the Cluster Configuration Repository. These options should only be used to fix a broken disk set configuration.

take

Take ownership of the disk set but do not inform the Cluster Framework that the disk set is available. This option is not for use with a multi-owner disk set.

release

Release ownership of the disk set without informing the Cluster Framework. This option should only be used if the disk set ownership was taken with the corresponding -C take option. This option is not for use with a multi-owner disk set.

purge

Remove the disk set without informing the Cluster Framework that the disk set has been purged. This option should only be used when the disk set is not accessible and requires rebuilding.

-d *drivename*

Delete drives or hosts from the named disk set. For a drive to be deleted, it must not be in use within the set. The last host cannot be deleted unless all of the drives within the set are deleted. Deleting the last host in a disk set destroys the disk set.

Specify a drive name in the form c*num*t*num*d*num*. Do not specify a slice number (s*num*). For drives in a Sun Cluster, you must specify a complete pathname for each drive. Such a name has the form:

/dev/did/[r]dsk/d*num*

This option fails on a multi-owner disk set if attempting to withdraw the master node while other nodes are in the set.

-f

Force one of three actions to occur: takes ownership of a disk set when used with -t; deletes the last disk drive from the disk set; or deletes the last host from the disk set. Deleting the last drive or host from a disk set requires the -d option.

When used to forcibly take ownership of the disk set, this causes the disk set to be grabbed whether or not another host owns the set. All of the disks within the set are taken over (reserved) and fail fast is enabled, causing the other host to panic if it had disk set ownership. The metadevice state database is read in by the host performing the take, and the shared metadevices contained in the set are accessible.

You can use this option to delete the last drive in the disk set, because this drive would implicitly contain the last state database replica.

You can use -f option to delete hosts from a set. When specified with a partial list of hosts, it can be used for one-host administration. One-host administration could be useful when a host is known to be non-functional, thus avoiding timeouts and failed commands. When specified with a complete list of hosts, the set is completely deleted. It is generally specified with a complete list of hosts to clean up after one-host administration has been performed.

-h *hostname...*

Specify one or more host names to be added to or deleted from a disk set. Adding the first host creates the set. The last host cannot be deleted unless all of the drives within the set have been deleted. The host name is not accepted if all of the drives within the set cannot be found on the specified host. The host name is the nodename established by the svc:/system/identity:node smf(5) service.

-j

Join a host to the owner list for a multi-owner disk set. The concepts of take and release, used with traditional disk sets, do not apply to multi-owner sets, because multiple owners are allowed.

As a host boots and is brought online, it must go through three configuration levels to be able to use a multi-owner disk set:

1. It must be included in the cluster nodelist, which happens automatically in a cluster or single-node sitatuion.

2. It must be added to the multi-owner disk set with the -a -h options documented elsewhere in this man page

3. It must join the set. When the host is first added to the set, it is automatically joined.

On manual restarts, the administrator must manually issue

metaset -s *multinodesetname* -j

to join the host to the owner list. After the cluster reconfiguration, when the host reenters the cluster, the node is automatically joined to the set. The metaset -j command joins the host to all multi-owner sets that the host has been added to. In a single node situation, joining the node to the disk set starts any necessary resynchronizations.

-L

When adding a disk to a disk set, force the disk to be repartitioned using the standard Solaris Volume Manager algorithm. See DESCRIPTION.

-l *length*

Set the size (in blocks) for the metadevice state database replica. The length can only be set when adding a new drive; it cannot be changed on an existing drive. The default (and maximum) size is 8192 blocks, which should be appropriate for most configurations. Replica sizes of less than 128 blocks are not recommended.

-M

Specify that the disk set to be created or modified is a multi-owner disk set that supports multiple concurrent owners.

This option is required when creating a multi-owner disk set. Its use is optional on all other operations on a multi-owner disk set and has no effect. Existing disk sets cannot be converted to multi-owner sets.

-o

Return an exit status of 0 if the local host or the host specified with the -h option is the owner of the disk set.

-P

Purge the named disk set from the node on which the metaset command is run. The disk set must not be owned by the node that runs this command. If the node does own the disk set, the command fails.

If you need to delete a disk set but cannot take ownership of the set, use the -P option.

-q

Displays an enumerated list of tags pertaining to "tagged data" that can be encountered during a take of the ownership of a disk set.

This option is not for use with a multi-owner disk set.

-r

Release ownership of a disk set. All of the disks within the set are released. The metadevices set up within the set are no longer accessible.

This option is not for use with a multi-owner disk set.

-s *setname*

Specify the name of a disk set on which metaset works. If no *setname* is specified, all disk sets are returned.

-t

Take ownership of a disk set safely. If metaset finds that another host owns the set, this host is not be allowed to take ownership of the set. If the set is not owned by any other host, all the disks within the set are owned by the host on which metaset was executed. The metadevice state database is read in, and the shared metadevices contained in the set become accessible. The -t option takes a disk set that has stale databases. When the databases are stale, metaset exits with code 66, and prints a message. At that point, the only operations permitted are the addition and deletion of replicas. Once the addition or deletion of the replicas has been completed, the disk set should be released and retaken to gain full access to the data.

This option is not for use with a multi-owner disk set.

-u *tagnumber*

Once a tag has been selected, a subsequent take with -u *tagnumber* can be executed to select the data associated with the given *tagnumber*.

w

Withdraws a host from the owner list for a multi-owner disk set. The concepts of take and release, used with traditional disk sets, do not apply to multi-owner sets, because multiple owners are allowed.

Instead of releasing a set, a host can issue

```
metaset -s multinodesetname -w
```

to withdraw from the owner list. A host automatically withdraws on a reboot, but can be manually withdrawn if it should not be able to use the set, but should be able to rejoin at a later time. A host that withdrew due to a reboot can still appear joined from other hosts in the set until a reconfiguration cycle occurs.

metaset -w withdraws from ownership of all multi-owner sets of which the host is a member. This option fails if you attempt to withdraw the master node while other nodes are in the disk set owner list. This option cancels all resyncs running on the node. A cluster reconfiguration process that is removing a node from the cluster membership list effectively withdraws the host from the ownership list.

-y

Execute a subsequent take. If the take operation encounters "tagged data," the take operation exits with code 2. You can then run the metaset command with the -q option to see an enumerated list of tags.

Examples EXAMPLE 1 Defining a Disk Set

This example defines a disk set.

```
# metaset -s relo-red -a -h red blue
```

The name of the disk set is relo-red. The names of the first and second hosts added to the set are red and blue, respectively. (The hostname is the nodename established by svc:/system/identity:node smf(5) service.) Adding the first host creates the disk set. A disk set can be created with just one host, with the second added later. The last host cannot be deleted until all of the drives within the set have been deleted.

EXAMPLE 2 Adding Drives to a Disk Set

This example adds drives to a disk set.

```
# metaset -s relo-red -a c2t0d0 c2t1d0 c2t2d0 c2t3d0 c2t4d0 c2t5d0
```

The name of the previously created disk set is relo-red. The names of the drives are c2t0d0, c2t1d0, c2t2d0, c2t3d0, c2t4d0, and c2t5d0. There is no slice identifier ("s*x*") at the end of the drive names.

EXAMPLE 3 Adding Multiple Mediator Hosts

The following command adds three mediator hosts to the specified disk set.

```
# metaset -s mydiskset -a -m myhost1,alias1 myhost2,alias2 myhost3,alias3
```

EXAMPLE 4 Purging a Disk Set from the Node

The following command purges the disk set relo-red from the node:

```
# metaset -s relo-red -P
```

EXAMPLE 5 Querying a Disk Set for Tagged Data

The following command queries the disk set relo-red for a list of the tagged data:

```
# metaset -s relo-red -q
```

This command produces the following results:

```
The following tag(s) were found:
 1 - vha-1000c - Fri Sep 20 17:20:08 2002
 2 - vha-1000c - Mon Sep 23 11:01:27 2002
```

EXAMPLE 6 Selecting a tag and taking a Disk set

The following command selects a tag and takes the disk set relo-red:

```
# metaset -s relo-red -t -u 2
```

EXAMPLE 7 Defining a Multi-Owner Disk Set

The following command defines a multi-owner disk set:

```
# metaset -s blue -M -a -h hahost1 hahost2
```

The name of the disk set is blue. The names of the first and second hosts added to the set are hahost1 and hahost2, respectively. The hostname is the nodename established by svc:/system/identity:node smf(5) service. Adding the first host creates the multi-owner disk set. A disk set can be created with just one host, with additional hosts added later. The last host cannot be deleted until all of the drives within the set have been deleted.

Files /etc/lvm/md.tab

Contains list of metadevice configurations.

Exit Status The following exit values are returned:

0

Successful completion.

>0

An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

Solaris Volume Manager Administration Guide

Notes Disk set administration, including the addition and deletion of hosts and drives, requires all hosts in the set to be accessible from the network.

Name metassist – automated volume creation utility to support Solaris Volume Manager

Synopsis metassist -V

metassist -?

metassist create [-v *n*] [-c] -F *config_file*

metassist create [-v *n*] [-c | -d] -F *request_file*

metassist create [-v *n*] [-c | -d] [-f] [-n *name*]
    [-p *datapaths*] [-r *redundancy*]
    [-a *available* [,*available*,...]]
    [-u *unavailable* [,*unavailable*,...]] -s *setname* -S *size*

metassist create -?

Description The metassist command provides assistance, through automation, with common Solaris Volume Manager tasks.

SUBCOMMANDS The following subcommands are supported:

create The create subcommand creates one or more Solaris Volume Manager volumes. You can specify this request on the command line or in a file specified on the command line.

If you create a volume using the command line, you can specify the characteristics of the volume in terms of the desired quality of service it will provide - its size, the number of redundant copies of the data it contains, the number of data paths by which it is accessible, and whether faulty components are replaced automatically. The diskset in which the volume will reside and the volume's size must be specified on the command line in this form of the command.

If you create a volume using a request in a file, you can specify the characteristics of the volume in terms of the quality of service they provide, as on the command line. Alternatively, the file can specify the types and component parts of the volume, (for example, mirrors, stripes, concatenations, and their component slices). The file may also specify volumes partly in terms of their types and partly in terms of their component parts, and may specify the characteristics of more than one volume. All volumes specified in a file must reside in the same diskset, whose name must be specified in the file.

If you specify the -c or -d option on the command line, the command runs without creating an actual volume or volumes. Instead, it outputs either a a Bourne shell command script (-c option) or a volume configuration (-d option). The command script, when run, creates the specified volume or volumes. The volume configuration specifies the volume or volumes in complete detail, naming all their components.

The input file given on the command line can take one of the following forms:

■ a volume request, which specifies a request for a volume with explicit attributes and components, or matching a given quality of service

■ a volume configuration, produced by a previous execution of the command

Options The following option is mandatory if you specify a volume request or volume configuration in a file:

-F *config_file* | *request_file* Specify the volume request or volume configuration file to process. If *config_file* or *request_file* is -, it is read from standard input.

The -d option cannot be specified when *inputfile* is a volume configuration file.

The following options are mandatory if you specify a volume request on the command line:

-s *set* Specify the disk set to use when creating volumes. All the volumes and hot spare pools are created in this disk set. If necessary, disks are moved into the diskset for use in the volumes and hot spare pools. If the diskset doesn't exist the command creates it. This option is required. metassist works entirely within a named disk set. Use of the local, or unnamed disk set, is not allowed.

-S *size* Specify the size of the volume to be created. The size argument consists of a numeric value (a decimal can be specified) followed by KB, MB, GB, or TB, indicating kilobytes, megabytes, gigabytes, or terabytes, respectively. Case is ignored when interpreting this option. This option is required.

The following options are optional command line parameters:

-a *device1*,*device2*,... Explicitly specify the devices that can be used in the creation of this volume. Named devices may be controllers or disks. Only used when specifying a volume on the command line.

-c Output the command script that would implement the specified or generated volume configuration. The command script is not run, and processing stops at this stage.

-d Output the volume configuration that satisfies the specified or generated volume request. No command script is generated or executed, and processing stops at this stage.

-f Specify whether the volume should support automatic component replacement after a fault. If this option is specified, a mirror is created and its submirrors are associated with a hot spare.

-n *name* Specify the name of the new volume. See metainit(1M) for naming guidelines.

-p *n*	Specify the number of required paths to the storage volume. The value of *n* cannot be greater than the number of different physical paths and logical paths to attached storage. Only used when specifying a volume on the command line.
-r *n*	Specify the redundancy level (0-4) of the data. The default is 0. Only used when specifying a volume on the command line. If redundancy is 0, a stripe is created. If redundancy is 1 or greater, a mirror with this number of submirrors is created. In this case, the volume can suffer a disk failure on *n*-1 copies without data loss. With the use of hot spares (see the -f option), a volume can suffer a disk failure on *n*+hsps-1 volumes without data loss, assuming non-concurrent failures.
-u *device1*,*device2*,...	Explicitly specify devices to exclude in the creation of this volume. Named devices can be controllers or disks. You can use this option alone, or to exclude some of the devices listed as available with the -a option, Only used when specifying a volume on the command line.
-v *value*	Specify the level of verbosity. Values from 0 to 2 are available, with higher numbers specifying more verbose output when the command is run. -v 0 indicates silent output, except for errors or other critical messages. The default level is 1.
-V	Display program version information.
-?	Display help information. This option can follow a subcommand for subcommand-specific help.

Examples

EXAMPLE 1 Creating a Mirror

The following example creates a two-way, 36Gb mirror on available devices from controller 1 and controller 2. It places the volume in diskset mirrorset.

```
# metassist create -r 2 -a c1,c2 -s mirrorset -S 36GB
```

EXAMPLE 2 Creating a Mirror with Additional Fault Tolerance

The following example creates a two-way, 36Gb mirror on available devices from controller 1 and controller 2. It provides additional fault tolerance in the form of a hot spare. It places the volume in diskset mirrorset.

```
# metassist create -f -r 2 -a c1,c2 -s mirrorset -S 36GB
```

EXAMPLE 3 Creating a Three-way Mirror and Excluding Devices

The following example creates a three-way, 180Gb mirror from storage devices on controller 1 or controller 2. It excludes the disks c1t2d0 and c2t2d1 from the volume. It places the volume in diskset mirrorset.

```
metassist create -r 3 -a c1,c2 -u c1t2d0, c2t2d1 \
    -s mirrorset -S 180GB
```

EXAMPLE 4 Determining and Implementing a Configuration

The following example determines and implements a configuration satisfying the request specified in a request file:

```
# metassist create -F request.xml
```

EXAMPLE 5 Determining a Configuration and Saving It in a volume-config File

The following example determines a configuration which satisfies the given request. It saves the configuration in a volume-config file without implementing it:

```
# metassist create -d -F request.xml > volume-config
```

EXAMPLE 6 Determining a Configuration and Saving It in a Shell Script

The following example determines a configuration which satisfies the given request. It saves the configuration in a shell script without implementing it:

```
# metassist create -c -F request.xml > setupvols.sh
```

EXAMPLE 7 Implementing the Given volume-config

The following example implements the given volume-config:

```
# metassist create -F config.xml
```

EXAMPLE 8 Converting the Given volume-config to a Shell Script

The following example converts the given volume-config to a shell script that you can run later:

```
# metassist create -c -F config.xml > setupvols.sh
```

Exit Status The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Files ■ /usr/share/lib/xml/dtd/volume-request.dtd
■ /usr/share/lib/xml/dtd/volume-defaults.dtd
■ /usr/share/lib/xml/dtd/volume-config.dtd

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm
Interface Stability	Committed

See Also mdmonitord(1M), metaclear(1M), metadb(1M), metadetach(1M), metahs(1M), metainit(1M), metaoffline(1M), metaonline(1M), metaparam(1M), metarecover(1M), metarename(1M), metareplace(1M), metaset(1M), metastat(1M), metasync(1M), metattach(1M), md.tab(4), md.cf(4), mddb.cf(4), md.tab(4), volume-config(4), volume-request(4), attributes(5), md(7D)

Notes The quality of service arguments are mutually exclusive with the -F *inputfile* argument.

When specifying a request file or quality of service arguments on the command line, the /etc/default/metassist.xml file is read for global and per-disk set defaults.

Characteristics of this file are specified in the DTD, in /usr/share/lib/xml/dtd/volume-defaults.dtd.

Characteristics of the XML request file are specified in the DTD, in /usr/share/lib/xml/dtd/volume-request.dtd.

Characteristics of the XML configuration file are specified in the DTD, in /usr/share/lib/xml/dtd/volume-config.dtd.

This command must be run as root.

This command requires a functional Solaris Volume Manager configuration before it runs.

Name metastat – display status for metadevice or hot spare pool

Synopsis /usr/sbin/metastat -h

/usr/sbin/metastat [-a] [-B] [-D] [-c] [-i] [-p] [-q]
     [-s *setname*] [-t] [*metadevice...*] [*hot_spare_pool*...]

/usr/sbin/metastat [-a] [-B] [-D] [-c] [-i] [-p] [-q]
     [-s *setname*] *component*...

Description The metastat command displays the current status for each metadevice (including stripes, concatenations, concatenations of stripes, mirrors, RAID5, soft partitions, and trans devices) or hot spare pool, or of specified metadevices, components, or hot spare pools.

It is helpful to run the metastat command after using the metattach command to view the status of the metadevice.

metastat displays the state of each Solaris Volume Manager RAID-1 volume on the system. The possible states include:

Okay   The device reports no errors.

Needs maintenance   A problem has been detected. This requires that the system administrator replace the failed physical device. Volumes displaying Needs maintenance have incurred no data loss, although additional failures could risk data loss. Take action as quickly as possible.

Last erred   A problem has been detected. Data loss is a possibility. This might occur if a component of a submirror fails and is not replaced by a hot spare, therefore going into Needs maintenance state. If the corresponding component also fails, it would go into Last erred state and, as there is no remaining valid data source, data loss could be a possibility.

Unavailable   A device cannot be accessed, but has not incurred errors. This might occur if a physical device has been removed with Solaris Dynamic Reconfiguration (DR) features, thus leaving the Solaris Volume Manager volume unavailable. It could also occur if an array or disk is powered off at system initialization, or if a >1TB volume is present when the system is booted in 32-bit mode.

                    After the storage has been made available, run the metastat command with the -i option to update the status of the metadevices. This clears the unavailable state for accessible devices.

See the *Solaris Volume Manager Administration Guide* for instructions on replacing disks and handling volumes in Needs maintenance or Last erred states.

Options   The following options are supported:

-a   Display all disk sets. Only metadevices in disk sets that are owned by the
              current host are displayed.

-B   Display the current status of all of the 64-bit metadevices and hot spares.

-c   Display concise output.

              There is one line of output for each metadevice. The output shows the basic
              structure and the error status, if any, for each metadevice.

              The -c output format is distinct from the -p output format. The -p option
              does not display metadevice status and is not intended as human-readable
              output.

-D   Display the current status of all of the descriptive name metadevices and
              hotspares.

-h   Display usage message.

-i   Check the status of RAID-1 (mirror) volumes, RAID-5 volumes, and hot
              spares. The inquiry checks each metadevice for accessibility, starting at the top
              level metadevice. When problems are discovered, the metadevice state
              databases are updated as if an error had occurred.

-p   Display the list of active metadevices and hot spare pools in the same format as
              md.tab. See md.tab(4).

              The -p output is designed for snapshotting the configuration for later recovery
              or setup.

-q   Display the status for metadevices without the device relocation information.

-s *setname* Specify the name of the disk set on which metastat works. Using the -s option
              causes the command to perform its administrative function within the
              specified disk set. Without this option, the command performs its function on
              metadevices and hot spare pools in the local disk set.

-t   Display the current status and timestamp for the specified metadevices and
              hot spare pools. The timestamp provides the date and time of the last state
              change.

Operands   The following operands are supported:

component   Display the status of the component hosting a soft partition, including
                   extents, starting blocks, and block count.

hot_spare_pool   Display the status of the specified hot spare pool(s).

       metadevice   Display the status of the specified metadevice(s). If a trans metadevice is specified, the status of the master and log devices is also displayed. Trans metadevices have been replaced by UFS logging. See NOTES.

Examples   **EXAMPLE 1**   Output Showing Mirror with Two Submirrors

The following example shows the partial output of the metastat command after creating a mirror, opt_mirror, consisting of two submirrors, opt_sub1 and opt_sub2.

```
# metastat opt_mirror
opt_mirror: Mirror
    Submirror 0: opt_sub1
      State: Okay
    Submirror 1: opt_sub2
      State: Resyncing
    Resync in progress: 15 % done
    Pass: 1
    Read option: roundrobin (default)
    Write option: parallel (default)
    Size: 2006130 blocks
    .
    .
    .
```

EXAMPLE 2   Soft Partition on Mirror with Submirror

The following example shows the partial output of the metastat command after creating a soft partition, d3, on concat d2, which is built on a soft partition.

```
# metastat
d2: Concat/Stripe
    Size: 204800 blocks
    Stripe 0:
        Device              Start Block  Dbase State        Hot Spare
        d0                      0        No    Okay

d0: Soft Partition
    Component: c0t3d0s0
    Status: Okay
    Size: 204800 blocks
        Extent              Start Block  Block count
            0                   129         204800

d3: Soft Partition
    Component: d2
    Status: Okay
    Size: 202752 blocks
        Extent              Start Block  Block count
            0                   129         202752
```

EXAMPLE 3   Trans Metadevice

The following example shows the output of the metastat command after creating a trans metadevice.

```
# metastat
d2: Concat/Stripe
    Size: 204800 blocks
    Stripe 0:
        Device              Start Block  Dbase State        Hot Spare
        d0                          0     No   Okay

d0: Soft Partition
    Component: c0t3d0s0
    Status: Okay
    Size: 204800 blocks
        Extent            Start Block  Block count
            0                   129       204800

d3: Soft Partition
    Component: d2
    Status: Okay
    Size: 202752 blocks
        Extent            Start Block  Block count
            0                   129       202752
```

EXAMPLE 4   Multi-owner disk set

The following example shows the output of the metastat command with a multi-owner disk set and application-based mirror resynchronization option. Application-based resynchronization is set automatically if needed.

```
# metastat -s oban
oban/d100: Mirror
    Submirror 0: oban/d10
      State: Okay
    Submirror 1: oban/d11
      State: Okay
    Pass: 1
    Read option: roundrobin (default)
    Write option: parallel (default)
    Resync option: application based
    Owner: None
    Size: 1027216 blocks (501 MB)

oban/d10: Submirror of oban/d100
    State: Okay
    Size: 1027216 blocks (501 MB)
    Stripe 0:
```

EXAMPLE 4 Multi-owner disk set *(Continued)*

```
        Device     Start Block  Dbase     State Reloc Hot Spare
        c1t3d0s0         0       No        Okay

oban/d11: Submirror of oban/d100
   State: Okay
   Size: 1027216 blocks (501 MB)
   Stripe 0:
        Device     Start Block  Dbase     State Reloc Hot Spare
        c1t4d0s0         0       No        Okay
```

Warnings metastat displays states as of the time the command is entered. It is unwise to use the output of the metastat -p command to create a md.tab(4) file for a number of reasons:

- The output of metastat -p might show hot spares being used.

- It might show mirrors with multiple submirrors. See metainit(1M) for instructions for creating multi-way mirrors using metainit and metattach.

- A slice may go into an error state after metastat -p is issued.

Exit Status The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm
Interface Stability	Committed

See Also mdmonitord(1M), metaclear(1M), metadb(1M), metadetach(1M), metahs(1M), metainit(1M), metaoffline(1M), metaonline(1M), metaparam(1M), metarecover(1M), metarename(1M), metareplace(1M), metaset(1M), metassist(1M), metasync(1M), metattach(1M), md.tab(4), md.cf(4), mddb.cf(4), md.tab(4), attributes(5), md(7D)

Solaris Volume Manager Administration Guide

Notes Trans metadevices have been replaced by UFS logging. Existing trans devices are *not* logging--they pass data directly through to the underlying device. See mount_ufs(1M) for more information about UFS logging.

Name metasync – handle metadevice resync during reboot

Synopsis `/usr/sbin/metasync -h`

`/usr/sbin/metasync [-s` *setname*`] [`*buffer_size*`]` *metadevice*

`/usr/sbin/metasync [-s` *setname*`] -r [`*buffer_size*`]`

`/usr/sbin/metasync -p` *metadevice*

`/usr/sbin/metasync -c` *metadevice*

Description The `metasync` command starts a resync operation on the specified *metadevice*. All components that need to be resynced are resynced. If the system crashes during a RAID5 initialization, or during a RAID5 resync, either an initialization or resync restarts when the system reboots.

Applications are free to access a metadevice at the same time that it is being resynced by `metasync`. Also, `metasync` performs the copy operations from inside the kernel, which makes the utility more efficient.

Use the `-r` option in boot scripts to resync all possible submirrors.

Options The following options are supported:

`-c` *metadevice*	Cancels the resync that is in progress on the specified metadevice. The resync will be stopped at its current point and can be resumed by running the "`metasync metadevice`" command. This option only applies to RAID1 volumes.
`-h`	Displays usage message.
`-p` *metadevice*	Regenerates parity information for RAID5 metadevices.
`-s` *setname*	Specifies the name of the diskset on which `metasync` will work. Using the `-s` option will cause the command to perform its administrative function within the specified diskset. Without this option, the command will perform its function on local metadevices.
`-r`	Specifies that the `metasync` command handle special resync requirements during a system reboot. `metasync -r` should only be invoked from the `svc:/system/mdmonitor` service. The `metasync` command only resyncs those metadevices that need to be resynced. `metasync` schedules all the mirror resyncs according to their pass numbers.

To override the default buffer_size value used by the `svc:/system/mdmonitor` service, you can edit `/etc/system` to specify:

`set md_mirror:md_resync_bufsz = 2048`

so that resyncs occur as quickly as possible.

Operands   *buffer_size*   Specifies the size (number of 512-byte disk blocks) of the internal copy buffer for the mirror resync. The size defaults to 1024 512-byte disk blocks. It can be no more than 2048 blocks. For best performance (quickest completion of the resync), 2048 blocks is the recommended size.

Exit Status   The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm

See Also   mdmonitord(1M), metaclear(1M), metadb(1M), metadetach(1M), metahs(1M), metainit(1M), metaoffline(1M), metaonline(1M), metaparam(1M), metarecover(1M), metarename(1M), metareplace(1M), metaset(1M), metassist(1M), metastat(1M), metattach(1M), md.tab(4), md.cf(4), mddb.cf(4), md.tab(4), attributes(5), md(7D)

Solaris Volume Manager Administration Guide

Notes   The metasync service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/mdmonitor

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name   metattach, metadetach – attach or detach a metadevice

Synopsis   /usr/sbin/metattach [-h]

/usr/sbin/metattach [-s *setname*] *mirror* [*metadevice*]

/usr/sbin/metattach [-s *setname*] [-i *interlace*] *concat/stripe component...*

/usr/sbin/metattach [-s *setname*] *RAID component...*

/usr/sbin/metattach [-s *setname*] [-A *alignment*] *softpart size* | *all*

/usr/sbin/metadetach [-s *setname*] [-f] *mirror submirror*

/usr/sbin/metadetach [-s *setname*] [-f] *trans*

Description   metattach adds submirrors to a mirror, grows metadevices, or grows soft partitions. Growing metadevices can be done without interrupting service. To grow the size of a mirror or trans, the slices must be added to the submirrors or to the master devices.

Solaris Volume Manager supports storage devices and logical volumes greater than 1 terabyte (TB) when a system runs a 64-bit Solaris kernel. Support for large volumes is automatic. If a device greater than 1 TB is created, Solaris Volume Manager configures it appropriately and without user intervention.

If a system with large volumes is rebooted under a 32–bit Solaris kernel, the large volumes are visible through metastat output. Large volumes cannot be accessed, modified or deleted, and no new large volumes can be created. Any volumes or file systems on a large volume in this situation are also unavailable. If a system with large volumes is rebooted under a version of Solaris prior to the Solaris 9 4/03 release, Solaris Volume Manager does not start. You must remove all large volumes before Solaris Volume Manager runs under an earlier version of the Solaris Operating System.

Solaris Volume Manager supports one-to-four-way mirrors. You can only attach a metadevice to a mirror if there are three or fewer submirrors beneath the mirror. Once a new metadevice is attached to a mirror, metattach automatically starts a resync operation to the new submirror.

metadetach detaches submirrors from mirrors and logging devices from trans metadevices.

When a submirror is detached from a mirror, it is no longer part of the mirror, thus reads and writes to and from that metadevice by way of the mirror are no longer performed through the mirror. Detaching the only existing submirror is not allowed. Detaching a submirror that has slices reported as needing maintenance (by metastat) is not allowed unless the -f (force) flag is used.

metadetach also detaches the logging device from a trans. This step is necessary before you can clear the trans volume. Trans metadevices have been replaced by UFS logging. Existing trans devices are not logging. They pass data directly through to the underlying device. See mount_ufs(1M) for more information about UFS logging.

Detaching the logging device from a busy trans device is not allowed unless the -f (force) flag is used. Even so, the logging device is not actually detached until the trans is idle. The trans is in the *Detaching* state (metastat) until the logging device is detached.

Options Root privileges are required for all of the following options except -h.

The following options are supported:

-A *alignment*   Set the value of the soft partition extent alignment. Use this option when it is important specify a starting offset for the soft partition. It preserves the data alignment between the metadevice address space and the address space of the underlying physical device.

For example, a hardware device that does checksumming should not have its I/O requests divided by Solaris Volume Manager. In this case, use a value from the hardware configuration as the value for the alignment. When using this option in conjunction with a software I/O load, the alignment value corresponds to the I/O load of the application. This prevents I/O from being divided unnecessarily and affecting performance.

-f   Force the detaching of metadevices that have components that need maintenance or are busy. You can use this option only when a mirror is in a maintenance state that can be fixed with metareplace(1M). If the mirror is in a maintenance state that can only be fixed with metasync(1M) (as shown by the output of metastat(1M)), metadetach -f has no effect, because the mirrors must be resynchronized before one of them can be detached.

-h   Display a usage message.

-i *interlace*   Specify the interlace value for stripes, where size is a specified value followed by either k for kilobytes, m for megabytes, or b for blocks. The units can be either uppercase or lowercase. If *size* is not specified, the size defaults to the interlace size of the last stripe of the metadevice. When an interlace size change is made on a stripe, it is carried forward on all stripes that follow.

-s *setname*   Specify the name of the diskset on which the metattach command or the metadetach command works.. Using the -s option causes the command to perform its administrative function within the specified diskset. Without this option, the command performs its function on local metadevices.

Operands The following operands are supported:

component   The logical name for the physical slice (partition) on a disk drive, such as /dev/dsk/c0t0d0s2, being added to the concatenation, stripe, concatenation of stripes, or RAID5 metadevice.

concat/stripe   The metadevice name of the concatenation, stripe, or concatenation of stripes.

log	The metadevice name of the logging device to be attached to the trans metadevice.
metadevice	The metadevice name to be attached to the mirror as a submirror. This metadevice must have been previously created by the metainit command.
mirror	The name of the mirror.
RAID	The metadevice name of the RAID5 metadevice.
size | *all*	The amount of space to add to the soft partition in K or k for kilobytes, M or m for megabytes, G or g for gigabytes, T or t for terabytes, and B or b for blocks (sectors). All values represent powers of 2, and upper and lower case options are equivalent. Only integer values are permitted. The literal all specifies that the soft partition should grow to occupy all available space on the underlying volume.
softpart	The metadevice name of the existing soft partition.
submirror	The metadevice name of the submirror to be detached from the mirror.
trans	The metadevice name of the trans metadevice (not the master or logging device).

Examples EXAMPLE 1 Concatenating a New Slice to a Metadevice

This example concatenates a single new slice to an existing metadevice, Volume.1. Afterwards, you would use the growfs(1M) command to expand the file system.

```
# metattach Volume.1 /dev/dsk/c0t1d0s2
```

EXAMPLE 2 Detaching Logging Device from Trans Metadevice

This example detaches the logging device from a trans metadevice d9. Notice that you do not have to specify the logging device itself, as there can only be one.

```
# metadetach d9
```

EXAMPLE 3 Expanding a RAID5 Metadevice

This example expands a RAID5 metadevice, d45, by attaching another slice.

```
# metattach d45 /dev/dsk/c3t0d0s2
```

When you add additional slices to a RAID5 metadevice, the additional space is devoted to data. No new parity blocks are allocated. The data on the added slices is, however, included in the overall parity calculations, so it is protected against single-device failure.

EXAMPLE 4 Expanding a Soft Partition

The following example expands a soft partition, d42, attaching all space available on the underlying device.

EXAMPLE 4 Expanding a Soft Partition   *(Continued)*

```
# metattach d42 all
```

When you add additional space to a soft partition, the additional space is taken from any available space on the slice and might not be contiguous with the existing soft partition.

EXAMPLE 5 Adding Space to Two-Way Mirror

This example adds space to a two-way mirror by adding a slice to each submirror. Afterwards, you would use the growfs(1M) command to expand the file system.

```
# metattach d9 /dev/dsk/c0t2d0s5
# metattach d10 /dev/dsk/c0t3d0s5
```

This example tells the mirror to grow to the size of the underlying devices

```
# metattach d11
```

This example increases the size of the UFS on the device so the space can be used.

```
# growfs -M /export /dev/md/rdsk/d11
```

EXAMPLE 6 Detaching a Submirror from a Mirror

This example detaches a submirror, d2, from a mirror, d4.

```
# metadetach d4 d2
```

EXAMPLE 7 Adding Four Slices to Metadevice

This example adds four slices to an existing metadevice, d9. Afterwards, you would use the growfs(1M) command to expand the file system.

```
# metattach d9 /dev/dsk/c0t1d0s2 /dev/dsk/c0t2d0s2 \\
    /dev/dsk/c0t3d0s2 /dev/dsk/c0t4d0s2
```

EXAMPLE 8 Setting the Value of the Soft Partition Extent Alignment

This example shows how to set the alignment of the soft partition to 1mb when the soft partition is expanded.

```
# metattach -s red -A 2m d13 1m
```

Exit Status   The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Solaris Volume Manager Administration Guide

Warnings   This section provides information regarding warnings for devices greater than 1 TB and for multi-way mirrors.

Devices and Volumes Greater Than 1 TB   Do not create large (>1 TB) volumes if you expect to run the Solaris Operating System with a 32-bit kernel or if you expect to use a version of the Solaris Operating System prior to Solaris 9 4/03.

Multi-Way Mirrors   When a submirror is detached from its mirror, the data on the metadevice might not be the same as the data that existed on the mirror prior to running metadetach. In particular, if the -f option was needed, the metadevice and mirror probably do not contain the same data.

Notes   Trans metadevices have been replaced by UFS logging. Existing trans devices are *not* logging. They pass data directly through to the underlying device. See mount_ufs(1M) for more information about UFS logging.

Name mib2mof – generate MOF file(s) from input SNMP MIB file(s)

Synopsis /usr/sadm/bin/mib2mof [-n] [-d *directory*] [-q] [-c] [-a]
           [-h] *files*

Description The mib2mof utility reads input Management Information Base (MIB) files and produces one or more Managed Object Format (MOF) files. MOF files contain a Common Information Model (CIM) class declaration that represents the MIB for the Solaris Simple Network Management Protocol (SNMP) provider. The SNMP provider allows Web-Based Enterprise Management (WBEM) applications to access SNMP device information.

SNMP scalar variables map to properties in the CIM class. Qualifiers on each property convey the following MIB information for each scalar variable:

- syntax
- read/write access
- OID (Object IDentifier)
- description (optional)
- index (if the variable is within a group [sequence] that defines a row)

The syntax of an SNMP scalar variable is represented in a CIM class by the property's CIM datatype. All properties are marked with write access (true or false).

The following table shows how a Solaris SNMP datatype in a MIB maps to a Web-Based Enterprise Management (WBEM) CIM datatype and then to an SNMP datatype used by the WBEM SNMP API:

SNMP SMI Datatype	SNMP Ver.	CIM Datatype	SNMP API Object type
INTEGER	v1	sint32	SnmpInt
OCTET STRING	v1	string	SnmpString
OBJECT IDENTIFIER	v1	string	SnmpOid
IpAddress	v1	string	SnmpIpAddress
Counter	v1	uint32	SnmpCounter
Gauge	v1	uint32	SnmpGauge
TimeTicks	v1	uint32	SnmpTimeticks
Opaque	v1	sint8[]	SnmpOpaque
DisplayString - see OCTET STRING	v1		
NetworkAddress - see IpAddress	v1		
Counter32 - see Counter	v2		
Counter64	v2	uint64	SnmpCounter64
Integer32	v2	sint32	SnmpInt
Gauge32 - see Gauge	v2		
Unsigned32	v2	uint32	SnmpGauge
TruthValue	v2	sint32	SnmpInt
BITS - see OCTET STRING	v2		

The mib2mof utility includes its required Solaris_SNMPmib_core.txt file (containing core MIB definitions), installed in /usr/sadm/mof. The mib2mof utility looks first for mib core file in local directory. If this file is not found in the local directory, mib2mof looks in /usr/sadm/mof.

A MOF file is generated for each SNMP group and table row sequence (that is, the columns in one row) found in the supplied MIBs. (This does not include the core MIB definitions contained in the Solaris_SNMPmib_core.txt file.)

There is no MOF file or property for an SNMP table - all table access is through the rows and columns of the table, and the SNMP variable for the table is marked as inaccessible in the MIB.

The MOF file created contains a CIM class that represents an SNMP group or row and a CIM class to represent a CIM association. The output file name (and CIM class) is of the format <SNMP_><MIB name><Group name>.mof.

Options The following options are supported:

-a	Generate MOF files for all of the input MIB files. If -a is not given, a MOF file is generated only for the last file of the input list.
-c	Do not use the default Solaris_SNMPmib_core.txt definitions file shipped with the Solaris SNMP Provider for WBEM. If this option is specified, you must specify another MIB_CORE definitions file as one of the input files.
-d *directory*	Generate output MOF files in the specified directory.
-h	Show how to invoke mib2mof and list its arguments.
-n	Parse the input MIB files without generating any output.
-q	Include the DESCRIPTION clause of SNMP OBJECT-TYPE as a qualifier in the generated MOF file.

Operands The following operands are supported:

files   List of SNMP MIB files to be converted.

Exit Status The mib2mof utility terminates with exit status 0.

Name mibiisa – Sun SNMP Agent

Synopsis mibiisa [-ar] [-c *config-dir*] [-d *debug-level*] [-p *port*]
          [-t *cache-timer*]

Description The mibiisa utility is an RFC 1157-compliant SNMP agent. It supports MIB-II as defined in
RFC 1213, with Sun extensions under Sun's enterprise number. The MIB (Management
Information Base) is both readable and writable. The mibiisa utility supports all SNMP
protocol operations including GET-REQUEST, GETNEXT-REQUEST, SET-REQUEST,
GET-REPLY, and TRAP.

The SMA (Systems Management Agent) is the default SNMP agent in Solaris. MIB-II
subagent mibiisa does not run by default. To enable mibiisa, rename the configuration file
from /etc/snmp/conf/mibiisa.rsrc- to /etc/snmp/conf/mibiisa.rsrc. SMA has the
capability to handle any MIB-II requests.

The mibiisa utility supports the coldStart, linkUp, linkDown, and authentication traps. The
authentication trap may be disabled by a command-line switch, which itself may be
overridden by a management station writing to a MIB variable in the standard SNMP MIB
group.

The mibiisa utility supports four distinct views of the MIB. The view used for any request is
determined by the community string contained in that request.

To enhance security, mibiisa supports an option to block all writes to the MIB. You can also
limit the set of management stations from which the agent will accept requests in the
configuration file used when starting the mibiisa. See the Security section for more
information.

Unless overridden, mibiisa uses UDP port 161, the standard SNMP port. The mibiisa utility
issues traps through the same port on which it receives SNMP requests.

The mibiisa utility must run with super-user privileges and is typically started at system
startup via /etc/rc3.d. mibiisa may not be started using inetd(1M). When started, mibiisa
detaches itself from the keyboard, disables all signals except SIGKILL, SIGILL, SIGUSR1, and
SIGUSR2, and places itself in the background.

Options The following options are supported by mibiisa:

-a   Disable the generation of authentication traps. However, an SNMP
                manager may write a value into snmpEnableAuthenTraps to enable or
                disable authentication traps.

-c *config-dir*   Specify a directory where it expects snmpd.conf file, on startup. The default
                directory is /etc/snmp/conf.

-d *debug-level* Debug. A value of 0 disables all debug and is the default. Levels 1 through 3
                represent increasing levels of debug output. When mibiisa receives the

signal SIGUSR1, it resets the debug-level to 0. When `mibiisa` receives the
signal SIGUSR2, it increments the debug-level by one.

Debug output is sent to the standard output in effect at the time `mibiisa` is
started. No matter what debug level is in effect, certain significant events are
logged in the system log.

`-p` *port*	Define an alternative UDP port on which `mibiisa` listens for incoming requests. The default is UDP port 161.
`-r`	Place the MIB into read-only mode.
`-t` *cache-timer*	By default, information fetched from the kernel is considered to be valid for 45 seconds from the time it is retrieved. This cache lifetime may be altered with this parameter. You cannot set *cache-timer* to any value less than 1.

Configuration File The `snmpd.conf` file is used for configuration information. Each entry in the file consists of a keyword followed by a parameter string. The keyword must begin in the first position. Parameters are separated from the keyword and from one another by white space. Case in keywords is ignored. Each entry must be contained on a single line. All text following (and including) a pound sign (#) is ignored. Keywords currently supported are:

`sysdescr`	The value to be used to answer queries for sysDescr.
`syscontact`	The value to be used to answer queries for sysContact.
`syslocation`	The value to be used to answer queries for sysLocation.
`trap`	The parameter names one or more hosts to receive traps. Only five hosts may be listed.
`system-group-read-community`	The community name to get read access to the system group and Sun's extended system group.
`system-group-write-community`	The community name to get write access to the system group and Sun's extended system group.
`read-community`	The community name to get read access to the entire MIB.
`write-community`	The community name to get write access to the entire MIB (implies read access).
`trap-community`	The community name to be used in traps.
`kernel-file`	The name of the file to use for kernel symbols.
`managers`	The names of hosts that may send SNMP queries. Only five hosts may be listed on any one line. This keyword may be repeated for a total of 32 hosts.

newdevice

The additional devices which are not built in SNMPD. The format is as follows: *newdevice* type *speed name* where *newdevice* is the keyword, type is an integer which has to match your schema file, *speed* is the new device's speed, and *name* is this new device's name.

An example snmpd.conf file is shown below:

```
sysdescr        Sun SNMP Agent, Sun Fire 4800, Company
                   Property Number 123456
syscontact      Cliff Claven
sysLocation     Room 1515, building 1
#
system-group-read-community     public
system-group-write-community    private
#
read-community  all_public
write-community all_private
#
trap            localhost
trap-community  SNMP-trap
#
#kernel-file    /vmunix
#
managers        lvs golden
managers        swap
```

Installation   The mibiisa utility and its configuration file, snmpd.conf, may be placed in any directory. However for Solaris 2.4 and subseqent releases, use /usr/lib/snmp for mibiisa itself and /etc/snmp/conf for the configuration file. You can modify the configuration file as appropriate. If you make any changes to snmpd.conf file keyword values, you must kill and restart mibiisa for the changes to take effect.

Your /etc/services file (or NIS equivalent) should contain the following entries:

snmp	161/udp		# Simple Network Mgmt Protocol
snmp-trap	162/udp	snmptrap	# SNMP trap (event) messages

The following is an example for Solaris 2.*x* and releases compatible with Solaris 2.*x*, such as Solaris 9:

```
#
# Start the SNMP agent
#
```

```
                if [ -f /etc/snmp/conf/snmpd.conf -a -x
                   /usr/lib/snmp/mibiisa ];
                then
                /opt/SUNWconn/snm/agents/snmpd
                echo 'Starting SNMP-agent.'
```

Security   SNMP, as presently defined, offers relatively little security. The mibiisa utility accepts requests from other machines, which can have the effect of disabling the network capabilities of your computer. To limit the risk, the configuration file lets you specify a list of up to 32 manager stations from which mibiisa will accept requests. If you do not specify any such manager stations, mibiisa accepts requests from anywhere.

The mibiisa utility also allows you to mark the MIB as "read-only" by using the -r option.

mibiisa supports four different community strings. These strings, however, are visible in the configuration file and within the SNMP packets as they flow on the network.

The configuration file should be owned by, and readable only by super-user. In other words the mode should be:

```
−rw−−−−−−−  1 root          2090 Oct 17 15:04 /etc/snmp/conf/snmpd.conf
```

Managers can be restricted based on the community strings. This can be configured by creating an optional secondary configuration file /etc/snmp/conf/mibiisa.acl. To enable such a restriction, add the security line in the /etc/snmp/conf/mibiisa.rsrc file.

An example mibiisa.acl file is as follows:

```
acl = {
        {
                communities = public
                access = read-only
                managers = xyz
        }
        {
                communities = private
                access = read-write
                managers = abc,pqrs
        }
}
```

An example mibiisa.rsrc file is as follows:

```
resource =
{
        {
                registration_file = "/etc/snmp/conf/mibiisa.reg"
                security = "/etc/snmp/conf/mibiisa.acl"
                policy = "spawn"
                type = "legacy"
```

```
                          command = "/usr/lib/snmp/mibiisa -r -p $PORT"
              }
       }
```

Mib   This section discusses some of the differences between the mibiisa MIB and the standard MIB-II (as defined in RFC 1213).

The following variables are read-only in the mibiisa MIB:

```
sysName
atIfIndex
ipDefaultTTL
```

These variables are read-write in the standard MIB-II.

The mibiisa MIB Address Translation tables support limited write access: only atPhysAddress may be written, either to change the physical address of an existing entry or to delete an entire ARP table entry.

The mibiisa MIB IP Net to Media table supports limited write access: only ipNetToMediaPhysAddress and ipNetToMediaType may be written, either to change the physical address of an existing entry or to delete an entire ARP table entry.

The following variables are read-write in the mibiisa MIB; however, these variables have fixed values. Any new values "set" to them are accepted, but have no effect:

```
ipRoutIfIndex
ipRouteMetric1
ipRouteMetric2
ipRouteMetric3
ipRouteMetric4
ipRouteType
ipRouteAge
ipRouteMask
ipRouteMetric5
```

The following mibiisa MIB variable reflects the actual state of the related table entry. "Sets" are accepted but have no effect:

```
tcpConnState
```

The following mibiisa MIB variables are readable, but return a fixed value:

icmpInDestUnreachs	Returns 1
icmpInTimeExcds	Returns 1
icmpInParmProbs	Returns 1
icmpInSrcQuenchs	Returns 1

`icmpInRedirects`	Returns 1
`icmpInEchos`	Returns 1
`icmpInEchoReps`	Returns 1
`icmpInTimestamps`	Returns 1
`icmpInTimestampReps`	Returns 1
`icmpInAddrMasks`	Returns 1
`icmpInAddrMaskReps`	Returns 1
`icmpOutDestUnreachs`	Returns 1
`icmpOutTimeExcds`	Returns 1
`icmpOutParmProbs`	Returns 1
`icmpOutSrcQuenchs`	Returns 1
`icmpOutRedirects`	Returns 1
`icmpOutEchos`	Returns 1
`icmpOutEchoReps`	Returns 1
`icmpOutTimestamps`	Returns 1
`icmpOutTimestampReps`	Returns 1
`icmpOutAddrMasks`	Returns 1
`icmpOutAddrMaskReps`	Returns 1
`ifInUnknownProtos`	Returns 0
`ipAdEntBcastAddr`	Returns 1
`ipAdEntReasmMaxSiz`	Returns 65535
`ipRouteMetric1`	Returns -1
`ipRouteMetric2`	Returns -1
`ipRouteMetric3`	Returns -1
`ipRouteMetric4`	Returns -1
`ipRouteAge`	Returns 0
`ipRouteMetric5`	Returns -1
`ipNetToMediaType`	Returns (3) dynamic
`ipRoutingDiscards`	Returns 0

The following variables return a fixed value of 0 for drivers not conforming to the GLD framework (see gld(7D)), including the old LAN drivers on SPARC machines:

ifInOctets	Returns 0
ifInNUcastPkts	Returns 0
ifInDiscards	Returns 0
ifOutOctets	Returns 0
ifOutNUcastPkts	Returns 0
ifOutDiscards	Returns 0

Schema Attributes   The following describes the attributes in the group and table definitions in the /var/snmp/mib/sun.mib file.

system   The system group reports statistics about a particular system (for example, a workstation or a printer).

sysDescr – A textual description of the entity. This value should include the full name and version identification of the system's hardware type, software operating-system, and networking software. This value must only contain printable ASCII characters. (string[255])

sysObjectID – The vendor's authoritative identification of the network management subsystem contained in the entity. This value is allocated within the SMI enterprises subtree (1.3.6.1.4.1) and provides an easy and unambiguous means for determining what type of equipment is being managed. For example, if vendor "Flintstones, Inc." was assigned the subtree 1.3.6.1.4.1.4242, it could assign the identifier 1.3.6.1.4.1.4242.1.1 to its "Fred Router." (objectid)

sysUpTime – Time (in hundredths of a second) since the network management portion of the system was last reinitialized. (timeticks)

sysContact – The textual identification of the contact person for this managed node, together with information on how to contact this person. (string[255])

sysName – An administratively-assigned name for this managed node. By convention, this is the node's fully-qualified domain name. (string[255])

sysLocation – The physical location of this node (for example, "telephone closet, 3rd floor" (string[255]))

sysServices – A value indicating the set of services that this entity primarily offers. (int) The value is a sum. This sum initially takes the value zero. Then, for each layer L in the range 1 through 7 for which this node performs transactions, 2 raised to (L - 1) is added to the sum. For example, a node that performs primarily routing functions would have a value of 4

(2**(3-1)). In contrast, a node that is a host offering application services would have a value of 72 (2**(4-1) + 2**(7-1)). Note that in the context of the Internet suite of protocols, values should be calculated accordingly:

Layer	Functionality
1	physical (such as repeaters)
2	datalink/subnetwork (such as bridges)
3	internet (such as IP gateways)
4	end-to-end (such as IP hosts)
7	applications (such as mail relays)

For systems including OSI protocols, Layers 5 and 6 may also be counted.

interfaces The interfaces group reports the number of interfaces handled by the agent.

ifNumber – The number of network interfaces, regardless of their current state, present on this system. (int)

ifTable The ifTable is a table of interface entries. The number of entries is given by the value of ifNumber.

ifIndex – A unique value for each interface. Its value ranges between 1 and the value of ifNumber. The value for each interface must remain constant at least from one reinitialization of the entity's network management system to the next reinitialization. (int)

ifDescr – A textual string containing information about the interface. This string should include the name of the manufacturer, the product name, and the version of the hardware interface. (string[255])

ifType – The type of interface, distinguished according to the physical/link protocol(s) immediately below the network layer in the protocol stack. (enum)

ifMtu – The size of the largest datagram that can be sent/received on the interface, specified in octets. For interfaces used for transmitting network datagrams, this is the size of the largest network datagram that can be sent on the interface. (int)

ifSpeed – An estimate of the interface's current bandwidth in bits-per-second. For interfaces that do not vary in bandwidth, or for those where no accurate estimation can be made, this object should contain the nominal bandwidth. (gauge)

ifPhysAddress – The interface's address at the protocol layer immediately below the network layer in the protocol stack. For interfaces without such an address (for example, a serial line), this object should contain an octet string of zero length. (octet[128])

ifAdminStatus – The desired state of the interface. The testing(3) state indicates that no operational packets can be passed. (enum)

ifOperStatus – The current operational state of the interface. The testing(3) state indicates that no operational packets can be passed. (enum)

ifLastChange – The value of sysUpTime at the time the interface entered its current operational state. If the current state was entered prior to the last reinitialization of the local network management subsystem, then this object contains a zero value. (timeticks)

ifInOctets – The total number of octets received on the interface, including framing characters. (counter) Returns a fixed value of 0.

ifInUcastPkts – The number of subnetwork-unicast packets delivered to a higher-layer protocol. (counter)

ifInNUcastPkts – The number of non-unicast (that is, subnetwork- broadcast or subnetwork-multicast) packets delivered to a higher-layer protocol. (counter) Returns a fixed value of 0.

ifInDiscards – The number of inbound packets chosen to be discarded, even though no errors had been detected to prevent their being deliverable to a higher-layer protocol. One possible reason for discarding such a packet could be to free up buffer space. (counter) Returns a fixed value of 0.

ifInErrors – The number of inbound packets that contained errors preventing them from being deliverable to a higher-layer protocol. (counter)

ifInUnknownProtos – The number of packets received via the interface that were discarded because of an unknown or unsupported protocol. (counter) Returns a fixed value of 0.

ifOutOctets – The total number of octets transmitted out of the interface, including framing characters. (counter) Returns a fixed value of 0.

ifOutUcastPkts – The total number of packets that higher-level protocols requested be transmitted to a subnetwork-unicast address, including those that were discarded or not sent. (counter)

ifOutNUcastPkts – The total number of packets that higher-level protocols requested be transmitted to a non- unicast (that is, a subnetwork-broadcast or subnetwork-multicast) address, including those that were discarded or not sent. (counter) Returns a fixed value of 0.

ifOutDiscards – The number of outbound packets that were chosen to be discarded even though no errors had been detected to prevent their being transmitted. One possible reason for discarding such a packet could be to free up buffer space. (counter) Returns a fixed value of 0.

ifOutErrors – The number of outbound packets that could not be transmitted because of errors. (counter)

ifOutQLen – The length of the output packet queue (in packets). (gauge)

ifSpecific – A reference to MIB definitions specific to the particular media being used to realize the interface. For example, if the interface is realized by an Ethernet, then the value of this object refers to a document defining objects specific to Ethernet. If this information is not present, its value should be set to the OBJECT IDENTIFIER { 0 0 }, which is a syntactically valid object identifier. Any conformant implementation of ASN.1 and BER must be able to generate and recognize this value. (objectid)

atTable   atTable Address Translation tables contain the NetworkAddress to physical address equivalences. Some interfaces do not use translation tables for determining address equivalences (for example, DDN-X.25 has an algorithmic method). If all interfaces are of this type, then the Address Translation table is empty, that is, has zero entries.

atIfIndex – The interface on which this entry's equivalence is effective. The interface identified by a particular value of this index is the same interface as identified by the same value of ifIndex. (int)

atPhysAddress – The media-dependent physical address. (octet[128]) Setting this object to a null string (one of zero length) has the effect of invaliding the corresponding entry in the atTable object. That is, it effectively dissociates the interface identified with said entry from the mapping identified with said entry. It is an implementation-specific matter as to whether the agent removes an invalidated entry from the table. Accordingly, management stations must be prepared to receive tabular information from agents that corresponds to entries not currently in use. Proper interpretation of such entries requires examination of the relevant atPhysAddress object.

atNetAddress – The NetworkAddress (that is, the IP address) corresponding to the media-dependent physical address. (netaddress)

ip   The ip group reports statistics about the Internet Protocol (IP) group.

ipForwarding – The indication of whether this entity is acting as an IP gateway in respect to the forwarding of datagrams received by, but not addressed to, this entity. IP gateways forward datagrams. IP hosts do not— except those source-routed via the host. (enum)

Note that for some managed nodes, this object may take on only a subset of the values possible. Accordingly, it is appropriate for an agent to return a "badValue" response if a management station attempts to change this object to an inappropriate value.

ipDefaultTTL – The default value inserted into the Time-To-Live field of the IP header of datagrams originated at this entity, whenever a TTL value is not supplied by the transport layer protocol. (int)

ipInReceives – The total number of input datagrams received from interfaces, including those received in error. (counter)

ipInHdrErrors — The number of input datagrams discarded due to errors in their IP headers, including bad checksums, version number mismatch, other format errors, time-to-live exceeded, errors discovered in processing their IP options, and so on. (counter)

ipInAddrErrors — The number of input datagrams discarded because the IP address in their IP header's destination field was not a valid address to be received at this entity. This count includes invalid addresses (for example, 0.0.0.0) and addresses of unsupported Classes (for example, Class E). For entities that are not IP Gateways and therefore do not forward datagrams, this counter includes datagrams discarded because the destination address was not a local address. (counter)

ipForwDatagrams — The number of input datagrams for which this entity was not their final IP destination, as a result of which an attempt was made to find a route to forward them to that final destination. In entities that do not act as IP Gateways, this counter will include only those packets that were Source-Routed via this entity, and the Source- Route option processing was successful. (counter)

ipInUnknownProtos — The number of locally-addressed datagrams received successfully but discarded because of an unknown or unsupported protocol. (counter)

ipInDiscards — The number of input IP datagrams for which no problems were encountered to prevent their continued processing, but which were discarded, for example, for lack of buffer space. Note that this counter does not include any datagrams discarded while awaiting reassembly. (counter)

ipInDelivers — The total number of input datagrams successfully delivered to IP user-protocols (including ICMP). (counter)

ipOutRequests — The total number of IP datagrams that local IP user-protocols (including ICMP) supplied to IP in requests for transmission. Note that this counter does not include any datagrams counted in ipForwDatagrams. (counter)

ipOutDiscards — The number of output IP datagrams for which no problem was encountered to prevent their transmission to their destination, but which were discarded (for example, for lack of buffer space). Note that this counter would include datagrams counted in ipForwDatagrams if any such packets met this (discretionary) discard criterion. (counter)

ipOutNoRoutes — The number of IP datagrams discarded because no route could be found to transmit them to their destination. Note that this counter includes any packets counted in ipForwDatagrams which meet this "no-route" criterion. Note that this includes any datagrams that a host cannot route because all its default gateways are down. (counter)

ipReasmTimeout — The maximum number of seconds that received fragments are held while they are awaiting reassembly at this entity. (int)

ipReasmReqds — The number of IP fragments received that needed to be reassembled at this entity. (counter)

ipReasmOKs – The number of IP datagrams successfully reassembled. (counter)

ipReasmFails – The number of failures detected by the IP reassembly algorithm, for whatever reason: timed out, errors, and the like. Note that this is not necessarily a count of discarded IP fragments since some algorithms (notably the algorithm in RFC 815) can lose track of the number of fragments by combining them as they are received. (counter)

ipFragOKs – The number of IP datagrams that have been successfully fragmented at this entity. (counter)

ipFragFails – The number of IP datagrams that have been discarded because they needed to be fragmented at this entity but could not be, for example, because their "Don't Fragment" flag was set. (counter)

ipFragCreates – The number of IP datagram fragments that have been generated as a result of fragmentation at this entity. (counter)

ipRoutingDiscards – The number of routing entries that were chosen to be discarded even though they were valid. One possible reason for discarding such an entry could be to free-up buffer space for other routing entries. (counter) Returns a fixed value of 0.

ipAddrTable   ipAddrTable is a table of addressing information relevant to this entity's IP addresses.

ipAdEntAddr – The IP address to which this entry's addressing information pertains. (netaddress)

ipAdEntIfIndex – The index value that uniquely identifies the interface to which this entry is applicable. The interface identified by a particular value of this index is the same interface as identified by the same value of ifIndex. (int)

ipAdEntNetMask – The subnet mask associated with the IP address of this entry. The value of the mask is an IP address with all the network bits set to 1, and all the hosts bits set to 0. (netaddress)

ipAdEntBcastAddr – The value of the least-significant bit in the IP broadcast address used for sending datagrams on the (logical) interface associated with the IP address of this entry. For example, when the Internet standard all-ones broadcast address is used, the value will be 1. This value applies to both the subnet and network broadcasts addresses used by the entity on this (logical) interface. (int) Returns a fixed value of 1.

ipAdEntReasmMaxSize – The size of the largest IP datagram that this entity can reassemble from incoming IP fragmented datagrams received on this interface. (int) Returns a fixed value of 65535.

ipRouteTable   The ipRouteTable is this entity's IP Routing table.

ipRouteDest – The destination IP address of this route. An entry with a value of 0.0.0.0 is considered a default route. Multiple routes to a single destination can appear in the table, but

access to such multiple entries is dependent on the table- access mechanisms defined by the network management protocol in use. (netaddress)

`ipRouteIfIndex` – The index value that uniquely identifies the local interface through which the next hop of this route should be reached. The interface identified by a particular value of this index is the same interface as identified by the same value of ifIndex. (int)

`ipRouteMetric1` – The primary routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route's ipRouteProto value. If this metric is not used, its value should be set to −1. (int) Returns a fixed value of −1.

`ipRouteMetric2` – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route's ipRouteProto value. If this metric is not used, its value should be set to −1. (int) Returns a fixed value of −1.

`ipRouteMetric3` – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route's ipRouteProto value. If this metric is not used, its value should be set to −1. (int) Returns a fixed value of −1.

`ipRouteMetric4` – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route's ipRouteProto value. If this metric is not used, its value should be set to −1. (int) Returns a fixed value of −1.

`ipRouteNextHop` – The IP address of the next hop of this route. (In the case of a route bound to an interface that is realized via a broadcast media, the value of this field is the agent's IP address on that interface.) (netaddress)

`ipRouteType` – The type of route. Note that the values direct (3) and indirect (4) refer to the notion of direct and indirect routing in the IP architecture. (enum)

Setting this object to the value invalid (2) has the effect of invalidating the corresponding entry in the ipRouteTable object. That is, it effectively dissociates the destination identified with said entry from the route identified with said entry. It is an implementation-specific matter as to whether the agent removes an invalidated entry from the table. Accordingly, management stations must be prepared to receive tabular information from agents that corresponds to entries not currently in use. Proper interpretation of such entries requires examination of the relevant ipRouteType object.

`ipRouteProto` – The routing mechanism through which this route was learned. Inclusion of values for gateway routing protocols is not intended to imply that hosts should support those protocols. (enum)

`ipRouteAge` – The number of seconds since this route was last updated or otherwise determined to be correct. Note that no semantics of "too old" can be implied except through knowledge of the routing protocol by which the route was learned. (int) Returns a fixed value of 0.

ipRouteMask – Indicate the mask to be logical-ANDed with the destination address before being compared to the value in the ipRouteDest field. For those systems that do not support arbitrary subnet masks, an agent constructs the value of the ipRouteMask by determining whether the value of the correspondent ipRouteDest field belongs to a class-A, B, or C network, and then using one of:

Mask	Network
255.0.0.0	class-A
255.255.0.0	class-B
255.255.255.0	class-C

If the value of the ipRouteDest is 0.0.0.0 (a default route), then the mask value is also 0.0.0.0. It should be noted that all IP routing subsystems implicitly use this mechanism. (netaddress)

ipRouteMetric5 – An alternate routing metric for this route. The semantics of this metric are determined by the routing-protocol specified in the route's ipRouteProto value. If this metric is not used, its value should be set to −1. (int) Returns a fixed value of −1.

ipRouteInfo – A reference to MIB definitions specific to the particular routing protocol responsible for this route, as determined by the value specified in the route's ipRouteProto value. If this information is not present, its value should be set to the OBJECT IDENTIFIER { 0 0 }, which is a syntactically valid object identifier. Any conformant implementation of ASN.1 and BER must be able to generate and recognize this value. (objectid)

ipNetToMediaTable   The ipNetToMediaTable is the IP Address Translation table used for mapping from IP addresses to physical addresses.

ipNetToMediaIfIndex – The interface on which this entry's equivalence is effective. The interface identified by a particular value of this index is the same interface as identified by the same value of ifIndex. (int)

ipNetToMediaPhysAddress – The media-dependent physical address. (octet[128])

ipNetToMediaNetAddress – The IpAddress corresponding to the media- dependent physical address. (netaddress)

ipNetToMediaType – The type of mapping. (enum) Returns a fixed value of (3)dynamic. Setting this object to the value invalid(2) has the effect of invalidating the corresponding entry in the ipNetToMediaTable. That is, it effectively dissociates the interface identified with said entry from the mapping identified with said entry. It is an implementation-specific matter as to whether the agent removes an invalidated entry from the table. Accordingly, management stations must be prepared to receive tabular information from agents that corresponds to entries not currently in use. Proper interpretation of such entries requires examination of the relevant ipNetToMediaType object.

icmp   The icmp group reports statistics about the ICMP group.

icmpInMsgs – The total number of ICMP messages that the entity received. Note that this counter includes all those counted by icmpInErrors. (counter)

icmpInErrors – The number of ICMP messages that the entity received but determined as having ICMP-specific errors (bad ICMP checksums, bad length, and the like.). (counter)

icmpInDestUnreachs – The number of ICMP Destination Unreachable messages received. (counter)

icmpInTimeExcds – The number of ICMP Time Exceeded messages received. (counter)

icmpInParmProbs – The number of ICMP Parameter Problem messages received. (counter)

icmpInSrcQuenchs – The number of ICMP Source Quench messages received. (counter)

icmpInRedirects – The number of ICMP Redirect messages received. (counter)

icmpInEchos – The number of ICMP Echo (request) messages received. (counter)

icmpInEchoReps – The number of ICMP Echo Reply messages received. (counter)

icmpInTimestamps – The number of ICMP Timestamp (request) messages received. (counter)

icmpInTimestampReps – The number of ICMP Timestamp Reply messages received. (counter)

icmpInAddrMasks – The number of ICMP Address Mask Request messages received. (counter)

icmpInAddrMaskReps – The number of ICMP Address Mask Reply messages received. (counter)

icmpOutMsgs – The total number of ICMP messages that this entity attempted to send. Note that this counter includes all those counted by icmpOutErrors. (counter)

icmpOutErrors – The number of ICMP messages that this entity did not send due to problems discovered within ICMP, such as a lack of buffers. This value should not include errors discovered outside the ICMP layer, such as the inability of IP to route the resultant datagram. In some implementations there may be no types of errors that contribute to this counter's value. (counter)

icmpOutDestUnreachs – The number of ICMP Destination Unreachable messages sent. (counter)

icmpOutTimeExcds – The number of ICMP Time Exceeded messages sent. (counter)

icmpOutParmProbs – The number of ICMP Parameter Problem messages sent. (counter)

`icmpOutSrcQuenchs` – The number of ICMP Source Quench messages sent. (counter)

`icmpOutRedirects` – The number of ICMP Redirect messages sent. For a host, this object will always be zero, since hosts do not send redirects. (counter)

`icmpOutEchos` – The number of ICMP Echo (request) messages sent. (counter)

`icmpOutEchoReps` – The number of ICMP Echo Reply messages sent. (counter)

`icmpOutTimestamps` – The number of ICMP Timestamp (request) messages sent. (counter)

`icmpOutTimestampReps` – The number of ICMP Timestamp Reply messages sent. (counter)

`icmpOutAddrMasks` – The number of ICMP Address Mask Request messages sent. (counter)

`icmpOutAddrMaskReps` – The number of ICMP Address Mask Reply messages sent. (counter)

tcp   The `tcp` group reports statistics about the TCP group.

`tcpRtoAlgorithm` – The algorithm used to determine the timeout value used for retransmitting unacknowledged octets. (enum)

`tcpRtoMin` – The minimum value permitted by a TCP implementation for the retransmission timeout, measured in milliseconds. More refined semantics for objects of this type depend upon the algorithm used to determine the retransmission timeout. In particular, when the timeout algorithm is rsre(3), an object of this type has the semantics of the LBOUND quantity described in RFC 793. (int)

`tcpRtoMax` – The maximum value permitted by a TCP implementation for the retransmission timeout, measured in milliseconds. More refined semantics for objects of this type depend upon the algorithm used to determine the retransmission timeout. In particular, when the timeout algorithm is rsre(3), an object of this type has the semantics of the UBOUND quantity described in RFC 793. (int)

`tcpMaxConn` – The limit on the total number of TCP connections that the entity can support. In entities where the maximum number of connections is dynamic, this object should contain the value –1. (int)

`tcpActiveOpens` – The number of times that TCP connections have made a direct transition to the SYN-SENT state from the CLOSED state. (counter)

`tcpPassiveOpens` – The number of times that TCP connections have made a direct transition to the SYN-RCVD state from the LISTEN state. (counter)

`tcpAttemptFails` – The number of times that TCP connections have made a direct transition to the CLOSED state from either the SYN-SENT state or the SYN-RCVD state, plus the number of times TCP connections have made a direct transition to the LISTEN state from the SYN-RCVD state. (counter)

tcpEstabResets — The number of times TCP connections have made a direct transition to the CLOSED state from either the ESTABLISHED state or the CLOSE-WAIT state. (counter)

tcpCurrEstab — The number of TCP connections for which the current state is either ESTABLISHED or CLOSE-WAIT. (gauge)

tcpInSegs — The total number of segments received, including those received in error. This count includes segments received on currently established connections. (counter)

tcpOutSegs — The total number of segments sent, including those on current connections but excluding those containing only retransmitted octets. (counter)

tcpRetransSegs — The total number of segments retransmitted - that is, the number of TCP segments transmitted containing one or more previously transmitted octets. (counter)

tcpInErrs — The total number of segments received in error (for example, bad TCP checksums). (counter)

tcpOutRsts — The number of TCP segments sent containing the RST flag. (counter)

tcpConnTable   The `tcpConnTable` is a table containing TCP connection-specific information.

tcpConnState — The state of this TCP connection. (enum)

The only value that may be set by a management station is deleteTCB(12). Accordingly, it is appropriate for an agent to return a "badValue" response if a management station attempts to set this object to any other value.

If a management station sets this object to the value deleteTCB(12), then this has the effect of deleting the TCB (as defined in RFC 793) of the corresponding connection on the managed node. This results in immediate termination of the connection.

As an implementation-specific option, an RST segment may be sent from the managed node to the other TCP endpoint. (Note, however, that RST segments are not sent reliably.)

tcpConnLocalAddress — The local IP address for this TCP connection. For a connection in the listen state that is willing to accept connections for any IP interface associated with the node, the value 0.0.0.0 is used. (netaddress)

tcpConnLocalPort — The local port number for this TCP connection. (int)

tcpConnRemAddress — The remote IP address for this TCP connection. (netaddress)

tcpConnRemPort — The remote port number for this TCP connection. (int)

upd   The udp group reports statistics about the UDP group.

udpInDatagrams — The total number of UDP datagrams delivered to UDP users. (counter) Returns a fixed value of 0.

udpNoPorts — The total number of received UDP datagrams for which there was no application at the destination port. (counter) Returns a fixed value of 0.

udpInErrors — The number of received UDP datagrams that could not be delivered for reasons other than the lack of an application at the destination port. (counter)

udpOutDatagrams — The total number of UDP datagrams sent from this entity. (counter) Returns a fixed value of 0.

udpTable   The udpTable is a table containing UDP listener information.

udpLocalAddress — The local IP address for this UDP listener. For a UDP listener that is willing to accept datagrams for any IP interface associated with the node, the value 0.0.0.0 is used. (netaddress)

udpLocalPort — The local port number for this UDP listener. (int)

snmp   The snmp group reports statistics about the SNMP group.

snmpInPkts — The total number of Messages delivered to the SNMP entity from the transport service. (counter)

snmpOutPkts — The total number of SNMP Messages passed from the SNMP protocol entity to the transport service. (counter)

snmpInBadVersions — The total number of SNMP Messages delivered to the SNMP protocol entity that were for an unsupported SNMP version. (counter)

snmpInBadCommunityNames — The total number of SNMP Messages delivered to the SNMP protocol entity that used a SNMP community name not known to said entity. (counter)

snmpInBadCommunityUses — The total number of SNMP Messages delivered to the SNMP protocol entity, which represented an SNMP operation not allowed by the SNMP community named in the Message. (counter)

snmpInASNParseErrs — The total number of ASN.1 or BER errors encountered by the SNMP protocol entity when decoding received SNMP Messages. (counter)

snmpInTooBigs — The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is "tooBig." (counter)

snmpInNoSuchNames — The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is "noSuchName." (counter)

snmpInBadValues — The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is "badValue." (counter)

snmpInReadOnlys – The total number valid SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is "readOnly." It should be noted that it is a protocol error to generate an SNMP PDU that contains the value "readOnly" in the error-status field. This object is provided as a means of detecting incorrect implementations of the SNMP. (counter)

snmpInGenErrs – The total number of SNMP PDUs delivered to the SNMP protocol entity for which the value of the error-status field is "genErr." (counter)

snmpInTotalReqVars – The total number of MIB objects successfully retrieved by the SNMP protocol entity as the result of receiving valid SNMP Get-Request and Get-Next PDUs. (counter)

snmpInTotalSetVars – The total number of MIB objects successfully altered by the SNMP protocol entity as the result of receiving valid SNMP Set-Request PDUs. (counter)

snmpInGetRequests – The total number of SNMP Get-Request PDUs accepted and processed by the SNMP protocol entity. (counter)

snmpInGetNexts – The total number of SNMP Get-Next PDUs accepted and processed by the SNMP protocol entity. (counter)

snmpInSetRequests – The total number of SNMP Set-Request PDUs accepted and processed by the SNMP protocol entity. (counter)

snmpInGetResponses – The total number of SNMP Get-Response PDUs accepted and processed by the SNMP protocol entity. (counter)

snmpInTraps – The total number of SNMP Trap PDUs accepted and processed by the SNMP protocol entity. (counter)

snmpOutTooBigs – The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status field is "tooBig." (counter)

snmpOutNoSuchNames – The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status is "noSuchName." (counter)

snmpOutBadValues – The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status field is "badValue." (counter)

snmpOutGenErrs – The total number of SNMP PDUs generated by the SNMP protocol entity for which the value of the error-status field is "genErr." (counter)

snmpOutGetRequests – The total number of SNMP Get-Request PDUs which have been generated by the SNMP protocol entity. (counter)

snmpOutGetNexts – The total number of SNMP Get-Next PDUs generated by the SNMP protocol entity. (counter)

snmpOutSetRequests — The total number of SNMP Set-Request PDUs generated by the SNMP protocol entity. (counter)

snmpOutGetResponses — The total number of SNMP Get-Response PDUs generated by the SNMP protocol entity. (counter)

snmpOutTraps — The total number of SNMP Trap PDUs generated by the SNMP protocol entity. (counter)

snmpEnableAuthenTraps — Indicates whether the SNMP agent process is permitted to generate authentication-failure traps. The value of this object overrides any configuration information. As such, it provides a means whereby all authentication-failure traps may be disabled. (enum)

Note that this object must be stored in non-volatile memory, so that it remains constant between reinitializations of the network management system.

The following are Sun-specific group and table definitions.

sunSystem   The sunSystem group reports general system information.

agentDescr — The SNMP agent's description of itself. (string[255])

hostID — The unique Sun hardware identifier. The value returned is four byte binary string. (octet[4])

motd — The first line of /etc/motd. (string[255])

unixTime — The UNIX system time. Measured in seconds since January 1, 1970 UTC. (counter)

sunProcessTable   The sunProcessTable table reports UNIX process table information.

psProcessID — The process identifier for this process. (int)

psParentProcessID — The process identifier of this process's parent. (int)

psProcessSize — The combined size of the data and stack segments (in kilobytes.) (int)

psProcessCpuTime — The CPU time (including both user and system time) consumed so far. (int)

psProcessState — The run-state of the process. (octet[4])

R	Runnable
T	Stopped
P	In page wait

D	Non-interruptable wait
S	Sleeping (less than 20 seconds)
I	Idle (more than 20 seconds)
Z	Zombie

psProcessWaitChannel – Reason process is waiting. (octet[16])

psProcessTTY – Terminal, if any, controlling this process. (octet[16])

psProcessUserName – Name of the user associated with this process. (octet[16])

psProcessUserID – Numeric form of the name of the user associated with this process. (int)

psProcessName – Command name used to invoke this process. (octet[64])

psProcessStatus – Setting this variable will cause a signal of the set value to be sent to the process. (int)

sunHostPerf   The sunHostPerf group reports hostperf information.

rsUserProcessTime – Total number of timeticks used by user processes since the last system boot. (counter)

rsNiceModeTime – Total number of timeticks used by "nice" mode since the last system boot. (counter)

rsSystemProcessTime – Total number of timeticks used by system processes since the last system boot. (counter)

rsIdleModeTime – Total number of timeticks in idle mode since the last system boot. (counter)

rsDiskXfer1 – Total number of disk transfers since the last boot for the first of four configured disks. (counter)

rsDiskXfer2 – Total number of disk transfers since the last boot for the second of four configured disks. (counter)

rsDiskXfer3 – Total number of disk transfers since the last boot for the third of four configured disks. (counter)

rsDiskXfer4 – Total number of disk transfers since the last boot for the fourth of four configured disks. (counter)

rsVPagesIn – Number of pages read in from disk. (counter)

rsVPagesOut – Number of pages written to disk. (counter)

rsVSwapIn – Number of pages swapped in. (counter)

rsVSwapOut – Number of pages swapped out. (counter)

rsVIntr – Number of device interrupts. (counter)

rsIfInPackets – Number of input packets. (counter)

rsIfOutPackets – Number of output packets. (counter)

rsIfInErrors – Number of input errors. (counter)

rsIfOutErrors – Number of output errors. (counter)

rsIfCollisions – Number of output collisions. (counter)

Files /etc/snmp/conf/snmpd.conf   configuration information

/etc/snmp/conf/mibiisa.acl   access control file

/var/snmp/mib/sun.mib   standard SNMP MIBII file

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/snmp/mibiisa
Interface Stability	Obsolete

See Also inetd(1M), select(3C), recvfrom(3SOCKET), sendto(3SOCKET), attributes(5), gld(7D)

Diagnostics

cannot dispatch request	The proxy cannot dispatch the request. The rest of the message indicates the cause of the failure.
select(3C) failed	A select(3C) call failed. The rest of the message indicates the cause of the failure.
sendto(3SOCKET) failed	A sendto(3SOCKET) call failed. The rest of the message indicates the cause of the failure.
recvfrom(3SOCKET) failed	A recvfrom(3SOCKET) call failed. The rest of the message indicates the cause of the failure.
no response from system	The SNMP agent on the target system does not respond to SNMP requests. This error might indicate that the

	SNMP agent is not running on the target system, the target system is down, or the network containing the target system is unreachable.
response too big	The agent could not fit the results of an operation into a single SNMP message. Split large groups or tables into smaller entities.
missing attribute	An attribute is missing from the requested group.
bad attribute type	An object attribute type received from the SNMP agent that does not match the attribute type specified by the proxy agent schema. The rest of the message indicates the expected type and received type.
cannot get sysUpTime	The proxy agent cannot get the variable *sysUpTime* from the SNMP agent.
sysUpTime type bad	The variable *sysUpTime* received from the SNMP agent has the wrong data type.
unknown SNMP error	An unknown SNMP error was received.
bad variable value	The requested specified an incorrect syntax or value for a set operation.
variable is read only	The SNMP agent did not perform the set request because a variable to set may not be written.
general error	A general error was received.
cannot make request PDU	An error occurred building a request PDU.
cannot make request varbind list	An error occurred building a request variable binding list.
cannot parse response PDU	An error occurred parsing a response PDU.

`request ID - response ID mismatch`	The response ID does not match the request ID.
`string contains non-displayable characters`	A displayable string contains non-displayable characters.
`cannot open schema file`	An error occurred opening the proxy agent schema file.
`cannot parse schema file`	The proxy agent couldn't parse the proxy agent schema file.
`cannot open host file`	An error occurred opening the file associated with the *na.snmp.hostfile* keyword in `/etc/snmp/conf/snmpd.conf`
`cannot parse host file`	The proxy agent was unable to parse the file associated with the *na.snmp.hostfile* keyword in `/etc/snmp/conf/snm.conf`.
`attribute unavailable for set operations`	The set could not be completed because the attribute was not available for set operations.

Bugs The mibiisa utility returns the wrong interface speed for the SBUS FDDI interface (for example, "bf0").

The mibiisa utility does not return a MAC address for the SBUS FDDI interface (for example, "bf0").

Process names retrieved from mibiisa contain a leading blank space.

When you change attribute values in the system group with an SNMP set request, the change is effective only as long as mibiisa is running. mibiisa does not save the changes to `/etc/snmp/conf/snmpd.conf`.

Name mkbootmedia – create bootable Solaris ISO image

Synopsis /usr/bin/mkbootmedia -v [-l *label*] *media-root iso*

Description The mkbootmedia utility takes *media-root* (the root of an on-disk Solaris install media) as input and creates a bootable Solaris ISO image in the file *iso*, using mkisofs(8). The file can then be burned onto a CD/DVD with utilities such as cdrw(1) or cdrecord(1). (Neither mkisofs(8) nor cdrecord(1) are SunOS man pages.)

Caution – The directory tree *media-root* must contain the file boot/grub/stage2_eltorito, which will be written to the media boot sectors. This file will be modified with some boot information, thus it must be writable. If necessary, first save a copy prior to running this utility.

Options The following options are supported:

-l *label*
Sets *label* as the label/volume name of the ISO image.

-v
Verbose. Multiple -v options increase verbosity.

Operands The following operands are supported:

media-root
Top-level directory of an on-disk Solaris install media.

iso
Name of the output file which will contain the resulting ISO image.

Examples EXAMPLE 1 Creating an ISO Image and Burning a CD/DVD

The following commands create an ISO image from the content of s10u1 and burn the image to a CD/DVD.

```
# /usr/bin/mkbootmedia s10u1 s10u1.iso
# /usr/bin/cdrw -i s10u1.iso
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also cdrw(1), attributes(5)

mkisofs(8), (/usr/share/man/man8/mkisofs.8), in the SUNWfsman package (not a SunOS man page)

Name mkdevalloc – Make device_allocate entries

Synopsis `/usr/sbin/mkdevalloc`

Description The `mkdevalloc` command writes to standard out a set of device_allocate(4) entries describing the system's frame buffer, audio, and removable media devices.

The `mkdevalloc` command is used by the device allocation service:

`svc:/system/device/allocate:default`

...to create or update the device_allocate(4) file. The device allocation service is managed by smf(5) and described in device_allocate(1M).

Entries are generated based on the device special files found in `/dev`. For the different categories of devices, the `mkdevalloc` command checks for the following files under `/dev`:

```
audio           /dev/audio, /dev/audioctl, /dev/sound/...
tape            /dev/rst*, /dev/nrst*, /dev/rmt/...
removable disk  /dev/sr*, /dev/nsr*, /dev/dsk/c0t?d0s?, /dev/rdsk/c0t?d0s?
frame buffer    /dev/fb
```

All entries set the *device-minimum* and *device-maximum* fields to the hex representations of `ADMIN_LOW` and `ADMIN_HIGH`, respectively. The *device-authorization* field is set to `solaris.device.allocate`, except for the `framebuffer` entry, where it is set to `*`. The *device-name*, *device-type* and *device-clean* fields are set to the following values:

```
                device-name     device-type   device-clean

audio           audio           audio         audio_clean_wrapper
tape            mag_tape_0,1,... st            st_clean
floppy          floppy_0,1,...  fd            disk_clean
removable disk  cdrom_0,1,...   sr            disk_clean
frame buffer    framebuffer     fb            /bin/true
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Obsolete

See Also allocate(1), device_allocate(1M), device_allocate(4), attributes(5), smf(5)

Notes `mkdevalloc` might not be supported in a future release of the Solaris operating system.

Name mkdevmaps – make device_maps entries

Synopsis /usr/sbin/mkdevmaps

Description The mkdevmaps command writes to standard out a set of device_maps(4) entries describing the system's frame buffer, audio, and removable media devices.

The mkdevmaps command is used by the device allocation service:

svc:/system/device/allocate:default

...to create or update the device_maps(4) file. The device allocation service is managed by smf(5) and described in device_allocate(1M).

Entries are generated based on the device special files found in /dev. For the different categories of devices, the mkdevmaps command checks for the following files under /dev:

```
audio           /dev/audio, /dev/audioctl, /dev/sound/...
tape            /dev/rst*, /dev/nrst*, /dev/rmt/...
removable disk  /dev/dsk/c0t?d0s?, /dev/rdsk/c0t?d0s?
frame buffer    /dev/fb
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Obsolete

See Also allocate(1), device_allocate(1M), device_maps(4), attributes(5), smf(5)

Notes mkdevmaps might not be supported in a future release of the Solaris operating system.

Name mkfifo – make FIFO special file

Synopsis /usr/bin/mkfifo [-m *mode*] *path*...

Description The mkfifo utility creates the FIFO special files named by its argument list. The arguments are taken sequentially, in the order specified; and each FIFO special file is either created completely or, in the case of an error or signal, not created at all.

If errors are encountered in creating one of the special files, mkfifo writes a diagnostic message to the standard error and continues with the remaining arguments, if any.

The mkfifo utility calls the library routine mkfifo(3C), with the *path* argument is passed as the *path* argument from the command line, and *mode* is set to the equivalent of a=rw, modified by the current value of the file mode creation mask umask(1).

Options The following option is supported:

-m *mode* Set the file permission bits of the newly-created FIFO to the specified *mode* value. The *mode* option-argument will be the same as the *mode* operand defined for the chmod(1) command. In <*symbolic*mode> strings, the *op* characters + and − will be interpreted relative to an assumed initial mode of a=rw.

Operands The following operand is supported:

file A path name of the FIFO special file to be created.

Usage See largefile(5) for the description of the behavior of mkfifo when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Environment Variables See environ(5) for descriptions of the following environment variables that affect the execution of mkfifo: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Exit Status The following exit values are returned:

0 All the specified FIFO special files were created successfully.

>0 An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed
Standard	See standards(5).

See Also   chmod(1), umask(1), mkfifo(3C), attributes(5), environ(5), largefile(5), standards(5)

Name mkfile – create a file

Synopsis mkfile [-nv] *size* [t | g | k | b | m] *filename*...

Description mkfile creates one or more files that are suitable for use as NFS-mounted swap areas, or as local swap areas. When a root user executes mkfile(), the sticky bit is set and the file is padded with zeros by default. When non-root users execute mkfile(), they must manually set the sticky bit using chmod(1). The default size is in bytes, but it can be flagged as terabytes, gigabytes, kilobytes, blocks, or megabytes, with the t, g, k, b, or m suffixes, respectively. Suffixes can be uppercase or lowercase.

Options -n Create an empty *filename*. The size is noted, but disk blocks are not allocated until data is written to them. Files created with this option cannot be swapped over local UFS mounts.

-v Verbose. Report the names and sizes of created files.

Exit Status The following exit values are returned:

0 Success.

>0 An error occurred.

Usage See largefile(5) for the description of the behavior of mkfile when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also chmod(1), swap(1M), attributes(5), largefile(5)

Name mkfs – construct a file system

Synopsis mkfs [-F *FSType*] [*generic_options*]
[-o *FSType-specific_options*] *raw_device_file*
[*operands*]

Description The mkfs utility constructs a file system on the *raw_device_file* by calling the specific mkfs module indicated by -F *FSType*.

Note: ufs file systems are normally created with the newfs(1M) command.

generic_options are independent of file system type. *FSType-specific_options* is a comma-separated list of *keyword=value* pairs (with no intervening spaces), which are *FSType*-specific. *raw_device_file* specifies the disk partition on which to write the file system. It is required and must be the first argument following the *specific_options* (if any). *operands* are *FSType*-specific. See the *FSType*-specific manual page of mkfs (for example, mkfs_ufs(1M)) for a detailed description.

Options The following are the generic options for mkfs:

-F Specify the *FSType* to be constructed. If -F is not specified, the *FSType* is determined from /etc/vfstab by matching the *raw_device_file* with a vfstab entry, or by consulting the /etc/default/fs file.

-V Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided and adding to them information derived from /etc/vfstab or /etc/default/fs. This option may be used to verify and validate the command line.

-m Return the command line which was used to create the file system. The file system must already exist. This option provides a means of determining the command used in constructing the file system.

-o Specify *FSType*-specific options. See the manual page for the mkfs module specific to the file system type.

Usage See largefile(5) for the description of the behavior of mkfs when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files /etc/default/fs Default file system type. Default values can be set for the following flags in /etc/default/fs. For example: LOCAL=ufs

LOCAL The default partition for a command if no *FSType* is specified.

/etc/vfstab List of default parameters for each file system

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also mkfs_ufs(1M), newfs(1M), vfstab(4), attributes(5), largefile(5)

Manual pages for the *FSType*-specific modules of mkfs.

Notes This command might not be supported for all *FSType*s.

You can use lofiadm to create a file that appears to a mkfs command as a raw device. You can then use a mkfs command to create a file system on that device. See lofiadm(1M) for examples of creating a UFS and a PC (FAT) file system (using mkfs_ufs(1M) and mkfs_pcfs(1M)) on a device created by lofiadm.

Name mkfs_pcfs – construct a FAT file system

Synopsis mkfs -F pcfs [*generic_options*] [-o *FSType_specific_options*]
           raw_device_file

Description The pcfs-specific module of mkfs constructs a File Allocation Table (FAT) on removable
media (JAZ disk, ZIP disk, PCMCIA card), a hard disk, or a file (see NOTES). FATs are the
standard MS-DOS and Windows file system format.

mkfs for pcfs determines an appropriate FAT size for the medium, then it installs an initial
boot sector and an empty FAT. A sector size of 512 bytes is used. mkfs for pcfs can also install
the initial file in the file system (see the pcfs-specific -o i option). This first file can optionally
be marked as read-only, system, and/or hidden.

If you want to construct a FAT with mkfs for pcfs on a medium that is not formatted, you
must first perform a low-level format on the medium with format(1M). The media must also
be partitioned with the fdisk(1M) utility. Note that all existing data on a disk partition, if any,
is destroyed when a new FAT is constructed.

generic_options are supported by the generic mkfs command. See mkfs(1M) for a description
of these options.

raw_device_file indicates the device on which to write unless the -o N option has been
specified, or if the -V or -m generic options are passed from the generic mkfs module.

Options See mkfs(1M) for the list of supported generic options.

The following options are supported:

-o *FSType_specific_options*
  Specify pcfs file system-specific options in a comma-separated list with no intervening
  spaces. If invalid options are specified, a warning message is printed and the invalid options
  are ignored.

  b=*label*
    Label the media with volume label. The volume label is restricted to 11 uppercase
    characters.

  B=*filename*
    Install *filename* as the boot loader in the file system's boot sector. If you don't specify a
    boot loader, an MS-DOS boot loader is installed. The MS-DOS boot loader requires
    specific MS-DOS system files to make a disk bootable. See NOTES for more information.

  fat=*n*
    The size of a FAT entry. Currently, 12, 16, and 32 are valid values. The default is 16.

  h
    Mark the first file installed as a hidden file. The -i option must also be specified.

hidden=*n*

Set the number of hidden sectors to *n*. This is the number of sectors on the physical disk preceding the start of the volume (which is the boot sector itself). This defaults to a computed valued (based on the fdisk table) for disks. This option may be used only in conjunction with the `nofdisk` option.

i=*filename*

Install *filename* as the initial file in the new file system. The initial file's contents are guaranteed to occupy consecutive clusters at the start of the files area. When creating bootable media, a boot program should be specified as the initial file.

nofdisk

Do not attempt to find an `fdisk` table on the medium. Instead rely on the `size` option for determining the partition size. By default, the created FAT is 16 bits and begins at the first sector of the device. This origination sector can be modified with the hidden option (`-h`).

nsect=*n*

The number of sectors per track on the disk. If not specified, the value is determined by using a `dkio(7I)` ioctl to get the disk geometry.

ntrack=*n*

The number of tracks per cylinder on the disk. If not specified, the value is determined by using a `dkio(7I)` ioctl to get the disk geometry.

N

No execution mode. Print normal output, but do not actually write the file system to the medium. This is most useful when used in conjunction with the verbose option.

r

Mark the first file installed as read-only. The `-i` option must also be specified.

reserve=*n*

Set the number of reserved sectors to *n*. This is the number of sectors in the volume, preceding the start of the first FAT, including the boot sector. The value should always be at least 1, and the default value is exactly 1.

s

Mark the first file installed as a system file. The `-i` option must also be specified.

size=*n*

The number of sectors in the file system. If not specified, the value is determined from the size of the partition given in the fdisk table.

spc=*n*

The size of the allocation unit for space within the file system, expressed as a number of sectors. The default value depends on the FAT entry size and the size of the file system.

v

Verbose output. Describe, in detail, operations being performed.

Files   *raw_device_file*

    The device on which to build the FAT.

    `mkfs_pcfs` supports MBR (Master Boot Record) partitions and GPT (GUID Partition Table) partitions. GPT is part of the EFI (Extensible Firmware Interface) standard. For both x86 and SPARC, for a GPT-labeled disk, you can specify the partition using the logical device pathname with no suffix, for example, `/dev/rdsk/c0t0d0s0`. In GPT, this corresponds to the first partition on the disk.

    On x86 for MBR partitions, you can specify the proper partition using the logical device pathname corresponding to the partition. For example, `/dev/rdsk/c0t0d0p1` corresponds to first partition in the MBR, or `/dev/rdsk/c0t0d0p5` corresponds to first logical partition in the extended partition. Alternatively, using a suffix is also acceptable. For example, in `/dev/rdsk/c0t0d0p0:c`, `mkfs_pcfs` recognizes `:c` as the first partition that can accept a FAT file system.

    For removable media with MBR partitions on SPARC, you need to specify a disk device name with a suffix to indicate the proper partition. For example, in the name `/dev/rdsk/c0t0d0s2:c`, the `:c` suffix indicates that the partition can accept the new FAT.

    For a file, *raw_device_file* is the block device name returned by `lofiadm(1M)`.

Examples   The media in these examples must be formatted before running `mkfs` for `pcfs`. See DESCRIPTION for more details.

    EXAMPLE 1   Creating a FAT File System on a Disk

    The following command creates a FAT file system on the second fdisk partition of a disk attached to an x86 based system:

    `mkfs -F pcfs /dev/rdsk/c0d0p0:d`

    EXAMPLE 2   Creating a FAT File System on a ZIP Disk

    The following command creates a FAT file system on a ZIP disk located on a SPARC based system:

    `mkfs -F pcfs /dev/rdsk/c0t4d0s2:c`

    EXAMPLE 3   Creating a FAT File System on a JAZ Disk

    The following command creates a FAT file system on a JAZ disk located on a SPARC based system and overrides the sectors/track and tracks/cylinder values obtained from the device's controller:

    `mkfs -F pcfs -o nsect=32,ntrack=64 /dev/rdsk/c0t3d0s2:c`

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/pcfs
Interface Stability	Committed

See Also fdisk(1M), format(1M), lofiadm(1M), mkfs(1M), attributes(5), dkio(7I)

Notes You can use lofiadm to create a file that appears to a mkfs command (for example, mkfs_pcfs or mkfs_ufs) as a raw device. You can then use a mkfs command to create a file system on that device. See lofiadm(1M) for examples of creating a UFS and a PC (FAT) file system on a device created by lofiadm.

Name mkfs_udfs – construct a udfs file system

Synopsis mkfs -F udfs [*generic_options*] [-o *specific_options*] *raw_device_file*
[*size*]

Description This is the universal disk format file system (udfs) -specific module of the mkfs command.
mkfs constructs a udfs file system with a root directory.

Options See mkfs(1M) for the list of supported *generic_options*.

The following options are supported:

-o *specific_options*   Specify a udfs-specific option. Specify udfs file system specific options
in a comma-separated list with no intervening spaces. If invalid
options are specified, a warning message is printed and the invalid
options are ignored.

The following *specific_options* are available:

N   Print the file system parameters without actually
creating the file system.

label=*string*   Specify the label to be written into the volume header
structures. Specify *string* as the name of the label. If
string is not specified, a default *string* is generated in
the form of *NoLabel*.

Operands The following operands are supported:

raw_device_file   Specify the disk partition on which to write.

size   Specify the number of 512-byte blocks in the file system.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/udfs

See Also fsck(1M), mkfs(1M), attributes(5)

Diagnostics not currently a valid file system

The specified device does not contain a valid udfs file system.

Invalid size: larger than the partition size

Number of blocks given as parameter to create the file system is larger than the size of the
device specified.

is mounted can't mkfs

Device is in use, cannot create file system when the device is in use.

```
preposterous size
```

Negative size parameter provided is invalid.

```
sector size must be between 512, 8192 bytes
```

Sector size given is not in the valid range.

```
Volume integrity sequence descriptors too long
File set descriptor too long.
```

Not enough space to create volume integrity sequence or file set descriptor.

```
mkfs: argument out of range
```

One of the arguments is out of range.

```
mkfs: bad numeric arg
```

One of the arguments is potentially a bad numeric.

Notes You can use lofiadm to create a file that appears to a mkfs command (for example, mkfs_pcfs or mkfs_ufs) as a raw device. You can then use a mkfs command to create a file system on that device. See lofiadm(1M) for examples of creating a UFS and a PC (FAT) file system on a device created by lofiadm.

Name mkfs_ufs – construct a UFS file system

Synopsis mkfs -F ufs [*generic_options*] [-o *FSType_specific_options*] *raw_device_file*
              [*size*]

Description The UFS-specific module of mkfs builds a UFS file system with a root directory and a
                lost+found directory (see fsck(1M)).

The UFS-specific mkfs is rarely run directly. Use the newfs(1M) command instead.

raw_device_file indicates the disk partition on which to create the new file system. If the -o N,
-V, or -m options are specified, the *raw_device_file* is not actually modified. *size* specifies the
number of disk sectors in the file system, where a disk sector is usually 512 bytes. This
argument must follow the *raw_device_file* argument and is required (even with -o N), unless
the -V or -m generic options are specified.

generic_options are supported by the generic mkfs command. See mkfs(1M) for a description
of these options.

Options The following generic options are supported:

-m   Print the command line that was used to create the existing file system.

-V   Print the current mkfs command line.

Options The following UFS-specific options are supported:

-o   Use one or more of the following values separated by commas (with no intervening
     spaces) to specify UFS-specific options:

apc=*n*   The number of alternate sectors per cylinder to reserve for bad block
               replacement for SCSI devices only. The default is 0.

               This option is not applicable for disks with EFI labels and is ignored.

bsize=*n*   The logical block size of the file system in bytes, either 4096 or 8192.
               The default is 8192. The sun4u architecture does not support the
               4096 block size.

calcbinsb   Sends to stdout a binary (machine-readable) version of the
               superblock that would be used to create a file system with the
               specified configuration parameters.

calcsb   Sends to stdout a human-readable version of the superblock that
               would be used to create a file system with the specified configuration
               parameters.

cgsize=*n*   The number of cylinders per cylinder group, ranging from 16 to 256.
               The default is calculated by dividing the number of sectors in the file
               system by the number of sectors in a gigabyte. Then, the result is
               multiplied by 32. The default value is always between 16 and 256.

The per-cylinder-group meta data must fit in a space no larger than what is available in one logical file system block. If too large a cgsize is requested, it is changed by the minimum amount necessary.

fragsize=*n*   The smallest amount of disk space in bytes that can be allocated to a file. *fragsize* must be a power of 2 divisor of *bsize*, where:

bsize / *fragsize* is 1, 2, 4, or 8.

This means that if the logical block size is 4096, legal values for *fragsize* are 512, 1024, 2048, and 4096. When the logical block size is 8192, legal values are 1024, 2048, 4096, and 8192. The default value is 1024.

For file systems greater than 1 terabyte or for file systems created with the mtb=y option, *fragsize* is forced to match block size (*bsize*).

free=*n*   The minimum percentage of free space to maintain in the file system between 0% and 99%, inclusively. This space is off-limits to users. Once the file system is filled to this threshold, only the superuser can continue writing to the file system.

The default is ((64 Mbytes/partition size) * 100), rounded down to the nearest integer and limited between 1% and 10%, inclusively.

This parameter can be subsequently changed using the tunefs(1M) command.

gap=*n*   Rotational delay. This option is obsolete in the Solaris 10 release. The value is always set to 0, regardless of the input value.

maxcontig=*n*   The maximum number of logical blocks, belonging to one file, that are allocated contiguously. The default is calculated as follows:

maxcontig = *disk drive maximum transfer size / disk block size*

If the disk drive's maximum transfer size cannot be determined, the default value for maxcontig is calculated from kernel parameters as follows:

If maxphys is less than ufs_maxmaxphys, which is typically 1 Mbyte, then maxcontig is set to maxphys. Otherwise, maxcontig is set to ufs_maxmaxphys.

You can set maxcontig to any positive integer value.

The actual value will be the lesser of what has been specified and what the hardware supports.

You can subsequently change this parameter by using tunefs(1M).

mtb=y   Set the parameters of the file system to allow eventual growth to over
                 a terabyte in total file system size. This option sets *fragsize* to be the
                 same as *bsize*, and sets *nbpi* to 1 Mbyte, unless the -i option is used to
                 make it even larger. If you explicitly set the *fragsize* or *nbpi*
                 parameters to values that are incompatible with this option, the
                 user-supplied value of *fragsize* or *nbpi* is ignored.

N   Print out the file system parameters that would be used to create the
                 file system without actually creating the file system.

nbpi=*n*   The number of bytes per inode, which specifies the density of inodes
                 in the file system. The number is divided into the total size of the file
                 system to determine the number of inodes to create.

                 This value should reflect the expected average size of files in the file
                 system. If fewer inodes are desired, a larger number should be used.
                 To create more inodes, a smaller number should be given. The
                 default is 2048.

                 The number of inodes can increase if the file system is expanded with
                 the growfs command.

nrpos=*n*   The number of different rotational positions in which to divide a
                 cylinder group. The default is 8.

                 This option is not applicable for disks with EFI labels and is ignored.

nsect=*n*   The number of sectors per track on the disk. The default is 32.

ntrack=*n*   The number of tracks per cylinder on the disk. The default is 16.

                 This option is not applicable for disks with EFI labels and is ignored.

opt=*s* | *t*   The file system can either be instructed to try to minimize the *time*
                 spent allocating blocks, or to try to minimize the *space* fragmentation
                 on the disk. The default is *time*.

                 This parameter can be subsequently changed with the tunefs(1M)
                 command.

rps=*n*   The rotational speed of the disk, in revolutions per second. The
                 default is 60.

                 Note that you specify *rps* for mkfs and *rpm* for newfs.

                 This option is not applicable for disks with EFI labels and is ignored.

Alternatively, parameters can be entered as a list of space-separated values (without keywords) whose meaning is positional. In this case, the -o option is omitted and the list follows the size operand. This is the way newfs passes the parameters to mkfs.

Operands The following operands are supported:

raw_device_file   The disk partition on which to write.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also fsck(1M), mkfs(1M), newfs(1M), tunefs(1M), dir_ufs(4), attributes(5), ufs(7FS)

Diagnostics The following error message typically occurs with very high density disks. On such disks, the file system structure cannot encode the proper disk layout information. However, such disks have enough onboard intelligence to make up for any layout deficiencies, so there is no actual impact on performance. The warning that performance might be impaired can be safely ignored.

```
Warning: insufficient space in super block for
rotational layout tables with nsect sblock.fs_nsect
and ntrak sblock.fs_ntrak. (File system performance may be impaired.)
```

The following error message occurs when the disk geometry results in a situation where the last truncated cylinder group cannot contain the correct number of data blocks. Some disk space is wasted.

```
Warning: inode blocks/cyl group (grp) >= data blocks (num) in last cylinder
```

If there is only one cylinder group and if the above condition holds true, mkfs fails with the following error:

```
File system creation failed. There is only one cylinder group and that is
not even big enough to hold the inodes.
```

The following error message occurs when the best calculated file system layout is unable to include the last few sectors in the last cylinder group. This is due to the interaction between how much space is used for various pieces of meta data and the total blocks available in a cylinder group. Modifying nbpi and cpg might reduce this number, but it is rarely worth the effort.

```
Warning: num sector(s) in last cylinder group unallocated
```

Notes You can use lofiadm to create a file that appears to the mkfs command (for example, mkfs_pcfs or mkfs_ufs) as a raw device. You can then use the mkfs command to create a file system on that device. See lofiadm(1M) for examples of creating a UFS and a PC (FAT) file system on a device created by lofiadm.

Both the block and character devices, such as devices in /dev/dsk and /dev/rdsk, must be available prior to running the mkfs command.

Name   mknod – make a special file

Synopsis   mknod *name* b *major minor*

mknod *name* c *major minor*

mknod *name* p

Description   mknod makes a directory entry for a special file.

Options   The following options are supported:

b   Create a block-type special file.

c   Create a character-type special file.

p   Create a FIFO (named pipe).

Operands   The following operands are supported:

major   The *major* device number.

minor   The *minor* device number; can be either decimal or octal. The assignment of major
device numbers is specific to each system. You must be the super-user to use this
form of the command.

name   A special file to be created.

Usage   See largefile(5) for the description of the behavior of mknod when encountering files greater
than or equal to 2 Gbyte (2^{31} bytes).

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   ftp(1), mknod(2), symlink(2), attributes(5), largefile(5)

Notes   If mknod(2) is used to create a device, the major and minor device numbers are always
interpreted by the kernel running on that machine.

With the advent of physical device naming, it would be preferable to create a symbolic link to
the physical name of the device (in the /devices subtree) rather than using mknod.

Name   mkntfs – create an NTFS file system

Synopsis   mkntfs [*options*] *device* [*number_of_sectors*]

mkntfs [-C] [-c *cluster-size*] [-F] [-f] [-H *heads*] [-h] [-I]
        [-L *volume-label*] [-l] [-n] [-p *part-start-sect*] [-Q] [-q]
        [-S *sectors-per-track*] [-s *sector-size*] [-T] [-V] [-v]
        [-z *mft-zone-multiplier*] [--debug] *device* [*number-of-sectors*]

Description   The mkntfs utility is used to create an NTFS file system on a device, usually a disk partition, or
file. The *device* operand is the special file corresponding to the device; for example,
/dev/dsk/c0d0p0. The *number-of-sectors* operand is the number of blocks on the device. If
omitted, mkntfs automatically figures the file system size.

Options   Supported options are listed below. Most options have both single-letter and full-name forms.
Multiple single-letter options that do not take an argument can be combined. For example,
-fv is the equivalent of -f -v. A full-name option can be abbreviated to a unique prefix of its
name.

Options are divided among basic, advanced, output, and help options, as listed below.

Basic Options   -C, --enable-compression
    Enable compression on the volume.

-f, --fast or -q, --quick
    Perform quick (fast) format. This option skips both zeroing of the volume and bad sector
    checking.

-L, --label *string*
    Set the volume label for the filesystem to *string*.

-n, --no-action
    Causes mkntfs to not actually create a file system, but display what it would do if it were to
    create a file system. All formatting steps are carried out except the actual writing to the
    device.

Advanced Options   -c, --cluster-size *bytes*
    Specify the size of clusters in bytes. Valid cluster size values are powers of two, with at least
    256, and at most 65536, bytes per cluster. If omitted, mkntfs uses 4096 bytes as the default
    cluster size.

    Note that the default cluster size is set to be at least equal to the sector size, as a cluster
    cannot be smaller than a sector. Also, note that values greater than 4096 have the side effect
    that compression is disabled on the volume. This is due to limitations in the NTFS
    compression algorithm used by Windows.

-F, --force
    Force mkntfs to run, even if the specified device is not a block special device, or appears to
    be mounted.

-H, --heads *num*

Specify the number of heads. The maximum is 65535 (0xffff). If omitted, mkntfs attempts to determine the number of heads automatically. If that fails a default of 0 is used. Note that specifying *num* is required for Windows to be able to boot from the created volume.

-I, --no-indexing

Disable content indexing on the volume. This option is only meaningful on Windows 2000 and later. Windows NT 4.0 and earlier ignore this, as they do not implement content indexing.

-p, --partition-start *sector*

Specify the partition start sector. The maximum is 4294967295 (2^{32-1}). If omitted, mkntfs attempts to determine *sector* automatically. If that fails, a default of 0 is used. Note that specifying *sector* is required for Windows to be able to boot from the created volume.

-S, --sectors-per-track *num*

Specify the number of sectors per track. The maximum is 65535 (0xffff). If omitted, mkntfs attempts to determine the number of sectors-per-track automatically and if that fails a default of 0 is used. Note that sectors-per-track is required for Windows to be able to boot from the created volume.

-s, --sector-size *bytes*

Specify the size of sectors in bytes. Valid sector size values are 256, 512, 1024, 2048, and 4096. If omitted, mkntfs attempts to determine the sector-size automatically. If that fails, a default of 512 bytes per sector is used.

-T, --zero-time

Fake the time to be 00:00:00 UTC, Jan 1, 1970, instead of the current system time. This can be useful for debugging purposes.

-z, --mft-zone-multiplier *num*

Set the master file table (MFT) zone multiplier, which determines the size of the MFT zone to use on the volume. The MFT zone is the area at the beginning of the volume reserved for the MFT, which stores the on-disk inodes (MFT records). It is noteworthy that small files are stored entirely within the inode; thus, if you expect to use the volume for storing large numbers of very small files, it is useful to set the zone multiplier to a higher value. Although the MFT zone is resized on the fly as required during operation of the NTFS driver, choosing an optimal value reduces fragmentation. Valid values are 1, 2, 3, and 4. The values have the following meaning:

```
MFT zone          MFT zone size
multiplier        (% of volume size)
1        12.5% (default)
2        25.0%
3        37.5%
4        50.0%
```

Output Options --debug

Includes the verbose output from the -v option, as well as additional output useful for debugging mkntfs.

-q, --quiet

Verbose execution. Errors are written to stderr, no output to stdout occurs at all. Useful if mkntfs is run in a script.

-v, --verbose
Verbose execution.

Help Options -h, --help

Show a list of options with a brief description of each one.

-l, --license

Display the mkntfs licensing information and exit.

-V, --version

Display the mkntfs version number and exit.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/ntfsprogs
Interface Stability	Uncommitted

See Also ntfsprogs(1M), ntfsresize(1M), ntfsundelete(1M), attributes(5)

http://wiki.linux-ntfs.org

Authors mkntfs was written by Anton Altaparmakov, Richard Russon, Erik Sornes and Szabolcs Szakacsits.

Name   mkpwdict – maintain password-strength checking database

Synopsis /usr/sbin/mkpwdict [-s *dict1*,... ,*dictN*]
              [-d *destination-path*]

Description The mkpwdict command adds words to the dictionary-lookup database used by
            pam_authtok_check(5) and passwd(1).

            Files containing words to be added to the database can be specified on the command-line
            using the -s flag. These source files should have a single word per line, much like
            /usr/share/lib/dict/words.

            If -s is omitted, mkpwdict will use the value of DICTIONLIST specified in
            /etc/default/passwd (see passwd(1)).

            The database is created in the directory specified by the -d option. If this option is omitted,
            mkpwdict uses the value of DICTIONDBDIR specified in /etc/default/passwd (see passwd(1)).
            The default location is /var/passwd.

Options The following options are supported:

    -s   Specifies a comma-separated list of files containing words to be added to the
          dictionary-lookup database.

    -d   Specifies the target location of the dictionary-database.

Files /etc/default/passwd   See passwd(1).

       /var/passwd   default destination directory

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also passwd(1), attributes(5), pam_authtok_check(5)

Name modinfo – display information about loaded kernel modules

Synopsis /usr/sbin/modinfo [-c] [-w] [-i *module-id*]

Description The modinfo utility displays information about the loaded modules. The format of the information is as follows:

Id Loadaddr Size Info Rev Module Name

where *Id* is the module ID, *Loadaddr* is the starting text address in hexadecimal, *Size* is the size of text, data, and bss in hexadecimal bytes, *Info* is module specific information, *Rev* is the revision of the loadable modules system, and *Module Name* is the filename and description of the module.

The module specific information is the block and character major numbers for drivers, the system call number for system calls, and unspecified for other module types.

Options The following options are supported:

-c   Display the number of instances of the module loaded and the module's current state.

-i *module-id*   Display information about this module only.

-w   Do not truncate module information at 80 characters.

Examples **EXAMPLE 1** Displaying the Status of a Module

The following example displays the status of module 2:

```
example% modinfo -i 2
Id   Loadaddr   Size Info Rev Module Name
 2   ff08e000   1734   -   1  swapgeneric (root and swap configuration)
```

EXAMPLE 2 Displaying the Status of Kernel Modules

The following example displays the status of some kernel modules:

```
example% modinfo
Id Loadaddr   Size Info Rev Module Name
 2 ff08e000   1734   -   1  swapgeneric
 4 ff07a000   3bc0   -   1  specfs (filesystem for specfs)
 6 ff07dbc0   2918   -   1  TS (time sharing sched class)
 7 ff0804d8    49c   -   1  TS_DPTBL (Time sharing dispatch table)
 8 ff04a000  24a30   2   1  ufs (filesystem for ufs)
 9 ff080978   c640 226   1  rpcmod (RPC syscall)
 9 ff080978   c640   -   1  rpcmod (rpc interface str mod)
10 ff08cfb8  2031c   -   1  ip (IP Streams module)
10 ff08cfb8  2031c   2   1  ip (IP Streams device)
```

EXAMPLE 3 Using the -c Option

Using the modinfo command with the -c option displays the number of instances of the module loaded and the module's current state.

```
example% modinfo -c
Id   Loadcnt Module Name                            State
  1         0 krtld                      UNLOADED/UNINSTALLED
  2         0 genunix                    UNLOADED/UNINSTALLED
  3         0 platmod                    UNLOADED/UNINSTALLED
  4         0 SUNW,UltraSPARC-IIi        UNLOADED/UNINSTALLED
  5         0 cl_bootstrap               UNLOADED/UNINSTALLED
  6         1 specfs                       LOADED/INSTALLED
  7         1 swapgeneric                UNLOADED/UNINSTALLED
  8         1 TS                           LOADED/INSTALLED
  9         1 TS_DPTBL                     LOADED/INSTALLED
 10         1 ufs                          LOADED/INSTALLED
 11         1 fssnap_if                    LOADED/INSTALLED
```

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also   modload(1M), modunload(1M), attributes(5)

Name modload – load a kernel module

Synopsis modload [-p] [-e *exec_file*] *filename*

Description The modload command loads the loadable module *filename* into the running system.

filename is an object file produced by ld -r. If *filename* is an absolute pathname then the file specified by that absolute path is loaded. If *filename* does not begin with a slash (/), then the path to load *filename* is relative to the current directory unless the -p option is specified.

The kernel's modpath variable can be set using the /etc/system file. The default value of the kernel's modpath variable is set to the path where the operating system was loaded. Typically this is /kernel /usr/kernel.

For example, the following command looks for ./drv/foo:

example# **modload drv/foo**

The following command looks for /kernel/drv/foo and then /usr/kernel/drv/foo:

example# **modload -p drv/foo**

Options The following options are supported:

-e *exec_file*   Specify the name of a shell script or executable image file that is executed after the module is successfully loaded. The first argument passed is the module ID (in decimal). The other argument is module specific. The module specific information is: the block and character major numbers for drivers, the system call number for system calls, or, for other module types, the index into the appropriate kernel table. See modinfo(1M)

-p   Use the kernel's internal modpath variable as the search path for the module.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also ld(1), add_drv(1M), kernel(1M), modinfo(1M), modunload(1M), system(4), attributes(5), modldrv(9S), modlinkage(9S), modlstrmod(9S), module_info(9S)

Writing Device Drivers

Notes Use add_drv(1M) to add device drivers, not modload. See *Writing Device Drivers* for procedures on adding device drivers.

Name modunload – unload a module

Synopsis modunload -i *module_id* [-e *exec_file*]

Description modunload unloads a loadable module from the running system. The *module_id* is the ID of the module as shown by modinfo(1M). If ID is 0, all modules that were autoloaded which are unloadable, are unloaded. Modules loaded by modload(1M) are not affected.

Options The following options are supported:

-e *exec_file* Specify the name of a shell script or executable image file to be executed before the module is unloaded. The first argument passed is the module id (in decimal). There are two additional arguments that are module specific. For loadable drivers, the second argument is the driver major number. For loadable system calls, the second argument is the system call number. For loadable exec classes, the second argument is the index into the execsw table. For loadable filesystems, the second argument is the index into the vfssw table. For loadable streams modules, the second argument is the index into the fmodsw table. For loadable scheduling classes, the second argument is the index into the class array. Minus one is passed for an argument that does not apply.

-i *module_id* Specify the module to be unloaded.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also modinfo(1M), modload(1M), update_drv(1M), attributes(5)

Notes The modunload command is often used on driver modules to force the system to reread the associated driver configuration file. While this works in the current Solaris release, it is not the supported way to reread the configuration file and is not guaranteed to work in future releases. The supported way for rereading driver configuration file is through the update_drv(1M) command.

Name mofcomp – compile MOF files into CIM classes

Synopsis /usr/sadm/bin/mofcomp [-c *cimom_hostname*] [-h]
        [-j *filename*] [-n *namespace*] [-o *dirname*]
        [-p *password*] [-CIQ] [-u *username*] [-v] [-version]
        [-x] *file*

Description The mofcomp utility is executed during installation to compile managed object format (MOF) files that describe the Common Information Model (CIM) and Solaris Schemas into the CIM Object Manager Repository, a central storage area for management data. The CIM Schema is a collection of class definitions used to represent managed objects that occur in every management environment. The Solaris Schema is a collection of class definitions that extend the CIM Schema and represent managed objects in a typical Solaris operating environment.

The mofcomp utility must be run as root or as a user with write access to the namespace in which you are compiling.

MOF is a language for defining CIM classes and instances. MOF files are ASCII text files that use the MOF language to describe CIM objects. A CIM object is a computer representation or model of a managed resource, such as a printer, disk drive, or CPU.

Many sites store information about managed resources in MOF files. Because MOF can be converted to Java, Java applications that can run on any system with a Java Virtual Machine can interpret and exchange this information. You can also use the mofcomp utility to compile MOF files at any time after installation.

Options The following options are supported:

-c *cimom_hostname*	Specify a remote system running the CIM Object Manager.
-C	Run the compiler set with the class option, which updates a class if it exists, and returns an error if the class does not exist. If you do not specify this option, the compiler adds a CIM class to the connected namespace, and returns an error if the class already exists.
-h	List the arguments to the mofcomp utility.
-I	Run the compiler set with the instance option, which updates an instance if it exists, and returns an error if the instance does not exist. If you do not specify this option, the compiler adds a CIM instance to the connected namespace, and returns an error if the instance already exists.
-j *filename*	Generate Java Beans and Java Interfaces to manage the CIM instances related to the CIM classes in the MOF being compiled.
	The contents of *filename* are:
	PACKAGE=*Java package name* IMPORTS=*import1:...:importN*

<EXCEPTIONS=*exception1:...:exceptionN*

PACKAGE is a valid Java package name to include in all generated Java source. IMPORTS is an optional colon separated list of valid Java classes to be imported in all generated Java source. EXCEPTIONS is an optional colon separated list of valid Java exceptions to be thrown by the methods in all generated Java source.

-n *namespace*   Requests that the compiler load the MOF file into the namespace specified as *namespace*. The default namespace (root\cimv2) is used unless this switch is used or a #pragma *namespace* ("namespace") statement appears in the MOF file. If both the -n *namespace* switch and the #pragma *namespace* construct are used, all namespaces are created, but the objects are created only in the #pragma namespaces.

-o *dirname*   Run compiler in standalone mode, without the CIM Object Manager. Specify dirname as the directory in which the compiler output is to be stored. In this mode, the CIM Object Manager need not be running.

-p *password*   Specify a password for connecting to the CIM Object Manager. Use this option for compilations that require privileged access to the CIM Object Manager. If you specify both -p and -u, you must type the password on the command line, which can pose a security risk. A more secure way to specify a password is to specify -u but not -p, so that the compiler will prompt for the password.

-Q   Run the compiler set with the qualifier types option, which updates a qualifier type if it exists, and returns an error if the qualifier type does not exist. If you do not specify this option, the compiler adds a CIM qualifier type to the connected namespace, and returns an error if the qualifier type already exists.

-u *username*   Specify user name for connecting to the CIM Object Manager. Use this option for compilations that require privileged access to the CIM Object Manager. If you specify both -p and -u, you must type the password on the command line, which can pose a security risk. A more secure way to specify a password is to specify -u but not -p, so that the compiler will prompt for the password.

-v   Run the compiler in verbose mode, which displays compiler messages.

-version   Display the version of the MOF compiler.

-x   Generate XML documents for the CIM classes defined in the input MOF file.

Operands The following operands are supported:

file The pathname of the file to be compiled.

Exit Status The mofcomp utility exits with 0 upon success and a positive integer upon failure.

Files MOF files are installed in /usr/sadm/mof.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWwbco

See Also init.wbem(1M), mofreg(1M), wbemadmin(1M), wbemlogviewer(1M), attributes(5), wbem(5)

Name   mofreg – register MOF classes with WBEM services

Synopsis   /usr/sadm/bin/mofreg -r *tag file*

/usr/sadm/bin/mofreg -s

/usr/sadm/bin/mofreg -u *tag* [*file*]

Description   The mofreg command is used by package and patch install scripts, or by any applications that wish to register managed object format (MOF) classes with Sun The Web-Based Enterprise Management (WBEM) services.

The WBEM services daemon (Common Information Model or CIM object manager) processes at start up the files that are specified by mofreg commands. Files are processed in the order that the individual mofreg commands are executed.

As an alternative to using the mofreg command, MOFs can be registered or unregistered by manipulating directories in /var/sadm/wbem/logr. Instead of running the mofreg -r tag file version fo the command you can create a directory named tag under /var/sadm/wbem/logr/preReg and copy file to the tag directory.

Similarly, instead of running the mofreg -u tag [file] command, you can create a directory named tag under /var/sadm/wbem/logr/preUnreg and copy the optional file to the tag directory.

The entries are processed in increasing order of last modification time of the tag directories. If you issue mofreg commands in rapid succession, the timestamps might be the same. If you have a situation where the timestamp order is critical, you can place appropriate sleeps between the successive registration or unregistration operations. As with the mofreg command, processing is done at next restart or by using the -s option.

This alternative mechanism is typically used in package install scripts which do not have access to /usr, and therefore do not have access to the mofreg command. This case arises when packages are installed for diskless clients.

Options   The following options are supported:

-r *tag file*   The *file* argument is the actual MOF registration file. Its form is identical to the MOF syntax as defined by the Distributed Management Task Force (DMTF). The only difference is the addition of the following 3 new pseudo-pragmas, which are variations of the namespace pragma. The name of file cannot end in .unreg.

```
#pragma namespace("__create")
#pragma namespace("__delete")
#pragma namespace("__modify")
```

These three pragmas are used specify if the elements following the pragmas should be created, deleted, or modified by the CIM object manager. The __delete pragma can currently only be applied for a mofreg -u command.

The *tag* argument is a unique string that specifies the identity of the registry action. This tag can be set to the package name or the patch number if the mofreg script is being invoked through packages/patches, though any tag can be specified.

Errors and warnings that are encountered when the CIM object manager handles the mofreg script are logged. Processing of the mofreg script stops at the first error. Specific warnings include:

```
Element already defined - the element already exists and
cannot be created.

Element not found - the element does not exist and
cannot be modified.
```

The error conditions are:

```
Key modification - A class cannot be modified if its keys
are being changed.

Other mod compilation errors.
```

-s   Forces the CIM object manager to immediately process outstanding registry requests, instead of at the next restart. This currently requires Java.

-u *tag* [*file*]   Undoes the operations performed during mof registry.

The *tag* argument must correspond to the value set during the original mofreg invocation. If no mofreg was done with the original *tag*, the command does not succeed.

If required, an *unreg* file can be specified. If no *unreg* file is specified, the CIM object manager automatically undoes the actions of the registry. Any class created by the registry process is removed and any classes modified by the registry revert to the old state.

The mofreg command does not take care of cases where packages and patches make conflicting changes to classes. This should be taken care of by the standard patch and package conflict resolution.

Exit Status   The following exit values are returned:

0   Successful completion.

1   An error occurred. The reason for error is displayed.

Name monitor – SPARC system PROM monitor

Synopsis STOP–A

BREAK

initial system power-on

exit from a client program, e.g., the Operating System

Description The CPU board of a workstation contains one or more EPROMs or EEPROMs. The program which executes from the PROMs is referred to as "the monitor". Among other things, the monitor performs system initialization at power-on and provides a user interface.

Monitor Prompt The monitor of earlier workstations was known as the SunMON monitor and displayed the > for its prompt. See the SunMON MONITOR USAGE section for further details.

Existing workstations use a monitor which is known as the OpenBoot monitor. The OpenBoot monitor typically displays ok as its prompt, but it may also display the > prompt under certain circumstances.

If the 'auto-boot?' NVRAM parameter is set to 'false' when the workstation is powered on, the system does not attempt to boot and the monitor issues its prompt. If 'auto-boot' is set to 'true', the system initiates the boot sequence. The boot sequence can be aborted by simultaneously pressing two keys on the system's keyboard: L1 and A (on older keyboards), or Stop and A (on newer keyboards). Either a lower case a or an upper case A works for the keyboard abort sequence. If a console has been attached by way of one of the system's serial ports then the abort sequence can be accomplished by sending a BREAK. See tip(1).

When the NVRAM 'security-mode' parameter has been turned on, or when the value of the 'sunmon-compat?' parameter is true, then the OpenBoot monitor displays the message: Type b (boot), c (continue), or n (new command mode)

and the > prompt appears.

Openboot Prom Usage Some of the more useful commands that can be issued from OpenBoot's ok prompt are described here. Refer to the *OpenBoot 2.x Command Reference Manual* book for a complete list of commands.

Help Help for various functional areas of the OpenBoot monitor can be obtained by typing help. The help listing provides a number of other key words which can then be used in the help command to provide further details.

NVRAM Parameters Each workstation contains one or more NVRAM devices which contains unique system ID information, as well as a set of user-configurable parameters. The NVRAM parameters allow the user a certain level of flexibility in configuring the system to act in a given manner under a specific set of circumstances.

See eeprom(1M) for a description of the parameters and information regarding setting the parameters from the OS level.

The following commands can be used at the OpenBoot monitor to access the NVRAM parameters.

printenv   Used to list the NVRAM parameters, along with their default values and current values.

setenv *pn pv*   Used to set or modify a parameter. The *pn* represents the parameter name, and *pv* represents the parameter value.

set-default *pn*   Used to set an individual parameter back to its default value.

set-defaults   Used to reset all parameters to their default values. (Note that 'set-defaults' only affects parameters that have assigned default values.)

Security Parameters   Newer OpenBoot monitors contain user interfaces that support the storage and listing of keys for later use by client programs.

list-security-keys   Lists the names of keys currently stored on a machine.

set-security-key *keyname* [*keydata*]   Stores key data *keydata* in a key named *keyname*. Actual key data can be up to 32 bytes in length. The maximum length of *keyname* is 64 bytes, which allows for the hex-formatted ASCII used to present the key data. If *keydata* is not present, *keyname* and its corresponding data is deleted.

Hardware Checks and Diagnostics   The following commands are available for testing or checking the system's hardware. If the 'diag-switch?' NVRAM parameter is set to true when the system is powered on, then a Power-On Self Test (POST) diagnostic is run, if present, sending its results messages to the system's serial port A. Not all of the commands shown are available on all workstations.

test-all   Run the diagnostic tests on each device which has provided a self-test.

test /memory   Run the main memory tests. If the NVRAM parameter 'diag-switch?' is set to true, then all of main memory is tested. If the parameter is false then only the amount of memory specified in the 'selftest-#megs' NVRAM parameter is tested.

test net   Test the network connection for the on-board network controller.

watch-net   Monitor the network attached to the on-board net controller.

watch-net-all   Monitor the network attached to the on-board net controller, as well as the network controllers installed in SBus slots.

watch-clock   Test the system's clock function.

System Information   The following commands are available for displaying information about the system. Not all commands are available on all workstations.

banner	Display the power-on banner.
.enet-addr	Display the system's Ethernet address.
.idprom	Display the formatted contents of the IDPROM.
module-info	Display information about the system's processor(s).
probe-scsi	Identify the devices attached to the on-board SCSI controller.
probe-scsi-all	Identify the devices attached to the on-board SCSI controller as well as those devices which are attached to SBus SCSI controllers.
show-disks	Display a list of the device paths for installed SCSI disk controllers.
show-displays	Display a list of the device paths for installed display devices.
show-nets	Display a list of the device paths for installed Ethernet controllers.
show-sbus	Display list of installed SBus devices.
show-tapes	Display a list of the device paths for installed SCSI tape controllers.
show-ttys	Display a list of the device paths for tty devices.
.traps	Display a list of the SPARC trap types.
.version	Display the version and date of the OpenBoot PROM.

Emergency Commands   These commands must be typed from the keyboard, they do not work from a console which is attached by way of the serial ports. With the exception of the Stop-A command, these commands are issued by pressing and holding down the indicated keys on the keyboard immediately after the system has been powered on. The keys must be held down until the monitor has checked their status. The Stop-A command can be issued at any time after the console display begins, and the keys do not need to be held down once they've been pressed. The Stop-D, Stop-F and Stop-N commands are not allowed when one of the security modes has been set. Not all commands are available on all workstations.

Stop (L1)	Bypass the Power-On Self Test (POST). This is only effective if the system has been placed into the diagnostic mode.
Stop-A (L1-A)	Abort the current operation and return to the monitor's default prompt.
Stop-D (L1-D)	Set the system's 'diag-switch?' NVRAM parameter to 'true', which places the system in diagnostic mode. POST diagnostics, if present, are run, and the messages are displayed by way of the system's serial port A.
Stop-F (L1-F)	Enter the OpenBoot monitor before the monitor has probed the system for devices. Issue the 'fexit' command to continue with system initialization.

Stop-N (L1-N)   Causes the NVRAM parameters to be reset to their default values. Note that not all parameters have default values.

Line Editor Commands The following commands can be used while the monitor is displaying the ok prompt. Not all of these editing commands are available on all workstations.

CTRL-A   Place the cursor at the start of line.

CTRL-B   Move the cursor backward one character.

ESC-B   Move the cursor backward one word.

CTRL-D   Erase the character that the cursor is currently highlighting.

ESC-D   Erase the portion of word from the cursor's present position to the end of the word.

CTRL-E   Place the cursor at the end of line.

CTRL-F   Move the cursor forward one character.

ESC-F   Move the cursor forward one word.

CTRL-H   Erase the character preceding the cursor (also use Delete or Back Space)

ESC-H   Erase the portion of the word which precedes the cursor (use also CTRL-W)

CTRL-K   Erase from the cursor's present position to the end of the line.

CTRL-L   Show the command history list.

CTRL-N   Recall the next command from the command history list

CTRL-P   Recall a previous command from the command history list.

CTRL-Q   Quote the next character (used to type a control character).

CTRL-R   Retype the current line.

CTRL-U   Erase from the cursor's present position to the beginning of the line.

CTRL-Y   Insert the contents of the memory buffer into the line, in front (to the left) of the cursor.

nvramrc The nvramrc is an area of the system's NVRAM where users may store Forth programs. The programs which are stored in the nvramrc are executed each time the system is reset, provided that the 'use-nvramrc?' NVRAM parameter has been set to 'true'. Refer to the *OpenBoot 2.x Command Reference Manual* book for information on how to edit and use the nvramrc.

Restricted Monitor The command 'old-mode' is used to move OpenBoot into a restricted monitor mode, causing the > prompt to be displayed. Only three commands are allowed while in the restricted monitor; the 'go' command (to resume a program which was interrupted with the

Stop-A command), the 'n' command (to return to the normal OpenBoot monitor), and boot commands. The restricted monitor's boot commands approximate the older SunMON monitor's boot command syntax. If a 'security-mode' has been turned on then the restricted monitor becomes the default monitor environment. The restricted monitor may also become the default environment if the 'sunmon-compat?' NVRAM parameter is set to true. Not all workstations have the 'sunmon-compat?' parameter.

SunMON Prom Usage

The following commands are available systems with older SunMON-based PROM:

+|−
    Increment or decrement the current address and display the contents of the new location.

^C *source destination n*
    (caret-C) Copy, byte-by-byte, a block of length *n* from the source address to the *destination* address.

^I *program*
    (caret-I) Display the compilation date and location of *program*.

^T *virtual_address*
    (caret-T) Display the physical address to which *virtual_address* is mapped.

b [!] [*device* [(*c* , *u* , *p*)]] [*pathname*] [*arguments_list*]

b[?]
    Reset appropriate parts of the system and bootstrap a program. A '!' (preceding the *device* argument) prevents the system reset from occurring. Programs can be loaded from various devices (such as a disk, tape, or Ethernet). 'b' with no arguments causes a default boot, either from a disk, or from an Ethernet controller. 'b?' displays all boot devices and their *device*s.

device	one of	
	le	Lance Ethernet
	ie	Intel Ethernet
	sd	SCSI disk, CDROM
	st	SCSI 1/4– or 1/2–inch tape
	fd	Diskette
	id	IPI disk
	mt	Tape Master 9-track 1/2–inch tape
	xd	Xylogics 7053 disk
	xt	Xylogics 1/2–inch tape
	xy	Xylogics 440/450 disk

c	A controller number (0 if only one controller),
u	A unit number (0 if only one driver), and
p	A partition.
pathname	A pathname for a program such as /stand/diag.
arguments_list	A list of up to seven arguments to pass to the program being booted.

c [*virtual_address*]

Resume execution of a program. When given, *virtual_address* is the address at which execution resumes. The default is the current PC. Registers are restored to the values shown by the d, and r commands.

d [*window_number*]

Display (dump) the state of the processor. The processor state is observable only after:

- An unexpected trap was encountered.
- A user program dropped into the monitor (by calling *abortent*).
- The user manually entered the monitor by typing L1−A or BREAK.

The display consists of the following:

- The special registers: PSR, PC, nPC, TBR, WIM, and Y
- Eight global registers
- 24 window registers (8 *in*, 8 *local*, and 8 *out*), corresponding to one of the 7 available windows. If a Floating-Point Unit is on board, its status register along with 32 floating-point registers are also shown.

window_number   Display the indicated *window_number*, which can be any value between 0 and 6, inclusive. If no window is specified and the PSR's current window pointer contains a valid window number, registers from the window that was active just prior to entry into the monitor are displayed. Otherwise, registers from window 0 are displayed.

e [*virtual_address*] [*action*] . . .

Open the 16-bit word at *virtual_address* (default zero). The address is interpreted in the address space defined by the s command. See the a command for a description of *action*.

f *virtual_address1 virtual_address2 pattern* [*size*]

Fill the bytes, words, or long words from *virtual_address1* (lower) to *virtual_address2* (higher) with the constant, *pattern*. The size argument can take one of the following values:

b   byte format (the default)

w   word format

l   long word format

For example, the following command fills the address block from `0x1000` to `0x2000` with the word pattern, `0xABCD`:

```
f 1000 2000 ABCD W
```

g [*vector*] [*argument*]
g [*virtual_address*] [*argument*]

Goto (jump to) a predetermined or default routine (first form), or to a user-specified routine (second form). The value of *argument* is passed to the routine. If the *vector* or *virtual_address* argument is omitted, the value in the PC is used as the address to jump to.

To set up a predetermined routine to jump to, a user program must, prior to executing the monitor's g command, set the variable *romp->v_vector_cmd to be equal to the virtual address of the desired routine. Predetermined routines need not necessarily return control to the monitor.

The default routine, defined by the monitor, prints the user-supplied *vector* according to the format supplied in *argument*. This format can be one of:

%x   hexadecimal

%d   decimal

g0

Force a panic and produce a crash dump when the monitor is running as a result of the system being interrupted,

g4

(Sun-4 systems only) Force a kernel stack trace when the monitor is running as a result of the system being interrupted,

h

Display the help menu for monitor commands and their descriptions. To return to the monitor's basic command level, press ESCAPE or q before pressing RETURN.

i [*cache_data_offset*] [*action*] . . .

Modify cache data RAM command. Display and/or modify one or more of the cache data addresses. See the a command for a description of *action*.

j [*cache_tag_offset*] [*action*] . . .

Modify cache tag RAM command. Display and/or modify the contents of one or more of the cache tag addresses. See the a command for a description of *action*.

k [*reset_level*]

Reset the system, where *reset_level* is:

0   Reset VMEbus, interrupt registers, video monitor (Sun-4 systems). This is the default.

1   Software reset.

2   Power-on reset. Resets and clears the memory. Runs the EPROM-based diagnostic self test, which can take several minutes, depending upon how much memory is being tested.

kb

Display the system banner.

l [*virtual_address*] [*action*] . . .
Open the long word (32 bit) at memory address *virtual_address* (default zero). The address is interpreted in the address space defined by the s command (below). See the a command for a description of *action*.

m [*virtual_address*] [*action*] . . .
Open the segment map entry that maps *virtual_address* (default zero). The address is interpreted in the address space defined by the s command. See the a command for a description of *action*.

ne

ni

Disable, enable, or invalidate the cache, respectively.

o [*virtual_address*] [action*] . . .
Open the byte location specified by *virtual_address* (default zero). The address is interpreted in the address space defined by the s command. See the a command for a description of *action*.

p [*virtual_address*] [*action*]. . .
Open the page map entry that maps *virtual_address* (default zero) in the address space defined by the s command. See the a command for a description of *action*.

q [*eeprom_offset*] [*action*]. . .
Open the EEPROM *eeprom_offset* (default zero) in the EEPROM address space. All addresses are referenced from the beginning or base of the EEPROM in physical address space, and a limit check is performed to insure that no address beyond the EEPROM physical space is accessed. This command is used to display or modify configuration parameters, such as: the amount of memory to test during self test, whether to display a standard or custom banner, if a serial port (A or B) is to be the system console, etc. See the a command for a description of *action*.

r [*register_number*]
r [*register_type*]
r [*w window_number*]
Display and/or modify one or more of the IU or FPU registers. A hexadecimal *register_number* can be one of:

0x00−0x0f   window(0,i0)−window(0,i7), window(0,i0)—window(0,i7)

0x16−0x1f   window(1,i0)−window(1,i7), window(1,i0)—window(1,i7)

`0x20–0x2f`	window(2,i0)–window(2,i7), window(2,i0)—window(2,i7)
`0x30–0x3f`	window(3,i0)–window(3,i7), window(3,i0)—window(3,i7)
`0x40–0x4f`	window(4,i0)–window(4,i7), window(4,i0)—window(4,i7)
`0x50–0x5f`	window(5,i0)–window(5,i7), window(5,i0)—window(5,i7)
`0x60–0x6f`	window(6,i0)–window(6,i7), window(6,i0)—window(6,i7)
`0x70–0x77`	`g0, g1, g2, g3, g4, g5, g6, g7`
`0x78–0x7d`	PSR, PC, nPC, WIM, TBR, Y.
`0x7e–0x9e`	FSR, f0–f31

Register numbers can only be displayed after an unexpected trap, a user program has entered the monitor using the *abortent* function, or the user has entered the monitor by manually typing L1−A or BREAK.

If a *register_type* is given, the first register of the indicated type is displayed. *register_type* can be one of:

f   floating-point

g   global

s   special

If w and a *window_number* (`0`—`6`) are given, the first *in*-register within the indicated window is displayed. If *window_number* is omitted, the window that was active just prior to entering the monitor is used. If the PSR's current window pointer is invalid, window 0 is used.

s [*asi*])
Set or display the Address Space Identifier. With no argument, s displays the current Address Space Identifier. The *asi* value can be one of:

`0x2`   control space

`0x3`   segment table

`0x4`   Page table

`0x8`   user instruction

`0x9`   supervisor instruction

`0xa`   user data

`0xb`   supervisor data

`0xc`   flush segment

        0xd   flush page

        0xe   flush context

        0xf   cache data

u [echo]

u [*port*] [*options*] [*baud_rate*]

u [u] [*virtual_address*]
> With no arguments, display the current I/O device characteristics including: current input device, current output device, baud rates for serial ports A and B, an input-to-output echo indicator, and virtual addresses of mapped UART devices. With arguments, set or configure the current I/O device. With the u argument (uu. . .), set the I/O device to be the *virtual_address* of a UART device currently mapped.

    echo   Can be either e to enable input to be echoed to the output device, or ne, to indicate that input is not echoed.

    port   Assign the indicated *port* to be the current I/O device. *port* can be one of:

            a   serial port A

            b   serial port B

            k   the workstation keyboard

            s   the workstation screen

    baud_rate   Any legal baud rate.

    options   can be any combination of:

            i   input

            o   output

            u   UART

            e   echo input to output

            ne   do not echo input

            r   reset indicated serial port (a and b ports only)

            If either a or b is supplied, and no *options* are given, the serial port is assigned for both input and output. If k is supplied with no options, it is assigned for input only. If s is supplied with no options, it is assigned for output only.

v *virtual_address1 virtual_address2* [size]
> Display the contents of *virtual_address1* (lower) *virtual_address2* (higher) in the format specified by size:

    b   byte format (the default)

w   word format

l   long word format

Enter return to pause for viewing; enter another return character to resume the display. To terminate the display at any time, press the space bar.

For example, the following command displays the contents of virtual address space from address 0x1000 to 0x2000 in word format:

v 1000 2000 W

w [*virtual_address*] [*argument*]
Set the execution vector to a predetermined or default routine. Pass *virtual_address* and *argument* to that routine.

To set up a predetermined routine to jump to, a user program must, prior to executing the monitor's w command, set the variable *romp->v_vector_cmd to be equal to the virtual address of the desired routine. Predetermined routines need not necessarily return control to the monitor.

The default routine, defined by the monitor, prints the user-supplied *vector* according to the format supplied in *argument*. This format can be one of:

%x   hexadecimal

%d   decimal

x

Display a menu of extended tests. These diagnostics permit additional testing of such things as the I/O port connectors, video memory, workstation memory and keyboard, and boot device paths.

y c *context_number*
Display context number.

y p|s *context_number virtual_address*
Flush the indicated context, context page, or context segment.

c   flush context *context_number*

p   flush the page beginning at *virtual_address* within context *context_number*

s   flush the segment beginning at *virtual_address* within context *context_number*

Attributes   See attributes(5) for descriptions of the following attributes:

OpenBoot 2.x Command Reference Manual

Name mount, umount – mount or unmount file systems and remote resources

Synopsis mount [-p | -v]

mount [-F *FSType*] [*generic_options*] [-o *specific_options*]
    [-O] *special* | *mount_point*

mount [-F *FSType*] [*generic_options*] [-o *specific_options*]
    [-O] *special mount_point*

mount -a [-F *FSType*] [-V] [*current_options*]
    [-o *specific_options*] [*mount_point*]...

umount [-f] [-V] [-o *specific_options*] *special* | *mount_point*

umount -a [-f] [-V] [-o *specific_options*] [*mount_point*]...

Description mount attaches a file system to the file system hierarchy at the *mount_point*, which is the pathname of a directory. If *mount_point* has any contents prior to the mount operation, these are hidden until the file system is unmounted.

umount unmounts a currently mounted file system, which may be specified either as a *mount_point* or as *special*, the device on which the file system resides.

The table of currently mounted file systems can be found by examining the mounted file system information file. This is provided by a file system that is usually mounted on /etc/mnttab. The mounted file system information is described in mnttab(4). Mounting a file system adds an entry to the mount table; a umount removes an entry from the table.

When invoked with both the *special* and *mount_point* arguments and the -F option, mount validates all arguments except for *special* and invokes the appropriate *FSType*-specific mount module. If invoked with no arguments, mount lists all the mounted file systems recorded in the mount table, /etc/mnttab. If invoked with a partial argument list (with only one of *special* or *mount_point*, or with both *special* or *mount_point* specified but not *FSType*), mount will search /etc/vfstab for an entry that will supply the missing arguments. If no entry is found, and the special argument starts with /, the default local file system type specified in /etc/default/fs will be used. Otherwise the default remote file system type will be used. The default remote file system type is determined by the first entry in the /etc/dfs/fstypes file. After filling in missing arguments, mount will invoke the *FSType*-specific mount module.

For file system types that support it, a file can be mounted directly as a file system by specifying the full path to the file as the special argument. In such a case, the nosuid option is enforced. If specific file system support for such loopback file mounts is not present, you can still use lofiadm(1M) to mount a file system image. In this case, no special options are enforced.

Only a user with sufficient privilege (at least PRIV_SYS_MOUNT) can mount or unmount file systems using mount and umount. However, any user can use mount to list mounted file systems and resources.

Options -F *FSType*

Used to specify the *FSType* on which to operate. The *FSType* must be specified or must be determinable from `/etc/vfstab`, or by consulting `/etc/default/fs` or `/etc/dfs/fstypes`.

-a [*mount_points...*]

Perform mount or umount operations in parallel, when possible.

If mount points are not specified, mount will mount all file systems whose `/etc/vfstab` "mount at boot" field is yes. If mount points are specified, then `/etc/vfstab` "mount at boot" field will be ignored.

If mount points are specified, umount will only umount those mount points. If none is specified, then umount will attempt to unmount all file systems in `/etc/mnttab`, with the exception of certain system required file systems: `/`, `/usr`, `/var`, `/var/adm`, `/var/run`, `/proc`, `/dev/fd` and `/tmp`.

-f

Forcibly unmount a file system.

Without this option, umount does not allow a file system to be unmounted if a file on the file system is busy. Using this option can cause data loss for open files; programs which access files after the file system has been unmounted will get an error (`EIO`).

-p

Print the list of mounted file systems in the `/etc/vfstab` format. Must be the only option specified. See `BUGS`.

-v

Print the list of mounted file systems in verbose format. Must be the only option specified.

-V

Echo the complete command line, but do not execute the command. umount generates a command line by using the options and arguments provided by the user and adding to them information derived from `/etc/mnttab`. This option should be used to verify and validate the command line.

generic_options

Options that are commonly supported by most *FSType*-specific command modules. The following options are available:

-m

Mount the file system without making an entry in `/etc/mnttab`.

-g

Globally mount the file system. On a clustered system, this globally mounts the file system on all nodes of the cluster. On a non-clustered system this has no effect.

-o

Specify *FSType*-specific options in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the *FSType*-specific module of the command. (See mount_ufs(1M).) When you use -o with a file system that has an entry in /etc/vfstab, any mount options entered for that file system in /etc/vfstab are ignored.

The following options are supported:

devices | nodevices
   Allow or disallow the opening of device-special files. The default is devices.

   If you use nosuid in conjunction with devices, the behavior is equivalent to that of nosuid.

exec | noexec
   Allow or disallow executing programs in the file system. Allow or disallow mmap(2) with PROT_EXEC for files within the file system. The default is exec.

loop
   Ignored for compatibility.

nbmand | nonbmand
   Allow or disallow non-blocking mandatory locking semantics on this file system. Non-blocking mandatory locking is disallowed by default.

   If the file system is mounted with the nbmand option, then applications can use the fcntl(2) interface to place non-blocking mandatory locks on files and the system enforces those semantics. If you enable this option, it can cause standards conformant applications to see unexpected errors.

   To avoid the possibility of obtaining mandatory locks on system files, do not use the nbmand option with the following file systems:

   /
   /usr
   /etc
   /var
   /proc
   /dev
   /devices
   /system/contract
   /system/object
   /etc/mnttab
   /etc/dfs/sharetab

   Do not use the remount option to change the nbmand disposition of the file system. The nbmand option is mutually exclusive of the global option. See -g.

ro | rw
:   Specify read-only or read-write. The default is rw.

setuid | nosetuid
:   Allow or disallow setuid or setgid execution. The default is setuid.

    If you specify setuid in conjunction with nosuid, the behavior is the same as nosuid.

    nosuid is equivalent to nosetuid and nodevices. When suid or nosuid is combined with setuid or nosetuid and devices or nodevices, the most restrictive options take effect.

    This option is highly recommended whenever the file system is shared by way of NFS with the root= option. Without it, NFS clients could add setuid programs to the server or create devices that could open security holes.

suid | nosuid
:   Allow or disallow setuid or setgid execution. The default is suid. This option also allows or disallows opening any device-special entries that appear within the filesystem.

    nosuid is equivalent to nosetuid and nodevices. When suid or nosuid is combined with setuid or nosetuid and devices or nodevices, the most restrictive options take effect.

    This option is highly recommended whenever the file system is shared using NFS with the root=*option*, because, without it, NFS clients could add setuid programs to the server, or create devices that could open security holes.

rstchown | norstchown
:   Allow or disallow restricted chown. If the file system is mounted with rstchown, the owner of the file is prevented from changing the owner ID of the file. If the file system is mounted with norstchown, the user can permit ownership changes for files they own. Only the super-user or a user with appropriate privilege can arbitrarily change owner IDs.

-O
:   Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error "device busy".

-r
:   Mount the file system read-only.

Examples EXAMPLE 1   Mounting and Unmounting a DVD Image Directly

The following commands mount and unmount a DVD image.

EXAMPLE 1 Mounting and Unmounting a DVD Image Directly   *(Continued)*

```
# mount -F hsfs /images/solaris.iso /mnt/solaris-image
# umount /mnt/solaris-image
```

Usage   See largefile(5) for the description of the behavior of mount and umount when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files   /etc/mnttab
   Table of mounted file systems.

   /etc/default/fs
   Default local file system type. Default values can be set for the following flags in /etc/default/fs. For example: LOCAL=ufs

   LOCAL:
      The default partition for a command if no *FSType* is specified.

   /etc/vfstab
   List of default parameters for each file system.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   lofiadm(1M), mount_hsfs(1M), mount_nfs(1M), mount_pcfs(1M), mount_smbfs(1M), mount_tmpfs(1M), mount_udfs(1M), mount_ufs(1M), mountall(1M), umountall(1M), fcntl(2), mmap(2), mnttab(4), vfstab(4), attributes(5), largefile(5), privileges(5), lofs(7FS), pcfs(7FS)

Notes   If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

Bugs   The mount -p output is incorrect for cachefs.

Name mountall, umountall – mount, unmount multiple file systems

Synopsis mountall [-F *FSType*] [-l | -r] [*file_system_table*]

umountall [-k] [-s] [-F *FSType*] [-l | -r] [-n] [-Z]

umountall [-k] [-s] [-h *host*] [-n] [-Z]

Description mountall is used to mount file systems specified in a file system table. The file system table must be in vfstab(4) format. If no *file_system_table* is specified, /etc/vfstab is used. If – is specified as *file_system_table*, mountall reads the file system table from the standard input. mountall mounts only those file systems with the mount at boot field set to yes in the *file_system_table*.

For each file system in the file system table, the following logic is executed: if there exists a file/usr/lib/fs/*FSType*/fsckall, where *FSType* is the type of the file system, save that file system in a list to be passed later, and all at once, as arguments to the /usr/lib/fs/*FSType*/fsckall script. The /usr/lib/fs/*FSType*/fsckall script checks all of the file systems in its argument list to determine whether they can be safely mounted. If no /usr/lib/fs/*FSType*/fsckall script exists for the *FSType* of the file system, the file system is individually checked using fsck(1M). If the file system does not appear mountable, it is fixed using fsck before the mount is attempted. File systems with a – entry in the fsckdev field are mounted without first being checked.

umountall causes all mounted file systems in the current zone except root, /usr, /var, /var/adm, /var/run, /proc, and /dev/fd to be unmounted. If the *FSType* is specified, mountall and umountall limit their actions to the *FSType* specified. There is no guarantee that umountall unmounts *busy* file systems, even if the -k option is specified.

Options The following options are supported:

-F   Specify the *FSType* of the file system to be mounted or unmounted.

-h *host*   Unmount all file systems listed in /etc/mnttab that are remote-mounted from host.

-k   Use the fuser -k *mount-point* command. See the fuser(1M) for details. The -k option sends the SIGKILL signal to each process using the file. As this option spawns kills for each process, the kill messages might not show up immediately. There is no guarantee that umountall unmounts *busy* file systems, even if the -k option is specified.

-l   Limit the action to local file systems.

-n   List the actions that would be performed for the specified options, but do not actually execute these actions. Repeating the command without the -n option executes the listed actions, assuming that the /etc/mnttab file has not changed in the interval prior to repeating the command.

-r   Limit the action to remote file system types.

-s   Do not perform the umount operation in parallel.

-Z   Apply the action(s) only to the file systems mounted in non-global zones. By
          default, umountall unmounts only file systems mounted in the current zone.
          Option -Z is ignored if used in a non-global zone.

Files /etc/mnttab
           Mounted file system table

/etc/vfstab
  Table of file system defaults

/usr/lib/fs/*FSType*/fsckall
  Script called by mountall to perform the file system check of all file systems of type *FSType*

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed
Output Stability	Uncommitted

See Also fsck(1M), fuser(1M), mount(1M), mnttab(4), vfstab(4), attributes(5)

Diagnostics No messages are printed if the file systems are mountable and clean.

Error and warning messages come from fsck(1M) and mount(1M).

Notes At this time, NFS is the only remote file system supported by the -l, -r, and -h options.

Name mountd – server for NFS mount requests and NFS access checks

Synopsis /usr/lib/nfs/mountd [-v] [-r]

Description mountd is an RPC server that answers requests for NFS access information and file system mount requests. It reads the file /etc/dfs/sharetab to determine which file systems are available for mounting by which remote machines. See sharetab(4). nfsd running on the local server will contact mountd the first time an NFS client tries to access the file system to determine whether the client should get read-write, read-only, or no access. This access can be dependent on the security mode used in the remoted procedure call from the client. See share_nfs(1M).

The command also provides information as to what file systems are mounted by which clients. This information can be printed using the showmount(1M) command.

The mountd daemon is automatically invoked by share(1M).

Only super user can run the mountd daemon.

SMF Management Since mountd must be running for nfsd to function properly, mountd is automatically started by the svc:/network/nfs/server service.

Startup SMF parameters for mountd can be manipulated using the sharectl(1M) command. The currently supported parameters are:

client_versmin=*num*
client_versmax=*num*
> The NFS client uses only NFS versions in the range specified by these variables. Valid values or versions are: 2, 3, and 4. By default, these variables are unspecified (commented out) and the client's default minimum is Version 2. The default maximum is version 4. You can override this range on a per-mount basis by using the -o vers= option to mount_nfs(1M).

Options The options shown below are supported for NVSv2/v3 clients. They are not supported for Solaris NFSv4 clients.

-r   Reject mount requests from clients. Clients that have file systems mounted will not be affected.

-v   Run the command in verbose mode. Each time mountd determines what access a client should get, it will log the result to the console, as well as how it got that result.

Files /etc/dfs/sharetab   shared file system table

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/file-system/nfs

See Also mount_nfs(1M), nfsd(1M), share(1M), share_nfs(1M), sharectl(1M), showmount(1M), sharetab(4), attributes(5)

Notes Some routines that compare hostnames use case-sensitive string comparisons; some do not. If an incoming request fails, verify that the case of the hostname in the file to be parsed matches the case of the hostname called for, and attempt the request again.

Name mount_hsfs – mount hsfs file systems

Synopsis mount -F hsfs [*generic_options*]
          [-o *FSType-specific_options*] [-O] *special* | *mount_point*

mount -F hsfs [*generic_options*]
          [-o *FSType-specific_options*] [-O] *special* *mount_point*

Description mount attaches an ISO 9660 filesystem (the High Sierra file system, hsfs, is a draft predecessor to ISO 9660, so the name reflects the filesystem's history) to the file system hierarchy at the *mount_point*, which is the pathname of a directory. If *mount_point* has any contents prior to the mount operation, these are hidden until the file system is unmounted.

If mount is invoked with *special* or *mount_point* as the only arguments, mount will search /etc/vfstab to fill in the missing arguments, including the *FSType-specific_options*; see mount(1M) for more details.

The hsfs file system supports direct mounting of files containing the file system as well as block devices. See mount(1M) and lofiadm(1M).

A file system conforming to ISO 9660 can contain extensions that allow it to overcome limitations of the original ISO 9660:1988 (version 1) standard. The following types of extensions are supported by hsfs:

Rock Ridge extensions
  This is the preferred type of extension as it allows file attributes, name length, and types equivalent to those on other UNIX-style filesystems. Example of supported features are device special files, POSIX permissions, symbolic links, and filenames of up to 255 bytes in length. Rock Ridge extensions also remove the ISO9660:1988 restriction on maximum nesting depth for directories (eight levels). hsfs automatically detects the presence of Rock Ridge extensions and uses them, unless mount options are specified to disable the use of Rock Ridge or to use a different extension.

ISO9660:1999 (version 2) extensions
  The first version of ISO9660, released in 1988, supported only uppercase ASCII filenames of no more than 31 characters in length. ISO9660 version 2, released in 1999, provides an extension that allows filenames of at least 207 bytes that can use UTF-8 characters and removes the limitation on the nesting depth for directories. Unlike Rock Ridge, it does not provide support for UNIX-style file types and file attributes. hsfs automatically detects this extension and will use it for filename lookup if no Rock Ridge extensions are found on the media.

Joliet extensions
  The Joliet extension was devised by Microsoft to allow Unicode (UCS-2) long filenames with CDROM-based media. It allows filename lengths of up to 110 Unicode characters and does not support UNIX-style file types and attributes. hsfs falls back to using Joliet if such an extension is present and neither Rock Ridge nor ISO9660 version 2 extensions are found.

If filenames are longer than the 64 UCS-2 characters officially allowed by Microsoft (that is, 110 Unicode characters), they can translate to up to 330 UTF-8 octets. Filenames that translate to more than 255 UTF-8 octets will be truncated.

Options   *generic_options*

See mount(1M) for the list of supported options.

-o

Specify hsfs file system specific options. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available:

global | noglobal

If global is specified and supported on the file system, and the system in question is part of a cluster, the file system will be globally visible on all nodes of the cluster. If noglobal is specified, the mount will not be globally visible. The default behavior is noglobal.

ro

Mount the file system read-only. This option is required.

rr | nrr

Enable (rr) or disable (nrr) the use of Rock Ridge. rr is the default and need not be specified. If you use nrr and Rock Ridge extensions are present in the file system, ignore them and search for other available extensions or fall back to plain ISO9660.

vers2 | novers2

Enable or disable the use of ISO9660 version 2 extensions. If vers2 is specified and ISO9660 version 2 extensions are available, hsfs will use ISO9660 version 2 even if the file system contains the preferred Rock Ridge extensions as well. If novers2 is specified, it will fall back to using either Joliet extensions or plain ISO9660 even if ISO9660 version 2 extensions are available.

joliet | nojoliet

Enable or disable the use of Joliet extensions. If joliet is specified and Joliet extensions are available, hsfs will use them even if the file system contains the preferred Rock Ridge and/or ISO9660 version 2 extensions. If nojoliet is specified, it will fall back to using plain ISO9660.

notraildot

File names on High Sierra file systems consist of a proper name and an extension separated by a '.' (dot) character. By default, the separating dot is always considered part of the file's name for all file access operations, even if there is no extension present. Specifying notraildot makes it optional to specify the trailing dot to access a file whose name lacks an extension.

Exceptions: This option is effective only on file systems for which Rock Ridge, ISO9660 version 2 or Joliet extensions are not active, either because they are not present on the CD-ROM, or they have been deliberately disabled via the nrr, novers2 and nojoliet option. If either extension is active, hsfs quietly ignores this option.

nomaplcase
> File names on High Sierra/ISO9660 CD–ROMs with no extensions present should be
> uppercase characters only. By default, hsfs maps file names read from a non-Rock
> Ridge disk to all lowercase characters. nomaplcase turns off this mapping. The
> exceptions for notraildot discussed above apply to nomaplcase.

-O
> Overlay mount. Allow the file system to be mounted over an existing mount point, making
> the underlying file system inaccessible. If a mount is attempted on a preexisting mount
> point without setting this flag, the mount will fail, producing the error: device busy.

Examples   EXAMPLE 1   Mounting and Unmounting a DVD Image Directly

The following commands mount and unmount a DVD image.

```
# mount -F hsfs /images/solaris.iso /mnt/solaris-image
# umount /mnt/solaris-image
```

Files   /etc/mnttab
table of mounted file systems

/etc/vfstab
list of default parameters for each file system

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   lofiadm(1M), mount(1M), mountall(1M), mount(2), mnttab(4), vfstab(4), attributes(5)

Notes   If the directory on which a file system is to be mounted is a symbolic link, the file system is
mounted on the directory to which the symbolic link refers, rather than on top of the symbolic
link itself.

Name   mount_nfs – mount remote NFS resources

Synopsis   mount [-F nfs] [*generic_options*] [-o *specific_options*] [-O] *resource*

mount [-F nfs] [*generic_options*] [-o *specific_options*] [-O] *mount_point*

mount [-F nfs] [*generic_options*] [-o *specific_options*]
       [-O] *resource mount_point*

Description   The mount utility attaches a named *resource* to the file system hierarchy at the pathname location *mount_point*, which must already exist. If *mount_point* has any contents prior to the mount operation, the contents remain hidden until the *resource* is once again unmounted.

mount_nfs starts the lockd(1M) and statd(1M) daemons if they are not already running.

If the resource is listed in the /etc/vfstab file, the command line can specify either *resource* or *mount_point*, and mount consults /etc/vfstab for more information. If the -F option is omitted, mount takes the file system type from /etc/vfstab.

If the resource is not listed in the /etc/vfstab file, then the command line must specify both the *resource* and the *mount_point*.

host can be an IPv4 or IPv6 address string. As IPv6 addresses already contain colons, enclose *host* in a pair of square brackets when specifying an IPv6 address string. Otherwise the first occurrence of a colon can be interpreted as the separator between the host name and path, for example, [1080::8:800:200C:417A]:tmp/file. See inet(7P) and inet6(7P).

host:pathname
   Where *host* is the name of the NFS server host, and *pathname* is the path name of the directory on the server being mounted. The path name is interpreted according to the server's path name parsing rules and is not necessarily slash-separated, though on most servers, this is the case.

nfs://host[:*port*]/*pathname*
   This is an NFS URL and follows the standard convention for NFS URLs as described in *NFS URL Scheme*, RFC 2224. See the discussion of URL's and the public option under NFS FILE SYSTEMS for a more detailed discussion.

host:pathname nfs://host[:*port*]/*pathname*
   host:*pathname* is a comma-separated list of *host*:*pathname*.

   See the discussion of replicated file systems and failover under NFS FILE SYSTEMS for a more detailed discussion.

hostlist pathname
   hostlist is a comma-separated list of hosts.

   See the discussion of replicated file systems and failover under NFS FILE SYSTEMS for a more detailed discussion.

The `mount` command maintains a table of mounted file systems in `/etc/mnttab`, described in `mnttab(4)`.

`mount_nfs` supports both NFSv3 and NFSv4 mounts. The default NFS version is NFSv4.

SMF Management The NFS client service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/nfs/client:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

Options See `mount(1M)` for the list of supported *generic_options*. See `share_nfs(1M)` for a description of server options.

`-o` *specific_options*
Set file system specific options according to a comma-separated list with no intervening spaces.

`acdirmax=`*n*
Hold cached attributes for no more than *n* seconds after directory update. The default value is `60`.

`acdirmin=`*n*
Hold cached attributes for at least *n* seconds after directory update. The default value is `30`.

`acregmax=`*n*
Hold cached attributes for no more than *n* seconds after file modification. The default value is `60`.

`acregmin=`*n*
Hold cached attributes for at least *n* seconds after file modification. The default value is `3`.

`actimeo=`*n*
Set *min* and *max* times for regular files and directories to *n* seconds. See "File Attributes," below, for a description of the effect of setting this option to `0`.

See "Specifying Values for Attribute Cache Duration Options," below, for a description of how `acdirmax`, `acdirmin`, `acregmax`, `acregmin`, and `actimeo` are parsed on a `mount` command line.

`bg` | `fg`
If the first attempt fails, retry in the background, or, in the foreground. The default is `fg`.

forcedirectio | noforcedirectio

If forcedirectio is specified, then for the duration of the mount, forced direct I/O is used. If the filesystem is mounted using forcedirectio, data is transferred directly between client and server, with no buffering on the client. If the filesystem is mounted using noforcedirectio, data is buffered on the client. forcedirectio is a performance option that is of benefit only in large sequential data transfers. The default behavior is noforcedirectio.

grpid

By default, the GID associated with a newly created file obeys the System V semantics; that is, the GID is set to the effective GID of the calling process. This behavior can be overridden on a per-directory basis by setting the set-GID bit of the parent directory; in this case, the GID of a newly created file is set to the GID of the parent directory (see open(2) and mkdir(2)). Files created on file systems that are mounted with the grpid option obeys BSD semantics independent of whether the set-GID bit of the parent directory is set; that is, the GID is unconditionally inherited from that of the parent directory.

hard | soft

Continue to retry requests until the server responds (hard) or give up and return an error (soft). The default value is hard. Note that NFSv4 clients do not support soft mounts.

intr | nointr

Allow (do not allow) keyboard interrupts to kill a process that is hung while waiting for a response on a hard-mounted file system. The default is intr, which makes it possible for clients to interrupt applications that can be waiting for a remote mount.

llock

Use local locking (no lock manager). Note that this is a private interface.

noac

Suppress data and attribute caching. The data caching that is suppressed is the write-behind. The local page cache is still maintained, but data copied into it is immediately written to the server.

nocto

Do not perform the normal close-to-open consistency. When a file is closed, all modified data associated with the file is flushed to the server and not held on the client. When a file is opened the client sends a request to the server to validate the client's local caches. This behavior ensures a file's consistency across multiple NFS clients. When nocto is in effect, the client does not perform the flush on close and the request for validation, allowing the possiblity of differences among copies of the same file as stored on multiple clients.

This option can be used where it can be guaranteed that accesses to a specified file system are made from only one client and only that client. Under such a condition, the effect of nocto can be a slight performance gain.

port=*n*

    The server IP port number. The default is NFS_PORT. If the port option is specified, and if the resource includes one or more NFS URLs, and if any of the URLs include a port number, then the port number in the option and in the URL must be the same.

posix

    Request POSIX.1 semantics for the file system. Requires a mount Version 2 mountd(1M) on the server. See standards(5) for information regarding POSIX.

proto=*netid* | rdma

    By default, the transport protocol that the NFS mount uses is the first available RDMA transport supported both by the client and the server. If no RDMA transport is found, then it attempts to use a TCP transport or, failing that, a UDP transport, as ordered in the /etc/netconfig file. If it does not find a connection oriented transport, it uses the first available connectionless transport.

    Use this option to override the default behavior.

    proto is set to the value of *netid* or rdma. *netid* is the value of the network_id field entry in the /etc/netconfig file.

    The UDP protocol is not supported for NFS Version 4. If you specify a UDP protocol with the proto option, NFS version 4 is not used.

public

    The public option forces the use of the public file handle when connecting to the NFS server. The resource specified might not have an NFS URL. See the discussion of URLs and the public option under NFS FILE SYSTEMS for a more detailed discussion.

quota | noquota

    Enable or prevent quota(1M) to check whether the user is over quota on this file system; if the file system has quotas enabled on the server, quotas are still checked for operations on this file system.

remount

    Remounts a read-only file system as read-write (using the rw option). This option cannot be used with other -o options, and this option works only on currently mounted read-only file systems.

retrans=*n*

    Set the number of NFS retransmissions to *n*. The default value is 5. For connection-oriented transports, this option has no effect because it is assumed that the transport performs retransmissions on behalf of NFS.

retry=*n*

    The number of times to retry the mount operation. The default for the mount command is 10000.

The default for the automounter is `0`, in other words, do not retry. You might find it useful to increase this value on heavily loaded servers, where automounter traffic is dropped, causing unnecessary server not responding errors.

rsize=*n*

Set the read buffer size to a maximum of *n* bytes. The default value is `1048576` when using connection-orientated transports with Version 3 or Version 4 of the NFS protocol, and `32768` when using connection-less transports. The default can be negotiated down if the server prefers a smaller transfer size. "Read" operations may not necessarily use the maximum buffer size. When using Version 2, the default value is `32768` for all transports.

sec=*mode*

Set the security *mode* for NFS transactions. If sec= is not specified, then the default action is to use AUTH_SYS over NFS Version 2 mounts, use a user-configured default auth over NFS version 3 mounts, or to negotiate a mode over Version 4 mounts.

The preferred mode for NFS Version 3 mounts is the default mode specified in /etc/nfssec.conf (see nfssec.conf(4)) on the client. If there is no default configured in this file or if the server does not export using the client's default mode, then the client picks the first mode that it supports in the array of modes returned by the server. These alternatives are limited to the security flavors listed in /etc/nfssec.conf.

NFS Version 4 mounts negotiate a security mode when the server returns an array of security modes. The client attempts the mount with each security mode, in order, until one is successful.

Only one mode can be specified with the sec= option. See nfssec(5) for the available *mode* options.

secure

This option has been deprecated in favor of the sec=*dh* option.

timeo=*n*

Set the NFS timeout to *n* tenths of a second. The default value is `11` tenths of a second for connectionless transports, and `600` tenths of a second for connection-oriented transports. This value is ignored for connectionless transports. Such transports might implement their own timeouts, which are outside the control of NFS.

vers=*NFS version number*

By default, the version of NFS protocol used between the client and the server is the highest one available on both systems. The default maximum for the client is Version 4. This can be changed by setting client_versmax to a valid version number (2, 3, or 4). Use the sharectl(1M) command to manipulate the client_versmax property. If the NFS server does not support the client's default maximum, the next lowest version attempted until a matching version is found.

wsize=*n*

Set the write buffer size to a maximum of *n* bytes. The default value is 1048576 when using connection-orientated transports with Version 3 or Version 4 of the NFS protocol, and 32768 when using connection-less transports. The default can be negotiated down if the server prefers a smaller transfer size. "Write" operations may not necessarily use the maximum buffer size. When using Version 2, the default value is 32768 for all transports.

xattr|noxattr

Allow or disallow the creation and manipulation of extended attributes. The default is xattr. See fsattr(5) for a description of extended attributes.

-0

Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount fails, producing the error "device busy."

Nfs File Systems   Background versus Foreground

File systems mounted with the bg option indicate that mount is to retry in the background if the server's mount daemon (mountd(1M)) does not respond. mount retries the request up to the count specified in the retry=*n* option. (Note that the default value for retry differs between mount and automount. See the description of retry, above.) Once the file system is mounted, each NFS request made in the kernel waits timeo=*n* tenths of a second for a response. If no response arrives, the time-out is multiplied by 2 and the request is retransmitted. When the number of retransmissions has reached the number specified in the retrans=*n* option, a file system mounted with the soft option returns an error on the request; one mounted with the hard option prints a warning message and continues to retry the request.

Hard versus Soft

File systems that are mounted read-write or that contain executable files should always be mounted with the hard option. Applications using soft mounted file systems can incur unexpected I/O errors, file corruption, and unexpected program core dumps. The soft option is not recommended.

Authenticated requests

The server can require authenticated NFS requests from the client. sec=*dh* authentication might be required. See nfssec(5).

URLs and the public option

If the public option is specified, or if the *resource* includes and NFS URL, mount attempts to connect to the server using the public file handle lookup protocol. See *WebNFS Client Specification*, RFC 2054. If the server supports the public file handle, the attempt is successful; mount does not need to contact the server's rpcbind(1M) and the mountd(1M) daemons to get the port number of the mount server and the initial file handle of *pathname*, respectively. If the NFS client and server are separated by a firewall that allows all outbound connections through specific ports, such as NFS_PORT, then this enables NFS operations

through the firewall. The public option and the NFS URL can be specified independently or together. They interact as specified in the following matrix:

```
                 Resource Style

                 host:pathname              NFS URL

public option    Force public file         Force public file
                  handle and fail           handle and fail
                  mount if not supported.   mount if not supported.

                 Use Native paths.         Use Canonical paths.

default          Use MOUNT protocol.       Try public file handle
                                            with Canonical paths.
                                            Fall back to MOUNT
                                            protocol if not
                                            supported.
```

A Native path is a path name that is interpreted according to conventions used on the native operating system of the NFS server. A Canonical path is a path name that is interpreted according to the URL rules. See *Uniform Resource Locators (URL)*, RFC 1738. See "Examples," below, for uses of Native and Canonical paths.

Replicated file systems and failover
> *resource* can list multiple read−only file systems to be used to provide data. These file systems should contain equivalent directory structures and identical files. The file systems can be specified either with a comma−separated list of *host:/pathname* entries and/or NFS URL entries, or with a comma −separated list of hosts, if all file system names are the same. If multiple file systems are named and the first server in the list is down, failover uses the next alternate server to access files. If the read−only option is not chosen, replication is disabled. File access, for NFS Versions 2 and 3, is blocked on the original if NFS locks are active for that file.

File Attributes To improve NFS read performance, files and file attributes are cached. File modification times get updated whenever a write occurs. However, file access times can be temporarily out-of-date until the cache gets refreshed.

The attribute cache retains file attributes on the client. Attributes for a file are assigned a time to be flushed. If the file is modified before the flush time, then the flush time is extended by the time since the last modification (under the assumption that files that changed recently are likely to change soon). There is a minimum and maximum flush time extension for regular files and for directories. Setting actimeo=*n* sets flush time to *n* seconds for both regular files and directories.

Setting actimeo=0 disables attribute caching on the client. This means that every reference to attributes is satisfied directly from the server though file data is still cached. While this

guarantees that the client always has the latest file attributes from the server, it has an adverse effect on performance through additional latency, network load, and server load.

Setting the noac option also disables attribute caching, but has the further effect of disabling client write caching. While this guarantees that data written by an application is written directly to a server, where it can be viewed immediately by other clients, it has a significant adverse effect on client write performance. Data written into memory-mapped file pages (mmap(2)) are not written directly to this server.

Specifying Values for Attribute Cache Duration Options

The attribute cache duration options are acdirmax, acdirmin, acregmax, acregmin, and actimeo, as described under OPTIONS. A value specified for actimeo sets the values of all attribute cache duration options except for any of these options specified following actimeo on a mount command line. For example, consider the following command:

```
example# mount -o acdirmax=10,actimeo=1000 server:/path /localpath
```

Because actimeo is the last duration option in the command line, its value (1000) becomes the setting for all of the duration options, including acdirmax. Now consider:

```
example# mount -o actimeo=1000,acdirmax=10 server:/path /localpath
```

Because the acdirmax option follows actimeo on the command line, it is assigned the value specified (10). The remaining duration options are set to the value of actimeo (1000).

Examples   EXAMPLE 1   Mounting an NFS File System

To mount an NFS file system:

```
example# mount serv:/usr/src /usr/src
```

This is an example of the use of a native path.

EXAMPLE 2   Mounting An NFS File System Read-Only With No suid Privileges

To mount an NFS file system read-only with no suid privileges:

```
example# mount -r -o nosuid serv:/usr/src /usr/src
```

EXAMPLE 3   Mounting An NFS File System Over Version 2, with the UDP Transport

To mount an NFS file system over Version 2, with the UDP transport:

```
example# mount -o vers=2,proto=udp serv:/usr/src /usr/src
```

EXAMPLE 4   Mounting an NFS File System Using An NFS URL

To mount an NFS file system using an NFS URL (a canonical path):

```
example# mount nfs://serv/usr/man /usr/man
```

EXAMPLE 5 Mounting An NFS File System Forcing Use Of The Public File Handle

To mount an NFS file system and force the use of the public file handle and an NFS URL (a canonical path) that has a non 7–bit ASCII escape sequence:

```
example# mount -o public nfs://serv/usr/%A0abc /mnt/test
```

EXAMPLE 6 Mounting an NFS File System Using a Native Path

To mount an NFS file system using a native path (where the server uses colons (":") as the component separator) and the public file handle:

```
example# mount -o public serv:C:doc:new /usr/doc
```

EXAMPLE 7 Mounting a Replicated Set of NFS File Systems with the Same Pathnames

To mount a replicated set of NFS file systems with the same pathnames:

```
example# mount serv−a,serv−b,serv−c:/usr/man /usr/man
```

EXAMPLE 8 Mounting a Replicated Set of NFS File Systems with Different Pathnames

To mount a replicated set of NFS file systems with different pathnames:

```
example# mount serv−x:/usr/man,serv−y:/var/man,nfs://serv-z/man /usr/man
```

Files /etc/mnttab
   table of mounted file systems

/etc/dfs/fstypes
   default distributed file system type

/etc/vfstab

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/nfs

See Also lockd(1M), mountall(1M), mountd(1M), nfsd(1M), quota(1M), sharectl(1M), statd(1M), mkdir(2), mmap(2), mount(2), open(2), umount(2), mnttab(4), nfssec.conf(4), attributes(5), fsattr(5), nfssec(5), standards(5), inet(7P), inet6(7P), lofs(7FS)

Callaghan, Brent, *WebNFS Client Specification*, RFC 2054, October 1996.

Callaghan, Brent, *NFS URL Scheme*, RFC 2224, October 1997.

Berners-Lee, Masinter & McCahill , *Uniform Resource Locators (URL)*, RFC 1738, December 1994.

Notes An NFS server should not attempt to mount its own file systems. See lofs(7FS).

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on *the directory to which the symbolic link refers,* rather than being mounted on top of the symbolic link itself.

SunOS 4.x used the biod maintenance procedure to perform parallel read-ahead and write-behind on NFS clients. SunOS 5.x made biod obsolete with multi-threaded processing, which transparently performs parallel read-ahead and write-behind.

Since the root (/) file system is mounted read-only by the kernel during the boot process, only the remount option (and options that can be used in conjunction with remount) affect the root (/) entry in the /etc/vfstab file.

Name mount_pcfs – mount pcfs file systems

Synopsis mount -F pcfs [*generic_options*]
[-o *FSType-specific_options*] *special* | *mount_point*

mount -F pcfs [*generic_options*]
[-o *FSType-specific_options*] *special* *mount_point*

Description mount attaches an MS-DOS file system (pcfs) to the file system hierarchy at the *mount_point*, which is the pathname of a directory. If *mount_point* has any contents prior to the mount operation, these are hidden until the file system is unmounted.

The pcfs file system supports direct mounting of files containing the file system as well as block devices. See mount(1M) and lofiadm(1M).

If mount is invoked with *special* or *mount_point* as the only arguments, mount will search /etc/vfstab to fill in the missing arguments, including the *FSType-specific_options*; see mount(1M) for more details.

The *special* argument is a special device file type, which is:

A DOS logical drive on a hard disk expressed as *device-name*:*logical-drive*, where *device-name* specifies the special block device-file for the whole disk and *logical-drive* is either a drive letter (c through z) or a drive number (1 through 24). Examples are /dev/dsk/c0t0d0p0:*c* and /dev/dsk/c0t0d0p0:*1*.

The *special* device file type must have a formatted MS-DOS file system with either a 12-bit, 16-bit, or 32-bit File Allocation Table.

Options *generic_options*
See mount(1M) for the list of supported options.

-o
Specify pcfs file system-specific options. The following options are supported:

clamptime | noclamptime
File timestamps in pcfs cover a range between January 1st 1980 and December 31st 2127. This is not equal to the range of time_t on Unix for either 32-bit or 64-bit applications. In particular, 32-bit applications fail with EOVERFLOW errors on the stat(2) system call when timestamps beyond the range of 32-bit time_t are encountered. In order to prevent such spurious failures, pcfs by default clamps timestamps to the common subset of possible pcfs timestamps and the range available to 32-bit applications in Unix. The clamptime mount option therefore is active by default. If you want access to the full range of possible timestamps on pcfs, mount the file system with the noclamptime mount option. Note that if noclamptime is used, only 64-bit applications will have access to timestamps beyond January 19th 2038, 03:14:06 UTC; 32-bit applications will encounter EOVERFLOW errors.

foldcase | nofoldcase

Force uppercase characters in filenames to lowercase when reading them from the filesystem. This is for compatibility with the previous behavior of pcfs. The default is nofoldcase.

hidden | nohidden

Allow or disallow listing of files with hidden or system bits set. Option hidden is the default. When nohidden is effect, hidden and system files are neither visible nor accessible. Note that PCFS in previous releases of the Solaris operating system used the nohidden option as the default.

atime | noatime

Enable or disable write access timestamps on DOS-formatted media. Default for fixed disks is atime, while for removable media noatime is used. The latter default is so that writes to flash-based media ("memory sticks") can be minimized, to prolong lifetime.

timezone=*timezone*

Timestamps on DOS-formatted media are recorded in the local time of the recording system. This can cause confusion when accessing removable media in which the recording and receiving system use different time zones. Use this option to force media timestamps to be interpreted for a specific time zone. The mount_pcfs command converts the given time zone name into a numerical offset that is passed to the pcfs kernel module, using the same rules as described in environ(5) for the TZ environment variable. By default, the timezone value is taken from the TZ environment variable.

uid=*user_id*

Specifies the owner for the contents of the file system. *user_id* is a decimal value. The default owner is the user ID of current process.

gid=*group_id*

Specifies the group ID for the contents of the file systems. *group_id* is a decimal value. The default group is the group ID of the current process.

umask=*user_mask*

Specifies the mask used for setting maximum access permissions on contents of the file system. The *user_mask* is an octal value, a bitmask, where each bit represents the permissions that should be disabled. The default *user_mask* is the file mode creation mask of the mounting process.

See Intro(2) for more information on masks.

Files /etc/mnttab

table of mounted file systems

/etc/vfstab

list of default parameters for each file system

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/pcfs

See Also `lofiadm(1M)`, `mount(1M)`, `mountall(1M)`, `Intro(2)`, `mount(2)`, `stat(2)`, `time(2)`, `mnttab(4)`, `vfstab(4)`, `attributes(5)`, `environ(5)`, `pcfs(7FS)`

Notes If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

Name   mount_smbfs, umount_smbfs – mount and unmount a shared resource from an SMB file server

Synopsis   /usr/sbin/mount [-F smbfs] [*generic-options*] [-o *name=value*]
        [-O] *resource*

/usr/sbin/mount [-F smbfs] [*generic-options*] [-o *name=value*]
    [-O] *mount-point*

/usr/sbin/mount [-F smbfs] [*generic-options*] [-o *name=value*]
    [-O] *resource mount-point*

/usr/sbin/umount [-F smbfs] [*generic-options*] *mount-point*

Description   The mount utility attaches a named resource, *resource*, to the file system hierarchy at the path name location, *mount-point*, which must already exist.

If *mount-point* has any contents prior to the mount operation, those contents remain hidden until the resource is unmounted. An authorized user with the SYS_MOUNT privilege can perform a mount operation. Also, a user can perform SMBFS mount operations on a directory the user owns.

If the resource is listed in the /etc/vfstab file, you can specify either *resource* or *mount-point* as the mount command will consult the /etc/vfstab file for more information. If the -F option is omitted, mount takes the file system type from the entry in the /etc/vfstab file.

If the resource is not listed in the /etc/vfstab file, the command line must specify both *resource* and *mount-point*.

The umount utility detaches a mounted file system from the file system hierarchy. An authorized user with the SYS_MOUNT privilege can perform a umount operation. Also, a user can perform SMBFS unmount operations on a directory the user owns.

The network/smb/client service must be enabled to successfully mount an SMB share. This service is enabled by default.

To enable the service, enter the following svcadm(1M) command:

svcadm enable network/smb/client

Operands   The mount command supports the following operands:

resource //*server*/*share*

The name of the resource to be mounted. In addition to its name, you can specify the following information about the resource:

- *server* is the DNS or NetBIOS name of the remote computer.
- *share* is the resource name on the remote server.

You can also specify the user account. See the "Options" section.

The mount command can read a password from standard input for the user account. If the password is not provided, mount first attempts to use the password stored by the smbadm add-key command (if any). If that password fails to authenticate, the mount_smbfs command prompts you for a password if standard input is a TTY.

mount-point

The path to the location where the file system is to be mounted or unmounted. The mount command maintains a table of mounted file systems in the /etc/mnttab file. See the mnttab(4) man page.

Options   See the mount(1M) man page for the list of supported *generic-options*.

-o *name*=*value* or

-o *name*

Sets the file system-specific properties. You can specify more than one name-value pair as a list of comma-separated pairs. No spaces are permitted in the list. The properties are as follows:

acdirmax=*n*

Hold cached attributes for no more than *n* seconds after directory update. The default value is 60.

acdirmin=*n*

Hold cached attributes for at least *n* seconds after directory update. The default value is 30.

acregmax=*n*

Hold cached attributes for no more than *n* seconds after file modification. The default value is 60.

acregmin=*n*

Hold cached attributes for at least *n* seconds after file modification. The default value is 3.

actimeo=*n*

Set minimum and maximum times for regular files and directories to *n* seconds. See "File Attributes," below, for a description of the effect of setting this option to 0.

See "Specifying Values for Attribute Cache Duration Options," below, for a description of how acdirmax, acdirmin, acregmax, acregmin, and actimeo are parsed on a mount command line.

dirperms=*octaltriplet*

Specifies the permissions to be assigned to directories. The value must be specified as an octal triplet, such as 755. The default value for the directory mode is taken from the fileperms setting, with execute permission added where fileperms has read permission.

Note that these permissions have no relation to the rights granted by the SMB server.

domain=*value*

Specifies the name of the workgroup or the Windows domain in which the user name is defined. If the domain name is not specified, the default system's SMB domain is used.

fileperms=*octaltriplet*

Specifies the permissions to be assigned to files. The value must be specified as an octal triplet, such as 644. The default value is 700.

Note that these permissions have no relation to the rights granted by the SMB server.

gid=*groupid*

Assigns the specified group ID to files. The default value is the group ID of the directory where the volume is mounted.

intr|nointr

Enable (or disable) cancellation of smbfs(7FS) I/O operations when the user interrupts the calling thread (for example, by hitting Ctrl-C while an operation is underway). The default is intr (interruption enabled), so cancellation is normally allowed.

noac

Suppress attribute caching. Local stat(2) calls always request attributes from the SMB server.

noprompt

Suppresses the prompting for a password when mounting a share. This property enables you to permit anonymous access to a share. Anonymous access does not require a password.

The mount operation fails if a password is required, the noprompt property is set, and no password is stored by the smbadm add-key command.

retry_count=*number*

Specifies the number of SMBFS retries to attempt before the connection is marked as broken. By default, 4 attempts are made.

timeout=*seconds*

Specifies the SMB request timeout. By default, the timeout is 15 seconds.

uid=*userid*

Assigns the specified user ID files. The default value is the owner ID of the directory where the volume is mounted.

user=*value*

Specifies the remote user name. If user is omitted, the logged-in user ID is used.

xattr|noxattr

Enable (or disable) Solaris Extended Attributes in this mount point. This option defaults to xattr (enabled Extended Attributes), but note: if the SMB server does not support SMB "named streams", smbfs(7FS) forces this option to noxattr. When a mount has the noxattr option, attempts to use Solaris Extended attributes fail with EINVAL.

-O

Overlays mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount fails, producing the error "device busy."

File Attributes To improve smbfs performance, file attributes are cached. File modification times get updated whenever any local modifications occur. However, file access times can be temporarily out-of-date until the cache gets refreshed.

The attribute cache retains file attributes on the client. Attributes for a file are assigned a time to be flushed. If the file is modified before the flush time, then the flush time is extended by the time since the last modification (under the assumption that files that changed recently are likely to change soon). There is a minimum and maximum flush time extension for regular files and for directories. Setting actimeo=*n* sets flush time to *n* seconds for both regular files and directories.

Setting actimeo=*n* disables attribute caching on the client. This means that every reference to attributes is satisfied directly from the server. While this guarantees that the client always has the latest file attributes from the server, it has an adverse effect on performance through additional latency, network load, and server load.

Setting the noac option also disables attribute caching. When smbfs is enhanced to support write caching, this option will have the further effect of disabling that write caching.

Specifying Values for Attribute Cache Duration Options The attribute cache duration options are acdirmax, acdirmin, acregmax, acregmin, and actimeo, as described under OPTIONS, above. A value specified for actimeo sets the values of all attribute cache duration options except for any of these options specified following actimeo on a mount command line. For example, consider the following command:

```
# mount -F smbfs -o acdirmax=10,actimeo=1000 \
    //server/share  /mountpoint
```

Because actimeo is the last duration option in the command line, its value (1000) becomes the setting for all of the duration options, including acdirmax. Now consider:

```
# mount -F smbfs -o actimeo=1000,acdirmax=10 \
    //server/share  /mountpoint
```

Because the acdirmax option follows actimeo on the command line, it is assigned the value specified (10). The remaining duration options are set to the value of actimeo (1000).

Examples EXAMPLE 1 Mounting an SMBFS Share

The following example shows how to mount the /tmp share from the nano server in the SALES workgroup on the local /mnt mount point. You must supply the password for the root user to successfully perform the mount operation.

```
# mount -F smbfs -o user=root,domain=SALES //nano.sfbay/tmp /mnt
Password:
```

EXAMPLE 2 Verifying That an SMBFS File System Is Mounted

The following example shows how to mount the /tmp share from the nano server on the local /mnt mount point. You must supply the password for the root user to successfully perform the mount operation.

```
# mount -F smbfs -o user=root //nano.sfbay/tmp /mnt
Password:
```

You can verify that the share is mounted in the following ways:

- View the file system entry in the /etc/mnttab file.

  ```
  # grep mnt /etc/mnttab
  //nano.sfbay/tmp   /mnt    smbfs   dev=4900000     1177097833
  ```

- View the output of the mount command.

  ```
  # mount | grep mnt
  mnt on //nano.sfbay/tmp read/write/setuid/devices/dev=4900000 on
  Tue Apr 20 13:37:13 2010
  ```

- View the output of the df /mnt command.

  ```
  # df /mnt
  /mnt             (//nano.sfbay/tmp): 3635872 blocks    -1 files
  ```

Obtain information about the mounted share by viewing the output of the df -k /mnt command.

```
# df -k /mnt
Filesystem          kbytes    used   avail capacity  Mounted on
//nano.sfbay/tmp
                    1882384   64448 1817936     4%    /mnt
```

EXAMPLE 3 Unmounting an SMB Share

This example assumes that an SMB share has been mounted on the /mnt mount point. The following command line unmounts the share from the mount point.

```
# umount /mnt
```

Files   /etc/mnttab

   Table of mounted file systems.

/etc/dfs/fstypes
   Default distributed file system type.

/etc/vfstab
   Table of automatically mounted resources.

/var/smb/smbfspasswd
   Stores per-user settings for the Solaris SMB client.

Attributes See the attributes(5) man page for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/smb
Interface Stability	Committed

See Also mount(1M), mountall(1M), smbadm(1M), svcadm(1M), acl(2), fcntl(2), link(2), mknod(2), mount(2), stat(2), symlink(2), umount(2), mnttab(4), smb(4), vfstab(4), attributes(5), pcfs(7FS), smbfs(7FS)

Notes The Solaris SMB client always attempts to use gethostbyname() to resolve host names. If the host name cannot be resolved, the SMB client uses NetBIOS name resolution (NBNS). The Solaris SMB client permits the use of NBNS to enable Solaris SMB clients in Windows environments to work without additional configuration.

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than being mounted on top of the symbolic link itself.

Name   mount_tmpfs – mount tmpfs file systems

Synopsis   mount [-F tmpfs] [-o *specific_options*] [-O] *special mount_point*

Description   tmpfs is a memory based file system which uses kernel resources relating to the VM system and page cache as a file system.

mount attaches a tmpfs file system to the file system hierarchy at the pathname location *mount_point*, which must already exist. If *mount_point* has any contents prior to the mount operation, these remain hidden until the file system is once again unmounted. The attributes (mode, owner, and group) of the root of the tmpfs filesystem are inherited from the underlying *mount_point*, provided that those attributes are determinable. If not, the root's attributes are set to their default values.

The *special* argument is usually specified as swap but is in fact disregarded and assumed to be the virtual memory resources within the system.

Options   -o *specific_options*   Specify tmpfs file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available:

size=*sz*	The *sz* argument controls the size of this particular tmpfs file system. If the argument is has a 'k' suffix, the number will be interpreted as a number of kilobytes. An 'm' suffix will be interpreted as a number of megabytes. No suffix is interpreted as bytes. In all cases, the actual size of the file system is the number of bytes specified, rounded up to the physical pagesize of the system.
xattr | noxattr	Allow or disallow the creation and manipulation of extended attributes. The default is xattr. See fsattr(5) for a description of extended attributes.

-O   Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount point without setting this flag, the mount will fail, producing the error device busy.

Files   /etc/mnttab   Table of mounted file systems

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   mount(1M), mkdir(2), mount(2), open(2), umount(2), mnttab(4), attributes(5), fsattr(5), tmpfs(7FS)

Notes   If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

Name mount_udfs – mount a udfs file system

Synopsis mount -F udfs [*generic_options*] [-o *specific_options*]
         [-O] *special mount_point*

mount -F udfs [*generic_options*] [-o *specific_options*]
         [-O] *special | mount_point*

Description The mount utility attaches a udfs file system to the file system hierarchy at the *mount_point*,
which is the pathname of a directory. If *mount_point* has any contents prior to the mount
operation, these are hidden until the file system is unmounted.

If mount is invoked with either *special* or *mount_point* as the only arguments, mount searches
/etc/vfstab to fill in the missing arguments, including the *specific_options*. See mount(1M).

The udfs file system supports direct mounting of files containing the file system as well as
block devices. See mount(1M) and lofiadm(1M).

If *special* and *mount_point* are specified without any *specific_options*, the default is rw.

If the directory on which a file system is to be mounted is a symbolic link, the file system is
mounted on the directory to which the symbolic link refers, rather than on top of the symbolic
link itself.

Options See mount(1M) for the list of supported *generic_options*.

The following options are supported:

-o *specific_options*
  Specify udfs file system specific options in a comma-separated list with no intervening
  spaces. The following *specific_options* are available:

  m
    Mount the file system without making an entry in /etc/mnttab.

  remount
    Remount the file system as read-write. The option is used in conjunction with the rw
    option.

    A file system mounted read-only can be remounted as read-write. This option fails if the
    file system is not currently mounted.

-O
  Overlay mount. Allow the file system to be mounted over an existing mount point, making
  the underlying file system inaccessible. If a mount is attempted on a pre-existing mount
  point without setting this flag, the mount fails, producing the error device busy.

Files /etc/mnttab

Table of mounted file systems

/etc/vfstab

List of default parameters for each file system

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/udfs

See Also fsck(1M), fsck_udfs(1M), lofiadm(1M), mount(1M), mountall(1M), mount(2), mnttab(4), vfstab(4), attributes(5)

Diagnostics not super user

The command is run by a non-root user. Run as root.

no such device

The device name specified does not exist.

not a directory

The specified mount point is not a directory.

is not an udfs file system

The device specified does not contain a udf 1.50 file system or the udfs file system module is not available.

is already mounted

The specified device is already in use.

not a block device

The device specified is not a block device. Use block device to mount.

write-protected

The device is read-only.

is corrupted. needs checking

The file system is in an inconsistent state. Run fsck.

Notes Copy-protected files can be stored on DVD-ROM media using Universal Disk Format (UDF). Reading these copy-protected files is not possible as this involves an authentication process. Unless an authentication process between the host and the drive is completed, reading these copy-protected files after mounting and before the authentication process, returns an error.

Name mount_ufs – mount ufs file systems

Synopsis mount -F ufs [*generic_options*] [-o *specific_options*]
       [-O] *special* | *mount_point*

mount -F ufs [*generic_options*] [-o *specific_options*]
       [-O] *special* *mount_point*

Description The mount utility attaches a ufs file system to the file system hierarchy at the *mount_point*, which is the pathname of a directory. If *mount_point* has any contents prior to the mount operation, these are hidden until the file system is unmounted.

The ufs file system supports direct mounting of files containing the file system as well as block devices. See mount(1M) and lofiadm(1M).

If mount is invoked with *special* or *mount_point* as the only arguments, mount will search /etc/vfstab to fill in the missing arguments, including the *specific_options*. See mount(1M).

If *special* and *mount_point* are specified without any *specific_options*, the default is rw.

If the directory on which a file system is to be mounted is a symbolic link, the file system is mounted on the directory to which the symbolic link refers, rather than on top of the symbolic link itself.

Options See mount(1M) for the list of supported *generic_options*.

The following options are supported:

-o *specific_options*
   Specify ufs file system specific options in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is printed and the invalid options are ignored. The following options are available:

   dfratime | nodfratime
      By default, writing access time updates to the disk may be deferred (dfratime) for the file system until the disk is accessed for a reason other than updating access times. nodfratime disables this behavior.

      If power management is enabled on the system, do not set nodfratime unless noatime is also set. If you set nodfratime without setting noatime, the disk is spun up every time a file within a file system on the disk is accessed - even if the file is not modified.

   forcedirectio | noforcedirectio
      If forcedirectio is specified and supported by the file system, then for the duration of the mount, forced direct I/O will be used. If the filesystem is mounted using forcedirectio, data is transferred directly between user address space and the disk. If the filesystem is mounted using noforcedirectio, data is buffered in kernel address space when data is transferred between user address space and the disk. forcedirectio is a performance option that is of benefit only in large sequential data transfers. The default behavior is noforcedirectio.

global | noglobal
:   If global is specified and supported on the file system, and the system in question is part of a cluster, the file system will be globally visible on all nodes of the cluster. If noglobal is specified, the mount will not be globally visible. The default behavior is noglobal.

intr | nointr
:   Allow (do not allow) keyboard interrupts to kill a process that is waiting for an operation on a locked file system. The default is intr.

largefiles | nolargefiles
:   If nolargefiles is specified and supported by the file system, then for the duration of the mount it is guaranteed that all regular files in the file system have a size that will fit in the smallest object of type off_t supported by the system performing the mount. The mount will fail if there are any files in the file system not meeting this criterion. If largefiles is specified, there is no such guarantee. The default behavior is largefiles.

    If nolargefiles is specified, mount will fail for ufs if the file system to be mounted has contained a large file (a file whose size is greater than or equal to 2 Gbyte) since the last invocation of fsck on the file system. The large file need not be present in the file system at the time of the mount for the mount to fail; it could have been created previously and destroyed. Invoking fsck (see fsck_ufs(1M)) on the file system will reset the file system state if no large files are present. After invoking fsck, a successful mount of the file system with nolargefiles specified indicates the absence of large files in the file system; an unsuccessful mount attempt indicates the presence of at least one large file.

logging | nologging
:   If logging is specified, then logging is enabled for the duration of the mounted file system. Logging is the process of storing transactions (changes that make up a complete UFS operation) in a log before the transactions are applied to the file system. Once a transaction is stored, the transaction can be applied to the file system later. This prevents file systems from becoming inconsistent, therefore reducing the possibility that fsck might run. And, if fsck is bypassed, logging generally reduces the time required to reboot a system.

    The default behavior is logging for all UFS file systems.

    The log is allocated from free blocks in the file system, and is sized approximately 1 Mbyte per 1 Gbyte of file system, up to a maximum of 256 Mbytes. The log size may be larger (up to a maximum of 512 Mbytes) dependent upon the number of cylinder groups present in the file system.

    Logging is enabled on any UFS file system, including root (/), except under the following conditions:

    - When logging is specifically disabled.
    - If there is insufficient file system space for the log. In this case, the following message is displayed and file system is still mounted:

```
# mount /dev/dsk/c0t4d0s0 /mnt
  /mnt: No space left on device
  Could not enable logging for /mnt on  /dev/dsk/c0t4d0s0.
```

The log created by UFS logging is continually flushed as it fills up. The log is totally flushed when the file system is unmounted or as a result of the lockfs -f command.

m

Mount the file system without making an entry in /etc/mnttab.

noatime

By default, the file system is mounted with normal access time (atime) recording. If noatime is specified, the file system will ignore access time updates on files, except when they coincide with updates to the ctime or mtime. See stat(2). This option reduces disk activity on file systems where access times are unimportant (for example, a Usenet news spool).

noatime turns off access time recording regardless of dfratime or nodfratime.

The POSIX standard requires that access times be marked on files. -noatime ignores them unless the file is also modified.

nosec

By default, Access Control Lists (ACLs) are supported on a mounted UFS file system. Use this option to disallow the setting or any modification of an ACL on a file within a mounted UFS file system. See getfacl(1) for background on ACLs.

onerror = *action*

This option specifies the action that UFS should take to recover from an internal inconsistency on a file system. Specify *action* as panic, lock, or umount. These values cause a forced system shutdown, a file system lock to be applied to the file system, or the file system to be forcibly unmounted, respectively. The default is panic.

quota

Quotas are turned on for the file system.

remount

Remounts a file system with a new set of options. All options not explicitly set with remount revert to their default values.

rq

Read-write with quotas turned on. Equivalent to rw, quota.

xattr | noxattr

Allow or disallow the creation and manipulation of extended attributes. The default is xattr. See fsattr(5) for a description of extended attributes.

-O

Overlay mount. Allow the file system to be mounted over an existing mount point, making the underlying file system inaccessible. If a mount is attempted on a pre-existing mount

point without setting this flag, the mount will fail, producing the error "device busy".

Examples   EXAMPLE 1   Turning Off (and On) Logging

The following command turns off logging on an already mounted file system. The subsequent command restores logging.

```
# mount -F ufs -o remount,nologging /export
# (absence of message indicates success)
# mount -F ufs -o remount,logging /export
```

In the preceding commands, the -F ufs option is not necessary.

Files   /etc/mnttab
table of mounted file systems

/etc/vfstab
list of default parameters for each file system

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   getfacl(1), fsck(1M), fsck_ufs(1M), lofiadm(1M), mount(1M), mountall(1M), fcntl(2), mount(2), stat(2), mnttab(4), vfstab(4), attributes(5), fsattr(5), largefile(5)

Notes   Since the root (/) file system is mounted read-only by the kernel during the boot process, only the remount option (and options that can be used in conjunction with remount) affect the root (/) entry in the /etc/vfstab file.

Name   mpathadm – multipath discovery and administration

Synopsis   mpathadm *subcommand direct-object* [*options*] [*operand*]

Description   The mpathadm command enables multipathing discovery and management. The mpathadm command is implemented as a set of subcommands, many with their own options, that are described in the section for that subcommand. Options not associated with a particular subcommand are described under OPTIONS. The mpathadm subcommands operate on a *direct-object*. These are described in this section for each subcommand. The *direct-objects*, *initiator-port*, *target-port*, and *logical-unit* in the subcommands are consistent with SCSI standard definitions.

The mpathadm command supports the following subcommands, which are described in detail in subsections that follow.

list   Display a list of discovered instances for a given object.

show   Display information about a given object instance.

modify   Modify properties of an object.

enable   Enable an object.

disable   Disable an object.

failover   Cause target port group failover for a logical-unit.

override   Set a path to be used over other paths on a logical-unit.

The mpathadm subcommands operate on a *direct-object*. These are described in this section for each subcommand.

list Subcommand   The syntax for the list subcommand is:

mpathadm list *direct-object* [*operands...*]

The list subcommand displays data for following direct-objects:

mpath-support [*mpath-support-name*, ...]
    List the multipathing support that can be administered by this CLI. This presents itself in the form of a library name registered through the MPAPI framework. If no mpath-support name *mpath-support-name* is specified, all registered multipathing support libraries will be displayed.

initiator-port [*initiator-port-name*, ...]
    List the initiator ports that are discovered on this system. If no *initiator-port-name* is specified, all discovered initiator ports are displayed.

{logical-unit | lu} [*options*] [*logical-unit-name*, ...]
    List the information on multipath logical units. If no *logical-unit-name* is specified, all discovered logical-units will be displayed.

Options for `list logical-unit` are as follows:

`-n, --name` *name*	Return the logical unit name that is associated with the given name string. This name can be extracted from the output of the `mpathadm show lu` command.
`-t, --target-port` *target-port-name*	Return the list of logical units names that are associated with the given *target-port-name*.

show Subcommand   The syntax for the `show` subcommand is:

```
# mpathadm show direct-object [operands...]
```

The `show` subcommand displays detailed information for following the direct-objects:

`mpath-support` [*mpath-support-name*, ...]
   Show the detailed information on the given *mpath-support-name* if the name exists. If the given *mpath-support-name* supports only a limited set of device products, the list of device products will be listed as part of the output.

`initiator-port` *initiator-port-name*[,*initiator-port-name*, ...]
   Show the detailed information for the given *initiator-port-name*.

{`logical-unit` | `lu`} [*logical-unit-name*, ...]
   Display the detailed information on multipath logical unit(s), including path and target port group information. Note that the name property in the logical unit information represents the identifier for this LUN, derived from the hardware, and used by this system. If the name is derived from SCSI Inquiry Vital Product Data (VPD) page 83h, the name type property represents an associated identifier type defined by the SCSI standards.

modify Subcommand   The syntax for the `modify` subcommand is:

```
# mpathadm modify direct-object [options] [operands...]
```

The `modify` subcommand modifies characteristics of the following direct-objects:

`mpath-support` [*options*] *mpath-support-name*, ...   Configuration management of an *mpath-support*. Options to modify mpath-support are as follows:

Set auto failback on | off. Applicable only when mpath-support provides auto failback support.

Set auto probing on | off. Applicable only when mpath-support provides auto probing support.

Change the default load balance type. The loadbalance type is one of the

supported types listed in the show mpath-support output.

{logical-unit | lu} [*options*] *logical-unit-name*, ...

Configuration management of a logical unit. Options to modify logical-unit are as follows:

Set auto-failback. Applicable only when mpath-support provides auto failback support

Set auto-probing. Applicable only when mpath-support provides auto probing support.

Set load-balance type for the logical unit. Applicable only when load balance configuration is supported at the logical unit level.

enable Subcommand

The syntax for the enable subcommand is:

mpathadm disable [*options*]

The enable subcommand supports the following direct-objects to be enabled:

path -i *initiator-port-name* -t *target-port-name*
-l *logical-unit-name*

The path that consists of the specified initiator port, target port, and logical unit will be enabled.

disable Subcommand

The syntax for the disable subcommand is:

mpathadm disable [*options*]

The disable subcommand supports the following direct-objects to be disabled:

path -i *initiator-port-name* -t *target-port-name*
-l *logical-unit-name*

The path that consists of the specified initiator port, target port, and logical unit will be disabled.

failover Subcommand

The syntax for the failover subcommand is:

mpathadm failover *direct-object* [*operand*]

The failover subcommand supports failover for the following direct-objects:

{logical-unit | lu} *logical-unit-name*

The target port group will failover when the given logical-unit is asymmetric and supports explicit

state change. The currently active target port group will be changed to the standby state and the standby target port group will be active.

override Subcommand

The syntax for the `override` subcommand is:

```
# mpathadm override [options]
```

The `override` subcommand controls whether or not the following direct-objects override another:

path {-i *initiator-port-name* -t *target-port-name* | -c}
-l *logical-unit-name*

  Cause a path that consists of the specified initiator port, target port, and logical unit to override other paths on the logical unit. Once a path overrides other paths, the mpath-support uses only that path regardless of any other path selection configuration. The -c option cancels the setting. The path that consists of the specified initiator port, target port, and logical unit will be disabled.

  Options for override path are as follows:

-i, --initiator-port *initiator-port-name*	Represent the initiator port element of a path. Options -t and -l must also be included.
-t, --target-port *target-port-name*	Represent the target port element of a path. Options -i and -l must also be included.
-l, --logical-unit *logical-unit*	Represent the logical unit element of a path. Options -i and -t must also be included.
-c, --cancel	Cancels overriding setting for the given logical unit. Option -l must also be included.

Options

The following options are supported:

-V, --version	Display the version information.
-?, --help	Display context help. Can be used following an mpathadm command with no arguments, following a subcommand, or following a subcommand direct-object combination. Responds with help information appropriate for your entry. For example, if you enter:

  # mpathadm add mpath-support-help

  ... mpathadm responds with a display of the options available for that combination of subcommand and direct-object.

Examples **EXAMPLE 1** Obtaining a List of Multipathing Support

The following command uses the `list` subcommand to list all currently registered `mpath-support` libraries.

```
# mpathadm list mpath-support
mpath-support: libmpscsi_vhci.so
```

EXAMPLE 2 Displaying the Properties of a Particular Multipathing Support

The following command uses the `show` subcommand to display the properties for a currently registered `mpath-support` library.

```
# mpathadm show mpath-support libmpscsi_vhci.so
mpath-support:     libmpscsi_vhci.so
      Vendor:  Sun Microsystems
      Driver Name:  scsi_vhci
      Default Load Balance:  round-robin
      Supported Load Balance Types:
            round-robin
        logical-block
Allows To Activate Target Port Group Access:  yes
Allows Path Override:  no
Supported Auto Failback Config:     1
Auto Failback:    on
Failback Polling Rate (current/max):  0/0
Supported Auto Probing Config:     0
Auto Probing:  NA
Probing Polling Rate (current/max):  NA/NA
Supported Devices:
      Vendor:     SUN
      Product:  T300
      Revision:
      Supported Load Balance Types:
            round-robin
      Vendor:     SUN
      Product:  T4
      Revision:
      Supported Load Balance Types:
            round-robin
```

EXAMPLE 3 Obtaining a List of Initiator Ports Discovered Through the `mpath-support` Libraries

The following command uses the `list initiator-port` subcommand to display a list of initiator ports discovered by the currently registered `mpath-support` libraries.

```
# mpathadm list initiator-port
Initiator-Port: iqn.1986-03.com.sun:01:080020b7ac2b.437a3b3e,4000002a0000
Initiator-Port: 2000000173018713
Initiator-Port: 2000000173818713
```

EXAMPLE 4 Displaying the Properties of a Particular Initiator Port

The following command uses the show initiator-port subcommand to display the properties of a particular initiator port discovered using the list initiator-port subcommand in an example above.

```
# mpathadm show initiator-port 2000000173018713
initiator-port:     2000000173018713
        Transport Type:    Fibre Channel
        OS device File:    devices/pci@1f,4000/pci@2/SUNW,qlca@5/fp@0,0:fc
```

EXAMPLE 5 Displaying the Properties of a Particular Logical Unit

The following command uses the show logical-unit subcommand to display the properties of the logical unit with the specified name.

```
# mpathadm show lu /dev/rdsk/c4t60003BA27D2120004204AC2B000DAB00d0s2
Logical Unit: /dev/rdsk/c4t60003BA27D2120004204AC2B000DAB00d0s2
          mpath-support libmpscsi_vhci.so
          Vendor: SUN
          Product: T4
          Revision: 0301
    Name Type: SCSI Inquiry VPD Page 83 type 3
    Name: 60003ba27d2120004204ac2b000dab00
    Asymmetric: yes
    Current Load Balance: round-robin
    Logical Unit Group ID: NA
    Aauto Failback: on
    Auto Probing: NA

Paths:
    Initiator Port Name: 2000000173818713
    Target Port Name: 20030003ba27d212
    Override Path: NA
    Path State: OK
    Disabled: no

    Initiator Port Name: 2000000173018713
    Target Port Name: 20030003ba27d095
    Override Path: NA
    Path State: OK
    Disabled: no

Target Port Group:
    ID: 2
    Explicit Failover: yes
    Access State: standby
    Target Ports:
            Name: 20030003ba27d212
```

EXAMPLE 5 Displaying the Properties of a Particular Logical Unit   *(Continued)*

```
        Relative ID: 0

    ID: 5
    Explicit Failover: yes
    Access State: active
    Target Ports
          Name: 20030003ba27d095
        Relative ID: 0
```

EXAMPLE 6 Enabling a Path

The following command uses the enable path subcommand to enable the path with the specified initiator port, target port, and logical unit.

```
# mpathadm enable path -i 2000000173018713 -t 20030003ba27d095     \
-l /dev/rdsk/c4t60003BA27D2120004204AC2B000DAB00d0s2
```

EXAMPLE 7 Modifying mpath-support To Turn On autofailback

```
# mpathadm modify mpath-support -a on libmpscsi_vhci.so
```

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/storage/multipath-utilities

Interface Stability	Committed

See Also   stmsboot(1M), libMPAPI(3LIB), exec_attr(4), attributes(5)

Name mpstat – report per-processor or per-processor-set statistics

Synopsis /usr/bin/mpstat [-aq] [-p | -P *set*] [-T u | d] [*interval* [*count*]]

Description The mpstat command reports processor statistics in tabular form. Each row of the table represents the activity of one processor. The first table summarizes all activity since boot. Each subsequent table summarizes activity for the preceding interval. All values are rates listed as events per second unless otherwise noted.

During execution of the kernel status command, the state of the kernel can change. If relevant, a state change message is included in the mpstat output, in one of the following forms:

```
<<processor 3 moved from pset: -1 to: 1>>
<<pset destroyed: 1>>
<<pset created: 1>>
<<processors added: 1, 3>>
<<processors removed: 1, 3>>
```

The mpstat command reports the following information:

CPU or SET   Without the -a option, mpstat reports CPU statistics for a processor ID. With the -a option, mpstat reports SET statistics for a processor set ID.

minf   minor faults

mjf   major faults

xcal   inter-processor cross-calls

intr   interrupts

ithr   interrupts as threads (not counting clock interrupt)

csw   context switches

icsw   involuntary context switches

migr   thread migrations (to another processor)

smtx   spins on mutexes (lock not acquired on first try)

srw   spins on readers/writer locks (lock not acquired on first try)

syscl   system calls

usr   percent user time

sys   percent system time

wt   the I/O wait time is no longer calculated as a percentage of CPU time, and this statistic will always return zero.

idl   percent idle time

sze	number of processors in the requested processor set
set	processor set membership of each CPU

Options The following options are supported:

-a	Aggregate output by processor set. Sort the output by set. The default output is sorted by CPU number.
-p	Report processor set membership of each CPU. Sort the output by set. The default output is sorted by CPU number.
-P *set*	Display only those processors in the specified *set*.
-q	Suppress messages related to state changes.
-T u│d	Specify u for a printed representation of the internal representation of time. See time(2). Specify d for standard date format. See date(1).
interval	Report once each *interval* seconds.
count	Only print *count* reports.

Examples EXAMPLE 1   Using mpstat to Generate User and System Operation Statistics

The following command generates processor statistics over a five–second interval in two reports. The command shows the processor set membership of each CPU. The default output is sorted by CPU number, aggregated by *processor set*, for user (usr) and system (sys) operations.

example% **mpstat -ap 5 2**

```
SET minf mjf xcal intr ithr csw icsw migr smtx srw syscl usr sys wt idl sze
  0    6   0  355  291  190   22    0    0    0   0    43   0   2  0  43   1
  1   24  17  534  207  200   70    1    0    2   0   600   4   1  0  84   2
  2   19   7  353  325  318   44    0    0    5   0   345   1   1  0  94   3
  3   36   2  149  237  236   14    0    0    4   0    97   0   0  0  98   2
SET minf mjf xcal intr ithr csw icsw migr smtx srw syscl usr sys wt idl sze
  0    1   0  720  405  304   55    0    0   18   0    12   0  15  0  81   1
  1    0  69 1955  230  200  313   33    4   41   9  7086  34  10  0  19   2
  2    0  46  685  314  300  203   11    0   54   1  5287  36   6  0  28   3
  3    0   0   14  386  384    0    0    0    0   0     0   0   0  0 100   2
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	See below.

Invocation is evolving. Human readable output is unstable.

See Also sar(1), date(1), iostat(1M), sar(1M), vmstat(1M), time(2), attributes(5)

Notes The sum of CPU utilization might vary slightly from 100 due to rounding errors in the production of a percentage figure.

The total time used for CPU processing is the sum of usr and sys output values, reported for user and system operations. The idl value reports the time that the CPU is idle for any reason other than pending disk I/O operations.

Run the iostat command with the -x option to report I/O service times in svc_t output. The iostat utility also reports the same wt, user (us), and system (sy) statistics. See iostat(1M) for more information.

When executing in a zone and if the pools facility is active, mpstat(1M) will only provide information for those processors which are a member of the processor set of the pool to which the zone is bound.

Name msgid – generate message IDs

Synopsis /usr/sbin/msgid

Description The msgid utility generates message IDs.

A message ID is a numeric identifier that uniquely identifies a message. Although the probability of two distinct messages having the same ID is high, this can be greatly reduced with the appropriate priority or facility.level designator (see syslogd(1M)). Specifically, the message ID is a hash signature on the message's unexpanded format string, generated by STRLOG_MAKE_MSGID() as defined in <sys/strlog.h>.

syslogd(1M) is a simple filter that takes strings as input and produces those same strings, preceded by their message IDs, as output. Every message logged by syslogd(1M) includes the message ID. The message ID is intended to serve as a small, language-independent identifier.

Examples **EXAMPLE 1** Using the msgid command to generate a message ID

The following example uses the msgid command to generate a message ID for the echo command.

```
example# echo hello | msgid205790 hello
```

EXAMPLE 2 Using the msgid command to generate a message catalog

The following example uses the msgid command to enumerate all of the messages in the binary ufs, to generate a message catalog.

```
example# strings /kernel/fs/ufs | msgid

137713 free:
    freeing free frag, dev:0x%lx, blk:%ld, cg:%d, ino:%lu, fs:%s
567420 ialloccg: block not in mapfs = %s
845546 alloc: %s: file system full
...
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also syslogd(1M), attributes(5), log(7D)

Name   mvdir – move a directory

Synopsis   /usr/sbin/mvdir *dirname name*

Description   mvdir moves directories within a file system. dirname must be a directory. If *name* does not exist, it will be created as a directory. If *name* does exist, and is a directory, dirname will be created as *name/dirname*. dirname and *name* may not be on the same path; that is, one may not be subordinate to the other. For example:

example% mvdir x/y x/z

is legal, but

example% mvdir x/y x/y/z

is not.

Operands   dirname   The name of the directory that is to be moved to another directory in the filesystem.

name   The name of the directory into which dirname is to be moved. If *name* does not exist, it will be created. It may not be on the same path as dirname.

Usage   See largefile(5) for the description of the behavior of mvdir when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Exit Status   0   Successful operation.

>0   Operation failed.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   mkdir(1), mv(1), attributes(5), largefile(5)

Name   named, in.named – Internet domain name server

Synopsis   named [-fgsVv] [-c *config-file*] [-d *debug-level*] [-m *flag*]
          [-n *#cpus*] [-p *port*] [-S *#max-socks*] [-t *directory*]
          [-u *user*] [-x *cache-file*] [-4 | -6]

Description   The named utility is a Domain Name System (DNS) server, part of the BIND 9 distribution from ISC. For more information on the DNS, see RFCs 1033, 1034, and 1035.

When invoked without arguments, named reads the default configuration file /etc/named.conf, reads any initial data, and listens for queries.

in.named is a link to named.

Options   The following options are supported:

-4

Use only IPv4 transport. By default, both IPv4 and IPv6 transports can be used. Options -4 and -6 are mutually exclusive.

-6

Use only IPv6 transport. By default, both IPv4 and IPv6 transports can be used. Options -4 and -6 are mutually exclusive.

-c *config-file*

Use *config-file* as the configuration file instead of the default /etc/named.conf. To ensure that reloading the configuration file continues to work after the server has changed its working directory due to to a possible *directory* option in the configuration file, *config-file* should be an absolute pathname.

-d *debug-level*

Set the daemon's debug level to *debug-level*. Debugging traces from named become more verbose as the debug level increases.

-f

Run the server in the foreground (that is, do not run as a daemon).

-g

Run the server in the foreground and force all logging to stderr.

-m *flag*

Turn on memory usage debugging flags. Possible flags are usage, trace, and record, size, and mctx. These correspond to the ISC_MEM_DEBUG*XXXX* flags described in <isc/mem.h>.

-n *#cpus*

Create *#cpus* worker threads to take advantage of multiple CPUs. If not specified, named will try to determine the number of CPUs present and create one thread per CPU. If it is unable to determine the number of CPUs, a single worker thread will be created.

-p *port*

Listen for queries on port *port*. If not specified, the default is port 53.

-S #*max-socks*

Allow named to use up to #*max-socks* sockets.

This option should be unnecessary for the vast majority of users. The use of this option could even be harmful, because the specified value might exceed the limitation of the underlying system API. It therefore should be set only when the default configuration causes exhaustion of file descriptors and the operational environment is known to support the specified number of sockets. Note also that the actual maximum number is normally a little smaller than the specified value because named reserves some file descriptors for its internal use.

-s

Write memory usage statistics to *stdout* on exit.

This option is mainly of interest to BIND 9 developers and might be removed or changed in a future release.

-t *directory*

Change the root directory using chroot(2) to *directory* after processing the command line arguments, but before reading the configuration file.

This option should be used in conjunction with the -u option, as chrooting a process running as root does not enhance security on most systems; the way chroot() is defined allows a process with root privileges to escape a chroot jail.

-u *user*

Set the real user ID using setuid(2) to *user* after completing privileged operations, such as creating sockets that listen on privileged ports.

-V

Report the version number and build options, and exit.

-v

Report the version number and exit.

-x *cache-file*

Load data from *cache-file* into the cache of the default view.

Do not use this option. It is of interest only to BIND 9 developers and might be removed or changed in a future release.

Extended Description

This section describes additional attributes of named.

SMF Properties

When starting named from the service management facility, smf(5), named configuration is read from the service configuration repository. Use svcprop(1) to list the properties and svccfg(1M) to make changes.

The following application configuration properties are available to administrators:

options/*server*
> Specifies the server executable to be used instead of the default server, /usr/sbin/named.

options/*configuration_file*
> Specifies the configuration file to be used instead of the default, /etc/named.conf. A directory option might be specified in the configuration file. To ensure that reloading the configuration file continues to work in such a situation, *configuration_file* should be specified as an absolute pathname. This pathname should not include the *chroot_dir* pathname. This property is the equivalent of the -c option.

options/*ip_interfaces*
> Specifies over which IP transport, IPv4 or IPv6, BIND will transmit. Possible values are IPv4 or IPv6. Any other setting assumes all, the default. This property is the equivalent of command line option -4 or -6

options/*listen_on_port*
> Specifies the default UDP and TCP port to be used for listening to DNS requests. This property is the equivalent of the command line option -p *port*.

options/*debug_level*
> Specifies the default debug level. The default is 0, which means no debugging. The higher the number the more verbose debug information becomes. Equivalent of the command line option -d *debug_level*.

options/*threads*
> Specifies the number of CPU worker threads to create. The default of 0 causes named to try and determine the number of CPUs present and create one thread per CPU. Equivalent of command line option -n *#cpus*.

options/*chroot_dir*
> Specifies the directory to be used as the root directory after processing SMF properties and the command line arguments but before reading the configuration file. Use this property when using a chroot(2) environment. Synonymous to command line option -t *pathname*.
>
> When using chroot(2), named is unable to disable itself when receiving rndc(1M) stop or halt commands. Instead, you must use the svcadm(1M) disable command.

In the event of a configuration error originating in one of the above SMF application options, named displays a message providing information about the error and the parameters that need correcting. The process then exits with exit code SMF_EXIT_ERR_CONFIG.

At startup, in the event of an error other than a configuration error, named exits with exit code SMF_EXIT_ERR_FATAL. Both of this code and SMF_EXIT_ERR_CONFIG cause the start method, smf_method(5), to place the service in the maintenance state, which can be observed with the svcs(1) command svcs -x.

In addition to the properties listed above, the following property can be used to invoke named as a user other than root:

start/*user*

　　Specifies the identity of the user that is invoking named. See smf_method(5) and chroot(2).
　　Note that the user must have solaris.smf.manage.bind authorization. Without this role
　　the named will be unable to manage its SMF FMRI and named will automatically be restarted
　　by the SMF after an rndc(1M) stop or halt command. See EXAMPLES for a sequence of
　　commands that establishes the correct authorization.

SIGNALS　In routine operation, signals should not be used to control the nameserver; rndc(1M) should
　　be used instead.

SIGHUP

　　Force a reload of the server.

SIGINT, SIGTERM

　　Shut down the server.

The result of sending any other signals to the server is undefined.

Configuration　The named configuration file is too complex to describe in detail here. A list of configuration
　　options is provided in the named.conf man page shipped with the BIND 9 distribution. A
　　complete description is provided in the *BIND 9 Administrator Reference Manual*.

Examples　**EXAMPLE 1**　Configuring named to Transmit Only over IPv4 Networks

The following command sequence configures named such that it will transmit only over IPv4
networks.

```
# svccfg -s svc:network/dns/server:default setprop \
> options/ip_interfaces=IPv4
# svcadm refresh svc:network/dns/server:default
#
```

EXAMPLE 2　Listing Current Configuration File and Setting an Alternative File

The following sequence of commands lists the current named configuration file and sets an
alternative file.

```
# svcprop -p options/configuration_file dns/server:default
/etc/named.conf
# svccfg -s dns/server:default setprop \
> options/configuration_file=/var/named/named.conf
# svcadm refresh dns/server:default
# svcprop -p options/configuration_file dns/server:default
/var/named/named.conf
```

EXAMPLE 3　Establishing Appropriate Authorization for named

To have named start with the solaris.smf.manage.bind authorization, perform the steps
shown below.

Add the user dnsadmin to the solaris.smf.manage.bind role:

EXAMPLE 3 Establishing Appropriate Authorization for named   *(Continued)*

```
# usermod -A solaris.smf.manage.bind dnsadmin
Observe effect of command:
# tail -1 /etc/user_attr
dnsadmin::::type=normal;auths=solaris.smf.manage.bind
```

Modify the service properties:

```
# svccfg
svc:> select svc:/network/dns/server:default
svc:/network/dns/server:default> setprop start/user = dnsadmin
svc:/network/dns/server:default> setprop start/group = dnsadmin
svc:/network/dns/server:default> exit
# svcadm refresh svc:/network/dns/server:default
# svcadm restart svc:/network/dns/server:default
```

Because only root has write access to create the default process-ID file, /var/run/named/named.pid, named must be configured to use an alternative path for the user dnsadmin. Here is an example of how to accomplish this:

```
# mkdir /var/named/tmp
# chown dnsadmin /var/named/tmp
```

Shown below is what you must add to named.conf to make use of the directory created above.

```
# head /etc/named.conf
options {
directory "/var/named";
pid-file "/var/named/tmp/named.pid";
};
```

Files /etc/named.conf
    default configuration file

/var/run/named/named.pid
    default process-ID file

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/dns/bind
Interface Stability	Volatile

The named.conf man page shipped with the BIND 9 distribution

Name named-checkconf – named configuration file syntax checking tool

Synopsis `named-checkconf [-hjvz] [-t` *directory*`]` *filename*

Description The `named-checkconf` utility checks the syntax, but not the semantics, of a specified configuration file.

Options The following options are supported:

-h
  Display the usage summary and exit.

-j
  When loading a zonefile, read the journal if it exists.

-t *directory*
  Change the root directory to *directory* so that include directives in the configuration file are processed as if run by a named configuration whose root directory has been similarly changed.

-v
  Print the version of the `named-checkconf` program and exit.

-z
  Perform a test load of the master zones found in `named.conf`.

Operands The following operands are supported:

filename
  The name of the configuration file to be checked. If not specified, it defaults to `/etc/named.conf`.

Exit Status 0
  No errors were detected.

1
  An error was detected.

Attributes See `attributes`(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/dns/bind
Interface Stability	Volatile

See Also `named`(1M), `named-checkzone`(1M), `attributes`(5)

See the BIND 9 *Administrator's Reference Manual.* As of the date of publication of this man page, this document is available at `https://www.isc.org/software/bind/documentation`.

Name named-checkzone, named-compilezone – zone file validity checking or converting tool

Synopsis named-checkzone [-Ddhjqv] [-c *class*] [-F *format*] [-f *format*]
            [-i *mode*] [-k *mode*] [-M *mode*] [-m *mode*] [-n *mode*]
            [-o *filename*] [-S *mode*] [-s *style*] [-t *directory*]
            [-W *mode*] [-w *directory*] *zonename filename*

named-compilezone [-Ddjqv] [-C *mode*] [-c *class*] [-F *format*]
            [-f *format*] [-i *mode*] [-k *mode*] [-m *mode*] [-n *mode*]
            [-o *filename*] [-s *style*] [-t *directory*]
            [-W *mode*] [-w *directory*] *zonename filename*

Description The named-checkzone utility checks the syntax and integrity of a zone file. It performs the same checks as named(1M) does when loading a zone. The named-checkzone utility is useful for checking zone files before configuring them into a name server.

named-compilezone is similar to named-checkzone, differing in that it always dumps the zone contents to a specified file in a specified format. Additionally, it applies stricter check levels by default, since the dump output will be used as an actual zone file loaded by named(1M). Unless manually specified otherwise, the check levels must be at least as strict as those specified in the named configuration file.

Options For either or both utilities, the following options are supported:

-c *class*
    Specify the class of the zone. If not specified, "IN" is assumed.

-D
    Dump zone file in canonical format.

-d
    Enable debugging.

-F *format*
    Specify the format of the output file specified. Possible formats are text (default) and raw. For named-checkzone, this does not cause any effects unless it dumps the zone contents.

-f *format*
    Specify the format of the zone file. Possible formats are text (default) and raw.

-h
    Display usage message for named-checkzone.

-i *mode*
    Perform post-load zone integrity checks. Possible modes are full (default), full-sibling, local, local-sibling, and none.

    Mode full checks that MX records refer to the A or AAAA record (both in-zone and out-of-zone hostnames). Mode local checks only MX records that refer to in-zone hostnames.

Mode full checks that SRV records refer to the A or AAAA record (both in-zone and out-of-zone hostnames). Mode local checks only SRV records that refer to in-zone hostnames.

Mode full checks that delegation NS records refer to A or AAAA record (both in-zone and out-of-zone hostnames). It also checks that glue address records in the zone match those advertised by the child. Mode local checks only NS records that refer to in-zone hostnames or check that some required glue exists, that is, when the nameserver is in a child zone.

Mode full-sibling and local-sibling disable sibling glue checks, but are otherwise the same as full and local, respectively.

Mode none disables the checks.

-k *mode*

Perform "check-name" checks with the specified failure mode. Possible modes are fail (default for named-compilezone), warn (default for named-checkzone) and ignore.

-j

Read the journal, if it exists, when loading the zone file.

-M *mode*

Check if an MX record refers to a CNAME. Possible modes are fail, warn (default) and ignore.

-m *mode*

Specify whether MX records should be checked to see if they are addresses. Possible modes are fail, warn (default) and ignore.

-n *mode*

Specify whether NS records should be checked to see if they are addresses. Possible modes are fail (default for named-compilezone), warn (default for named-checkzone) and ignore.

-o *filename*

Write zone output to *filename*. If filename is - (a hyphen), then write to standard out. The hyphen mandatory for named-compilezone

-q

Run in quiet mode, reporting only the exit status.

-S *mode*

Check if a SRV record refers to a CNAME. Possible modes are fail, warn (default) and ignore.

-s *style*

Specify the style of the dumped zone file. Possible styles are full (default) and relative. The full format is most suitable for processing automatically by a separate script. The relative format is more human-readable and is thus suitable for editing by hand. For

named-checkzone this option does not cause any effects unless it dumps the zone contents. It also has no effect if the output format is not text.

-t *directory*

chroot to directory so that include directives in the configuration file are processed as if run by a similarly chrooted named.

-v

Print the version of the named-checkzone program and exit.

-W *mode*

Specify whether to check for non-terminal wildcards. Non-terminal wildcards are almost always the result of a failure to understand the wildcard matching algorithm (RFC 1034). Possible modes are warn (default) and ignore.

-w *directory*

chdir to *directory* so that relative filenames in master file $INCLUDE directives work. This is similar to the directory clause in named.conf.

Operands   The following operands are supported:

filename
    The name of the zone file.

zonename
    The domain name of the zone being checked.

Exit Status   0
    No errors were detected.

1
    An error was detected.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/dns/bind
Interface Stability	Volatile

See Also   named(1M), named-checkconf(1M), attributes(5)

RFC 1035

See the BIND 9 *Administrator's Reference Manual*. As of the date of publication of this man page, this document is available at https://www.isc.org/software/bind/documentation.

Name   ncaconfd – Solaris Network Cache and Accelerator (NCA) configuration daemon

Synopsis   `/usr/lib/inet/ncaconfd [-al ]` *interface1* [*interface2* ...]

Description   Use the ncaconfd utility to set up NCA on a system. At boot time, the ncakmod initialization script reads in nca.if(4) to determine on which interface(s) NCA should run. ncaconfd then sets up the interface.

ncaconfd also operates as a daemon if the nca_active key is set to enabled in ncakmod.conf(4) file. In this case, ncaconfd will continue as a daemon after all the NCA interfaces have been set up, listening for routing changes. The changes are then passed to NCA to control which interface NCA should use to make active outgoing TCP connections.

Options   The following options are supported:

-a   Enable active connections.

-l   Enable logging.

Files   `/etc/nca/ncakmod.conf`

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/http-cache-accelerator
Interface Stability	Committed

See Also   ncakmod(1), nca.if(4), ncakmod.conf(4), attributes(5), nca(7d)

Name ncheck – generate a list of path names versus i-numbers

Synopsis ncheck [-F *FSType*] [-V] [*generic_options*]
　　　　[-o *FSType-specific_options*] [*special*]...

Description ncheck with no options generates a path-name versus i-number list of all files on *special*. If *special* is not specified on the command line the list is generated for all *special*s in /etc/vfstab which have a numeric fsckpass. *special* is the raw device on which the file system exists.

Options -F　　　　　　　Specify the *FSType* on which to operate. The *FSType* should either be specified here or be determinable from /etc/vfstab by finding an entry in the table that has a numeric fsckpass field and an fsckdev that matches *special*.

　　-V　　　　　　Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from /etc/vfstab. This option may be used to verify and validate the command line.

　　generic_options　　Options that are commonly supported by most FSType-specific command modules. The following options are available:

　　　　-i *i-list*　　Limit the report to the files on the *i-list* that follows. The *i-list* must be separated by commas with no intervening spaces.

　　　　-a　　　　Print the names "." and ". ." which are ordinarily suppressed.

　　　　-s　　　　Report only special files and files with set-user-ID mode. This option may be used to detect violations of security policy.

　　-o　　　　　　Specify *FSType-specific_options* in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the FSType-specific module of the command.

Usage See largefile(5) for the description of the behavior of ncheck when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files /etc/vfstab　　list of default parameters for each file system

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also vfstab(4), attributes(5), largefile(5) Manual pages for the FSType-specific modules of ncheck

Notes This command may not be supported for all *FSTypes*.

Name ncheck_ufs – generate pathnames versus i-numbers for ufs file systems

Synopsis ncheck -F ufs [*generic_options*] [-o m] [*special*]...

Description ncheck -F ufs generates a pathname versus i-number list of files for the ufs file system residing on *special*. Names of directory files are followed by '/.'.

Options See ncheck(1M) for the list of *generic_options* supported.

-o   Specify ufs file system specific options. The available option is:

m   Print mode information.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also ff(1M), ncheck(1M), attributes(5)

Diagnostics When the file system structure is improper, '??' denotes the "parent" of a parentless file and a pathname beginning with '. . .' denotes a loop.

Name ndd – get and set driver configuration parameters

Synopsis ndd [-set] *driver parameter* [*value*]

Description ndd gets and sets selected configuration parameters in some kernel drivers. Currently, ndd only supports the drivers that implement the TCP/IP Internet protocol family. Each driver chooses which parameters to make visible using ndd. Since these parameters are usually tightly coupled to the implementation, they are likely to change from release to release. Some parameters may be read-only.

Note – It is strongly encouraged that you use ipadm(1M), rather than ndd, to modify or retrieve TCP/IP Internet protocols. The current ndd command will be made obsolete in a future release, replaced by ipadm(1M). Please see NOTES for more information.

If the ndd -set option is omitted, ndd queries the named *driver*, retrieves the value associated with the specified *parameter*, and prints it. If the -set option is given, ndd passes *value*, which must be specified, down to the named *driver* which assigns it to the named *parameter*.

By convention, drivers that support ndd also support a special read-only *parameter* named "?" which can be used to list the parameters supported by the driver.

Examples EXAMPLE 1   Getting Parameters Supported By The TCP Driver

To see which parameters are supported by the TCP driver, use the following command:

```
example% ndd /dev/tcp \?
```

The parameter name "?" may need to be escaped with a backslash to prevent its being interpreted as a shell meta character.

The following command sets the value of the parameter *ip_forwarding* in the dual stack IP driver to zero. This disables IPv4 packet forwarding.

```
example% ndd -set /dev/ip ip_forwarding 0
```

Similarly, in order to disable IPv6 packet forwarding, the value of parameter *ip6_forwarding*

```
example% ndd -set /dev/ip ip6_forwarding 0
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also dladm(1M), ipadm(1M), ioctl(2), attributes(5), nca(7d), arp(7P), ip(7P), ip6(7P), tcp(7P), udp(7P)

Notes The parameters supported by each driver may change from release to release. Like programs that read /dev/kmem, user programs or shell scripts that execute ndd should be prepared for parameter names to change.

The ioctl() command that ndd uses to communicate with drivers is likely to change in a future release. User programs should avoid making dependencies on it.

The use of ndd to administer Layer 2 (Data Link layer) drivers is strongly discouraged as this capability is to be obsoleted in a future release, replaced by dladm(1M). Please refer to the driver-specific man page in section 7D of the SunOS man pages.

The use of ndd to administer the drivers that implement the TCP/IP Internet protocol family (IP/TCP/SCTP/UDP/ICMP) is strongly discouraged as this capability is to be obsoleted in a future release, replaced by ipadm. Please see ipadm(1M) for instructions for modifying and retrieving supported protocol properties.

The meanings of many ndd parameters make sense only if you understand how the driver is implemented.

Name ndmpadm – administer Network Data Management Protocol activities

Synopsis /usr/sbin/ndmpadm [-?] *subcommand* [*options*] [*direct-object*]

Description The ndmpadm command can be used to query the ndmpd(1M) daemon to get the status of active sessions, terminate a session, query backup devices, and set or get the current NDMP (Network Data Management Protocol) service variables and properties. ndmpadm is implemented as a set of subcommands, many with their own direct object, which are described in the section for a given subcommand. Certain subcommands support options, which are described along with the subcommand.

The ndmpadm command supports the following subcommands:

disable
  Disable the specified authentication password handling.

enable
  Enable the specified authentication password handling.

get
  Get the value of an NDMP configuration property.

kill-sessions
  Terminate an active session.

set
  Set the value of an NDMP configuration property.

show-devices
  Get a list of tape devices connected to the server.

show-sessions
  Display the details of active NDMP sessions.

Options The following option is supported:

-?   Display a list of all subcommands and options.

Sub-commands The ndmpadm command supports the subcommands described below.

disable Subcommand The syntax for the disable subcommand is:

 # ndmpadm disable -a *auth-type*

This subcommand disables the authentication type specified by *auth-type* for an NDMP client's remote access. Valid values for *auth-type* are cram-md5 or cleartext.

enable Subcommand The syntax for the enable subcommand is:

 # ndmpadm enable -a *auth-type* **-u** *username*

This subcommand prompts for the user's password twice for confirmation and activates the specified authentication type with the given username and password for NDMP client access. Valid values for *auth-type* are cram-md5 or cleartext.

get Subcommand   The syntax for the get subcommand is:

ndmpadm get [-p] [*property***] [[-p]** *property***=***value***]...**

The property names are the same as used for the set subcommand and are described below. If you do not specify a property, the get subcommand returns all configuration properties.

kill-sessions   The kill-sessions subcommand allows you to terminate the session number *ID*.
Subcommand

The syntax for the kill-sessions subcommand is:

ndmpadm kill-sessions *ID*

set Subcommand   The syntax for the set subcommand is:

ndmpadm set [-p] *property***=***value* **[[-p]** *property***=***value***]...**

The properties you can set with the set subcommand are described in the ndmp(4) man page.

show-devices   The syntax for the show-devices subcommand is:
Subcommand
ndmpadm show-devices

This subcommand lists the name, vendor, serial number, and other information about the current tape drive and libraries connected to the system.

show-sessions   The show-sessions subcommand displays details of a session. The syntax for the
Subcommand   show-sessions subcommand is:

ndmpadm show-sessions [-i tape,scsi,data,mover] [*ID***]**

The show-sessions subcommand supports the following arguments:

-i tape,scsi,data,mover
    Identify a type of interface about which to obtain data. If no interface is specified, show-sessions displays information for all types of interfaces.

ID
    Identifies a particular session about which to display data. If no *ID* is specified, show-sessions displays data for all sessions.

Examples   **EXAMPLE 1**   Obtaining the Status of All NDMP Connections

The following command obtains status on all connections.

ndmpadm show-devices

EXAMPLE 2 Obtaining the Status of Certain Types of Connections

The following command obtains status on tape and SCSI interfaces.

```
# ndmpadm show-sessions -i scsi,tape
```

EXAMPLE 3 Limiting Protocol Version

The following command limits the use of the NDMP protocol to version 3.

```
# ndmpadm set -p version=3
```

EXAMPLE 4 Obtaining Current Version Number

The following command obtains the version number of the currently running NDMP.

```
# ndmpadm get -p version
```

EXAMPLE 5 Disconnecting a Specific Session

The command shown below disconnects session 5. The session number was previously obtained from an ndmpadm show-sessions command.

```
# ndmpadm kill-session 5
```

EXAMPLE 6 Obtaining the Values for All NDMP Properties

The following command obtains the values for all NDMP properties.

```
# ndmpadm get
```

EXAMPLE 7 Enabling CRAM-MD5 Authentication

The following command enables CRAM-MD5 authentication.

```
# ndmpadm enable -a cram-md5 -u admin
Enter new password:*****
Re-enter password:*****
```

EXAMPLE 8 Disabling Clear Text Password Authentication

The following command disables clear text password authentication.

```
# ndmpadm disable -a cleartext
```

Exit Status   0   Successful completion.

1   An error occurred, such as the ndmpd daemon is not running, that prevented ndmpadm from contacting the demon.

2   Invalid command-line options were specified.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/storage/ndmp
Interface Stability	Committed

See Also dump(1), tar(1), ndmpd(1M), ndmpstat(1M), svccfg(1M), syslogd(1M), ndmp(4), attributes(5), smf(5)

Notes The ndmpd(1M) daemon is managed by the service management facility (smf(5)), under the service identifier:

```
svc:/system/ndmpd
```

Administrative actions on this service, such as setting and getting a property can be alternatively performed using svccfg(1M). For example to enable Direct Access Recovery (DAR) mode:

```
# svccfg -s svc:/system/ndmpd
svc:/system/ndmpd> setprop ndmpd/dar-support = yes
```

...and to get the list of properties:

```
# svccfg -s svc:/system/ndmpd
svc:/system/ndmpd> listprop
```

Name ndmpd – Network Data Management Protocol daemon

Synopsis /usr/lib/ndmp/ndmpd

Description The ndmpd daemon handles client Network Data Management Protocol (NDMP) requests. NDMP is an open, enterprise-wide, network-based data management protocol used for backup and recovery. The ndmpd daemon enables users to manage data backup and recovery using Data Management Application (DMA) clients. The NDMP protocol is used to coordinate data movement and control between a DMA and an NDMP server or between two NDMP servers.

By default, ndmpd is disabled.

Exit Status 0   Successful completion.

1   An error occurred that prevented the ndmpd daemon from initializing, such as failure to fork a process, mutex initialization.

2   Invalid command-line options were specified.

Files /usr/lib/ndmp/ndmpd
Network data management protocol server binary.

/var/ndmp/ndmp.log
Network data management protocol log messages file. This file is deleted upon reboot.

/var/ndmp/dumpdates
A text file that stores information about the date and the level of dump backups.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/storage/ndmp
Interface Stability	Committed

See Also svcs(1), ndmpadm(1M), svcadm(1M), svccfg(1M), syslogd(1M), attributes(5), smf(5)

Notes The ndmpd daemon is managed by the service management facility (smf(5)), under the service identifier:

svc:/system/ndmpd:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name ndmpstat – show NDMP backup progress statistics

Synopsis ndmpstat [*tapes*] [*interval* [*count*]]

Description The ndmpstat utility reports Network Data Management Protocol (NDMP) statistics, among which are NDMP worker threads, disk IO, tape IO, files operation, performance, and backup activity.

ndmpstat reports the aggregate statistics for all tapes and disks. In order to obtain statistics for specific tape devices, the tape device name should be passed as argument to the utility.

When invoked, ndmpstat begins its display with a one-line summary of the NDMP daemon activity since the NDMP service was invoked.

Display Fields The fields in ndmpstat output are described as follows:

wthr
    Report the number of worker threads in each of the four following states:

    r
        the number of worker threads running

    w
        the number of blocked worker threads that are waiting for resources such as I/O and paging

    b
        the number of backup operations currently running

    r
        the number of restore operations currently running

file
    Report on usage of filesystem.

    rd
        the number of files being read

    wr
        the number of files being written

disk
    Report the number of disk operations per interval.

    rd
        the number of disk blocks being read

    wr
        the number of disk blocks being written

tape

Report the number of tape operations per interval. There are slots for up to four tapes, labeled with a single number. The number indicates the name of the device under /dev/rmt.

rd

the number of tape blocks being read

wr

the number of tape blocks being written

bytes

Report the number of bytes transferred. This is the aggregate value of both tape and disk devices. The number is in kilobytes.

rd

the number of kilobytes being read

wr

the number of kilobytes being written

perf

Displays a rough estimate of performance of the backup/restore operation in megabytes per second.

bk

backup performance

rs

restore performance

prcnt

Display the comparative usage of resources, in percent.

dsk

disk I/O time

tpe

tape I/O time

otr

other time (memory or idle)

See EXAMPLES.

Operands The following operands are supported:

count Specifies the number of times that the statistics display is repeated.

tape Specifies which tapes are to be given priority in the output. A command line is limited to a maximum of four tape devices. A common tape name is /dev/rmt/*n*, where *n* is an integer.

interval   Specifies the number of seconds over which ndmpstat summarizes activity. The specified interval remains in effect till the command is terminated.

Examples   EXAMPLE 1   Using ndmpstat

The following command displays a summary of NDMP daemon activity at five-second intervals.

```
example% ndmpstat 5
wthr     file      disk      tape        bytes       perf      prcnt

Name   netadm – administer network configuration profiles

Synopsis   netadm enable [-p *profile-type*] [-c *ncu-class*] *profile-name*

netadm disable [-p *profile-type*] [-c *ncu-class*] *profile-name*

netadm list [-x] [-p *profile-type*] [-c *ncu-class*]
      [*profile-name*]

netadm show-events

netadm scan-wifi *linkname*

netadm select-wifi *linkname*

netadm help

Description   The netadm utility is used to administer network profiles and interact with the NWAM daemon.

There are three types of network profiles: Network Configuration Profiles (NCPs), Locations, and External Network Modifiers (ENMs).

At any given time, there is one active NCP and one active Location on a system. Enabling a different NCP or Location (with activation-mode manual) will implicitly disable the current active NCP or Location. The current Location (if its activation-mode is manual) can also be disabled, though the effect of this will be to "turn off" some aspects of the system's networking capabilities, such as name services. Explicitly disabling an NCP is not permitted, as that would effectively shut down the basic network connectivity of the system. An NCP is only disabled implicitly when a different NCP is enabled.

Conversely, there can be zero or more active ENMs at any given time. Thus enabling or disabling one ENM has no effect on other active ENMs.

Enabling and disabling of individual NCUs is also allowed; the specified NCU must be part of the currently active NCP, and must have its activation mode set to manual. If an NCU class is not specified, all NCUs (one link and/or one interface) with the given name will be enabled or disabled.

Enabling and disabling of objects is performed asynchronously. Thus, the request to enable or disable can succeed, while the action itself fails. A failure of this sort will be reflected in the object state; maintenance state indicates that the last action taken failed.

Sub-commands   The following subcommands are supported:

enable [-p *profile-type*] [-c *ncu-class*] *profile-name*
    Enable the specified profile. If the profile name is not unique, the profile type must be specified to identify the profile to be enabled. If the profile type is NCU and the name is not unique (that is, there is both a link and interface NCU with the same name), both NCUs will be enabled, unless the -c option is used to specify the NCU class. Profile type must be one of ncp, ncu, loc, or enm; NCU class must be one of phys or ip.

disable [-p *profile-type*] [-c *ncu-class*] *profile-name*
    Disable the specified profile. If the profile name is not unique, the profile type must be
    specified to identify the profile to be disabled. If the profile type is NCU and the name is not
    unique (that is, there is both a link and interface NCU with the same name), both NCUs
    will be disabled, unless the -c option is used to specify the NCU class. Profile type must be
    one of ncu, loc, or enm; NCU class must be one of phys or ip.

list [-x] [-p *profile-type*] [-c *ncu-class*] [*profile-name*]
    List all available profiles and their current state. If a particular profile is specified by name,
    list only the current state of that profile. If the profile name is not unique, all profiles with
    the given name will be listed; or the profile type and/or NCU class can be included to
    identify a specific profile. If only a type is provided, list all profiles of that type. Listing the
    active NCP will include the NCUs that make up that NCP.

    The -x option causes the list subcommand to display a fourth column of output, headed
    AUXILIARY STATE, after the first three column headings in the default display, TYPE,
    PROFILE, and STATE. The AUXILIARY STATE column shows why a profile is in a given state.

    Possible STATE values are:

    disabled
        A manually-activated profile that has not been activated.

    offline
        A conditionally- or system-activated profile that has not been activated. It might not be
        active because its conditions have not been satisfied; or it might be that another profile
        has more specific conditions that are met and has been activated instead (in the case of
        profile types that must be activated one at a time, such as Locations).

    online
        A conditionally- or system-activated profile whose conditions have been met and that
        has been successfully activated; or a manually-activated profile that has been
        successfully activated at the request of the user.

    maintenance
        Activation of the profile was attempted, but failed.

    initialized
        The profile represents a valid configuration object for which no action has yet been
        taken.

    uninitialized
        The profile represents a configuration object not present in the system; for example, an
        NCU corresponding to a physical link that has been removed.

show-events
    Listen for stream of events from the NWAM daemon and display them.

scan-wifi *linkname*
    Initiate a wireless scan on link linkname.

select-wifi *linkname*

Select a wireless network to connect to from scan results on link linkname. Prompts for selection, WiFi key, and so forth, if necessary.

help

Display a usage message with short descriptions for each subcommand.

Examples   **EXAMPLE 1**   Enabling a User-Specified Location

The following command enables a user-specified location.

```
# netadm enable -p loc office
Disabled loc 'home'.
Enabled loc 'office'
```

EXAMPLE 2   Disabling an ENM

The following command disables an ENM.

```
# netadm disable -p enm myvpn
Disabled enm 'myvpn'.
```

EXAMPLE 3   Listing All NCPs

The following command lists all NCPs.

```
# netadm list -xp ncp
TYPE          PROFILE      STATE          AUXILIARY STATE
ncp           Automatic    disabled       disabled by administrator
ncp           User         online         active
ncu:phys      nge0         online         interface/link is up
ncu:ip        nge0         online         interface/link is up
ncu:phys      nge1         offline        interface/link is down
ncu:ip        nge1         offline        conditions for activation are
                                          unmet
```

EXAMPLE 4   Listing NCUs in Active NCP

The following command lists all `ip` NCUs in the active NCP.

```
# netadm list -c ip
TYPE          PROFILE      STATE
ncu:ip        bge0         online
ncu:ip        bge1         disabled
```

EXAMPLE 5   Forcing a Scan

The following command forces a scan on the wireless interface `wpi0`.

```
# netadm scan-wifi wpi0
```

EXAMPLE 6 Selecting a WiFi Network

The following command selects a WiFi network that is broadcasting its ESSID.

```
# netadm select-wifi wpi0
1: ESSID testing BSSID 0:40:96:29:e9:d8
2: ESSID sunwifi BSSID 0:b:e:9f:b5:80
3: ESSID sunwifi BSSID 0:b:e:85:26:c0
4: ESSID sunwifi BSSID 0:b:e:49:2f:80
5: Other

Choose WLAN to connect to [1-5]: 2
#
```

EXAMPLE 7 Selecting a WiFi Network (Alternative)

The following command selects a WiFi network that is not broadcasting its ESSID.

```
# netadm select-wifi wpi0
1: ESSID testing BSSID 0:40:96:29:e9:d8
2: ESSID sunwifi BSSID 0:b:e:85:26:c0
3: ESSID sunwifi BSSID 0:b:e:9f:b5:80
4: ESSID sunwifi BSSID 0:b:e:49:2f:80
5: ESSID sunwifi BSSID 0:b:e:49:62:c0
6: Other

Choose WLAN to connect to [1-6]: 6

Enter WLAN name: oraclewifi
1: None
2: WEP
3: WPA
Enter security mode: 2

Enter WLAN key for ESSID oraclewifi: 123456

Enter key slot [1-4]: 1
#
```

EXAMPLE 8 Monitoring nwamd

The following command monitors nwamd(1M) when switching locations.

```
# netadm show-events
EVENT           DESCRIPTION
OBJECT_ACTION   loc Automatic -> action refresh
OBJECT_STATE    loc Automatic -> state offline*, method/service executi
OBJECT_STATE    loc Automatic -> state online, active
OBJECT_ACTION   loc home -> action refresh
OBJECT_ACTION   loc NoNet -> action refresh
OBJECT_ACTION   loc User -> action refresh
```

EXAMPLE 8 Monitoring nwamd   *(Continued)*

```
OBJECT_ACTION    loc home -> action enable
OBJECT_STATE     loc home -> state offline*, method/service executing
OBJECT_STATE     loc Automatic -> state offline, conditions for activati
OBJECT_STATE     loc home -> state online, active
^C
#
```

Attributes See attributes(5) for descriptions of the following attributes:

Name   netcfg – create and modify network configuration profiles

Synopsis   netcfg

netcfg *subcommand* [*options*...]

netcfg [-d] -f *command-file*

netcfg help [*subcommand*]

Description   The netcfg utility manipulates system network configuration profiles. netcfg can be invoked interactively, with an individual subcommand, or by specifying a command file that contains a series of subcommands.

The netcfg utility operates on several different types of configuration profiles:

- Network Configuration Profiles (NCPs)
- Locations
- External Network Modifiers (ENMs)
- Known WLANs

For more details on these profile types, refer to the "Profiles" section.

netcfg commands are performed within a scope. There are three scopes: global, profile, and NCP. When netcfg is invoked without any arguments, the editing session begins in the global scope. In the global scope, NCPs, Location and ENM profiles, and Known WLAN entries are available to operate on. Selecting an NCP will move the editing session to the NCP scope; from there, individual NCUs may be created or selected to move into the profile scope. Also, at the global scope, selecting or creating a Location, ENM, or Known WLAN will move the editing session to the profile scope.

Within a given profile scope, profile properties may be viewed and modified.

In interactive mode, changes are not stored to persistent storage until commit is invoked. Commit is implicitly invoked at "end" or "exit", or can be explicitly invoked by the user. When commit is invoked, the entire profile is committed. In order to maintain the consistency of persistent storage, the commit operation includes a verify step; if verification fails, the commit also fails. If an implicit commit fails, the user will be given the option of ending or exiting without committing the current changes, or remaining in the current scope to make further changes.

Profiles   The NWAM service manages network configuration by storing desired property values in profiles. It then determines which profile should be active at a given time, depending on current network conditions, and activates that profile. In addition to the Network Configuration Profiles (NCPs) discussed in the previous section, nwamd also manages Location and ENM profiles.

Network Configuration Profiles (NCPs)
An NCP specifies the configuration of the local network components, including physical links, IP tunnel links, and IP interfaces. An IP interface must be associated with an underlying link of either type. These components are collectively referred to as Network Configuration Units, or NCUs.

There can be any number of NCPs configured on a system. The Automatic NCP is created and managed by nwamd, and cannot be modified by the user. This NCP consists of one link NCU and one interface NCU for each physical link present in the system. As links are added or removed from the system, their corresponding NCUs are added or removed from the Automatic NCP. The policy implemented in this NCP is to prefer wired links over wireless, and to plumb IP on all connected wired links, or one wireless link if no wired links are connected.

The system will also create a User NCP upon upgrade from an earlier version of the NWAM service, based on the configuration found in the old /etc/nwam/llp file. In most cases, when the NWAM service was active at upgrade, the Automatic NCP is active initially, even if a User NCP is created. However, if explicit changes, such as a static IP address, are detected in the old configuration, the User NCP is active initially.

Finally, the user can create any number of additional NCPs. These NCPs are managed entirely by the user; NCUs must be added or removed explicitly, and it is possible to add NCUs that do not map to any link currently installed in the system, or to remove NCUs that do map to a link present in the system. The user can determine the policy for these NCPs.

After making its initial NCP selection, the system does not change the active NCP. The user can do this at any time using the GUI or the netadm(1M) command.

Locations
A Location specifies system-wide network configuration, including name services, domain, IP Filter, and IPsec configuration.

External Network Modifiers (ENMs)
External Network Modifiers are, as the name suggests, applications external to the NWAM service that can modify and/or create network configuration. nwamd activates or deactivates an ENM depending on conditions that are specified as part of the ENM profile. Alternatively, the user might choose to manually activate/deactivate ENMs as needed.

While Location profiles allow a specific set of network-related services to be configured automatically based on current network conditions, that set of services is limited. ENMs provide additional flexibility, allowing the user to specify changes to SMF service properties and/or state, or any other system settings, to be applied under specific conditions.

Properties
netcfg supports the following types of properties:

- NCU properties
- properties of interface NCUs
- properties common to all link NCUs
- location properties
- ENM properties

- known WLAN properties

These properties are described in the following subsections.

NCU Properties   The following properties are common to all NCUs.

type: enumerated value: *link | interface*
  Specifies the NCU type, either *link* or *interface*. The value is implicitly determined based on the specified class.

class: enumerated value: *phys* for link NCUs; *ip* for interface NCU
  Specifies the NCU class.

parent: string: *name of parent NCP*
  Specifies the NCP of which this NCU is a component.

The type, class, and parent properties are set when the NCU is created and cannot be changed later.

enabled: boolean: true | false
  If the activation-mode is manual, the enabled property reflects the NCU's current state. This property is read-only; it is changed indirectly by enabling or disabling the NCU using netadm(1M).

  The default value is true.

Properties of Interface   ip-version: list of enumerated values: ipv4 | ipv6
NCUs   The version(s) of IP that should be used on this NCU.

  The default value is ipv4,ipv6.

ipv4-addrsrc: list of enumerated values: dhcp | static
  Identifies the source of IPv4 addresses assigned to this NCU; multiple values may be assigned. If one of the values assigned is static, the ipv4-addr property must include at least one IPv4 address to be assigned to the NCU.

  The default value is dhcp.

ipv4-addr: list of IPv4 address(es)
  One or more IPv4 addresses to be assigned to this NCU.

ipv4-default-route:*IPv4 address*
  The IPv4 address of the default router; if this property is set, a default route for IPv4 traffic will be associated with this interface when it is brought up.

ipv6-addrsrc: list of enumerated values: dhcp | autoconf | static
  Identifies the source of IPv6 addresses assigned to this NCU; multiple values can be assigned. If one of the values assigned is static, the ipv6-addr property must include at least one IPv6 address to be assigned to the NCU.

  The default value is dhcp,autoconf.

ipv6-addr: list of IPv6 address(es)
   One or more IPv6 addresses to be assigned to this NCU.

ipv6-default-route: *IPv6 address*
   The IPv6 address of the default router; if this property is set, a default route for IPv6 traffic
   will be associated with this interface when it is brought up.

Properties Common to   activation-mode: enumerated value: manual | prioritized
All LINK NCUs   The type of trigger for automatic activation of this NCU.

   The default value is manual.

priority-group: uint64: *group priority number*
   If activation-mode is set to prioritized, this property specifies the priority group to
   which this NCU belongs. A group consists of one or more NCUs; smaller numbers are
   higher priority. The highest priority group that is determined to be available will be
   activated by nwamd(1M), and will remain so until it is no longer available, or until a higher
   priority group becomes available.

priority-mode: enumerated value: exclusive | shared | all
   If activation-mode is set to prioritized, this property specifies the mode used to determine
   availability and activation behavior for a priority group.

   exclusive
      At least one NCU must be available to make the group available, and only one NCU will
      be activated. If more than one member NCU is available, nwamd(1M) will randomly
      choose one to activate.

   shared
      At least one NCU must be available to make the group available; all available NCUs will
      be activated.

   all
      All group member NCUs must be available to make the group available; all member
      NCUs will be activated.

link-mac-addr: string: 48-bit MAC address
   The MAC address assigned to this link. By default, NWAM will request the
   factory-assigned or default MAC address for the link; set a different value here to override
   that selection.

link-autopush: list of strings: modules to be pushed over the link
   Identifies a list of modules that should be automatically pushed over the link when it is
   opened.

link-mtu: uint64: MTU size for this link
   This property will be automatically set to the default MTU for the physical link; that value
   may be overridden by setting this property to a different value.

Note that the range of allowed MTU values depends on the underlying hardware. Because NCUs may be created before the underlying hardware is present with driver attached, it is not possible to verify the value set at the time the NCU is edited. If an NCU fails to activate because of an invalid MTU size, this will be indicated in the system log, and the NCU will be placed in maintenance state.

Location Properties   activation-mode: enumerated value: manual | system | conditional-all | conditional-any

The type of trigger for automatic activation of this location.

The default value is manual.

enabled: boolean: true | false

If the activation-mode is manual, the enabled property reflects the location's current state. This property is read-only; it is changed indirectly by enabling or disabling the location using netadm(1M).

The default value is false.

conditions: list of strings: *conditional expressions*

If activation-mode is set to conditional-all or conditional-any, this property specifies the test to determine whether this location should be activated. The conditional expression is made up of a sequence of conditions that can be assigned a boolean value, such as "advertised-domain is sun.com" or "ip:bge0 is-not active." The format of these expressions is defined in the "Condition Expressions" section, below. If multiple conditions are specified, either all must be true to meet the activation requirements (when activation-mode is conditional-all) or any one may be true (when activation-mode is conditional-any).

Note the distinction between advertised-domain and system-domain. The advertised domain is learned by means of external communication, such as the DNSdmain or NISdmain advertised by a DHCP server. This attribute is useful for conditional activation of locations; for example, if the advertised domain is mycompany.com, activate the "work" location. The system domain is the domain which is currently assigned to the system; that is, it is the value returned by the domainname(1M) command. This attribute is useful for conditional activation of ENMs, as it will only become true after a location has been activated and the system is configured for that particular domain.

default-domain: string: *system domain name*

The domain name that should be applied to the system; this domain name will be used by NIS and LDAP.

nameservices: enum value list: files | dns | nis | ldap

Specifies the name services that should be configured, such as DNS, NIS, and LDAP.

nameservices-config-file: string: *path to* nsswitch.conf *file*

Specifies the nsswitch.conf file to be used. This property must always have a value. If the nameservices property specifies a single name service, this property will, by default,

contain /etc/nsswitch.*nameservice* for the name service specified in the nameservices
property; this value can be changed by the user. If the nameservices property identifies
more than one name service, the user must specify an additional value for this property.

dns-nameservice-configsrc: enum value list: manual | dhcp
    Specifies the source(s) that should be used to obtain configuration information for the DNS
    name service. If manual is included, the remaining dns-nameservice-* properties will be
    used.

dns-nameservice-domain: string: *domain name*
dns-nameservice-servers: string list: *name server address(es)*
dns-nameservice-search: string list: *domain search string*
dns-nameservice-sortlist: string list: *IP address, netmask pair(s)*
dns-nameservice-options: string list: *resolver variable(s) to be modified*
    If DNS is one of the configured name services and manual is one of its configuration
    sources, these properties specify its configuration parameters. Only the servers property is
    required; search and domain are mutually exclusive and only one can be specified, which
    will override the domain provided by the DHCP server if dhcp is also used. The format of
    these values are the same as the respective options in resolv.conf(4).

nis-nameservice-configsrc: enum value list: manual | dhcp
    Specifies the source(s) that should be used to obtain configuration information for the NIS
    name service. If manual is included, the remaining nis-nameservice-* properties will be
    used.

nis-nameservice-servers: string list: *name server address(es)*
    If NIS is one of the configured name services and manual is one of its configuration sources,
    this property specifies its server address. If this property is not specified, the NIS client will
    be started in broadcast mode.

ldap-nameservice-configsrc: enum value list: manual
    Specifies the source that should be used to obtain configuration information for the LDAP
    name service. manual is currently the only option for LDAP; thus the ldap-nameservice-*
    properties must be provided to complete LDAP configuration.

ldap-nameservice-servers: string list: *name server address(es)*
    If LDAP is one of the configured name services, this property specifies its server address.
    This property is required, and it is expected that the specified server will have a client
    profile which will be used to complete client configuration.

nfsv4-domain: string: *domain name to be used for NVSv4*
    Specifies the NVSv4 domain to be used. If this value is unspecified, the name service
    domain will be used.

ipfilter-config-file: string: *path to ipfilter IPv4 configuration file*
ipfilter-v6-config-file: string: *path to ipfilter IPv6*
ipnat-config-file: string: *path to* ipnat *configuration file*
ippool-config-file: string:*path to* ippool *configuration file*

These properties each specify the path to the rules file for a component of the ipfilter(5) configuration. If a given config-file property is set, the corresponding IP filter component will be enabled, reading configuration from the specified file.

ike-config-file: string: *path to IKE configuration file*
Specifies the IKE configuration file. If a value is specified, the svc:/network/ipsec/ike service will be enabled, reading configuration from the specified file.

ipsecpolicy-config-file: string: *path to IPsec policy configuration file*
Specifies the IPsec policy configuration file. If a value is specified, the svc:/network/ipsec/policy service will be enabled, reading configuration from the specified file.

ENM Properties activation-mode: enumerated value: manual | conditional-all | conditional-any
The type of trigger for automatic activation of this ENM.

The default value is manual.

enabled: boolean: true | false
If the activation-mode is manual, the enabled property reflects the ENM's current state. This property is read-only; it is changed indirectly by enabling or disabling the ENM using netadm(1M).

The default value is false.

conditions: list of strings: *conditional expressions*
If activation-mode is set to conditional-all or conditional-any, this property specifies the test to determine whether or not this ENM should be activated. The conditional expression is made up of a sequence of conditions that can be assigned a boolean value, such as "system-domain is sun.com" or "ip:bge0 is-not active." The format of these expressions is defined in the "Condition Expressions" section below. If multiple conditions are specified, either all must be true to meet the activation requirements (when activation-mode is conditional-all) or any one may be true (when activation-mode is conditional-any).

Note the distinction between advertised-domain and system-domain. The advertised domain is learned by means of external communication, such as the DNSdmain or NISdmain advertised by a DHCP server. This attribute is useful for conditional activation of locations; for example, if the advertised domain is mycompany.com, activate the "work" location. The system domain is the domain which is currently assigned to the system; that is, it is the value returned by the |domainname|(1M) command. This attribute is useful for conditional activation of ENMs, as it will only become true after a location has been activated and the system configured for that particular domain.

fmri: string: *service FMRI*
If this ENM is implemented as an SMF service, this property identifies that service. If this property is specified, the ENM will be activated by enabling the service and deactivated by disabling the service.

start: string: *start command*
> If this ENM is not implemented as an SMF service, this property identifies the command that should be exec'ed to start or activate the ENM. This property will be ignored if the FMRI property is set.

stop: string: *stop command*
> If this ENM is not implemented as an SMF service, this property identifies the command that should be exec'ed to stop/deactivate the ENM. This property will be ignored if the FMRI property is set.

Known WLAN
Properties
bssids: list of strings: WLAN BSSID(s) (AP MAC addresses)
> If a specific Access Point should be preferred over others with the same name/ESSID, this property allows the AP's BSSID to be specified.

priority: uint64: a numeric priority value
> The relative priority of this WLAN; a smaller number represents higher priority.
>
> Note that this number can be changed if subsequent changes to the set of Known WLAN objects require such a change. For example, consider a system that is configured with two Known WLAN objects, wlanA and wlanB. wlanA has priority 1, and wlanB has priority 2. A new Known WLAN, wlanC, is created and assigned priority 2. In this case, the complete list will be updated such that wlanA has priority 1, wlanC has priority 2, and wlanB has priority 3. No two WLANs can have the same priority value, so the addition of wlanC at priority 2 forces wlanB to be shifted down in priority. If any additional WLANs existed at lower priorities than wlanB, they would be shifted accordingly.

keyslot: uint64: the key slot to be used for this WLAN
> If the WLAN uses an encryption mode that supports multiple keyslots, the slot to place the key can be specified in this property. If unspecified, slot 1 is used by default.

keyname: list of strings: Secure object name(s)
> Allows the user to associate secure objects created using dladm(1M) with Known WLANs.

Condition Expressions   Locations and ENMs can be activated based on a set of user-specified conditions. The following table summarizes the syntax of those condition expressions.

Object Type	Object	Condition
ncp|ncu|enm|loc	name	is/is-not active

```
Object Type     Condition                        Object
-----------------------------------------------------------
essid           is/is-not/contains/does-not-contain name string
bssid           is/is-not                         bssid string
ip-address      is/is-not                         IPv4 or IPv6
                                                  address
ip-address      is-in-range/is-not-in-range       IPv4 or IPv6
                                                  address plus
```

```
                                                netmask/prefixlen
advertised-domain is/is-not/contains/does-not-contain name string
system-domain     is/is-not/contains/does-not-contain name string
```

Options The following options are not associated with any particular netcfg subcommand:

-d
> Removes all configuration before reading subcommands from the command file (see following option).

-f *command_file*
> Reads and executes netcfg subcommands from *command_file*.

Sub-commands The following subcommands are supported.

cancel
> End the current profile specification without committing the current changes to persistent storage, and pop up to the next higher scope.
>
> This subcommand is valid in the NCP and profile scopes.

clear *prop-name*
> Clear the value for the specified property.
>
> This subcommand is valid in the profile scope.

commit
> Commit the current profile to persistent storage. Because a configuration must be correct to be committed, this operation automatically performs a verify on the object as well. The commit operation is attempted automatically upon leaving the current scope (with either the end or exit subcommand).
>
> This subcommand is valid in the profile scope.
>
> Note that, in non-interactive mode, a commit is not required, as the commit is implicit for any subcommand that changes a value.

create [-t *template*] *object-type* [*class*] *object-name*
> Create an in-memory profile of the specified type and name. The -t *template* option specifies that the new object should be identical to *template*, where *template* is the name of an existing object of the same type. If the -t option is not used, the new object is created with default values. For NCPs, only a "User" NCP can be created.
>
> This subcommand is valid in the global and NCP scopes.

destroy { -a | *object-type* [*class*] *object-name* }
> Remove all or the specified profile from memory and persistent storage. This action is immediate; it does not need to be committed. A destroyed object cannot be reverted.
>
> This subcommand is valid in the global and NCP scopes if a specific object is specified; the -a option is only valid in the global scope.

end

    End the current profile specification, and pop up to the next higher scope. The current object is verified and committed before ending; if either the verify or commit fails, an appropriate error message is issued and the user is given the opportunity to end without committing the current changes, or to remain in the current scope and continue editing.

    This subcommand is valid in any scope.

exit

    Exit the netcfg session. The current profile is verified and committed before ending; if either fails, an appropriate error message is issued and the user is given the opportunity to exit without committing the current changes, or to remain in the current scope and continue editing.

    This subcommand is valid in any scope.

export [-d] [-f *output-file*] [*object-type* [*class*] *object-name*]

    Print the current configuration at the current or specified scope to standard out, or to a file specified with the -f option. The -d option generates a destroy -a as the first line of output. This subcommand produces output in a form suitable for use in a command file. System created objects, including the Automatic NCP and the Automatic, NoNet, and User locations, cannot be exported.

    This subcommand is valid in any scope.

get [-V] *prop-name*

    Get the current (in-memory) value of the specified property. By default, both the property name and value are printed; if the -V option is specified, only the property value is displayed.

    This subcommand is valid in the profile scope.

help [*subcommand*]

    Display general help or help about a specific subcommand.

    This subcommand is valid in any scope.

list [-a] [*object-type* [*class*] *object-name*]

    List all profiles, property-value pairs and resources that exist at the current or specified scope. When listing properties of an object, the default behavior is to only list properties that apply to the specified configuration. That is, if listing an IP NCU for which ipv4-addrsrc is dhcp, the ipv4-addr property will not be listed. Including the -a option will result in all properties being listed, whether or not they apply to the current settings.

    This subcommand is valid in any scope.

revert

    Delete any current changes to the current profile and revert to the values from persistent storage.

This subcommand is valid in the profile scope.

select *object-type* [*class*] *object-name*
Select one of the profiles available at the current scope level and jump down into that object's scope. The selected object will be loaded into memory from persistent storage.

This subcommand is valid in the global and NCP scopes.

set *prop-name=value1*[,*value2*...]
Set the current (in-memory) value of the specified property. If performed in non-interactive mode, the change is also committed to persistent storage.

The delimiter for values of multi-valued properties is ",” (comma). If any of the individual values in such a property contains a comma, it must be escaped (that is, written as \,). Commas within properties that can only have a single value are not interpreted as delimiters and need not be escaped.

This subcommand is valid in the profile scope.

verify
Verify that the current in-memory object has a valid configuration.

This subcommand is valid in the profile scope.

walkprop [-a]
Walk each property associated with the current profile. For each property, the name and current value are displayed, and a prompt is given to allow the user to change the current value.

The delimiter for values of multi-valued properties is "," (comma). If any of the individual values in such a property contains a comma, it must be escaped (that is, written as \,). Commas within properties that can only have a single value are not interpreted as delimiters and need not be escaped.

By default, only properties that are required based on properties that are already set will be walked; that is, if ipv4-addrsrc is set to dhcp, ipv4-addr will not be walked. Including the -a option will result in all available properties being walked.

This subcommand is valid in the profile scope.

This subcommand is only meaningful in interactive mode.

Examples

EXAMPLE 1   Setting an NCU Property

The following command sets an NCU property from the command line (that is, in non-interactive mode).

```
# netcfg "select ncp User; select ncu phys net1; set link-mtu=1492"
```

EXAMPLE 2 Listing Top-Level Profiles

The following command lists all top-level profiles from the command line.

```
# netcfg list
NCPs:
        Automatic
        User
Locations:
        Automatic
        home
        NoNet
        office
ENMs:
        enmtest
        myenm
WLANs:
        sunwifi
        coffeeshop
        linksys
```

EXAMPLE 3 Destoying a Location Profile

The following command destroys a Location profile from the command line.

```
# netcfg destroy loc home
Destroyed loc 'home'
```

EXAMPLE 4 Creating an NCU Profile

The following command sequence interactively creates an NCU profile.

```
# netcfg
netcfg> select ncp user
netcfg:ncp:User> create ncu ip net1
Created ncu 'net1'.  Walking properties ...
ip-version (ipv4,ipv6) [ipv4|ipv6]> ipv4
ipv4-addrsrc (dhcp) [dhcp|static]> static
ipv4-addr> 168.1.2.3
netcfg:ncp:User:ncu:net1> list
ncu:net1
      type:           interface
      class:          ip
      parent:         "User"
      enabled         true
      ip version:     ipv4
      ipv4-addrsrc:   static
      ipv4-addr:      "168.1.2.3"
      ipv6-addrsrc    dhcp,autoconf
netcfg:ncp:User:ncu:net1> commit
Committed changes
```

EXAMPLE 4   Creating an NCU Profile   *(Continued)*

```
netcfg:ncp:User:ncu:net1> end
netcfg:ncp:User> exit
```

EXAMPLE 5   Manipulating an ENM

The following command sequence selects an existing ENM, display its contents, and changes a property value.

```
# netcfg
netcfg>select enm myenm
netcfg:enm:myenm>list
ENM:myenm
        activation-mode  manual
        enabled          true
        start            "/usr/local/bin/myenm start"
        stop             "/usr/local/bin/myenm stop"
netcfg:enm:myenm>set stop="/bin/alt_stop"
netcfg:enm:myenm>list
ENM:myenm
        activation-mode  manual
        enabled          true
        start            "/usr/local/bin/myenm start"
        stop             "/bin/alt_stop"
netcfg:enm:myenm>exit
Committed changes
```

EXAMPLE 6   Configuring a Static Address

The following command sequence configures a static address of 192.168.2.12/24 on interface bge0 using the Home NCP. This interface is enabled by default when the Home NCP is activated.

```
# netcfg
netcfg> create ncp Home
```

First configure phys NCU:

```
netcfg:ncp:Home> create ncu phys bge0
Created ncu 'bge0'.  Walking properties ...
activation-mode (manual) [manual|prioritized]>
link-mac-addr>
link-autopush>
link-mtu>
netcfg:ncp:Home:ncu:bge0> end
Committed changes
netcfg:ncp:Home>
```

Then, configure IP NCU:

EXAMPLE 6   Configuring a Static Address   *(Continued)*

```
netcfg:ncp:Home> create ncu ip bge0
Created ncu 'bge0'.  Walking properties ...
ip-version (ipv4,ipv6) [ipv4|ipv6]>
ipv4-addrsrc (dhcp) [dhcp|static]> static
ipv4-addr> 192.168.2.10/24
ipv4-default-route>
ipv6-addrsrc (dhcp,autoconf) [dhcp|autoconf|static]>
ipv6-default-route>
netcfg:ncp:Home:ncu:bge0> list
ncu:bge0
    type               interface
    class              ip
    parent             "Home"
    enabled            true
    ip-version         ipv4,ipv6
    ipv4-addrsrc       static
    ipv4-addr          "192.168.2.10/24"
    ipv6-addrsrc       dhcp,autoconf
netcfg:ncp:Home:ncu:bge0> exit
Committed changes
#
```

Switch to the Home NCP using netadm(1M).

EXAMPLE 7   Configuring Location Based on a Condition

The following command sequences configures a location based on a condition. The location is activated whenever the IP address is in the 10.0.8.0/24 subnet. Also, NIS is configured in this location.

```
netcfg> select loc office
netcfg:loc:office> list
loc:office
        activation-mode             conditional-any
        conditions                  "ip-address is 10.0.8.0/24"
        enabled                     false
        nameservices                dns,nis
        nameservices-config-file    "/etc/nsswitch.nis"
        dns-nameservice-configsrc   dhcp
        nis-nameservice-configsrc   manual
        nis-nameservice-servers     "10.2.18.24"
        default-domain              "labs.east.sun.com"
netcfg:loc:office>
```

EXAMPLE 8 Creating a Known WLAN

The following command sequence establishes a known WLAN named `coffeeshop` with a WEP key.

```
netcfg> select wlan coffeeshop
netcfg:wlan:coffeeshop> list
known wlan:coffeeshop
        priority                2
        keyname                 "foo"
        security-mode           wep
netcfg:wlan:coffeeshop> set priority=1
netcfg:wlan:coffeeshop> end
Committed changes
```

EXAMPLE 9 Exporting Current Configuration to a File

The following command exports the current configuration to a file.

```
netcfg> export -f /tmp/nwam.config
```

Or, perform the same task from the Unix command line:

```
# netcfg export -f /tmp/nwam.config
```

EXAMPLE 10 Importing Current Configuration from a File

The following command imports the current configuration from a file.

```
# netcfg -f /tmp/nwam.config
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also dladm(1M), domainname(1M), netadm(1M), netcfgd(1M), nwamd(1M), resolv.conf(4), attributes(5), ipfilter(5)

See also nwam-manager(1M), available in the JDS/GNOME man page collection.

Name netcfgd – network configuration management daemon

Synopsis `/lib/inet/netcfgd`

Description `netcfgd` is a system daemon to manage network configuration. This daemon is started automatically by svc:/network/netcfg:default and should not be invoked directly. It does not constitute a programming interface.

netcfgd manages access to a network configuration repository, insuring that readers and writers have the appropriate authorizations. Specifically, an application wishing to read network configuration must have the `solaris.network.autoconf.read` authorization; while an application wishing to write network configuration must have the `solaris.network.autoconf.write` authorization. These authorizations are registered in `auth_attr(4)`, and are included in the `Network Autoconf` profile found in `prof_attr(4)`.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also `svcs(1)`, `netcfg(1M)`, `nwamd(1M)`, `svcadm(1M)`, `auth_attr(4)`, `prof_attr(4)`, `attributes(5)`, `smf(5)`

See also `nwam-manager(1M)`, available in the JDS/GNOME man page collection.

Name netservices – enable or disable network services

Synopsis netservices open

netservices limited

Description The netservices command uses the Solaris service management facility, smf(5), to control services that accept over the network from remote clients.

When netservices is invoked with the limited command-line argument, all network services except the secure shell daemon, sshd(1M), are either disabled or constrained to respond to local requests only.

Invoking netservices with the open command-line argument enables a large set of network services, as in previous releases of Solaris.

To customize the configuration set enabled by netservices, use svcadm(1M) to enable or disable individual services. Use svccfg(1M) to set properties that determine whether a service accepts input from remote clients. See the man pages for individual services for the names of service instances and their properties.

Note that the netservices command has an interface stability of Obsolete.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Obsolete

See Also svcadm(1M), svccfg(1M), sshd(1M), attributes(5), smf(5)

Name netstat – show network status

Synopsis netstat [-anvR] [-f *address_family*] [-P *protocol*]

netstat -g [-nv] [-f *address_family*]

netstat -p [-n] [-f *address_family*]

netstat -s [-f *address_family*] [-P *protocol*]
    [-T u | d] [*interval* [*count*]]

netstat -m [-T u | d] [-v] [*interval* [*count*]]

netstat -i [-I *interface*] [-an] [-f *address_family*]
    [-T u | d] [*interval* [*count*]]

netstat -r [-anvR] [-f *address_family* | *filter*]

netstat -M [-ns] [-f *address_family*]

netstat -D [-I *interface*] [-f *address_family*]

netstat -d [-f *address_family*]

Description The netstat command displays the contents of certain network-related data structures in various formats, depending on the options you select.

The netstat command has the several forms shown in the SYNOPSIS section, above, listed as follows:

- The first form of the command (with no required arguments) displays a list of active sockets for each protocol.
- The second, third, and fourth forms (-g, -p, and -s options) display information from various network data structures.
- The fifth form (-m option) displays STREAMS memory statistics.
- The sixth form (-i option) shows the state of the interfaces.
- The seventh form (-r option) displays the routing table.
- The eighth form (-M option) displays the multicast routing table.
- The ninth form (-D option) displays the state of DHCP on one or all interfaces.
- The tenth form (-d option) displays the table of destination cache entries.

These forms are described in greater detail below.

With no arguments (the first form), netstat displays connected sockets for PF_INET, PF_INET6, and PF_UNIX, unless modified otherwise by the -f option.

Options -a

Show the state of all sockets, all routing table entries, or all interfaces, both physical and logical. Normally, listener sockets used by server processes are not shown. Under most conditions, only interface, host, network, and default routes are shown and only the status of physical interfaces is shown.

-d

Show the destination cache entry table. See DISPLAYS, below.

-f *address_family*

Limit all displays to those of the specified *address_family*. The value of *address_family* can be one of the following:

inet   For the AF_INET address family showing IPv4 information.

inet6   For the AF_INET6 address family showing IPv6 information.

unix   For the AF_UNIX address family.

sdp   For the Socket Description Protocol (SDP) protocol and address family. The address state displayed for an SDP socket are listed below. Flags displayed by netstat are followed by their meanings.

     LST Listen
     EST Established
     PL Path Lookup
     HS Hello Request Sent
     HR Hello Request Received
     HAR Hello Ack Recvd
     HAS Hello Ack sent
     DR Fin received
     DS Fin sent
     DSA Fin Ack recvd
     DRC Simultaneous Disconnect
     DSC Disconnect sent (peer already closed)
     TW1 Time Wait 1
     TW2 Time Wait 2
     CLD Closed
     ERR Error
     INV Invalid
     UNK Unknown

For the SDP protocol and address family, netstat displays the following column headings:

Local Address   Local IP address

Remote Address	Remote IP address
State	Current state of the socket
RxBPending	Bytes unread
TxBQueued	Bytes queued for Tx (includes `TxBPosted`)
TxBPosted	Bytes sent to HW for transmission
LAdvtSz	Local advertised buffer size
RAdvtSz	Remote advertised buffer size
LAdvtBuff	Number of local advertised Rx buffers
RAdvtBuff	Number of remote advertised Rx buffers
LPostBuff	Number of Rx buffers currently posted

-f *filter*

With -r only, limit the display of routes to those matching the specified filter. A filter rule consists of a *keyword*:*value* pair. The known keywords and the value syntax are:

af:{inet|inet6|unix|sdp|*number*}   Selects an address family. This is identical to -f *address_family* and both syntaxes are supported.

outif:{*name*|*ifIndex*|any|none}   Selects an output interface. You can specify the interface by name (such as hme0) or by ifIndex number (for example, 2). If any is used, the filter matches all routes having a specified interface (anything other than null). If none is used, the filter matches all routes having a null interface. Note that you can view the index number (*ifIndex*) for an interface with the -a option of ifconfig(1M).

dst:{*ip-address*[/*mask*]|any|none}   Selects a destination IP address. If specified with a mask length, then any routes with matching or longer (more specific) masks are selected. If any is used, then all but addresses but 0 are selected. If none is used, then address 0 is selected.

flags:[+ -]?[ABDGHLMSU]+   Selects routes tagged with the specified flags. By default, the flags as specified must be set in order to match. With a leading +, the flags specified must be set but others are ignored. With a leading -, the flags specified must not be set and others are permitted.

You can specify multiple instances of -f to specify multiple filters. For example:

```
% netstat -nr -f outif:hme0 -f outif:hme1 -f dst:10.0.0.0/8
```

The preceding command displays routes within network 10.0.0.0/8, with mask length 8 or greater, and an output interface of either hme0 or hme1, and excludes all other routes.

-g

Show the multicast group memberships for all interfaces. If the -v option is included, source-specific membership information is also displayed. See DISPLAYS, below.

-i

Show the state of the interfaces that are used for IP traffic. Normally this shows statistics for the physical interfaces. When combined with the -a option, this will also report information for the logical interfaces. See ifconfig(1M).

-m

Show the STREAMS memory statistics.

-n

Show network addresses as numbers. netstat normally displays addresses as symbols. This option may be used with any of the display formats.

-p

Show the net to media tables. See DISPLAYS, below.

-r

Show the routing tables. Normally, only interface, host, network, and default routes are shown, but when this option is combined with the -a option, all routes will be displayed, including cache. If you have not set up a multicast route, -ra might not show any multicast routing entries, although the kernel will derive such an entry if needed.

-s

Show per-protocol statistics. When used with the -M option, show multicast routing statistics instead. When used with the -a option, per-interface statistics will be displayed, when available, in addition to statistics global to the system. See DISPLAYS, below.

-T u | d
Display a time stamp.

Specify u for a printed representation of the internal representation of time. See time(2). Specify d for standard date format. See date(1).

-v

Verbose. Show additional information for the sockets, STREAMS memory statistics, routing table, and multicast group memberships.

-I *interface*
Show the state of a particular interface. *interface* can be any valid interface such as hme0 or eri0. Normally, the status and statistics for physical interfaces are displayed. When this option is combined with the -a option, information for the logical interfaces is also reported.

-M

Show the multicast routing tables. When used with the -s option, show multicast routing statistics instead.

-P *protocol*

Limit display of statistics or state of all sockets to those applicable to *protocol*. The protocol can be one of ip, ipv6, icmp, icmpv6, icmp, icmpv6, igmp, udp, tcp, rawip. rawip can also be specified as raw. The command accepts protocol options only as all lowercase.

-D

Show the status of DHCP configured interfaces.

-R

This modifier displays extended security attributes for sockets and routing table entries. The -R modifier is available only if the system is configured with the Solaris Trusted Extensions feature.

With -r only, this option displays the routing entries' gateway security attributes. See route(1M) for more information on security attributes.

When displaying socket information using the first form of the commmand, this option displays additional information for Multi-Level Port(MLP) sockets. This includes:

- The label for the peer if the socket is connected.
- The following flags can be appended to the socket's "State" output:

    P   The socket is a MLP on zone-private IP addresses.

    S   The socket is a MLP on IP addresses shared between zones.

Operands *interval*   Display statistics accumulated since last display every *interval* seconds, repeating forever, unless *count* is specified. When invoked with *interval*, the first row of netstat output shows statistics accumulated since last reboot.

The following options support *interval*: -i, -m, -s and -Ms. Some values are configuration parameters and are just redisplayed at each interval.

count   Display interface statistics the number of times specified by *count*, at the interval specified by *interval*.

Displays

Active Sockets (First Form)   The display for each active socket shows the local and remote address, the send and receive queue sizes (in bytes), the send and receive windows (in bytes), and the internal state of the protocol.

The symbolic format normally used to display socket addresses is either:

hostname.*port*

when the name of the host is specified, or

network.port

if a socket address specifies a network but no specific host.

The numeric host address or network number associated with the socket is used to look up the corresponding symbolic hostname or network name in the *hosts* or *networks* database.

If the network or hostname for an address is not known, or if the -n option is specified, the numerical network address is shown. Unspecified, or "wildcard", addresses and ports appear as an asterisk (*). For more information regarding the Internet naming conventions, refer to inet(7P) and inet6(7P).

For SCTP sockets, because an endpoint can be represented by multiple addresses, the verbose option (-v) displays the list of all the local and remote addresses.

TCP Sockets   The possible state values for TCP sockets are as follows:

BOUND	Bound, ready to connect or listen.
CLOSED	Closed. The socket is not being used.
CLOSING	Closed, then remote shutdown; awaiting acknowledgment.
CLOSE_WAIT	Remote shutdown; waiting for the socket to close.
ESTABLISHED	Connection has been established.
FIN_WAIT_1	Socket closed; shutting down connection.
FIN_WAIT_2	Socket closed; waiting for shutdown from remote.
IDLE	Idle, opened but not bound.
LAST_ACK	Remote shutdown, then closed; awaiting acknowledgment.
LISTEN	Listening for incoming connections.
SYN_RECEIVED	Initial synchronization of the connection under way.
SYN_SENT	Actively trying to establish connection.
TIME_WAIT	Wait after close for remote shutdown retransmission.

SCTP Sockets   The possible state values for SCTP sockets are as follows:

CLOSED	Closed. The socket is not being used.
LISTEN	Listening for incoming associations.
ESTABLISHED	Association has been established.
COOKIE_WAIT	INIT has been sent to the peer, awaiting acknowledgment.

COOKIE_ECHOED	State cookie from the INIT-ACK has been sent to the peer, awaiting acknowledgement.
SHUTDOWN_PENDING	SHUTDOWN has been received from the upper layer, awaiting acknowledgement of all outstanding DATA from the peer.
SHUTDOWN_SENT	All outstanding data has been acknowledged in the SHUTDOWN_SENT state. SHUTDOWN has been sent to the peer, awaiting acknowledgement.
SHUTDOWN_RECEIVED	SHUTDOWN has been received from the peer, awaiting acknowledgement of all outstanding DATA.
SHUTDOWN_ACK_SENT	All outstanding data has been acknowledged in the SHUTDOWN_RECEIVED state. SHUTDOWN_ACK has been sent to the peer.

Network Data Structures (Second Through Fifth Forms)

The form of the display depends upon which of the -g, -m, -p, or -s options you select.

-g   Displays the list of multicast group membership.

-m   Displays the memory usage, for example, STREAMS mblks.

-p   Displays the net to media mapping table. For IPv4, the address resolution table is displayed. See arp(1M). For IPv6, the neighbor cache is displayed.

-s   Displays the statistics for the various protocol layers.

The statistics use the MIB specified variables. The defined values for ipForwarding are:

forwarding(1)   Acting as a gateway.

not-forwarding(2)   Not acting as a gateway.

The IPv6 and ICMPv6 protocol layers maintain per-interface statistics. If the -a option is specified with the -s option, then the per-interface statistics as well as the total sums are displayed. Otherwise, just the sum of the statistics are shown.

For the second, third, and fourth forms of the command, you must specify at least -g, -p, or -s. You can specify any combination of these options. You can also specify -m (the fifth form) with any set of the -g, -p, and -s options. If you specify more than one of these options, netstat displays the information for each one of them.

Interface Status (Sixth Form)

The interface status display lists information for all current interfaces, one interface per line. If an interface is specified using the -I option, it displays information for only the specified interface.

The list consists of the interface name, mtu (maximum transmission unit, or maximum packet size)(see ifconfig(1M)), the network to which the interface is attached, addresses for each interface, and counter associated with the interface. The counters show the number of input

packets, input errors, output packets, output errors, and collisions, respectively. For Point-to-Point interfaces, the Net/Dest field is the name or address on the other side of the link.

If the -a option is specified with either the -i option or the -I option, then the output includes names of the physical interface(s), counts for input packets and output packets for each logical interface, plus additional information.

If the -n option is specified, the list displays the IP address instead of the interface name.

If an optional *interval* is specified, the output will be continually displayed in *interval* seconds until interrupted by the user or until *count* is reached. See OPERANDS.

The physical interface is specified using the -I option. When used with the *interval* operand, output for the -I option has the following format:

```
input   eri0            output       input           (Total)  output
packets errs  packets errs  colls   packets errs  packets errs  colls
227681  0     659471  1     502     261331  0     99597   1     502
10      0     0       0     0       10      0     0       0     0
8       0     0       0     0       8       0     0       0     0
10      0     2       0     0       10      0     2       0     0
```

If the input interface is not specified, the first interface of address family inet or inet6 will be displayed.

Routing Table (Seventh Form)
The routing table display lists the available routes and the status of each. Each route consists of a destination host or network, and a gateway to use in forwarding packets. The *flags* column shows the status of the route. These flags are as follows:

U   Indicates route is up.

G   Route is to a gateway.

H   Route is to a host and not a network.

M   Redundant route established with the -multirt option.

S   Route was established using the -setsrc option.

D   Route was created dynamically by a redirect.

B   Packets will be silently dropped (RTF_BLACKHOLE set).

R   Packets will be dropped with ICMP error sent (RTF_REJECT set).

I   Indirect routes (gateway not directly reachable) established with the -indirect option.

Z   (non-global exclusive-IP zone only) The route was statically added on boot based on routing information configured using zonecfg(1M) in the global zone.

If the -a option is specified, there will be routing entries with the following flags:

b   Broadcast addresses.

C   Clones interface host route entries for on-link destinations.

L   Local addresses for the host.

Interface routes are created for each interface attached to the local host; the gateway field for such entries shows the address of the outgoing interface.

The use column displays the number of packets sent or forwarded using the route in question.

The *interface* entry indicates the network interface utilized for the route.

Multicast Routing Tables (Eighth Form)   The multicast routing table consists of the virtual interface table and the actual routing table.

DHCP Interface Information (Ninth Form)   The DHCP interface information consists of the interface name, its current state, lease information, packet counts, and a list of flags.

The states correlate with the specifications set forth in *RFC 2131*.

Lease information includes:

- when the lease began;
- when lease renewal will begin; and
- when the lease will expire.

The flags currently defined include:

BOOTP   The interface has a lease obtained through BOOTP (IPv4 only).

BUSY   The interface is busy with a DHCP transaction.

PRIMARY   The interface is the primary interface. See dhcpinfo(1) and ifconfig(1M).

FAILED   The interface is in failure state and must be manually restarted.

Packet counts are maintained for the number of packets sent, the number of packets received, and the number of lease offers declined by the DHCP client. All three counters are initialized to zero and then incremented while obtaining a lease. The counters are reset when the period of lease renewal begins for the interface. Thus, the counters represent either the number of packets sent, received, and declined while obtaining the current lease, or the number of packets sent, received, and declined while attempting to obtain a future lease.

Destination Cache Entry Table (Tenth Form)   The destination cache entry display shows the recorded path MTU, the age (in seconds) of the entry, and flags. The P flag indicates that a path MTU is recorded. The S flag indicates that the path MTU is smaller than the minumum that IP will allow. The U flag indicates that some transport metrics (round-trip time, and so forth) are cached in the destination cache entry.

Files /etc/default/inet_type   DEFAULT_IP setting

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also arp(1M), dhcpinfo(1), dhcpagent(1M), ifconfig(1M), iostat(1M), kstat(1M), mibiisa(1M), savecore(1M), vmstat(1M), zonecfg(1M), hosts(4), inet_type(4), networks(4), protocols(4), services(4), attributes(5), dhcp(5), kstat(7D), inet(7P), inet6(7P)

Droms, R., *RFC 2131, Dynamic Host Configuration Protocol*, Network Working Group, March 1997.

Droms, R. *RFC 3315, Dynamic Host Configuration Protocol for IPv6 (DHCPv6)*. Cisco Systems. July 2003.

Notes When displaying interface information, netstat honors the DEFAULT_IP setting in /etc/default/inet_type. If it is set to IP_VERSION4, then netstat will omit information relating to IPv6 interfaces, statistics, connections, routes and the like.

However, you can override the DEFAULT_IP setting in /etc/default/inet_type on the command-line. For example, if you have used the command-line to explicitly request IPv6 information by using the inet6 address family or one of the IPv6 protocols, it will override the DEFAULT_IP setting.

If you need to examine network status information following a kernel crash, use the mdb(1) utility on the savecore(1M) output.

The netstat utility obtains TCP statistics from the system by opening /dev/tcp and issuing queries. Because of this, netstat might display an extra, unused connection in IDLE state when reporting connection status.

Previous versions of netstat had undocumented methods for reporting kernel statistics published using the kstat(7D) facility. This functionality has been removed. Use kstat(1M) instead.

netstat restricts its output to information that is relevant to the zone in which netstat runs. (This is true for both shared-IP and exclusive-IP zones.)

Name netstrategy – return network configuration information

Synopsis /usr/sbin/netstrategy

Description The netstrategy command determines the network configuration strategy in use on a system and returns information in a form that is easily consumable by a script. The command returns three tokens:

<*root filesystem type*> <*primary interface*> <*network config strategy*>

These tokens are described as follows:

<*root filesystem type*>
Type of filesystem that contains the bootable kernel, as would be specified in the *fstype* column of the mnttab(4).

<*primary interface*>
Name of the primary network interface. For a diskless machine, this is the interface used to load the kernel.

<*network config strategy*>
The means by which a system obtains its IP address for booting. This can be one of rarp, dhcp, or none.

The netstrategy command is not intended for use on a command line.

Options The netstrategy command has no options.

Exit Status 0   Success.

!=0   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also ifconfig(1M), mnttab(4), attributes(5)

Name newaliases – rebuild the data base for the mail aliases file

Synopsis `newaliases`

Description newaliases rebuilds the random access data base for the mail aliases file /etc/mail/aliases.

newaliases accepts all the flags that sendmail(1M) accepts. However, most of these flags have no effect, except for the -C option and three of the `Processing Options` that can be set from a configuration file with the -o option:

-C */path/to/alt/config/file*	Use alternate configuration file.
-oA*file*	Specify possible alias files.
-oL*n*	Set the default log level to *n*. Defaults to 9.
-on	Validate the RHS of aliases when rebuilding the aliases(4) database.

newaliases runs in verbose mode (-v option) automatically.

Examples EXAMPLE 1 Running the newaliases Command

The following command runs newaliases on an alias file different from the /etc/mail/aliases default in sendmail(1M):

```
example% newaliases -oA/path/to/alternate/alias/file
```

Exit Status newaliases returns an exit status describing what it did. The codes are defined in /usr/include/sysexits.h.

EX_OK	Successful completion on all addresses.
EX_NOUSER	User name not recognized.
EX_UNAVAILABLE	Catchall. Necessary resources were not available.
EX_SYNTAX	Syntax error in address.
EX_SOFTWARE	Internal software error, including bad arguments.
EX_OSERR	Temporary operating system error, such as "cannot fork".
EX_NOHOST	Host name not recognized.
EX_TEMPFAIL	Message could not be sent immediately, but was queued.

Files

/etc/aliases	Symbolic link to /etc/mail/aliases
/etc/mail/aliases.pag	
/etc/mail/aliases.dir	ndbm files maintained by newaliases
/etc/mail/aliases.db	Berkeley DataBase file maintained by newaliases

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/smtp/sendmail

See Also sendmail(1M), aliases(4), attributes(5)

Name newfs – construct a UFS file system

Synopsis newfs [-NSBTv] [*mkfs-options*] *raw-device*

Description newfs is a friendly front-end to the mkfs(1M) program for making UFS file systems on disk partitions. newfs calculates the appropriate parameters to use and calls mkfs.

If run interactively (that is, standard input is a tty), newfs prompts for confirmation before making the file system.

If the -N option is not specified and the inodes of the device are not randomized, newfs calls fsirand(1M).

You must be super-user or have appropriate write privileges to use this command.

Creating a
Multiterabyte UFS File
System

Keep the following limitations in mind when creating a multiterabyte UFS file system:

- *nbpi* is set to 1 Mbyte unless you specifically set it higher. You cannot set *nbpi* lower than 1 Mbyte on a multiterabyte UFS file system.

- *fragsize* is set equal to *bsize*.

Options The following options are supported:

-N

Print out the file system parameters that would be used to create the file system without actually creating the file system. fsirand(1M) is not called here.

-S

Sends to stdout a human-readable version of the superblock that would be used to create a filesystem with the specified configuration parameters.

-B

Sends to stdout a binary (machine-readable) version of the superblock that would be used to create a filesystem with the specified configuration parameters.

-T

Set the parameters of the file system to allow eventual growth to over a terabyte in total file system size. This option sets *fragsize* to be the same as *bsize*, and sets *nbpi* to 1 Mbyte, unless the -i option is used to make it even larger. If you use the -f or -i options to specify a *fragsize* or *nbpi* that is incompatible with this option, the user-supplied value of *fragsize* or *nbpi* is ignored.

-v

Verbose. newfs prints out its actions, including the parameters passed to mkfs.

mkfs-options

Options that override the default parameters are:

-a *apc*

The number of alternate sectors per cylinder to reserve for bad block replacement for SCSI devices only. The default is 0.

This option is not applicable for disks with EFI labels and is ignored.

-b *bsize*
  The logical block size of the file system in bytes, either 4096 or 8192. The default is 8192. The sun4u architecture does not support the 4096 block size.

-c *cgsize*
  The number of cylinders per cylinder group, ranging from 16 to 256. The default is calculated by dividing the number of sectors in the file system by the number of sectors in a gigabyte. Then, the result is multiplied by 32. The default value is always between 16 and 256.

  mkfs can override this value. See mkfs_ufs(1M) for details.

  This option is not applicable for disks with EFI labels and is ignored.

-C *maxcontig*
  The maximum number of logical blocks, belonging to one file, that are allocated contiguously. The default is calculated as follows:

  maxcontig = *disk drive maximum transfer size / disk block size*

  If the disk drive's maximum transfer size cannot be determined, the default value for maxcontig is calculated from kernel parameters as follows:

  If maxphys is less than ufs_maxmaxphys, which is typically 1 Mbyte, then maxcontig is set to maxphys. Otherwise, maxcontig is set to ufs_maxmaxphys.

  You can set maxcontig to any positive integer value.

  The actual value will be the lesser of what has been specified and what the hardware supports.

  You can subsequently change this parameter by using tunefs(1M).

-d *gap*
  Rotational delay. This option is obsolete in the Solaris 10 release. The value is always set to 0, regardless of the input value.

-f *fragsize*
  The smallest amount of disk space in bytes that can be allocated to a file. *fragsize* must be a power of 2 divisor of *bsize*, where:

  bsize / *fragsize* is 1, 2, 4, or 8.

  This means that if the logical block size is 4096, legal values for *fragsize* are 512, 1024, 2048, and 4096. When the logical block size is 8192, legal values are 1024, 2048, 4096, and 8192. The default value is 1024.

  For file systems greater than 1 terabyte or for file systems created with the -T option, *fragsize* is forced to match block size (*bsize*).

-i *nbpi*

The number of bytes per inode, which specifies the density of inodes in the file system. The number is divided into the total size of the file system to determine the number of inodes to create.

This value should reflect the expected average size of files in the file system. If fewer inodes are desired, a larger number should be used. To create more inodes, a smaller number should be given. The default for *nbpi* is as follows:

```
Disk size              Density

Less than 1GB          2048
Less than 2GB          4096
Less than 3GB          6144
3GB to 1 Tbyte         8192
Greater than 1 Tbyte
   or created with -T  1048576
```

The number of inodes can increase if the file system is expanded with the growfs command.

-m *free*

The minimum percentage of free space to maintain in the file system, between 0% and 99%, inclusively. This space is off-limits to users. Once the file system is filled to this threshold, only the super-user can continue writing to the file system.

The default is ((64 Mbytes/partition size) * 100), rounded down to the nearest integer and limited between 1% and 10%, inclusively.

This parameter can be subsequently changed using the tunefs(1M) command.

-n *nrpos*

The number of different rotational positions in which to divide a cylinder group. The default is 8.

This option is not applicable for disks with EFI labels and is ignored.

-o *space* | *time*

The file system can either be instructed to try to minimize the *time* spent allocating blocks, or to try to minimize the *space* fragmentation on the disk. The default is *time*.

This parameter can subsequently be changed with the tunefs(1M) command.

-r *rpm*

The rotational speed of the disk in revolutions per minute. The default is driver- or device-specific.

Note that you specify *rpm* for newfs and *rps* for mkfs.

This option is not applicable for disks with EFI labels and is ignored.

-s *size*
> The size of the file system in sectors. The default is to use the entire partition.

-t *ntrack*
> The number of tracks per cylinder on the disk. The default is taken from the disk label.

> This option is not applicable for disks with EFI labels and is ignored.

Operands The following operands are supported:

raw-device
> The name of a raw special device residing in the /dev directory (for example, /dev/rdsk/c0t0d0s6) on which to create the file system.

Usage See largefile(5) for the description of the behavior of newfs when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples **EXAMPLE 1** Displaying the Parameters for the Raw Special Device

The following example verbosely displays the parameters for the raw special device, c0t0d0s6. It does not actually create a new file system:

```
example# newfs -Nv /dev/rdsk/c0t0d0s6
mkfs -F ufs -o N /dev/rdsk/c0t0d0s6 1112940 54 15 8192 1024 16 10 60
2048 t 0 −1 8 /dev/rdsk/c0t0d0s6: 1112940 sectors in
1374 cylinders of 15 tracks, 54 sectors 569.8MB in 86 cyl
groups (16 c/g, 6.64MB/g, 3072 i/g) super-block backups
(for fsck -b #) at:
32, 13056, 26080, 39104, 52128, 65152, 78176, 91200, 104224, . . .
```

EXAMPLE 2 Creating a UFS File System That Will Eventually Be Grown to a Multiterabyte UFS File System

The following example creates a UFS file system that will eventually be grown to a multiterabyte UFS file system.

This command creates a 800-Gbyte file system on the volume, /dev/md/rdsk/d99.

```
# newfs -T /dev/md/rdsk/d99
newfs: construct a new file system /dev/md/rdsk/d99: (y/n)? y
   /dev/md/rdsk/d99: 1677754368 sectors in 45512 cylinders of
   144 tracks, 256 sectors
   819216.0MB in 1821 cyl groups (25 c/g, 450.00MB/g, 448 i/g) . . .
```

Then, if you increase the volume size for this file system, you can use the growfs command to expand the file system. The file system is grown to 1.2 terabytes in this example:

```
# growfs -v /dev/md/rdsk/d99
/usr/lib/fs/ufs/mkfs -G /dev/md/rdsk/d99 2516631552 /dev/md/rdsk/d99:
   2516631552 sectors in 68268 cylinders of 144 tracks, 256  sectors
   1228824.0MB in 2731 cyl groups (25 c/g, 450.00MB/g, 448 i/g). . .
```

Exit Status   The following exit values are returned:

0
  The operation was successful.

1, 10
  Usage error or internal error. A message is output to STDERR explaining the error.

Other exit values may be returned by mkfs(1M), which is called by newfs.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

Diagnostics   newfs: No such file or directory
  The device specified does not exist, or a disk partition was not specified.

special: cannot open
  You must write access to the device to use this command.

Name newkey – create a new Diffie-Hellman key pair in the publickey database

Synopsis newkey -h *hostname* [-s nis | files | ldap]

newkey -u *username* [-s nis | files | ldap]

Description newkey establishes new public keys for users and machines on the network. These keys are needed when using secure RPC or secure NFS service.

newkey prompts for a password for the given *username* or hostname and then creates a new public/secret Diffie-Hellman 192 bit key pair for the user or host. The secret key is encrypted with the given password. The key pair can be stored in the /etc/publickey file or the NIS publickey map.

newkey consults the publickey entry in the name service switch configuration file (see nsswitch.conf(4)) to determine which naming service is used to store the secure RPC keys. If the publickey entry specifies a unique name service, newkey will add the key in the specified name service. However, if there are multiple name services listed, newkey cannot decide which source to update and will display an error message. The user is required to specify the source explicitly with the -s option.

In the case of NIS, newkey should be run by the superuser on the master NIS server for that domain.

In the case of LDAP, newkey should be run by the superuser on a machine that also recognizes the directory manager's bind distinguished name (DN) and password to perform an LDAP update for the host.

Options -h *hostname* Create a new public/secret key pair for the privileged user at the given hostname. Prompts for a password for the given hostname.

-u *username* Create a new public/secret key pair for the given *username*. Prompts for a password for the given *username*.

-s nis
-s files
-s ldap Update the database in the specified source: nis (for NIS), files, or ldap (LDAP). Other sources may be available in the future.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also chkey(1), keylogin(1), nsswitch.conf(4), publickey(4), attributes(5)

Name nfs4cbd – NFS Version 4 callback daemon

Synopsis `/usr/lib/nfs/nfs4cbd`

Description The `nfs4cbd` daemon manages communication endpoints for the NFS Version 4 protocol callback program. `nfs4cbd` runs on the NFS Version 4 client and creates a listener port for each transport over which callbacks can be sent.

The `nfs4cbd` daemon is provided for the exclusive use of the NFS version 4 client.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/nfs

See Also `svcs(1)`, `mount_nfs(1M)`, `svcadm(1M)`, `attributes(5)`, `smf(5)`

Notes The `nfs4cbd` service is managed by the service management facility, `smf(5)`, under the service identifier:

`svc:/network/nfs/cbd`

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

If it is disabled, it will be enabled by `mount_nfs(1M)` and `automountd(1M)` on the first NFSv4 mount, unless its `application/auto_enable` property is set to `false`.

This daemon might not exist in a future release of Solaris.

Name nfsd – NFS daemon

Synopsis /usr/lib/nfs/nfsd [-a] [-c #_conn] [-l listen_backlog]
             [-p protocol] [-t device] [nservers]

Description nfsd is the daemon that handles client file system requests. Only users with {PRIV_SYS_NFS} and sufficient privileges to write to /var/run can run this daemon.

The nfsd daemon is automatically invoked using share(1M) with the -a option.

By default, nfsd starts over the TCP and UDP transports for versions 2 and 3. By default, it starts over the TCP for version 4. You can change this with the -p option.

A previously invoked nfsd daemon started with or without options must be stopped before invoking another nfsd command.

To change startup parameters for nfsd, use the sharectl(1M) command.

SMF Management The nfsd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/nfs/server

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

If nfsd is killed with SIGTERM, it will not be restarted by the service management facility. Instead, nfsd can be restarted by other signals, such as SIGINT.

The sharectl(1M) command can be used to manage all the parameters related to nfsd. The following are the parameters currently supported:

server_versmax=*num*
server_versmin=*num*
    The NFS server only uses NFS versions in the range specified by these variables. Valid values or versions are: 2, 3, and 4. If one or both of these parameters are left unset, the default minimum version is 2, while the default maximum version is 4.

server_delegation=on | off
    By default, this variable is on and the NFS server provides delegations to clients. The user can turn off delegations for all exported file systems by setting this variable to off (case-sensitive). This variable applies only to NFS Version 4.

max_connections=*num*
    Sets the maximum number of concurrent, connection-oriented connections. The default is unlimited and is obtained by setting to -1. Equivalent to the -c option in nfsd.

listen_backlog=*num*
    Set connection queue length for the NFS over a connection-oriented transport. The default value is 32, meaning 32 entries in the queue. Equivalent to the -l option in nfsd.

protocol=ALL

Start nfsd over the specified protocol only. Equivalent to the -p option in nfsd. ALL is equivalent to -a on the nfsd command line. Mutually exclusive of NFS SMF parameter device. One or the other of NFS SMF parameters device and protocol must not be set. If both are set, the nfs/server service goes into maintenance mode. For the UDP protocol, only version 2 and version 3 service is established. NFS Version 4 is not supported for the UDP protocol. Equivalent to the -p option.

device=*devname*

Start NFS daemon for the transport specified by the specified device only. Equivalent to the -t option in nfsd. Mutually exclusive of NFS SMF parameter protocol. One or the other of NFS SMF parameters device and protocol must not be set.

servers=*num*

Maximum number of concurrent NFS requests. Equivalent to last numeric argument on the nfsd command line. The default is 1024. Equivalent to the *nservers* operand.

See EXAMPLES, below.

Options The following options are supported:

-a   Start an NFS daemon over all available connectionless and connection-oriented transports, including UDP and TCP. Equivalent of setting the protocol parameter to ALL in the SMF for NFS using the sharectl(1M) command.

-c *#_conn*   This sets the maximum number of connections allowed to the NFS server over connection-oriented transports. By default, the number of connections is unlimited. Equivalent of the max_connections parameter in the SMF for NFS using the sharectl(1M) command.

-l   Set connection queue length for the NFS TCP over a connection-oriented transport. The default value is 32 entries. Equivalent of the listen_backlog parameter in the SMF for NFS using the sharectl(1M) command.

-p *protocol*   Start a NFS daemon over the specified protocol. Equivalent of the protocol parameter in the SMF for NFS using the sharectl(1M) command.

-t *device*   Start a NFS daemon for the transport specified by the given device. Equivalent of the device parameter in the SMF for NFS using the sharectl(1M) command.

Operands The following operands are supported:

nservers   This sets the maximum number of concurrent NFS requests that the server can handle. This concurrency is achieved by up to *nservers* threads created as needed in the kernel. *nservers* should be based on the load expected on this server. 16 is the usual number of *nservers*. If *nservers* is not specified, the maximum number of concurrent NFS requests will default to 1. Equivalent of the servers parameter in

the SMF for NFS using the [sharectl(1M)](#) command.

Usage If the NFS_PORTMON variable is set in /etc/system, then clients are required to use privileged ports (ports < IPPORT_RESERVED) to get NFS services. This variable is equal to zero by default. This variable has been moved from the "nfs" module to the "nfssrv" module. To set the variable, edit the /etc/system file and add this entry:

```
set nfssrv:nfs_portmon = 1
```

Examples **EXAMPLE 1** Turning Off Delegation

The nfsd properties specified in these examples are described under "SMF Management," above.

Delegation is an NFSv4 feature in which the server delegates the management of a file to a client. For example, the server could grant (or not grant) either a read delegation or a write delegation to a client. The following command does this, setting the server_delegation property to off.

```
# sharectl set -p server_delegation=off nfs
```

EXAMPLE 2 Determining Value of Delegation

The following command obtains the current value of the server_delegation property.

```
# sharectl get -p server_delegation nfs
server_delegation=on
```

EXAMPLE 3 Setting Maximum Number of Concurrent Requests

The following command sets the maximum number of concurrent NFS requests.

```
# sharectl set -p servers=32 nfs
```

EXAMPLE 4 Setting Connection Queue Length

The following command sets the maximum queue length for the NFS over a connection-oriented transport.

```
# sharectl set -p listen_backlog=48 nfs
```

Exit Status 0   Daemon started successfully.

1   Daemon failed to start.

Files .nfs*XXX*   Client machine pointer to an open-but-unlinked file.

/etc/system   System configuration information file.

/var/nfs/v4_state
/var/nfs/v4_oldstate   Directories used by the server to manage client state information. These directories should not be removed.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Oracle Solaris Administration: Network Services

Notes Manually starting and restarting nfsd is not recommended. If it is necessary to do so, use svcadm to enable or disable the nfs service (svc:/network/nfs/server). If it is disabled, it will be enabled by share_nfs(1M), unless its application/auto_enable property is set to false. See the *Oracle Solaris Administration: Network Services*, and svcadm(1M) for more information.

Name   nfslogd – nfs logging daemon

Synopsis   `/usr/lib/nfs/nfslogd`

Description   The nfslogd daemon provides operational logging to the Solaris NFS server. It is the nfslogd daemon's job to generate the activity log by analyzing the RPC operations processed by the NFS server. The log will only be generated for file systems exported with logging enabled. This is specified at file system export time by means of the share_nfs(1M) command.

NFS server logging is not supported on Solaris machines that are using NFS Version 4.

Each record in the log file includes a time stamp, the IP address (or hostname if it can be resolved) of the client system, the file or directory name the operation was performed on, and the type of operation. In the basic format, the operation can either be an input (i) or output (o) operation. The basic format of the NFS server log is compatible with the log format generated by the Washington University FTPd daemon. The log format can be extended to include directory modification operations, such as mkdir, rmdir, and remove. The extended format is not compatible with the Washington University FTPd daemon format. See nfslog.conf(4) for details.

The NFS server logging mechanism is divided in two phases. The first phase is performed by the NFS kernel module, which records raw RPC requests and their results in work buffers backed by permanent storage. The location of the work buffers is specified in the /etc/nfs/nfslog.conf file. Refer to nfslog.conf(4) for more information. The second phase involves the nfslogd user-level daemon, which periodically reads the work buffers, interprets the raw RPC information, groups related RPC operations into single transaction records, and generates the output log. The nfslogd daemon then sleeps waiting for more information to be logged to the work buffers. The amount of time that the daemon sleeps can be configured by modifying the IDLE_TIME parameter in /etc/default/nfslogd. The work buffers are intended for internal consumption of the nfslogd daemon.

NFS operations use file handles as arguments instead of path names. For this reason the nfslogd daemon needs to maintain a database of file handle to path mappings in order to log the path name associated with an operation instead of the corresponding file handle. A file handle entry is added to the database when a client performs a lookup or other NFS operation that returns a file handle to the client.

Once an NFS client obtains a file handle from a server, it can hold on to it for an indefinite time, and later use it as an argument for an NFS operation on the file or directory. The NFS client can use the file handle even after the server reboots. Because the database needs to survive server reboots, it is backed by permanent storage. The location of the database is specified by the *fhtable* parameter in the /etc/nfs/nfslog.conf file. This database is intended for the internal use of the nfslogd daemon.

In order to keep the size of the file handle mapping database manageable, nfslogd prunes the database periodically. It removes file handle entries that have not been accessed in more than a specified amount of time. The PRUNE_TIMEOUT configurable parameter in

/etc/default/nfslogd specifies the interval length between successive runs of the pruning process. A file handle record will be removed if it has not been used since the last time the pruning process was executed. Pruning of the database can effectively be disabled by setting the PRUNE_TIMEOUT as high as INT_MAX.

When pruning is enabled, there is always a risk that a client may have held on to a file handle longer than the PRUNE_TIMEOUT and perform an NFS operation on the file handle after the matching record in the mapping database had been removed. In such case, the pathname for the file handle will not be resolved, and the log will include the file handle instead of the pathname.

There are various configurable parameters that affect the behavior of the nfslogd daemon. These parameters are found in /etc/default/nfslogd and are described below:

UMASK
: Sets the file mode for the log files, work buffer files and file handle mapping database.

MIN_PROCESSING_SIZE
: Specifies the minimum size, in bytes, that the buffer file must reach before processing the work information and writing to the log file. The value of MIN_PROCESSING_SIZE must be between 1 and ulimit.

IDLE_TIME
: Specifies the amount of time, in seconds, the daemon should sleep while waiting for more information to be placed in the buffer file. IDLE_TIME also determines how often the configuration file will be reread. The value of IDLE_TIME must be between 1 and INT_MAX.

MAX_LOGS_PRESERVE
: The nfslogd periodically cycles its logs. MAX_LOGS_PRESERVE specifies the maximum number of log files to save. When MAX_LOGS_PRESERVE is reached, the oldest files will be overwritten as new log files are created. These files will be saved with a numbered extension, beginning with filename.0. The oldest file will have the highest numbered extension up to the value configured for MAX_LOGS_PRESERVE. The value of MAX_LOGS_PRESERVE must be between 1 and INT_MAX.

CYCLE_FREQUENCY
: Specifies how often, in hours, the log files are cycled. CYCLE_FREQUENCY is used to insure that the log files do not get too large. The value of CYCLE_FREQUENCY must be between 1 and INT_MAX.

MAPPING_UPDATE_INTERVAL
: Specifies the time interval, in seconds, between updates of the records in the file handle to path mapping tables. Instead of updating the atime of a record each time that record is accessed, it is only updated if it has aged based on this

parameter. The record access time is used by the pruning routine to determine whether the record should be removed from the database. The value of this parameter must be between 1 and INT_MAX.

PRUNE_TIMEOUT   Specifies when a database record times out, in hours. If the time that elapsed since the record was last accessed is greater than PRUNE_TIMEOUT then the record can be pruned from the database. The default value for PRUNE_TIMEOUT is 168 hours (7 days). The value of PRUNE_TIMEOUT must be between 1 and INT_MAX.

Exit Status The following exit values are returned:

0   Daemon started successfully.

1   Daemon failed to start.

Files /etc/nfs/nfslogtab

/etc/nfs/nfslog.conf

/etc/default/nfslogd

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/file-system/nfs

See Also share_nfs(1M), nfslog.conf(4), attributes(5)

Name nfsmapid – NFS user and group id mapping daemon

Synopsis /usr/lib/nfs/nfsmapid

Description The nfsmapid daemon maps to and from NFS version 4 owner and owner_group
identification attributes and local UID and GID numbers used by both the NFS version 4
client and server.

nfsmapid uses the passwd and group entries in the /etc/nsswitch.conf file to direct how it
performs the mappings.

The nfsmapid daemon has no external, customer-accessible interfaces. You can, however,
administratively configure nfsmapid in one of the following ways:

- Specify the nfsmapid_domain parameter in the SMF for NFS using the sharectl(1M)
  command.
- Specify the _nfsv4idmapdomain DNS resource record.

The currently selected NFSv4 domain is available in the file /var/run/nfs4_domain.

Please refer to the *Oracle Solaris Administration: Network ServicesOracle Solaris
Administration: Network Services* for further details.

SMF Management The nfsmapid service is managed by the service management facility, smf(5), under the
service identifier:

svc:/network/nfs/mapid

Administrative actions on this service, such as enabling, disabling, or requesting restart, can
be performed using svcadm(1M). The service's status can be queried using the svcs(1)
command.

If it is disabled, it will be enabled by mount_nfs(1M), share_nfs(1M), and automountd(1M),
unless its application/auto_enable property is set to false.

nfsmapid caches a user's UID and GID. If a user subsequently changes a UID or GID, using
one of the utilities listed below, the nfsmapid cache becomes stale. At this point, any NFS
operation that gets or set attributes will result in the exchange of this stale information. To
resolve this situation, restart nfsmapid, as follows:

svcadm restart svc:/network/nfs/mapid:default

The startup SMF parameter designating a domain name (nfsmapid_domain) can be
manipulated with the sharectl(1M) command.

nfsmapid_domain
     The setting for the NFS SMF parameter nfsmapid_domain overrides the domain used by
     nfsmapid for building and comparing outbound and inbound attribute strings,
     respectively. Also, this setting overrides any other mechanism for setting the NFSv4
     domain. In the absence of a nfsmapid_domain setting, the nfsmapid daemon determines
     the NFSv4 domain as follows:

- If a properly configured /etc/resolv.conf (see resolv.conf(4)) exists, nfsmapid queries specified nameserver(s) for the domain.

- If a properly configured /etc/resolv.conf (see resolv.conf(4)) exists, but the queried name server does not have a proper record of the domain name, nfsmapid attempts to obtain the domain name through the BIND interface (see resolver(3RESOLV)).

- If no /etc/resolv.conf exists, nfsmapid falls back on using the configured domain name (see domainname(1M)), which is returned with the leading domain suffix removed. For example, for widgets.sales.acme.com, sales.acme.com is returned.

- If /etc/resolv.conf does not exist, no domain name has been configured (or no /etc/defaultdomain exists), nfsmapid falls back on obtaining the domain name from the host name, if the host name contains a fully qualified domain name (FQDN).

If a domain name is still not obtained following all of the preceding steps, nfsmapid will have no domain configured. This results in the following behavior:

- Outbound owner and owner_group attribute strings are encoded as literal ID's. For example, the UID 12345 is encoded as 12345.

- nfsmapid ignores the domain portion of the inbound attribute string and performs name service lookups only for the user or group. If the user/group exists in the local system name service databases, then the proper UID/GID will be mapped even when no domain has been configured.

This behavior implies that the same administrative user/group domain exists between NFSv4 client and server (that is, the same UID/GIDs for users/groups on both client and server). In the case of overlapping ID spaces, the inbound attribute string could potentially be mapped to the wrong id. However, this is not functionally different from mapping the inbound string to nobody, yet provides greater flexibility. See EXAMPLES, below.

The utilities that allow you to change UID and GID are:

- usermod(1M)
- userdel(1M)
- groupmod(1M)
- groupdel(1M)

Files /var/run/nfs4_domain   Contains the domain name currently used by NFSv4.

Examples EXAMPLE 1   Setting Domain Name

The following command uses sharectl to set the domain name.

sharectl set -p nfsmapid_domain=sun.com nfs

The nfsmapid_domain property is described under NOTES, below.

EXAMPLE 2 Obtaining Domain Name

The following command uses sharectl to obtain the current domain name.

```
# sharectl get -p nfsmapid_domain nfs
nfsmapid_domain=sun.com
```

Oracle Solaris Administration: Network Services

Notes The nfsmapid daemon might not exist in a future release of Solaris.

Name   nfsref – NFS referral utility

Synopsis   nfsref [-t *svc_type*] add *path location* [location ...]

nfsref [-t *svc_type*] remove *path*

nfsref [-t *svc_type*] lookup *path*

Description   The nfsref command manages NFS Version 4 referrals, which are server-side pointers used to redirect clients to actual locations of file systems. Referrals are based on reparse points (see reparsed(1M) and libreparse(3LIB)). The path arguments in all forms of the synopsis refer to the path to the reparse point symbolic link. This command currently implements one "service type" - nfs-basic, which is the default.

The first form of the command, nfsref add, creates a referral pointing to the specified locations. If a reparse point does not exist, one is created. If it does exist, NFS service data is added or replaces existing NFS service data. Each location has a *host*:/*path* format. The path can contain spaces, which must be escaped to ensure proper shell parsing.

The second form of the command, nfsref delete, removes an NFS referral. It removes NFS service data from the specified reparse point, and removes the reparse point if there are no other types of service data present.

The third form of the command, nfsref lookup, displays the locations to which the specified NFS referral points.

Options   The following options are supported:

-t *svc_type*
   Specify a service type. Currently, only nfs-basic is supported.

Examples   EXAMPLE 1   Adding an NFS Referral

The following command creates an NFS referral at the server path /pool/home/bob, pointing to the resource homeserver:/homepool/bob.

```
# nfsref add /pool/home/bob homeserver:/homepool/bob
Created reparse point /pool/home/bob

# nfsref lookup /pool/home/bob
homeserver:/homepool/bob
```

EXAMPLE 2   Removing an NFS Referral

The following command removes an NFS referral at the server path /pool/home/bob.

```
# nfsref remove /pool/home/bob homeserver:/homepool/bob
Removed svc_type 'nfs-basic' from /pool/home/bob
```

Exit Status 0

Successful completion.

>0

An error occurred.

Files /usr/lib/reparsed/*.so.1

Per-service plugins for reparsed.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/file-system/nfs
Interface Stability	Consolidation Private

See Also reparsed(1M), libreparse(3LIB), attributes(5)

Name nfsstat – NFS statistics

Synopsis nfsstat [-cnrsza] [-T u | d] [-v *version*] [*interval* [*count*]]

nfsstat -m [*pathname*]...

Description nfsstat displays statistical information about the NFS and RPC (Remote Procedure Call), interfaces to the kernel. It can also be used to reinitialize this information. If no options are given the default is as follows:

nfsstat -csnra

The default displays everything, but reinitializes nothing.

Options -a

Display NFS_ACL information.

-c

Display client information. Only the client side NFS, RPC, and NFS_ACL information is printed. Can be combined with the -n, -r, and -a options to print client side NFS, RPC, and NFS_ACL information only.

-m [*pathname*...]

Display statistics for each NFS mounted file system. If *pathname* is not specified, displays statistics for all NFS mounted file systems. If *pathname* is specified, displays statistics for the NFS mounted file systems indicated by *pathname*.

This includes the server name and address, mount flags, current read and write sizes, the retransmission count, the attribute cache timeout values, failover information, and the timers used for dynamic retransmission. The dynamic retransmission timers are displayed only where dynamic retransmission is in use. By default, NFS mounts over the TCP protocols and NFS Version 3 mounts over either TCP or UDP do not use dynamic retransmission.

If you specify the -m option, this is the only option that nfsstat uses. If you specify other options with -m, you receive an error message alerting that the -m flag cannot be combined with other options.

-n

Display NFS information. NFS information for both the client and server side are printed. Can be combined with the -c and -s options to print client or server NFS information only.

-r

Display RPC information.

-s

Display server information.

-T u | d
Display a time stamp.

Specify u for a printed representation of the internal representation of time. See time(2).
Specify d for standard date format. See date(1).

-v *version*
Specify which NFS version for which to print statistics. When followed by the optional
version argument, (2|3|4), specifies statistics for that version. By default, prints statistics for
all versions.

-z
Zero (reinitialize) statistics. This option is for use by the super user only, and can be
combined with any of the above options to zero particular sets of statistics after printing
them.

Operands   The following operands are supported:

count
Display only count reports

interval
Report once each interval seconds.

pathname
Specify the pathname of a file in an NFS mounted file system for which statistics are to be
displayed.

Displays   The server RPC display includes the following fields:

badcalls
The total number of calls rejected by the RPC layer (the sum of badlen and xdrcall as
defined below).

badlen
The number of RPC calls with a length shorter than a minimum-sized RPC call.

calls
The total number of RPC calls received.

dupchecks
The number of RPC calls that looked up in the duplicate request cache.

dupreqs
The number of RPC calls that were found to be duplicates.

nullrecv
The number of times an RPC call was not available when it was thought to be received.

xdrcall
The number of RPC calls whose header could not be XDR decoded.

The server NFS display shows the number of NFS calls received (calls) and rejected
(badcalls), and the counts and percentages for the various calls that were made.

The server NFS_ACL display shows the counts and percentages for the various calls that were made.

The client RPC display includes the following fields:

calls
    The total number of RPC calls made.

badcalls
    The total number of calls rejected by the RPC layer.

badverfs
    The number of times the call failed due to a bad verifier in the response.

badxids
    The number of times a reply from a server was received which did not correspond to any outstanding call.

cantconn
    The number of times the call failed due to a failure to make a connection to the server.

cantsend
    The number of times a client was unable to send an RPC request over a connectionless transport when it tried to do so.

interrupts
    The number of times the call was interrupted by a signal before completing.

newcreds
    The number of times authentication information had to be refreshed.

nomem
    The number of times the call failed due to a failure to allocate memory.

retrans
    The number of times a call had to be retransmitted due to a timeout while waiting for a reply from the server. Applicable only to RPC over connection-less transports.

timeouts
    The number of times a call timed out while waiting for a reply from the server.

timers
    The number of times the calculated time-out value was greater than or equal to the minimum specified time-out value for a call.

The client NFS display shows the number of calls sent and rejected, as well as the number of times a CLIENT handle was received (clgets), the number of times the CLIENT handle cache had no unused entries (cltoomany), as well as a count of the various calls and their respective percentages.

The client NFS_ACL display shows the counts and percentages for the various calls that were made.

The -m option includes information about mount flags set by mount options, mount flags internal to the system, and other mount information. See mount_nfs(1M).

The following mount flags are set by mount options:

forcedirectio
    Data transferred directly between client and server, with no buffering on client.

grpid
    BSD group id inheritance. See description in mount_nfs(1M).

hard
    Hard mount.

intr
    Interrupts allowed on hard mount.

llock
    Local locking being used (no lock manager). Note that this is a private interface.

noac
    Client is not caching attributes.

nointr
    No interrupts allowed on hard mount.

nocto
    No close-to-open consistency.

retrans
    NFS retransmissions.

rpctimesync
    RPC time sync.

rsize
    Read buffer size in bytes.

sec
    sec has one of the following values:

    dh
        des–style authentication (encrypted timestamps).

    krb5
        kerberos v5–style authentication.

    krb5i
        kerberos v5–style authentication with integrity.

krb5p

kerberos v5–style authentication with privacy.

No authentication.

short

Short hand UNIX–style authentication.

sys

UNIX-style authentication (UID, GID).

soft

Soft mount.

timeo

Initial NFS timeout, in tenths of a second.

wsize

Write buffer size in bytes.

The following mount flags are internal to the system:

acl

Server supports NFS_ACL.

down

Server is down.

dynamic

Dynamic transfer size adjustment.

link

Server supports links.

mirrormount

Mounted automatically by means of the mirrormount mechanism.

printed

"Not responding" message printed.

readdironly

Use readdir instead of readdirplus.

referral

Mounted automatically by means of the referral mechanism.

symlink

Server supports symbolic links.

The following flags relate to additional mount information:

proto
   Protocol.

vers
   NFS version.

The -m option also provides attribute cache timeout values. The following fields in -m output provide timeout values for attribute cache:

acdirmax
   Maximum seconds to hold cached directory attributes.

acdirmin
   Minimum seconds to hold cached directory attributes.

acregmax
   Maximum seconds to hold cached file attributes.

acregmin
   Minimum seconds to hold cached file attributes.

The following fields in -m output provide failover information:

currserver
   Which server is currently providing NFS service. See the *Oracle Solaris Administration: IP Services* for additional details.

failover
   How many times a new server has been selected.

noresponse
   How many times servers have failed to respond.

remap
   How many times files have been re-evaluated to the new server.

The fields in -m output shown below provide information on dynamic retransmissions. These items are displayed only where dynamic retransmission is in use.

cur
   Current backed-off retransmission value, in milliseconds.

dev
   Estimated deviation, in milliseconds.

srtt
   The value for the smoothed round-trip time, in milliseconds.

Exit Status   The following exit values are returned:

0
   Successful completion.

>0
   An error occurred.

Installing Oracle Solaris 11 Systems

Oracle Solaris Administration: IP Services

Name nscadm – network storage control utility

Synopsis nscadm freeze *device*

nscadm unfreeze *device*

nscadm isfrozen *device*

Description The nscadm command performs several network storage control functions.

The nscadm freeze command closes existing references to the specified device, and blocks future accesses. This allows maintenance of virtual volume device drivers (for example, RAID 0, RAID 1, RAID 5) to be performed without shutting down the system.

The nscadm unfreeze command reverses the effects of nscadm freeze for the specified device.

The nscadm isfrozen command returns the current status of the specified device.

Options The nscadm command supports the following option.

-h   Display the usage menu.

Operands The nscadm command line supports the following operand.

device
   Specifies the storage device to be acted upon by nscadm.

Exit Status For the freeze and unfreeze, subcommands nscadm returns the following exit values:

0   Success

255   Error

For the isfrozen subcommand, nscadm returns the following exit values:

0   Device is currently frozen.

1   Device is not currently frozen.

255   Error

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Name nscd – name service cache daemon

Synopsis `/usr/sbin/nscd [-f` *configuration-file*`] [-g] [-e` *cachename,* `yes`
`| no] [-i` *cachename*`]`

Description The `nscd` daemon is a process that provides a cache for most name service requests. The
service properties of the `svc:/system/name-service/cache` SMF service determine the
behavior of the cache daemon. See `nscd.conf(4)`.

nscd provides caching for the `passwd(4)`, `group(4)`, `hosts(4)`, `ipnodes(4)`, `exec_attr(4)`,
`prof_attr(4)`, `user_attr(4)`, `ethers(4)`, `rpc(4)`, `protocols(4)`, `networks(4)`, `bootparams(4)`,
`auth_attr(4)`, `services(4)`, `netmasks(4)`, `project(4)` databases through standard `libc`
interfaces, such as `gethostbyname(3NSL)`, `getipnodebyname(3SOCKET)`,
`gethostbyaddr(3NSL)`, and others. The shadow file is specifically not cached. `getspnam(3C)`
calls remain uncached as a result.

Each cache has a separate time-to-live for its data. By default, modifying the local database
(/etc/hosts, /etc/passwd, and so forth) causes that cache to become invalidated upon the
next call to `nscd`.

The updating and refreshing of any of the services that `svc:/system/name-service/cache` is
optionally dependent upon (listed below) causes `nscd` to restart, which effectively clears all
caches.

- `svc:/network/dns/client`, see `resolv.conf(4)`
- `svc:/network/nis/client`, see `ypbind(1M)` and `ypfiles(4)`
- `svc:/network/ldap/client`, see `ldapclient(1M)`
- `svc:/system/name-service/switch`, see `nsswitch.conf(4)`

See `nscd.conf(4)`.

nscd also acts as its own administration tool. If an instance of `nscd` is already running,
commands are passed to the running version transparently.

When running with per-user lookups enabled (see `nscd.conf(4)`), `nscd` forks one and only
one child process (that is, a per-user `nscd`) on behalf of the user making the request. The
per-user `nscd` will use the credentials of the user to open a per-user connection to the name
repository configured for the per-user style of lookups. The lookup will be performed in the
child process. The results are cached in the process and are available only to the same user. The
caches are managed exactly the same as the main `nscd` daemon manages its own caches.
Subsequent requests from the user will be handled by that per-user `nscd` until it terminates.
The per-user `nscd` uses a configurable inactivity time-to-live (TTL) value and terminates itself
after the inactivity TTL expires.

The maximum number of per-user nscds that can be created by the main `nscd` is configurable
(see `nscd.conf(4)`). After the maximum number of them are created, the main `nscd` will use
an LRU algorithm to terminate less active child nscds as needed.

The main nscd daemon creates, monitors, and manages all the child nscds. It creates a user's own nscd upon receiving the user's first per-user lookup. When the nscd daemon is started, if per-user lookups are enabled, it checks to ensure all conditions are met before getting ready to create a per-user nscd. When the daemon is stopped, it terminates all the per-user nscds under its control.

Per-user nscds use the same configuration as the main nscd. They read and use the same default configuration file or the one specified with the -f command line option. Once the configuration is read, the per-user nscd will use it for its entire lifetime.

Options   Several of the options described below require a *cachename* specification. Supported values for *cachename* are: passwd, group, hosts, ipnodes, exec_attr, prof_attr, user_attr, ethers, rpc, protocols, networks, bootparams, auth_attr, services, netmasks, printers, and project.

-f *configuration-file*
Causes nscd to read its configuration data from the specified file. This option is obsolete and will be removed in a future release.

-g
Prints current configuration and statistics to standard output. This is the only option executable by non-root users.

-e *cachename*, yes|no
Enables or disables the specified cache.

-i *cachename*
Invalidate the specified cache.

Examples   EXAMPLE 1   Stopping and Restarting the nscd Daemon.

```
example# svcadm disable system/name-service/cache
```

```
example# svcadm enable system/name-service/cache
```

Files   /etc/nscd.conf   Obsolete. Formerly determined the behavior of the cache daemon

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   svcs(1), svcadm(1M), ypbind(1M), getspnam(3C), gethostbyname(3NSL), getipnodebyname(3SOCKET), auth_attr(4), bootparams(4), ethers(4), exec_attr(4), group(4), hosts(4), netmasks(4), networks(4), nscd.conf(4), nsswitch.conf(4), passwd(4), prof_attr(4), project(4), protocols(4), resolv.conf(4), rpc(4), services(4), user_attr(4), attributes(5)

Notes The output from the `-g` option to `nscd` is subject to change. Do not rely upon it as a programming interface.

The `nscd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/system/name-service/cache
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

The obsolete service `svc:/system/name-service-cache` has been retained for backwards compatibility with scripts that might reference it. Its only purpose is to serve as an `optional_all` dependency on the service `svc:/system/name-service/cache`. The obsolete service name will be removed in a future release.

Name nscfg – import, export name service configurations

Synopsis /usr/sbin/nscfg *command* [*cmd_options*] [*operands*]

/usr/sbin/nscfg import [-fnvq] *FMRI*]

/usr/sbin/nscfg export [-nvq] *FMRI*]

/usr/sbin/nscfg unconfig [-nvq] *FMRI*]

/usr/sbin/nscfg validate [-vq] *FMRI*]

/usr/sbin/nscfg help

Description The nscfg utility imports or exports legacy name service configuration files into or out of the SMF repository. Given a valid SMF configuration and corresponding FMRI, nscfg will regenerate the legacy naming service configuration files, such as nsswitch.conf, resolv.conf, nscd.conf, and so forth, into their legacy locations. Alternatively, nscfg can import those same configuration files populating the SMF repository if it is currently unpopulated.

The following are SMF services that can be operands to nscfg. In many instances, the legacy configuration file that is replaced by the SMF service is listed.

svc:/system/name-service/switch:default
  Legacy file: /etc/nsswitch.conf

  Name service switch configuration (used by nscd).

svc:/system/name-service/cache:default
  Legacy file: /etc/nscd.conf

  Name service cache (nscd).

svc:/network/dns/client:default
  Legacy file: /etc/resolv.conf

  DNS naming service.

svc:/network/nis/domain:default
  Legacy file: /etc/defaultdomain

  Legacy file: /var/yp/binding/$DOMAIN/*

  Shared NIS domain configuration. Used by all NIS services. Also (historical) shared use with LDAP naming services. Must be enabled when using nis/client or ldap/client.

svc:/network/nis/client:default
  NIS client naming service (ypbind and related)

svc:/network/ldap/client:default
  Legacy file: /var/ldap/*

  LDAP client naming service (ldap_cachemgr and related).

svc:/network/nis/server:default
   NIS server service (`ypserv`).

svc:/network/nis/passwd:default
   NIS server `passwd` service (`rpc.yppasswd`).

svc:/network/nis/xfr:default
   NIS server `xfr` service (`ypxfrd`)

svc:/network/nis/update:default
   NIS server update service (`rpc.ypupdated`)

svc:/system/name-service/upgrade:default
   Import legacy configuration files into SMF service.

Sub-commands The `nscfg` utility supports the subcommands described below. Options are described in the context of the subcommands.

import [-fvq] *FMRI*
   If none of the SMF repository properties for the specified FMRI are currently populated, import the legacy configuration files associated with the specified FMRI into the SMF repository.

   With -f, force the repopulation of the SMF repository with the legacy configuration, even if currently populated.

   With -v, issue verbose progress messages during the requested operation. With -q, issue no error or other messages during the requested operation.

export [-vq] *FMRI*
   Export the SMF configuration for the specified FMRI to legacy configuration files. This operation removes any existing affected legacy file(s) and generates new one(s) using the SMF configuration.

unconfig [-vq] *FMRI*
   Unconfigure the SMF configuration for the specified FMRI. This operation resets the specified FMRI and any existing legacy file(s) to their initial unconfigured state.

   With -v, issue verbose progress messages during the requested operation. With -q, issue no error or other messages during the requested operation.

validate [-vq] *FMRI*
   Validate the SMF configuration for the specified FMRI. This operation checks the current configuration and verifies whether any errors exist.

   With -v, issue verbose progress messages during the requested operation. With -q, issue no error or other messages during the requested operation.

Examples **EXAMPLE 1** Importing DNS Client Configuration

The following command imports the DNS client configuration, stored in `resolv.conf`, into the SMF repository.

```
# nscfg import svc:/network/dns/client:default
```

EXAMPLE 2 Exporting SMF LDAP Client Configuration

The following command exports the SMF LDAP client configuration to the legacy configuration files in /var/ldap.

```
# nscfg export svc:/network/ldap/client:default
```

EXAMPLE 3 Resetting Name Service Switch Configuration

The following command resets the name service switch configuration to its initial unconfigured state. The command generates no output and exits quietly with status only.

```
# nscfg unconfig -q svc:/system/name-service/switch:default
```

EXAMPLE 4 Validating LDAP Client Configuration

The following command validates the LDAP client configuration for errors or inconsistencies. The command generates no output and exits quietly with status only.

```
# nscfg validate -q svc:/network/ldap/client:default
```

Exit Status 0

Command successfully executed.

1

An error occurred.

2

Configuration unmodified, no change necessary.

3

No configuration to import.

Name   nslookup – query Internet name servers interactively

Synopsis   nslookup [-*option*] [*name* | -] [*server*]

Description   The nslookup utility is a program to query Internet domain name servers. It has two modes: interactive and non-interactive. Interactive mode allows the user to query name servers for information about various hosts and domains or to print a list of hosts in a domain. Non-interactive mode is used to print just the name and requested information for a host or domain.

Parameters   Interactive mode is entered in the following cases:

1. No arguments are given (the default name server is used).

2. The first argument is a hyphen (-) and the second argument is the host name or Internet address of a name server.

Non-interactive mode is used when the name or Internet address of the host to be looked up is given as the first argument. The optional second argument specifies the host name or address of a name server.

Options can also be specified on the command line if they precede the arguments and are prefixed with a hyphen. For example, to change the default query type to host information, and the initial timeout to 10 seconds, type:

nslookup -query=hinfo -timeout=10

Interactive Commands   host [*server*]
Look up information for host using the current default server or using server, if specified. If host is an Internet address and the query type is A or PTR, the name of the host is returned. If host is a name and does not have a trailing period, the search list is used to qualify the name. To look up a host not in the current domain, append a period to the name.

server *domain*
lserver *domain*
Change the default server to *domain*; lserver uses the initial server to look up information about *domain*, while server uses the current default server. If an authoritative answer can't be found, the names of servers that might have the answer are returned.

root
Not implemented.

finger
Not implemented.

ls
Not implemented.

view
Not implemented.

help
    Not implemented.

?
    Not implemented.

exit
    Exits the program.

set *keyword*[=*value*]
    This command is used to change state information that affects the lookups. Valid keywords
    are:

    all
        Prints the current values of the frequently used options to set. Information about the
        current default server and host is also printed.

    class=*value*
        Change the query class to one of:

        IN
            the Internet class

        CH
            the Chaos class

        HS
            the Hesiod class

        ANY
            wildcard

        The class specifies the protocol group of the information.

        (Default = IN; abbreviation = cl)

    [no]debug
        Turn on or off the display of the full response packet and any intermediate response
        packets when searching.

        (Default = nodebug; abbreviation = [no]deb)

    [no]d2
        Turn debugging mode on or off. This displays more about what nslookup is doing.

        (Default = nod2)

    domain=*name*
        Sets the search list to *name*.

[no]search
  If the lookup request contains at least one period but doesn't end with a trailing period, append the domain names in the domain search list to the request until an answer is received.

  (Default = search)

port=*value*
  Change the default TCP/UDP name server port to *value*.

  (Default = 53; abbreviation = po)

querytype=*value*
type=*value*
  Change the top of the information query.

  (Default = A; abbreviations = q, ty)

[no]recurse
  Tell the name server to query other servers if it does not have the information. (Default = recurse; abbreviation = [no]rec)

retry=*number*
  Set the number of retries to number.

timeout=*number*
  Change the initial timeout interval for waiting for a reply to number seconds.

[no]vc
  Always use a virtual circuit when sending requests to the server.

  (Default = novc)

[no]fail
  Try the next nameserver if a nameserver responds with SERVFAIL or a referral (nofail) or terminate query (fail) on such a response.

  (Default = nofail)

Files   /etc/resolv.conf
  resolver configuration file

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	network/dns/bind
Interface Stability	Volatile

See Also dig(1M), host(1M), named(1M), attributes(5)

See the BIND 9 *Administrator's Reference Manual*. As of the date of publication of this man page, this document is available at https://www.isc.org/software/bind/documentation.

Notes BIND 9 nslookup is deprecated and not as full featured as its BIND 8 version. For more features and functionality refer to dig(1M).

nslookup and dig(1M) now report "Not Implemented" as NOTIMP rather than NOTIMPL. This will have impact on scripts that are looking for NOTIMPL.

Name nsupdate – Dynamic DNS update utility

Synopsis nsupdate [-dv] [-y *keyname:secret* | -k *keyfile*] [-t *timeout*]
[-u *udptimeout*] [-r *udpretries*] [*filename*]

Description The nsupdate utility submits Dynamic DNS Update requests as defined in RFC 2136 to a name server. This utility allows resource records to be added or removed from a zone without manually editing the zone file. A single update request can contain requests to add or remove more than one resource record.

Zones that are under dynamic control with nsupdate or a DHCP server should not be edited by hand. Manual edits could conflict with dynamic updates and cause data to be lost.

The resource records that are dynamically added or removed with nsupdate must be in the same zone. Requests are sent to the zone's master servers identified by the MNAME field of the zone's SOA record.

Transaction signatures can be used to authenticate the Dynamic DNS updates using the TSIG resource record type described in RFC 2845. The signatures rely on a shared secret that should only be known to nsupdate and the name server. Currently, the only supported encryption algorithm for TSIG is HMAC-MD5, which is defined in RFC 2104. Once other algorithms are defined for TSIG, applications will need to ensure that they select the appropriate algorithm as well as the key when authenticating each other. For instance, suitable key and server statements would be added to /etc/named.conf so that the name server can associate the appropriate secret key and algorithm with the IP address of the client application that will be using TSIG authentication. The nsupdate utility does not read /etc/named.conf.

The nsupdate utility uses the -y or -k option to provide the shared secret needed to generate a TSIG record for authenticating Dynamic DNS update requests. These options are mutually exclusive. See OPTIONS.

Options The following options are supported:

-d	Operate in debug mode. This provides tracing information about the update requests that are made and the replies received from the name server.
-k *keyfile*	Read the shared secret from the file *keyfile*, whose name is of the form K{*name*}.+157.+{*random*}.private. For historical reasons, the file K{*name*}.+157.+{*random*}.key must also be present.
-r *udpretries*	Set the number of UDP retries. The default is 3 retries. If *udpretries* is set to zero, only one update request is made.
-t *timeout*	Set *timeout* interval in seconds before update is aborted. The default is 300 seconds. A setting of zero disables the timeout.
-u *udptimeout*	Set interval in seconds between UDP retires, the default is 3 seconds. A setting of zero causes the interval to be calculated based on the timeout (-t) and the number of UDP retries (-r).

-v
Use a TCP connection. Using a TCP connection could be preferable when a batch of update requests is made. By default, nsupdate uses UDP to send update requests to the name server.

-y *keyname*:*secret*
Generate a signature from *keyname*:*secret*, where*keyname* is the name of the key and *secret* is the base64 encoded shared secret.

Use of the -y option is discouraged because the shared secret is supplied as a command line argument in clear text and could be visible in the output from ps(1) or in a history file maintained by the user's shell.

Input Format The nsupdate utility reads input from *filename* or the standard input. Each command is supplied on exactly one line of input. Some commands are for administrative purposes. The others are either update instructions or prerequisite checks on the contents of the zone. These checks set conditions that some name or set of resource records (RRset) either exists or is absent from the zone. These conditions must be met if the entire update request is to succeed. Updates will be rejected if the tests for the prerequisite conditions fail.

Every update request consists of zero or more prerequisites and zero or more updates. This condition allows a suitably authenticated update request to proceed if some specified resource records are present or missing from the zone. A blank input line (or the send command) causes the accumulated commands to be sent as one Dynamic DNS update request to the name server.

The command formats and their meaning are as follows:

server *servername* [*port*]
Send all dynamic update requests to the name server *servername*. When no server statement is provided, nsupdate sends updates to the master server of the correct zone. The MNAME field of that zone's SOA record identifies the master server for that zone. The *port* argument is the port number on *servername* where the dynamic update requests get sent. If no port number is specified, the default DNS port number of 53 is used.

local *address* [*port*]
Send all dynamic update requests using the local *address*. When no local statement is provided, nsupdate sends updates using an address and port chosen by the system. The *port* argument can also be used to make requests come from a specific port. If no port number is specified, the system assigns one.

zone *zonename*
Specify that all updates are to be made to the zone *zonename*. If no zone statement is provided, nsupdate attempts to determine the correct zone to update based on the rest of the input.

class *classname*
Specify the default class. If no class is specified the default class is IN.

key *name secret*
    Specify that all updates are to be TSIG signed using the *name secret* pair. The key command
    overrides any key specified on the command line with -y or -k.

prereq nxdomain *domain-name*
    Require that no resource record of any type exists withthe name *domain-name*.

prereq yxdomain *domain-name*
    Require that *domain-name* exists (has as at least one resource record, of any type).

prereq nxrrset *domain-name* [*class*] *type*
    Require that no resource record exists of the specified *type*, *class* and *domain-name*. If *class*
    is omitted, IN (internet) is assumed.

prereq yxrrset *domain-name* [*class*] *type*
    Require that a resource record of the specified *type*, *class* and *domain-name* must exist. If
    class is omitted, IN (internet) is assumed.

prereq yxrrset *domain-name* [*class*] *type data...*
    The *data* from each set of prerequisites of this form sharing a common *type*, *class*, and
    domain-name are combined to form a set of RRs. This set of RRs must exactly match the set
    of RRs existing in the zone at the given *type*, *class*, and *domain-name*. The *data* are written
    in the standard text representation of the resource record's RDATA.

update delete *domain-name* [*ttl*] [*class*] [*type* [*data...*]]
    Delete any resource records named *domain-name*. If *type* and *data* are provided, only
    matching resource records are removed. The internet class is assumed if *class* is not
    supplied. The *ttl* is ignored, and is only provided for compatibility.

update add *domain-name ttl* [*class*] *type data...*
    Add a new resource record with the specified *ttl*, *class* and *data*.

show
    Display the current message, containing all of the prerequisites and updates specified since
    the last send.

send
    Sends the current message. This is equivalent to entering a blank line.

answer
    Displays the answer.

Lines beginning with a semicolon are comments and are ignored.

Examples   EXAMPLE 1   Inserting and Deleting Resource Records from the Zone

The examples below show how nsupdate could be used to insert and delete resource records
from the example.com zone. Notice that the input in each example contains a trailing blank
line so that a group of commands are sent as one dynamic update request to the master name
server for example.com.

EXAMPLE 1 Inserting and Deleting Resource Records from the Zone   *(Continued)*

```
# nsupdate
> update delete oldhost.example.com A
> update add newhost.example.com 86400 A 172.16.1.1
> send
```

Any A records for oldhost.example.com are deleted. An A record for newhost.example.com
with IP address 172.16.1.1 is added. The newly-added record has a 1 day TTL (86400 seconds).

EXAMPLE 2 Adding CNAME Only If No Records Exist

The following command adds a CNAME only if no records already exist for it.

```
# nsupdate
> prereq nxdomain nickname.example.com
> update add nickname.example.com 86400 CNAME somehost.example.com
> send
```

The prerequisite condition gets the name server to check that there are no resource records of
any type for nickname.example.com. If there are, the update request fails. If this name does
not exist, a CNAME for it is added. This action ensures that when the CNAME is added, it cannot
conflict with the long-standing rule in RFC 1034 that a name must not exist as any other
record type if it exists as a CNAME. (The rule has been updated for DNSSEC in RFC 4035 to
allow CNAMEs to have RSIG, DNSKEY, and NSEC records.)

Files   /etc/resolv.conf   used to identify default name server

K{*name*}.+157.+{*random*}.key   base-64 encoding of HMAC-MD5 key created by
                                    dnssec-keygen(1M).

K{*name*}.+157.+{*random*}.private base-64 encoding of HMAC-MD5 key created by
                                    dnssec-keygen(1M)

Bugs The TSIG key is redundantly stored in two separate files. This is a consequence of nsupdate
using the DST library for its cryptographic operations and could change in future releases.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/dns/bind
Interface Stability	Volatile

Name ntfscat – display NTFS files and streams on the standard output

Synopsis ntfscat [*options*] *device* [*file*]

Description The ntfscat command reads a file or stream from an NTFS volume and display the contents on the standard output.

The case of the filename passed to ntfscat is ignored.

Options Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, -fv is the equivalent of -f -v. A full-name option can be abbreviated to a unique prefix of its name.

-a, --attribute *type*
  Display the contents of a particular attribute type. By default, the unnamed $DATA attribute will be shown. The attribute can be specified by a number in decimal or hexadecimal, or by name.

  ```
  Hex     Decimal Name
  0x10    16      "$STANDARD_INFORMATION"
  0x20    32      "$ATTRIBUTE_LIST"
  0x30    48      "$FILE_NAME"
  0x40    64      "$OBJECT_ID"
  0x50    80      "$SECURITY_DESCRIPTOR"
  0x60    96      "$VOLUME_NAME"
  0x70    112     "$VOLUME_INFORMATION"
  0x80    128     "$DATA"
  0x90    144     "$INDEX_ROOT"
  0xA0    160     "$INDEX_ALLOCATION"
  0xB0    176     "$BITMAP"
  0xC0    192     "$REPARSE_POINT"
  0xD0    208     "$EA_INFORMATION"
  0xE0    224     "$EA"
  0xF0    240     "$PROPERTY_SET"
  0x100   256     "$LOGGED_UTILITY_STREAM"
  ```

  The attribute names can be specified without the leading dollar sign ($) symbol. If you use the $ symbol, you must quote the name to prevent the shell from interpreting the name.

-f, --force
  Overrides some sensible defaults, such as not using a mounted volume. Use this option with caution.

-h, --help
  Show a list of options with a brief description of each.

-i, --inode *num*
  Specify a file by its inode number instead of its name.

-n, --attribute-name *name*
    Display the attribute identified by *name*.

-q, --quiet
    Suppress some debug, warning, and error messages.

-V, --version
    Show the version number, copyright, and license information.

-v, --verbose
    Display more debug, warning, and error messages.

Examples   EXAMPLE 1   Displaying Contents of File in Root

The following command displays the contents of a file in the root of an NTFS volume.

```
# ntfscat /dev/dsk/c0d0p1 boot.ini
```

EXAMPLE 2   Displaying Contents of File in Subdirectory

The following command displays the contents of a file in a subdirectory of an NTFS volume.

```
# ntfscat /dev/dsk/c0d0p1 /winnt/system32/drivers/etc/hosts
```

EXAMPLE 3   Display Contents of an Attribute

The following command displays the contents of the $INDEX_ROOT attribute of the root directory (inode 5).

```
# ntfscat /dev/dsk/c0d0p1 -a INDEX_ROOT -i 5
```

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/ntfsprogs
Interface Stability	Uncommitted

http://wiki.linux-ntfs.org

Authors   ntfscat was written by Richard Russon, Anton Altaparmakov and Szabolcs Szakacsits.

Name   ntfsclone – clone, image, restore, or rescue an NTFS

Synopsis   ntfsclone [*options*] *source*

ntfsclone --save-image [*options*] *source*

ntfsclone --resotore-image [*options*] *source*

ntfsclone --metadata [*options*] *source*

Description   The ntfsclone utility efficiently clones (which includes copy, save, backup, and restore operations) or rescues an NTFS filesystem to a sparse file, an image, a device (partition), or to standard output. It works at disk sector level and copies only the written data (that is, not empty space). Unused disk space becomes zero (cloning to sparse file), encoded with control codes (saving in special image format), left unchanged (cloning to a disk/partition) or filled with zeros (cloning to standard output).

ntfsclone can be useful in making backups—taking an exact snapshot of an NTFS filesystem—and restoring it later on. It also can be used to test NTFS read/write functionality and allows you to troubleshoot users' issues using the clone, without the risk of destroying the original file system.

If not using the special image format (see section of the same name below), the clone is an exact copy of the original NTFS file system, from sector to sector. Thus, it can also be mounted just like the original NTFS filesystem. For example, if you clone to a file and the kernel has a loopback device and NTFS support, then the file can be mounted using:

 # mount -t ntfs -o loop ntfsclone.img

Windows Cloning   You must exercise great care to copy, move or restore a system or boot partition to another computer, or to a different disk or partition (for example, /dev/dsk/c0d0p1 to /dev/dsk/c0d0p2, /dev/dsk/c0d0p1 to /dev/dsk/c0d1p1 or to a different disk sector offset).

Under most circumstances, to enable Windows to boot you must copy, move, or restore NTFS to the same partition that has the following characteristics as the original partition and disk:

- starts at the same sector
- on the same type of disk
- having the same BIOS legacy cylinder setting

The ntfsclone utility guarantees an exact copy of NTFS but does not deal with booting issues. This is by design: ntfsclone is a file system, not a system, utility. Its goal is only NTFS cloning, not Windows cloning. Because of this, ntfsclone can be used as a very fast and reliable building block for Windows cloning, but is not a complete answer. You can find useful tips on NTFS cloning at the NTFS web site, http://wiki.linux-ntfs.org.

Sparse Files   A file containing unallocated blocks (holes) is referred to as a "sparse file". The reported size of such files is always higher than the disk space consumed by them. The du(1) command reports the real disk space used by a sparse file. The holes are always read as zeros. All major Linux file

systems, such as, ext2, ext3, reiserfs, Reiser4, JFS, and XFS support sparse files. However, the ISO 9600 CD-ROM file system, as one example, does not.

Special Image Format It is recommended that you save an NTFS filesystem to a special image format. Instead of representing unallocated blocks as holes, they are encoded using control codes. Thus, the image saves space without requiring sparse file support. The image format is ideal for streaming file system images over the network. The disadvantage of the special image format is that you cannot mount the image directly; you must first restore it.

To save an image using the special image format, use the `-s` or the `--save-image` option. To restore an image, use the `-r` or the `--restore-image` option. Note that you can restore images from standard input by using a hyphen (`-`) as the source file.

Metadata-only Cloning Using the `-m` or `--metadata` option, ntfsclone can save only the NTFS metadata and the clone still will be mountable. In this usage, all non-metadata file content is lost; reading back the data results in all zeros.

The metadata-only image can be compressed very well, usually to a size in the range of 1 to 8 MB. It is convenient to transfer such an image for investigation and troubleshooting.

In metadata-only mode, ntfsclone saves none of the user's data, which includes the resident user's data embedded into metadata. All is filled with zeros. Moreover, all the file timestamps, and deleted and unused spaces inside the metadata are filled with zeros. Thus, this mode is inappropriate, for example, for forensic analyses.

Note that filenames are not removed. Because a filename might contain sensitive information, consider the possibilities for breaches of security or privacy before sending out a metadata-only image.

Options Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, `-fv` is the equivalent of `-f -v`. A full-name option can be abbreviated to a unique prefix of its name.

`-f`, `--force`
Forces ntfsclone to proceed, even if the filesystem is marked "dirty" following a consistency check.

`-h`, `--help`
Show a list of options with a brief description of each one.

`-i`, `--ignore-fs-check`
Ignore the result of the file system consistency check. This option can be used only with the `--meta-data` option. Any clusters that cause an inconsistency are saved.

`-m`, `--metadata`
Clone only metadata. With this option, you must clone only to a file.

`-o`, `--output` *file*
Clone NTFS to the non-existent *file*. If *file* is a hyphen (`-`), clone to the standard output.

-O, -—overwrite *file*
  Clone NTFS to *file*, overwriting *file* if it already exists.

-—rescue
  Ignore disk read errors so that a disk having bad sectors, for example, a failing disk, can be
  rescued with minimal impact on the disk. ntfsclone works at the lowest, sector level in
  this mode, enabling more data to be rescued. The contents of the unreadable sectors are
  filled with the question mark (?) character; the beginning of such sectors are marked by the
  string: BadSector.

-r, -—restore-image *source*
  Restore from the special image format specified by *source*. If *source* is a hyphen (-), the
  image is read from the standard input.

-s, -—save-image
  Save to the special image format. In terms of space usage and speed, this is the most efficient
  option if imaging is done to the standard output. This option is useful for image
  compression, encryption, or streaming through a network.

Examples   **EXAMPLE 1**   Cloning with Overwrite Option

The following command clones with the -—overwrite option.

```
# ntfsclone --overwrite /dev/dsk/c0d2p1 /dev/dsk/c0d0p1
```

EXAMPLE 2   Saving to Special Image Format

The following command clones to the special image format to its original partition.

```
# ntfsclone --save-image --output backup.img /dev/dsk/c0d0p1
```

EXAMPLE 3   Restoring from a Special Image File

The following command restores an NTFS from a special image file.

```
# ntfsclone --restore-image --overwrite /dev/dsk/c0d0p1 backup.img
```

EXAMPLE 4   Saving to a Compressed Image

The following command saves an NTFS to a compressed image file.

```
# ntfsclone --save-image -o - /dev/dsk/c0d0p1
```

EXAMPLE 5   Restoring from a Compressed Image

The following command restores an NTFS volume from a compressed image file.

```
# gunzip -c backup.img.gz | \
ntfsclone --restore-image --overwrite /dev/dsk/c0d0p1 -
```

EXAMPLE 6   Backing up to a Remote Host Using ssh

The following command backs up to a remote host, using ssh(1). Note that ssh will probably require a password.

```
# ntfsclone --save-image --output - /dev/dsk/c0d0p1 | \
gzip -c | ssh host 'cat > backup.img.gz'
```

EXAMPLE 7   Restoring from a Remote Host Using ssh

The following command restores from a remote host, using ssh(1). Note that ssh will probably require a password.

```
# ssh host 'cat backup.img.gz' | gunzip -c  | \
ntfsclone --restore-image --overwrite /dev/dsk/c0d0p1 -
```

EXAMPLE 8   Streaming an Image File from a Web Server

The following command streams an image file from a web server and restore it to a partition.

```
# wget -qO - http://server/backup.img | \
ntfsclone --restore-image --overwrite /dev/dsk/c0d0p1 -
```

EXAMPLE 9   Cloning to a New File

The following command clones an NTFS volume to a non-existent file.

```
# ntfsclone --output ntfs-clone.img /dev/dsk/c0d0p1
```

EXAMPLE 10   Packing NTFS Metadata

The following command packs NTFS metadata into an image file. Note that bzip2 takes a much longer time than gzip, but produces an archive that is up to ten times smaller than the latter produces.

```
# ntfsclone --metadata --output ntfsmeta.img /dev/dsk/c0d0p1
bzip2 ntfsmeta.img
```

EXAMPLE 11   Unpacking NTFS Metadata

The following command unpacks NTFS metadata into a sparse file.

```
# bunzip2 -c ntfsmeta.img.bz2 | \
cp --sparse=always /proc/self/fd/0 ntfsmeta.img
```

Exit Status   The return code is zero on success, non-zero otherwise.

Name   ntfscluster – identify files in a specified region of an NTFS volume

Synopsis   ntfscluster [*options*] *device*

Description   The ntfscluster utility has three modes of operation: info, sector, and cluster, described as follows.

Info
The default mode, info is currently not implemented. It will display general information about the NTFS volume when it is working.

Sector
The sector mode displays a list of files that have data in the specified range of sectors. This mode is put in effect by the -—sector option.

Cluster
The cluster mode displays a list of files that have data in the specified range of clusters. When the cluster size is one sector, this is equivalent to the sector mode of operation. This mode is put in effect by the -—cluster option.

Options   Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, -fv is the equivalent of -f -v. A full-name option can be abbreviated to a unique prefix of its name.

-c, --cluster *range*
Any files whose data is in this range of clusters will be displayed.

-F, --filename *filename*
Display information about *filename*.

-f, --force
Overrides some sensible defaults, such as not working with a mounted volume. Use this option with caution.

-h, --help
Show a list of options with a brief description of each.

-I, --inode *num*
Show information about this inode.

-i, --info
This option is not yet implemented.

-q, --quiet
Suppress some debug, warning, and error messages.

-s, --sector *range*
Any files whose data is in this range of sectors will be displayed.

-V, --version
Show the version number, copyright, and license information.

-v, --verbose
    Display more debug, warning, and error messages.

Examples   **EXAMPLE 1**   Displaying Information About a Volume

The following command displays information about the volume /dev/dsk/c0d0p1.

    # **ntfscluster /dev/dsk/c0d0p1**

EXAMPLE 2   Displaying List of Files in a Cluster Range

The following command looks for files in the first 500 clusters of /dev/dsk/c0d0p1.

    # **ntfscluster -c 0-500 /dev/dsk/c0d0p1**

Name   ntfscmp – compare two NTFS file systems and report the differences

Synopsis   ntfscmp [*options*] *device1 device2*

Description   The ntfscmp utility compares all aspects of two NTFS file systems and reports all differences it finds. The file systems can be on block devices or in image files. ntfscmp can be used for volume verification. However, its primary purpose is to be an efficient development tool, used to quickly locate, identify, and check the correctness of the metadata changes made to NTFS.

If one is interested only in the NTFS metadata changes, it can be useful to compare the metadata images created by using the --metadata option of ntfsclone(1M) to eliminate the usually uninteresting timestamp changes.

The terse output of ntfscmp is intentional, because the provided information is sufficient to determine exact differences. More copious output can be obtained by using diff(1) to compare the verbose output of ntfsinfo(1M) for each reported inode.

Options   Supported options are listed below. Options have both single-letter and full-name forms.

-h, --help
   Display help and exit.

-P, --no-progress-bar
   Do not show progress bars.

-v, --verbose
   Display more debug, warning, and error messages.

Exit Status   The exit code is 0 on success, non-zero otherwise.

Name ntfscp – copy file to an NTFS volume

Synopsis ntfscp [*options*] *device source_file destination*

Description The ntfscp utility copies files to an NTFS volume. *destination* (see Synopis) can be either a file or a directory. If *destination* is a directory specified by name, *source_file* is copied into this directory. If *destination* is a directory specified by inode number, an unnamed data attribute is created for this inode and *source_file* is copied into it. Consider possible negative consequence before specifying a directory by inode number: it is unusual to have an unnamed data stream in a directory.

Data Streams All data on NTFS is stored in streams, which can have names. A file can have more than one data stream, but exactly one must have no name. The size of a file is the size of its unnamed data stream. Usually, when you do not specify a stream name, you are seeking access to the unnamed data stream. If you want access to a named data stream, you need to add :*stream_name* to the filename. For example, by opening some.mp3:artist you will open stream artist in some.mp3. In an operating system, such as Windows, that prevents you from accessing named data streams, you need to use some program like FAR or utilities from cygwin to access those streams.

Options Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, -fv is the equivalent of -f -v. A full-name option can be abbreviated to a unique prefix of its name.

-a, --attribute *num*
    Write to attribute designated by *num*.

-f, --force
    Overrides some sensible defaults, such as not working with a mounted volume. Use this option with caution.

-h, --help
    Show a list of options with a brief description of each one.

-i, --inode
    Treat *destination* (see Synopsis) as inode number.

-N, --attr-name *name*
    Write to attribute with this name.

-n, --no-action
    Use this option to make a test run before doing the actual copy operation. Volume will be opened read-only and no write will be done.

-q, --quiet
    Suppress some debug, warning, and error messages.

-V, --version
    Show the version number, copyright, and license information.

-v, --verbose
> Display more debug, warning, and error messages.

Examples   EXAMPLE 1   Copying from Home to Root Directory

The following command copies new_boot.ini from /home/user as boot.ini to the root of an /dev/dsk/c0d0p1 NTFS volume.

```
# ntfscp /dev/dsk/c0d0p1 /home/user/new_boot.ini boot.ini
```

EXAMPLE 2   Copying a Stream

The following command copies myfile to C:\some\path\myfile:stream (assume that /dev/dsk/c0d0p1 drive designator is C).

```
# ntfscp -N stream /dev/dsk/c0d0p1 myfile /some/path
```

Name ntfsfix – fix common errors and force operating system to check NTFS

Synopsis ntfsfix [*options*] *device*

Description The ntfsfix utility fixes some common NTFS problems. Note that it is not a version of chkdsk. It repairs some fundamental NTFS inconsistencies, resets the NTFS journal file, and schedules an NTFS consistency check for the next reboot of the operating system.

Run ntfsfix on an NTFS volume if you think it was damaged by the operating system or in some other way and it cannot be mounted.

Options Supported options are listed below.

-h, --help
    Show a list of options with a brief description of each.

-V, --version
    Show the version number, copyright, and license information.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/ntfsprogs
Interface Stability	Uncommitted

See Also mkntfs(1M), ntfsprogs(1M), parted(1M), attributes(5)

http://wiki.linux-ntfs.org

Authors ntfsfix was written by Anton Altaparmakov, with contributions from Szabolcs Szakacsits.

Name ntfsinfo – dump a file's attributes

Synopsis ntfsinfo [*options*] *device*

Description The ntfsinfo utility dumps the attributes of inode *inode-number* or the file *path-filename* and/or information about the MFT (-m option). Run ntfsinfo without arguments for a full list of options.

Options Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, -fv is the equivalent of -f -v. A full-name option can be abbreviated to a unique prefix of its name.

-F, --file *file*
   Show information about *file*.

-f, --force
   Overrides some sensible defaults, such as not overwriting an existing file. Use this option with caution.

-h, --help
   Show a list of options with a brief description of each.

-i, --inode *num*
   Show information about inode identified by *num*.

-m, --mft
   Show information about the volume.

-q, --quiet
   Suppress some debug, warning, and error messages.

-t, --notime
   Do not display timestamps in the output.

-V, --version
   Show the version number, copyright, and license information.

-v, --verbose
   Display more debug, warning, and error messages.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/ntfsprogs
Interface Stability	Uncommitted

http://wiki.linux-ntfs.org

Authors   ntfsinfo was written by Matthew J. Fanto, Anton Altaparmakov, Richard Russon, Szabolcs Szakacsits, Yuval Fledel, Yura Pakhuchiy and Cristian Klein.

Name ntfslabel – display or change the label on an NTFS file system

Synopsis ntfslabel [*options*] *device* [*new_label*]

Description The ntfslabel utility displays or changes the file system label on the NTFS file system located on *device* (see Synopsis).

If the optional argument *new_label* is not present, ntfslabel displays the current file system label.

If the optional argument *new_label* is present, ntfslabel sets the file system label to be *new_label*. NTFS file system labels can be at most 128 Unicode characters long; if *new_label* is longer than 128 Unicode characters, ntfslabel truncates it and displays a warning message.

It is also possible to set the file system label using the -L option of mkntfs(1M) during creation of the file system.

Options Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, -fv is the equivalent of -f -v. A full-name option can be abbreviated to a unique prefix of its name.

-f, --force
Overrides some sensible defaults, such as not working with a mounted volume. Use this option with caution.

-h, --help
Show a list of options with a brief description of each.

-n, --no-action
Do not actually write a new label to disk.

-q, --quiet
Suppress some debug, warning, and error messages.

-V, --version
Show the version number, copyright, and license information.

-v, --verbose
Display more debug, warning, and error messages.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/ntfsprogs
Interface Stability	Uncommitted

See Also   mkntfs(1M), ntfsprogs(1M), parted(1M), attributes(5)

http://wiki.linux-ntfs.org

Authors   ntfslabel was written by Matthew J. Fanto, with contributions from Anton Altaparmakov and Richard Russon.

Name   ntfsls – list directory contents on an NTFS file system

Synopsis   `ntfsls` [*options*] *device*

Description   The `ntfsls` utility lists information about the files specified by the `PATH` option (the root directory by default). *device* (see Synopsis) is the special file corresponding to the device (for example, `/dev/dsk/c0d0p0`*num*) or an NTFS image file.

Options   Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, `-fv` is the equivalent of `-f -v`. A full-name option can be abbreviated to a unique prefix of its name.

`-a, --all`
    Display all files. If this option is not specified file names in the POSIX namespace are not displayed.

`-F, --classify`
    Append one of the indicators shown below to entries.

    `* / = @ |`

`-f, --force`
    Force execution. For example, this option is necessary to run on an NTFS partition stored in a normal file.

`-h, --help`
    Display usage information and exit.

`-i, --inode`
    Display the inode number of each file. This is the MFT reference number, in NTFS terminology.

`-l, --long`
    Use a long listing format.

`-p, --path` *path*
    The directory whose contents to list or the file (including the path) about which to display information.

`-q, --quiet`
    Suppress some debug, warning, and error messages.

`-R, --recursive`
    Show the contents of all directories beneath the specified directory.

`-s, --system`
    Unless this options is specified, all files beginning with a dollar sign character will not be listed, as these files are usually system files.

`-v, --verbose`
    Display more debug, warning, and error messages.

-V, --version
Display the ntfsls version number and exit.

-x, --dos
Display short file names, that is, files in the DOS namespace, instead of long file names, that is, files in the WIN32 namespace.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/ntfsprogs
Interface Stability	Uncommitted

See Also , ntfsprogs(1M), parted(1M), attributes(5)

http://wiki.linux-ntfs.org

Authors This version of ntfsls was written by Lode Leroy, Anton Altaparmakov, Richard Russon, Carmelo Kintana and Giang Nguyen.

Name   ntfsprogs – list of NTFS tools

Synopsis   ntfsprogs

Description   ntfsprogs is the name of a suite of NTFS utilities based around a shared library. The tools are available for free and come with full source code. The tools are listed below.

mkntfs(1M)
> Create an NTFS filesystem.

ntfscat(1M)
> Dump a file's content to the standard output.

ntfsclone(1M)
> Efficiently clone, backup, restore, or rescue NTFS.

ntfscluster(1M)
> Locate the files that use the specified sectors or clusters.

ntfscmp(1M)
> Compare two NTFS file systems and report the differences.

ntfscp(1M)
> Copy a file to an NTFS volume.

ntfsfix(1M)
> Check and fix some common errors, clear the log file, and make the operating system perform a thorough check next time it boots.

ntfsinfo(1M)
> Show information about NTFS or one of the files or directories within it.

ntfslabel(1M)
> Show, or set, an NTFS filesystem's volume label.

ntfsls(1M)
> List information about files in a directory residing on an NTFS.

ntfsmount(1M) (not a SunOS man page)
> Read-write NTFS user space driver.

ntfsresize(1M)
> Resize NTFS without losing data.

ntfsundelete(1M)
> Recover deleted files from NTFS.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/ntfsprogs
Interface Stability	Uncommitted

http://wiki.linux-ntfs.org

Authors   The tools were written by Anton Altaparmakov, Carmelo Kintana, Cristian Klein, Erik Sornes, Giang Nguyen, Holger Ohmacht, Lode Leroy, Matthew J. Fanto, Per Olofsson, Richard Russon, Szabolcs Szakacsits, Yura Pakhuchiy, and Yuval Fledel.

Name ntfsresize – resize an NTFS file system without data loss

Synopsis ntfsresize [*options*] --info *device*

ntfsresize [*options*] [--size *size*[k|M|G]] *device*

Description The ntfsresize program safely resizes Windows XP, Windows Server 2003, Windows 2000, Windows NT4 and Longhorn NTFS filesystems without data loss. All NTFS versions used by 32-bit and 64-bit Windows "operating systems" are supported. Defragmentation is not required prior to resizing, because ntfsresize can relocate any data if needed, without risking data integrity.

ntfsresize can be used to shrink or enlarge any NTFS file system located on an unmounted device (usually a disk partition). The new file system will have a size that you specify. The size parameter can have one of the optional modifiers k, M, G, denoting, respectively, kilobytes, megabytes, or gigabytes. ntfsresize conforms to the SI, ATA, an IEEE standards and the disk manufacturers by supporting $k=10^3$, $M=10^6$ and $G=10^9$.

If both ---info and ---size options are omitted then the NTFS file system will be enlarged to the underlying device size.

To resize a file system on a partition, you must resize both the file system and the partition, by editing the partition table on the disk. Similarly to other command-line file system resizers, ntfsresize does not manipulate the size of the partitions. To do that you must use a disk partitioning tool, such as fdisk(1M). Alternatively, you could use one of the many user friendly partitioners that uses ntfsresize internally. Such partitioners include, among others, Mandriva's DiskDrake, QTParted, SUSE/Novell's YaST Partitioner, IBM's EVMS, GParted, or Debian/Ubuntu's Partman.

Back up your data and your partition table before using any partitioning tool. For an NTFS file system, you can use ntfsclone(1M) as a means of backup.

To shrink an NTFS partition, first use ntfsresize to shrink the size of the file system. Then use a utility such as fdisk(1M) to shrink the size of the partition by deleting the partition and recreating it with the smaller size. Do not make the partition smaller than the new size of NTFS; otherwise, you will not be able to boot from that partition. If you mistakenly made a too-small partition, you would have to recreate the partition to be as large as newly sized NTFS file system.

To enlarge an NTFS file system, you must first enlarge the size of the underlying partition. You can use fdisk(1M) to delete the partition and recreate it with a larger size. Make sure the newly sized partition does not overlap with any other partition. Then use ntfsresize to enlarge the file system.

When recreating a partition, make sure you create it at the same starting sector and with the same partition type as was used in the partition you are replacing. Otherwise, you will not be able to access your file system. Use the fdisk u command to switch from the default cylinder

unit to the reliable sector unit. Also, if the bootable flag was set in the old partition, make sure to set it in the recreated partiton. Otherwise, you might not be able to boot from the new partition.

Extended Description

There are a handful of very rarely met restrictions in the use of ntfsresize. An example of such a restriction occurs with a file system stored on a disk having unknown bad sectors. Relocation of the first MFT extent and resizing into the middle of a $MFTMirr extent are not supported. These cases are detected and resizing is restricted to a safe size or the closest safe size is displayed.

Upon completion of a resizing, ntfsresize schedules an NTFS consistency check. In Windows, this check is performed by chkdsk. Upon the first subsequent reboot into Windows, you will note chkdsk running in a blue background. This is normal. Windows might force a quick reboot after the consistency check. Depending on your hardware configuration, Windows might alert you to a systems setting change and recommend or require a reboot. Acknowledge the message and reboot a second time.

Options

Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, -fv is the equivalent of -f -v. A full-name option can be abbreviated to a unique prefix of its name.

-b, --bad-sectors

By default, ntfsresize exits upon encountering bad sectors. This option allows the utility to proceed in spite of such sectors.

Prior using this option, it is strongly recommended that you use ntfsclone(1M) with the --rescue option to make a backup, then, in Windows, run chkdsk /f /r volume: from the command line. If the disk guarantee displays as valid, then replace it, as it is defective. Note that no software can repair bad sector errors. The most that can be done is to work around these defects.

This option has no effect if a disk has no bad sectors.

-f, --force

ntfsresize always marks a file system for consistency check before a real (not using -—no-action) resize operation and it leaves that way for extra safety. Thus, if an NTFS file system was marked by ntfsresize, it is safe to use this option. You must use this option, if you need to resize several times without booting into Windows between each resizing step.

-h, --help

Display usage information and exit.

-i, --info

Used when you want to shrink a file system. Causes ntfsresize to determine the smallest shrunken file system size supported. Most of the time the smallest size is the space already used on the file system. ntfsresize does not shrink a file system to a smaller size than what is returned by this option. Depending on several factors, it might be unable to shrink to this

theoretical size. Although the integrity of your data should be never at risk, it is nevertheless strongly recommended to make a test run by using the --no-action option before actual resizing.

Based on testing, the smallest attainable size is approximately space used in the file system plus 20–200 MB. Note also that Windows might need an additional 50–100 MB to boot safely.

This option never causes any changes to the file system; the partition is opened read-only.

-n, --no-action
    Use this option to make a test run before doing the resize operation. Volume will be opened read-only and ntfsresize displays what it would do if it were to resize the file system. Proceed with the actual resizing only if the test run passed.

-P, --no-progress-bar
    Do not display progress bars during ntfsresize operation.

-s, --size *size*[k|M|G]]
    Resize file system to *size* bytes. The new file system will have a size that you specify. The size parameter can have one of the optional modifiers k, M, G, denoting, respectively, kilobytes, megabytes, or gigabytes. ntfsresize conforms to the SI, ATA, an IEEE standards and the disk manufacturers by supporting k=10^3, M=10^6 and G=10^9. Before performing an actual resizing, run ntfsresize with the --no-action option, along with this option, first.

-v, --verbose
    Display copious output.

-V, --version
    Display the version number of ntfsresize.

Exit Status Display zero on success, non-zero otherwise.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/ntfsprogs
Interface Stability	Uncommitted

See Also fdisk(1M), ntfsclone(1M), parted(1M), attributes(5)

http://wiki.linux-ntfs.org

Notes In Linux version 2.6, with partitions that have been manipulated by parted(1M), use of ntfsresize preceded corruption of partition tables, which resulted in unbootable Windows systems. This occurred even if the NTFS file system was consistent. This problem is independent of NTFS and, thus, ntfsresize. Moreover, ntfsresize never touches the

partition table. Under the conditions just described, you can, in the BIOS, change `Disk Access Mode` to LBA to regain the ability to boot. For further discussion of this condition see the `ntfsresize` FAQ at: `http://mlf.linux.rulez.org/mlf/ezaz/ntfsresize.html`.

Authors   `ntfsresize` was written by Szabolcs Szakacsits, with contributions from Anton Altaparmakov and Richard Russon.

Name ntfsundelete – recover a deleted file from an NTFS volume

Synopsis ntfsundelete [*options*] *device*

Description The ntfsundelete utility can, under the right circumstances, recover a deleted file from an NTFS volume. The command has three modes of operation:

Scan
　　The default mode, scan simply reads an NTFS Volume and looks for files that have been deleted. It then displays a list, giving the inode number, name, and size of each deleted file.

Undelete
　　The undelete mode takes the files either matching the regular expression (option -m) or specified by the *inode-expressions* and recovers as much of the data as possible. It saves the result to another location.

Copy
　　The "wizard's" option. Saves a portion of the MFT to a file, which can be useful when debugging ntfsundelete.

There are many circumstances under which ntfsundelete is unable to recover a file. For example, consider the following scenario. When a file is deleted the MFT Record is marked as not in use and the bitmap representing the disk usage is updated. If the power is not turned off immediately, the free space, where the file used to reside might get overwritten. Worse, the MFT Record might be reused for another file. If this happens, it is impossible to tell where the file was on disk.

Even if all the clusters of a file are not in use, there is no guarantee that they have not been overwritten by some short-lived file.

ntfsundelete cannot recover compressed or encrypted files. During a scan, it will display such a file as being 0% recoverable.

Locale In NTFS, all filenames are stored as Unicode. A filename is converted into the current locale for display by ntfsundelete. The utility has successfully displayed Chinese pictogram filenames and then correctly recovered them.

Extended MFT Records In rare circumstances, a single MFT Record will not be large enough to hold the metadata describing a file (a file would have to be in hundreds of fragments for this to happen). In these cases, one MFT record might hold the filename, while another will hold the information about the data. ntfsundelete will not try and piece together such records. It will simply list unnamed files with data.

Recovered File's Size and Creation Date To recover a file, ntfsundelete has to read the file's metadata. Unfortunately, when a file is deleted, the metadata can be left in an inconsistent state. For example, the file size might be recorded as zero; the creation date of a file might be set to the time it was deleted or to a random time. In such situations, ntfsundelete picks the largest file size it finds and writes that to disk. It also tries to set the file's creation date to the last-modified date. This date might be the correct last modified date, or something unexpected.

Options   Supported options are listed below. Most options have both single-letter and full-name forms. Multiple single-letter options that do not take an argument can be combined. For example, -fv is the equivalent of -f -v. A full-name option can be abbreviated to a unique prefix of its name.

-b, --byte *num*
  Fill in the parts of unrecoverable file clusters with byte represented by *num*. The default is zeros.

-C, --case
  Make filename search, when attempting a match with the -–match option, case-sensitive. The default filename search is case-insensitive.

-c, --copy *range*
  This "wizard" option writes a block of MFT FILE records to a file. The default file is mft which will be created in the current directory. This option can be combined with the --output and --destination options.

-d, --destination *dir*
  Specify the location of the output file for the --copy and --undelete options.

-f, --force
  Overrides some sensible defaults, such as not overwriting an existing file. Use this option with caution.

-h, --help
  Show a list of options with a brief description of each one.

-i, --inodes *range*
  Recover the files within the specified range of inode numbers. *range* can be a single inode number, several numbers separated by commas, or a range separated by a dash (-).

-m, -–match *pattern*
  Filter the output by looking only for filenames that match *pattern*. The pattern can include the wildcards ?, matching exactly one character, or *, matching zero or more characters. By default, the matching is case-insensitive. To make the search case-sensitive, use the --case option.

-O, --optimistic
  Recover parts of the file even if they are currently marked as in use.

-o, --output *file*
  Set the name of the output file created by the --copy or --undelete options.

-P, --parent
  Display the parent directory of a deleted file.

-p, --percentage *num*
  Filter the output of the --scan option by matching only files with *num* percent of recoverable content.

-q, --quiet

Reduce the amount of output to a minimum. This option is not useful with the --scan option.

-s, --scan

Search through an NTFS volume and display a list of files that could be recovered. This is the default action of ntfsundelete. This list can be filtered by filename, size, percentage recoverable, or last modification time, using the --match, --size, --percent, and --time options, respectively.

In the output from this option, the %age (percentage) field displays how much of a file can potentially be recovered.

-S, --size *range*

Filter the output of the --scan option by looking for a particular range of file sizes. *range* can be specified as two numbers separated by a hyphen (-). A unit of size can be abbreviated using the suffixes k, m, g, and t, for kilobytes, megabytes, gigabytes, and terabytes respectively.

-t, --time *since*

Filter the output of the --scan option. Match only files that have been altered since this time. The time must be given as number and a suffix of d, w, m, or y for, respectively, days, weeks, months, or years.

-T, --truncate

The default behavior of ntfsundelete is to round *up* a file's size to the nearest cluster (which will be a multiple of 512 bytes). In cases where the utility has complete data about the size of a file, this option restores the file to exactly that size.

-u, --undelete

Specifies undelete mode. You can specify the files to be recovered using by using --match or --inodes options. This option can be combined with --output, --destination, and --byte.

When the file is recovered it will be given its original name, unless the --output option is used.

-v, --verbose

Increase the amount of output that ntfsundelete displays.

-V, --version

Display the version number, copyright, and license for ntfsundelete.

Examples   EXAMPLE 1   Searching for Deleted Files

The following command searches for deleted files on a specific device.

```
# ntfsundelete /dev/dsk/c0d0p1
```

EXAMPLE 2 Scanning for Files Matching a Wildcard

The following command searches for deleted files that match *.doc.

```
# ntfsundelete /dev/dsk/c0d0p1 -s -m '*.doc'
```

EXAMPLE 3 Searching for Files of a Certain Size

The following command looks for deleted files between 5000 and 6000000 bytes, with at least 90% of the data recoverable, on /dev/dsk/c0d0p1.

```
# ntfsundelete /dev/dsk/c0d0p1 -S 5k-6m -p 90
```

EXAMPLE 4 Searching for Recently Changed Files

The following command searches for deleted files altered in the last two days.

```
# ntfsundelete /dev/dsk/c0d0p1 -t 2d
```

EXAMPLE 5 Specifying an Inode Range

The following command undeletes inodes 2, 5 and 100 to 131 of device /dev/sda1.

```
# ntfsundelete /dev/sda1 -u -i 2,5,100-131
```

EXAMPLE 6 Specifying an Output File and Directory

The following command undeletes inode number 3689, names the file work.doc, and stores it in the user's home directory.

```
# ntfsundelete /dev/dsk/c0d0p1 -u -i 3689 -o work.doc -d ~
```

EXAMPLE 7 Saving MFT Records

The following command saves MFT records 3689 to 3690 to a file debug.

```
# ntfsundelete /dev/dsk/c0d0p1 -c 3689-3690 -o debug
```

Attributes See attributes(5) for descriptions of the following attributes:

Name   nwamd – network auto-magic daemon

Synopsis   /lib/inet/nwamd

Description   nwamd is a system daemon to manage network interfaces.

This daemon is started automatically by the network/physical:default service and should not be invoked directly. It does not constitute a programming interface.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Volatile

See Also   svcs(1), netcfgd(1M), netadm(1M), netcfg(1M), svcadm(1M), attributes(5), nwam(5), smf(5)

See also nwam-manager(1M), available in the JDS/GNOME man page collection.

Notes   The networking service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/physical:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name obpsym – Kernel Symbolic Debugging for OpenBoot Firmware

Synopsis modload -p misc/obpsym

Description obpsym is a kernel module that installs OpenBoot callback handlers that provide kernel symbol information to OpenBoot. OpenBoot firmware user interface commands use the callbacks to convert numeric *addresses* to kernel symbol names for display purposes, and to convert kernel symbol names to numeric *literals* allowing symbolic names to be used as input arguments to user interface commands.

Once obpsym is installed, kernel symbolic names may be used anywhere at the OpenBoot firmware's user interface command prompt in place of a literal (numeric) string. For example, if obpsym is installed, the OpenBoot firmware commands ctrace and dis typically display symbolic names and offsets in the form *modname:symbolname + offset.* User interface Commands such as dis can be given a kernel symbolic name such as ufs:ufs_mount instead of a numeric address.

Placing the command

forceload: misc/obpsym

into the [system](4) file forces the kernel module misc/obpsym to be loaded and activates the kernel callbacks during the kernel startup sequence.

obpsym may be useful as a kernel debugger in situations where other kernel debuggers are not useful. For example, on SPARC machines, if obpsym is loaded, you may be able to use the OpenBoot firmware's ctrace command to display symbolic names in the stack backtrace after a watchdog reset.

Kernel Symbolic Name Syntax The syntax for a kernel symbolic name is:

[*module-name* :] *symbol-name*

Where *module-name* is the name of the kernel module that the symbol *symbol-name* appears in. A NULL module name is taken as "all modules, in no particular order" by obpsym. The module name unix is equivalent to a NULL module name, so that conflicts with words defined in the firmware's vocabulary can be avoided.

Typically, OpenBoot firmware reads a word from the input stream and looks the word up in its internal *vocabulary* before checking if the word is a *literal*. Thus, kernel symbols, such as reset may be given as unix:reset to avoid the unexpected side effect of the firmware finding and executing a matching word in its vocabulary.

Files /etc/system   System configuration information file.

/platform/*platform-name*/kernel/misc/obpsym   Platform-specific kernel symbol information.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/library/processor

See Also   kmdb(1), uname(1), kernel(1M), modload(1M), modunload(1M), system(4), attributes(5)

OpenBoot 2.x Command Reference Manual

Warnings   Some OpenBoot firmware user interface commands may use system resources incompatibly with the way they are used by the Unix kernel. These commands and the use of this feature as a kernel debugger may cause interactions that the Unix kernel is not prepared to deal with. If this occurs, the Unix kernel and/or the OpenBoot firmware user interface commands may react unpredictably and may panic the system, or may hang or may cause other unpredictable results. For these reasons, the use of this feature is only minimally supported and recommended to be used only as a kernel debugger of last resort.

If a breakpoint or watchpoint is triggered while the console frame buffer is powered off, the system can crash and be left in a state from which it is difficult to recover. If one of these is triggered while the monitor is powered off, you will not be able to see the debugger output.

Notes   *platform-name* can be found using the -i option of uname(1)

obpsym is supported only on architectures that support OpenBoot firmware.

On some systems, OpenBoot must be completely RAM resident so the obpsym symbol callback support can be added to the firmware, if the firmware doesn't include support for the symbol callbacks. On these systems, obpsym may complain that it requires that "you must use ramforth to use this module".

See the *OpenBoot 2.x Command Reference Manual* for details on how to use the *ramforth* command, how to place the command into *nvramrc*, and how to set *use-nvramrc?* to true. On systems with version 1.x OpenBoot firmware, *nvramrc* doesn't exist, and the *ramforth* command must be typed manually after each reset, in order to use this module.

Once installed, the symbol table callbacks can be disabled by using the following OpenBoot firmware command:

```
0 0 set-symbol-lookup
```

Name oplhpd – Hot plug daemon for SPARC Enterprise Server line

Synopsis /usr/platform/SUNW,SPARC-Enterprise/lib/sparcv9/lib/oplhpd

Description The hot plug daemon for SPARC Enterprise Servers is a daemon process that runs on the SUNW,SPARC-Enterprise family of servers. The daemon is started by the service management facility (see smf(5)) and communicates with the service processor when hot plug PCI cassettes change their dynamic reconfiguration state.

The service FMRI for oplhpd is:

svc:/platform/sun4u/oplhpd:default

A domain supports only one running oplhpd process at a time.

Errors OPLHPD uses syslog(3C) to report status and error messages. All of the messages are logged with the LOG_DAEMON facility.

Error messages are logged with the LOG_ERR and LOG_NOTICE priorities, and informational messages are logged with the LOG_DEBUG priority. The default entries in the /etc/syslog.conf file log all of the OPLHPD error messages to the /var/adm/messages log.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/domain-configuration/sparc-enterprise, SUNWdcsr
Interface Stability	Committed

See Also svcs(1), inetadm(1M), svcadm(1M), syslog(3C), syslog.conf(4), attributes(5), smf(5)

Name   parted – partition manipulation program

Synopsis   `parted [`*options*`] [`*device* `[`*command* `[`*options*`...]...]]`

Description   `parted` is a disk partitioning and partition resizing program. It allows you to create, destroy, resize, move, and copy `ext2`, `linux-swap`, `FAT`, `FAT32`, and `reiserfs` partitions. It can create, resize, and move Macintosh HFS partitions, as well as detect `jfs`, `ntfs`, `ufs`, and `xfs` partitions. It is useful for creating space for new operating systems, reorganizing disk usage, and copying data to new hard disks.

This manual page documents `parted` briefly. Complete `parted` documentation is distributed with the package in "GNU Info" format.

`parted` is implemented with a set of top-level options and a set of subcommands, most of which have their own options and operands. These subcommands are described below. `parted` has an optional operand:

device   The block device to be used. When none is given, `parted` uses the first block device it finds.

If you invoke `parted` without an argument, the program displays a command prompt.

Options   The following options are supported:

-a *alignment-type*, --align *alignment-type*
    Sets alignment for newly created partitions. Valid alignment types are:

    none
        Use the minimum alignment allowed by the disk type.

    cylinder
        Align partitions to cylinders.

    minimal
        Use minimum alignment as given by the disk topology information. This and the *opt* value will use layout information provided by the disk to align the logical partition table addresses to actual physical blocks on the disks. The *min* value is the minimum alignment needed to align the partition properly to physical blocks, which avoids performance degradation.

    optimal
        Use optimum alignment as given by the disk topology information. This aligns to a multiple of the physical block size in a way that guarantees optimal performance.

-h, --help
    Displays a help message.

-l, --list
    Lists partition layout on all block devices.

-m, --machine
      Displays machine-parseable output.

-s, --script
      Never prompts for user intervention.

-v, --version
      Displays the version number.

Sub-commands If you omit a subcommand in a `parted` command line, the utility issues a command prompt.

check *partition*
      Do a simple check on *partition*.

cp [*source-device*] *source dest*
      Copy the source partition's filesystem on *source-device* (or the current device if no other
      device was specified) to the *dest* partition on the current device.

help *command*
      Display general help, or help on a command, if specified.

mkfs *partition fs-type*
      Make a filesystem *fs-type* on partition. *fs-type* can be one of fat16, fat32, ext2, linux-wap,
      or reiserfs.

mklabel *label-type*
      Create a new disk label (partition table) of *label-type*. *label-type* should be one of bsd, dvh,
      gpt, loop, mac, msdos, pc98, or sun.

mkpart *part-type* [*fs-type*] *start end*
      Make a *part-type* partition with file system *fs-type* (if specified), beginning at *start* and
      ending at *end* (by default, in megabytes). *fs-type* can be one of fat16, fat32, ext2, HFS,
      linux-swap, NTFS, reiserfs, or ufs. *part-type* should be one of primary, logical, or
      extended.

mkpartfs *part-type fs-type start end*
      Make a *part-type* partition with file system *fs-type*, beginning at *start* and ending at *end* (by
      default, in megabytes).

      Use of this subcommand is discouraged. Instead use mkpart to create an empty partition,
      and then use external tools such as mke2fs(8) (part of Linux) to create the filesystem.

move *partition start end*
      Move partition so that it begins at *start* and ends at *end*. Note that move never changes the
      minor number.

name *partition name*
      Set the name of partition to *name*. This option works only on Mac, PC98, and GPT disk
      labels. The name can be placed in quotes, if necessary.

print
   Display the partition table.

quit
   Exit from parted.

rescue *start end*
   Rescue a lost partition that was located somewhere between *start* and *end*. If a partition is found, parted will ask if you want to create an entry for it in the partition table.

resize *partition start end*
   Resize the file system on *partition* so that it begins at *start* and ends at *end* (by default, in megabytes).

rm *partition*
   Delete *partition*.

select *device*
   Choose *device* as the current device to edit. *device* should usually be a Solaris or Linux hard disk device, but it can be a partition, software raid device, or an SVM or LVM logical volume if necessary.

set *partition flag state*
   Change the state of the *flag* on *partition* to *state*. Supported flags are: boot, root, swap, hidden, raid, lvm, lba, and palo. *state* should be either on or off.

unit *unit*
   Set *unit* as the unit to use when displaying locations and sizes, and for interpreting those given by the user when not suffixed with an explicit unit. *unit* can be one of s (sectors), B (bytes), kB, MB, GB, TB, % (percentage of device size), cyl (cylinders), chs (cylinders, heads, sectors), or compact (megabytes for input, and a human-friendly form for output).

version
   Display version information and a copyright message.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/storage/parted
Interface Stability	Uncommitted

See Also fdisk(1M), mkfs(1M), attributes(5)

The parted program is fully documented in the info(1) format GNU partitioning software manual.

Notes ext3 filesystem functionality does not currently work. To manage ext3 type filesystems use tools like resize2fs(8) or mke2fs(8) (both part of Linux). Note that the currently supported ext2 filesystem will be deprecated once ext3 support is finalized. Further note that ext3 support will have limited functionality that is yet to be defined. Use tools like resize2fs(8) and mke2fs(8) to manage these types of filesystems.

To manually resize an ext3 filesystem or a partition, use resize2fs(8), fdisk(8), or similar tools. For LVM situations, you will need to use the LVM commands to resize the LVM elements.

Author This manual page was written by Timshel Knoll for the Debian GNU/Linux system. It is here adapted for the Solaris operating system.

Name   pbind – control and query bindings of processes or LWPs

Synopsis   pbind -b *processor_id pid* [/*lwpid*]...

pbind [-q] [*pid* [/*lwpid*]]...

pbind -Q [*processor_id*]...

pbind -u *pid* [/*lwpid*]...

pbind -U [*processor_id*]...

Description   pbind controls and queries bindings of processes and LWPs (lightweight processes) to processors. pbind can also remove processor bindings that were previously established.

When an LWP is bound to a processor, it will be executed only by that processor except when the LWP requires a resource that is provided only by another processor. The binding is not exclusive, that is, the processor is free to execute other LWPs as well.

Bindings are inherited, so new LWPs and processes created by a bound LWP will have the same binding. Binding an interactive shell to a processor, for example, binds all commands executed by the shell.

Superusers may bind or unbind any process or LWP, while other users can bind or unbind any process or LWP for which they have permission to signal, that is, any process that has the same effective user ID as the user.

Options   The following options are supported:

-b *processor_id*
Binds all or a subset of the LWPs of the specified processes to the processor *processor_id*. Specify *processor_id* as the processor ID of the processor to be controlled or queried. *processor_id* must be present and on-line. Use the psrinfo command to determine whether or not *processor_id* is present and on-line. See psrinfo(1M).

-q
Displays the bindings of the specified processes or of all processes. If a process is composed of multiple LWPs which have different bindings and the LWPs are not explicitly specified, the bindings of only one of the bound LWPs will be displayed. The bindings of a subset of LWPs can be displayed by appending "/lwpids" to the process IDs. Multiple LWPs may be selected using "-" and "," delimiters. See EXAMPLES.

-Q
Displays the LWPs bound to the specified list of processors, or all LWPs with processor bindings. For processes composed of multiple LWPs, the bindings of individual LWPs will be displayed.

-u
Removes the bindings of all or a subset of the LWPs of the specified processes, allowing them to be executed on any on-line processor.

-U

   Removes the bindings of all LWPs bound to the specified list of processors, or to any
   processor if no argument is specified.

Operands The following operands are supported:

pid

   The process ID of the process to be controlled or queried.

lwpid

   The set of LWP IDs of the specified process to be controlled or queried. The syntax for
   selecting LWP IDs is as follows:

   ```
   2,3,4-8      LWP IDs 2, 3, and 4 through 8
   -4           LWPs whose IDs are 4 or below
   4-           LWPs whose IDs are 4 or above
   ```

processor_id

   The processor ID of the processor to be controlled or queried.

Examples **EXAMPLE 1**   Binding Processes

The following example binds processes 204 and 223 to processor 2:

```
example% pbind -b 2 204 223
process id 204: was 2, now 2
process id 223: was 3, now 2
```

EXAMPLE 2   Unbinding a Process

The following example unbinds process 204:

```
example% pbind -u 204
```

EXAMPLE 3   Querying Bindings

The following example queries bindings. It demonstrates that process 1 is bound to processor
0, process 149 has at least one LWP bound to CPU3, and process 101 has no bound LWPs.

```
example% pbind -q 1 149 101
process id 1: 0
process id 149: 3
process id 101: not bound
```

EXAMPLE 4   Querying LWP Bindings

The following example queries bindings of LWPs. It demonstrates that LWP 1 of process 149 is
bound to CPU3, and LWP 2 of process 149 is not bound.

```
example% pbind -q 149/1-2
lwp id 149/1: 3
lwp id 149/2: not bound
```

EXAMPLE 5 Querying LWP Bindings for Processor 2:

The following example queries all LWPs bound to processor 2:

```
example% pbind -Q 2
lwp id 149/4: 2
lwp id 149/5: 2
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

Exit Status The following exit values are returned:

0
　Successful completion.

>0
　An error occurred.

See Also psradm(1M), psrinfo(1M), psrset(1M), processor_bind(2), processor_info(2),
sysconf(3C), attributes(5)

Diagnostics pbind: cannot query pid 31: No such process
　The process specified did not exist or has exited.

pbind: cannot bind pid 31: Not owner
　The user does not have permission to bind the process.

pbind: cannot bind pid 31: Invalid argument
　The specified processor is not on-line.

Name pcitool – interrupt routing tool

Synopsis /usr/sbin/pcitool -h

x86:

/usr/sbin/pcitool pci@*unit-address* -i *cpu#,ino#* | all [-r [-c] |
    -w *cpu#* [-g]] [-v] [-q]

SPARC:

/usr/sbin/pcitool pci@*unit-address* -i *ino#* | all [-r [-c] |
    -w *cpu#* [-g]] [-v] [-q]

/usr/sbin/pcitool pci@*unit-address* -m *msi#* | all [-r [-c] |
    -w *cpu#* [-g]] [-v] [-q]

Description PCItool is a low-level tool that provides a facility for getting and setting interrupt routing information.

Interrupt Routing The pcitool -i command displays device and CPU routing information for INOs on a given nexus, and allows rerouting of a given INO or INO group to a specific CPU.

On SPARC platforms, the INO is mapped to an interrupt mondo, where as one or more MSI/Xs are mapped to an INO. So, INO and MSI/Xs are individually retargetable. Use the -i option to retrieve or reroute a given INO; use the -m option for MSI/Xs.

Specifying *cpu#* is available on the x86 platform. In combination with *ino#*, this identifies an exclusive vector. The *cpu#* argument is not supported on the SPARC platform.

Required Privileges A user must have all privileges in order to access interrupt information. A regular user can access interrupt information following an su(1M) to root or if he is granted the "Maintenance and Repair" rights profile in the user_attr file. See user_attr(4) and rbac(5).

Options The following options are supported:

-h

Display command usage.

-q

No errors are displayed as messages. However, pcitool still returns Unix error codes.

-r [-c]

Display device and CPU routing information for INOs on a given nexus. The device path and instance number of each device for each displayed INO is displayed. On some platforms, interrupts dedicated to the root complex are indicated by the string (Internal) appended to their pathnames.

With -c, dump interrupt controller information.

If neither -r nor -w are provided on the command line, -r is assumed. See Examples.

-v

Verbose output.

-w *cpu#* [-g]

Route the given INO or MSI/X to the given CPU. Display the new and original routing information. The INO or MSI/X must be specified.

On some platforms (such as x86) multiple MSI interrupts of a single function need to be rerouted together. Use -g to do this. The -g option works only on supported platforms and only for groups of MSI interrupts. (A "group" of 1 is accepted.) When -g is used, the vector provided must be the lowest-numbered vector of the group. The size of the group is determined internally. See Examples.

Examples **EXAMPLE 1** Displaying All INOs

The command for showing all INOs on /pci@0,0 is:

```
# pcitool /pci@0,0 -i all
```

EXAMPLE 2 Displaying Output for Specific INO

The command for showing INO 0x0,0x21 on the root nexus /pci@0,0 differs slightly between x86 and SPARC platforms.

On an x86 platform:

```
# pcitool /pci@0,0 -i 0,21
0x0,0x21:                    mpt                          0
/pci@7b,0/pci1022,7458@11/pci1000,3060@2
```

On a SPARC platform:

```
# pcitool /pci@0,0 -i 21
0x0,0x21:                    mpt                          0
/pci@7b,0/pci1022,7458@11/pci1000,3060@2
```

Output shown above is an example and might vary from your output.

EXAMPLE 3 Displaying Output for Specific MSI

The command for showing MSI 0x1 on the root nexus /pci@0,0, along with sample output, is shown below.

```
# pcitool /pci@0,0 -m 0x1
0x0,0x1: pcieb    0    /pci@7b,0/pci10de,5d@e
```

EXAMPLE 4 Rerouting an INO from One CPU to Another

Successful rerouting INO 21 from CPU 0 to CPU 1 produces the output shown below.

On an x86 platform:

EXAMPLE 4 Rerouting an INO from One CPU to Another   *(Continued)*

```
# pcitool /pci@0,0 -i 0,21 -w 1
0x0,0x21 -> 0x1,0x20
```

On a SPARC platform:

```
# pcitool /pci@0,0 -i 21 -w 1
0x0,0x21 -> 0x1,0x20
```

EXAMPLE 5 Rerouting an MSI from One CPU to Another

Successful rerouting MSI 1 from CPU 1 to CPU 0 produces the output shown below.

```
# pcitool /pci@0,0 -m 1 -w 0
0x1,0x1 -> 0x0,0x1
```

EXAMPLE 6 Rerouting a Group of INOs

Successful rerouting of a group of INOs starting at 24 from CPU 0 to CPU 1 produces the output shown below.

On an x86 platform:

```
# pcitool /pci@0,0 -i 3,24 -w 1 -g
0x3,0x24 => 0x1,0x22
```

On a SPARC platform:

```
# pcitool /pci@0,0 -i 24 -w 1 -g
0x3,0x24 => 0x1,0x22
```

Exit Status   0

No error.

EINVAL

Out-of-range, misaligned, or otherwise invalid argument has been passed in.

ETIME

Timeout waiting for pending interrupt to settle before changing interrupts to a new CPU.

EIO

An I/O error occurred.

Name   pginfo – display information about processor groups

Synopsis   pginfo [-T] [-p] [-v] [-r *string*] [-R *string*]
                    [*pg* ... | -c *processor_id* ...]

pginfo -s [-v] [-r *string*] [-R *string*] [*pg* ... | -c *processor_id* ...]

pginfo -c | -I [-r *string*] [-R *string*] [*pg* ... | -c *processor_id* ...]

pginfo -h

Description   The pginfo displays information about the Processor Group (PG) hierarchy, its contents, and its characteristics. A PG is a set of CPUs that are grouped together by a common characteristic.

PGs are used by the operating system to represent the CPUs that share performance relevant hardware such as the execution pipelines, caches, and so forth. These PGs are organized into a hierarchy that models the processor topology of the machine. In this hierarchy, each CPU (strand) has a leaf PG that represents the CPUs that share the most hardware with it. Each successive ancestor of the leaf PG shares progressively less hardware with the CPU until the root PG is reached. The root PG contains all of the CPUs in the system and represents the group of CPUs sharing the least hardware with each other. (See EXAMPLES below for an example of PG hierarchy.)

If a machine does not have any performance-relevant hardware sharing relationships, then pginfo displays only a root PG that contains all of the CPUs in the system.

By default, pginfo displays information about each PG in the system, including its PG ID, sharing relationship, and online and offline CPUs. It displays the PGs in depth first order by default and uses indentation to help show how the PGs are related to each other (see EXAMPLES below).

You can specify options to:

- Display the PG hierarchy graphically
- List the PG sharing relationships that exist on the running system
- Give current PG utilization information, specifying PGs of interest by PG ID, CPU ID, or sharing relationship
- Specify that only CPU or PG IDs be displayed

In addition, there is a -p option to show which PGs contain the CPUs that correspond to the CPUs with a common physical relationship such as system, chip, and core. These physical relationships describe the physical characteristics of the CPUs and might or might not encapsulate performance-relevant processor sharing relationships.

If the system configuration repeatedly changes when pginfo is obtaining a snapshot of system data, pginfo displays an error message and terminates with exit status 1.

Options   The following options are supported:

-c *processor_id* ...

Interpret arguments as processor IDs and display only information about PGs that contain the specified processors.

When used with the -T option, this option limits the PG hierarchy displayed to include only the lineage of each of the specified CPUs. This option cannot be used when specifying PGs of interest by PG ID.

-C

Display only CPU IDs for all CPUs belonging to the PGs. This option cannot be used at the same time as the -I option.

-h

Display short help message and exit with exit status 0.

-I

Display only PG IDs for the PGs. This option cannot be used at the same time as the -C option.

-p

Display the physical relationship that corresponds to a PGs. If a PG has the same CPUs as the whole system, a processor core, or a chip, system, core, or chip will be displayed, as appropriate, after the sharing relationship of the PG in square brackets ("[ ]").

-r *string1,string2,...*

Display only information about PGs with a sharing relationship name that matches any of the specified strings.

Each specified string can be a whole relationship name or a portion of one or more relationship names and the string matching is case-insensitive. The possible relationship names are in the list of sharing relationships that the -s option displays.

You can specify multiple -r options, which results in matching all PGs with a relationship name that contain any of the specified strings. When used with the -T option, this option limits the PG hierarchy displayed to include only the lineage of each of the PGs with the specified relationship.

-R *string1,string2,...*

Display only information about PGs with a sharing relationship name *other* than the one(s) specified.

String matching is the same as described above for the -r option. Multiple -R options can be entered.

-s

Display all sharing relationships supported on the running system for the specified PGs. The -v option can be used with this option to get the list of PGs for each sharing relationship.

-T

In the resulting hierarchy, the lineage of each CPU (hardware strand) is arranged from the PGs that share the most hardware in common with the CPU to the PGs that share the least with the CPU. If any CPUs, PGs, or relationships of interest are specified, the resulting PG hierarchy is limited to the lineages of the PGs with the specified CPUs, PGs, or relationships in the PG hierarchy.

-v

Verbose mode. Display additional information about PGs. When used without -s, -C, or -I, it is equivalent to giving the -T and -p options together at the same time. When used with the -s option, it gives the list of PGs for each sharing relationship.

Operands The following operands can be given on the command line by specifying one or more of their corresponding IDs or the keyword all. Multiple IDs can be specified as a space-separated list (for example, 1 3), a range of numbers (for example, 5-8), or both (for example, 1 3 5-8 13-16). PGs and CPUs cannot be specified at the same time.

pg   PGs of interest can be specified on the command line by PG ID.

processor_id When the -c option is entered, CPUs of interest can be specified on the command line by CPU ID.

If an invalid PG or CPU is specified, the pginfo command displays a message on standard error showing the invalid ID and continues processing other PGs or CPUs specified on the command line. When none of the specified PGs or CPUs are valid, pginfo exits with an exit status of 2.

Examples In the examples below, the system contains one UltraSPARC T1 processor chip with 8 cores and 32 strands.

EXAMPLE 1 Displaying Information About Every PG

The following command, using no arguments, displays information about every PG.

```
$ pginfo
PG  RELATIONSHIP         CPUs
0   System               0-31
3    Data_Pipe_to_memory 0-31
2     Floating_Point_Unit 0-31
1      Integer_Pipeline   0-3
4      Integer_Pipeline   4-7
5      Integer_Pipeline   8-11
6      Integer_Pipeline   12-15
7      Integer_Pipeline   16-19
8      Integer_Pipeline   20-23
9      Integer_Pipeline   24-27
10     Integer_Pipeline   28-31
```

EXAMPLE 2 Displaying Information About All Sharing Relationships

The following command displays information about all sharing relationships.

```
$ pginfo -s -v
RELATIONSHIP        PGs
------------------- -------
System              0
Data_Pipe_to_memory 3
Floating_Point_Unit 2
Integer_Pipeline    1 4-10
```

EXAMPLE 3 Displaying PG Hierarchy

The following command displays general information about all PGs in the system. The output shows which PGs belong to chips and cores.

```
$ pginfo -p -T
0 (System) CPUs: 0-31
'-- 3 (Data_Pipe_to_memory [system,chip]) CPUs: 0-31
   '-- 2 (Floating_Point_Unit [system,chip]) CPUs: 0-31
       |-- 1 (Integer_Pipeline [core]) CPUs: 0-3
       |-- 4 (Integer_Pipeline [core]) CPUs: 4-7
       |-- 5 (Integer_Pipeline [core]) CPUs: 8-11
       |-- 6 (Integer_Pipeline [core]) CPUs: 12-15
       |-- 7 (Integer_Pipeline [core]) CPUs: 16-19
       |-- 8 (Integer_Pipeline [core]) CPUs: 20-23
       |-- 9 (Integer_Pipeline [core]) CPUs: 24-27
       '-- 10 (Integer_Pipeline [core]) CPUs: 28-31
```

EXAMPLE 4 Displaying List with Specific Criterion

The following command displays a list of CPUs sharing integer pipeline with CPU 0. This example also demonstrates the use of -r option to filter PGs by sharing relationship name.

```
$ pginfo -r integer_pipeline -C -c 0
0 1 2 3
```

EXAMPLE 5 Using Option to Exclude by Specific Criterion

The following command lists all PGs other than the ones that have Integer_Pipeline as their relationship.

```
$ pginfo -R Integer_Pipeline
PG RELATIONSHIP        CPUs
0  System              0-31
3  Data_Pipe_to_memory 0-31
2  Floating_Point_Unit 0-31
```

Exit Status 0

Successful completion.

1

An error occurred.

2

Invalid syntax.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Uncommitted

The command line options and output are Uncommitted.

See Also pgstat(1M), attributes(5)

Name   pgstat – report utilization statistics for Processor Groups

Synopsis   pgstat [-A] [-C] [-p] [-s *key* | -S *key*] [-t *number*] [-T u | d] [-v]
[-r *string*] [-R *string*] [-P *pg* ...] [-c *processor_id*...]
[*interval* [*count*]]

pgstat -h

Description   The pgstat displays utilization statistics about Processor Groups (PGs). A PG is a set of CPUs
that are grouped together by a common characteristic.

PGs are used by the operating system to represent CPUs that share performance relevant
hardware, such as execution pipelines, caches, and so forth. These PGs are organized into a
hierarchy that models the processor topology of the machine. In this hierarchy, each CPU
(strand) has a leaf PG that represents the CPUs that share the most hardware with it. Each
successive ancestor of the leaf PG shares progressively less hardware with the CPU until the
root PG is reached. The root PG contains all of the CPUs in the system and represents the
group of CPUs sharing the least hardware with each other. (See "Examples" below for an
example of PG hierarchy).

If a machine does not have any performance-relevant hardware sharing relationships, then
pgstat displays only a root PG that contains all of the CPUs in the system.

By default, pgstat does the following:

- Measures the hardware and software utilization of all PGs in the PG hierarchy over a one
  second interval.

- Displays the utilization of the PGs in depth first order using indentation to help show how
  the PGs relate to each other.

- Displays the ID, sharing relationship, hardware load, software load, and online CPUs for
  each PG at the end of each interval.

The interval and count can be given as arguments to specify the number of seconds in the
sampling interval and number of times to measure and display the utilization for the specified
PGs.

You can specify options to further tailor the output, organize the output a certain way, and
specify PGs of interest (see "Options" below for details).

A hyphen ("-") is displayed when the utilization for a given PG is not supported and a
question mark (?) is displayed when the utilization is not available. On systems where the
CPU hardware performance counters are needed to measure the hardware utilization, the
hardware utilization might be unavailable because the counters are being used by a
cpc(3CPC) consumer such as attributes(5), cputrack(1), dtrace(1M), or another
application that uses libcpc(3LIB).

Options   The following options are supported:

-A

　　Display summary of utilization data when pgstat is run over multiple intervals.

-c *processor_id*...

　　Display utilization about PGs that contain the specified CPUs. The CPUs can be specified
　　as a comma separated list of CPU IDs. A hyphen ("-") can be used to specify contiguous
　　ranges of CPU IDs (for example, 0-3).

-C

　　Display utilization of each CPU in each PG.

-h

　　Display short help message and exit with exit status 0.

-p

　　Display the physical relationship that corresponds to a PG. If a PG has the same CPUs as
　　the whole system, a processor core, or a chip, system, core, or chip, as appropriate, is
　　displayed after the sharing relationship of the PG in square brackets ("[]").

-P *pg*,...

　　Display utilization for specified PGs. Multiple PGs can be specified as a comma-separated
　　list of PG IDs. A hyphen ("-") can be used to specify a contiguous range of PG IDs (for
　　example, 0-3).

-r *string1,string2*,...

　　Display utilization only for PGs with a sharing relationship name that matches any of the
　　specified strings. The string can be a whole relationship name or a portion of one or more
　　relationship names. The string matching is case-insensitive.

　　Multiple -r options can be entered, which results in matching all PGs with a relationship
　　name that matches any of the specified strings.

-R *string1,string2*,...

　　Display information only about PGs with a sharing relationship name *other* than the one(s)
　　specified.

　　String matching is the same as described above for the -r option. Multiple -R options can
　　be entered.

-s *key*

　　Sort output lines by the specified key in descending order. The specified key can be one of
　　the following:

　　pg
　　　　Sort by PG ID.

　　hwload
　　　　Sort by hardware utilization.

swload

    Sort by software utilization.

user

    Sort by user time.

sys

    Sort by system time.

idle

    Sort by idle time.

depth

    Sort by descending PG tree from root to leaves, depth-first (default).

breadth

    Sort by descending PG tree from root to leaves, breadth-first.

-S *key*

    Sort output lines by the specified key in ascending order. Possible key values are the same as for the -s option.

-t *number*

    Show the top number of PGs for the specified integer number.

-T u | d

    Display timestamp for each sampling interval in Unix time (see time(2)) or the standard date format used by date(1).

-v

    Display extra information about each PG including hardware utilization and capacity and software user, system, and idle times.

Output Headings pgstat displays the column headings, which are listed below, along with the meanings of those headings.

PG

    Processor Group ID.

RELATIONSHIP

    Sharing relationship for PG.

HW

    Hardware load in percent (calculated as UTIL/CAP for interval).

UTIL

    Hardware utilization of PG's shared hardware component over the interval. This can be a large number, so K, M, B, and T are used for denoting thousand, million, billion, and trillion, respectively.

CAP

Approximate maximum possible utilization for PG's shared hardware component over the interval. This can be a large number, so K, M, B, and T are used for denoting thousand, million, billion, and trillion, respectively.

SW

Software load in percent (calculated as (USR + SYS) / (USR + SYS + IDLE))

USR

Percentage of time that software threads ran in user mode on CPUs in PG during interval.

SYS

Percentage of time that software threads ran in system mode on CPUs in PG during interval.

IDLE

Percentage of time that no software threads ran on CPUs in PG during interval.

CPUS

CPU IDs for CPUs in PG.

Examples In the following examples, the system contains one UltraSPARC T1 processor chip with 8 cores and 32 strands.

EXAMPLE 1 Displaying Utilization for Specified Period

The following command displays utilization for all PGs over the last two seconds.

```
$ pgstat 1 2
PG  RELATIONSHIP          HW    SW  CPUS
 0  System                 -  0.4%  0-31
 3   Data_Pipe_to_memory   -  0.4%  0-31
 2    Floating_Point_Unit  0%  0.4%  0-31
 1     Integer_Pipeline    0%   0%  0-3
 4     Integer_Pipeline    0%   0%  4-7
 5     Integer_Pipeline    0%   0%  8-11
 6     Integer_Pipeline    0%  0.2%  12-15
 7     Integer_Pipeline    0%   0%  16-19
 8     Integer_Pipeline  2.8%  2.7%  20-23
 9     Integer_Pipeline  0.1%  0.2%  24-27
10     Integer_Pipeline    0%   0%  28-31
PG  RELATIONSHIP          HW    SW  CPUS
 0  System                 -  0.4%  0-31
 3   Data_Pipe_to_memory   -  0.4%  0-31
 2    Floating_Point_Unit  0%  0.4%  0-31
 1     Integer_Pipeline    0%  0.2%  0-3

```

Exit Status   The following exit values are returned:

0

Successful completion.

1

Unable to get PG information from the system.

2

Specified interval, count, or all CPUs, PGs, and sharing relationships invalid.

3

Invalid syntax.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Name picld – PICL daemon

Synopsis /usr/lib/picl/picld

Description The Platform Information and Control Library (PICL) provides a mechanism to publish platform-specific information for clients to access in a platform-independent way. picld maintains and controls access to the PICL information from clients and plug-in modules. The daemon is started in both single-user and multi-user boot mode.

Upon startup, the PICL daemon loads and initializes the plug-in modules. These modules use the libpicltree(3PICLTREE) interface to create nodes and properties in the PICL tree to publish platform configuration information. After the plug-in modules are initialized, the daemon opens the PICL daemon door to service client requests to access information in the PICL tree.

PICL Tree The PICL tree is the repository of all the nodes and properties created by the plug-in modules to represent the platform configuration. Every node in the PICL tree is an instance of a well-defined PICL class. The name of the base PICL class is picl, which defines a basic set of properties that all nodes in the tree must possess. Two of those properties are name and _class, where name contains the name of the node, and the _class contains the PICL class name of the node. Certain nodes in the PICL tree have well-known names. For example, the name of the root node of the PICL tree is / and the name of the root node of the sub-tree containing platform device nodes is platform.

PICL plug–in Modules The PICL plug-in modules are shared objects that publish platform-specific data in the PICL tree. They are located in well-known directories so that the daemon can locate and load them.

Plug-in modules are located in one of the following plug-in directories depending on the plaform-specific nature of the data that they collect and publish:

/usr/platform/ʻuname -iʼ/lib/picl/plugins
/usr/platform/ʻuname -mʼ/lib/picl/plugins

A plug-in module can specify its dependency on another plug-in module using the -l or -R linker option. The plug-ins are loaded by the daemon using dlopen(3C) according to the specified dependencies. Each plug-in module must define a .init section, which is executed when the plug-in module is loaded, to register themselves with the daemon. See picld_plugin_register(3PICLTREE) for additional information on plug-in registration.

The plug-in modules use the libpicltree(3PICLTREE) interface to publish nodes and properties in the PICL tree so that clients can access them.

When the PICL daemon invokes the initialization routine of the plug-in module, the plug-in collects the platform information and creates nodes and/or properties to represent the configuration in the PICL tree. A plug-in can create additional threads to monitor the platform configuration and update the PICL tree with any changes. This enables a PICL plug-in to operate as a daemon within the PICL framework.

An environmental monitor is an example of a plug-in module that uses a thread to monitor the temperatures and fan speeds of the platform, then publishes the environmental information in the PICL tree so clients can access them.

Clients use the libpicl(3PICL) interface to send requests to picld for accessing the PICL tree.

Exit Status picld does not return an exit status.

Files /var/run/picld_door   PICL daemon door

/usr/lib/picl/picld   PICL daemon

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/picl

See Also svcs(1), svcadm(1M), dlopen(3C), libpicl(3PICL), libpicltree(3PICLTREE), picld_log(3PICLTREE), picld_plugin_register(3PICLTREE), attributes(5), smf(5)

Notes The picld service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/picl

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name ping – send ICMP (ICMP6) ECHO_REQUEST packets to network hosts

Synopsis `/usr/sbin/ping` *host* [*timeout*]

`/usr/sbin/ping -s [-l | -U] [-abdlLnrRv] [-A` *addr_family*`]`
    `[-c` *traffic_class*`] [-g` *gateway* `[-g` *gateway*`...]]`
    `[-N` *next_hop_router*`] [-F` *flow_label*`] [-I` *interval*`]`
    `[-i` *interface*`] [-P` *tos*`] [-p` *port*`] [-t` *ttl*`]` *host*
    `[`*data_size*`] [`*npackets*`]`

Description The utility `ping` utilizes the ICMP (ICMP6 in IPv6) protocol's `ECHO_REQUEST` datagram to elicit an ICMP (ICMP6) `ECHO_RESPONSE` from the specified *host* or network *gateway*. If *host* responds, `ping` will display:

host `is alive`

...on the standard output and exit. Otherwise, after *timeout* seconds, it will write:

`no answer from` *host*

The default value of *timeout* is `20` seconds.

When you specify the `s` flag, sends one datagram per second (adjust with `-I`) and prints one line of output for every `ECHO_RESPONSE` that it receives. `ping` produces no output if there is no response. In this second form, `ping` computes round trip times and packet loss statistics; it displays a summary of this information upon termination or timeout. The default *data_size* is 56 bytes, or you can specify a size with the *data_size* command-line argument. If you specify the optional *npackets*, `ping` sends ping requests until it either sends *npackets* requests or receives *npackets* replies.

When using `ping` for fault isolation, first `ping` the local host to verify that the local network interface is running.

Options The following options are supported:

`-A` *addr_family*
    Specify the address family of the target host. *addr_family* can be either `inet` or `inet6`. Address family determines which protocol to use. For an argument of `inet`, IPv4 is used. For `inet6`, IPv6 is used.

    By default, if the name of a host is provided, not the literal IP address, and a valid IPv6 address exists in the name service database, `ping` will use this address. Otherwise, if the name service database contains an IPv4 address, it will try the IPv4 address.

    Specify the address family `inet` or `inet6` to override the default behavior. If the argument specified is `inet`, `ping` will use the IPv4 address associated with the host name. If none exists, `ping` will state that the host is unknown and exit. It does not try to determine if an IPv6 address exists in the name service database.

    If the specified argument is `inet6`, `ping` uses the IPv6 address that is associated with the host name. If none exists, `ping` states that the host is unknown and exits.

-F *flow_label*

Specify the flow label of probe packets. The value must be an integer in the range from 0 to 1048575. This option is valid only on IPv6.

-D

Turn off fragmentation. For IPv4, this means setting the Don't Fragment bit. For IPv4 and IPv6, this means do not allow fragmentation as the datagrams are sent. If the *data_size* exceeds the MTU, then ping might report that sending failed due to Message too long.

-I *interval*

Turn on the statistics mode and specify the interval between successive transmissions. The default is one second. See the discussion of the -s option.

-L

Turn off loopback of multicast packets. Normally, members are in the host group on the outgoing interface, a copy of the multicast packets will be delivered to the local machine.

-N *next_hop_router*

Specify a next-hop router so that the probe packet goes through the specified router along its path to the target host. This option essentially bypasses the system routing table and leaves the probe packet header unmodified. Only one next-hop router can be specified.

-P *tos*

Set the type of service (*tos*) in probe packets to the specified value. The default is zero. The value must be an integer in the range from 0 to 255. Gateways also in the path can route the probe packet differently, depending upon the value of *tos* that is set in the probe packet. This option is valid only on IPv4.

-R

Record route. Sets the IPv4 record route option, which stores the route of the packet inside the IPv4 header. The contents of the record route are only printed if the -v and -s options are given. They are only set on return packets if the target host preserves the record route option across echos, or the -l option is given. This option is valid only on IPv4.

-U

Send UDP packets instead of ICMP (ICMP6) packets. ping sends UDP packets to consecutive ports expecting to receive back ICMP (ICMP6) PORT_UNREACHABLE from the target host.

-a

ping all addresses, both IPv4 and IPv6, of the multihomed destination. The output appears as if ping has been run once for each IP address of the destination. If this option is used together with -A, ping probes only the addresses that are of the specified address family. When used with the -s option and *npackets* is not specified, ping continuously probes the destination addresses in a round robin fashion. If *npackets* is specified, ping sends *npackets* number of probes to each IP address of the destination and then exits.

-b

Bypass the global IPsec policy and send and receive packets in the clear for this connection only. This option can be used to troubleshoot network connectivity independent of IPsec. Because this option bypasses system-wide policy for this connection, it can only be used by superuser or a user granted the sys_net_config privilege.

-c *traffic_class*

Specify the traffic class of probe packets. The value must be an integer in the range from 0 to 255. Gateways along the path can route the probe packet differently, depending upon the value of *traffic_class* set in the probe packet. This option is valid only on IPv6.

-d

Set the SO_DEBUG socket option.

-g *gateway*

Specify a loose source route gateway so that the probe packet goes through the specified host along the path to the target host. The maximum number of gateways is 8 for IPv4 and 127 for IPv6. Note that some factors such as the link MTU can further limit the number of gateways for IPv6.

-i *interface_address*

Specify the outgoing interface address to use for multicast packets for IPv4 and both multicast and unicast packets for IPv6. The default interface address for multicast packets is determined from the (unicast) routing tables. *interface_address* can be a literal IP address, for example, 10.123.100.99, or an interface name, for example, eri0, or an interface index, for example 2.

-l

Use to send the probe packet to the given host and back again using loose source routing. Usually specified with the -R option. If any gateways are specified using -g, they are visited twice, both to and from the destination. This option is ignored if the -U option is used.

-n

Show network addresses as numbers. ping normally does a reverse name lookup on the IP addresses it extracts from the packets received. The -n option blocks the reverse lookup, so ping prints IP addresses instead of host names.

-p *port*

Set the base UDP *port* number used in probes. This option is used with the -U option. The default base *port* number is 33434. The ping utility starts setting the destination port number of UDP packets to this base and increments it by one at each probe.

-r

Bypass the normal routing tables and send directly to a host on an attached network. If the host is not on a directly attached network, an error is returned. This option can be used to ping a local host through an interface that has been dropped by the router daemon. See in.routed(1M).

-s

Send one datagram per second and collect statistics.

-t *ttl*

Specify the IPv4 time to live, or IPv6 hop limit, for unicast and multicast packets. The default time to live (hop limit) for unicast packets can be set with the ipadm(1M) set-prop subcommand, using the icmp_ipv4_ttl property for IPv4 and the icmp_ipv6_hoplimit property for IPv6. The default time to live (hop limit) for multicast is one hop. See EXAMPLES. For further information, see ipadm(1M).

Note – You might observe property names that begin with "_" (underbar). These properties are private to a protocol and are subject to change or removal. See ipadm(1M).

-v

Verbose output. List any ICMP (ICMP6) packets, other than replies from the target host.

Operands *host*

The network host

Examples EXAMPLE 1 Using ping With IPv6

This example shows ping sending probe packets to all the IPv6 addresses of the host xyz, one at a time. It sends an ICMP6 ECHO_REQUEST every second until the user interrupts it.

```
istanbul% ping -s -A inet6 -a xyz
PING xyz: 56 data bytes
64 bytes from xyz (4::114:a00:20ff:ab3d:83ed): icmp_seq=0. time=0.479 ms
64 bytes from xyz (fec0::114:a00:20ff:ab3d:83ed): icmp_seq=1. time=0.843 ms
64 bytes from xyz (4::114:a00:20ff:ab3d:83ed): icmp_seq=2. time=0.516 ms
64 bytes from xyz (fec0::114:a00:20ff:ab3d:83ed): icmp_seq=3. time=4.943 ms
64 bytes from xyz (4::114:a00:20ff:ab3d:83ed): icmp_seq=4. time=0.485 ms
64 bytes from xyz (fec0::114:a00:20ff:ab3d:83ed): icmp_seq=5. time=2.201 ms
^C
----xyz PING Statistics----
6 packets transmitted, 6 packets received, 0% packet loss
round-trip (ms)  min/avg/stddev = 0.479/1.583/4.943/1.823
```

EXAMPLE 2 Using ipadm to Set Hop Limits

The following commands use ipadm(1M) to set IPv4 and IPv6 hop limits.

```
# ipadm set-prop -p _ipv6_hoplimit=100 icmp
# ipadm set-prop -p _ipv4_ttl=100 icmp
```

Exit Status The following exit values are returned:

0

Successful operation; the machine is alive.

non-zero
> An error has occurred. Either a malformed argument has been specified, or the machine was not alive.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	network/ping

Name pkg2du – convert driver packages to Driver Update format

Synopsis /usr/bin/pkg2du [-f] [-v] [-d *dir*] [-o *iso*] [-l *label*]
[-r *release*] *pkg* [*pkg* ...]

Description The /usr/bin/pkg2du utility takes one or more packages as input and converts them to Driver Update (DU) format. If the -d option is specified, the resulting DU directory tree is placed in the directory *dir*. If the -o option is specified, a Solaris ISO image of the DU directory tree is written in the file *iso*. The ISO image can be burned onto CD/DVD using cdrw(1) or cdrecord(1) (not a SunOS man page) and used during Solaris installation.

At least one of the -d and -o options must be specified. If both are specified, then both an ISO image and a directory tree are generated.

Options The following options are supported:

-d *dir*
Directory where the DU directory should be created.

-o *iso*
Create a Solaris ISO image of the DU directory.

-f
If *dir*/DU or *iso* exists, remove it without asking first.

-l *label*
Label/volume name of the ISO image (if -o option is specified).

-r *release*
Solaris release number to use. It takes the form of the return from uname -r command, for example, 5.10. If unspecified, the release number of the currently running Solaris is used.

-v
Verbose. Multiple -v options increase verbosity.

Operands The following operands are supported:

pkg [*pkg*...]
One or more packages to be converted to DU format.

Examples EXAMPLE 1 Creating a DU CD/DVD

The following commands create a DU CD or DVD containing packages SUNWfoo and SUNWbar.

```
# /usr/bin/pkg2du -r 5.10 -o my.iso SUNWfoo SUNWbar
# /usr/bin/cdrw -i my.iso
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

mkisofs(8) (not a SunOS man page)

Name pkgadd – transfer software packages to the system

Synopsis pkgadd [-nv] [-a *admin*] [-G] [-x *proxy*]
       [[-M] -R *root_path*] [-r *response*] [-k *keystore*]
       [-P *passwd*] [-V *fs_file*]
       [-d *device* | -d *datastream pkginst* | all]
       [*pkginst* | -Y *category* [, *category*]...]

pkgadd -s [-d *device* | -d *datastream pkginst* | all]
       [*pkginst* | -Y *category* [, *category*]...]

Description pkgadd transfers the contents of a software package from the distribution medium or
directory to install it onto the system. Used without the -d *device* source specifier, pkgadd
looks in the default spool directory (/var/spool/pkg) for the package. Used with the -s
option, it writes the package to a spool directory instead of installing it.

The pkgadd utility requires an amount of temporary space the size of the package that is being
installed. pkgadd determines which temporary directory to use by checking for the existance
of the $TMPDIR environment variable. If $TMPDIR is not defined, pkgadd uses P_tmpdir from
stdio.h. P_tmpdir has a default of /var/tmp/.

Certain unbundled and third-party packages are no longer entirely compatible with the latest
version of pkgadd. These packages require user interaction throughout the installation and
not just at the very beginning, or require that their request scripts be run as the root user.

To install these older packages (released prior to Solaris 2.4), set the following environment
variable: NONABI_SCRIPTS=TRUE

As long as this environment variable is set, pkgadd permits keyboard interaction throughout
the installation and package request scripts are run as root.

If you have package request scripts that require running as user root (instead of noaccess [the
default] or user install), use the rscript_alt parameter in the admin(4) file to make an
appropriate selection. See admin(4).

Note that, in Solaris 8 and Solaris 9, the default user when running a request script was either
root or nobody, depending on the operating system's patch level. In the current release, the
default user is noaccess.

When running pkgadd in the global zone (see zones(5)), a package that contains a request
script (see pkgask(1M)) is added only to the global zone. The package is not propagated to any
current or yet-to-be-installed non-global zone. This behavior mimics the effect of the -G
option, described below.

Package commands are largefile(5)-aware. They handle files larger than 2 GB in the same
way they handle smaller files. In their current implementations, pkgadd, pkgtrans(1) and
other package commands can process a datastream of up to 4 GB.

The -d, -Y, and *pkginst* arguments shown in the SYNOPSIS are described under OPERANDS,
following OPTIONS.

Options   The supported options are described as follows. The -d *device* source specifier is described
under OPERANDS, below.

-a *admin*

Define an installation administration file, *admin*, to be used in place of the default
administration file. The token none overrides the use of any *admin* file, and thus forces
interaction with the user. Unless a full path name is given, pkgadd first looks in the current
working directory for the administration file. If the specified administration file is not in
the current working directory, pkgadd looks in the /var/sadm/install/admin directory
for the administration file.

-G

Add package(s) in the current zone only. When used in the global zone, the package is
added to the global zone only and is not propagated to any existing or yet-to-be-created
non-global zone. When used in a non-global zone, the package(s) are added to the
non-global zone only.

This option causes package installation to fail if, in the pkginfo file for a package,
SUNW_PKG_ALLZONES is set to true. See pkginfo(4).

-k *keystore*

Use *keystore* as the location from which to get trusted certificate authority certificates when
verifying digital signatures found in packages. If no keystore is specified, then the default
keystore locations are searched for valid trusted certificates. See KEYSTORE LOCATIONS for
more information.

-M

Instruct pkgadd not to use the $*root_path*/etc/vfstab file for determining the client's
mount points. This option assumes the mount points are correct on the server and it
behaves consistently with Solaris 2.5 and earlier releases.

-n

Installation occurs in non-interactive mode. Suppress output of the list of installed files.
The default mode is interactive.

-P *passwd*

Password to use to decrypt keystore specified with -k, if required. See PASS PHRASE
ARGUMENTS for more information about the format of this option's argument.

-r *response*

Identify a file or directory which contains output from a previous pkgask(1M) session. This
file supplies the interaction responses that would be requested by the package in interactive
mode. *response* must be a full pathname.

-R *root_path*

Define the full path name of a directory to use as the *root_path*. All files, including package
system information files, are relocated to a directory tree starting in the specified *root_path*.
The *root_path* may be specified when installing to a client from a server (for example,
/export/root/client1).

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-s *spool*

Write the package into the directory *spool* instead of installing it.

-v

Trace all of the scripts that get executed by pkgadd, located in the *pkginst*/install directory. This option is used for debugging the procedural and non-procedural scripts.

-V *fs_file*

Specify an alternative *fs_file* to map the client's file systems. For example, used in situations where the $*root_path*/etc/vfstab file is non-existent or unreliable.

-x *proxy*

Specify a HTTP[S] proxy to use when downloading packages The format of proxy is *host*:*port*, where *host* is the hostname of the HTTP[S] proxy, and *port* is the port number associated with the proxy. This switch overrides all other methods of specifying a proxy. See ENVIRONMENT VARIABLES for more information on alternate methods of specifying a default proxy.

When executed without options or operands, pkgadd uses /var/spool/pkg (the default spool directory).

Operands The following operands are supported:

Sources By default, pkgadd looks in the /var/spool/pkg directory when searching for instances of a package to install or spool. Optionally, the source for the package instances to be installed or spooled can be specified using:

-d *device*
-d *datastream pkgname*,... | all

Install or copy a package from *device*. *device* can be any of the following:

- A full path name to a directory or the identifiers for tape or removable medium (for example, /var/tmp).

- A datastream created by pkgtrans (see pkgtrans(1)).

- A URL pointing to a datastream created by pkgtrans. The supported Universal Resource Identifiers (URIs) are http: and https:.

The second form of the -d specifier, above, indicates the syntax you use when specifying a datastream. In this case you must specify either a comma-separated list of package names or the keyword all.

Instances By default, pkgadd searches the specified source, and presents an interactive menu allowing the user to select which package instances found on the source are to be installed. As an alternative, the package instances to be installed can be specified using:

pkginst
　　The package instance or list of instances to be installed. The token all may be used to refer to all packages available on the source medium. The format *pkginst*.* can be used to indicate all instances of a package.

　　The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, the asterisk must be surrounded by single quotes (') or preceded by a backslash (\).

-Y *category*[,*category*...]
　　Install packages based on the value of the CATEGORY parameter stored in the package's pkginfo(4) file. All packages on the source medium whose CATEGORY matches one of the specified categories will be selected for installation or spooling.

Keystore Locations Package such as pkgadd use a set of trusted certificates to perform signature validation on any signatures found within the packages. If there are no signatures included in the packages then signature validation is skipped. The certificates can come from a variety of locations. If -k *keystore* is specified, and *keystore* is a directory, then *keystore* is assumed to be the base directory of the certificates to be used. If *keystore* is a file, then the file itself is assumed to have all required keys and certificates. When -k is not specified, then /var/sadm/security is used as the base directory.

Within the specified base directory, the store locations to be searched are different based on the application doing the searching and the type of store being searched for. The following directories are searched in the specified order:

1. *<store_dir>*/*<app_name>*/*<store_type>*
2. *<store_dir>*/*<store_type>*

Where *<store_dir>* is the directory specified by -k, *<app_name>* is the name of the application doing the searching, and *<store_type>* is one of keystore (for private keys), certstore (for untrusted public key certificates), or truststore (for trusted certificate authority certificates).

For example, when pkgadd is run with -k /export/certs, then the following locations are successively searched to find the trust store:

1. /export/certs/pkgadd/truststore
2. /export/certs/truststore

This searching order enables administrators to have a single location for most applications, and special certificate locations for certain applications.

Keystore And Certificate Formats The packaging utilities, such as pkgtrans, require access to a set of keys and certificates in order to sign, and optionally verify, packages.

The keystore files found by following the search pattern specified in KEYSTORE LOCATIONS must each be a self-contained PKCS#12-format file.

When signing a package with pkgtrans, if a certstore has more than one public key certificate, then each public key must have a friendlyName attribute in order to be identifiable and selectable with the -a option when signing packages. In addition, the public key certificate selected with -a and found in the certstore must have an associated private key in the keystore.

Several browsers and utilities can be used to export and import certificates and keys into a PKCS#12 keystore. For example, a trusted certificate can be exported from Mozilla, and then imported into a PKCS#12 keystore for use with pkgadd with the OpenSSL Toolkit.

Pass Phrase Arguments pkgtrans and pkgadd accept password arguments, typically using -p to specify the password. These allow the password to be obtained from a variety of sources. Both of these options take a single argument whose format is described below. If no password argument is given and a password is required then the user is prompted to enter one: this will typically be read from the current terminal with echoing turned off.

pass:*password*
> The actual password is *password*. Because the password is visible to utilities such as ps this form should only be used where security is not important.

env:*var*
> Obtain the password from the environment variable *var*. Because the environment of other processes is visible on certain platforms this option should be used with caution.

file:*pathname*
> The first line contained within *pathname* is the password. *pathname* need not refer to a regular file: it could, for example, refer to a device or named pipe. For example, to read the password from standard input, use file:/dev/stdin.

console
> Read the password from /dev/tty.

Examples EXAMPLE 1 Installing a Package from a Solaris DVD

The following example installs a package from a Solaris DVD. You are prompted for the name of the package you want to install.

example# **pkgadd -d /cdrom/cdrom0/s0/Solaris_10/Product**

EXAMPLE 2 Installing a Set of Packages from a Datastream

The example command shown below installs all of the packages in the datastream specified by the -d source specifier. Prior to this command, this datastream must have been created with the pkgtrans(1) command.

EXAMPLE 2 Installing a Set of Packages from a Datastream   *(Continued)*

example# **pkgadd -d /var/tmp/datastream all**

The keyword all specifies that all of the packages found in the designated datastream will be installed.

Exit Status   0

Successful completion

1

Fatal error.

2

Warning.

3

Interruption.

4

Administration.

5

Administration. Interaction is required. Do not use pkgadd -n.

10

Reboot after installation of all packages.

20

Reboot after installation of this package.

Environment Variables   HTTPPROXY

Specifies an HTTP proxy host. Overrides administration file setting, and http_proxy environment variable.

HTTPPROXYPORT

Specifies the port to use when contacting the host specified by HTTPPROXY. Ignored if HTTPPROXY is not set.

http_proxy

URL format for specifying proxy host and port. Overrides administration file setting.

Files   /var/sadm/install/logs/

Location where pkgadd logs an instance of software installation.

Application Packaging Developer's Guide

http://www.openssl.org

Notes When transferring a package to a spool directory, the -r, -n, and -a options cannot be used.

The -r option can be used to indicate a directory name as well as a filename. The directory can contain numerous response files, each sharing the name of the package with which it should be associated. This would be used, for example, when adding multiple interactive packages with one invocation of pkgadd. In this situation, each package would need a response file. If you create response files with the same name as the package (for example, pkinst1 and pkinst2), then name the directory in which these files reside after the -r.

The -n option causes the installation to halt if any interaction is needed to complete it.

If the default *admin* file is too restrictive, the administration file may need to be modified to allow for total non-interaction during a package installation. See admin(4) for details.

If a package stream is specified with -d, and a digital signature is found in that stream, the default behavior is to attempt to validate the certificate and signature found. This behavior can be overridden with admin file settings. See admin(4) for more information.

Name pkgadm – manage packaging and patching system

Synopsis pkgadm addcert [-ty] [-a *app*] [-k *keystore*] [-e *keyfile*]
          [-f *format*] [-n *name*] [-P *passarg*]
          [-p *import_passarg*] [-R *rootpath*] certfile

pkgadm removecert [-a *app*] [-k *keystore*] -n *name*
          [-P *passarg*] [-R *rootpath*]

pkgadm listcert [-a *app*] [-f *format*] [-k *keystore*] -n *name*
          [-P *passarg*] [-o *outfile*] [-R *rootpath*]

pkgadm dbstatus [-R *rootpath*]

pkgadm sync [-R *rootpath*] [-q]

pkgadm -V

pkgadm -?

Description The pkgadm utility is used for managing the packaging and patching system. It has several
subcommands that perform various operations relating to packaging. The pkgadm command
includes subcommands for managing certificates and keys used.

Managing Keys and Certificates pkgadm maintains the packaging-system-wide keystore in /var/sadm/security, and
individual user's certificates in ~/.pkg/security. The following subcommands operate on
the package keystore database:

addcert
    Add (import) a certificate into the database, with optional trust. Once added, trusted
    certificates can be used to verify signed packages and patches. Non-trusted user certificates
    and their associated keys can be used to sign packages and patches. Added user certificates
    are *not* used to build certificate chains during certificate verification.

removecert
    Removes a user certificate/private key pair, or a trusted certificate authority certificate from
    the keystore. Once removed, the certificate and keys cannot be used.

listcert
    Print details of one or more certificates in the keystore.

sync
    Writes the contents file and rolls the contents log file. With use of the -q option, forces the
    contents file server to quit.

Internal Install Database The Solaris operating system relies upon enhanced System V revision 4 (SVr4) packages as the
basis for its software installation and revision management. The package maintenance
software stores information about installed packages in an internal database. The pkgadm
subcomand dbstatus is used to determine how the package internal database is implemented.
The dbstatus command returns a string that indicates the type of internal database in use. In

the current implementation, the dbstatus command always returns the string text, which indicates that the contents(4) package database is inuse. Future releases of Solaris might supply alternative database implementations.

Options   The following options are supported:

-a *app*
> If this option is used, then the command only affects the keystore associated with a particular application. Otherwise, the global keystore is affected.

-e *keyfile*
> When adding a non-trusted certificate/key combination, this option can be used to specify the file that contains the private key. If this option is not used, the private key must be in the same file as the certificate being added.

-f *format*
> When adding certificates, this specifies the format to expect certificates and private keys in. Possible values when adding are:

> pem
>> Certificate and any private key uses PEM encoding.

> der
>> Certificate and any private key uses DER encoding.

> When printing certificates, this specifies the output format used when printing. Acceptable values for format are:

> pem
>> Output each certificate using PEM encoding.

> der
>> Output each certificate using DER encoding.

> text
>> Output each certificate in human-readable format.

-k *keystore*
> Overrides the default location used when accessing the keystore.

-n *name*
> Identifies the entity in the store on which you want to operate. When adding a user certificate, or removing certificates, this name is required. The name is associated with the certificate/key combination, and when adding, can be used later to reference the entity. When printing certificates, if no alias is supplied, then all keystore entities are printed.

-o *outfile*
> Output the result of the command to *outfile*. Only used when examining (printing) certificates from the key store. Standard out is the default.

-P *passarg*

Password retrieval method to use to decrypt keystore specified with -k, if required. See PASS PHRASE ARGUMENTS in pkgadd(1M) for more information about the format of this option's argument. console is the default.

-p *import_passarg*

This option's argument is identical to -P, but is used for supplying the password used to decrypt the certificate and/or private key being added. console is the default.

-q

(Applies to sync subcommand.) Shuts down the contents file cache daemon.

-R *rootpath*

Defines the full name of a directory to use as the root (/) path. The default user location of the certificate operations is ${HOME}/.pkg. If the -R option is supplied, the certificates and keys will be stored under <*altroot*>/var/sadm/security. Note that this operation fails if the user does not have sufficient permissions to access this directory. The listcert command requires read permission, while addcert and removecert require both read and write permission.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-t

Indicates the certificate being added is a trusted CA certificate. The details of the certificate (including the Subject Name, Validity Dates, and Fingerprints) are printed and the user is asked to verify the data. This verification step can be skipped with -y. When importing a trusted certificate, a private key should not be supplied, and will be rejected if supplied. Once a certificate is trusted, it can be used as a trust anchor when verifying future untrusted certificates.

-V

Print version associated with packaging tools.

-y

When adding a trusted certificate, the details of the certificate (Subject name, Issuer name, Validity dates, Fingerprints) are shown to the user and the user is asked to verify the correctness before proceeding. With -y, this additional verification step is skipped.

-?

Print help message.

Operands   The following operand is supported:

certfile

File containing the certificate and optional private key, used when adding a trust anchor or certificate/key combination. Certificates must be encoded using PEM or binary DER.

Keystore Aliases All keystore entries (user cert/key and trusted certificate entries) are accessed via unique aliases. Aliases are case-sensitive.

An alias is specified when you add an entity to a keystore using the addcert or trustcert subcommand. If an alias is not supplied for a trust anchor, the trust anchor's Common Name is used as the alias. An alias is required when adding a signing certificate or chain certificate. Subsequent pkgcert or other package tool commands must use this same alias to refer to the entity.

Keystore Passwords See the pkgadd(1M) man page for a description of the passwords supplied to the pkgadm utility.

Examples EXAMPLE 1 Adding a Trust Anchor

The following example adds a well-known and trusted certificate to be used when verifying signatures on packages.

```
example% pkgadm addcert -t /tmp/certfile.pem
```

EXAMPLE 2 Adding a Signing Certificate

The following example adds a signing certificate and associated private key, each of which is in a separate file, which can then be used to sign packages.

```
example% pkgadm addcert -a pkgtrans -e /tmp/keyfile.pem \
/tmp/certfile.pem
```

EXAMPLE 3 Printing Certificates

The following example prints all certificates in the root keystore.

```
example% pkgadm listcert
```

Exit Status 0

successful completion

non-zero
fatal error

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	package/svr4
Interface Stability	Committed

See Also pkginfo(1), pkgmk(1), pkgparam(1), pkgproto(1), pkgtrans(1), svcs(1), installf(1M), pkgadd(1M), pkgask(1M), pkgrm(1M), removef(1M), svcadm(1M), admin(4), contents(4), exec_attr(4), pkginfo(4), attributes(5), rbac(5), smf(5)

Application Packaging Developer's Guide

Notes   The service for `pkgadm` is managed by the service management facility, smf(5), under the service identifier:

```
svc:/system/pkgserv
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name pkgask – stores answers to a request script

Synopsis pkgask [-d *device*] [-R *root_path*] -r *response pkginst*...

Description pkgask allows the administrator to store answers to an interactive package (one with a request script, that is, a user-created file that must be named request). Invoking this command generates a response file that is then used as input at installation time. The use of this response file prevents any interaction from occurring during installation since the file already contains all of the information the package needs.

Options The following options are supported

-d *device* Run the request script for a package on *device*. *device* can be a directory pathname or the identifiers for tape or removable medium (for example, /var/tmp and /dev/dsk/c1d0s0). The default device is the installation spool directory.

-R *root_path* Define the full path name of a directory to use as the *root_path*. All files, including package system information files, are relocated to a directory tree starting in the specified *root_path*.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-r *response* Identify a file or directory which should be created to contain the responses to interaction with the package. The name must be a full pathname. The file, or directory of files, can later be used as input to the pkgadd(1M) command.

Operands The following operands are supported:

pkginst Specify the package instance, or list of instances for which request scripts will be created. The token all may be used to refer to all packages available on the source medium.

Exit Status 0 Successful completion.

>0 An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also pkginfo(1), pkgmk(1), pkgparam(1), pkgproto(1), pkgtrans(1), installf(1M), pkgadd(1M), pkgchk(1M), pkgrm(1M), removef(1M), admin(4), attributes(5)

Application Packaging Developer's Guide

Notes   The -r option can be used to indicate a directory name as well as a filename. The directory name is used to create numerous response files, each sharing the name of the package with which it should be associated. This would be used, for example, when you will be adding multiple interactive packages with one invocation of pkgadd(1M). Each package would need a response file. To create multiple response files with the same name as the package instance, name the directory in which the files should be created and supply multiple instance names with the pkgask command. When installing the packages, you will be able to identify this directory to the pkgadd(1M) command.

If the default admin file is too restrictive, the administration file may need to be modified to allow for total non-interaction during a package installation. See admin(4) for details.

Name   pkgchk – check package installation accuracy

Synopsis   pkgchk [-l | -acfnqvx] [-i *file* | -]
        [-p *path*... | -P *partial-path*...] [-R *root_path*]
        [[-m *pkgmap* [-e *envfile*]] | pkginst... | -Y *category,category*...]

   pkgchk -d *device* [-l | -fv] [-i *file* | -] [-M] [-p *path*]...
        [-V *fs_file*]
        [pkginst... | -Y *category*[,*category*...]]

Description   pkgchk checks the accuracy of installed files or, by using the -l option, displays information
about package files. pkgchk checks the integrity of directory structures and files. Discrepancies
are written to standard error along with a detailed explanation of the problem.

   The first synopsis defined above is used to list or check the contents and/or attributes of
objects that are currently installed on the system, or in the indicated pkgmap. Package names
may be listed on the command line, or by default, the entire contents of a machine will be
checked.

   The second synopsis is used to list or check the contents of a package which has been spooled
on the specified device, but not installed. Note that attributes cannot be checked for spooled
packages.

Options   The following options are supported:

-a

   Audit the file attributes only and do not check file contents. Default is to check both.

-c

   Audit the file contents only and do not check file attributes. Default is to check both.

-d *device*

   Specify the device on which a spooled package resides. *device* can be a directory path name
   or the identifiers for tape or removable medium (for example, /var/tmp.

-e *envfile*

   Request that the package information file named as *envfile* be used to resolve parameters
   noted in the specified pkgmap file.

-f

   Correct file attributes if possible. If used with the -x option, this option removes hidden
   files. When pkgchk is invoked with this option, it creates directories, named pipes, links,
   and special devices if they do not already exist. If the -d option calls out an uninstalled
   package, the -f option will only take effect if the package is in directory (not stream)
   format. All file attributes will be set to agree with the entries in the pkgmap file except that
   setuid, setgid, and sticky bits will not be set in the mode.

-i *file* | –

Read a list of path names from *file* or from stdin (–) and compare this list against the installation software database or the indicated pkgmap file. Path names that are not contained in *file* or stdin are not checked.

-l

List information on the selected files that make up a package. This option is not compatible with the -a, -c, -f, -g, and -v options.

-m pkgmap

Check the package against the package map file, pkgmap.

-M

Instruct pkgchk not to use the $*root_path*/etc/vfstab file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.

-n

Do not check volatile or editable files' contents. This should be used for most post-installation checking.

-p *path*

Check the accuracy only of the path name or path names listed. *path* can be one or more path names separated by commas (or by whitespace, if the list is quoted).

To specify a *path* that includes a comma, you must use the -i option, described above. See EXAMPLES.

-P *partial-path*

Check the accuracy of only the partial path name or path names listed. *partial-path* can be one or more partial path names separated by commas (or by whitespace, if the list is quoted). This option can be used instead of -p and is not compatible with the other option. This option matches any path name that contains the string contained in the partial path. See the note about paths that contain commas in the description of -p.

-q

Quiet mode. Do not give messages about missing files.

-R *root_path*

Define the full name of a directory to use as the *root_path*. All files, including package system information files, are relocated to a directory tree starting in the specified *root_path*. The *root_path* may be specified when installing to a client from a server (for example, /export/root/client1).

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-v

Verbose mode. Files are listed as processed.

-V *fs_file*

Specify an alternative *fs_file* to map the client's file systems. For example, used in situations where the $*root_path*/etc/vfstab file is non-existent or unreliable.

-x

Search exclusive directories, looking for files which exist that are not in the installation software database or the indicated pkgmap file.

-Y *category*

Check packages based on the value of the CATEGORY parameter stored in the installed or spooled package's pkginfo(4) file.

Operands   *pkginst*

The package instance or instances to be checked. The format *pkginst.** can be used to check all instances of a package. The default is to display all information about all installed packages.

The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, an asterisk must be surrounded by single quotes (') or preceded by a backslash (\);

partial-path

A portion of a path, such as a file or directory name.

Examples   EXAMPLE 1   Using pkgchk for Displaying Package Installation Information

The following example displays package installation information for /usr/bin/ls:

example% **pkgchk -l -p /usr/bin/ls**

EXAMPLE 2   Checking on Java Font Properties

The following example displays package installation information for all Java font properties installed on the system.

example% **pkgchk -l -P font.properties**

EXAMPLE 3   Specifying a Path That Contains a Comma

Assume you want to specify the path:

/platform/SUNW,Netra-T12/lib

List this path in a file. Here is one way in which you can do that:

example% **echo "/platform/SUNW,Netra-T12/lib" > /tmp/p**

You can then enter:

EXAMPLE 3 Specifying a Path That Contains a Comma   *(Continued)*

```
example% pkgchk -i /tmp/p -l
Pathname: /platform/SUNW,Netra-T12/lib
Type: directory
Expected mode: 0755
Expected owner: root
Expected group: bin
Referenced by the following packages:
        system/core-osar
Current status: installed
```

Exit Status   0

Successful completion.

>0

An error occurred.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   pkginfo(1), pkgtrans(1), pkgadd(1M), pkgask(1M), pkgrm(1M), pkginfo(4), attributes(5), largefile(5)

Application Packaging Developer's Guide

Notes   Package commands are largefile(5)-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, pkgadd(1M), pkgtrans(1) and other package commands can process a datastream of up to 4 GB.

Name pkgcond – determine type and capability of target

Synopsis /usr/bin/pkgcond [-nv] *condition*

Description The pkgcond command allows you to determine the type of target being operated on (global zone, non-global zone, diskless client, and so forth) and the capabilities available for that type of client (can add a driver, path is writable, and so forth). The pkgcond command is intended to be invoked from package and patch scripts, but can also be used in situations that mimic the context of these scripts. See NOTES for further guidance.

pkgcond has one mandatory argument, a condition. The command tests whether the condition is true for the specified path. The condition can be one of the following:

- can_add_driver [*path*]
- can_remove_driver [*path*]
- can_update_driver [*path*]
- is_alternative_root [*path*]
- is_boot_environment [*path*]
- is_diskless_client [*path*]
- is_global_zone [*path*]
- is_mounted_miniroot [*path*]
- is_netinstall_image [*path*]
- is_nonglobal_zone [*path*]
- is_path_writable *path*
- is_running_system [*path*]
- is_sparse_root_nonglobal_zone [*path*]
- is_what [*path*]
- is_whole_root_nonglobal_zone [*path*]

The *path* argument usually denotes the root of the global zone or non-global zone, or alternate root. If path is optional and not specified, the default is /.

The behavior of the is_what condition is somewhat special, because it displays results of all other conditions to standard output.

Options The following options are supported:

-n

  Negate return status (0 becomes 1 and 1 becomes 0). It negates results in the case of is_what condition.

-v

  Verbose mode. Displays detailed data about intermediate checks performed.

Examples EXAMPLE 1 Listing All Available Information

The following command lists all available information about the current running system, in a user-friendly way.

example# **pkgcond -n is_what**

EXAMPLE 2 Determining if Target is an Alternate Root

The following command determines whether an alternate boot environment exists under
/altroot_mount.

example# **pkgcond is_alternative_root /altroot_mount**

Exit Status 0

Condition is true unless -n was specified.

1

Condition is false unless -n was specified.

2

Command line usage error.

3

Command failed to perform the test due to a fatal error.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Uncommitted

See Also pkgtrans(1), pkgadd(1M), pkgask(1M), pkgchk(1M), pkgrm(1M), pkginfo(4),
attributes(5)

Notes Supported usage of pkgcond is subject to the following constraints:

1. Do not use pkgcond outside of the Solaris marketing release in which it is provided (for
   example, do not use Solaris 10 pkgcond against a Solaris 9 target).

2. Restrict use of the optional path argument according to the following rules:

   ■ The command pkgcond *condition* $ROOTDIR can be used in patch level scripts.

   ■ The command pkgcond *condition* $PKG_INSTALL_ROOT can be used in package level
     scripts.

   ■ A command of the form pkgcond *condition without* the optional path argument can be
     used in any context.

Use of pkgcond with an arbitrary path argument is *not* recommended or supported, as the
results returned might not be accurate.

Name pkgrm – remove a package from the system

Synopsis pkgrm [-nv] [-a *admin*] [[-A | -M] -R *root_path*]
        [-V *fs_file*]
        [pkginst... | -Y *category*[,*category*...]]

    pkgrm -s *spool*
        [pkginst... | -Y *category*[,*category*...]]

Description pkgrm will remove a previously installed or partially installed package from the system. A check is made to determine if any other packages depend on the one being removed. If a dependency exists, the action taken is defined in the admin file.

The default state for the command is in interactive mode, meaning that prompt messages are given during processing to allow the administrator to confirm the actions being taken. Non-interactive mode can be requested with the -n option.

The -s option can be used to specify the directory from which spooled packages should be removed.

Certain unbundled and third-party packages are no longer entirely compatible with the latest version of pkgrm. These packages require user interaction throughout the removal and not just at the very beginning.

To remove these older packages (released prior to Solaris 2.4), set the following environment variable: NONABI_SCRIPTS=TRUE pkgrm permits keyboard interaction throughout the removal as long as this environment variable is set.

Options The following options are supported:

-a *admin*
    Use the installation administration file, admin, in place of the default admin file. pkgrm first looks in the current working directory for the administration file. If the specified administration file is not in the current working directory, pkgrm looks in the /var/sadm/install/admin directory for the administration file.

-A
    Remove the package files from the client's file system, absolutely. If a file is shared with other packages, the default behavior is to not remove the file from the client's file system.

-M
    Instruct pkgrm not to use the $*root_path*/etc/vfstab file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.

-n
    Non-interactive mode. If there is a need for interaction, the command will exit.

Use of this option requires that at least one package instance be named upon invocation of the command. Certain conditions must exist for a package to be removed non-interactively or a non-restrictive admin file needs to be used.

-R *root_path*

Defines the full path name of a directory to use as the *root_path*. All files, including package system information files, are relocated to a directory tree starting in the specified *root_path*.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-s *spool*

Remove the specified package(s) from the directory *spool*. The default directory for spooled packages is /var/sadm/pkg.

-v

Trace all of the scripts that get executed by pkgrm, located in the *pkginst*/install directory. This option is used for debugging the procedural and non-procedural scripts.

-V *fs_file*

Specify an alternative *fs_file* to map the client's file systems. Used in situations where the $*root_path*/etc/vfstab file is non-existent or unreliable.

-Y *category*

Remove packages based on the value of the CATEGORY parameter stored in the installed or spooled package's pkginfo(4) file. No package with the CATEGORY value of system can removed from the file system with this option.

Operands   The following operand is supported:

pkginst

Specifies the package to be removed. The format *pkginst*.* can be used to remove all instances of a package.

The asterisk character (*) is a special character to some shells and may need to be escaped. In the C-Shell, "*" must be surrounded by single quotes (') or preceded by a backslash (\).

Examples   **EXAMPLE 1**   Removing All Instances of SUNWjunk from client1

The following example removes all instances of SUNWjunk from client1:

example% pkgrm -R /export/root/client1 SUNWjunk*

Note the caveat on the use of the -R option in the description of that option, above.

Exit Status The following exit values are returned:

0

Successful completion.

1

Fatal error.

2

Warning.

3

Interruption.

4

Administration.

10

Reboot after removal of all packages.

20

Reboot after removal of this package.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also pkginfo(1), pkgmk(1), pkgparam(1), pkgproto(1), pkgtrans(1), installf(1M), pkgadd(1M), pkgask(1M), pkgchk(1M), removef(1M), admin(4), pkginfo(4), attributes(5), largefile(5)

Application Packaging Developer's Guide

Notes Package commands are largefile(5)-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, pkgadd(1M), pkgtrans(1) and other package commands can process a datastream of up to 4 GB.

Name plockstat – report user-level lock statistics

Synopsis plockstat [-vACHV] [-n *count*] [-s *depth*] [-e *secs*]
      [-x *arg* [=val]] *command* [*arg*]...

plockstat [-vACHV] [-n *count*] [-s *depth*] [-e *secs*]
      [-x *arg* [=val]] -p *pid*

Description The plockstat utility gathers and displays user-level locking statistics. By default, plockstat monitors all lock contention events, gathers frequency and timing data about those events, and displays the data in decreasing frequency order, so that the most common events appear first.

plockstat gathers data until the specified command completes or the process specified with the -p option completes.

plockstat relies on DTrace to instrument a running process or a command it invokes to trace events of interest. This imposes a small but measurable performance overhead on the processes being observed. Users must have the dtrace_proc privilege and have permission to observe a particular process with plockstat. Refer to the *Solaris Dynamic Tracing Guide* for more information about DTrace security features.

Options The following options are supported:

-A   Watch all lock events. This option is equivalent to -CH.

-C   Watch contention events.

-H   Watch hold events.

-e *secs*   Exit after the number of seconds specified have elapsed.

-n *count*   Display only the specified number of entries for each output category.

-s *depth*   Record a stack trace rather than just the calling function.

-p *pid*   Specify a process ID from which plockstat is to gather data.

-v   Print out a message to indicate that tracing has started.

-x *arg*[=*val*] Enable or modify a DTrace runtime option or D compiler option. The list of options is found in the *Solaris Dynamic Tracing Guide*. Boolean options are enabled by specifying their name. Options with values are set by separating the option name and value with an equals sign (=).

-V   Print the Dtrace commands used to gather the data. The output can then be used directly with the dtrace(1M) command.

Operands The following operands are supported:

arg   A string to be passed as an argument to *command*.

command   The name of a utility to be invoked.

count	A positive integer value.
pid	A process identifier for a process to be monitored.
secs	Duration specified as a positive integer number of seconds.

Display Headers The following headers appear over columns of data in plockstat output.

Count
> Number of times an event occurred.

nsec
> Average duration of an event, in nanoseconds.

Lock
> Address of a lock, displayed symbolically if possible.

Caller
> Address of a caller, displayed symbolically if possible.

Exit Status The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/dtrace
Interface Stability	See below.

The command-line syntax is Committed. The human-readable output is Uncommitted.

See Also dtrace(1M), lockstat(1M), mutex_init(3C), pthread_mutex_lock(3C), pthread_rwlock_rdlock(3C), pthread_rwlock_wrlock(3C), pthread_rwlock_unlock(3C), rwlock(3C), attributes(5), fasttrap(7D)

Solaris Dynamic Tracing Guide

Name pntadm – DHCP network table management utility

Synopsis pntadm -C [-r *resource*] [-p *path*] [-u *uninterpreted*] *network*

pntadm -A *name_IP_address* [-c *comment*] [-e *mm/dd/yyyy*]
    [-f *num* | *keywords*] [-h *client_hostname*]
    [-i [-a] *client_ID*] [-m [-y] *macro*] [-s *server*]
    [-r *resource*] [-p *path*] [-u *uninterpreted*] *network*

pntadm -M *name_IP_address* [-c *comment*] [-e *mm/dd/yyyy*]
    [-f *num* | *keywords*] [-h *client_hostname*]
    [-i [-a] *client ID*] [-m [-y] *macro*]
    [-n *new_client_IP_address*] [-s *server*] [-r *resource*]
    [-p *path*] [-u uninterpreted] *network*

pntadm -D *name_IP_address* [-y] [-r *resource*] [-p *path*]
    [-u uninterpreted] *network*

pntadm -P [-v] [-x] [-r *resource*] [-p *path*]
    [-u uninterpreted] *network*

pntadm -R [-r *resource*] [-p *path*] [-u uninterpreted] *network*

pntadm -L [-r *resource*] [-p *path*] [-u uninterpreted]

pntadm -B [-v] [*batchfile*]

Description The pntadm command is used to manage the Dynamic Host Configuration Protocol (DHCP)
network tables. It is used to add and remove networks under DHCP management, and add,
delete, or modify IP address records within network tables, or to view tables. For a description
of the format of DHCP network tables, see dhcp_network(4).

pntadm can be run as root or by other users assigned to the DHCP Management profile. See
rbac(5) and user_attr(4).

If the networks you want to add are subnetted, you need to update the netmasks(4) table.

One of the following options (function flags) must be specified with the pntadm command: -A,
-B, -C, -D, -L, -M, -P, or -R.

The pntadm utility is obsolete and is subject to removal in a future release of Oracle Solaris.

Options The following options are supported:

-A *name_IP_address*
  Add a client entry with hostname or client IP address, *name_IP_address*, to the named
  DHCP network table.

  The following sub-options are optional:

  -c *comment*
    Comment text. The default is NULL.

-e *mm/dd/yyyy*
Absolute lease. The default is `0`.

-f *num | keywords*
Flag value. The default is `00`.

The flag (-f) option can be specified either as a single number denoting the intended flag value, or as a series of the following keywords, combined using the plus (+) symbol:

DYNAMIC or `00`
Server manager's assignment.

PERMANENT or `01`
Lease on entry is permanent.

MANUAL or `02`
Administrator managed assignment.

UNUSABLE or `04`
Entry is not valid.

BOOTP or `08`
Entry reserved for BOOTP clients.

For a more detailed description of the flag values, see dhcp_network(4).

-h *client_hostname*
Client hostname. The default is NULL.

When the -h option is used in this mode, the *client_hostname* is added to the hosts table within the resource used for storing host names (files or DNS). The command will fail if this *client_hostname* is already present in the hosts table.

-i *client_ID* [-a]
Client identifier [-a]. The default is `00`.

The -i option modified with -a specifies that the client identifier is in ASCII format, and thus needs to be converted to hexadecimal format before insertion into the table.

-m *macro* [-y]
Macro name. Default is UNKNOWN.

The -m option modified with -y verifies the existence of the named macro in the dhcptab table before adding the entry.

-s *server*
Server IP or name. Default is system name (uname -n).

-B
Activate batch mode. pntadm will read from the specified file or from standard input a series of pntadm commands and execute them within the same process. Processing many

pntadm commands using this method is much faster than running an executable batchfile itself. Batch mode is recommended for using pntadm in scripts.

The following sub-option is optional:

-v

   Display commands to standard output as they are processed.

-C

Create the DHCP network table for the network specified by *network*. See Operands. For details, see dhcp_network(4) and networks(4).

-D *name_IP_address*

Delete the specified client entry with hostname or client IP address, *name_IP_address*, in the named DHCP network table. (See dhcp_network(4).)

The following sub-option is optional:

-y

   Remove associated host table entry. The -y option requests that all hostnames associated with the IP address in the hosts table in the resource be removed.

-L

List the DHCP network tables presently configured, one per line, on standard output. If none are found, no output is printed and an exit status of 0 is returned.

-M *name_IP_address*

Modify the specified client entry with hostname or client IP address, *name_IP_address*, in the named DHCP network table. See dhcp_network(4). The default for the sub-options is what they currently are set to.

The following sub-options are optional.

-c *comment*
   New comment text.

-e *mm/dd/yy*
   New absolute lease expiration date. Time defaults to 12:00 AM of the day specified.

-f *num* | *keyboard*
   New flag value, see explanation following the description of the -A option.

-h *host_name*
   New client hostname.

   The -h option allows you to change the current *hostname* associated with the IP address or to add a new *hostname* to the hosts table if an entry associated with this IP address does not exist.

-i *client_ID*
   New client identifier [-a].

-m *macro* [-y]
　　Macro name defined in dhcptab.

-n *new_client_IP_address*
　　New IP address.

-s *server*
　　New server IP or name.

For more detailed description of the sub-options and flag values, see dhcp_network(4).

-P

Display the named DHCP network table.

The following sub-options are optional:

-v

Display lease time in full verbose format and resolve IP addresses for the clients and server to hostnames.

-x

Display lease time in raw format.

These flag codes are used with the -P sub-options:

-v	-x	Description
D	00	DYNAMIC
P	01	PERMANENT
M	02	MANUAL
U	04	UNUSABLE
B	08	BOOTP

See dhcp_network(4) for information on these sub-options and associated flag codes.

-p *path*
　　Override the dhcpsvc.conf(4) configuration value for data store resource path, *path* See dhcpsvc.conf(4)

-R
　　Remove the named DHCP network table. See dhcp_network(4).

-r *data_store_resource*
　　Override the /etc/inet/dhcpsvc.conf configuration value for RESOURCE= with the *data_store_resource* specified. See the dhcpsvc.conf(4) man page for more details on resource type, and the *Oracle Solaris DHCP Service Developer's Guide* for more information about adding support for other data stores.

-u *uninterpreted*
Data which will be ignored by pntadm, but passed to the currently configured public module to be interpreted by the data store. This might be used for a database account name or other authentication or authorization parameters required by a particular data store.

Operands   The following operand is supported:

network
The network address or network name which corresponds to the dhcp network table. See dhcp_network(4).

Examples   **EXAMPLE 1**   Creating a Table for the 10.0.0.0 DHCP Network

The following command creates a table for the 10.0.0.0 (subnetted to class C) DHCP network table. Note that if you have an alias for this network in your networks(4) table, you can use that value rather than the dotted Internet Address notation.

example# **pntadm -C 10.0.0.0**

EXAMPLE 2   Adding an Entry to the 10.0.0.0 Table

The following command adds an entry to the 10.0.0.0 table in the files resource in the /var/mydhcp directory:

example# **pntadm -r SUNWfiles -p /var/mydhcp -A 10.0.0.1 10.0.0.0**

EXAMPLE 3   Modifying the 10.0.0.1 Entry of the 10.0.0.0 Table

The following command modifies the 10.0.0.1 entry of the 10.0.0.0 table, changing the macro name to Green, setting the flags field to MANUAL and PERMANENT:

example# **pntadm -M 10.0.0.1 -m Green -f 'PERMANENT+MANUAL' 10.0.0.0**

EXAMPLE 4   Changing the 10.0.0.1 Entry to 10.0.0.2

The following command changes the 10.0.0.1 entry to 10.0.0.2, making an entry in the hosts(4) table called myclient:

example# **pntadm -M 10.0.0.1 -n 10.0.0.2 -h myclient 10.0.0.0**

EXAMPLE 5   Setting the Client ID as ASCII

The following command sets the client ID as ASCII aruba.foo.com for the myclient entry:

example# **pntadm -M myclient -i 'aruba.foo.com' -a 10.0.0.0**

EXAMPLE 6   Deleting the myclient Entry from the 10.0.0.0 Table

The following command deletes the myclient (10.0.0.2) entry from the 10.0.0.0 table:

example# **pntadm -D myclient 10.0.0.0**

EXAMPLE 7   Listing the Configured DHCP Network Tables

The following command lists the configured DHCP network tables:

```
example# pntadm -L
192.168.0.0
10.0.0.0
```

EXAMPLE 8   Executing pntadm Commands in Batch Mode

The following command runs a series of pntadm commands contained in a batch file:

```
example# pntadm -B addclients
```

Exit Status   0

Successful completion.

1

Object already exists.

2

Object does not exist.

3

Non-critical error.

4

Critical error.

Files   ■   /etc/inet/dhcpsvc.conf
   ■   /etc/inet/hosts

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/dhcp
Interface Stability	Obsolete

Name   polkit-is-privileged – check PolicyKit privileges

Synopsis   `polkit-is-privileged [-hvV] -u user -p privilege [-r resource]`

Description   The `polkit-is-privileged` command queries system policy to determine whether a user is allowed for a given privilege and resource. The resource name can be omitted. On the Solaris operating system, RBAC authorizations names should be used as privilege names.

Currently, the only consumer of PolicyKit is `hald(1M)`.

Options   The following options are supported:

-h, --help	Display list of options and exit.
-p *privilege*, --privilege *privilege*	Name of privilege associated with user. Command tests for this privilege.
-r *resource*, --resource *resource*	Name of resource associated with user and privilege. Command tests for this resource.
-u *user*, --user *user*	User name or user id that is tested for.
-v, --verbose	Verbose mode.
-V, --version	Displays version number.

Attributes   See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/library/policykit
Interface Stability	Volatile

See Also   `auths(1)`, `profiles(1)`, `hald(1M)`, `getauthattr(3C)`, `auth_attr(4)`, `policy.conf(4)`, `prof_attr(4)`, `user_attr(4)`, `attributes(5)`

Name pooladm – activate and deactivate the resource pools facility

Synopsis /usr/sbin/pooladm [-n] [-s] [-c] [*filename*] | -x

/usr/sbin/pooladm [-d | -e]

Description The pooladm command provides administrative operations on pools and sets. pooladm reads the specified filename and attempts to activate the pool configuration contained in it.

Before updating the current pool run-time configuration, pooladm validates the configuration for correctness.

Without options, pooladm prints out the current running pools configuration.

Options The following options are supported:

-c   Instantiate the configuration at the given location. If a filename is not specified, it defaults to /etc/pooladm.conf.

-d   Disable the pools facility so that pools can no longer be manipulated.

-e   Enable the pools facility so that pools can be manipulated.

-n   Validate the configuration without actually updating the current active configuration. Checks that there are no syntactic errors and that the configuration can be instantiated on the current system. No validation of application specific properties is performed.

-s   Update the specified location with the details of the current dynamic configuration.

This option requires update permission for the configuration that you are going to update. If you use this option with the -c option, the dynamic configuration is updated before the static location.

-x   Remove the currently active pool configuration. Destroy all defined resources, and return all formerly partitioned components to their default resources.

Operands The following operands are supported:

filename   Use the configuration contained within this file.

Examples EXAMPLE 1   Instantiating a Configuration

The following command instantiates the configuration contained at /home/admin/newconfig:

example# **/usr/sbin/pooladm** -c **/home/admin/newconfig**

EXAMPLE 2   Validating the Configuration Without Instantiating It

The following command attempts to instantiate the configuration contained at /home/admin/newconfig. It displays any error conditions that it encounters, but does not actually modify the active configuration.

EXAMPLE 2 Validating the Configuration Without Instantiating It   *(Continued)*

example# **/usr/sbin/pooladm** -n -c **/home/admin/newconfig**

EXAMPLE 3 Removing the Current Configuration

The following command removes the current pool configuration:

example# **/usr/sbin/pooladm** -x

EXAMPLE 4 Enabling the Pools Facility

The following command enables the pool facility:

example# **/usr/sbin/pooladm -e**

EXAMPLE 5 Enabling the Pools Facility Using SMF

The following command enables the pool facility through use of the Service Management
Facility. See smf(5).

example# **/usr/sbin/svcadm enable svc:/system/pools:default**

EXAMPLE 6 Saving the Active Configuration to a Specified Location

The following command saves the active configuration to /tmp/state.backup:

example# **/usr/sbin/pooladm -s /tmp/state.backup**

Files /etc/pooladm.conf   Configuration file for pooladm.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/resource-mgmt/resource-pools
Interface Stability	See below.

The invocation is Committed. The output is Uncommitted.

See Also poolcfg(1M), poolbind(1M), psrset(1M), svcadm(1M), pset_destroy(2), libpool(3LIB),
attributes(5), smf(5)

*Oracle Solaris Administration: Oracle Solaris Zones, Oracle Solaris 10 Zones, and Resource
Management*

Notes Resource bindings that are not presented in the form of a binding to a partitionable resource,
such as the scheduling class, are not necessarily modified in a pooladm -x operation.

The pools facility is not active by default when Solaris starts. pooladm -e explicitly activates the pools facility. The behavior of certain APIs related to processor partitioning and process binding are modified when pools is active. See libpool(3LIB).

You cannot enable the pools facility on a system where processor sets have been created. Use the psrset(1M) command or pset_destroy(2) to destroy processor sets manually before you enable the pools facility.

Because the Resource Pools facility is an smf(5) service, it can also be enabled and disabled using the standard SMF interfaces.

Name poolbind – bind processes, tasks, or projects or query binding of processes to resource pools

Synopsis /usr/sbin/poolbind -p *poolname* -e *command* [*arguments*]...

/usr/sbin/poolbind -p *poolname* [-i *idtype*] *id*...

/usr/sbin/poolbind -q *pid*...

/usr/sbin/poolbind -Q *pid*...

Description The poolbind command allows an authorized user to bind zones, projects, tasks, and processes to pools. With the -e option (see below), it can execute a command you specify, placing the executed command in a specified pool. It can also enable you to query a process to determine which pool a process is bound to.

Options The following options are supported:

-e *command* [*arguments*...]   Executes *command*, bound to the pool you specify with -p.

-i *idtype*   This option, together with the *idlist* arguments, specifies one or more processes to which the poolbind command is to apply. The interpretation of *idlist* depends on the value of *idtype*. The valid *idtype* arguments and corresponding interpretations of *idlist* are as follows:

    pid   *idlist* is a list of process IDs. Binds the specified processes to the specified pool. This is the default behavior if no idtype is specified.

    taskid   *idlist* is a list of task IDs. Bind all processes within the list of task IDs to the specified pool.

    projid   *idlist* is a list of project IDs. Bind all processes within the list of projects to the specified pool. Each project ID can be specified as either a project name or a numerical project ID. See project(4).

    zoneid   *idlist* is a list of zone IDs. Bind all processes within the list of zones to the specified pool. Each zone ID can be specified as either a zone name or a numerical zone ID. See zones(5).

-p *poolname*   Specifies the name of a pool to which the specified zone, project, tasks, or processes are to be bound.

-q *pid* ...   Queries the pool bindings for a given list of process IDs. If the collection of resources associated with the process does not correspond to any currently existing pool, or if there are multiple pools with the set of resources that the process is bound to, the query fails for that particular process ID.

-Q *pid* ...   Queries the resource bindings for a given list of process IDs.
                                The resource bindings are each reported on a separate line.

Examples   EXAMPLE 1   Binding All Processes

The following command binds all processes in projects 5 and 7 to the pool web_app:

```
example# /usr/sbin/poolbind -p web_app -i projid 5 7
```

EXAMPLE 2   Binding the Running Shell

The following command binds the running shell to the pool web_app:

```
 example# /usr/sbin/poolbind -p web_app $$
```

EXAMPLE 3   Querying the Pool Bindings

The following command queries the bindings to verify that the shell is bound to the given
pool:

```
example# /usr/sbin/poolbind -q $$
```

EXAMPLE 4   Querying the Resource Bindings

The following command queries the bindings to verify that the shell is bound to the given
resources:

```
example# /usr/sbin/poolbind -Q $$
```

Exit Status   The following exit values are returned:

0   Successful completion.

1   Requested operation could not be completed.

2   Invalid command line options were specified.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/resource-mgmt/resource-pools
Interface Stability	See below.

The invocation is Committed. The output is Uncommitted.

See Also   pooladm(1M), poolcfg(1M), libpool(3LIB), project(4), attributes(5), zones(5)

*Oracle Solaris Administration: Oracle Solaris Zones, Oracle Solaris 10 Zones, and Resource
Management*

Name poolcfg – create and modify resource pool configuration files

Synopsis /usr/sbin/poolcfg -c *command* [-d | [*filename*]]

/usr/sbin/poolcfg -f *command_file* [-d | [*filename*]]

/usr/sbin/poolcfg -h

Description The poolcfg utility provides configuration operations on pools and sets. These operations are performed upon an existing configuration and take the form of modifications to the specified configuration file. If you use the -d option, the modifications occur to the kernel state. Actual activation of the resulting configuration is achieved by way of the pooladm(1M) utility.

Pools configuration files are structured files that must have been constructed using poolcfg itself or libpool(3LIB) directly.

An invocation of poolcfg with the pool dynamic location and write permission will hang if the dynamic location has already been opened for writing.

The configurations which are created by this utility can be used by pooladm to instantiate the configuration upon a target host.

Options The following options are supported:

-c *command*   Specify *command* as an editing command. See USAGE.

-d   Operate directly on the kernel state. No *filename* is allowed.

-f *command_file*   Take the commands from *command_file*. *command_file* consists of editing commands, one per line.

-h   Display extended information about the syntax of editing commands.

Usage

Scripts A script consists of editing commands, one per line, of the following:

info [*entity-name*]
     Display configuration (or specified portion) in human readable form to standard output. If no entity is specified, system information is displayed. Therefore, poolcfg -c 'info' afile is an equivalent invocation to poolcfg -c 'info system name' afile.

create *entity-name* [*property-list*]
     Make an entity of the specified type and name.

destroy *entity-name*
     Remove the specified entity.

modify *entity-name* [*property-list*]
     Change the listed properties on the named entity.

associate *pool-name* [*resource-list*]
     Connect one or more resources to a pool, or replace one or more existing connections.

transfer to [*resourcetype*] *name*[*component-list*]
  Transfer one or more discrete components to a resource .

transfer [*quantity*] from [*resourcetype*] [*src*] to [*tgt*]
  Transfer a resource quantity from *src* to *tgt*.

transfer [*quantity*] to [*resourcetype*] [*tgt*] from [*src*]
  Transfer a resource quantity to *tgt* from *src*.

discover
  Create a system entity, with one pool entity and resources to match current system
  configuration. All discovered resources of each resource type are recorded in the file, with
  the single pool referring to the default resource for each resource type.

  This command is a NO-OP when poolcfg operates directly on the kernel. See the -d
  option.

  You should avoid use of this command. The preferred method for creating a configuration
  is to export the dynamic configuration using pooladm(1M) with the -s option.

rename *entity-name* to *new-name*
  Change the name of an entity on the system to its new name.

Property Lists   The property list is specified by:

(proptype name = value [; proptype name = value]*)

where the last definition in the sequence for a given proptype, name pair is the one that holds.
For property deletion, use ~ proptype name.

Resource Lists   A resource list is specified by:

(resourcetype name [; resourcetype name]*)

where the last specification in the sequence for a resource is the one that holds. There is no
deletion syntax for resource lists.

Component Lists   A component list is specified by:

(componenttype name [; componenttype name]*)

where the last specification in the sequence for a component is the one that holds. There is no
deletion syntax for component lists.

Recognized Entities   system   Machine level entity

                      pool   Named collection of resource associations

Resource Types   pset   Processor set resource

Property Types boolean   Takes one of two values true or false.

int   A 64–bit signed integer value.

uint   A 64–bit unsigned integer value.

string   Strings are delimited by quotes ("), and support the character escape sequences defined in `formats(5)`.

float   Scientific notation is not supported.

Examples   **EXAMPLE 1**   Writing a poolcfg Script

The following `poolcfg` script creates a pool named `Accounting`, and a processor set, `small-1`. The processor set is created first, then the pool is created and associated with the set.

```
create pset small-1 ( uint pset.min = 1 ; uint pset.max = 4)
create pool Accounting
associate pool Accounting ( pset small-1 )
```

EXAMPLE 2   Reporting on pool_0

The following command reports on `pool_0` to standard output in human readable form:

```
 # poolcfg -c 'info pool pool_0' /etc/pooladm.conf
```

EXAMPLE 3   Destroying pool_0 and Its Associations

The following command destroys `pool_0` and associations, but not the formerly associated resources:

```
# poolcfg -c 'destroy pool pool_0' /etc/pooladm.conf
```

EXAMPLE 4   Displaying the Current Configuration

The following command displays the current configuration:

```
$ poolcfg -c 'info' /etc/pooladm.conf
system example_system
                int system.version 1
                boolean system.bind-default true
                string system.comment Discovered by libpool

                pool pool_default
                    boolean pool.default true
                    boolean pool.active true
                    int pool.importance 5
                    string pool.comment
                    string.pool.scheduler FSS
                    pset pset_default

                pset pset_default
```

EXAMPLE 4 Displaying the Current Configuration   *(Continued)*

```
int pset.sys_id -1
string pset.units population
boolean pset.default true
uint pset.max 4294967295
uint pset.min 1
string pset.comment
boolean pset.escapable false
uint pset.load 0
uint pset.size 2

cpu
    int cpu.sys_id 0
    string cpu.comment

cpu
    int cpu.sys_id 2
    string cpu.comment
```

EXAMPLE 5 Moving cpu with ID 2 to Processor Set pset1 in the Kernel

The following command moves cpu with ID 2 to processor set pset1 in the kernel:

```
# poolcfg -dc 'transfer to pset pset1 ( cpu 2 )'
```

EXAMPLE 6 Moving 2 cpus from Processor Set pset1 to Processor Set pset2 in the Kernel

The following command moves 2 cpus from processor set pset1 to processor set pset2 in the kernel:

```
# poolcfg -dc 'transfer 2 from pset pset1 to pset2'
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/resource-mgmt/resource-pools
Interface Stability	See below.

The invocation is Committed. The output is Uncommitted.

Oracle Solaris Administration: Oracle Solaris Zones, Oracle Solaris 10 Zones, and Resource Management

Name poold – automated resource pools partitioning daemon

Synopsis poold [-l *level*]

Description poold provides automated resource partitioning facilities. poold can be enabled or disabled using the Solaris Service Management Facility, smf(5). poold requires the Resource Pools facility to be active in order to operate.

The dynamic resource pools service's fault management resource identifier (FMRI) is:

svc:/system/pools/dynamic

The resource pools service's FMRI is:

svc:/system/pools

poold's configuration details are held in a libpool(3LIB) configuration and you can access all customizable behavior from this configuration.

poold periodically examines the load on the system and decides whether intervention is required to maintain optimal system performance with respect to resource consumption. poold also responds to externally initiated (with respect to poold) changes of either resource configuration or objectives.

If intervention is required, poold attempts to reallocate the available resources to ensure that performance objectives are satisfied. If it is not possible for poold to meet performance objectives with the available resources, then a message is written to the log. poold allocates scarce resources according to the objectives configured by the administrator. The system administrator must determine which resource pools are most deserving of scarce resource and indicate this through the importance of resource pools and objectives.

Options The following options are supported:

-l *level*   Specify the vebosity level for logging information.

Specify *level* as ALERT, CRIT, ERR, WARNING, NOTICE, INFO, and DEBUG. If *level* is not supplied, then the default logging level is INFO.

ALERT   A condition that should be corrected immediately, such as a corrupted system database.

CRIT   Critical conditions, such as hard device errors.

ERR   Errors.

WARNING   Warning messages.

NOTICE   Conditions that are not error conditions, but that may require special handling.

INFO   Informational messages.

DEBUG   Messages that contain information normally of use only when
             debugging a program.

When invoked manually, with the -l option, all log output is directed to standard error.

Examples   EXAMPLE 1   Modifying the Default Logging Level

The following command modifies the default logging level to ERR:

```
# /usr/lib/pool/poold -l ERR
```

EXAMPLE 2   Enabling Dynamic Resource Pools

The following command enables dynamic resource pools:

```
# /usr/sbin/svcadm enable svc:/system/pools/dynamic
```

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/resource-mgmt/resource-pools
Interface Stability	See below.

The invocation is Committed. The output is Uncommitted.

*Oracle Solaris Administration: Oracle Solaris Zones, Oracle Solaris 10 Zones, and Resource
Management*

Name poolstat – report active pool statistics

Synopsis poolstat [-p *pool-list*] [-r *rset-list*] [-T u | d] [*interval* [*count*]]

poolstat [-p *pool-list*] [-o *format* -r *rset-list*]
        [-T u | d] [*interval* [*count*]]

Description The poolstat utility iteratively examines all active pools on the system. It reports statistics based on the selected output mode. poolstat provides options to examine only specified pools and report resource set-specific statistics.

Without options, poolstat examines all pools, reports basic statistics for their resource sets, and exits.

DISPLAY FORMATS In default output format, poolstat outputs a header line and a line for each pool. The line begins with the pool ID and its name, followed by a column of statistical data for the processor set attached to the pool.

The columns are defined as follows:

id   Pool ID.

pool   Pool name.

rid   Resource set id.

rset   Resource set name.

type   Resource set type.

min   Minimum resource set size.

max   Maximum resource set size.

size   Current resource set size.

used   The measure of how much of the resource set is currently is use. This is calculated as the percentage utilization of the resource set multiplied by its size. If resource set has been reconfigured during last sampling interval, this value might be not reported (-).

load   The absolute representation of the load that is put on the resource set. For the definition of this property see libpool(3LIB).

Options The following options are supported:

-o *format*   Report statistics according to the format specification given in format. See DISPLAY FORMATS.

The -o option accepts lists as arguments. Items in a list can be either separated by commas or enclosed in quotes and separated by commas or spaces.

You can specify multiple -o options. The format specification is interpreted as the whitespace separated concatenation of all the format option arguments.

The -o option must be used in conjunction with the -r option.

-p *pool-list*   Report only pools whose names are in the given list. If the -r option is also used, this option selects only resource sets which belong to pools in the given list. Statistics for pools or resource sets are reported in the same order in which pool names are listed on the pool-list. Pool can be specified by name or by ID.

The -p option accepts lists as arguments. Items in a *pool-list* can only be separated by spaces.

-r *rset-list*   Report resource set statistics. If the *rset-list* argument is "all", then all possible resource set types are selected.

The -r option accepts lists as arguments. Items in a list can be either separated by commas or enclosed in quotes and separated by commas or spaces.

The following resource set types are supported:

all   All resource set types

pset   Processor set

-T u | d   Display a time stamp.

Specify u for a printed representation of the internal representation of time. See time(2). Specify d for standard date format. See date(1).

Operands   The following operands are supported:

count   The number of times that the statistics are repeated. By default, poolstat reports statistics only once.

If neither interval nor count are specified, statistics are reported once. If interval is specified and count is not, statistics are reported indefinitely.

interval   The sampling interval in seconds.

If neither interval nor count are specified, statistics are reported once. If interval is specified and count is not, statistics are reported indefinitely.

Examples   EXAMPLE 1   Using poolstat

The following example shows the default output from the poolstat utility:

```
% poolstat
                       pset
  id pool          size used load
   0 pool_default     4  3.6  6.2
   1 pool_admin       4  3.3  8.4
```

EXAMPLE 2 Reporting Resource Set Statistics

The following example reports resource set statistics.

```
% poolstat -r pset
  id pool          type rid rset         min  max size used load
  0 pool_default   pset -1 pset_default   1  65K    2  1.2  8.3
  1 pool_admin     pset  1 pset_admin     1   1     1  0.4  5.2
  2 pool_other     pset -1 pset_default   1  65K    2  1.2  8.3
```

Resource sets attached to multiple pools, as pset_default in the example above, are listed multiple times, once for each pool.

EXAMPLE 3 Restricting the Output to the List of Pools

The following example restricts the output to the list of pools

```
% poolstat -p pool_default
                    pset
 id pool       size used load
 0 pool_default   8  5.3 10.3

% poolstat -p 'pool_admin pool_default'
                     pset
  id pool       size used load
  1 pool_admin     6  4.3  5.3
  0 pool_default   2  1.9  2.0

% poolstat -r all -p 'pool_admin pool_default'
  id pool          type rid rset         min  max size used load
  1 pool_admin     pset  1 pset_admin     1   1     1  0.9  2.3
  2 pool_default   pset -1 pset_default   1  65K    2  2.0  2.0
```

EXAMPLE 4 Customizing Output

The following example customizes output:

```
% poolstat -r -o pool,rset,size,load
  pool          rset          size load
  pool_default  pset_default     4  4.5
  pool_admin    pset_admin       4  2.1
```

Exit Status The following exit values are returned:

0   Successful completion.

1   An error occurred.

2   Invalid command line options were specified.

Attributes   See `attributes`(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/resource-mgmt/resource-pools
Interface Stability	Committed

See Also   `libpool`(3LIB), `attributes`(5)

Oracle Solaris Administration: Oracle Solaris Zones, Oracle Solaris 10 Zones, and Resource Management

Notes   The system ids associated with resources can change after the system reboots or the resource configuration is altered.

Name   ports – creates /dev entries and inittab entries for serial lines

Synopsis   /usr/sbin/ports [-r *rootdir*]

Description   devfsadm(1M) is now the preferred command for /dev and /devices and should be used instead of ports.

The ports command creates symbolic links in the /dev/term and /dev/cua directories to the serial-port character device files in /devices and adds new entries in /etc/inittab for non-system ports found. System-board ports are given single lower-case letters for names (such as a and b) while other ports are named numerically.

ports searches the kernel device tree to find the serial devices attached to the system. It also checks /dev/term and /dev/cua to see what symbolic links to serial devices already exist. ports then performs the following:

1. Assigns new numbers (or letters for system-board ports) to ports that are attached to the system but do not have /dev/term and /dev/cua entries. The numbers or letters assigned are the lowest-unused numbers or letters.

2. Removes dangling links: links from /dev/term and /dev/cua pointing to no-longer-existing ports.

3. Creates new /dev/term and /dev/cua links for new serial devices.

If the configuration has not changed, ports exits without doing anything.

Notice to Driver Writers   ports considers devices with a node type of DDI_NT_SERIAL, DDI_NT_SERIAL_MB, DDI_NT_SERIAL_DO, or DDI_NT_SERIAL_MB_DO to be serial port devices. Devices with one of these node types must create minor device names that obey the following conventions when calling ddi_create_minor_node(9F).

- The minor name for non-system port devices (DDI_NT_SERIAL) consists of an ASCII numeric string, where the first port on the device is named 0, the second named 1, the third named 2, up to the number of ports provided by the device.

- The minor name for non-system dialout devices (DDI_NT_SERIAL_DO) is the ASCII numeric port name, concatenated with ,cu. For example, the minor name for the first dialout port on the serial board is 0,cu.

- The minor name for system-board port devices (DDI_NT_SERIAL_MB) consists of a string containing a single ASCII lowercase character, where the first port on the device is named a, the second is named b, the third is named c, for all ports on the device (or up through port z).

- The minor name for system-board dialout devices (DDI_NT_SERIAL_MB_DO) consists of the lowercase character port name, concatenated with ,cu. For example, the minor name for the first dialout port on the on-board serial device is a,cu.

To prevent disks from attempting to automatically generate links for a device, drivers must specify a private node type and refrain from using one of the above node types when calling ddi_create_minor_node(9F).

Options The following options are supported:

  -r *rootdir*   Causes ports to presume that the /dev/term, /dev/cua, and /devices
                  directories are found under *rootdir*, not directly under /.

Examples **EXAMPLE 1** Creating the Serial and Dialout Minor Device Nodes

The following example creates the serial and dialout minor device nodes from the xkserial
driver's attach(9E) function:

```
/*
 * Create the minor number by combining the instance number
 * with the port number.
 */ #define XKNUMPORTS          8
#define XKMINORNUM(i, p)      ((i) << 4 | (p))
#define XKMINORNUM_DO(i, p)  ((i) << 4 | (p) | 0x80)
int
xkserialattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
   int instance, portnum;
   char name[8];
       /* other stuff in attach... */
   instance = ddi_get_instance(dip);
   for (portnum = 0; portnum < XKNUMPORTS; portnum++) {
       /*
        * create the serial port device
        */
       sprintf(name, "%d", portnum);
       ddi_create_minor_node(dip, name, S_IFCHR,
          XKMINORNUM(instance, portnum), DDI_NT_SERIAL, 0);

       /*
        * create the dialout device
        */
       sprintf(name,"%d,cu", portnum);
       ddi_create_minor_node(dip, name, S_IFCHR,
           XKMINORNUM_DO(instance, portnum), DDI_NT_SERIAL_DO, 0);
   }
}
```

EXAMPLE 2 Installing the xkserial Port Driver on a Sun Fire 4800

The following example installs the xkserial port driver on a Sun Fire 4800 (with the driver
controlling the fictional XKSerial 8 port serial board), with these special files in /devices:

```
# ls -l /devices/ssm@0,0/pci@18,700000/pci@1/xkserial@f,800000/
crw-r-----   1 root sys   32,  16 Aug 29 00:02 xkserial@2000:0
crw-r-----   1 root sys   32, 144 Aug 29 00:02 xkserial@2000:0,cu
crw-r-----   1 root sys   32,  17 Aug 29 00:02 xkserial@2000:1
```

EXAMPLE 2   Installing the xkserial Port Driver on a Sun Fire 4800   *(Continued)*

```
crw-r-----  1 root sys  32, 145 Aug 29 00:02 xkserial@2000:1,cu
crw-r-----  1 root sys  32,  18 Aug 29 00:02 xkserial@2000:2
crw-r-----  1 root sys  32, 146 Aug 29 00:02 xkserial@2000:2,cu
crw-r-----  1 root sys  32,  19 Aug 29 00:02 xkserial@2000:3
crw-r-----  1 root sys  32, 147 Aug 29 00:02 xkserial@2000:3,cu
crw-r-----  1 root sys  32,  20 Aug 29 00:02 xkserial@2000:4
crw-r-----  1 root sys  32, 148 Aug 29 00:02 xkserial@2000:4,cu
crw-r-----  1 root sys  32,  21 Aug 29 00:02 xkserial@2000:5
crw-r-----  1 root sys  32, 149 Aug 29 00:02 xkserial@2000:5,cu
crw-r-----  1 root sys  32,  22 Aug 29 00:02 xkserial@2000:6
crw-r-----  1 root sys  32, 150 Aug 29 00:02 xkserial@2000:6,cu
crw-r-----  1 root sys  32,  23 Aug 29 00:02 xkserial@2000:7
crw-r-----  1 root sys  32, 151 Aug 29 00:02 xkserial@2000:7,cu
```

/dev/term contain symbolic links to the serial port device nodes in /devices

```
# ls -l /dev/term
/dev/term/0 -> ../../devices/[....]/xkserial@2000:0
/dev/term/1 -> ../../devices/[....]/xkserial@2000:1
/dev/term/2 -> ../../devices/[....]/xkserial@2000:2
/dev/term/3 -> ../../devices/[....]/xkserial@2000:3
/dev/term/4 -> ../../devices/[....]/xkserial@2000:4
/dev/term/5 -> ../../devices/[....]/xkserial@2000:5
/dev/term/6 -> ../../devices/[....]/xkserial@2000:6
/dev/term/7 -> ../../devices/[....]/xkserial@2000:7
```

and /dev/cua contain symbolic links to the dialout port device nodes in /devices

```
# ls -l /dev/cua

/dev/cua/0 -> ../../devices/[....]/xkserial@2000:0,cu
/dev/cua/1 -> ../../devices/[....]/xkserial@2000:1,cu
/dev/cua/2 -> ../../devices/[....]/xkserial@2000:2,cu
/dev/cua/3 -> ../../devices/[....]/xkserial@2000:3,cu
/dev/cua/4 -> ../../devices/[....]/xkserial@2000:4,cu
/dev/cua/5 -> ../../devices/[....]/xkserial@2000:5,cu
/dev/cua/6 -> ../../devices/[....]/xkserial@2000:6,cu
/dev/cua/7 -> ../../devices/[....]/xkserial@2000:7,cu
```

Files   /dev/term/*n*   Logical serial port devices

/dev/cua/*n*   Logical dialout port devices

/etc/inittab   Controls dispatching by init.

Writing Device Drivers

Name poweradm – manage power management properties

Synopsis `poweradm [-v] get [-a all|smf|platform|current]` *property* `...`

`poweradm [-v] set` *property*=*value* `...`

`poweradm [-v] list`

`poweradm -?`

Description The `poweradm` program is used to display and manage the Power Management settings within a Solaris instance.

The Power Management properties and their values are stored in the service management facility (see `smf(5)`).

All users can run the `list` and `get` forms given in the SYNOPSIS. These commands allow all users to view the current Power Management settings within a Solaris instance.

Only users and roles that belong to the Maintenance and Repair RBAC profile can execute the `set` form of `poweradm` given in the SYNOPSIS. See also the NOTES section below.

`poweradm` supports the following service property:

`administrative-authority`

The value for this property is specified as a string and can have the values:

- `smf`
- `platform`
- `none`

...with `platform` as the default value. The significance of this property is the source of administrative control for power management within the Solaris kernel. That is, this property indicates the origin of `time-to-full-capacity` and `time-to-minimum-responsiveness` settings within the Solaris kernel. Only a Solaris user with appropriate privileges can set this property.

When the `administrative-authority` is set to `platform` the values of `time-to-full-capacity` and `time-to-minimum-responsiveness` will be taken from the platform code. Setting these values in SMF using the `poweradm` command will have no effect upon the values in the kernel, while `administrative-authority` is set to `platform`. Under this condition, the `poweradm` command will indicate that the kernel is currently using the platform values. As these values are changed by the platform administrator, so they will be modified in kernel. Also, commands to enable or disable the power management within the Solaris kernel will come from the platform code. When the `administrative-authority` is set to `smf`, the values of `time-to-full-capacity` and `time-to-minimum-responsiveness` will be taken from SMF. As these values in SMF are changed by the Solaris administrator, so they will be applied to kernel. Setting these values in the platform will have no effect upon the values in the kernel while administrative-authority is set to smf. Under this condition, he poweradm

command will indicate that the kernel is currently using the values from SMF. As these values are changed by the Solaris administrator, so they will be modified in kernel.

When the `administrative-authority` is set to `none`, power management within the Solaris kernel will be turned off, although the power service will continue to run. Any power management instructions from the platform will be ignored, as will the settings in SMF. Only when `administrative-authority` is set to one of the other values will power management within the Solaris kernel restart, using the settings from the specified source.

`time-to-full-capacity`
   Specified in microseconds.

   This parameter constrains the dynamic capacity adjustment allowed while the system is in an active state.

   This parameter defines the maximum time the system is allowed to reach (re-provision and make available) its full capacity, returning from any lower-capacity/less-responsive state, while it has been using any or all of the PM features falling within this bound.

   By default, this value is taken from the platform (for example, `i86pc`), because the default setting for `administrative-authority` is set to `platform`.

   Alternatively, if `administrative-authority` is set to `smf`, this value is taken from the definition provided by the power service (that is, SMF). At install time this value is set to be `undefined`. If the Solaris administrator chooses to modify this property, a value appropriate to the needs of the workload or applications must be picked.

`time-to-minimum-responsiveness`
   Specified in milliseconds.

   This parameter constrains the dynamic capacity adjustment allowed while the system is in an inactive state.

   This parameter defines how long the system is allowed to return to its active state—that is, to provide the minimum capacity required to meet the above time-to-full-capacity constraint.

   Moderate values (seconds) allow hardware components or subsystems on the platform to be placed in slower-response inactive states; larger values still (for example, 30 seconds to minutes) allow for such as whole system suspension, using techniques such as suspend-to-RAM.

   By default, this value is taken from the platform (for example, `i86pc`), because the default setting for `administrative-authority` is set to `platform`.

   Alternatively, if `administrative-authority` is set to `smf`, this value is taken from the definition provided by the power service (that is, SMF). At install time this value is set to be `undefined`. If the Solaris administrator chooses to modify this property, a value appropriate to the needs of the workload or applications must be picked.

suspend-enable

By default, only a small number of machines are allowed to suspend. Setting this property to true will permit other machines to attempt to suspend. By default this property is set to false, unless a machine has S3 according the the ACPI kstat module and is on the white list. If these two conditions are met, the default is true. The value of administrative-authority has no effect upon this property.

Options The following options are supported.

-?

Display a synopsis of available subcommands and options.

-v

Provide verbose output. Can be used with any of the subcommands listed below.

Sub-commands The following subcommands are supported:

get [-a all|smf|platform|current]

Retrieves the current value of the named property. The -a option can be used to indicate the origin of the value either: SMF (smf), the platform (platform), the current value used by the kernel (current) or all of the preceding (all). By default, if no origin is specified then current is assumed.

The administrative-authority and suspend-enable properties do not have a platform value

set *property=value*...

Changes the named *property* to the given *value*. The properties administrative-authority and suspend-enable are automatically synchronized to the new value in the kernel. The properties time-to-full-capacity and time-to-minimum-responsiveness are synchronized to the kernel if and only if administrative-authority is set to smf. If the -v option is used and the kernel cannot be updated immediately because administrative-authority is not set to smf, a warning message will be issued.

Only users and roles that belong to the Maintenance and Repair RBAC profile can execute the set subcommand.

list

Lists all the available Power Management properties values and indicate whether power management is active.

Exit Status 0

Successful completion.

1

An error occurred.

2

Invalid command line options were specified.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/kernel/power
Interface Stability	Committed

See Also attributes(5), smf(5), smf_security(5)

Notes The power service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/system/power:default
```

The properties that can be set by poweradm are defined in that service as:

- active_control/administrative-authority, which is described under administrative-authority above

- active_config/time-to-full-capacity, which is described under time-to-full-capacity above

- active_config/time-to-minimum-responsiveness, which is described under time-to-minimum-responsiveness above

- suspend/suspend-enable, which is described under suspend-enable above

If the service is disabled, no power management settings will be uploaded to the kernel in the future. Existing settings will not be undone until the next reboot. Disabling all power management is best accomplished by setting administrative-authority to none.

If administrative-authority is set to the value smf before both time-to-full-capacity and time-to-minimum-responsiveness have been set, the service will go into maintenance mode. In such a situation, set administrative-authority to the value none then set both time-to-full-capacity and time-to-minimum-responsiveness to the values you want, clear the service and then set administrative-authority to smf.

To set properties in the active_config and suspend property groups, the solaris.smf.value.power_config authorization is required. To set properties in the active_control property group requires the solaris.smf.value.power_control authorization is required. Both of these authorizations are part of the Maintenance and Repair profile.

Name powertop – report and analyze events that affect power management

Synopsis powertop [-c *processor_id*] [-d *count*] [-t *interval*] [-v] [-h]

Description PowerTOP is an observability tool that shows how effectively the system is taking advantage of the CPU's power management features. By running the tool on an otherwise idle system, the user can see for how long the CPU is running at dif- ferent power states. Ideally, an unutilized (idle) system spends 100% of its time running at the lowest power state, but because of background user and kernel activity (random software periodically waking to poll status), idle systems can consume more power than they should.

The tool analyzes system activity periodically and displays a summary of how long the processor is executing at each supported power state. It also displays the top activities responsible for causing the CPU to wake up and use more energy. This report allows the user to identify and diagnose problematic areas of the system and optimize its power efficiency.

PowerTOP averages the amount of activity that is preventing the CPU from entering a lower power state and presents it on the "Wakeups-from-idle per second" field. This value represents the total number of wake-ups divided by the current interval. Notice that not all events are displayed on the screen at all times.

During execution, a user can force a refresh of the analysis by pressing the R key. The interval time is restored to the default or to a specified value. To quit the application, the user must press the Q key.

PowerTOP allows you to freeze each of its three subwindows, enabling you to better analyze each subwindow's contents. When you have three different DTrace scripts running at the same time, freezing subwindows lowers CPU consumption . This feature is activated by pressing the i, f, or e key while the tool running. Pressing one of these keys freezes the idle, frequency, or event report, respectively. Pressing it once more, unfreezes it. This feature is most useful when invoked while the application being analyzed is running.

PowerTOP runs on some virtual domains. However, the report for idle state transitions might or might not be accurate as the physical CPU can be shared by different virtual CPUs. Both wakeup count and event report displays information regarding the current virtualized environment.

Options The following options are supported:

-c [*processor_id*]
  Specifies which CPU the tool should observe.

-d [*count*]
  Dumps the results of *count* analysis of system activity to the screen.

-h
  Displays the command's usage.

-t [*interval*]

Specifies the interval, in seconds, at which the tool analyzes the system. The possible values are in the range of 1 through 30; the default is 5 seconds.

-v

Switches to verbose mode, including noting firings of the kernel cyclic subsystem in the event report.

Examples   EXAMPLE 1   Setting the Interval

The following command sets the interval to two seconds.

% **powertop -t 2**

EXAMPLE 2   Analyzing and Dumping System Activity

The following command analyzes and dumps system activity to the standard output four times.

% **powertop -d 4**

EXAMPLE 3   Reporting Cyclic Subsystem Activity

The following command reports cyclic subsystem activity.

% **powertop -v**

EXAMPLE 4   Analyzing Activity on a Specific Processor

The following command runs PowerTOP and only displays data for CPU 3:

% **powertop -c 3**

Exit Status   0

Successful operation.

1

An error occurred.

2

Incorrect usage.

Attributes   See attributes(5) for descriptions of the following attributes:

Usage You must have DTrace privileges to run PowerTOP and root (superuser) privileges or assume the Primary Administrator role for the tool to suggest improvements to the system.

Name pppd – point to point protocol daemon

Synopsis pppd [*tty_name*] [*speed*] [*options*]

Description The point-to-point protocol (PPP) provides a method for transmitting datagrams over serial point-to-point links. PPP is composed of three components: a facility for encapsulating datagrams over serial links, an extensible link control protocol (LCP), and a family of network control protocols (NCP) for establishing and configuring different network-layer protocols.

The encapsulation scheme is provided by driver code in the kernel. pppd provides the basic LCP authentication support and several NCPs for establishing and configuring the Internet Protocol (referred to as the IP Control Protocol or "IPCP") and IPv6 (IPV6CP).

Options The following sections discuss the pppd options:

Options Files Options are taken from files and the command line. pppd reads options from the files /etc/ppp/options, $HOME/.ppprc and /etc/ppp/options.*ttyname* (in that order) before processing the options on the command line. (Command-line options are scanned for the terminal name before the options.*ttyname* file is read.) To form the name of the options.*ttyname* file, the initial /dev/ is removed from the terminal name, and any remaining forward slash characters (/) are replaced with dots. For example, with serial device /dev/cua/a, option file /etc/ppp/options.cua.a is read.

An options file is parsed into a series of words that are delimited by whitespace. Whitespace can be included in a word by enclosing the word in double-quotes ("). A backslash (\) quotes the succeeding character. A hash (#) starts a comment, which continues until the end of the line. There is no restriction on using the file or call options within an options file.

Frequently Used Options

    <tty_name> Communicate over the named device. The string /dev/ is prepended if necessary. If no device name is given, or if the name of the terminal connected to the standard input is given, pppd uses that terminal and does not fork to put itself in the background. A value for this option from a privileged source cannot be overridden by a non-privileged user.

    <speed> Set the baud rate to <speed> (a decimal number). The default is to leave the baud rate unchanged. This option is normally needed for dial-out only.

    asyncmap *<map>* Set the async character map to *<map>*. The map describes which control characters cannot be successfully received over the serial line. pppd asks the peer to send these characters as a 2-byte escape sequence. The argument is a 32 bit hex number, with each bit representing a character to escape. Bit 0 (00000001) represents the character 0x00; bit 31 (80000000) represents the character 0x1f or ^_. If multiple asyncmap options are given, the values are ORed together. If no asyncmap option is given, pppd attempts to negotiate a value of 0. If the

	peer agrees, this disables escaping of the standard control characters. Use the default-asyncmap option to disable negotiation and escape all control characters.
auth	Require the peer to authenticate itself before allowing network packets to be sent or received. This option is the default if the system has a default route. If the auth or the noauth option is not specified, pppd allows the peer to use only those IP addresses to which the system does not already have a route.
call *name*	Read options from the file /etc/ppp/peers/*name*. This file may contain privileged options, including noauth, even if pppd is not being run by root. The *name* string may not begin with a slash ("/") or include consecutive periods ("..") as a pathname component.
callback *number*	Request a callback to the given telephone number using Microsoft CBCP.
connect *script*	Use the executable or shell command specified by *script* to set up the serial line. This script would typically use the chat(1M) program to dial the modem and start the remote PPP session. A value for this option originating from a privileged source cannot be overridden by a non-privileged user.
crtscts	Use hardware flow control, that is, RTS/CTS, to control the flow of data on the serial port. If the crtscts, nocrtscts, cdtrcts or nocdtrcts option is not provided, the hardware flow control setting for the serial port is left unchanged. Some serial ports lack a true RTS output and use this mode to implement unidirectional flow control. The serial port suspends transmission when requested by the modem by means of CTS but cannot request the modem to stop sending to the computer. This mode allows the use of DTR as a modem control line.
defaultroute	Add a default route to the system routing tables when IPCP negotiation successfully completes, using the peer as the gateway. This entry is removed when the PPP connection is broken. This option is privileged if the nodefaultroute option is specified.
disconnect *script*	Run the executable or shell command specified by *script* after pppd terminates the link. Typically, this script is used to command the modem to hang up if hardware modem control signals are not available. disconnect is not run if the modem has already hung up. A value for this option originating from a privileged source cannot be overridden by a non-privileged user.
escape *xx,yy,...*	Specifies that certain characters be escaped on transmission regardless of whether the peer requests them to be escaped with its async control

character map. The characters to be escaped are specified as a list of hex numbers separated by commas. Note that almost any character can be specified for the escape option, unlike the asyncmap option which allows only control characters to be specified. Characters that cannot be escaped are those containing hex values 0x20 through 0x3f and 0x5e.

file *name*   Read options from file *name*. If this option is used on the command line or in $HOME/.ppprc, the file must be readable by the user invoking pppd. See Options Files for a list of files that pppd always reads, regardless of the use of this option.

init *script*   Run the executable or shell command specified by *script* to initialize the serial line. This script would typically use the chat(1M) program to configure the modem to enable auto-answer. A value for this option from a privileged source cannot be overridden by a non-privileged user.

lock   Directs pppd to create a UUCP-style lock file for the serial device to ensure exclusive access to the device.

mru *n*   Set the Maximum Receive Unit (MRU) value to *n*. pppd asks the peer to send packets of no more than *n* bytes. Minimum MRU value is 128. Default MRU value is 1500. A value of 296 is recommended for slow links (40 bytes for TCP/IP header + 256 bytes of data). For IPv6, MRU must be at least 1280.

mtu *n*   Set the Maximum Transmit Unit (MTU) value to *n*. Unless the peer requests a smaller value via MRU negotiation, pppd requests the kernel networking code to send data packets of no more than *n* bytes through the PPP network interface. For IPv6, MTU must be at least 1280.

passive   Enables the "passive" option in the LCP. With this option, pppd attempts to initiate a connection; if no reply is received from the peer, pppd waits passively for a valid LCP packet instead of exiting, as it would without this option.

Options   <local_IP_address>:<remote_IP_address>
          Set the local and/or remote interface IP addresses. Either one may be omitted, but the colon is required. The IP addresses are specified with a host name or in decimal dot notation, for example: :10.1.2.3. The default local address is the first IP address of the system unless the noipdefault option is provided. The remote address is obtained from the peer if not specified in any option. Thus, in simple cases, this option is not required. If a local and/or remote IP address is specified with this option, pppd will not accept a different value from the peer in the IPCP negotiation unless the ipcp-accept-local and/or ipcp-accept-remote options are given, respectively.

allow-fcs *fcs-type*

Set allowable FCS type(s) for data sent to the peer. The *fcs-type* is a comma-separated list of "crc16", "crc32", "null", or integers. By default, all known types are allowed. If this option is specified and the peer requests a type not listed, a LCP Configure-Nak is sent to request only the listed types.

allow-ip *address(es)*

Allow peers to use the given IP address or subnet without authenticating themselves. The parameter is parsed in the same manner as each element of the list of allowed IP addresses is parsed in the secrets files. See the Authentication section more more details.

bsdcomp *nr,nt*

Request that the peer compress packets that it sends using the BSD-Compress scheme, with a maximum code size of *nr* bits, and agree to compress packets sent to the peer with a maximum code size of *nt* bits. If *nt* is not specified, it defaults to the value given for *nr*. Values in the range 9 to 15 may be used for *nr* and *nt*; larger values provide better compression but consume more kernel memory for compression dictionaries. Alternatively, a value of 0 for *nr* or *nt* disables compression in the corresponding direction. Use nobsdcomp or bsdcomp 0 to disable BSD-Compress compression entirely. If this option is read from a privileged source, a nonprivileged user may not specify a code size larger than the value from the privileged source.

cdtrcts

Use a non-standard hardware flow control such as DTR/CTS to control the flow of data on the serial port. If the crtscts, nocrtscts, cdtrcts or nocdtrcts option is not specified, the hardware flow control setting for the serial port is left unchanged. Some serial ports lack a true RTS output. Such serial ports use this mode to implement true bi-directional flow control. Note that this flow control mode does not permit using DTR as a modem control line.

chap-interval *n*

If this option is given, pppd will rechallenge the peer every *n* seconds.

chap-max-challenge *n*

Set the maximum number of CHAP challenge transmissions to *n* (default 10).

chap-restart *n*

Set the CHAP restart interval (retransmission timeout for challenges) to *n* seconds. The default is 3.

connect-delay *n*

Wait for up to *n* milliseconds after the connect script finishes for a valid PPP packet from the peer. When the wait period elapses or when a valid PPP packet is received from the peer, pppd begins negotiation by sending its first LCP packet. The default value is 1000 (1 second). A wait period applies only if the connect or pty option is used.

datarate *n*

Set maximum data rate to *n* (in bytes per second) when using the pty, notty, record, or socket options.

debug

Enables connection debugging facilities. If this option is given, pppd logs the contents of all control packets sent or received in a readable form. The packets are logged through syslog with facility daemon and level debug. This information can be directed to a file by configuring /etc/syslog.conf appropriately.

default-asyncmap

Disable asyncmap negotiation, forcing all control characters to be escaped for both the transmit and the receive direction.

default-fcs

Disable FCS Alternatives negotiation entirely. By default, no FCS Alternatives option is sent to the peer, but the option is accepted. If this option is specified by the peer, then LCP Configure-Reject is sent.

default-mru

Disable MRU [Maximum Receive Unit] negotiation. With this option, pppd uses the default MRU value of 1500 bytes for the transmit and receive directions.

deflate *nr,nt,e*

Request that the peer compress packets that it sends, using the deflate scheme, with a maximum window size of $2^{**}nr$ bytes, and agree to compress packets sent to the peer with a maximum window size of $2^{**}nt$ bytes and effort level of *e* (1 to 9). If *nt* is not specified, it defaults to the value given for *nr*. If *e* is not specified, it defaults to 6. Values in the range 9 to 15 may be used for *nr* and *nt*; larger values provide better compression but consume more kernel memory for compression dictionaries. (Value 8 is not permitted due to a zlib bug.) Alternatively, a value of 0 for *nr* or *nt* disables compression in the corresponding direction. Use nodeflate or deflate 0 to disable deflate compression entirely. (Note: pppd requests deflate compression in preference to BSD-Compress if the peer can do either.) If this option is read from a privileged source, a nonprivileged user may not specify a code size larger than the value from the privileged source.

demand

Initiate the link only on demand, that is, when data traffic is present. With this option, the remote IP address must be specified by the user on the command line or in an options file. pppd initially configures and enables the interface for IP traffic without connecting to the peer. When traffic is available, pppd connects to the peer and performs negotiation, authentication and other actions. When completed, pppd passes data packets across the link. The demand option implies the persist option. If this behavior is not desired, use the nopersist option after the demand option. The idle and holdoff options can be used in conjunction with the demand option.

domain *d*

Append the domain name *d* to the local host name for authentication purposes. For example, if gethostname() returns the name porsche, but the fully qualified domain name is porsche.Quotron.COM, you could specify domain Quotron.COM. With this configuration, pppd uses the name porsche.Quotron.COM for accessing secrets in the secrets file and as the default name when authenticating to the peer. This option is privileged.

endpoint *endpoint-value*

Set the endpoint discriminator (normally used for RFC 1990 Multilink PPP operation). The *endpoint-value* consists of a class identifier and a class-dependent value. The class identifier is one of "null," "local," "IP," "MAC," "magic," "phone," or a decimal integer. If present, the class-dependent value is separated from the identifier by a colon (":") or period (".") . This value may be a standard dotted-decimal IP address for class "IP," an optionally colon-or-dot separated hex Ethernet address for class "MAC" (must have 6 numbers), or an arbitrary string of bytes specified in hex with optional colon or dot separators between bytes. Although this option is available, this implementation does not support multilink.

fcs *fcs-type*

Set FCS type(s) desired for data sent by the peer. The *fcs-type* is a comma-separated list of crc16, crc32, null, or integers. By default, an FCS Alternatives option is not specified, and the medium-dependent FCS type is used. If this option is specified and the peer sends an LCP Configure-Nak, only the listed types are used. If none are in common, the FCS Alternatives option is omitted from the next LCP Configure-Request to drop back to the default.

hide-password

When logging the contents of PAP packets, this option causes pppd to exclude the password string from the log. This is the default.

holdoff *n*

Specifies how many seconds to wait before re-initiating the link after it terminates. This option is effective only if the persist or demand option is used. The holdoff period is not applied if the link is terminated because it was idle.

ident *string*

Set the LCP Identification string. The default value is a version string similar to that displayed by the --version option.

idle *n*

Specifies that pppd must disconnect if the link is idle for *n* seconds. The link is idle when no data packets (i.e. IP packets) are being sent or received. Do not use this option with the persist option but without the demand option.

ipcp-accept-local

With this option, pppd accepts the peer's idea of the local IP address, even if the local IP address is specified in an option.

ipcp-accept-remote

With this option, pppd accepts the peer's idea of its remote IP address, even if the remote IP address is specified in an option.

ipcp-max-configure *n*

Set the maximum number of IPCP Configure-Request transmissions to *n* (default 10).

ipcp-max-failure *n*

Set the maximum number of IPCP Configure-NAKs sent before sending Configure-Rejects instead to *n* (default 10).

ipcp-max-terminate *n*

Set the maximum number of IPCP terminate-request transmissions to *n* (default 3).

ipcp-restart *n*

Set the IPCP restart interval (retransmission timeout) to *n* seconds (default 3).

ipparam *string*

Provides an extra parameter to the ip-up and ip-down scripts. When this option is given, the *string* supplied is given as the sixth parameter to those scripts. See the Scripts section.

ipv6 *<local_interface_identifier>,<remote_interface_identifier>*

Set the local and/or remote 64-bit interface identifier. Either one may be omitted. The identifier must be specified in standard ASCII notation of IPv6 addresses (for example: ::dead:beef). If the ipv6cp-use-ipaddr option is given, the local and remote identifiers are derived from the respective IPv4 addresses (see above). The ipv6cp-use-persistent option can be used instead of the ipv6 <local>,<remote> option.

ipv6cp-accept-local

Accept peer's interface identifier for the local link identifier.

ipv6cp-max-configure *n*

Set the maximum number of IPv6CP Configure-Request transmissions to *n* (default 10).

ipv6cp-max-failure *n*

Set the maximum number of IPv6CP Configure-NAKs sent before sending Configure-Rejects instead to *n* (default 10).

ipv6cp-max-terminate *n*

Set the maximum number of IPv6CP terminate-request transmissions to *n* (default 3).

ipv6cp-restart *n*

Set the IPv6CP restart interval (retransmission timeout) to *n* seconds (default 3).

ipv6cp-use-ipaddr

If either the local or remote IPv6 address is unspecified, use the corresponding configured IPv4 address as a default interface identifier. (This option uses the configured addresses, not the negotiated addresses. Do not use it with ipcp-accept-local if the local IPv6 identifier is unspecified or with ipcp-accept-remote if the remote IPv6 identifier is unspecified.)

ipv6cp-use-persistent

Use uniquely-available persistent value for link local address.

kdebug *n*

Enable debugging code in the kernel-level PPP driver. Argument *n* is the sum of the following values: 1 to enable general debug messages, 2 to request that contents of received

packets be printed, and 4 to request contents of transmitted packets be printed. Messages printed by the kernel are logged by syslogd(1M) to a file directed in the /etc/syslog.conf configuration file. Do not use the kdebug option to debug failed links. Use the debug option instead.

lcp-echo-failure *n*

If this option is given, pppd presumes the peer to be dead if *n* LCP Echo-Requests are sent without receiving a valid LCP Echo-Reply. If this happens, pppd terminates the connection. This option requires a non-zero value for the lcp-echo-interval parameter. This option enables pppd to terminate after the physical connection is broken (for example, if the modem has hung up) in situations where no hardware modem control lines are available.

lcp-echo-interval *n*

If this option is given, pppd sends an LCP Echo-Request frame to the peer every *n* seconds. Normally the peer responds to the Echo-Request by sending an Echo-Reply. This option can be used with the lcp-echo-failure option to detect that the peer is no longer connected.

lcp-max-configure *n*

Set the maximum number of LCP Configure-Request transmissions to *n* (default 10).

lcp-max-failure *n*

Set the maximum number of LCP Configure-NAKs sent before starting to send Configure-Rejects instead to *n* (default 10).

lcp-max-terminate *n*

Set the maximum number of LCP Terminate-Request transmissions to *n* (default 3).

lcp-restart *n*

Set the LCP restart interval (retransmission timeout) to *n* seconds (default 3).

linkname *name*

Sets the logical name of the link to *name*. pppd creates a file named ppp-*name*.pid in /var/run containing its process ID. This is useful in determining which instance of pppd is responsible for the link to a given peer system. This is a privileged option.

local

Do not use modem control lines. With this option, pppd ignores the state of the CD (Carrier Detect) signal from the modem and does not change the state of the DTR (Data Terminal Ready) signal.

logfd *n*

Send log messages to file descriptor *n*. pppd sends log messages to (at most) one file or file descriptor (as well as sending the log messages to syslog), so this option and the logfile option are mutually exclusive. By default pppd sends log messages to stdout (file descriptor 1) unless the serial port is open on stdout.

logfile *filename*

Append log messages to the file *filename* (and send the log messages to syslog). The file is opened in append mode with the privileges of the user who invoked pppd.

login

Use the system password database for authenticating the peer using PAP, and record the user in the system wtmp file. Note that the peer must have an entry in the /etc/ppp/pap-secrets file and the system password database to be allowed access.

maxconnect *n*

Terminate the connection after it has been available for network traffic for *n* seconds (that is, *n* seconds after the first network control protocol starts). An LCP Time-Remaining message is sent when the first NCP starts, and again when 5, 2, and 0.5 minutes are remaining.

maxfail *n*

Terminate after *n* consecutive failed connection attempts. A value of 0 means no limit. The default value is 10.

modem

Use the modem control lines. This option is the default. With this option, pppd waits for the CD (Carrier Detect) signal from the modem to be asserted when opening the serial device (unless a connect script is specified), and drops the DTR (Data Terminal Ready) signal briefly when the connection is terminated and before executing the connect script.

ms-dns <*addr*>

If pppd is acting as a server for Microsoft Windows clients, this option allows pppd to supply one or two DNS (Domain Name Server) addresses to the clients. The first instance of this option specifies the primary DNS address; the second instance (if given) specifies the secondary DNS address. If the first instance specifies a name that resolves to multiple IP addresses, then the first two addresses are used. (This option is present in some older versions of pppd under the name dns-addr.)

ms-lanman

If pppd connects as a client to a Microsoft server and uses MS-CHAPv1 for authentication, this option selects the LAN Manager password style instead of Microsoft NT.

ms-wins <*addr*>

If pppd acts as a server for Microsoft Windows or Samba clients, this option allows pppd to supply one or two WINS (Windows Internet Name Services) server addresses to the clients. The first instance of this option specifies the primary WINS address; the second instance (if given) specifies the secondary WINS address. As with ms-dns, if the name specified resolves to multiple IP addresses, then the first two will be taken as primary and secondary.

name *name*

Set the name of the local system for authentication purposes to *name*. This is a privileged option. With this option, pppd uses lines in the secrets files that have *name* as the second field to look for a secret to use in authenticating the peer. In addition, unless overridden with the user option, *name* is used as the name to send to the peer when authenticating the local system. (Note that pppd does not append the domain name to *name*.)

no-accm-test

Disable use of asyncmap (ACCM) checking using LCP Echo-Request messages. If the lcp-echo-failure is used on an asynchronous line, pppd includes all control characters in the first *n* LCP Echo-Request messages. If the asyncmap is set incorrectly, the link drops rather than continue operation with random failures. This option disables that feature.

noaccomp

Disable HDLC Address/Control compression in both directions (send and receive).

noauth

Do not require the peer to authenticate itself. This option is privileged.

nobsdcomp

Disables BSD-Compress compression; pppd will not request or agree to compress packets using the BSD-Compress scheme. This option is not necessary if noccp is specified.

noccp

Disable CCP (Compression Control Protocol) negotiation. This option should only be required if the peer has bugs or becomes confused by requests from pppd for CCP negotiation. If CCP is disabled, then BSD and deflate compression do not need to be separately disabled.

nocrtscts

Disable hardware flow control (i.e. RTS/CTS) on the serial port. If the crtscts, nocrtscts, cdtrcts or nocdtrcts options are not given, the hardware flow control setting for the serial port is left unchanged.

nocdtrcts

This option is a synonym for nocrtscts. Either option will disable both forms of hardware flow control.

nodefaultroute

Disable the defaultroute option. You can prevent non-root users from creating default routes with pppd by placing this option in the /etc/ppp/options file.

nodeflate

Disables deflate compression; pppd will not request or agree to compress packets using the deflate scheme. This option is not necessary if noccp is specified.

nodeflatedraft

Do not use Internet Draft (incorrectly assigned) algorithm number for deflate compression. This option is not necessary if noccp is specified.

nodetach

Do not detach from the controlling terminal. Without this option, pppd forks to become a background process if a serial device other than the terminal on the standard input is specified.

noendpoint

Do not send or accept the Multilink Endpoint Discriminator option.

noident

Disable use of LCP Identification. LCP Identification messages will not be sent to the peer, but received messages will be logged. (Specify this option twice to completely disable LCP Identification. In this case, pppd sends LCP Code-Reject in response to received LCP Identification messages.)

noip

Disable IPCP negotiation and IP communication. Use this option only if the peer has bugs or becomes confused by requests from pppd for IPCP negotiation.

noipv6

Disable IPv6CP negotiation and IPv6 communication. IPv6 is not enabled by default.

noipdefault

Disables the default behavior when no local IP address is specified, which is to determine (if possible) the local IP address from the hostname. With this option, the peer must supply the local IP address during IPCP negotiation (unless it specified explicitly on the command line or in an options file).

nolog

Do not send log messages to a file or file descriptor. This option cancels the logfd and logfile options. nologfd acts as an alias for this option.

nomagic

Disable magic number negotiation. With this option, pppd cannot detect a looped-back line. Use this option only if the peer has bugs. Do not use this option to work around the "Serial line is looped back" error message.

nopam

This privileged option disables use of pluggable authentication modules. If this option is specified, pppd reverts to standard authentication mechanisms. The default is not to use PAM.

nopcomp

Disable protocol field compression negotiation in the receive and the transmit direction.

nopersist

Exit once a connection has been made and terminated. This is the default unless the persist or demand option is specified.

noplink

Cause pppd to use I_LINK instead of I_PLINK. This is the default. When I_LINK is used, the system cleans up terminated interfaces (even when SIGKILL is used) but does not allow ifconfig(1M) to unplumb PPP streams or insert or remove modules dynamically. Use the plink option if ifconfig(1M) modinsert, modremove or unplumb support is needed.

nopredictor1

Do not accept or agree to Predictor-1 compression. (This option is accepted for compatibility. The implementation does not support Predictor-1 compression.)

noproxyarp

    Disable the proxyarp option. If you want to prevent users from creating proxy ARP entries with pppd, place this option in the /etc/ppp/options file.

notty

    Normally, pppd requires a terminal device. With this option, pppd allocates itself a pseudo-tty master/slave pair and uses the slave as its terminal device. pppd creates a child process to act as a character shunt to transfer characters between the pseudo-tty master and its standard input and output. Thus, pppd transmits characters on its standard output and receives characters on its standard input even if they are not terminal devices. This option increases the latency and CPU overhead of transferring data over the ppp interface as all of the characters sent and received must flow through the character shunt process. An explicit device name may not be given if this option is used.

novj

    Disable Van Jacobson style TCP/IP header compression in both the transmit and the receive direction.

novjccomp

    Disable the connection-ID compression option in Van Jacobson style TCP/IP header compression. With this option, pppd does not omit the connection-ID byte from Van Jacobson compressed TCP/IP headers, nor does it ask the peer to do so. This option is unnecessary if novj is specified.

pam

    This privileged option enables use of PAM. If this is specified, pppd uses the pam(3PAM) framework for user authentication with a service name of "ppp" if the login option and PAP authentication are used. The default is not to use PAM.

papcrypt

    Indicates that pppd should not accept a password which, before encryption, is identical to the secret from the /etc/ppp/pap-secrets file. Use this option if the secrets in the pap-secrets file are in crypt(3C) format.

pap-max-authreq *n*

    Set the maximum number of PAP authenticate-request transmissions to *n* (default 10).

pap-restart *n*

    Set the PAP restart interval (retransmission timeout) to *n* seconds (default 3).

pap-timeout *n*

    Set the maximum time that pppd waits for the peer to authenticate itself with PAP to *n* seconds (0= no limit). The default is 30 seconds.

password *string*

    Password string for authentication to the peer.

persist

    Do not exit after a connection is terminated; instead try to reopen the connection.

plink

Cause pppd to use I_PLINK instead of I_LINK. The default is to use I_LINK, which cleans up terminated interface (even if SIGKILL is used), but does not allow ifconfig(1M) to unplumb PPP streams or insert or remove modules dynamically. Use this option if ifconfig(1M) modinsert/modremove/unplumb support is needed. See also the plumbed option.

plugin *filename*

Load the shared library object file *filename* as a plugin. This is a privileged option. Unless the filename specifies an explicit path, /etc/ppp/plugins and /usr/lib/inet/ppp will be searched for the object to load in that order.

plumbed

This option indicates that pppd should find a plumbed interface and use that for the session. If IPv4 addresses or IPv6 interface IDs or link MTU are otherwise unspecified, they are copied from the interface selected. This mode mimics some of the functionality of the older aspppd implementation and may be helpful when pppd is used with external applications that use ifconfig(1M).

pppmux *timer*

Enable PPP Multiplexing option negotiation and set transmit multiplexing timeout to *timer* microseconds.

privgroup *group-name*

Allows members of group *group-name* to use privileged options. This is a privileged option. Because there is no guarantee that members of *group-name* cannot use pppd to become root themselves, you should be careful using this option. Consider it equivalent to putting the members of *group-name* in the root or sys group.

proxyarp

Add an entry to the system's Address Resolution Protocol (ARP) table with the IP address of the peer and the Ethernet address of this system. When you use this option, the peer appears to other systems to be on the local Ethernet. The remote address on the PPP link must be in the same subnet as assigned to an Ethernet interface.

pty *script*

Specifies that the command *script*, and not a specific terminal device is used for serial communication. pppd allocates itself a pseudo-tty master/slave pair and uses the slave as its terminal device. *script* runs in a child process with the pseudo-tty master as its standard input and output. An explicit device name may not be given if this option is used. (Note: if the record option is used in conjunction with the pty option, the child process will have pipes on its standard input and output.)

receive-all

With this option, pppd accepts all control characters from the peer, including those marked in the receive asyncmap. Without this option, pppd discards those characters as specified in *RFC 1662*. This option should be used only if the peer has bugs, as is often found with dial-back implementations.

record *filename*
> Directs pppd to record all characters sent and received to a file named *filename*. *filename* is opened in append mode, using the user's user-ID and permissions. Because this option uses a pseudo-tty and a process to transfer characters between the pseudo-tty and the real serial device, it increases the latency and CPU overhead of transferring data over the PPP interface. Characters are stored in a tagged format with timestamps that can be displayed in readable form using the pppdump(1M) program. This option is generally used when debugging the kernel portion of pppd (especially CCP compression algorithms) and not for debugging link configuration problems. See the debug option.

remotename *name*
> Set the assumed name of the remote system for authentication purposes to *name*. Microsoft WindowsNT does not provide a system name in its CHAP Challenge messages, and this option is often used to work around this problem.

refuse-chap
> With this option, pppd will not agree to authenticate itself to the peer using standard Challenge Handshake Authentication Protocol (CHAP). (MS-CHAP is not affected.)

refuse-mschap
> Do not agree to authenticate to peer with MS-CHAPv1. If this option is specified, requests for MS-CHAPv1 authentication from the peer are declined with LCP Configure-Nak. That option does not disable any other form of CHAP.

refuse-mschapv2
> Do not agree to authenticate to peer with MS-CHAPv2. If specified, this option requests that MS-CHAPv2 authentication from the peer be declined with LCP Configure-Nak. That option does not disable any other form of CHAP.

refuse-pap
> With this option, pppd will not agree to authenticate itself to the peer using Password Authentication Protocol (PAP).

require-chap
> Require the peer to authenticate itself using standard CHAP authentication. MS-CHAP is not affected.

require-mschap
> Require the peer to authenticate itself using MS-CHAPv1 authentication.

require-mschapv2
> Require the peer to authenticate itself using MS-CHAPv2 authentication.

require-pap
> Require the peer to authenticate itself using PAP authentication.

show-password
> When logging contents of PAP packets, this option causes pppd to show the password string in the log message.

silent

  With this option, pppd will not transmit LCP packets to initiate a connection until a valid
  LCP packet is received from the peer. This is like the "passive" option with older versions of
  pppd and is retained for compatibility, but the current passive option is preferred.

small-accm-test

  When checking the asyncmap (ACCM) setting, pppd uses all 256 possible values by default.
  See no-accm-test. This option restricts the test so that only the 32 values affected by
  standard ACCM negotiation are tested. This option is useful on very slow links.

socket *host*:*port*

  Connect to given host and port using TCP and run PPP over this connection.

sync

  Use synchronous HDLC serial encoding instead of asynchronous. The device used by pppd
  with this option must have sync support. Currently supports zs, se, and hsi drivers.

unit *n*

  Set PPP interface unit number to *n*, if possible.

updetach

  With this option, pppd detaches from its controlling terminal after establishing the PPP
  connection. When this is specified, messages sent to stderr by the connect script, usually
  chat(1M), and debugging messages from the debug option are directed to pppd's standard
  output.

usehostname

  Enforce the use of the hostname with domain name appended, if given, as the name of the
  local system for authentication purposes. This overrides the name option. Because the name
  option is privileged, this option is normally not needed.

usepeerdns

  Ask the peer for up to two DNS server addresses. Addresses supplied by the peer, if any, are
  passed to the /etc/ppp/ip-up script in the environment variables DNS1 and DNS2. In
  addition, pppd creates an /etc/ppp/resolv.conf file containing one or two nameserver
  lines with the address(es) supplied by the peer.

user *name*

  Sets the name used for authenticating the local system to the peer to *name*.

vj-max-slots *n*

  Sets the number of connection slots to be used by the Van Jacobson TCP/IP header
  compression and decompression code to *n*, which must be between 2 and 16 (inclusive).

welcome *script*

  Run the executable or shell command specified by *script* before initiating PPP negotiation,
  after the connect script, if any, has completed. A value for this option from a privileged
  source cannot be overridden by a non-privileged user.

xonxoff

Use software flow control, that is, XON/XOFF, to control the flow of data on the serial port.

Obsolete Options   The following options are obsolete:

+ua *name*   Read a PAP user name and password from the file *name*. This file must have
                  two lines for name and password. Name and password are sent to the peer
                  when the peer requests PAP authentication.

+ipv6   Enable IPv6 and IPv6CP without specifying interface identifiers.

--version   Show version number and exit.

--help   Show brief help message and exit.

Extended   The following sections discuss miscellaneous features of pppd:
Description

Security   pppd allows system administrators to provide legitimate users with PPP access to a server
           machine without fear of compromising the security of the server or the network it runs on.
           Access control is provided by restricting IP addresses the peer may use based on its
           authenticated identity (if any), and through restrictions on options a non-privileged user may
           use. Options that permit potentially insecure configurations are privileged. Privileged options
           are accepted only in files that are under the control of the system administrator or when pppd
           is being run by root.

           By default, pppd allows an unauthenticated peer to use a given IP address only if the system
           does not already have a route to that IP address. For example, a system with a permanent
           connection to the wider Internet will normally have a default route, meaning all peers must
           authenticate themselves to set up a connection. On such a system, the auth option is the
           default. Conversely, a system with a PPP link that comprises the only connection to the
           Internet probably does not possess a default route, so the peer can use virtually any IP address
           without authenticating itself.

           Security-sensitive options are privileged and cannot be accessed by a non-privileged user
           running pppd, either on the command line, in the user's $HOME/.ppprc file, or in an options
           file read using the file option. Privileged options may be used in /etc/ppp/options file or in
           an options file read using the call option. If pppd is run by the root user, privileged options
           can be used without restriction. If the /etc/ppp/options file does not exist, then only root
           may invoke pppd. The /etc/ppp/options file must be created (but may be empty) to allow
           ordinary non-root users to access pppd.

           When opening the device, pppd uses the invoking user's user ID or the root UID (that is, 0),
           depending if the device name was specified by the user or the system administrator. If the
           device name comes from a privileged source, that is, /etc/ppp/options or an options file read
           using the call option, pppd uses full root privileges when opening the device. Thus, by
           creating an appropriate file under /etc/ppp/peers, the system administrator can allow users

to establish a PPP connection via a device that they would not normally have access to. Otherwise pppd uses the invoking user's real UID when opening the device.

Authentication   During the authentication process, one peer convinces the other of its identity by sending its name and some secret information to the other. During authentication, the first peer becomes the "client" and the second becomes the "server." Authentication names can (but are not required to) correspond to the peer's Internet hostnames.

pppd supports four authentication protocols: the Password Authentication Protocol (PAP) and three forms of the Challenge Handshake Authentication Protocol (CHAP). With the PAP protocol, the client sends its name and a cleartext password to the server to authenticate itself. With CHAP, the server initiates the authentication exchange by sending a challenge to the client who must respond with its name and a hash value derived from the shared secret and the challenge.

The PPP protocol is symmetrical, meaning that each peer may be required to authenticate itself to the other. Different authentication protocols and names can be used for each exchange.

By default, pppd authenticates if requested and does not require authentication from the peer. However, pppd does not authenticate itself with a specific protocol if it has no secrets that can do so.

pppd stores authentication secrets in the /etc/ppp/pap-secrets (for PAP), and /etc/ppp/chap-secrets (for CHAP) files. Both files use the same format. pppd uses secrets files to authenticate itself to other systems and to authenticate other systems to itself.

Secrets files contain one secret per line. Secrets are specific to a particular combination of client and server and can only be used by that client to authenticate itself to that server. Each line in a secrets file has a minimum of three fields that contain the client and server names followed by the secret. Often, these three fields are followed by IP addresses that are used by clients to connect to a server.

A secrets file is parsed into words, with client name, server name and secrets fields allocated one word each. Embedded spaces or other special characters within a word must be quoted or escaped. Case is significant in all three fields.

A secret beginning with an at sign ("@") is followed by the name of a file containing the secret. An asterisk (*) as the client or server name matches any name. When choosing a match, pppd selects the one with the fewest wildcards. Succeeding words on a line are interpreted by pppd as acceptable IP addresses for that client. IP Addresses are disallowed if they appear in lines that contain only three words or lines whose first word begins with a hyphen ("-"). To allow any address, use "*". An address starting with an exclamation point ("!") indicates that the specified address is not acceptable. An address may be followed by "/" and a number *n* to indicate a whole subnet (all addresses that have the same value in the most significant *n* bits).

In this form, the address may be followed by a plus sign ("+") to indicate that one address from the subnet is authorized, based on the ppp network interface unit number in use. In this case, the host part of the address is set to the unit number, plus one.

When authenticating the peer, pppd chooses a secret with the peer's name in the first field of the secrets file and the name of the local system in the second field. The local system name defaults to the hostname, with the domain name appended if the domain option is used. The default can be overridden with the name option unless the usehostname option is used.

When authenticating to the peer, pppd first determines the name it will use to identify itself to the peer. This name is specified with the user option. If the user option is not used, the name defaults to the host name of the local system. pppd then selects a secret from the secrets file by searching for an entry with a local name in the first field and the peer's name in the second field. pppd will know the name of the peer if standard CHAP authentication is used because the peer will have sent it in the Challenge packet. However, if MS-CHAP or PAP is being used, pppd must determine the peer's name from the options specified by the user. The user can specify the peer's name directly with the remotename option. Otherwise, if the remote IP address was specified by a name, rather than in numeric form, that name will be used as the peer's name. If that fails, pppd uses the null string as the peer's name.

When authenticating the peer with PAP, the supplied password is compared with data in the secrets file. If the password and secret do not match, the password is encrypted using crypt() and checked against the secret again. If the papcrypt option is given, the first unencrypted comparison is omitted for better security, and entries must thus be in encrypted crypt(3C) form.

If the login option is specified, the username and password are also checked against the system password database. This allows you to set up the pap-secrets file to enable PPP access only to certain users, and to restrict the set of IP addresses available to users. Typically, when using the login option, the secret in /etc/ppp/pap-secrets would be "", which matches any password supplied by the peer. This makes having the same secret in two places unnecessary. When login is used, the pam option enables access control through pam(3PAM).

Authentication must be completed before IPCP (or other network protocol) can be started. If the peer is required to authenticate itself and fails, pppd closes LCP and terminates the link. If IPCP negotiates an unacceptable IP address for the remote host, IPCP is closed. IP packets are sent or received only when IPCP is open.

To allow hosts that cannot authenticate themselves to connect and use one of a restricted set of IP addresses, add a line to the pap-secrets file specifying the empty string for the client name and secret.

Additional pppd options for a given peer may be specified by placing them at the end of the secrets entry, separated by two dashes (––). For example

```
peername servername secret ip-address -- novj
```

Routing   When IPCP negotiation is complete, pppd informs the kernel of the local and remote IP
           addresses for the PPP interface and creates a host route to the remote end of the link that
           enables peers to exchange IP packets. Communication with other machines generally requires
           further modification to routing tables and/or Address Resolution Protocol (ARP) tables. In
           most cases the defaultroute and/or proxyarp options are sufficient for this, but further
           intervention may be necessary. If further intervention is required, use the /etc/ppp/ip-up
           script or a routing protocol daemon.

           To add a default route through the remote host, use the defaultroute option. This option is
           typically used for "client" systems; that is, end-nodes that use the PPP link for access to the
           general Internet.

           In some cases it is desirable to use proxy ARP, for example on a server machine connected to a
           LAN, to allow other hosts to communicate with the remote host. proxyarp instructs pppd to
           look for a network interface on the same subnet as the remote host. That is, an interface
           supporting broadcast and ARP that is not a point-to-point or loopback interface and that is
           currently up. If found, pppd creates a permanent, published ARP entry with the IP address of
           the remote host and the hardware address of the network interface.

           When the demand option is used, the interface IP addresses are already set at the time when
           IPCP comes up. If pppd cannot negotiate the same addresses it used to configure the interface,
           it changes the interface IP addresses to the negotiated addresses. This may disrupt existing
           connections. Using demand dialing with peers that perform dynamic IP address assignment is
           not recommended.

Scripts   pppd invokes scripts at various stages during processing that are used to perform site-specific
           ancillary processing. These scripts may be shell scripts or executable programs. pppd does not
           wait for the scripts to finish. The scripts are executed as root (with the real and effective
           user-id set to 0), enabling them to update routing tables, run privileged daemons, or perform
           other tasks. Be sure that the contents of these scripts do not compromise your system's
           security. pppd runs the scripts with standard input, output and error redirected to /dev/null,
           and with an environment that is empty except for some environment variables that give
           information about the link. The pppd environment variables are:

           DEVICE   Name of the serial tty device.

           IFNAME   Name of the network interface.

           IPLOCAL   IP address for the link's local end. This is set only when IPCP has started.

           IPREMOTE   IP address for the link's remote end. This is set only when IPCP has started.

           PEERNAME   Authenticated name of the peer. This is set only if the peer authenticates
                         itself.

           SPEED   Baud rate of the tty device.

           ORIG_UID   Real user-id of user who invoked pppd.

PPPLOGNAME   Username of the real user-id who invoked pppd. This is always set.

pppd also sets the following variables for the ip-down and auth-down scripts:

CONNECT_TIME   Number of seconds between the start of PPP negotiation and connection termination.

BYTES_SENT   Number of bytes sent at the level of the serial port during the connection.

BYTES_RCVD   Number of bytes received at the level of the serial port during the connection.

LINKNAME   Logical name of the link, set with the linkname option.

If they exist, pppd invokes the following scripts. It is not an error if they do not exist.

/etc/ppp/auth-up   Program or script executed after the remote system successfully authenticates itself. It is executed with five command-line arguments: interface-name peer-name user-name tty-device speed. Note that this script is not executed if the peer does not authenticate itself, for example, when the noauth option is used.

/etc/ppp/auth-down   Program or script executed when the link goes down if /etc/ppp/auth-up was previously executed. It is executed in the same manner with the same parameters as /etc/ppp/auth-up.

/etc/ppp/ip-up   A program or script that is executed when the link is available for sending and receiving IP packets (that is, IPCP has come up). It is executed with six command-line arguments: interface-name tty-device speed local-IP-address remote-IP-address ipparam.

/etc/ppp/ip-down   A program or script which is executed when the link is no longer available for sending and receiving IP packets. This script can be used for undoing the effects of the /etc/ppp/ip-up script. It is invoked in the same manner and with the same parameters as the ip-up script.

/etc/ppp/ipv6-up   Similar to /etc/ppp/ip-up, except that it is executed when the link is available for sending and receiving IPv6 packets. Executed with six command-line arguments: interface-name tty-device speed local-link-local-address remote-link-local-address ipparam.

/etc/ppp/ipv6-down   Similar to /etc/ppp/ip-down, but executed when IPv6 packets can no longer be transmitted on the link. Executed with the same parameters as the ipv6-up script.

Examples   **EXAMPLE 1**   Using the auth Option

The following examples assume that the /etc/ppp/options file contains the auth option.

EXAMPLE 1 Using the auth Option   *(Continued)*

pppd is commonly used to dial out to an ISP. You can do this using the "pppd call isp"
command where the /etc/ppp/peers/isp file is set up to contain a line similar to the
following:

```
cua/a 19200 crtscts connect '/usr/bin/chat -f /etc/ppp/chat-isp' noauth
```

For this example, chat(1M) is used to dial the ISP's modem and process any login sequence
required. The /etc/ppp/chat-isp file is used by chat and could contain the following:

```
ABORT "NO CARRIER"
ABORT "NO DIALTONE"
ABORT "ERROR"
ABORT "NO ANSWER"
ABORT "BUSY"
ABORT "Username/Password Incorrect"
"" "at"
OK "at&f&d2&c1"
OK "atdt2468135"
"name:" "^Umyuserid"
"word:" "\qmypassword"
"ispts" "\q^Uppp"
"~-^Uppp-~"
```

See the chat(1M) man page for details of chat scripts.

EXAMPLE 2 Using pppd with proxyarp

pppd can also provide a dial-in ppp service for users. If the users already have login accounts,
the simplest way to set up the ppp service is to let the users log in to their accounts and run
pppd as shown in the following example:

```
example% pppd proxyarp
```

EXAMPLE 3 Providing a User with Access to PPP Facilities

To provide a user with access to the PPP facilities, allocate an IP address for the user's
machine, create an entry in /etc/ppp/pap-secrets or /etc/ppp/chap-secrets. This enables
the user's machine to authenticate itself. For example, to enable user "Joe" using machine
"joespc" to dial in to machine "server" and use the IP address "joespc.my.net," add the
following entry to the /etc/ppp/pap-secrets or /etc/ppp/chap-secrets files:

```
joespc     server     "joe's secret"     joespc.my.net
```

Alternatively, you can create another username, for example "ppp," whose login shell is
/usr/bin/pppd and whose home directory is /etc/ppp. If you run pppd this way, add the
options to the /etc/ppp/.ppprc file.

EXAMPLE 3 Providing a User with Access to PPP Facilities   *(Continued)*

If your serial connection is complex, it may be useful to escape such control characters as XON (^Q) and XOFF (^S), using asyncmap a0000. If the path includes a telnet, escape ^] (asyncmap 200a0000). If the path includes a rlogin command, add escape ff option to the options, because rlogin removes the window-size-change sequence [0xff, 0xff, 0x73, 0x73, followed by any 8 bytes] from the stream.

Exit Status   The pppd exit status indicates errors or specifies why a link was terminated. Exit status values are:

0   pppd has detached or the connection was successfully established and terminated at the peer's request.

1   An immediately fatal error occurred. For example, an essential system call failed.

2   An error was detected in the options given. For example, two mutually exclusive options were used, or /etc/ppp/options is missing and the user is not root.

3   pppd is not setuid-root and the invoking user is not root.

4   The kernel does not support PPP. For example, the PPP kernel driver is not included or cannot be loaded.

5   pppd terminated because it was sent a SIGINT, SIGTERM or SIGHUP signal.

6   The serial port could not be locked.

7   The serial port could not be opened.

8   The connect script failed and returned a non-zero exit status.

9   The command specified as the argument to the pty option could not be run.

10   The PPP negotiation failed because no network protocols were able to run.

11   The peer system failed or refused to authenticate itself.

12   The link was established successfully, but terminated because it was idle.

13   The link was established successfully, but terminated because the connect time limit was reached.

14   Callback was negotiated and an incoming call should arrive shortly.

15   The link was terminated because the peer is not responding to echo requests.

16   The link was terminated by the modem hanging up.

17   The PPP negotiation failed because serial loopback was detected.

18   The init script failed because a non-zero exit status was returned.

19   Authentication to the peer failed.

Files

/var/run/spppn.pid	Process-ID for pppd process on PPP interface unit *n*.
/var/run/ppp-*name*.pid	Process-ID for pppd process for logical link name (see the linkname option).
/etc/ppp/pap-secrets	Usernames, passwords and IP addresses for PAP authentication. This file should be owned by root and not readable or writable by any other user, otherwise pppd will log a warning.
/etc/ppp/chap-secrets	Names, secrets and IP addresses for all forms of CHAP authentication. The /etc/ppp/pap-secrets file should be owned by root should not readable or writable by any other user, otherwise, pppd will log a warning.
/etc/ppp/options	System default options for pppd, read before user default options or command-line options.
$HOME/.ppprc	User default options, read before /etc/ppp/options.*ttyname*.
/etc/ppp/options.*ttyname*	System default options for the serial port in use; read after $HOME/.ppprc. The *ttyname* component of this filename is formed when the initial /dev/ is stripped from the port name (if present), and slashes (if any) are converted to dots.
/etc/ppp/peers	Directory with options files that may contain privileged options, even if pppd was invoked by a user other than root. The system administrator can create options files in this directory to permit non-privileged users to dial out without requiring the peer to authenticate, but only to certain trusted peers.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/ppp
Interface Stability	Committed

Simpson, W. *RFC 1662, HDLC-like Framing* . Network Working Group. July 1994.

Notes These signals affect pppd behavior:

SIGINT, SIGTERM	Terminate the link, restore the serial device settings and exit.
SIGHUP	Terminate the link, restore the serial device settings and close the serial device. If the persist or demand option is specified, pppd attempts to reopen the serial device and start another connection after the holdoff period. Otherwise pppd exits. If received during the holdoff period, SIGHUP causes pppd to end the holdoff period immediately.
SIGUSR1	Toggles the state of the debug option and prints link status information to the log.
SIGUSR2	Causes pppd to renegotiate compression. This is useful to re-enable compression after it has been disabled as a result of a fatal decompression error. (Fatal decompression errors generally indicate a bug in an implementation.)

Diagnostics Messages are sent to the syslog daemon using facility LOG_DAEMON. To see error and debug messages, edit the /etc/syslog.conf file to direct the messages to the desired output device or file, or use the updetach or logfile options.

The debug option causes the contents of all LCP, PAP, CHAP or IPCP control packets sent or received to be logged. This is useful if PPP negotiation does not succeed or if authentication fails.

Debugging can also be enabled or disabled by sending a SIGUSR1 signal, which acts as a toggle to the pppd process.

Name pppoec – PPPoE chat utility

Synopsis pppoec [-o*millisecs*] [-s*millisecs*] [-v] *device*
          [*service* [[except]*server*... [only]]]

pppoec [-o*millisecs*] [-v] -i [*device*]

Description The pppoec utility implements the client-side negotiation of PPPoE. It is intended to be used with the pppd(1M) connect option, in the same manner as the chat(1M) utility is used for asynchronous dial-up PPP.

When given with the -i flag, pppoec sends out a broadcast query on the given interface named by the *device* parameter. You can specify no other arguments in this mode. All responding PPPoE servers and the offered services are displayed on standard output.

Otherwise, when given without the -i flag, pppoec does the full PPPoE client-side negotiation. The *device* parameter is the intended Ethernet interface, and must already be plumbed with sppptun(1M). The optional *service* parameter specifies a particular service desired; other offered services will be ignored. The optional *server* parameter specifies a specific server desired. You can specify *server* as an Ethernet address in the usual x:x:x:x:x:x format (with "*" in any of the six byte positions interpreted to mean "any"), or as a symbolic name resolved through /etc/ethers (or NIS), or as a PPPoE access concentrator name. The sense of the match (true or false) can be inverted by specifying the keyword except before this string. This parameter can be specified more than once, and the first match is taken.

If you specify the *server* parameter, then the selected servers become "preferred." If no preferred server responds, then the first responding server is used instead. To exclude non-matching servers entirely, append the keyword only.

Options The following options are supported:

-i   Sends out broadcast query over interface specified by *device*.

-o   Sets the initial wait time in milliseconds for PADO from the server before PADI is retried. The default is 500 milliseconds for normal operation, or 3000 milliseconds (3 seconds) for inquiry (-i) mode.

-s   Sets the initial wait time in milliseconds for PADS from the server before PADR is retried. The default is 2000 milliseconds (2 seconds).

-v   Displays verbose progress messages, including all PPPoE messages sent, and all state machine transitions.

You normally do not need to adjust the parameters set with -o and -s. They are provided for coping with unusually slow servers.

Operands The following operands are supported:

device   plumbed Ethernet interface

server   preferred server or, if you specify `only`, the specified server

service   desired service; other available services are ignored

Examples   EXAMPLE 1   Connecting to Any Service on hme0

The following command enables you to connect to any PPPoE service on hme0:

```
# /usr/bin/pppd spptun plugin pppoe.so \
connect "/usr/lib/inet/pppoec hme0" debug
```

Often, a command such as the preceding is specified in an /etc/ppp/peers file instead. For example, enter the following in /etc/ppp/peers/myisp:

```
spptun
plugin pppoe.so
connect "/usr/lib/inet/pppoec hme0"
debug
```

To invoke the PPP connection described in the file, enter:

```
% /usr/bin/pppd call myisp
```

Note that, because the /etc/ppp/peers files are considered privileged by pppd, you need not be root to invoke the preceding command.

EXAMPLE 2   Connecting to a Particular Service

A more complex example: on hme0, connect to only the internet service offered by PPPoE servers with access concentrator name isp, but not to any Ethernet addresses starting with 40:0:1a.

`# /usr/lib/inet/pppoec hme0 internet except 40:0:1a:*:*:* isp only`

Note that the except 40:0:1a:*:*:* filter must come before isp, because the filters are first-match.

Exit Status   The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Files   /usr/lib/inet/pppoec   executable command

        /dev/spptun   Solaris PPP tunneling device driver.

        /etc/ppp/connect-errors   usual location of error output (see DIAGNOSTICS, below)

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/ppp/tunnel

See Also pppd(1M), sppptun(1M), pppoed(1M), sppptun(7M)

RFC 2516, Method for Transmitting PPP Over Ethernet (PPPoE), Mamakos et al, February 1999

Diagnostics Error messages are written to standard error, which is normally redirected by pppd to /etc/ppp/connect-errors. The errors can also be redirected to pppd's standard output by using the updetach option.

If you specify the -v, verbose progress messages are displayed, including all PPPoE messages sent, and all state machine transitions. Specifying the updetach or nodetach pppd option is helpful when using verbose mode.

Name pppoed – PPPoE server daemon

Synopsis ppoed [*options*]

Description The pppoed daemon implements the server-side negotiation of PPPoE. When a client requests service from this daemon, a copy of pppd(1M) is invoked to handle the actual PPP communication.

At startup, options are read from the command line and the /etc/ppp/pppoe file. After these options have been read, options in the per-device /etc/ppp/pppoe.*device* files are read, using the device names specified on the command line or in /etc/ppp/pppoe. Device names are not permitted in the per-device files. It is not an error if any of these files are absent; missing files are ignored.

Options are reread in the same order on SIGHUP. Except for the possibility of short delays due to the processing time, SIGHUP does not interfere with any client operations. Current status, including options read, is dumped to /tmp/pppoed.*pid* on SIGINT.

The options are used to set up a list of services to be offered to PPPoE clients on the broadcast domains (Ethernet subnets) specified by the named devices. Option parsing is always in one of two modes, either global mode or service mode. The initial mode at the beginning of each file (and the command line) is global mode. Options specified in global mode serve as default values for subsequently defined services. Service mode is entered by the service *name* option. In this mode, the named option is defined. Options that appear in this mode override any global mode definitions for the current service.

The option parsing follows standard shell tokenizing rules, using whitespace to delimit tokens, quotes to enclose strings that can contain whitespace, and escape sequences for special characters. Environment variables are substituted using familiar $VAR and ${VAR} syntax and set using NEWVAR=*string*. Variables are both usable in subsequent options and provided to the pppd(1M) processes spawned for each client, but they are interpreted as they are encountered during option processing. Thus, all set variables are seen by all processes spawned; position in the configuration files has no effect on this.

Options The pppoed daemon supports the following options:

client [except] *client-list* This option restricts the clients that may receive the service. If the except keyword is given, then the clients on the list cannot access the service, but others can. If this keyword is not given, then only the listed clients can access the service.

This option can be specified more than once for a given service. For a given client, first match among all listed options encountered specifies the handling. If it matches an option with except specified, then access is denied. Otherwise, it is granted. The client list within a service is prepended to any list specified in the global context.

If no `client` options are given or if all options are specified
with `except`, then all clients are permitted by default. If any
`client` options without `except` are specified, then no clients
are permitted by default.

The *client-list* is a comma-separated list of client identifiers.
The match is made if any client on the list matches; thus, these
are logically "ORed" together. Each client identifier can be
either a symbolic name (resolved through `/etc/ethers` or
NIS, as defined by `/etc/nsswitch.conf`) or a hexadecimal
Ethernet address in the format `x:x:x:x:x:x`. In the latter case,
any byte of the address can be "*", which matches any value in
that position. For example, `40:0:1a:*:*:*` matches Ethernet
adapters from the manufacturer assigned block `40:0:1a`.

debug	Increase debug logging detail level by one. The detail levels are 0 (no logging), 1 (errors only; the default), 2 (warnings), 3 (informational messages), and 4 (debug messages). Log messages are written by default to syslog(3C) using facility *daemon* (see the `log` option below). When specified on the command line or in the global context of the `/etc/ppp/pppoe` file, this option also sets the daemon's default (non-service-related) detail level.
device *device-list*	Specify the devices on which the service is available. The *device-list* is a comma-separated list of logical device names (without the leading `/dev/`), such as `hme0`. This option is ignored if encountered in the per-device `/etc/ppp/pppoe.`*device* files.
extra *string*	Specifies extra options to pppd(1M). It defaults to "plugin pppoe.so directtty" and usually does not need to be overridden.
file *path*	Suspends parsing of the current file, returns to global mode, and reads options from *path*. This file must be present and readable; if it is not, an error is logged. When the end of that file is reached, processing returns to the current file and the mode is reset to global again.

The global mode options specified in files read by this
command use the options set in the current file's global mode;
this condition extends to any file included by those files. All
files read are parsed as though the command line had specified
this option, and thus inherit the command line's global modes.

	This option can be used to revert to global mode at any point in an option file by specifying file /dev/null.
group *name*	Specifies the group ID (symbolic or numeric) under which pppd is executed. If pppoed is not run as root, this option is ignored.
log *path*	Specifies an alternate debug logging file. Debug messages are sent to this file instead of syslog. The special name syslog is recognized to switch logging back to syslog. When specified on the command line or in the global context of the /etc/ppp/pppoe file, this option also sets the daemon's default (non-service-related) log file.
nodebug	Set debug logging detail level to 0 (no logging). When specified on the command line or in the global context of the /etc/ppp/pppoe file, this option also sets the daemon's default (non-service-related) detail level.
nowildcard	Specifies that the current service should not be included in response to clients requesting "any" service. The client must ask for this service by name. When specified on the command line or in the global context of the /etc/ppp/pppoe file, this option causes pppoed to ignore all wildcard service requests.
path *path*	Specifies the path to the pppd executable. Defaults to /usr/bin/pppd.
pppd *string*	Passes command-line arguments to pppd. It can be used to set the IP addresses or configure security for the session. The default value is the empty string.
server *string*	Specifies the PPPoE Access Concentrator name to be sent to the client. It defaults to "Solaris PPPoE".
service *name*	Closes any service being defined and begins definition of a new service. The same service name can be used without conflict on multiple devices. If the same service name is used on a single device, then the last definition encountered during parsing overrides all previous definitions.
user *name*	Specifies the user ID, symbolic or numeric, under which pppd is executed. If pppoed is not run as root, this option is ignored.
wildcard	Specifies that the service should be included in responses to client queries that request "any" service, which is done by requesting a service name of length zero. When specified on the command line or in the global context of the

/etc/ppp/pppoe file, this option causes pppoed to ignore all
wildcard service requests. This is the default.

Examples   EXAMPLE 1   Configuring for Particular Services

In the /etc/ppp/pppoe file:

```
service internet
    device $DEV
    pppd "proxyarp 192.168.1.1:"
service debugging
    device hme0,$DEV
    pppd "debug proxyarp 192.168.1.1:"
```

You then invoke the daemon with:

```
example% /usr/lib/inet/pppoed DEV=eri0
```

The lines in /etc/ppp/pppoe and the preceding command result in offering services
"internet" and "debugging" (and responding to wildcard queries) on interface eri0, and
offering only service "debugging" on interface hme0.

Signals   The pppoed daemon responds to the following signals:

SIGHUP   Causes pppoed to reparse the original command line and all configuration files,
and close and reopen any log files.

SIGINT   Causes a snapshot of the state of the pppoed daemon to be written to
/tmp/pppoed.*pid* (where *pid* is the decimal process ID of the daemon).

Files   /usr/lib/inet/pppoed   executable command

/dev/sppptun   Solaris PPP tunneling device driver

/etc/ppp/pppoe   main configuration option file

/etc/ppp/pppoe.*device*   per–device configuration option file

/etc/ppp/pppoe-errors   location of output from pppd's stderr

/etc/ppp/pppoe.if   list of Ethernet interfaces to be plumbed at boot time

/tmp/pppoed.*pid*   ASCII text file containing dumped pppoed state information

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/ppp/tunnel

See Also   pppd(1M), pppoec(1M), sppptun(1M), sppptun(7M)

Mamakos, L., et al. *RFC 2516, A Method for Transmitting PPP Over Ethernet (PPPoE)*. Network Working Group. February 1999

Notes   Because pppd is installed setuid root, this daemon need not be run as root. However, if it is not run as root, the user and group options are ignored.

The Ethernet interfaces to be used must be plumbed for PPPoE using the sppptun(1M) utility before services can be offered.

The daemon operate runs even if there are no services to offer. If you want to modify a configuration, it is not necessary to terminate the daemon. Simply use pkill -HUP pppoed after updating the configuration files.

The PPPoE protocol is far from perfect. Because it runs directly over Ethernet, there is no possibility of security and the MTU is limited to 1492 (violating RFC 1661's default value of 1500). It is also not possible to run the client and the server of a given session on a single machine with a single Ethernet interface for testing purposes. The client and server portions of a single session must be run on separate Ethernet interfaces with different MAC addresses.

Name pppstats – print PPP statistics

Synopsis pppstats [-a] [-v] [-r] [-z] [-c <*count*>] [-w <*secs*>]
[*interface*]

Description The pppstats utility reports PPP-related statistics at regular intervals for the specified PPP
interface. If the interface is unspecified, pppstats defaults to sppp0. The display is split
horizontally into input and output sections containing columns of statistics describing the
properties and volume of packets received and transmitted by the interface.

Options The pppstats options are:

-a   Display absolute values rather than deltas. With this option, all reports show
statistics for the time elapsed since the link was initiated. Without this option,
the second and subsequent reports show statistics for the time since the last
report.

-c *count*   Repeat the display *count* times. If this option is not specified, the default repeat
count is 1 if the -w option is not specified, otherwise infinity.

-r   Display additional statistics summarizing the compression ratio achieved by the
packet compression algorithm in use.

-v   Display additional statistics relating to the performance of the Van Jacobson
TCP header compression algorithm.

-w *wait*   Pause *wait* seconds between each display. If this option is not specified, the
default interval is five seconds.

-z   Instead of the standard display, show statistics indicating the performance of the
packet compression algorithm in use.

Extended Description The following fields are printed on the input side when the -z option is not used:

IN   Total number of bytes received by this interface.

PACK   Total number of packets received by this interface.

VJCOMP   Number of header-compressed TCP packets received by this interface.

VJUNC   Number of header-uncompressed TCP packets received by this interface. Not
reported when the -r option is specified.

VJERR   Number of corrupted or bogus header-compressed TCP packets received by this
interface. Not reported when the -r option is specified.

VJTOSS   Number of VJ header-compressed TCP packets dropped on reception by this
interface because of preceding errors. Only reported when the -v option is
specified.

NON-VJ   Total number of non-TCP packets received by this interface. Only reported when
the -v option is specified.

RATIO Compression ratio achieved for received packets by the packet compression scheme in use, defined as the uncompressed size divided by the compressed size. Only reported when the -r option is specified.

UBYTE Total number of bytes received, after decompression of compressed packets. Only reported when the -r option is specified.

The following fields are printed on the output side:

OUT Total number of bytes transmitted from this interface.

PACK Total number of packets transmitted from this interface.

VJCOMP Number of TCP packets transmitted from this interface with VJ-compressed TCP headers.

VJUNC Number of TCP packets transmitted from this interface with VJ-uncompressed TCP headers. Not reported when the -r option is specified.

NON-VJ Total number of non-TCP packets transmitted from this interface. Not reported when the -r option is specified.

VJSRCH Number of searches for the cached header entry for a VJ header compressed TCP packet. Only reported when the -v option is specified.

VJMISS Number of failed searches for the cached header entry for a VJ header compressed TCP packet. Only reported when the -v option is specified.

RATIO Compression ratio achieved for transmitted packets by the packet compression scheme in use, defined as the size before compression divided by the compressed size. Only reported when the -r option is specified.

UBYTE Total number of bytes to be transmitted before packet compression is applied. Only reported when the -r option is specified.

When the -z option is specified, pppstats displays the following fields relating to the packet compression algorithm currently in use. If packet compression is not in use, these fields display zeroes. The fields displayed on the input side are:

COMPRESSED BYTE Number of bytes of compressed packets received.

COMPRESSED PACK Number of compressed packets received.

INCOMPRESSIBLE BYTE Number of bytes of incompressible packets (that is, those which were transmitted in uncompressed form) received.

INCOMPRESSIBLE PACK Number of incompressible packets received.

COMP RATIO Recent compression ratio for incoming packets, defined as the uncompressed size divided by the compressed size (including both compressible and incompressible packets).

The fields displayed on the output side are:

COMPRESSED BYTE   Number of bytes of compressed packets transmitted.

COMPRESSED PACK   Number of compressed packets transmitted.

INCOMPRESSIBLE BYTE   Number of bytes of incompressible packets received; that is, those that were transmitted by the peer in uncompressed form.

INCOMPRESSIBLE PACK   Number of incompressible packets transmitted.

COMP RATIO   Recent compression ratio for outgoing packets.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/ppp
Interface Stability	Committed

See Also   pppd(1M), attributes(5)

Name praudit – print contents of an audit trail file

Synopsis praudit [-lrsx] [-d*del*] [*filename*]...

Description praudit reads the listed *filename*s (or standard input, if no *filename* is specified) and interprets the data as audit trail records as defined in audit.log(4). By default, times, user and group IDs (UIDs and GIDs, respectively) are converted to their ASCII representation. Record type and event fields are converted to their ASCII representation. A maximum of 100 audit files can be specified on the command line.

Options The following options are supported:

-d*del*
    Use *del* as the field delimiter instead of the default delimiter, which is the comma. If *del* has special meaning for the shell, it must be quoted. The maximum size of a delimiter is three characters. The delimiter is not meaningful and is not used when the -x option is specified.

-l
    Print one line per record.

-r
    Print records in their raw form. Times, UIDs, GIDs, record types, and events are displayed as integers. This option is useful when naming services are offline. The -r option and the -s option are exclusive. If both are used, a format usage error message is output.

-s
    Display records in their short form. Numeric fields' ASCII equivalents are looked up by means of the sources specified in the /etc/nsswitch.conf file (see nsswitch.conf(4)). All numeric fields are converted to ASCII and then displayed. The short ASCII representations for the record type and event fields are used. This option and the -r option are exclusive. If both are used, a format usage error message is output.

-x
    Print records in XML form. Tags are included in the output to identify tokens and fields within tokens. Output begins with a valid XML prolog, which includes identification of the DTD which can be used to parse the XML.

Files /etc/security/audit_event
    Audit event definition and class mappings.

/etc/security/audit_class
    Audit class definitions.

/usr/share/lib/xml/dtd
    Directory containing the versioned DTD file referenced in XML output, for example, adt_record.dtd.1.

/usr/share/lib/xml/style
    Directory containing the versioned XSL file referenced in XML output, for example, adt_record.xsl.1.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	See below.

The command stability is evolving. The output format is unstable.

See the section on Solaris Auditing in *Oracle Solaris Administration: Security Services*.

Name projadd – administer a new project on the system

Synopsis projadd [-n] [-f *filename*] [-p *projid* [-o]] [-c *comment*]
              [-U *user* [,*user*]...] [-G *group* [,*group*]...]
              [[-K *name* [=*value* [,*value*]...]...]] *project*

Description projadd adds a new project entry to the /etc/project file. If the files backend is being used for the project database, the new project is available for use immediately upon the completion of the projadd command.

Options The following options are supported:

-c *comment*	Add a project comment. Comments are stored in the project's entry in the /etc/project file. Generally, comments contain a short description of the project and are used as the field for the project's full name.
	Specify *comment* as a text string. *comment* cannot contain a colon (:) or NEWLINE.
-f *filename*	Specify the project file to modify. If no *filename* is specified, the system project file, /etc/project, is modified.
-G *group*[,group...]	Specify a group list for the project.
-K *name*[=*value*[,*value*...]	Specify an attribute list for the project. Multiple -K options can be specified to set values on multiple keys, such as:
	-K *key1*=*value1* -K "*key2*=(*value2a*),(*value2b*)"
	Resource control attributes use parentheses to specify values for a key. Because many user shells interpret parentheses as special characters, it is best to enclose an argument to -K that contains parentheses with double quotes, as shown above and in EXAMPLES, below. See resource_controls(5) for a description of the resource controls you can specify for a project.
-n	Syntax check. Check the format of the existing system project file and modifications only. The contents of the existing project file, such as user names, group names, and resources that are specified in the project attributes are not checked.
-o	This option allows the project ID specified by the -p option to be non-unique within the project file.
-p *projid*	Set the project ID of the new project.
	Specify *projid* as a non-negative decimal integer below UID_MAX as defined in limits.h. *projid* defaults to the next available

unique number above the highest number currently assigned. For example, if *projid*s 100, 105, and 200 are assigned, the next default *projid* is 201. *projid*s between 0-99 are reserved by SunOS.

-U *user*[,user...]   Specify a user list for the project.

Operands The following operands are supported:

project   The name of the project to create. The *project* operand is a string consisting of characters from the set of alphabetic characters, numeric characters, underline (_), and hyphen (-). The period ('.') is reserved for projects with special meaning to the operating system. The first character of the project name must be a letter. An error message is displayed if these restrictions are not met.

Examples EXAMPLE 1 Adding a Project

The following command creates the project salesaudit and sets the resource controls specified as arguments to the -K option.

```
projadd -p 111 -G sales,finance -c "Auditing Project" \
    -K "rcap.max-rss=10GB" \
    -K "process.max-file-size=(priv,50MB,deny)" \
    -K "task.max-lwps=(priv,100,deny)" salesaudit
```

This command would produce the following entry in /etc/project:

```
salesaudit:111:Auditing Project::sales,finance: \
process.max-file-size=(priv,52428800,deny); \
rcap.max-rss=10737418240;task.max-lwps=(priv,100,deny)
```

Note that the preceding would appear as one line in /etc/project.

Comparing the projadd command and resulting output in /etc/project, note the effect of the scaling factor in the resource cap (rcap.max-rss=10GB) and the resource control (process.max-file-size=(priv,50MB,deny)). Modifiers, such as B, KB, and MB, and scaling factors are specified in resource_controls(5).

Exit Status The following exit values are returned:

0   Successful completion.

2   The command syntax was invalid. A usage message for projadd is displayed.

3   An invalid argument was provided to an option.

4   The *projid* given with the -p option is already in use.

5   The project files contain an error. See project(4).

6   The project to be added, group, user, or resource does not exist.

9   The project is already in use.

10   Cannot update the /etc/project file.

Files /etc/project   System project file

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	See below.

Invocation is evolving. Human readable output is unstable.

See Also projects(1), groupadd(1M), groupdel(1M), groupmod(1M), grpck(1M), projdel(1M), projmod(1M), useradd(1M), userdel(1M), usermod(1M), project(4), attributes(5), resource_controls(5)

Notes In case of an error, projadd prints an error message and exits with a non-zero status.

projadd adds a project definition only on the local system. If a network name service such as NIS or LDAP is being used to supplement the local /etc/project file with additional entries, projadd cannot change information supplied by the network name service.

Name projdel – delete a project from the system

Synopsis `projdel [-f` *filename*`]` *project*

Description The `projdel` utility deletes a project from the system and makes the appropriate changes to the system file.

Options The following options are supported:

`-f` *filename* Specify the project file to modify. If no *filename* is specified, the system project file, `/etc/project`, is modified.

Operands The following operands are supported:

project The name of the project to be deleted.

Exit Status The following exit values are returned:

0 Successful completion.

2 The command syntax was invalid. A usage message for `projdel` is displayed.

3 An invalid argument was provided to an option.

4 The *projid* given with the `-p` option is already in use.

5 The project files contain an error. See `project(4)`.

6 The project to be modified, group, user, or resource does not exist.

9 The project is already in use.

10 Cannot update the `/etc/project` file.

Files `/etc/project` System project file

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface stabilty	See below.

Invocation is evolving. Human readable output is unstable.

See Also `projects(1)`, `groupadd(1M)`, `groupdel(1M)`, `groupmod(1M)`, `grpck(1M)`, `logins(1M)`, `projadd(1M)`, `projmod(1M)`, `useradd(1M)`, `userdel(1M)`, `usermod(1M)`, `project(4)`, `attributes(5)`

Diagnostics In case of an error, projdel prints an error message and exits with a non-zero status.

Notes projdel deletes a project definition only on the local system. If a network name service such as NIS or LDAP is being used to supplement the local /etc/project file with additional entries, projdel cannot change information supplied by the network name service.

Name projmod – modify a project's information on the system

Synopsis
```
projmod [-n] [-A|-f filename | -]

projmod [-n] [-A|-f filename | -] [-p projid [-o]]
    [-c comment] [-a|-s|-r] [-U user [,user]... ]
    [-G group [,group]... ]
    [ [-K name [=value [,value]...]...]]
    [-l new_projectname] project
```

Description The projmod utility modifies a project's definition on the system. projmod changes the definition of the specified project and makes the appropriate project-related system file and file system changes.

Options The following options are supported:

-A   Apply the project's resource controls, as defined in the system's
                        project database, to the project if it is active.

-a   Specify that the users, groups, attributes, or attribute values
                        specified by the -U, -G or -K options should be added to the
                        project, rather than replacing the existing member or attribute
                        list.

-c *comment*   Specify *comment* as a text string. Generally, *comment* contains a
                        short description of the project. This information is stored in
                        the project's /etc/project entry.

-f *filename* | –   Specify the project file to modify or validate or specify input
                        from stdin for validation. As noted under OPERANDS, if you
                        do not specify a project in a projmod command line, projmod
                        validates the argument to -f. If you do not use this option, the
                        system project file, /etc/project, is modified.

-G *group* [,*group*...] Specify a replacement list of member groups of the project.
                        When used in conjunction with the -a or -r options, this option
                        specifies a list of groups to be added or removed from the
                        project.

-K *name*[=*value*[,*value*...] Specify a replacement list of project attributes for the project.
                        When used in conjunction with the -a, -r, or -s options, this
                        option specifies a list of attribute values to be added, removed,
                        or replaced in the project. Attributes must be delimited by
                        semicolons (;). Multiple -K options can be specified to set, add,
                        remove, or substitute values on multiple keys, such as:

                        -K *key1*=*value1* -K "*key2*=(*value2a*),(*value2b*)"

                        Resource control attributes use parentheses to specify values for
                        a key. Because many user shells interpret parentheses as special

characters, it is best to enclose an argument to -K that contains parentheses with double quotes, as shown above and in EXAMPLES, below. See resource_controls(5) for a description of the resource controls you can specify for a project.

-l *new_projectname*	Specify the new project name for the project. The *new_projectname* argument is a string consisting of characters from the set of alphabetic characters, numeric characters, period (.), underline (_), and hyphen (-). The first character should be alphabetic. An error message is written if these restrictions are not met. The project name must also be unique within the project file.
-n	Syntax check. Check the format of the existing system project file and modifications only. The contents of the existing project file, such as user names, group names, and resources that are specified in the project attributes are not checked.
-o	This option allows the project ID specified by the -p option to be non-unique within the project file.
-p *projid*	Specify a new project ID for the project. It must be a non-negative decimal integer less than MAXUID as defined in param.h. This value must be unique within the project file if the -o option is not specified.
-r	Specify that the users, groups, attributes, or attribute values specified by the -U, -G or -K options should be removed from the project, rather than replacing the existing member or attribute list.
-s	Specify that the list of attributes specified by the -K option should have their values replaced. If the attributes do not exist, they are added as if the a option was used. This option has no effect the -U or -G options.
-U *user* [,*user*...]	Specify a replacement list of member users of the project. When used in conjunction with the -a or -r options, this option specifies a list of users to be added or removed from the project.

Operands The following operands are supported:

project   An existing project name to be modified or displayed.

(none)   If no operand is given, the project file is validated without modifying any project.

Examples   **EXAMPLE 1**   Using the -K Option for Addition of an Attribute Value

Consider the following project(4) entry:

```
salesaudit:111:Auditing Project::sales,finance: \
  process.max-file-size=(priv,52428800,deny); \
  task.max-lwps=(priv,100,deny)
```

The preceding would appear as one line in /etc/project. For this and the following examples, the focus is on the attributes field in the project entry. That is, the last field, the field following the last semicolon.

The attributes field for the project salesaudit lists the following resource control:

```
task.max-lwps=(priv,1000,signal=KILL)
```

The following projmod command adds an action clause to the preceding entry:

```
# projmod -a -K "task.max-lwps=(priv,100,deny)" salesaudit
```

...with the resulting attributes field in the entry for salesaudit:

```
task.max-lwps=(priv,100,deny),(priv,1000,signal=KILL)
```

EXAMPLE 2   Using the -K Option for the Substitution of an Attribute Value

Assume an attributes field in a project(4) entry for the project salesaudit that lists the following resource control:

```
task.max-lwps=(priv,100,deny),(priv,1000,signal=KILL)
```

The following projmod command substitutes the action clause specified in the command for the action clauses in the preceding entry:

```
# projmod -s -K "task.max-lwps=(priv,500,signal=SIGSTOP)" salesaudit
```

...with the resulting attributes field in the entry for salesaudit:

```
task.max-lwps=(priv,500,signal=SIGSTOP)
```

EXAMPLE 3   Using the -K Option for Removal of an Attribute Value

Assume an attributes field in a project(4) entry for a project salesaudit that lists the following resource control:

```
task.max-lwps=(priv,100,deny),(priv,1000,signal=KILL)
```

The following projmod command removes the first action clause from the preceding entry:

```
# projmod -r -K "task.max-lwps=(priv,100,deny)" salesaudit
```

...with the resulting attributes field in the entry for salesaudit:

EXAMPLE 3   Using the -K Option for Removal of an Attribute Value   *(Continued)*

```
task.max-lwps=(priv,1000,signal=KILL)
```

EXAMPLE 4   Specifying Multiple Attribute Values

Suppose you want to achieve the following resource controls for the project salesaudit:

```
task.max-lwps=(priv,100,deny)
process.max-file-size=(priv,50MB,deny)
```

The following projmod command adds these resource controls for salesaudit:

```
# projmod -a -K "task.max-lwps=(priv,100,deny)" \
-K "process.max-file-size=(priv,50MB,deny)" salesaudit
```

...with the resulting attributes field in the entry for salesaudit:

```
task.max-lwps=(priv,100,deny);process.max-file-size=(priv,52428800,deny)
```

In this example, note the effect of the use of the modifier and scaling factor for the resource control process.max-file-size. The specification in projmod:

```
"process.max-file-size=(priv,50MB,deny)"
```

...becomes, in /etc/project:

```
process.max-file-size=(priv,52428800,deny)
```

That is, 50MB is expanded to 52428800. The modifiers, such as MB, and scaling factors you can use for resource controls are specified in resource_controls(5).

EXAMPLE 5   Binding a Pool to a Project

The following command sets the project.pool attribute for the project sales.

```
# projmod -a -K project.pool=salespool sales
```

EXAMPLE 6   Evaluating Input from stdin

The following command uses the -f option without a project name operand to evaluate the contents of an NIS projects map.

```
# ypcat project | projmod -f -
```

Exit Status   In case of an error, projmod prints an error message and exits with one of the following values:

The following exit values are returned:

0   Successful completion.

2   The command syntax was invalid. A usage message for projmod is displayed.

| | 3 | An invalid argument was provided to an option. |

        3   An invalid argument was provided to an option.

        4   The *projid* given with the `-p` option is already in use.

        5   The project files contain an error. See `project(4)`.

        6   The project to be modified, group, user, or resource does not exist.

        9   The project is already in use.

       10   Cannot update the `/etc/project` file.

Files `/etc/group`   System file containing group definitions

     `/etc/project`   System project file

     `/etc/passwd`   System password file

     `/etc/shadow`   System file containing users' encrypted passwords and related information

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	See below.

Invocation is evolving. Human readable output is unstable.

See Also `groupadd(1M)`, `groupdel(1M)`, `groupmod(1M)`, `projadd(1M)`, `projdel(1M)`, `useradd(1M)`, `userdel(1M)`, `usermod(1M)`, `passwd(4)`, `project(4)`, `attributes(5)`, `resource_controls(5)`

Notes The `projmod` utility modifies project definitions only in the local `/etc/project` file. If a network name service such as NIS or LDAP is being used to supplement the local files with additional entries, `projmod` cannot change information supplied by the network name service. However `projmod` verifies the uniqueness of project name and project ID against the external name service.

Name prstat – report active process statistics

Synopsis prstat [-acHJLmRrtTv] [-d u | d] [-C *psrsetlist*] [-h *lgrplist*]
         [-j *projlist*] [-k *tasklist*] [-n *ntop*[,*nbottom*]]
         [-p *pidlist*] [-P *cpulist*] [-s *key* | -S *key*]
         [-u *euidlist*] [-U *uidlist*] [-z *zoneidlist*] [-Z]
         [*interval* [*count*]]

Description The prstat utility iteratively examines all active processes on the system and reports statistics based on the selected output mode and sort order. prstat provides options to examine only processes matching specified PIDs, UIDs, zone IDs, CPU IDs, and processor set IDs.

The -j, -k, -C, -p, -P, -u, -U, and -z options accept lists as arguments. Items in a list can be either separated by commas or enclosed in quotes and separated by commas or spaces.

If you do not specify an option, prstat examines all processes and reports statistics sorted by CPU usage.

Options The following options are supported:

-a

  Report information about processes and users. In this mode prstat displays separate reports about processes and users at the same time.

-c

  Print new reports below previous reports instead of overprinting them.

-C *psrsetlist*

  Report only processes or lwps that are bound to processor sets in the given list. Each processor set is identified by an integer as reported by psrset(1M). The load averages displayed are the sum of the load averages of the specified processor sets (see pset_getloadavg(3C)). Processes with one or more LWPs bound to processor sets in the given list are reported even when the -L option is not used.

-d u | d

  Specify u for a printed representation of the internal representation of time. See time(2). Specify d for standard date format. See date(1).

-h *lgrplist*

  Report only processes or lwps whose home *lgroup* is in the given list of *lgroups*. No processes or lwps will be listed for invalid *lgroups*.

-H

  Report information about home *lgroup*. In this mode, prstat adds an extra column showing process or lwps home *lgroup* with the header LGRP.

-j *projlist*

  Report only processes or lwps whose project ID is in the given list. Each project ID can be specified as either a project name or a numerical project ID. See project(4).

-J

Report information about processes and projects. In this mode prstat displays separate reports about processes and projects at the same time.

-k *tasklist*

Report only processes or lwps whose task ID is in *tasklist*.

-L

Report statistics for each light-weight process (LWP). By default, prstat reports only the number of LWPs for each process.

-m

Report microstate process accounting information. In addition to all fields listed in -v mode, this mode also includes the percentage of time the process has spent processing system traps, text page faults, data page faults, waiting for user locks and waiting for CPU (latency time).

-n *ntop*[,*nbottom*]

Restrict number of output lines. The *ntop* argument determines how many lines of process or lwp statistics are reported, and the *nbottom* argument determines how many lines of user, task, or projects statistics are reported if the -a, -t, -T, -J or -Z options are specified. By default, prstat displays as many lines of output that fit in a window or terminal. When you specify the -c option or direct the output to a file, the default values for ntop and nbottom are 15 and 5.

-p *pidlist*

Report only processes whose process ID is in the given list.

-P *cpulist*

Report only processes or lwps which have most recently executed on a CPU in the given list. Each CPU is identified by an integer as reported by psrinfo(1M).

-R

Put prstat in the real time scheduling class. When this option is used, prstat is given priority over time-sharing and interactive processes. This option is available only for superuser.

-r

Disable lookups for user names and project names. (Note that this does not apply to lookups for the -j, -u, or -U options.)

-s *key*

Sort output lines (that is, processes, lwps, or users) by *key* in descending order. Only one *key* can be used as an argument.

There are five possible key values:

cpu

Sort by process CPU usage. This is the default.

pri
    Sort by process priority.

rss
    Sort by resident set size.

size
    Sort by size of process image.

time
    Sort by process execution time.

-S *key*
    Sort output lines by *key* in ascending order. Possible *key* values are the same as for the -s option. See -s.

-t
    Report total usage summary for each user. The summary includes the total number of processes or LWPs owned by the user, total size of process images, total resident set size, total cpu time, and percentages of recent cpu time and system memory.

-T
    Report information about processes and tasks. In this mode prstat displays separate reports about processes and tasks at the same time.

-u *euidlist*
    Report only processes whose effective user ID is in the given list. Each user ID may be specified as either a login name or a numerical user ID.

-U *uidlis*t
    Report only processes whose real user ID is in the given list. Each user ID may be specified as either a login name or a numerical user ID.

-v
    Report verbose process usage. This output format includes the percentage of time the process has spent in user mode, in system mode, and sleeping. It also includes the number of voluntary and involuntary context switches, system calls and the number of signals received. Statistics that are not reported are marked with the - sign.

-z *zoneidlist*
    Report only processes or LWPs whose zone ID is in the given list. Each zone ID can be specified as either a zone name or a numerical zone ID. See zones(5).

-Z
    Report information about processes and zones. In this mode, prstat displays separate reports about processes and zones at the same time.

Output The following list defines the column headings and the meanings of a prstat report:

PID
    The process ID of the process.

USERNAME
   The real user (login) name or real user ID.

SWAP
   The sum of swap reservations of the associated processes for each user, project, task, or
   zone. This counts shared memory only once for each user, project, task, or zone. Swap is
   reserved when anonymous memory is allocated or files are mapped private. The value of
   swap is expressed in kilobytes (K), megabytes (M), or gigabytes (G).

RSS
   The resident set size of the process (RSS), in kilobytes (K), megabytes (M), or gigabytes (G).
   The RSS value is an estimate provided by proc(4) that might underestimate the actual
   resident set size. Users who want to get more accurate usage information for capacity
   planning should use the -x option to pmap(1) instead.

STATE
   The state of the process:

   cpu*N*
      Process is running on CPU *N*.

   sleep
      Sleeping: process is waiting for an event to complete.

   wait
      Waiting: process is waiting for CPU usage to drop to the CPU-caps enforced limits. See
      the description of CPU-caps in resource_controls(5).

   run
      Runnable: process in on run queue.

   zombie
      Zombie state: process terminated and parent not waiting.

   stop
      Process is stopped.

PRI
   The priority of the process. Larger numbers mean higher priority.

NICE
   Nice value used in priority computation. Only processes in certain scheduling classes have
   a nice value.

TIME
   The cumulative execution time for the process.

CPU
   The percentage of recent CPU time used by the process. If executing in a non-global zone
   and the pools facility is active, the percentage will be that of the processors in the processor
   set in use by the pool to which the zone is bound.

PROCESS
   The name of the process (name of executed file).

LWPID
   The lwp ID of the lwp being reported.

NLWP
   The number of lwps in the process.

With the some options, in addition to a number of the column headings shown above, there are:

NPROC
   Number of processes in a specified collection.

MEMORY
   Percentage of memory used by a specified collection of processes.

The following columns are displayed when the -v or -m option is specified

USR
   The percentage of time the process has spent in user mode.

SYS
   The percentage of time the process has spent in system mode.

TRP
   The percentage of time the process has spent in processing system traps.

TFL
   The percentage of time the process has spent processing text page faults.

DFL
   The percentage of time the process has spent processing data page faults.

LCK
   The percentage of time the process has spent waiting for user locks.

SLP
   The percentage of time the process has spent sleeping.

LAT
   The percentage of time the process has spent waiting for CPU.

VCX
   The number of voluntary context switches.

ICX
   The number of involuntary context switches.

SCL
   The number of system calls.

SIG
   The number of signals received.

Under the -L option, one line is printed for each lwp in the process and some reporting fields
show the values for the lwp, not the process.

The following column is displayed when the -H option is specified:

LGRP
   The home *lgroup* of the process or lwp.

Operands   The following operands are supported:

count
   Specifies the number of times that the statistics are repeated. By default, prstat reports
   statistics until a termination signal is received.

interval
   Specifies the sampling interval in seconds; the default interval is 5 seconds.

Examples   EXAMPLE 1   Reporting the Five Most Active Super-User Processes

The following command reports the five most active super-user processes running on CPU1
and CPU2:

```
example% prstat -u root -n 5 -P 1,2 1 1

PID    USERNAME  SWAP    RSS STATE  PRI  NICE      TIME  CPU PROCESS/LWP
 306    root     3024K 1448K sleep   58    0   0:00.00 0.3% sendmail/1
 102    root     1600K  592K sleep   59    0   0:00.00 0.1% in.rdisc/1
 250    root     1000K  552K sleep   58    0   0:00.00 0.0% utmpd/1
 288    root     1720K 1032K sleep   58    0   0:00.00 0.0% sac/1
   1    root      744K  168K sleep   58    0   0:00.00 0.0% init/1
TOTAL:       25, load averages:  0.05, 0.08, 0.12
```

EXAMPLE 2   Displaying Verbose Process Usage Information

The following command displays verbose process usage information about processes with
lowest resident set sizes owned by users root and john.

```
example% prstat -S rss -n 5 -vc -u root,john

 PID USERNAME USR SYS TRP TFL DFL LCK SLP LAT VCX ICX SCL SIG PROCESS/LWP
   1 root     0.0 0.0  -   -   -   - 100  -    0   0   0   0 init/1
 102 root     0.0 0.0  -   -   -   - 100  -    0   0   3   0 in.rdisc/1
 250 root     0.0 0.0  -   -   -   - 100  -    0   0   0   0 utmpd/1
1185 john     0.0 0.0  -   -   -   - 100  -    0   0   0   0 csh/1
 240 root     0.0 0.0  -   -   -   - 100  -    0   0   0   0 switchd/4
 TOTAL:       71, load averages:  0.02, 0.04, 0.08
```

Exit Status The following exit values are returned:

0
    Successful completion.

1
    An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also date(1), lgrpinfo(1), plgrp(1), proc(1), ps(1), time(2), psrinfo(1M), psrset(1M), sar(1M), pset_getloadavg(3C), proc(4), project(4), attributes(5), resource_controls(5), zones(5)

Notes The snapshot of system usage displayed by prstat is true only for a split-second, and it may not be accurate by the time it is displayed. When the -m option is specified, prstat tries to turn on microstate accounting for each process; the original state is restored when prstat exits. See proc(4) for additional information about the microstate accounting facility.

The total memory size reported in the SWAP and RSS columns for groups of processes can sometimes overestimate the actual amount of memory used by processes with shared memory segments.

Name prtconf – print system configuration

Synopsis /usr/sbin/prtconf [-V] | [-F] | [-x] | [-bpv] | [-acdDlPuv]
          [*dev_path*]

Description The prtconf command prints the system configuration information. The output includes the total amount of memory, and the configuration of system peripherals formatted as a device tree.

If a device path is specified on the command line for those command options that can take a device path, prtconf will only display information for that device node.

Options The following options are supported:

-a   Display all the ancestors device nodes, up to the root node of the device tree, for the device specified on the command line.

-b   Display the firmware device tree root properties for the purpose of platform identification. These properties are "name", "compatible", "banner-name" and "model".

-c   Display the device subtree rooted at the device node specified on the command line, that is, display all the children of the device node specified on the command line.

-d   Display vendor ID and device ID for PCI and PCI Express devices, in addition to the nodename.

-D   For each system peripheral in the device tree, displays the name of the device driver used to manage the peripheral.

-l   Show the /dev/chassis location associated with the device node. If -v is used, -l is implied.

-F   Returns the device path name of the console frame buffer, if one exists. If there is no frame buffer, prtconf returns a non-zero exit code. This flag must be used by itself. It returns only the name of the console, frame buffer device or a non-zero exit code. For example, if the console frame buffer on a SUNW,Ultra-30 is ffb, the command returns: /SUNW,ffb@1e,0:ffb0. This option could be used to create a symlink for /dev/fb to the actual console device.

-p   Displays information derived from the device tree provided by the firmware (PROM) on SPARC platforms or the booting system on x86 platforms. The device tree information displayed using this option is a snapshot of the initial configuration and may not accurately reflect reconfiguration events that occur later.

-P   Includes information about pseudo devices. By default, information regarding pseudo devices is omitted.

-u   Together with -v, displays information for each device listing properties from the vendor and admin lists, if any.

-v   Specifies verbose mode.

-V   Displays platform-dependent PROM (on SPARC platforms) or booting system (on x86 platforms) version information. This flag must be used by itself. The output is a string. The format of the string is arbitrary and platform-dependent.

-x   Reports if the firmware on this system is 64-bit ready. Some existing platforms may need a firmware upgrade in order to run the 64-bit kernel. If the operation is not applicable to this platform or the firmware is already 64-bit ready, it exits silently with a return code of zero. If the operation is applicable to this platform and the firmware is not 64-bit ready, it displays a descriptive message on the standard output and exits with a non-zero return code. The hardware platform documentation contains more information about the platforms that may need a firmware upgrade in order to run the 64-bit kernel.

          This flag overrides all other flags and must be used by itself.

Operands   The following operands are supported:

dev_path   The path to a target device minor node, device nexus node, or device link for which device node configuration information is displayed

Exit Status   The following exit values are returned:

0   No error occurred.

non-zero   With the -F option (SPARC only), a non-zero return value means that the output device is not a frame buffer. With the -x option, a non-zero return value means that the firmware is not 64–bit ready. In all other cases, a non-zero return value means that an error occurred.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Uncommitted

See Also   fuser(1M), modinfo(1M), sysdef(1M), driver(4), driver.conf(4), attributes(5)

Sun Hardware Platform Guide

SPARC Only   openprom(7D)

Notes   The output of the prtconf command is highly dependent on the version of the PROM installed in the system. The output will be affected in potentially all circumstances.

The driver not attached message means that no driver is currently attached to that instance of the device. In general, drivers are loaded and installed (and attached to hardware instances) on demand, and when needed, and may be uninstalled and unloaded when the device is not in use.

On x86 platforms, the use of prtconf -vp provides a subset of information from prtconf -v. The value of integer properties from prtconf -vp might require byte swapping for correct interpretation.

Name prtdiag – display system diagnostic information

Synopsis `/usr/sbin/prtdiag [-v] [-l]`

Description prtdiag displays system configuration and diagnostic information on sun4u, sun4v, and x86 systems.

The diagnostic information lists any failed field replaceable units (FRUs) in the system.

The interface, output, and location in the directory hierarchy for prtdiag are uncommitted and subject to change in future releases.

prtdiag does not display diagnostic information and environmental status when executed on the Sun Enterprise 10000 server. See the
/var/opt/SUNWssp/adm/${SUNW_HOSTNAME}/messages file on the system service processor (SSP) to obtain such information for this server.

Options The following options are supported:

-l Log output. If failures or errors exist in the system, output this information to syslogd(1M) only.

-v Verbose mode. Displays the time of the most recent AC Power failure, and the most recent hardware fatal error information, and (if applicable) environmental status. The hardware fatal error information is useful to repair and manufacturing for detailed diagnostics of FRUs.

Exit Status The following exit values are returned:

0 No failures or errors are detected in the system.

1 Failures or errors are detected in the system.

2 An internal prtdiag error occurred, for example, out of memory.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/library/platform
Interface Stability	Uncommitted*

*The output is unstable.

See Also modinfo(1M), prtconf(1M), psrinfo(1M), sysdef(1M), syslogd(1M), attributes(5), openprom(7D)

Notes Not all diagnostic and system information is available on every Solaris platform, and therefore cannot be displayed by prtdiag. On those platforms, further information can be obtained from the System Controller.

Name prtdscp – display DSCP IP addresses

Synopsis prtdscp [-v]

prtdscp [-v] -h

prtdscp [-v] -d

prtdscp [-v] -s

Description prtdscp displays the IP addresses associated with a Domain to Service Processor
Communications Protocol (DSCP) link. If no arguments are specified, prtdscp displays the
IP addresses on both ends of the DSCP link. The IP address of either the Service Processor or
domain side can be displayed separately by the use of the -s or -d options, respectively.

Options The following options are supported:

-v   Verbose mode. Print additional details about the program's internal progress to
        stderr.

-h   Help. Print a brief synopsis of the program's usage and exit. All other command line
        arguments are ignored.

-d   Display only the local domain's IP address.

-s   Display only the remote Service Processor's IP address.

Examples **EXAMPLE 1** Displaying both addresses

The following example displays both the local domain's IP address and the remote SP's IP
address:

```
# prtdscp
Domain Address: 192.168.103.2
SP Address: 192.168.103.1
```

EXAMPLE 2 Displaying the local IP address

The following example displays the local domain's IP address:

```
# prtdscp -d
192.168.103.2
```

EXAMPLE 3 Displaying the remote IP address

The following example display the remote SP's IP address:

```
# prtdscp -s
192.168.103.1
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/domain-service-processor-protocol/sparc-enterprise, SUNWdscpu.u
Interface Stability	Committed

See Also   attributes(5)

Name   prtfru – print FRUID-specific information about the FRUs on a system or domain

Synopsis   /usr/sbin/prtfru [-d] | [-clx] [*container*]

Description   The prtfru utility is used to obtain FRUID data from the system or domain. Its output is that of a tree structure echoing the path in the FRU (Field-Replaceable Unit) tree to each container. When a container is found, the data from that container is printed in a tree-like structure as well.

prtfru without any arguments will print the FRU hierarchy and all of the FRUID container data. prtfru prints to stdout which may be redirected to a file.

Options   The following options are supported:

-c   Prints *only* the containers and their data. This option does not print the FRU tree hierarchy.

-d   Prints a DTD for the current registry to stdout.

-l   Prints *only* the FRU tree hierarchy. This option does not print the container data.

-x   Prints in XML format with a system identifier (SYSTEM) of prtfrureg.dtd.

Options -c and -l can be used together to obtain a list of the containers.

Operands   The folowing operand is supported:

container   The name of a particular container in the FRU hierarchy, that is, either the name or path/name of a container as displayed in the -l option.

Exit Status   The following exit values are returned:

0   All information was found and printed successfully.

>0   An error has occurred.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/fru-id

See Also   fruadm(1M), attributes(5)

Name prtpicl – print PICL tree

Synopsis /usr/sbin/prtpicl [-c *picl_class*] [-v]

Description The prtpicl command prints the PICL tree maintained by the PICL daemon. The output of prtpicl includes the name and PICL class of the nodes.

Options The following options are supported:

-c *picl_class*   Print only the nodes of the named PICL class.

-v   Print in verbose mode. In verbose mode, prtpicl prints a list of properties and values for each node. Verbose mode is disabled by default.

Exit Status The following exit values are returned:

0   Successful completion.

non-zero   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/picl

See Also picld(1M), attributes(5)

Name prtvtoc – report information about a disk geometry and partitioning

Synopsis `prtvtoc [-fhs] [-t` *vfstab*`] [-m` *mnttab*`]` *device*

Description The `prtvtoc` command allows the contents of the label to be viewed. The command can be used only by the super-user.

The *device* name can be the file name of a raw device in the form of `/dev/rdsk/c?t?d?s2` or can be the file name of a block device in the form of `/dev/dsk/c?t?d?s2`.

Options The following options are supported:

-f   Report on the disk free space, including the starting block address of the free space, number of blocks, and unused partitions.

-h   Omit the headers from the normal output.

-m *mnttab*   Use *mnttab* as the list of mounted filesystems, in place of `/etc/mnttab`.

-s   Omit all headers but the column header from the normal output.

-t *vfstab*   Use *vfstab* as the list of filesystem defaults, in place of `/etc/vfstab`.

Examples EXAMPLE 1   Using the `prtvtoc` Command

The following example uses the `prtvtoc` command on a 424-megabyte hard disk:

```
example# prtvtoc /dev/rdsk/c0t3d0s2
* /dev/rdsk/c0t3d0s2 partition map
*
* Dimension:
*      512 bytes/sector
*       80 sectors/track
*        9 tracks/cylinder
*      720 sectors/cylinder
*     2500 cylinders
*     1151 accessible cylinders
*
* Flags:
*    1: unmountable
*   10: read-only
* *                       First    Sector   Last
* Partition   Tag   Flags  Sector   Count   Sector   Mount Directory
      0        2     00        0    76320   76319    /
      1        3     01    76320   132480  208799
      2        5     00        0   828720  828719
      5        6     00   208800   131760  340559    /opt
      6        4     00   340560   447120  787679    /usr
      7        8     00   787680    41040  828719    /export/home
example#
```

EXAMPLE 1 Using the `prtvtoc` Command   *(Continued)*

The data in the `Tag` column above indicates the type of partition, as follows:

Name	*Number*
UNASSIGNED	0x00
BOOT	0x01
ROOT	0x02
SWAP	0x03
USR	0x04
BACKUP	0x05
STAND	0x06
VAR	0x07
HOME	0x08
ALTSCTR	0x09
CACHE	0x0a
RESERVED	0x0b
SYSTEM	0x0c
BOOT	0x18

The data in the `Flags` column above indicates how the partition is to be mounted, as follows:

Name	*Number*
MOUNTABLE, READ AND WRITE	0x00
NOT MOUNTABLE	0x01
MOUNTABLE, READ ONLY	0x10

EXAMPLE 2 Using the `prtvtoc` Command with the `-f` Option

The following example uses the `prtvtoc` command with the `-f` option on a 424-megabyte hard disk:

```
example# prtvtoc -f /dev/rdsk/c0t3d0s2
FREE_START=0 FREE_SIZE=0 FREE_COUNT=0 FREE_PART=34
```

EXAMPLE 3 Using the prtvtoc Command on a Disk Over One Terabyte

The following example uses uses the prtvtoc command on a disk over one terabyte:.

```
example# prtvtoc /dev/rdsk/c1t1d0s2
* /dev/rdsk/c1t1d0s2 partition map
*
* Dimensions:
*      512 bytes/sector
* 3187630080 sectors
* 3187630013 accessible sectors
*
* Flags:
*    1: unmountable
*   10: read-only
*
*                          First     Sector    Last
* Partition  Tag  Flags    Sector     Count    Sector  Mount Directory
0      2    00           34    262144    262177
1      3    01       262178    262144    524321
6      4    00       524322 3187089340 3187613661
8     11    00   3187613662     16384 318763004
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also devinfo(1M), fmthard(1M), format(1M), mount(1M), attributes(5)

Warnings The mount command does not check the "not mountable" bit.

Name psradm – change processor operational status

Synopsis psradm -f | -i | -n | -s [-v] [-F] *processor_id*

psradm -a -f | -i | -n | -s [-v] [-F]

Description The psradm utility changes the operational status of processors. The legal states for the processor are on-line, off-line, spare, faulted, and no-intr.

An on-line processor processes LWPs (lightweight processes) and can be interrupted by I/O devices in the system.

An off-line processor does not process any LWPs. Usually, an off-line processor is not interruptible by I/O devices in the system. On some processors or under certain conditions, it might not be possible to disable interrupts for an off-line processor. Thus, the actual effect of being off-line might vary from machine to machine.

A spare processor does not process any LWPs. A spare processor can be brought on-line, off-line or to no-intr by a privileged user of the system or by the kernel in response to changes in the system state.

A faulted processor is identified by the kernel, which monitors the behavior of processors over time. A privileged user can set the state of a faulted processor to be on-line, off-line, spare or no-intr, but must use the force option to do so.

A no-intr processor processes LWPs but is not interruptible by I/O devices.

A processor can not be taken off-line or made spare if there are LWPs that are bound to the processor unless the additional -F option is used. The -F option removes processor bindings of such LWPs before changing the processor's operational status. On some architectures, it might not be possible to take certain processors off-line or spare if, for example, the system depends on some resource provided by the processor.

At least one processor in the system must be able to process LWPs. At least one processor must also be able to be interrupted. Since an off-line or spare processor can be interruptible, it is possible to have an operational system with one processor no-intr and all other processors off-line or spare but with one or more accepting interrupts.

If any of the specified processors are powered off, psradm might power on one or more processors.

Only users with the PRIV_SYS_RES_CONFIG privilege can use the psradm utility.

Options The following options are supported:

-a   Perform the action on all processors, or as many as possible.

-f   Take the specified processors off-line.

-F   Force the transition to the additional specified state. Required if one or more of the specified processors was in the faulted state. Set the specified processors to faulted, if no other transition option was specified. Forced transitions can only be made to faulted, spare, or off-line states. Administrators are encouraged to use the -Q option for pbind(1M) to find out which threads will be affected by forced a processor state transition.

-i   Set the specified processors no-intr.

-n   Bring the specified processors on-line.

-s   Make the specified processors spare.

-v   Output a message giving the results of each attempted operation.

Operands   The following operands are supported:

processor_id   The processor ID of the processor to be set on-line or off-line, spare, or no-intr.

Specify *processor_id* as an individual processor number (for example, 3), multiple processor numbers separated by spaces (for example, 1 2 3), or a range of processor numbers (for example, 1-4). It is also possible to combine ranges and (individual or multiple) *processor_id*s (for example, 1-3 5 7-8 9).

Examples   **EXAMPLE 1**   Setting Processors to off-line

The following example sets processors 2 and 3 off-line:

% psradm -f 2 3

EXAMPLE 2   Setting Processors to no-intr

The following example sets processors 1 and 2 no-intr:

% psradm -i 1 2

EXAMPLE 3   Setting Processors to spare

The following example sets processors 1 and 2 spare, even if either of the processors was in the faulted state:

% psradm -F -s 1 2

EXAMPLE 4   Setting All Processors on-line

% psradm -a -n

EXAMPLE 5 Forcing Processors to off-line

The following example sets processors 1 and 2 offline, and revokes the processor bindings from the processes bound to them:

```
% psradm -F -f 1 2
```

Exit Status The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Files /etc/wtmpx   Records logging processor status changes

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also pbind(1M), psrinfo(1M), psrset(1M), p_online(2), processor_bind(2), attributes(5)

Diagnostics psradm: processor 4: Invalid argument
The specified processor does not exist in the configuration.

psradm: processor 3: Device busy
The specified processor could not be taken off-line because it either has LWPs bound to it, is the last on-line processor in the system, or is needed by the system because it provides some essential service.

psradm: processor 3: Device busy
The specified processor could not be set no-intr because it is the last interruptible processor in the system, or or it is the only processor in the system that can service interrupts needed by the system.

psradm: processor 3: Device busy
The specified processor is powered off, and it cannot be powered on because some platform-specific resource is unavailable.

psradm: processor 0: Not owner
The user does not have permission to change processor status.

psradm: processor 2: Operation not supported
The specified processor is powered off, and the platform does not support power on of individual processors.

Name psrinfo – displays information about processors

Synopsis psrinfo [-p] [-v] [*processor_id*]...

psrinfo [-p] -s *processor_id*

Description psrinfo displays information about processors. Each physical processor may support multiple virtual processors. Each virtual processor is an entity with its own interrupt ID, capable of executing independent threads.

Without the *processor_id* operand, psrinfo displays one line for each configured processor, displaying whether it is on-line, non-interruptible (designated by no-intr), spare, off-line, faulted or powered off, and when that status last changed. Use the processor_id operand to display information about a specific processor. See OPERANDS.

Options The following options are supported:

-s *processor_id* Silent mode. Displays 1 if the specified processor is fully on-line. Displays 0 if the specified processor is non-interruptible, spare, off-line, faulted or powered off.

Use silent mode when using psrinfo in shell scripts.

-p Display the number of physical processors in a system.

When combined with the -v option, reports additional information about each physical processor.

-v Verbose mode. Displays additional information about the specified processors, including: processor type, floating point unit type and clock speed. If any of this information cannot be determined, psrinfo displays unknown.

When combined with the -p option, reports additional information about each physical processor.

Operands The following operands are supported:

processor_id The processor ID of the processor about which information is to be displayed.

Specify *processor_id* as an individual processor number (for example, 3), multiple processor numbers separated by spaces (for example, 1 2 3), or a range of processor numbers (for example, 1-4). It is also possible to combine ranges and (individual or multiple) *processor_id*s (for example, 1-3 5 7-8 9).

Examples   EXAMPLE 1   Displaying Information About All Configured Processors in Verbose Mode

The following example displays information about all configured processors in verbose mode.

```
psrinfo -v
```

EXAMPLE 2   Determining If a Processor is On-line

The following example uses psrinfo in a shell script to determine if a processor is on-line.

```
if [ "`psrinfo -s 3 2> /dev/null`" —eq 1 ]
then
    echo "processor 3 is up"
fi
```

EXAMPLE 3   Displaying Information About the Physical Processors in the System

With no additional arguments, the -p option displays a single integer: the number of physical processors in the system:

```
> psrinfo -p
                8
```

psrinfo also accepts command line arguments (processor IDs):

```
> psrinfo -p 0 512    # IDs 0 and 512 exist on the
1                     # same physical processor

> psrinfo -p 0 1      # IDs 0 and 1 exist on different
2                     # physical processors
```

In this example, virtual processors 0 and 512 exist on the same physical processor. Virtual processors 0 and 1 do not. This is specific to this example and is and not a general rule.

Exit Status   The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   psradm(1M), p_online(2), processor_info(2), attributes(5)

Diagnostics   psrinfo: processor 9: Invalid argument   The specified processor does not exist.

Name psrset – creation and management of processor sets

Synopsis psrset -a [-F] *processor_set_id processor_id*...

psrset -b *processor_set_id pid* [*/lwpid*]...

psrset -c [-F] [*processor_id*]...

psrset -d *processor_set_id*...

psrset -e *processor_set_id command* [*argument(s)*]

psrset -f *processor_set_id*

psrset [-i] [*processor_set_id*]...

psrset -n *processor_set_id*

psrset -p [*processor_id*]...

psrset [-q] [*pid* [*/lwpid*]]...

psrset -Q [*processor_set_id*]...

psrset -r [-F] *processor_id*...

psrset -u *pid* [*/lwpid*]...

psrset -U [*processor_set_id*]...

Description The psrset utility controls the management of processor sets. Processor sets allow the binding of processes or LWPs to groups of processors, rather than just a single processor. Processors assigned to processor sets can run only LWPs that have been bound to that processor set.

This command cannot be used to modify processor disposition when pools are enabled. Use pooladm(1M) and poolcfg(1M) to modify processor set configuration through the resource pools facility.

Options The following options are supported:

-a   Assign the specified processors to the specified processor set. With the additional -F option, all LWPs bound to the specified processors will be unbound prior to changing processor sets.

This option is restricted to users with the PRIV_SYS_RES_CONFIG privilege.

-b   Bind all or a subset of the LWPs of the specified processes to the specified processor set.

LWPs bound to a processor set are restricted to run only on the processors in that set. Processes can only be bound to non-empty processor sets, that is, processor sets that have had processors assigned to them.

Bindings are inherited, so new LWPs and processes created by a bound LWP have the same binding. Binding an interactive shell to a processor, for example, binds all commands executed by the shell.

This option is restricted to users with the PRIV_SYS_RES_CONFIG privilege.

-c   Create a new processor set and displays the new processor set ID. With the additional -F option, all LWPs bound to the specified processors will be unbound prior to assigning them to the processor set being created.

      If a list of processors is given, it also attempts to assign those processors to the processor set. If this succeeds, the processors are idle until LWPs are bound to the processor set. This option is restricted to users with the PRIV_SYS_RES_CONFIG privilege.

      Only a limited number of processor sets can be active (created and not destroyed) at a given time. This limit is always be greater than the number of processors in the system. If the -c option is used when the maximum number of processor sets is already active, the command fails.

      The following format is used for the first line of output of the -c option when the LC_MESSAGES locale category specifies the "C" locale. In other locales, the strings created, processor, and set can be replaced with more appropriate strings corresponding to the locale.

      "created processor set %d\n" *processor set ID*

-d   Remove the specified processor set, releasing all processors and processes associated with it.

      This option is restricted to users with the PRIV_SYS_RES_CONFIG privilege.

-e   Execute a command (with optional arguments) in the specified processor set.

      The command process and any child processes are executed only by processors in the processor set.

      This option is restricted to users with the PRIV_SYS_RES_CONFIG privilege.

-f   Disables interrupts for all processors within the specified processor set. See psradm(1M).

      If some processors in the set cannot have their interrupts disabled, the other processors still have their interrupts disabled, and the command reports an error and return non-zero exit status.

      This option is restricted to users with the PRIV_SYS_RES_CONFIG privilege.

-F   Forces the specified processor set operation by unbinding all threads bound to the specified processor. Only the -a or the -r option can be used in combination with this option. Administrators are encouraged to use the -Q option for pbind(1M) to find out which threads will be affected by such operation.

-i   Display a list of processors assigned to each named processor set. If no argument is given, a list of all processor sets and the processors assigned to them is displayed. This is also the default operation if the psrset command is not given an option.

-n   Enable interrupts for all processors within the specified processor set. See psradm(1M).

This option is restricted to users with the PRIV_SYS_RES_CONFIG privilege.

-p   Display the processor set assignments for the specified list of processors. If no argument is given, the processor set assignments for all processors in the system is given.

-q   Display the processor set bindings of the specified processes or of all processes. If a process is composed of multiple LWPs which have different bindings and the LWPs are not explicitly specified, the bindings of only one of the bound LWPs is displayed. The bindings of a subset of LWPs can be displayed by appending "/lwpids" to the process IDs. Multiple LWPs may be selected using "-" and "," delimiters. See EXAMPLES.

-Q   Display the LWPs bound to the specified list of processor sets, or all LWPs with processor set bindings.

-r   Remove a list of processors from their current processor sets. Processors that are removed return to the general pool of processors.

Processors with LWPs bound to them using pbind(1M) can be assigned to or removed from processor sets using the -F option.

This option is restricted to users with the PRIV_SYS_RES_CONFIG privilege.

-u   Remove the processor set bindings of a subset or all the LWPs of the specified processes, allowing them to be executed on any on-line processor if they are not bound to individual processors through pbind.

Users with the PRIV_SYS_RES_CONFIG privilege can unbind any process or LWP from any active processor set. Other users can unbind processes and LWPs from processor sets that do not have the PSET_NOESCAPE attribute set. In addition, the user must have permission to control the affected processes; the real or effective user ID of the user must match the real or saved user ID of the target processes.

-U   Removes the bindings of all LWPs bound to the specified list of processor sets, or to any processor set if no argument is specified.

Operands The following operands are supported:

    pid   Specify *pid* as a process ID.

    lwpid   The set of LWPIDs of the specified process to be controlled or queried. The syntax for selecting LWP IDs is as follows:

```
2,3,4-8      LWP IDs 2, 3, and 4 through 8
-4           LWPs whose IDs are 4 or below
4-           LWPs whose IDs are 4 or above
```

    processor_id   Specify *processor_id* as an individual processor number (for example, 3), multiple processor numbers separated by spaces (for example, 1 2 3), or a range of processor numbers (for example, 1-4). It is also possible to combine ranges and (individual or multiple) *processor_id*s (for example, 1-3 5 7-8 9).

    processor_set_id Specify *processor_set_id* as a processor set ID.

Exit Status The following exit values are returned:

    0   Successful completion.

    non-0   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also pbind(1M), pooladm(1M), poolcfg(1M), psradm(1M), psrinfo(1M), processor_bind(2), processor_info(2), pset_bind(2), pset_create(2), pset_info(2), sysconf(3C), libpool(3LIB), attributes(5), privileges(5)

Diagnostics The following output indicates that the specified process did not exist or has exited:

```
psrset: cannot query pid 31: No such process
```

The following output indicates that the user does not have permission to bind the process:

```
psrset: cannot bind pid 31: Not owner
```

The following output indicates that the user does not have permission to assign the processor:

```
psrset: cannot assign processor 4: Not owner
```

The following output indicates that the specified processor is not on-line, or the specified processor does not exist.

```
psrset: cannot assign processor 8: Invalid argument
```

The following output indicates that an LWP in the specified process is bound to a processor and cannot be bound to a processor set that does not include that processor:

```
psrset: cannot bind pid 67: Device busy
```

The following output indicates that the specified processor could not be added to the processor set. This can be due to bound LWPs on that processor, or because that processor cannot be combined in the same processor set with other processors in that set, or because the processor is the last one in its current processor set:

```
psrset: cannot assign processor 7: Device busy
```

The following output indicates that the specified processor set does not exist:

```
psrset: cannot execute in processor set 8: Invalid argument
```

The following output indicates that the maximum number of processor sets allowed in the system is already active:

```
psrset: cannot create processor set: Not enough space
```

The following output indicates that the pools facility is active.

```
psrset: cannot assign processor 7: Operation not supported
psrset: cannot bind pid 31: Operation not supported
psrset: cannot bind pid 31: Operation not supported
psrset: could not create processor set: Operation not supported
psrset: could not remove processor set 1: Operation not supported
psrset: cannot exec in processor set 1: Operation not supported
psrset: cannot remove processor 7: Operation not supported
psrset: cannot unbind pid 31: Operation not supported
```

Name pwck, grpck – password/group file checkers

Synopsis /usr/sbin/pwck [*filename*]

/usr/sbin/grpck [*filename*]

Description pwck scans the password file and notes any inconsistencies. The checks include validation of the number of fields, login name, user ID, group ID, and whether the login directory and the program-to-use-as-shell exist. The default password file is /etc/passwd.

grpck verifies all entries in the group file. This verification includes a check of the number of fields, group name, group ID, whether any login names belong to more than NGROUPS_MAX groups, and that all login names appear in the password file. grpck also issues a warning if it finds an entry (a single line) in the group file longer than 2047 characters. Such an entry causes group maintenance commands, such as groupdel(1M) and groupmod(1M), to fail.

The default group file is /etc/group.

All messages regarding inconsistent entries are placed on the stderr stream.

Files ■ /etc/group
■ /etc/passwd

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also groupdel(1M), groupmod(1M), getpwent(3C), group(4), passwd(4), attributes(5)

Diagnostics Group entries in /etc/group with no login names are flagged.

Group file '*filename*' is empty
    The /etc/passwd or /etc/group file is an empty file.

cannot open file *filename*: No such file or directory
    The /etc/passwd or /etc/group file does not exist.

Notes If no filename argument is given, grpck checks the local group file, /etc/group, and also makes sure that all login names encountered in the checked group file are known to the system getpwent(3C) routine. This means that the login names may be supplied by a network name service.

Name pwconv – installs and updates /etc/shadow with information from /etc/passwd

Synopsis pwconv

Description The pwconv command creates and updates /etc/shadow with information from /etc/passwd.

pwconv relies on a special value of 'x' in the password field of /etc/passwd. This value of 'x' indicates that the password for the user is already in /etc/shadow and should not be modified.

If the /etc/shadow file does not exist, this command will create /etc/shadow with information from /etc/passwd. The command populates /etc/shadow with the user's login name, password, and password aging information. If password aging information does not exist in /etc/passwd for a given user, none will be added to /etc/shadow. However, the last changed information will always be updated.

If the /etc/shadow file does exist, the following tasks will be performed:

Entries that are in the /etc/passwd file and not in the /etc/shadow file will be added to the /etc/shadow file.

Entries that are in the /etc/shadow file and not in the /etc/passwd file will be removed from /etc/shadow.

Password attributes (for example, password and aging information) that exist in an /etc/passwd entry will be moved to the corresponding entry in /etc/shadow.

The pwconv command can only be used by the super-user.

Files
- /etc/opasswd
- /etc/oshadow
- /etc/passwd
- /etc/shadow

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also passwd(1), usermod(1M), passwd(4), attributes(5)

Diagnostics pwconv exits with one of the following values:

0   SUCCESS.

1   Permission denied.

2   Invalid command syntax.

3   Unexpected failure. Conversion not done.

4   Unexpected failure. Password file(s) missing.

5   Password file(s) busy. Try again later.

6   Bad entry in `/etc/shadow` file.

Name quot – summarize file system ownership

Synopsis quot [-acfhnv] *filesystem*...

quot -a [-cfhnv]

Description quot displays the number of blocks (1024 bytes) in the named *filesystem* (one or more) currently owned by each user. There is a limit of 2048 blocks. Files larger than this will be counted as a 2048 block file, but the total block count will be correct.

Options The following options are supported:

-a   Generate a report for all mounted file systems.

-c   Display three columns giving a file size in blocks, the number of files of that size, and a cumulative total of blocks containing files of that size or a smaller size.

-f   Display three columns giving, for each user, the number of blocks owned, the count of number of files, and the user name. This option is incompatible with the -c and -v options.

-h   Estimate the number of blocks in the file. This does not account for files with holes in them.

-n   Attach names to the list of files read from standard input. quot -n cannot be used alone, because it expects data from standard input. For example, the pipeline

ncheck myfilesystem | sort +0n | quot -n myfilesystem

will produce a list of all files and their owners. This option is incompatible with all other options.

-v   In addition to the default output, display three columns containing the number of blocks not accessed in the last 30, 60, and 90 days.

Operands *filesystem*   mount-point of the filesystem(s) being checked

Usage See largefile(5) for the description of the behavior of quot when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Exit Status 0   Successful operation.

32   Error condition (bad or missing argument, bad path, or other error).

Files /etc/mnttab   Lists mounted file systems.

/etc/passwd   Used to obtain user names

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also du(1), mnttab(4), passwd(4), attributes(5), largefile(5)

Notes This command can only be used by the super-user.

Name quota – display a user's ufs or zfs file system disk quota and usage

Synopsis quota [-v] [*username*]

Description quota displays users' UFS or ZFS disk usage and limits. Only the super-user may use the optional *username* argument to view the limits of other users.

quota without options only display warnings about mounted file systems where usage is over quota. Remotely mounted file systems which do not have quotas turned on are ignored.

username can be the numeric UID of a user.

Options -v   Display user's quota on all mounted file systems where quotas exist.

Usage See largefile(5) for the description of the behavior of quota when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files /etc/mnttab   list of currently mounted filesystems

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also edquota(1M), quotaon(1M), quotacheck(1M), repquota(1M), rquotad(1M), attributes(5), largefile(5), zones(5)

Notes quota displays quotas for NFS mounted UFS- or ZFS-based file systems if the rquotad daemon is running. See rquotad(1M). In a zones(5) environment, quota displays quotas only for the zone in which it is invoked.

quota can display entries for the same file system multiple times for multiple mount points. For example,

```
# quota -v user1
```

might display identical quota information for user1 at the mount points /home/user1, /home/user2, and /home/user, if all three mount points are mounted from the same file system with quotas turned on.

Name quotacheck – ufs file system quota consistency checker

Synopsis quotacheck [-fp] [-v] *filesystem*...

quotacheck -a [-fpv]

Description quotacheck examines each mounted ufs file system, builds a table of current disk usage, and compares this table against the information stored in the file system's disk quota file. If any inconsistencies are detected, both the quota file and the current system copy of the incorrect quotas are updated.

filesystem is either a file system mount point or the block device on which the file system resides.

quotacheck expects each file system to be checked to have a quota file named quotas in the root directory. If none is present, quotacheck will not check the file system.

quotacheck accesses the character special device in calculating the actual disk usage for each user. Thus, the file systems that are checked should be quiescent while quotacheck is running.

Options The following options are supported:

-a   Check the file systems which /etc/mnttab indicates are ufs file systems. These file systems must be read-write mounted with disk quotas enabled, and have an rq entry in the mntopts field in /etc/vfstab.

-f   Force check on file systems with logging enabled. Use in combination with the -p option.

-p   Check quotas of file systems in parallel. For file systems with logging enabled, no check is performed unless the -f option is also specified.

-v   Indicate the calculated disk quotas for each user on a particular file system. quotacheck normally reports only those quotas modified.

Usage See largefile(5) for the description of the behavior of quotacheck when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files /etc/mnttab   Mounted file systems

/etc/vfstab   List of default parameters for each file system

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also edquota(1M), quota(1M), quotaon(1M), repquota(1M), attributes(5), largefile(5), quotactl(7I), mount_ufs(1M)

Name quotaon, quotaoff – turn ufs file system quotas on and off

Synopsis quotaon [-v] *filesystem*...

quotaon -a [-v]

quotaoff [-v] *filesystem*...

quotaoff -a [-v]

Description quotaon turns on disk quotas for one or more ufs file systems.

Before a file system may have quotas enabled, a file named quotas, owned by root, must exist in the root directory of the file system. See edquota(1M) for details on how to modify the contents of this file.

quotaoff turns off disk quotas for one or more ufs file systems.

The file systems specified must already be mounted.

These commands update the mntopts field of the appropriate entries in /etc/mnttab to indicate when quotas are on or off for each file system. If quotas are on, the string quota will be added to mntopts; if quotas are off, the quota string is not present.

filesystem must be either the mount point of a file system, or the block device on which the file system resides.

Options

quotaon -a This option is normally used at boot time to enable quotas. It applies only to those file systems in /etc/vfstab which have "rq" in the mntopts field, are currently mounted "rw", and have a quotas file in the root directory.

-v Display a message for each file system after quotas are turned on.

quotaoff -a Force all file systems in /etc/mnttab to have their quotas disabled.

-v Display a message for each file system affected.

Usage See largefile(5) for the description of the behavior of quotaon and quotaoff when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files /etc/mnttab   mounted file systems

/etc/vfstab   list of default parameters for each file system

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

Name raidctl – RAID hardware utility

Synopsis raidctl -C ″*disks*″ [-r *raid_level*] [-z *capacity*] [-s *stripe_size*] [-f]
         controller

raidctl -d [-f] *volume*

raidctl -F *filename* [-f] *controller*...

raidctl -a {set | unset} -g *disk* {volume | controller}

raidctl -p ″*param=value*″ [-f] *volume*

raidctl -c [-f] [-r *raid_level*] *disk1 disk2* [*disk3*...]

raidctl -l -g *disk controller*

raidctl -l *volume*

raidctl -l *controller*...

raidctl [-l]

raidctl -S [volume | controller]

raidctl -S -g *disk controller*

raidctl -h

Description The raidctl utility is a hardware RAID configuration tool that supports different RAID controllers by providing a CLI (command-line interface) to end-users to create, delete or display RAID volume(s). The utility can also used to set properties of a volume, assign hot-spare (HSP) disks to volumes or controllers, and to update firmware/fcode/BIOS for RAID controllers.

The raidctl utility requires privileges that are controlled by the underlying file system permissions. Only privileged users can manipulate the RAID system configuration. If a non-privileged user attempts to run raidctl, the command fails with an exit status of 1.

The raidctl utility, as described in this man page, defines a broad set of command line options to provide management for full-featured RAID controllers. However, support for a given option depends on two elements:

- the presence of a software driver
- the firmware level of the RAID device

The dependency on a software driver is due to the design of raidctl. The utility is built on a common library that enables the insertion of plug-in modules for different drivers. Currently, the Solaris operating system is shipped with a plug-in for the mpt driver. This plug-in does not support all of the raidctl options. On a given storage device, options might be further limited by the device's firmware level.

The level of support for the various raidctl options cannot be determined by raidctl. The user must rely on the documentation for his RAID controller or hardware platform.

Currently, raidctl Currently, raidctl provides some level of support for the following RAID controllers:

- LSI1020 SCSI HBA
- LSI1030 SCSI HBA
- LSI1064 SAS HBA
- LSI1068 SAS HBA

All of the above HBAs are maintained by the mpt driver, on X86-32/64 and SPARC platforms.

Options   The following options are supported:

-C *"disks"* [-r *raid_level*] [-z *capacity*] [-s *stripe_size*] [-f] controller
Create a RAID volume using specified disks.

When creating a RAID volume using this option, the identity of the newly created volume is automatically generated and raidctl reports it to the user.

The argument specified by this option contains the elements used to form the volume that is created. Elements can be either disks or sub-volumes, where disks are separated by space(s) and a sub-volume is a set of disks grouped by parenthesis. All disks should be in C.ID.L expression (for example, 0.1.2 represents a physical disk of channel 0, target id 1, and logical unit number 2). The argument must match the RAID level specified by the -r option, even if it's omitted. This means the argument can only be:

for RAID 0
At least 2 disks

for RAID 1
Only 2 disks

for RAID 1E
At least 3 disks

for RAID 5
At least 3 disks

for RAID 10
At least 2 sub-volumes, each sub-volume must be formed by 2 disks

for RAID 50
At least 2 sub-volumes, each sub-volume must be formed by at least 3 disks, and the disk amount in each sub-volume should be the same

For example, the expression "0.0.0 0.1.0" means that the 2 specified disks form a RAID volume, which can either be a RAID 0 or a RAID 1 volume. "(0.0.0 0.1.0)(0.2.0 0.3.0)" means that the first 2 disks and the last 2 disks form 2 sub-volumes, and that these 2 sub-volumes form a RAID 10 volume. See the EXAMPLES section for more samples.

The -r option specifies the RAID level of the volume that is created. Possible levels are 0, 1, 1E, 5, 10, 50. If this option is omitted, raidctl creates a RAID 1 volume by default.

The -z option specifies the capacity of the volume that is created. The unit can be tera-bytes, giga-bytes, or mega-bytes (for example, 2t, 10g, 20m, and so on). If this option is omitted, raidctl calculates the maximum capacity of the volume that can be created by the specified disks and uses this value to create the volume.

The -s option specifies the stripe size of the volume that is created. The possible values are 512, 1k, 2k, 4k, 8k, 16k, 32k, 64k, or 128k. If this option is omitted, raidctl chooses an appropriate value for the volume (for example, 64k).

In some cases, the creation of a RAID volume can cause data on specified disks to be lost (for instance, on LSI1020, LSI1030, SAS1064, or SAS1068 HBAs), and raidctl prompts the user for confirmation about the creation. Use the -f option to force the volume creation without prompting the user for confirmation.

The controller argument is used to identify which RAID controller the specified disks belongs. The -l option can be used to list the controller's ID number.

-d [-f] *volume*
Delete the RAID volume specified as volume. The volume is specified in canonical form (for example, c0t0d0).

When a volume is deleted, all data is lost. Therefore, unless the -f option is specified, raidctl prompts the user for confirmation before deleting the volume.

When a RAID 1 volume is deleted from a LSI1020, LSI1030, SAS1064, or SAS1068 HBA, the primary and secondary disks are "split". If the volume was in SYNCING state, the primary contains the data, and the secondary does not. If the volume state was OPTIMAL, both disks contain a complete image of the data.

-F *filename* [-f] *controller*…
Update the firmware running on the specified controller(s). The raidctl utility prompts the user for confirmation of this action, unless the -f option is provided.

-a {set | unset} -g *disk* {volume | controller}
If the volume is specified, raidctl sets or unsets the disk as a local hot-spare disk dedicated to the volume, depending on the value specified by the -a option. If the controller is specified, raidctl sets or unsets the disk as a global hot-spare disk.

-p ″*param=value*″ [-f] *volume*
Change the property value for a given RAID volume. This option can be used to change cache write policy or to activate a volume. When changing the cache write policy, *param* should be the string wp (SET_WR_POLICY), and *value* can be either on or off. When used to activate a volume, *param* should be state and *value* should be activate.

Changing a RAID volume's property can affect the internal behavior of the RAID controller, so raidctl prompts the user for a confirmation before applying the change, unless the -f option is specified.

-c [-f] [-r *raid_level*] *disk1 disk2* [*disk3...*]
    Create a volume using the specified disks. This is an alternative to the -C option with similar functionality. This option is preserved for compatibility reasons, but only works with LSI1020, LSI1030, SAS1064, and SAS1068 HBAs to create RAID 0, RAID 1, or RAID 1E volumes. For other HBAs, the user can only use the -C option.

    The -r option can be used to specify the RAID level of the target volume. If the -r option is omitted, raidctl creates a RAID 1 volume.

    Disks must be specified in Solaris canonical format (for example, c0t0d0).

    Creating a RAID 1 volume with this option replaces the contents of disk2 with the contents of disk1.

    When the user creates a RAID volume with this option, the RAID volume assumes the identity of disk1. Other disks become invisible and the RAID volume appears as one disk.

    Creating a volume with this option is by default interactive. The user must answer a prompt affirmatively to create the volume. Use the -f option to force the volume creation without prompting the user for confirmation.

-l -g *disk controller*
    Display information about the specified disk of the given controller. The output includes the following information:

    Disk
        Displays the disk in C.ID.L expression disk.

    Vendor
        Displays the vendor ID string.

    Product
        Displays the product ID string.

    Capacity
        Displays the total capacity of the disk.

    Status
        Displays the current status of disk. The status can be either "GOOD" (operating normally), "FAILED" (non-functional), or "MISSING" (disk not present).

    HSP
        Indicates if the disk has been set as a global hot-spare disk, local hot-spare disk, or a normal one. If it is a local hot-spare disk, all volumes which this disk is assigned to are displayed.

    GUID
        GUID string for the specified disk. This is an additional datum and might be unavailable in some cases.

-l *volume*

Display information about the specified volume. The output includes the following information:

Volume

Displays volume in canonical format.

Sub

Displays sub-volumes, if the specified volume is of RAID 10 or RAID 50 volume.

Disk

Displays all disks that form the specified volume.

Stripe Size

Displays the stripe size of the volume.

Status

Displays the status of the specified volume, or the sub-volumes or disks that form the specified volume. For an inactive volume, the status should be INACTIVE; otherwise it can be OPTIMAL (operating optimally), DEGRADED (operating with reduced functionality), FAILED (non-functional), or SYNC (disks are syncing). For a disk, the status can be GOOD, FAILED, or MISSING.

Cache

Indicates whether the cache is applied to I/O write activities. The cache can be either "ON" or "OFF".

RAID level

Displays the RAID level. The RAID level can be either 0, 1, 1E, 5, 10, or 50.

-l *controller* ...

Display information about the specified controller(s). The output includes the following information:

Controller

Displays the RAID controller's ID number.

Type

Displays the RAID controller's product type.

fw_version

Displays the controller's firmware version.

[-l]

List all RAID related objects that the raidctl utility can manipulate, including all available RAID controllers, RAID volumes, and physical disks. The -l option can be omitted.

The output includes the following information:

Controller

Displays the RAID controller's ID number.

Volume
   Displays the logical RAID volume name.

Disk
   Displays the RAID disk in C.ID.L expression.

-S [volume | controller]
   Takes a snapshot of the RAID configuration information including all available RAID
   devices, RAID controllers, volumes, and disks.

   Each line of the output specifies a RAID device and its related information, separated by
   space(s). All volumes and disks belong to the last specified controller.

   The output lists the following information:

   Controller
      Displays the controller ID number, and the controller type string in double-quotation
      marks.

   Volume
      Displays the RAID volume name, number of component disks, the C.ID.L expression of
      the component disks, the RAID level, and the status. The status can be either OPTIMAL,
      DEGRADED, FAILED, or SYNCING.

   Disk
      Displays the C.ID.L expression of the disk, and the status. The status can be either GOOD,
      FAILED, or HSP (disk has been set as a stand-by disk).

   If a volume or a controller is specified, a snapshot is only taken of the information for the
   specified volume or controller.

-S -g *disk controller*
   Takes a snapshot of the information for the specified disk.

-h
   Print out the usage string.

Examples   EXAMPLE 1   Creating the RAID Configuration

The following command creates a RAID 0 volume of 10G on controller 0, and the stripe size is
set to 64k:

raidctl -C "0.0.0 0.2.0" -r 0 -z 10g -s 64k 0

The following command creates a RAID 1 volume on controller 2:

raidctl -C "0.0.0 1.1.0" -r 1 2

The following command creates a RAID 5 volume on controller 2:

raidctl -C "0.0.0 0.1.0 0.2.0" -r 5 2

The following command creates a RAID 10 volume on controller 0:

EXAMPLE 1   Creating the RAID Configuration   *(Continued)*

```
# raidctl -C "(0.0.0 0.1.0)(0.2.0 0.3.0)" -r 10 0
```

The following command creates a RAID 50 volume on controller 0:

```
# raidctl -C "(0.0.0 0.1.0 0.2.0)(0.3.0 0.4.0 0.5.0)" -r 50 0
```

EXAMPLE 2   Displaying the RAID Configuration

The following command displays all available controllers, volumes, and disks:

```
# raidctl -l
```

```
Controller: 0
Controller: 2
        Volume:c2t0d0
        Disk: 0.0.0
        Disk: 0.1.0
        Disk: 0.2.0
        Disk: 0.3.0(HSP)
```

The following command displays information about controller 2:

```
# raidctl -l 2
```

```
Controller      Type           Fw_version
-----------------------------------------------------------------
c2              LSI 1030       1.03.39.00
```

The following command displays information about the specified volume:

```
# raidctl -l c2t0d0
```

```
Volume                 Size    Stripe  Status  Cache   RAID
        Sub                    Size                    Level
            Disk
-----------------------------------------------------------------
c2t0d0                 10240M  64K     OPTIMAL ON      RAID5
            0.0.0  5120M              GOOD
            0.1.0  5120M              GOOD
            0.2.0  5120M              GOOD
```

The following command displays information about disk 0.0.0 on controller 0:

```
# raidctl -l -g 0.0.0  0
```

```
Disk    Vendor Product         Firmware Capacity      Status HSP
-----------------------------------------------------------------
0.0.0   HITACHI H101473SCSUN72G SQ02     68.3G         GOOD   N/A
GUID:2000000cca02536c
```

EXAMPLE 3 Deleting the RAID Configuration

The following command deletes a volume:

```
# raidctl -d c0t0d0
```

EXAMPLE 4 Updating Flash Images on the Controller

The following command updates flash images on the controller 0:

```
# raidctl -F lsi_image.fw 0
```

EXAMPLE 5 Setting or Unsetting a Hot-Spare Disk

The following command sets disk 0.3.0 on controller 2 as a global hot-spare disk:

```
# raidctl -a set -g 0.3.0 2
```

The following command sets disk 0.3.0 on controller 2 as a local hot-spare disk to volume c2t0d0:

```
# raidctl -a set -g 0.3.0 c2t0d0
```

The following command converts disk 0.3.0 on controller 2 from a global hot-spare disk to a normal one:

```
# raidctl -a unset -g 0.3.0 2
```

The following command removes disk 0.3.0 from being a local hot-spare disk from volume c2t0d0:

```
# raidctl -a unset -g 0.3.0 c2t0d0
```

EXAMPLE 6 Setting the Volume's Property

The following command sets the write policy of the volume to "off":

```
# raidctl -a set -p "wp=off" c0t0d0
```

EXAMPLE 7 Creating Volumes with the -c Option

The following command creates a RAID 1 volume:

```
# raidctl -c c0t0d0 c0t1d0
```

The following command creates a RAID 0 volume:

```
# raidctl -c -r 0 c0t1d0 c0t2d0 c0t3d0
```

EXAMPLE 8 Taking a Snapshot of the RAID Configuration

The following command takes a snapshot of all RAID devices:

```
# # raidctl -S

1 "LSI 1030"
```

EXAMPLE 8 Taking a Snapshot of the RAID Configuration *(Continued)*

```
c1t1d0 2 0.2.0 0.3.0 1 DEGRADED
0.2.0 GOOD
0.3.0 FAILED
```

The following command takes a snapshot about volume c1t0d0:

```
# raidctl -S c1t0d0
```

```
c1t0d0 2 0.0.0 0.1.0 1 OPTIMAL
```

The following command takes a snapshot about disk 0.1.0 on controller 1:

```
# raidctl -S -g 0.1.0 1
```

```
0.1.0 GOOD
```

Exit Status The following exit values are returned:

0

    Successful completion.

1

    Invalid command line input or permission denied.

2

    Request operation failed.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also attributes(5), mpt(7D)

Oracle Solaris Administration: Common Tasks

Warnings Do not create raid volumes on internal SAS disks if you are going to use the Solaris Multipathing I/O feature (also known as MPxIO). Creating a new raid volume under Solaris Multipathing gives your root device a new GUID which does not match the GUID for the existing devices. This causes a boot failure since your root device entry in /etc/vfstab does not match.

Notes The -z option is not supported on systems that use the mpt driver and LSI RAID controllers.

Name ramdiskadm – administer ramdisk pseudo device

Synopsis /usr/sbin/ramdiskadm -a *name size* [g | m | k | b]

/usr/sbin/ramdiskadm -d *name*

/usr/sbin/ramdiskadm

Description The ramdiskadm command administers ramdisk(7D), the ramdisk driver. Use ramdiskadm to create a new named ramdisk device, delete an existing named ramdisk, or list information about existing ramdisks.

Ramdisks created using ramdiskadm are not persistent across reboots.

Options The following options are supported:

-a *name size*   Create a ramdisk named *name* of size *size* and its corresponding block and character device nodes.

name must be composed only of the characters a-z, A-Z, 0-9, _ (underbar), and - (hyphen), but it must not begin with a hyphen. It must be no more than 32 characters long. Ramdisk names must be unique.

The size can be a decimal number, or, when prefixed with 0x, a hexadecimal number, and can specify the size in bytes (no suffix), 512-byte blocks (suffix b), kilobytes (suffix k), megabytes (suffix m) or gigabytes (suffix g). The size of the ramdisk actually created might be larger than that specified, depending on the hardware implementation.

If the named ramdisk is successfully created, its block device path is printed on standard out.

-d *name*   Delete an existing ramdisk of the name *name*. This command succeeds only when the named ramdisk is not open. The associated memory is freed and the device nodes are removed.

You can delete only ramdisks created using ramdiskadm. It is not possible to delete a ramdisk that was created during the boot process.

Without options, ramdiskadm lists any existing ramdisks, their sizes (in decimal), and whether they can be removed by ramdiskadm (see the description of the -d option, above).

Examples **EXAMPLE 1**   Creating a 2MB Ramdisk Named mydisk

```
# ramdiskadm -a mydisk 2m
/dev/ramdisk/mydisk
```

EXAMPLE 2 Listing All Ramdisks

```
# ramdiskadm
Block Device                Size  Removable
/dev/ramdisk/miniroot   134217728   No
/dev/ramdisk/certfs       1048576   No
/dev/ramdisk/mydisk       2097152   Yes
```

Exit Status ramdiskadm returns the following exit values:

0   Successful completion.

>0   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also attributes(5), ramdisk(7D)

Notes The abilities of ramdiskadm and the privilege level of the person who uses the utility are controlled by the permissions of /dev/ramdiskctl. Read access allows query operations, for example, listing device information. Write access is required to do any state-changing operations, for example, creating or deleting ramdisks.

As shipped, /dev/ramdiskctl is owned by root, in group sys, and mode 0644, so all users can do query operations but only root can perform state-changing operations. An administrator can give write access to non-privileged users, allowing them to add or delete ramdisks. However, granting such ability entails considerable risk; such privileges should be given only to a trusted group.

Name   rcapadm – configure resource capping daemon

Synopsis   `rcapadm`

   ```
   rcapadm [ [-n] -E | -D]
       [-i interval=value,...,interval=value] [-c percent]
       [-z zonename -m maxvalue]
   ```

Description   The `rcapadm` command allows a user with the privileges described below to configure various attributes of the resource capping daemon. If used without arguments, `rcapadm` displays the current status of the resource capping daemon if it has been configured. See `rcapd(1M)` for more information.

   In the current release of the Solaris operating environment, `rcapadm` is available to users with all privileges and to users who have the Process Management profile in their list of profiles. The System Administrator role includes the Process Management profile.

Options   `-c percent`   Set the minimum physical memory utilization for memory cap enforcement. Caps will not be enforced until the physical memory available to processes is low. The *percent* value should be in the range 0 to 100. The minimum (and default) value is `0`, which means that memory caps are always enforced.

   `-D`   Disable the resource capping daemon so that it will not be started when the system is booted. Also stop the resource capping daemon now, if the `-n` option is not specified and it is currently running.

   `-E`   Enable the resource capping daemon so that it will be started each time the system is booted. Also start the resource capping daemon now, if the `-n` option is not specified and it is not currently running.

   `-i interval=value,...,interval=value`   Set intervals for various periodic operations performed by `rcapd`. All intervals are specified in seconds. You can set the following intervals:

   scan   The interval at which `rcapd` scans for new processes. The default scan interval is every 15 seconds. The minimum value is 1 second.

   sample   The interval of process resident set size sampling. The default sample interval is every 5 seconds. The minimum value is 1 second.

report The interval at which various paging
statistics are updated by rcapd, in seconds.
These statistics can be viewed by using
rcapstat(1SRM). The default reporting
interval is every 5 seconds. When the
interval is set to 0, statistics will not be
updated.

Note – Paging refers to the act of relocating
portions of memory, called pages, to or
from physical memory. rcapd pages out
the most infrequently used pages.

config The reconfiguration interval, in seconds.
At each reconfiguration event, rcapd
checks its configuration file for updates,
and scans the project databases for new
project caps. The default reconfiguration
interval is every 60 seconds. The
minimum interval is 0. When the interval
is set to 0, no periodic reconfiguration
occurs, although the running daemon can
still be reconfigured by sending it SIGHUP.

-m *maxvalue* Used in conjunction with the -z option. Specifies a
value for rcap.max-rss, a dynamically-set cap on the
usage of physical memory for the zone specified by -z.
You can apply a scale (K, M, G, T) to the value you
specify. K means kilobyte; M, megabyte; G, gigabyte; and
T, terabyte. For example, 100M is 100 megabytes.

To remove an existing cap, specify 0M.

-n Do not affect the running state of the resource capping
daemon when enabling or disabling it.

-z *zonename* Used in conjunction with the -m option. Specifies the
zone for which you are dynamically specifying a cap
on physical memory usage (using -m).

Note – To set a persistent cap on memory usage within a zone, use zonecfg(1M).

Examples **EXAMPLE 1** Configuring the Resource Capping Daemon with Immediate Enforcement

rcapadm -E -i scan=*15***,sample=***5***,report=***5***,config=***60* **-c** *0*

EXAMPLE 2 Specifying a Resource Cap for a Zone

The command shown below specifies the maximum amount of memory that can be consumed by a specified zone. Note that this value lasts only until the next reboot. To set a persistent cap, use zonecfg(1M).

```
# rcapadm -z testzone -m 512M
```

Exit Status The following exit values are returned:

0   Successful completion. The modifications to the current configuration were valid and made successfully.

1   An error occurred. A fatal error occurred either in obtaining or modifying the resource capping configuration.

2   Invalid command-line options were specified.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/resource-mgmt/resource-caps
Interface Stability	Committed

The -z and -m options are committed interfaces.

See Also rcapstat(1), rcapd(1M), zonecfg(1M), project(4), attributes(5), zones(5)

"Physical Memory Control Using the Resource Capping Daemon" in *Oracle Solaris Administration: Oracle Solaris Zones, Oracle Solaris 10 Zones, and Resource Management*

Name rcapd – resource cap enforcement daemon

Synopsis rcapd [-d]

Description The rcapd daemon enforces resource caps on collections of processes. Per-project and per-zone physical memory caps are supported. For information about projects, see project(4). For zones information, see zones(5)

When the resident set size (RSS) of a collection of processes exceeds its cap, rcapd takes action and reduces the RSS of the collection.

The virtual memory system divides physical memory into segments known as pages. To read data from a file into memory, the virtual memory system reads in individual pages. To reduce resource consumption, the daemon can page out, or relocate, infrequently used pages to an area outside of physical memory.

In the project file, caps are defined for projects that have positive values for the following project attribute:

rcap.max-rss   The total amount of physical memory, in bytes, that is available to the project's member processes

See project(4) for a description of project attributes.

For a system with one or more zones, you can dynamically set the rcap.max-rss value for a zone with rcapadm(1M). To set a persistent cap on memory usage within a zone, you use zonecfg(1M).

You configure rcapd through the use of rcapadm(1M). The daemon can be monitored with rcapstat(1). Configuration changes are incorporated into rcapd by sending it SIGHUP (see kill(1)), or according to the configuration interval (see rcapadm(1M)).

Options The following option is supported:

-d   Enable debug mode. Messages are displayed on the invoking user's terminal.

Examples EXAMPLE 1   Setting Resident Set Size Cap Attribute

The following line in the /etc/project database sets an RSS cap of 1073741824 bytes for a project named foo.

foo:100::foo,root::rcap.max-rss=10737418240

Exit Status The following exit values are returned:

0   Successful completion.

1   An error occurred.

2   Invalid command-line options were specified.

Files   /etc/project   Project database.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/resource-mgmt/resource-caps
Interface Stability	Committed

See Also   rcapstat(1), svcs(1), rcapadm(1M), zonecfg(1M), svcadm(1M), project(4), attributes(5), smf(5), zones(5)

"Physical Memory Control Using the Resource Capping Daemon" in *Oracle Solaris Administration: Oracle Solaris Zones, Oracle Solaris 10 Zones, and Resource Management*

Notes   If killed with SIGKILL, rcapd can leave processes in a stopped state. Use SIGTERM to cause rcapd to terminate properly.

A collection's RSS can exceed its cap for some time before the cap is enforced, even if sufficient pageable memory is available. This period of time can be reduced by shortening the RSS sampling interval with rcapadm.

The rcapd service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/rcap:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name rctladm – display or modify global state of system resource controls

Synopsis rctladm [-lu] [-e *action*] [-d *action*] [*name*...]

Description The rctladm command allows the examination and modification of active resource controls
on the running system. An instance of a resource control is referred to as an *rctl*. See
setrctl(2) for a description of an rctl; see resource_controls(5) for a list of the rctls
supported in the current release of the Solaris operating system. Logging of rctl violations
can be activated or deactivated system-wide and active rctls (and their state) can be listed.

An rctladm command without options is the equivalent of an rctladm with the -l option. See
the description of -l below.

Options The following options are supported:

-d *action*
-e *action*

Disable (-d) or enable (-e) the global action on the specified rctls. If no rctl is specified,
no action is taken and an error status is returned. You can use the special token all with
the disable option to deactivate all global actions on a resource control.

You can set the syslog action to a specific degree by assigning a severity level. To do this,
specify syslog=*level*, where *level* is one of the string tokens given as valid severity levels in
syslog(3C). You can omit the common LOG_ prefix on the severity level. Note that not all
rctls support the syslog action. See resource_controls(5).

-l

List information about rctls. The name, global event actions and statuses, and global flags
are displayed. If one or more name operands are specified, only those rctls matching the
names are displayed.

-u

Configure resource controls based on the contents of /etc/rctladm.conf. Any name
operands are ignored.

Operands The following operands are supported:

name

The name of the rctl to operate on. Multiple rctl names can be specified. If no names are
specified, and the list action has been specified, then all rctls are listed. If the enable or
disable action is specified, one or more rctl names must be specified.

Examples EXAMPLE 1 Activating System Logging for Specific Violations

The following command activates system logging of all violations of task.max-lwps.

```
# rctladm -e syslog task.max-lwps
#
```

EXAMPLE 2 Examining the Current Status of a Specific Resource

The following command examines the current status of the task.max-lwps resource.

```
$ rctladm -l task.max-lwps
task.max-lwps               syslog=DEBUG
$
```

Exit Status The following exit values are returned:

0
　Successful completion.

1
　A fatal error occurred. A message is written to standard error to indicate each resource
　control for which the operation failed. The operation was successful for any other resource
　controls specified as operands.

2
　Invalid command line options were specified.

Files /etc/rctladm.conf
　Each time rctladm is executed, it updates the contents of rctladm.conf with the current
　configuration.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also setrctl(2), getrctl(2), prctl(1), rctlblk_get_global_flags(3C),
rctlblk_get_global_action(3C), attributes(5), resource_controls(5)

Notes By default, there is no global logging of rctl violations.

Name rdate – set system date from a remote host

Synopsis rdate *hostname*

Description rdate sets the local date and time from the *hostname* given as an argument. You must have the authorization solaris.system.date on the local system. Typically, rdate is used in a startup script.

rdate requests are responded to by the "time" service on the specified host. To enable the "time" service, use the following commands:

```
svcadm enable time:stream
svcadm enable time:dgram
```

Usage The rdate command is IPv6–enabled. See ip6(7P).

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/network-clients

See Also inetd(1M), inetd.conf(4), attributes(5), ip6(7P)

Name   reboot – restart the operating system

Synopsis   /usr/sbin/reboot [-dlnq] [-f | -p] [*boot_arguments*]

/usr/sbin/reboot [-f [-e *environment*] | -p] [-dlnq] [*boot_arguments*]

Description   The reboot utility restarts the kernel. The kernel is loaded into memory by the PROM monitor, which transfers control to the loaded kernel.

On x86 systems, when the -f flag is specified, the running kernel will load the next kernel into memory, then transfer control to the newly loaded kernel. This form of reboot is shown in the second synopsis, above.

Although reboot can be run by the super-user at any time, shutdown(1M) is normally used first to warn all users logged in of the impending loss of service. See shutdown(1M) for details.

The reboot utility performs a sync(1M) operation on the disks, and then a multi-user reboot is initiated. See init(1M) for details. On x86 systems, reboot may also update the boot archive as needed to ensure a successful reboot.

The reboot utility normally logs the reboot to the system log daemon, syslogd(1M), and places a shutdown record in the login accounting file /var/adm/wtmpx. These actions are inhibited if the -n or -q options are present.

Normally, the system reboots itself at power-up or after crashes.

Options   The following options are supported:

-d

Force a system crash dump before rebooting. See dumpadm(1M) for information on configuring system crash dumps.

-e

If -f is present, reboot to the specified boot environment.

This option is currently available only on x86 systems.

-f

For x86 systems:

Fast reboot, bypassing firmware and boot loader. The new kernel will be loaded into memory by the running kernel, and control will be transferred to the newly loaded kernel. If disk or kernel arguments are specified, they must be specified before other boot arguments.

For SPARC systems:

Speeds up rebooting by skipping some POST tests.

The service `svc:/system/boot-config:default` is enabled by default. It requires `solaris.system.shutdown` as `action_authorization` and `value_authorization`. When the `config/fastreboot_default` property is set to `true`, reboot will behave as `reboot -f`. The value of this property can be changed using `svccfg(1M)` and `svcadm(1M)`, to control the default reboot behavior.

See EXAMPLES for details.

-l

    Suppress sending a message to the system log daemon, `syslogd(1M)` about who executed `reboot`.

-n

    Avoid calling `sync(2)` and do not log the reboot to `syslogd(1M)` or to `/var/adm/wtmpx`. The kernel still attempts to sync filesystems prior to reboot, except if the `-d` option is also present. If `-d` is used with `-n`, the kernel does not attempt to sync file systems.

-p

    Reboot to prom. This flag can be used to reboot the system through firmware without changing the default reboot behavior as denoted by the `config/fastreboot_default` property setting in `system/boot-config` service.

    The `-p` and `-f` options are mutually exclusive.

-q

    Quick. Reboot quickly and ungracefully, without shutting down running processes first.

Operands The following operands are supported:

boot_arguments

    An optional *boot_arguments* specifies arguments to the `uadmin(2)` function that are passed to the boot program and kernel upon restart. The form and list of arguments is described in the `boot(1M)` and `kernel(1M)` man pages.. If the arguments are specified, whitespace between them is replaced by single spaces unless the whitespace is quoted for the shell. If the *boot_arguments* begin with a hyphen, they must be preceded by the `- -` delimiter (two hyphens) to denote the end of the reboot argument list.

Examples **EXAMPLE 1** Passing the `-r` and `-v` Arguments to boot

In the following example, the delimiter `- -` (two hyphens) must be used to separate the options of reboot from the arguments of `boot(1M)`.

```
example# reboot -dl -- -rv
```

EXAMPLE 2 Rebooting Using a Specific Disk and Kernel

The following example reboots using a specific disk and kernel.

```
example# reboot disk1 kernel.test/unix
```

EXAMPLE 3 Fast Rebooting

The following examples use the -f option to perform fast reboots.

If the service svc:/system/boot-config:default is enabled and property config/fastreboot_default is set to true, the -f option can be omitted.

On an x86 system, the following command reboots to the default entry in the GRUB (see grub(5)) menu file menu.lst.

```
example# reboot -f
```

The following command reboots to another UFS root disk.

```
example# reboot -f -- '/dev/dsk/c1d0s0'
```

The following command reboots to another ZFS root pool.

```
example# reboot -f -- 'rpool/ROOT/root2'
```

The following command reboots to mykernel on the same disk with -k option.

```
example# reboot -f -- '/platform/i86pc/mykernel/amd64/unix -k'
```

The following command reboots to mykernel off another root disk mounted on /mnt.

```
example# reboot -f -- '/mnt/platform/i86pc/mykernel/amd64/unix -k'
```

The following command reboots to /platform/i86pc/kernel/$ISADIR/unix on another boot environment named second_root.

```
example# reboot -f -e second_root
```

The following command reboots to the same kernel with -kv options.

```
example# reboot -f -- '-kv'
```

The following commands disable the fast-reboot-by-default behavior.

```
example# svccfg -s "system/boot-config:default" \
setprop config/fastreboot_default=false
example# svcadm refresh svc:/system/boot-config:default
```

The following commands re-enable the fast-reboot-by-default behavior.

```
example# svccfg -s "system/boot-config:default" \
setprop config/fastreboot_default=true
example# svcadm refresh svc:/system/boot-config:default
```

EXAMPLE 4 Rebooting to a Particular GRUB Menu

The following commands will reboot to entry 2 in the GRUB menu.

```
example# bootadm list-menu
  the location for the active GRUB menu is: /rpool/boot/grub/menu.lst
  default 0
```

EXAMPLE 4 Rebooting to a Particular GRUB Menu *(Continued)*

```
timeout 10
0 zfsbe1
1 zfsbe1 failsafe
2 zfsbe2
3 zfsbe2 Solaris xVM
4 zfsbe2 failsafe
example# reboot 2
```

Files /var/adm/wtmpx
  login accounting file

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also mdb(1), boot(1M), dumpadm(1M), fsck(1M), halt(1M), init(1M), kernel(1M), shutdown(1M), svcadm(1M), svccfg(1M), sync(1M), syslogd(1M), sync(2), uadmin(2), reboot(3C), attributes(5), grub(5)

Notes The reboot utility does not execute the scripts in /etc/rc*num*.d or execute shutdown actions in inittab(4). To ensure a complete shutdown of system services, use shutdown(1M) or init(1M) to reboot a Solaris system.

Name rem_drv – remove a device driver from the system

Synopsis rem_drv [-b *basedir*] [-C] [-n] *device_driver*

Description The rem_drv command informs the system that the device driver *device_driver* is no longer valid. If possible, rem_drv unloads *device_driver* from memory. rem_drv also updates the system driver configuration files.

If rem_drv has been executed, the next time the system is rebooted it automatically performs a reconfiguration boot (see kernel(1M)).

Options The following options are supported:

-b *basedir*
Sets the path to the root directory of the diskless client. Used on the server to execute rem_drv for a client. The client machine must be rebooted to unload the driver.

Note – The root file system of any non-global zones must not be referenced with the -b option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-C
Remove dangling device attribute nodes bound to the driver being removed. This causes any device ownership or permissions customizations made to any node not to be preserved if the driver is added back. Recommended for use when reprovisioning a machine from one configuration or use to another where past administrative customizations might not be desired.

-n
Do not try to detach and unload *device_driver*, just modify the system configuration files for that driver.

Examples **EXAMPLE 1** Removing the sd Driver

The following example removes the sd driver from use:

example% rem_drv sd

EXAMPLE 2 Removing a Diskless Client

The following example removes the driver from the sun1 diskless client. The driver is not uninstalled or unloaded until the client machine is rebooted.

example% rem_drv -b /export/root/sun1 sd

Note the caveat on the use of the -b option in the description of that option, above.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also add_drv(1M), kernel(1M), update_drv(1M), attributes(5), zones(5), devfs(7FS)

Name   remove_allocatable – remove entries from allocation databases

Synopsis   /usr/sbin/remove_allocatable [-f] -n *name*

/usr/sbin/remove_allocatable [-f] [-d] -t *dev-type*

Description   remove_allocatable removes entries of user allocatable devices from the device allocation mechanism. remove_allocatable also removes entries of some non-allocatable devices, such as printers, whose label range is managed by the mechanism.

Options   The following options are supported:

-d   Removes system-supplied default attributes of the device type that is specified with -t.

-f   Force the removal of an entry. remove_allocatable exits with an error if this option is not specified when an entry with the specified device name no longer exists.

-n *name*   Removes the entry for the device *name*.

-t *dev-type*   Removes devices of type *dev-type*.

Exit Status   When successful, remove_allocatable returns an exit status of 0 (true). remove_allocatable returns a nonzero exit status in the event of an error. The exit codes are as follows:

1   Invocation syntax error

2   Unknown system error

3   Device *name* or *dev-type* not found. This error occurs only when the -f option is not specified.

4   Permission denied. User does not have DAC or MAC access to database.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/trusted
Interface Stability	See below.

The invocation is Uncommitted. The options are Uncommitted. The output is Not-an-Interface.

See Also   allocate(1), deallocate(1), add_allocatable(1M), attributes(5), device_clean(5)

Notes The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

Name removef – remove a file from software database

Synopsis removef [[-M] -R *root_path*] [-V *fs_file*] *pkginst path* . . .

removef [[-M] -R *root_path*] [-V *fs_file*] -f *pkginst*

Description removef informs the system that the user, or software, intends to remove a pathname. Output from removef is the list of input pathnames that may be safely removed (no other packages have a dependency on them).

Options The following options are supported:

-f

After all files have been processed, removef should be invoked with the -f option to indicate that the removal phase is complete.

-M

Instruct removef not to use the $*root_path*/etc/vfstab file for determining the client's mount points. This option assumes the mount points are correct on the server and it behaves consistently with Solaris 2.5 and earlier releases.

-R *root_path*

Define the full path name of a directory to use as the *root_path*. All files, including package system information files, are relocated to a directory tree starting in the specified *root_path*. The *root_path* may be specified when installing to a client from a server (for example, /export/root/client1).

removef inherits the value of the PKG_INSTALL_ROOT environment variable. (See ENVIRONMENT VARIABLES, below.) If PKG_INSTALL_ROOT is set, such as when the -R option is used with pkgadd(1M) or pkgrm(1M)

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-V *fs_file*

Specify an alternative *fs_file* to map the client's file systems. For example, used in situations where the $*root_path*/etc/vfstab file is non-existent or unreliable.

Operands The following operands are supported:

path

The pathname to be removed.

pkginst

The package instance from which the pathname is being removed.

Examples   EXAMPLE 1   Using removef

The following example uses the removef command in an optional pre-install script:

```
echo "The following files are no longer part of this package
     and are being removed."
removef $PKGINST /myapp/file1 /myapp/file2 |
while read pathname
do
     echo "$pathname"
     rm -f $pathname
done
removef -f $PKGINST || exit 2
```

Environment Variables   removef inherits the value of the following environment variable. This variable is set when pkgadd(1M) or pkgrm(1M)

PKG_INSTALL_ROOT
    If present, defines the full path name of a directory to use as the system's PKG_INSTALL_ROOT path. All product and package information files are then looked for in the directory tree, starting with the specified PKG_INSTALL_ROOT path. If not present, the default system path of / is used.

Exit Status   0
    Successful completion.

>0
    An error occurred.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   pkginfo(1), pkgmk(1), pkgparam(1), pkgproto(1), pkgtrans(1), installf(1M), pkgadd(1M), pkgask(1M), pkgchk(1M), pkgrm(1M), attributes(5), largefile(5)

Application Packaging Developer's Guide

Notes   Package commands are largefile(5)-aware. They handle files larger than 2 GB in the same way they handle smaller files. In their current implementations, pkgadd(1M), pkgtrans(1) and other package commands can process a datastream of up to 4 GB.

Name reparsed – reparse point daemon

Synopsis /usr/lib/reparse/reparsed

Description The reparsed daemon processes kernel upcalls to interpret "reparse points", which are the basis of Microsoft DFS referrals and NFS referrals support on Solaris SMB and NFS file servers. Only the root user or a user with equivalent privileges can run this daemon. The daemon is under SMF control.

Exit Status 0

Daemon started successfully.

>0

Daemon failed to start.

Error information is reported to syslog at level LOG_ERR.

Files /usr/lib/reparsed/*.so.1

Per-service plugins for reparsed.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Consolidation Private

See Also nfsref(1M), svcadm(1M), syslogd(1M), libreparse(3LIB), attributes(5)

Notes Do not manually stop, start or restart the reparsed daemon. If you need to change the state of the daemon, use these commands:

```
# svcadm disable svc:/system/filesystem/reparse
# svcadm enable svc:/system/filesystem/reparse
# svcadm restart svc:/system/filesystem/reparse
```

See svcadm(1M) for additional information.

Name repquota – summarize quotas for a ufs file system

Synopsis repquota [-v] *filesystem*...

repquota -a [-v]

Description repquota prints a summary of the disk usage and quotas for the specified ufs file systems. The current number of files and amount of space (in kilobytes) is printed for each user along with any quotas created with edquota(1M).

The *filesystem* must have the file quotas in its root directory.

Only the super-user may view quotas which are not their own.

Options The following options are supported:

-a   Report on all mounted ufs file systems that have rq in the mntopts field of the /etc/vfstab file.

-v   Report quotas for all users, even those who do not consume resources.

Usage See largefile(5) for the description of the behavior of repquota when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also edquota(1M), quota(1M), quotacheck(1M), quotaon(1M), attributes(5), largefile(5), quotactl(7I)

Name rmmount – removable media mounter for CD-ROM, Jaz drive, and others

Synopsis /usr/sbin/rmmount [-D]

Description The rmmount utility is a removable media mounter that is executed by volume management whenever a removable medium, such as a CD-ROM is inserted. Removable media is managed by an application or a volume manager. rmmount can also be called by using volrmmount(1).

Upon insertion of a medium and following invocation of the volcheck(1) command, rmmount determines what type of file system (if any) is on that medium. If a file system is present, rmmount mounts the file system in one of the locations listed below.

For a CD-ROM or a DVD-ROM:

/cdrom/cdrom0	symbolic link to mounted CD-ROM in local CD-ROM drive
/cdrom/CD-ROM_name	mounted named CD-ROM
/cdrom/CD-ROM_name/partition	mounted named CD-ROM with partitioned file system
/cdrom/unnamed_cdrom	mounted unnamed CD-ROM

For a Zip drive:

/rmdisk/zip0	symbolic link to mounted Zip medium in local Zip drive
/rmdisk/*Zip_name*	mounted named Zip medium
/rmdisk/*Zip_name*/partition	mounted named Zip medium with partitioned file system
/rmdisk/unnamed_zip	mounted unnamed Zip medium

For a Jaz drive:

/rmdisk/jaz0	symbolic link to mounted Jaz medium in local Jaz drive
/rmdisk/*Jaz_name*	mounted named Jaz medium
/rmdisk/*Jaz_name*/partition	mounted named Jaz medium with partitioned file system
/rmdisk/unnamed_Jaz	mounted unnamed Jaz medium

For a generic "rmdisk" drive:

/rmdisk/rmdisk0	symbolic link to mounted removable medium in local removable medium drive
/rmdisk/*rmdisk_name*	mounted named removable medium
/rmdisk/*rmdisk_name*/partition	mounted named removable medium with partitioned file system

/rmdisk/unnamed_rmdisk　　　　　　　　mounted unnamed removable medium

If the media is read-only (for example, a CD-ROM), the file system is mounted read-only.

If a file system is not identified, rmmount does not mount a file system. See the *Oracle Solaris Administration: Common Tasks* for more information on the location of CD-ROM and other media without file systems.

If a file system type has been determined, it is then checked to see that it is "clean." If the file system is "dirty," fsck -p (see fsck(1M)) is run in an attempt to clean it. If fsck fails, the file system is mounted read-only.

After the mount is complete, "actions" associated with the media type are executed. These actions allow for the notification to other programs that new media are available.

Actions are executed in the order in which they appear in the configuration file. The action function can return either 1 or 0. If it returns 0, no further actions will be executed. This allows the function to control which applications are executed.

In order to execute an action, rmmount performs a dlopen(3C) on the shared object and calls the action function defined within it. The definition of the interface to actions can be found in /usr/include/rmmount.h.

File systems mounted by rmmount are always mounted with the nosuid flag set, thereby disabling setuid programs and access to block or character devices in that file system. Upon ejection, rmmount unmounts mounted file systems and executes actions associated with the media type. If a file system is "busy" (that is, it contains the current working directory of a live process), the ejection will fail.

Options　-D　　　Turn on the debugging output from the rmmount dprintf calls.

Files　/usr/lib/rmmount/*.so.1　　　shared objects used by rmmount.

Oracle Solaris Administration: Common Tasks

Name rmt – remote magtape protocol module

Synopsis /usr/sbin/rmt

Description rmt is a program used by the remote dump and restore programs in manipulating a magnetic tape drive through an interprocess communication connection. rmt is normally started up with an rexec(3SOCKET) or rcmd(3SOCKET) call.

The rmt program accepts requests that are specific to the manipulation of magnetic tapes, performs the commands, then responds with a status indication. All responses are in ASCII and in one of two forms. Successful commands have responses of:

A*number*\n   where *number* is an ASCII representation of a decimal number.

Unsuccessful commands are responded to with:

E*error-number*\n*error-message*\n   where *error-number* is one of the possible error numbers described in Intro(3), and *error-message* is the corresponding error string as printed from a call to perror(3C).

The protocol consists of the following commands:

S\n   Return the status of the open device, as obtained with a MTIOCGET ioctl call. If the operation was successful, an "ack" is sent with the size of the status buffer, then the status buffer is sent (in binary).

C*device*\n   Close the currently open device. The *device* specified is ignored.

I*operation*\n*count*\n   Perform a MTIOCOP ioctl(2) command using the specified parameters. The parameters are interpreted as the ASCII representations of the decimal values to place in the *mt_op* and *mt_count* fields of the structure used in the ioctl call. When the operation is successful the return value is the *count* parameter.

L*offset*\n*whence*\n   Perform an lseek(2) operation using the specified parameters. The response value is returned from the lseek call.

O*device*\n*mode*\n   Open the specified *device* using the indicated *mode*. *device* is a full pathname, and *mode* is an ASCII representation of a decimal number suitable for passing to open(9E). If a device is already open, it is closed before a new open is performed.

R*count*\n   Read *count* bytes of data from the open device. rmt performs the requested read(9E) and responds with A*count-read*\n if the read was successful; otherwise an error in standard format is returned. If the read was successful, the data read is sent.

W*count*\n   Write data onto the open device. rmt reads *count* bytes from the connection, aborting if a premature EOF is encountered. The

response value is returned from the write(9E) call.

Any other command causes rmt to exit.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/network-clients

See Also ufsdump(1M), ufsrestore(1M), Intro(3), ioctl(2), lseek(2), perror(3C), rcmd(3SOCKET), rexec(3SOCKET), attributes(5), mtio(7I), open(9E), read(9E), write(9E)

Diagnostics All responses are of the form described above.

Bugs Do not use this for a remote file access protocol.

Name rmvolmgr – HAL-aware removable volume manager

Synopsis /usr/sbin/rmvolmgr [-chns]

Description The rmvolmgr command is a volume manager that can automatically mount and unmount
removable media and hot-pluggable storage. The default mount point is /media.

rmvolmgr is one of a number of Hardware Abstraction Layer (HAL)-aware tools that are
shipped with the Solaris operating system. See hald(1M).

Multiple instances of rmvolmgr can be run simultaneously. A system instance of rmvolmgr
runs by default as a service management facility (SMF) service (see smf(5)). Its fault
management resource identifier (FMRI) is:

svc:/system/filesystem/rmvolmgr

You can run your own instance of rmvolmgr by adding it to the .xinitrc file or a similar
session startup script. In such a case, the *system* rmvolmgr instance will not manage volumes
that belong to you, the owner of the startup script. For example, a user logged on to the
workstation console (/dev/console) who invokes his own instance of rmvolmgr will own
locally connected devices, such as CD-ROM drives and devices connected to the local USB or
FireWire ports.

In addition to mounting volumes under /media, rmvolmgr also creates legacy symbolic links
under /cdrom and /rmdisk.

rmvolmgr also provides backwards compatibility with CDE removable media interfaces by
maintaining notification files under /tmp/.removable. This functionality can be disabled by
using the -c option.

The -c and -n options can also be specified as SMF properties. See "Examples."

Options The following options are supported:

-c   Disable CDE compatibility.

-h   Display help information and exit.

-n   Do not create legacy mountpoint symbolic links.

-s   Invoke in system instance mode.

Examples EXAMPLE 1   Using SMF Properties to Set Options

The following svccfg(1M) command and subcommands use SMF properties to set the -c and
-n options.

```
example# svccfg
svc:> select rmvolmgr
svc:/system/filesystem/rmvolmgr> listprop rmvolmgr/*
rmvolmgr/legacy_mountpoints    boolean  true
```

EXAMPLE 1 Using SMF Properties to Set Options *(Continued)*

```
rmvolmgr/cde_compatible         boolean  true
svc:/system/filesystem/rmvolmgr> setprop \
  rmvolmgr/legacy_mountpoints=false
svc:/system/filesystem/rmvolmgr> setprop rmvolmgr/cde_compatible=false
svc:/system/filesystem/rmvolmgr> exit
example#
```

Attributes See attributes(5) for descriptions of the following attributes:

Name   rndc – name server control utility

Synopsis   rndc [-V] [-b *src-addr*] [-c *config-file*] [-k *key-file*] [-s *server*]
        [-p *port*] [-y *key_id*] *command*

Description   The rndc utility controls the operation of a name server. It supersedes the ndc utility that was
        provided in previous BIND releases. If rndc is invoked with no command line options or
        arguments, it prints a short summary of the supported commands and the available options
        and their arguments.

        The rndc utility communicates with the name server over a TCP connection, sending
        commands authenticated with digital signatures. The only supported authentication
        algorithm in the current versions of rndc and named(1M) is HMAC-MD5, which uses a shared
        secret on each end of the connection. This algorithm provides TSIG-style authentication for
        the command request and the name server's response. All commands sent over the channel
        must be signed by a *key_id* known to the server.

        The rndc utility reads a configuration file to determine how to contact the name server and
        decide what algorithm and key it should use.

Options   The following options are supported:

   -b *source-address*
        Use *source-address* as the source address for the connection to the server. Multiple
        instances are permitted to allow setting of both the IPv4 and IPv6 source addresses.

   -c *config-file*
        Use *config-file* as the configuration file instead of the default /etc/rndc.conf.

   -k *key-file*
        Use *key-file* as the key file instead of the default, /etc/rndc.key. The key in
        /etc/rndc.key is used to authenticate commands sent to the server if the *config-file* does
        not exist.

   -s *server*
        The *server* argument is the name or address of the server that matches a server statement in
        the configuration file for rndc. If no server is supplied on the command line, the host
        named by the default-server clause in the options statement of the rndc configuration file is
        used.

   -p *port*
        Send commands to TCP port *port* instead of BIND 9's default control channel port, 953.

   -V
        Enable verbose logging.

   -y *key_id*
        Use the key *key_id* from the configuration file. The *key_id* argument must be known by
        named with the same algorithm and secret string for control message validation to succeed.
        If no *key_id* is specified, rndc will first look for a key clause in the server statement of the

server being used, or if no server statement is present for that host, then the default-key clause of the options statement. The configuration file contains shared secrets that are used to send authenticated control commands to name servers. It should therefore not have general read or write access.

For the complete set of commands supported by rndc, see the *BIND 9 Administrator Reference Manual* or run rndc without arguments to see its help message.

Limitations The rndc utility does not support all the commands of the BIND 8 ndc utility.

There is no way to provide the shared secret for a *key_id* without using the configuration file.

Several error messages tend toward the cryptic.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	network/dns/bind
Interface Stability	Volatile

See Also named(1M), rndc-confgen(1M), named.conf(4), rndc.conf(4), attributes(5)

See the BIND 9 *Administrator's Reference Manual*. As of the date of publication of this man page, this document is available at https://www.isc.org/software/bind/documentation.

Name rndc-confgen – rndc key generation tool

Synopsis rndc-confgen [-ah] [-b *keysize*] [-c *keyfile*] [-k *keyname*]
       [-p *port*] [-r *randomfile*] [-s *address*] [-t *chrootdir*]
       [-u *user*]

Description The rndc-confgen utility generates configuration files for rndc(1M). This utility can be used
as a convenient alternative to writing by hand the rndc.conf(4) file and the corresponding
controls and key statements in named.conf. It can also be run with the -a option to set up a
rndc.key file and avoid altogether the need for a rndc.conf file and a controls statement.

Options The following options are supported:

-a

Perform automatic rndc configuration. This option creates a file rndc.key in /etc (or
however *sysconfdir* was specified when BIND was built) that is read by both rndc and
named(1M) on startup. The rndc.key file defines a default command channel and
authentication key allowing rndc to communicate with named with no further
configuration.

Running rndc-confgen with -a specified allows BIND 9 and rndc to be used as drop-in
replacements for BIND 8 and ndc, with no changes to the existing BIND 8 named.conf file.

If a more elaborate configuration than that generated by rndc-confgen -a is required, for
example if rndc is to be used remotely, you should run rndc-confgen without the -a
option and set up rndc.conf and named.conf files, as directed.

-b *keysize*
Specify the size of the authentication key in bits. The *keysize* argument must be between 1
and 512 bits; the default is 128.

-c *keyfile*
Used with the -a option to specify an alternate location for rndc.key.

-h
Print a short summary of the options and arguments to rndc-confgen.

-k *keyname*
Specify the key name of the rndc authentication key. The *keyname* argument must be a
valid domain name. The default is rndc-key.

-p *port*
Specify the command channel port where named listens for connections from rndc. The
default is 953.

-r *randomfile*
Specify a source of random data for generating the authorization. By default, /dev/random
is used. The *randomdev* argument specifies the name of a character device or file containing
random data to be used instead of the default. The special value keyboard indicates that
keyboard input should be used.

-s *address*
> Specify the IP address where named listens for command channel connections from rndc. The default is the loopback address 127.0.0.1.

-t *chrootdir*
> Used with the -a option to specify a directory where named will run after the root directory is changed with chroot(2). An additional copy of the rndc.key will be written relative to this directory so that it will be found by the named in the new directory.

-u *user*
> Used with the -a option to set the owner of the rndc.key file generated. If -t is also specified only the file in the chroot area has its owner changed.

Examples   EXAMPLE 1   Create Automatic rndc Configuration

The following command creates an automatic rndc configuration, so that rndc can be used immediately.

```
# rndc-confgen -a
```

EXAMPLE 2   Print a Sample rndc.conf File

The following command prints a sample rndc.conf file with corresponding controls and key statements. These statements can subsequently be manually inserted in the file named.conf.

```
# rndc-confgen
```

Name roleadd – administer a new role account on the system

Synopsis roleadd [-c *comment*] [-d *dir*] [-e *expire*] [-f *inactive*]
          [-g *group*] [-G *group* [, *group*...]] [-m [-k *skel_dir*]]
          [-u *uid* [-o]] [-s *shell*] [-S *repository*]
          [-A *authorization* [,*authorization*...]] [-K *key=value*] *role*

roleadd -D [-b *base_dir*] [-e *expire*] [-f *inactive*]
          [-g *group*] [-A *authorization* [,*authorization*...]]
          [-P *profile* [,*profile*...] [-K *key=value*]]

Description roleadd adds a role entry to the passwd and shadow and user_attr databases specified by the
-S option. The default repository is files. The -A and -P options respectively assign
authorizations and profiles to the role. Roles cannot be assigned to other roles. The -K option
adds a *key=value* pair to user_attr for a role. Multiple *key=value* pairs can be added with
multiple -K options.

roleadd also creates supplementary group memberships for the role (-G option) and creates
the home directory (-m option) for the role if requested. The new role account remains locked
until the passwd(1) command is executed.

Specifying roleadd -D with the -g, -b, -f, -e, or -K option (or any combination of these
option) sets the default values for the respective fields. See the -D option. Subsequent roleadd
commands without the -D option use these arguments.

The system file entries created with this command have a limit of 512 characters per line.
Specifying long arguments to several options can exceed this limit.

The role (role) field accepts a string of no more than eight bytes consisting of characters from
the set of alphabetic characters, numeric characters, period (.), underscore (_), and hyphen
(-). The first character should be alphabetic and the field should contain at least one lower case
alphabetic character. A warning message is written if these restrictions are not met. A future
Solaris release might refuse to accept role fields that do not meet these requirements.

The role field must contain at least one character and must not contain a colon (:) or a
newline (\n).

An administrator must be granted the User Management Profile to be able to create a new
role. The authorizations required to set the various fields in passwd, shadow and user_attr
can be found in passwd(4), shadow(4), and user_attr(4). The authorizations required to
assign groups can be found in group(4).

Options The following options are supported:

-A *authorization*
    One or more comma separated authorizations defined in auth_attr(4). Only a user or role
    who has grant rights to the authorization can assign it to an account

-b *base_dir*

The default base directory for the system if -d *dir* is not specified. *base_dir* is concatenated with the account name to define the home directory. If the -m option is not used, *base_dir* must exist.

-c *comment*

Any text string. It is generally a short description of the role. This information is stored in the role's passwd entry.

-d *dir*

The home directory of the new role. It defaults to *base_dir*/*account_name*, where *base_dir* is the base directory for new login home directories and *account_name* is the new role name. This creates an auto_home entry for the user.

The argument to the option can be specified as *server*:*dir* where *server* is the hostname of the machine on which the home directory resides and *dir* is the path to the user's home directory. If the server is a remote host then the home directory needs to be created on the remote host for the system to mount it, when the user logs in. If no server name is specified then the home directory will be created on the host where the command is executed, when the -m option is used.

-D

Display the default values for *group*, *base_dir*, *skel_dir*, *shell*, *inactive*, *expire* and *key=value* pairs. When used with the -g, -b, -f, or -K, options, the -D option sets the default values for the specified fields. The default values are:

group
  other (GID of 1)

base_dir
  /export/home

skel_dir
  /etc/skel

shell
  /bin/pfsh

inactive
  0

expire
  Null

auths
  Null

profiles
  Null

key=value (pairs defined in user_attr(4)
  not present

-e *expire*

Specify the expiration date for a role. After this date, no user is able to access this role. The expire option argument is a date entered using one of the date formats included in the template file /etc/datemsk. See getdate(3C).

If the date format that you choose includes spaces, it must be quoted. For example, you can enter 10/6/90 or October 6, 1990. A null value (" ") defeats the status of the expired date. This option is useful for creating temporary roles.

-f *inactive*

The maximum number of days allowed between uses of a role ID before that ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status.

-g *group*

An existing group's integer ID or character-string name. Without the -D option, it defines the new role's primary group membership and defaults to the default group. You can reset this default value by invoking roleadd -D -g *group*.

-G *group*

An existing group's integer ID or character-string name. It defines the new role's supplementary group membership. Duplicates between *group* with the -g and -G options are ignored. No more than NGROUPS_MAX groups can be specified.

-k *skel_dir*

A directory that contains skeleton information (such as .profile) that can be copied into a new role's home directory. This directory must already exist. The system provides the /etc/skel directory that can be used for this purpose.

-K *key=value*

A *key=value* pair to add to the role's attributes. Multiple -K options can be used to add multiple *key=value* pairs. The generic -K option with the appropriate key can be used instead of the specific implied key options (-A and -P). See user_attr(4) for a list of valid *key=value* pairs. The "type" key is not a valid key for this option. Keys can not be repeated.

-m

Create the new role's home directory if it does not already exist. If the directory already exists, it must have read, write, and execute permissions by *group*, where *group* is the role's primary group. If the server name specified to the -d option is a remote host then the system will not attempt to create the home directory.

If the directory does not already exist, a new ZFS dataset will be created. In the global zone, the dataset is created as rpool/export/home/*rolename*. For non-global zones, the dataset will be created as *ROOT-dataset*/export/home/*rolename*. The mountpoint for the ZFS dataset is /export/home/*rolename* by default. If -d *path* is specified and it is a path on the local machine, the dataset will be mounted at the specified location. The role is delegated

permissions to create ZFS snapshots and promote them. The newly created dataset will inherit the encryption setting from its parent. If it is encrypted, the role is granted permission to change its wrapping key.

-o

This option allows a UID to be duplicated (non-unique).

-P *profile*

One or more comma-separated execution profiles defined in prof_attr(4).

-s *shell*

Full pathname of the program used as the user's shell on login. It defaults to an empty field causing the system to use /bin/pfsh as the default. The value of *shell* must be a valid executable file.

-S *repository*

The valid repositories are files, ldap. The repository specifies which name service will be updated. The default repository is files. When the repository is files, the authorizations, profiles, and roles can be present in other name service repositories and can be assigned to a user in the files repository. When the repository is ldap, all the assignable attributes must be present in the ldap repository.

-u *uid*

The UID of the new role. This UID must be a non-negative decimal integer below MAXUID as defined in <sys/param.h>. The UID defaults to the next available (unique) number above the highest number currently assigned. For example, if UIDs 100, 105, and 200 are assigned, the next default UID number is 201. (UIDs from 0-99 are reserved for possible use in future applications.)

Files   /etc/datemsk

/etc/passwd

/etc/shadow

/etc/group

/etc/skel

/usr/include/limits.h

/etc/user_attr

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Committed

See Also passwd(1), pfexec(1), profiles(1), roles(1), users(1B), groupadd(1M), groupdel(1M), groupmod(1M), grpck(1M), logins(1M), pwck(1M), userdel(1M), usermod(1M), getdate(3C), auth_attr(4), group(4), passwd(4), prof_attr(4), shadow(4), user_attr(4), attributes(5)

Diagnostics In case of an error, roleadd prints an error message and exits with a non-zero status.

The following indicates that login specified is already in use:

UX: roleadd: ERROR: login is already in use. Choose another.

The following indicates that the *uid* specified with the -u option is not unique:

UX: roleadd: ERROR: uid *uid* is already in use. Choose another.

The following indicates that the *group* specified with the -g option is already in use:

UX: roleadd: ERROR: group *group* does not exist. Choose another.

The following indicates that the *uid* specified with the -u option is in the range of reserved UIDs (from 0-99):

UX: roleadd: WARNING: uid *uid* is reserved.

The following indicates that the *uid* specified with the -u option exceeds MAXUID as defined in <sys/param.h>:

UX: roleadd: ERROR: uid *uid* is too big. Choose another.

The following indicates that the /etc/passwd or /etc/shadow files do not exist:

UX: roleadd: ERROR: Cannot update system files - login cannot be created.

The following indicates that the user executing the command does not have sufficient authorization to perform the operation:

UX: roleadd: ERROR: Permission denied.

Name roledel – delete a role's login from the system

Synopsis `roledel [-r] [-S repository] role`

Description The `roledel` utility deletes a role account from the system and makes the appropriate account-related changes to the system file and file system. `roledel` also removes the role from each user's list of assumable roles.

An administrator must be granted the User Management Profile to be able to delete an existing role.

Options The following options are supported:

`-r`
  Remove the role's home directory from the system. This directory must exist. The files and directories under the home directory will no longer be accessible following successful execution of the command. The ZFS dataset that was created for the role's home directory will be removed.

  The `auto_home` entry for the role will be deleted.

`-S repository`
  The valid repositories are `files`, `ldap`. The repository specifies which name service will be updated. The default repository is `files`.

Operands The following operands are supported:

`role`   An existing role name to be deleted.

Exit Status The following exit values are returned:

0   Successful completion.

2   Invalid command syntax. A usage message for the `roledel` command is displayed.

6   The account to be removed does not exist.

8   The account to be removed is in use.

10   Cannot update the `/etc/group` or `/etc/user_attr` file but the login is removed from the `/etc/passwd` file.

12   Cannot remove or otherwise modify the home directory.

Files `/etc/passwd`   system password file

`/etc/shadow`   system file containing roles' encrypted passwords and related information

`/etc/group`   system file containing group definitions

`/etc/user_attr` system file containing additional role attributes

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also auths(1), passwd(1), profiles(1), roles(1), users(1B), groupadd(1M), groupdel(1M), groupmod(1M), logins(1M), roleadd(1M), rolemod(1M), useradd(1M), userdel(1M), usermod(1M), passwd(4), prof_attr(4), user_attr(4), attributes(5)

Notes The roledel utility only deletes an account definition that is in the group, passwd, shadow, and user_attr databases in the repository.

Name rolemod – modify a role's login information on the system

Synopsis rolemod [-u *uid* [-o]] [-g *group*] [-G [+|-]*group* [, *group*...]]
[-d *dir* [-m]] [-s *shell*] [-c *comment*] [-l *new_name*]
[-f *inactive*] [-e *expire*]
[-A [+|-]*authorization* [, *authorization*]]
[-S *repository*]
[-P [+|-]*profile* [, *profile*]] [-K *key*[+|-]=*value*] *role*

Description The rolemod utility modifies a role's login information on the system. It changes the definition of the specified login and makes the appropriate login-related system file and file system changes.

The system file entries created with this command have a limit of 512 characters per line. Specifying long arguments to several options may exceed this limit.

An administrator must be granted the User Security Profile to be able to modify the security attributes for an existing role. To be able to modify non-security attributes of an existing user requires the User Management Profile. The authorizations required to set the various fields in passwd, shadow and user_attr can be found in passwd(4), shadow(4), user_attr(4). The authorizations required to assign groups can be found in group(4).

Options The following options are supported:

-A [+|]*authorization*
   One or more comma separated authorizations as deined in auth_attr(4). Only role with grant rights to the authorization can assign it to an account. This replaces any existing authorization setting. If no authorization list is specified, the existing setting is removed.

   A prefix + adds the authorization to the existing authorization; a prefix - removes the authorization from the existing authorization. With no prefix, the value for *authorization* replaces the existing authorization.

-c *comment*
   Specify a comment string. *comment* can be any text string. It is generally a short description of the login, and is currently used as the field for the user's full name. This information is stored in the user's /etc/passwd entry.

-d *dir*
   Specify the new home directory of the role. It defaults to *base_dir/login*, where *base_dir* is the base directory for new login home directories, and login is the new login. This creates or modifies an auto_home entry for the user.

   The argument to the option can be specified as *server:dir* where *server* is the hostname of the machine on which the home directory resides and *dir* is the path to the user's home directory. If the server is a remote host then the home directory needs to be created on the remote host for the system to mount it, when the user logs in. If no server name is specified then the home directory will be created on the host where the command is executed, when the -m option is used.

-e *expire*

Specify the expiration date for a role. After this date, no role will be able to access this login. The expire option argument is a date entered using one of the date formats included in the template file /etc/datemsk. See getdate(3C).

For example, you may enter 10/6/90 or October 6, 1990. A value of " '' defeats the status of the expired date.

-f *inactive*

Specify the maximum number of days allowed between uses of a login ID before that login ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status.

-g *group*

Specify an existing group's integer ID or character-string name. It redefines the role's primary group membership.

-G [+|-]*group*

An existing group's integer ID or character-string name. It defines the new user's supplementary group membership. Duplicates between group with the -g and -G options are ignored. No more than NGROUPS_MAX groups can be specified. GIDs 0-99 are reserved for allocation by the Solaris Operating System.

A prefix + adds the group to the existing group; a prefix - removes the group from the existing group. With no prefix, *group* replaces the existing group.

-K *key*[+|-]=*value*

Replace existing or add to a role's *key=value* pair attributes. Multiple -K options can be used to replace or add multiple *key=value* pairs. However, keys must not be repeated. The generic -K option with the appropriate key may be used instead of the specific implied key options (-A and -P). See user_attr(4) for a list of valid *key=value* pairs. If no value is specified, the existing key is removed.

The keyword type can be specified with the value role or the value normal. When using the value normal, the account changes from a role user to a normal user; using the value role keeps the account a role user.

A prefix + adds the value to the existing value; a prefix - removes the value from the existing value. With no prefix, *value* replaces the existing value.

The prefix +/- operation is applicable only to the following keys: auths, profiles, roles, project, limitpriv, and defaultpriv.

-l *new_logname*

Specify the new login name for the role. The *new_logname* argument is a string no more than eight bytes consisting of characters from the set of alphabetic characters, numeric characters, period (.), underline (_), and hypen (−). The first character should be alphabetic and the field should contain at least one lower case alphabetic character. A warning message will be written if these restrictions are not met. A future Solaris release

may refuse to accept login fields that do not meet these requirements. The *new_logname* argument must contain at least one character and must not contain a colon (:) or NEWLINE (\n).

-m

Move the role's home directory to the new directory specified with the -d option. If the directory already exists, it must have permissions read/write/execute by *group*, where *group* is the role's primary group. If the server name specified to the -d option is a remote host then the system will not attempt to create the home directory.

If the directory does not already exist, a new ZFS dataset will be created. In the global zone, the dataset is created as rpool/export/home/*rolename*. For non-global zones, the dataset will be created as *ROOT-dataset*/export/home/*rolename*. The mountpoint for the ZFS dataset is /export/home/*rolename* by default. If -d *path* is specified and it is a path on the local machine, the dataset will be mounted at the specified location. The role is delegated permissions to create ZFS snapshots and promote them. The newly created dataset will inherit the encryption setting from its parent. If it is encrypted, the role is granted permission to change its wrapping key.

-o

This option allows the specified UID to be duplicated (non-unique).

-P [+|-]*profile*

One or more comma-separated execution profiles defined in auth_attr(4). This replaces any existing profile setting. If no profile list is specified, the existing setting is removed.

A prefix + adds the profile to the existing profile; a prefix - removes the profile from the existing profile. With no prefix, *profile* replaces the existing profile.

-s *shell*

Specify the full pathname of the program that is used as the role's shell on login. The value of *shell* must be a valid executable file.

-S *repository*

The valid repositories are files, ldap. The repository specifies which name service will be updated. The default repository is files. When the repository is files, the authorizations, profiles, and roles can be present in other name service repositories and can be assigned to a user in the files repository. When the repository is ldap, all the assignable attributes must be present in the ldap repository.

-u *uid*

Specify a new UID for the role. It must be a non-negative decimal integer less than MAXUID as defined in <param.h>. The UID associated with the role's home directory is not modified with this option; a role will not have access to their home directory until the UID is manually reassigned using chown(1).

Operands The following operands are supported:

login
  An existing login name to be modified.

Exit Status In case of an error, rolemod prints an error message and exits with one of the following values:

2
  The command syntax was invalid. A usage message for the rolemod command is displayed.

3
  An invalid argument was provided to an option.

4
  The *uid* given with the -u option is already in use.

5
  The password files contain an error. pwconv(1M) can be used to correct possible errors. See passwd(4).

6
  The login to be modified does not exist, the *group* does not exist, or the login shell does not exist.

8
  The login to be modified is in use.

9
  The *new_logname* is already in use.

10
  Cannot update the /etc/group or /etc/user_attr file. Other update requests will be implemented.

11
  Insufficient space to move the home directory (-m option). Other update requests will be implemented.

12
  Unable to complete the move of the home directory to the new home directory.

Files /etc/group
  system file containing group definitions

/etc/datemsk
  system file of date formats

/etc/passwd
  system password file

/etc/shadow
  system file containing users' and roles' encrypted passwords and related information

/etc/user_attr
> system file containing additional user and role attributes

Name root_archive – manage bootable miniroot archives

Synopsis /boot/solaris/bin/root_archive pack *archive root*

/boot/solaris/bin/root_archive unpack *archive root*

Description The root_archive utility is used to manipulate boot archives. The utility can pack and unpack boot archives and image miniroots. Both ufs and hsfs (iso9660) format archives can be unpacked, although only ufs format is generated when packing.

For normal, boot-related system administration, bootadm(1M) is recommended.

Subcommands The root_archive command has the following subcommands:

pack *archive root* Pack the contents of the root directory into the boot archive *archive*.

unpack *archive root* Unpack the contents of the boot archive named *archive* to the directory named *root*.

Exit Status The following exit values are returned:

0 The command completed successfully.

1 The command exited due to an error.

Name route – manually manipulate the routing tables

Synopsis route [-fnvq] *sub-command* [[*modifiers*] *args*]

route [-fnvq] [-p [-R *root-dir*]] add | delete [*modifiers*] *destination gateway*
    [*args*]

route [-fnvq] change | get [*modifiers*] *destination*
    [*gateway* [*args*]]

route [-fn] monitor [*modifiers*]

route [-fnvq] flush [*modifiers*]

route -p [-R *root-dir*] show

Description route manually manipulates the network routing tables. These tables are normally
maintained by the system routing daemon, such as in.routed(1M) and in.ripngd(1M).

route supports a limited number of general options, but a rich command language. Users can
specify an arbitrary request that can be delivered by means of the programmatic interface
discussed in route(7P).

route uses a routing socket and the new message types RTM_ADD, RTM_DELETE, RTM_GET, and
RTM_CHANGE. While only superusers can modify routing tables, the RTM_GET operation is
allowed for non-privileged users.

Options -f   Flush the routing tables of all gateway entries. If you use the -f option in
conjunction with any of the route sub-commands, route flushes the gateways
before performing the sub-command. Specify the table to flush by placing the
inet or inet6 modifier immediately after the -f option. If unspecified,
flushing IPv4 (inet) routes is the default.

-n   Prevent attempts to print host and network names symbolically when
reporting actions. This option is useful when name servers are unavailable.

-p   Make changes to the network route tables persistent across system restarts. The
operation is applied to the network routing tables first and, if successful, is then
applied to the list of saved routes used at system startup. In determining
whether an operation was successful, a failure to add a route that already exists
or to delete a route that is not in the routing table is ignored. Particular care
should be taken when using host or network names in persistent routes, as
network-based name resolution services are not available at the time routes are
added at startup.

-q   Suppress all output.

-R *root-dir*   Specify an alternate root directory where route applies changes. This option is
ignored unless used in conjunction with the -p option. When -R is specified,
route changes are applied only to the list of saved routes to be used at startup,
not to the network routing tables. In addition, certain checks, such as the

existence of network interfaces used with -ifp, are skipped. This can be useful from within JumpStart scripts, where the root directory of the system being modified is in a location other than /.

-v   Print additional details in verbose mode.

Subcommands The following subcommands are supported:

add   Add a route.

change   Change aspects of a route (such as its gateway).

delete   Delete a specific route.

flush   Remove all gateway entries from the routing table.

get   Look up and display the route for a destination.

monitor   Continuously report any changes to the routing information base, routing lookup misses, or suspected network partitionings.

show   Display the list of routes to be applied at system startup. Can be used only in conjunction with the -p option.

The add and delete sub-commands have the following syntax:

```
route [ -fnvq ] cmd destination gateway [metric/netmask]
```

where *cmd* is add or delete, *destination* is the destination host or network, and *gateway* is the next-hop intermediary through which packets should be routed. Modifiers described in OPERANDS can be placed anywhere on the command line.

The get and change sub-commands have the following syntax:

```
route [ -fnvq ] cmd destination [gateway [metric/netmask]]
```

where *cmd* is get or change, *destination* is the destination host or network, and *gateway* is the next-hop intermediary through which packets should be routed. Modifiers described in OPERANDS can be placed anywhere on the command line.

The monitor sub-command has the following syntax:

```
route monitor [ -inet | -inet6 ]
```

Operands route executes its sub-commands on routes to destinations by way of gateways.

Destinations and By default, destination and gateway addresses are interpreted as IPv4 addresses. All symbolic
Gateways names are tried first as a host name, using getipnodebyname(3SOCKET). If this lookup fails in the AF_INET case, getnetbyname(3SOCKET) interprets the name as that of a network.

Including an optional modifier on the command line before the address changes how the route sub-command interprets it.

The following modifiers are supported:

-inet   Force the address to be interpreted as an IPv4 address, that is, under the AF_INET
           address family.

-inet6   Force the address to be interpreted as an IPv6 address, that is, under the AF_INET6
           address family.

For IPv4 addresses, routes to a particular host are by default distinguished from those to a network by interpreting the Internet address specified as the destination. If the destination has a *local address part* (that is, the portion not covered by the netmask) of 0, or if the destination is resolved as the symbolic name of a network, then the route is assumed to be to a network; otherwise, it is presumed to be a route to a host.

You can force this selection by using one of the following modifiers:

-host   Force the destination to be interpreted as a host.

-net   Force the destination to be interpreted as a network.

For example:

Destination	Destination Equivalent
128.32	-host 128.0.0.32
128.32.130	-host 128.32.0.130
-net 128.32	128.32.0.0
-net 128.32.130	128.32.130.0

Two modifiers avoid confusion between addresses and keywords (for example., host used as a symbolic host name). You can distinguish a *destination* by preceding it with the -dst modifier. You can distinguish a gateway address by using the -gateway modifier. If the destination is directly reachable by way of an interface requiring no intermediary IP router to act as a gateway, this can be indicated by using the -interface or -iface modifier.

In the following example, the route does not refer to an external gateway (router), but rather to one of the machine's interfaces. Packets with IP destination addresses matching the destination and mask on such a route are sent out on the interface identified by the gateway address. For interfaces using the ARP protocol, this type of route is used to specify that all matching destinations are local to the physical link. That is, a host could be configured to ARP for all addresses, without regard to the configured interface netmask, by adding a default route using this command. For example:

```
example# route add default hostname -interface
```

where gateway address *hostname* is the name or IP address associated with the network interface over which all matching packets should be sent. On a host with a single network interface, *hostname* is usually the same as the *nodename* returned by the uname -n command. See uname(1).

For backward compatibility with older systems, directly reachable routes can also be specified by placing a 0 after the gateway address:

```
example# route add default hostname 0
```

This value was once a route metric, but this metric is no longer used. If the value is specified as 0, then the destination is directly reachable (equivalent to specifying -interface). If it is non-zero but cannot be interpreted as a subnet mask, then a gateway is used (default).

With the AF_INET address family or an IPv4 address, a separate subnet mask can be specified. This can be specified in one of the following ways:

- IP address following the gateway address . This is typically specified in *decimal dot* notation as for inet_addr(3SOCKET) rather than in symbolic form.
- IP address following the -netmask qualifier.
- Slash character and a decimal length appended to the destination address.

If a subnet mask is not specified, the mask used is the subnet mask of the output interface selected by the gateway address, if the classful network of the destination is the same as the classful network of the interface. Otherwise, the classful network mask for the destination address is used.

Each of the following examples creates an IPv4 route to the destination 192.0.2.32 subnet with a subnet mask of 255.255.255.224:

```
example# route add 192.0.2.32/27 somegateway
example# route add 192.0.2.32 -netmask 255.255.255.224 somegateway
example# route add 192.0.2.32 somegateway 255.255.255.224
```

For IPv6, only the slash format is accepted. The following example creates an IPv6 route to the destination 33fe:: with a netmask of 16 one-bits followed by 112 zero-bits.

```
example# route add -inet6 3ffe::/16 somegateway
```

In cases where the gateway does not uniquely identify the output interface (for example, when several interfaces have the same address), you can use the -ifp *ifname* modifier to specify the interface by name. For example, -ifp lo0 associates the route with the lo0 interface. If the named interface is an underlying interface in an IPMP (IP multipathing) group, then requests to add a route will automatically be translated to the corresponding IPMP IP interface, and requests to delete or change a route on an underlying interface will fail.

When the routing table contains several equal routes, that is, routes for the same destination and mask, then IP attempts to spread the traffic over those routes. The spreading is such that an individual transport connection uses the same route to avoid packet reordering as seen by, for example, TCP. The details of the spreading algorithm is not documented and is likely to evolve over time.

Routing Flags   Routes have associated flags that influence operation of the protocols when sending to destinations matched by the routes. These flags can be set (and in some cases cleared, indicated by ~) by including the following modifiers on the command line:

Modifier	Flag	Description
-interface	~RTF_GATEWAY	Destination is directly reachable
-iface	~RTF_GATEWAY	Alias for interface modifier
-static	RTF_STATIC	Manually added route
-nostatic	~RTF_STATIC	Pretend route was added by kernel or routing daemon
-reject	RTF_REJECT	Emit an ICMP unreachable when matched
-blackhole	RTF_BLACKHOLE	Silently discard packets
-proto1	RTF_PROTO1	Set protocol specific routing flag #1
-proto2	RTF_PROTO2	Set protocol specific routing flag #2
-private	RTF_PRIVATE	Do not advertise this route
-multirt	RTF_MULTIRT	Creates the specified redundant route
-setsrc	RTF_SETSRC	Assigns the default source address
-indirect	RTF_INDIRECT	Allows adding routes where gateway is not on-link

The optional -indirect modifier allows adding routes where the gateway is not directly reachable. When an indirect route is the best match for a packet to be sent or forwarded, then IP proceeds to look up that gateway to find a route that is directly reachable. The -indirect modifier can be used even if the gateway is directly reachable.

The optional modifiers -rtt, -rttvar, -sendpipe, -recvpipe, -mtu, -hopcount, -expire, and -ssthresh provide initial values to quantities maintained in the routing entry by transport level protocols, such as TCP. These can be individually locked either by preceding each modifier to be locked by the -lock meta-modifier, or by specifying that all ensuing metrics can be locked by the -lockrest meta-modifier.

Some transport layer protocols can support only some of these metrics. The following optional modifiers are supported:

-expire   Lifetime for the entry. This optional modifier is not currently supported.

-hopcount	Maximum hop count. This optional modifier is not currently supported.
-mtu	Maximum MTU in bytes.
-recvpipe	Receive pipe size in bytes.
-rtt	Round trip time in microseconds.
-rttvar	Round trip time variance in microseconds.
-sendpipe	Send pipe size in bytes.
-ssthresh	Send pipe size threshold in bytes.
-secattr	Security attributes of the route. This modifier is available only if the system is configured with the Solaris Trusted Extensions feature.

The -secattr modifier has the following format:

min_sl=*val*,max_sl=*val*,doi=*val*,cipso

or:

sl=VAL,doi=VAL,cipso

In the first form, above, the *val* for min_sl and max_sl is a sensitivity label in either hex or string form. The *val* for doi is a non-negative integer. The route will apply only for packets with the same domain of interpretation as defined by the doi value and within the accreditation range defined by the min_sl and max_sl values. The cipso keyword is optional and set by default. Valid min_sl, max_sl and doi keyword/value pairs are mandatory. Note that if *val* contains a space, it must be protected by double quotes.

The second form, above, is equivalent to specifying the first form with the same VAL for min_sl and max_sl. The second form should be used for the get command, because get uses only a single sensitivity label.

Compatibility   The modifiers host and net are taken to be equivalent to -host and -net. To specify a symbolic address that matches one of these names, use the dst or gateway keyword to distinguish it. For example: -dst host

The following two flags are also accepted for compatibility with older systems, but have no effect.

Modifier	Flag
-cloning	RTF_CLONING
-xresolve	RTF_XRESOLVE

The -ifa hostname modifier is also accepted, but has no effect.

Files /etc/defaultrouter   List of default routers

/etc/hosts   List of host names and net addresses

/etc/networks   List of network names and addresses

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also uname(1), in.ripngd(1M), in.routed(1M), netstat(1M), routed(1M), ioctl(2), getipnodebyname(3SOCKET), getnetbyname(3SOCKET), inet_addr(3SOCKET), defaultrouter(4), hosts(4), networks(4), attributes(5), arp(7P), ip(7P), route(7P), routing(7P)

Diagnostics add [host | network] *destination*:*gateway flags*

The specified route is being added to the tables. The values printed are from the routing table entry supplied in the ioctl(2) call. If the gateway address used was not the primary address of the gateway (the first one returned by getipnodebyname(3SOCKET)) the gateway address is printed numerically as well as symbolically.

delete [host | network] *destination*:*gateway flags*
change [host | network] *destination*:*gateway flags*

As add, but when deleting or changing an entry.

destination done

When the -f flag is specified, or the flush sub-command is used, each routing table entry deleted is indicated with a message of this form.

Network is unreachable

An attempt to add a route failed because the gateway listed was not on a directly-connected network. Give the next-hop gateway instead.

not in table

A delete operation was attempted for an entry that is not in the table.

entry exists

An add operation was attempted for a route that already exists in the kernel.

`routing table overflow`	An operation was attempted, but the system was unable to allocate memory to create the new entry.
`insufficient privileges`	An attempt to add, delete, change, or flush a route failed because the calling process does not have appropriate privileges.

Notes Specifying that destinations are local (with the `-interface` modifier) assumes that the routers implement `proxy` ARP, meaning that they respond to ARP queries for all reachable destinations. Normally, using either router discovery or RIP is more reliable and scalable than using proxy ARP. See `in.routed(1M)` for information related to RIP.

Combining the all destinations are local route with subnet or network routes can lead to unpredictable results. The search order as it relates to the all destinations are local route are undefined and can vary from release to release.

Name routeadm – IP forwarding and routing configuration

Synopsis routeadm [-p [*option*]]

routeadm [-R *root-dir*] [-e *option* ...] [-d *option*...]
 [-r *option*...] [-s *var=value*]

routeadm [-l *fmri*]

routeadm [-m *fmri key=value* [*key=value*]...]

routeadm [-u]

Description The routeadm command is used to administer system-wide configuration for IP forwarding and routing. IP forwarding is the passing of IP packets from one network to another; IP routing is the use of a routing protocol to determine routes.

IP routing functions are also represented as services within the service management facility (SMF), and can be administered by means of svcadm(1M) also, using the following fault management resource identifiers (FMRIs):

svc:/network/routing/route:default
svc:/network/routing/ripng:default

See EXAMPLES for relevant examples.

In addition to enabling and disabling routing and forwarding, routeadm is used to interact with SMF-based routing daemon services. Routing daemon services are identified by the presence of a routeadm application property group, which routeadm uses in administering the given service. Routing daemon services can also specify properties relating to their operation in the routing application property group; these can be modified by means of routeadm -m. If an FMRI for a service without such a property group is specified, an error is issued and the operation is not carried out. If a routing daemon has not been converted to SMF, the ipv4*[or 6]*-routing-daemon, ipv4*[or 6]*-routing-daemon-args, and ipv4*[or 6]*-routing-stop-cmd variables can be used to specify the appropriate daemon for IPv4 or IPv6 routing. routeadm will then run that daemon using the svc:/network/routing/legacy-routing:ipv4*[or 6]* service as appropriate. This conversion process occurs when you issue an enable (-e), disable (-d) or an update (-u) command.

The first usage, in the SYNOPSIS above, reports the current configuration.

Options The following command-line options are supported:

-p [*option*]
 Print the configuration in parseable format. If *option* is specified, only the configuration for the specified option or variable is displayed.

-R *root-dir*

Specify an alternate root directory where routeadm applies changes. This can be useful from within JumpStart scripts, where the root directory of the system being modified is mounted elsewhere.

Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system, might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-e *option...*

Enable the specified option. The effect is to prepare the associated services for enabling. By means of the routing-svcs variable, the routing daemons are specified to be enabled on subsequent boot or when routeadm -u is run.

-d *option...*

Disable the specified option. The effect is to prepare the associated services for disabling. By means of the routing-svcs variable, the routing daemons are specified to be disabled on subsequent boot or when routeadm -u is run.

-l *fmri*

List all properties in the routing application property group for the SMF routing daemon service.

-m *fmri key=value*

Change property value of property *key* to *value* in routing application property group for the SMF routing daemon service. For multi-valued properties, the property name can be used multiple times in the modify operation, and each associated value will be added.

-r *option...*

Revert the specified option to the system default. The system defaults are specified in the description of each *option*.

-u

Apply the currently configured options to the running system. These options might include enabling or disabling IP forwarding and launching or killing routing daemons, if any are specified. It does not alter the state of the system for those settings that have been set to default. This option is meant to be used by administrators who do not want to reboot to apply their changes. In addition, this option upgrades non-SMF configurations from the invocations of daemon stop commands, which might include a set of arguments, to a simple enabling of the appropriate service.

-s *key=value*

Specify string values for specific variables in a comma-separated list with no intervening spaces. If invalid options are specified, a warning message is displayed and the program exits. The following variables can be specified:

routing-svcs=*fmrilist*
> Specifies the routing daemon services to be enabled. Routing daemon services are determined to be IPv4 or IPv6 (and so enabled or disabled when routeadm -e/-d ipv4*(6)*-routing is run) on the basis of property values in the routeadm application property group. Default: route:default ripng:default

ipv4-routing-daemon=<*full_path_to_routing_daemon*>
> Specifies the routing daemon to be started when ipv4-routing is enabled. The routing daemon specified must be an executable binary or shell-script. If the specified program maps to an SMF service, the service will be used, and daemon arguments to the program will be transferred to the properties of the service at enable time. Default: ""

ipv4-routing-daemon-args=<*args*>
> Specifies the startup arguments to be passed to the ipv4-routing-daemon when ipv4-routing is enabled. Default: no arguments

ipv4-routing-stop-cmd=<*command*>
> Specifies the command to be executed to stop the routing daemon when ipv4-routing is disabled. <*command*> can be an executable binary or shell-script, or a string that can be parsed by system(3C). Default: ""

ipv6-routing-daemon=<*full_path_to_routing_daemon*>
> Specifies the routing daemon to be started when ipv6-routing is enabled. The routing daemon specified must be an executable binary or shell-script. If the specified program maps to an SMF service, the service will be used, and daemon arguments to the program will be transferred to the properties of the service at enable time. Default: ""

ipv6-routing-daemon-args=<*args*>
> Specifies the startup arguments to be passed to the ipv6-routing-daemon when ipv6-routing is enabled. Default: ""

ipv6-routing-stop-cmd=<*command*>
> Specifies the command to be executed to stop the routing daemon when ipv6-routing is disabled. <*command*> can be an executable binary or shell-script, or a string that can be parsed by system(3C). Default: ""

Multiple -e, -d, and -r options can be specified on the command line. Changes made by -e, -d, and -r are persistent, but are not applied to the running system unless routeadm is called later with the -u option.

Use the following options as arguments to the -e, -d, and -r options (shown above as *option...*).

ipv4-forwarding
> Controls the global forwarding configuration for all IPv4 interfaces. The system default is disabled. If enabled, IP will forward IPv4 packets to and from interfaces when appropriate. If disabled, IP will not forward IPv4 packets to and from interfaces when appropriate.

ipv4-routing

Determines whether an IPv4 routing daemon is run. The system default is enabled unless the /etc/defaultrouter file exists (see defaultrouter(4)), in which case the default is disabled. The value of this option reflects the state of all IPv4 routing services, such that if any IPv4 routing service is enabled, ipv4-routing is enabled. This allows users to interact with routing services using svcadm(1M), as well as through routeadm. IPv4 routing services, specified by means of the routing-svcs variable, will be prepared for enable on next boot when the user explicitly enables ipv4-routing. The SMF routing daemon service for in.routed (svc:/network/routing/route:default) is specified by default.

ipv6-forwarding

Controls the global forwarding configuration for all IPv6 interfaces. The system default is disabled. If enabled, IP will forward IPv6 packets to and from interfaces when appropriate. If disabled, IP will not forward IPv6 packets to and from interfaces when appropriate.

ipv6-routing

Determines whether an IPv6 routing daemon is run. The system default is disabled. The value of this option reflects the state of all IPv6 routing services, such that, if any IPv6 routing service is enabled, ipv6-routing is enabled. This allows users to interact with routing services via svcadm(1M) as well as through routeadm. IPv6 routing services, specified by means of the routing-svcs variable, will be prepared for enable on next boot when the user explicitly enables ipv6-routing. The SMF routing daemon service for in.ripngd (svc:/network/routing/ripng:default) is specified by default.

The forwarding and routing settings are related but not mutually dependent. For example, a router typically forwards IP packets and uses a routing protocol, but nothing would prevent an administrator from configuring a router that forwards packets and does not use a routing protocol. In that case, the administrator would enable forwarding, disable routing, and populate the router's routing table with static routes.

The forwarding settings are global settings. Each interface also has an IFF_ROUTER forwarding flag that determines whether packets can be forwarded to or from a particular interface. That flag can be independently controlled by means of ifconfig(1M)'s router option. When the global forwarding setting is changed (that is, -u is issued to change the value from enabled to disabled or vice-versa), all interface flags in the system are changed simultaneously to reflect the new global policy. Interfaces configured by means of DHCP automatically have their interface-specific IFF_ROUTER flag cleared.

When a new interface is plumbed by means of ifconfig, the value of the interface-specific forwarding flag is set according to the current global forwarding value. Thus, the forwarding value forms the "default" for all new interfaces.

Examples   EXAMPLE 1   Enabling IPv4 Forwarding

IPv4 forwarding is disabled by default. The following command enables IPv4 forwarding:

example# **routeadm -e ipv4-forwarding**

EXAMPLE 2 Apply Configured Settings to the Running System

In the previous example, a system setting was changed, but will not take effect until the next reboot unless a command such as the following is used:

```
example# routeadm -u
```

EXAMPLE 3 Making a Setting Revert to its Default

To make the setting changed in the first example revert to its default, enter the following:

```
example# routeadm -r ipv4-forwarding
example# routeadm -u
```

EXAMPLE 4 Starting in.routed with the -q Flag

Setting the -q flag is represented in the SMF service by setting the quiet_mode property to true. The following sequence of commands starts in.routed with the -q flag:

```
example# routeadm -m route:default quiet_mode=true
example# routeadm -e ipv4-routing -u
```

See in.routed(1M) for details of property names and how they relate to daemon behavior.

Exit Status The following exit values are returned:

0   Successful completion.

!=0   An error occurred while obtaining or modifying the system configuration.

Files /etc/inet/routing.conf   Parameters for IP forwarding and routing. (Not to be edited.)

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also ifconfig(1M), in.routed(1M), ipadm(1M), svcadm(1M), gateways(4), attributes(5), smf(5)

Name rpcbind – universal addresses to RPC program number mapper

Synopsis `rpcbind [-d] [-w]`

Description `rpcbind` is a server that converts RPC program numbers into universal addresses. It must be running on the host to be able to make RPC calls on a server on that machine.

When an RPC service is started, it tells `rpcbind` the address at which it is listening, and the RPC program numbers it is prepared to serve. When a client wishes to make an RPC call to a given program number, it first contacts `rpcbind` on the server machine to determine the address where RPC requests should be sent.

`rpcbind` should be started before any other RPC service. Normally, standard RPC servers are started by port monitors, so `rpcbind` must be started before port monitors are invoked.

When `rpcbind` is started, it checks that certain name-to-address translation-calls function correctly. If they fail, the network configuration databases can be corrupt. Since RPC services cannot function correctly in this situation, `rpcbind` reports the condition and terminates.

`rpcbind` maintains an open transport end for each transport that it uses for indirect calls. This is the UDP port on most systems.

The `rpcbind` service is managed by the service management facility, `smf(5)`, under the service identifier:

`svc:/network/rpc/bind`

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. `rpcbind` can only be started by the superuser or someone in the Primary Administrator role.

The configuration properties of this service can be modified with `svccfg(1M)`.

The following SMF property is used to allow or disallow access to `rpcbind` by remote clients:

`config/local_only = true`

The default value, `true`, shown above, disallows remote access; a value of `false` allows remove access. See EXAMPLES.

The FMRI `svc:network/rpc/bind` property group `config` contains the following property settings:

enable_tcpwrappers   Specifies that the TCP wrappers facility is used to control access to TCP services. The value `true` enables checking. The default value for enable_tcpwrappers is `false`. If the enable_tcpwrappers parameter is enabled, then all calls to `rpcbind` originating from non-local addresses are automatically wrapped by the TCP wrappers facility. The `syslog` facility code daemon is used to log

allowed connections (using the info severity level) and denied traffic (using the warning severity level). See syslog.conf(4) for a description of syslog codes and severity levels. The Interface Stability of the TCP wrappers facility and its configuration files is Volatile. As the TCP wrappers facility is not controlled by Sun, intrarelease incompatibilities are not uncommon. See attributes(5).

verbose_logging Specifies whether the TCP wrappers facility logs all calls orjust the denied calls. The default is false. This option has no effect if TCP wrappers are not enabled.

allow_indirect Specifies whether rpcbind allows indirect calls at all. By default, rpcbind allows most indirect calls, except to a number of standard services(keyserv, automount, mount, nfs, rquota, and selected NIS and rpcbind procedures). Setting allow_indirect to false causes all indirect calls to be dropped. The default is true. NIS broadcast clients rely on this functionality on NIS servers.

Options The following options are supported:

-d Run in debug mode. In this mode, rpcbind does not fork when it starts. It prints additional information during operation, and aborts on certain errors. With this option, the name-to-address translation consistency checks are shown in detail.

-w Do a warm start. If rpcbind aborts or terminates on SIGINT or SIGTERM, it writes the current list of registered services to /var/run/portmap.file and /var/run/rpcbind.file. Starting rpcbind with the -w option instructs it to look for these files and start operation with the registrations found in them. This allows rpcbind to resume operation without requiring all RPC services to be restarted.

Examples EXAMPLE 1 Allowing Remote Access

The following sequence of commands allows remote access to rpcbind.

```
# svccfg -s svc:/network/rpc/bind setprop config/local_only = false
# svcadm refresh svc:/network/rpc/bind
```

Files /var/run/portmap.file   Stores the information for RPC services registered over IP based transports for warm start purposes.

/var/run/rpcbind.file   Stores the information for all registered RPC services for warm start purposes.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	See below.

TCP wrappers is Volatile.

See Also smf(5), rpcinfo(1M), svcadm(1M), svccfg(1M), rpcbind(3NSL), syslog.conf(4), attributes(5), smf(5)

For information on the TCP wrappers facility, see the hosts_access(4) man page, delivered as part of the Solaris operating environment in /usr/sfw/man and available in the security/tcp-wrapper package.

Notes Terminating rpcbind with SIGKILL prevents the warm-start files from being written.

All RPC servers are restarted if the following occurs: rpcbind crashes (or is killed with SIGKILL) and is unable to to write the warm-start files; rpcbind is started without the -w option after a graceful termination. Otherwise, the warm start files are not found by rpcbind.

Name   rpc.bootparamd, bootparamd – boot parameter server

Synopsis   /usr/sbin/rpc.bootparamd [-d]

Description   rpc.bootparamd is a server process that provides information from a bootparams database to diskless clients at boot time. See bootparams(4)

The source for the bootparams database is determined by the nsswitch.conf(4) file (on the machine running the rpc.bootparamd process).

Options   The following options are supported:

-d   Display debugging information.

Files   /etc/bootparams   boot parameter data base

/etc/nsswitch.conf   configuration file for the name-service switch

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/boot/network

See Also   svcs(1),svcadm(1M), bootparams(4), nsswitch.conf(4), attributes(5), smf(5)

Notes   A diskless client requires service from at least one rpc.bootparamd process running on a server that is on the same IP subnetwork as the diskless client.

Some routines that compare hostnames use case-sensitive string comparisons; some do not. If an incoming request fails, verify that the case of the hostname in the file to be parsed matches the case of the hostname called for, and attempt the request again.

The rpc.bootparamd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rpc/bootparams

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name   rpcinfo – report RPC information

Synopsis   rpcinfo [-m | -s] [*host*]

rpcinfo -p [*host*]

rpcinfo -T *transport host prognum* [*versnum*]

rpcinfo -l [-T *transport*] *host prognum versnum*

rpcinfo [-n *portnum*] -u *host prognum* [*versnum*]

rpcinfo [-n *portnum*] -t *host prognum* [*versnum*]

rpcinfo -a *serv_address* -T *transport prognum* [*versnum*]

rpcinfo -b [-T *transport*] *prognum versnum*

rpcinfo -d [-T *transport*] *prognum versnum*

Description   rpcinfo makes an RPC call to an RPC server and reports what it finds.

In the first synopsis, rpcinfo lists all the registered RPC services with rpcbind on *host*. If *host* is not specified, the local host is the default. If -s is used, the information is displayed in a concise format.

In the second synopsis, rpcinfo lists all the RPC services registered with rpcbind, version 2. Note that the format of the information is different in the first and the second synopsis. This is because the second synopsis is an older protocol used to collect the information displayed (version 2 of the rpcbind protocol).

The third synopsis makes an RPC call to procedure 0 of *prognum* and *versnum* on the specified *host* and reports whether a response was received. *transport* is the transport which has to be used for contacting the given service. The remote address of the service is obtained by making a call to the remote rpcbind.

The *prognum* argument is a number that represents an RPC program number (see rpc(4)).

If a *versnum* is specified, rpcinfo attempts to call that version of the specified *prognum*. Otherwise, rpcinfo attempts to find all the registered version numbers for the specified *prognum* by calling version 0, which is presumed not to exist; if it does exist, rpcinfo attempts to obtain this information by calling an extremely high version number instead, and attempts to call each registered version. Note that the version number is required for -b and -d options.

The EXAMPLES section describe other ways of using rpcinfo.

Options   -T *transport*   Specify the transport on which the service is required. If this option is not specified, rpcinfo uses the transport specified in the NETPATH environment variable, or if that is unset or NULL, the transport in the netconfig(4) database is used. This is a generic option, and can be used in conjunction with other options as shown in the SYNOPSIS.

-a *serv_address*	Use *serv_address* as the (universal) address for the service on *transport* to ping procedure 0 of the specified *prognum* and report whether a response was received. The -T option is required with the -a option. If *versnum* is not specified, rpcinfo tries to ping all available version numbers for that program number. This option avoids calls to remote rpcbind to find the address of the service. The *serv_address* is specified in universal address format of the given transport.
-b	Make an RPC broadcast to procedure 0 of the specified *prognum* and *versnum* and report all hosts that respond. If *transport* is specified, it broadcasts its request only on the specified transport. If broadcasting is not supported by any transport, an error message is printed. Use of broadcasting should be limited because of the potential for adverse effect on other systems.
-d	Delete registration for the RPC service of the specified *prognum* and *versnum*. If *transport* is specified, unregister the service on only that transport, otherwise unregister the service on all the transports on which it was registered. Only the owner of a service can delete a registration, except the superuser, who can delete any service.
-l	Display a list of entries with a given *prognum* and *versnum* on the specified *host*. Entries are returned for all transports in the same protocol family as that used to contact the remote rpcbind.
-m	Display a table of statistics of rpcbind operations on the given *host*. The table shows statistics for each version of rpcbind (versions 2, 3 and 4), giving the number of times each procedure was requested and successfully serviced, the number and type of remote call requests that were made, and information about RPC address lookups that were handled. This is useful for monitoring RPC activities on *host*.
-n *portnum*	Use *portnum* as the port number for the -t and -u options instead of the port number given by rpcbind. Use of this option avoids a call to the remote rpcbind to find out the address of the service. This option is made obsolete by the -a option.
-p	Probe rpcbind on *host* using version 2 of the rpcbind protocol, and display a list of all registered RPC programs. If *host* is not specified, it defaults to the local host. This option is not useful for IPv6; use -s (see below) instead. Note that version 2 of the rpcbind protocol was previously known as the portmapper protocol.
-s	Display a concise list of all registered RPC programs on *host*. If *host* is not specified, it defaults to the local host.

-t   Make an RPC call to procedure 0 of *prognum* on the specified *host* using
                            TCP, and report whether a response was received. This option is made
                            obsolete by the -T option as shown in the third synopsis.

-u   Make an RPC call to procedure 0 of *prognum* on the specified *host* using
                            UDP, and report whether a response was received. This option is made
                            obsolete by the -T option as shown in the third synopsis.

Examples   EXAMPLE 1   RPC services.

To show all of the RPC services registered on the local machine use:

example% rpcinfo

To show all of the RPC services registered with rpcbind on the machine named klaxon use:

example% rpcinfo klaxon

The information displayed by the above commands can be quite lengthy. Use the -s option to
display a more concise list:

example% rpcinfo -s klaxon

program	vrsn	netid(s)	service	owner
100000	2,3,4	tcp,udp,ticlts,ticots,ticotsord	rpcbind	superuser
100008	1	ticotsord,ticots,ticlts,udp,tcp	walld	superuser
100002	2,1	ticotsord,ticots,ticlts,udp,tcp	rusersd	superuser
100001	2,3,4	ticotsord,ticots,tcp,ticlts,udp	rstatd	superuser
100012	1	ticotsord,ticots,ticlts,udp,tcp	sprayd	superuser
100007	3	ticotsord,ticots,ticlts,udp,tcp	ypbind	superuser
100029	1	ticotsord,ticots,ticlts	keyserv	superuser
100078	4	ticotsord,ticots,ticlts	-	superuser
100024	1	ticotsord,ticots,ticlts,udp,tcp	status	superuser
100021	2,1	ticotsord,ticots,ticlts,udp,tcp	nlockmgr	superuser
100020	1	ticotsord,ticots,ticlts,udp,tcp	llockmgr	superuser

To show whether the RPC service with program number *prognum* and version *versnum* is
registered on the machine named klaxon for the transport TCP use:

example% rpcinfo -T tcp klaxon *prognum versnum*

To show all RPC services registered with version 2 of the rpcbind protocol on the local machine use:

example% rpcinfo -p

To delete the registration for version 1 of the walld (program number 100008) service for all transports use:

example# rpcinfo -d 100008 1

or

example# rpcinfo -d walld 1

Attributes See attributes(5) for descriptions of the following attributes:

Name rpc.mdcommd – multi-node disk set services

Synopsis /usr/sbin/rpc.mdcommd

Description rpc.mdcommd is an rpc(4) daemon that functions as a server process. rpc.mdcommd manages communication among hosts participating in a multi-node disk set configuration.

rpc.mdcommd is invoked by inetd(1M).

Exit Status The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm
Interface Stability	Committed

See Also svcs(1), inetadm(1M), inetd(1M), metaset(1M), svcadm(1M), rpc(3NSL), rpc(4), services(4), attributes(5), smf(5)

Solaris Volume Manager Administration Guide

Notes The rpc.mdcommd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rpc/mdcomm

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

Name rpc.metad – remote metaset services

Synopsis `/usr/sbin/rpc.metad`

Description `rpc.metad` is an rpc(4) daemon (functioning as a server process) that is used to manage local copies of metadevice diskset information. The `rpc.metad` daemon is controlled by inetadm(1M).

Exit Status The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm

See Also svcs(1), inetadm(1M), inetd(1M), metaset(1M), rpc.metamhd(1M), svcadm(1M), rpc(3NSL), services(4), attributes(5), smf(5)

Solaris Volume Manager Administration Guide

Notes The `rpc.metad` service is managed by the service management facility, smf(5), under the service identifier:

`svc:/network/rpc/meta:default`

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

Name rpc.metamedd – remote mediator services

Synopsis /usr/sbin/rpc.metamedd

Description rpc.metamedd is an rpc(4) server which is used to manage mediator information for use in 2–string HA configurations. The rpc.metamedd daemon is controlled by inetadm(1M).

Exit Status The following exit values are returned:

0 Successful completion.

>0 An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm
Interface Stability	Committed

See Also svcs(1), inetadm(1M), inetd(1M), svcadm(1M), rpc(4), services(4), attributes(5), smf(5)

Sun Cluster documentation, *Solaris Volume Manager Administration Guide*

Notes The rpc.metamedd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rpc/metamed:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

Name rpc.metamhd – remote multihost disk services

Synopsis /usr/sbin/rpc.metamhd

Description rpc.metamhd is an rpc(4) daemon (functioning as a server process) that is used to manage multi-hosted disks. The rpc.metamhd daemon is controlled by inetadm(1M).

Exit Status The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/svm

See Also svcs(1), inetadm(1M), inetd(1M), metaset(1M), rpc.metad(1M), svcadm(1M), rpc(3NSL), services(4), attributes(5), smf(5)

Solaris Volume Manager Administration Guide

Notes The rpc.metamhd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rpc/metamh:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

Name   rpc.rexd, rexd – RPC-based remote execution server

Synopsis   /usr/sbin/rpc.rexd [-s]

Description   rpc.rexd is the Sun RPC server for remote program execution. This daemon is started by
inetd(1M) whenever a remote execution request is made.

For non-interactive programs, the standard file descriptors are connected directly to TCP
connections. Interactive programs involve pseudo-terminals, in a fashion that is similar to the
login sessions provided by rlogin(1). This daemon may use NFS to mount file systems
specified in the remote execution request.

There is a 10240 byte limit for arguments to be encoded and passed from the sending to the
receiving system.

Options   The following option is supported:

-s   Secure. When specified, requests must have valid DES credentials. If the request does
not have a DES credential it is rejected. The default publickey credential is rejected.
Only newer on(1) commands send DES credentials.

If access is denied with an authentication error, you may have to set your publickey
with the chkey(1) command.

Specifying the -s option without presenting secure credentials will result in an error
message: Unix too weak auth (DesONly)!

Security   rpc.rexd uses pam(3PAM) for account and session management. The PAM configuration
policy, listed through /etc/pam.conf, specifies the modules to be used for rpc.rexd. Here is a
partial pam.conf file with rpc.rexd entries for account and session management using the
UNIX module.

```
rpc.rexd   account requisite      pam_roles.so.1
rpc.rexd   account required       pam_projects.so.1
rpc.rexd   account required       pam_unix_account.so.1

rpc.rexd      session required       pam_unix_session.so.1
```

If there are no entries for the rpc.rexd service, the entries for the "other" service will be used.
rpc.rexd uses the getpwuid() call to determine whether the given user is a legal user.

Files   /dev/pts*n*   Pseudo-terminals used for interactive mode

/etc/passwd   Authorized users

/tmp_rex/rexd??????   Temporary mount points for remote file systems

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/nis

See Also `chkey(1)`, `on(1)`, `rlogin(1)`, `svcs(1)`, inetadm(1M), inetd(1M), svcadm(1M), pam(3PAM), `pam.conf(4)`, `publickey(4)`, `attributes(5)`, `pam_authtok_check(5)`, `pam_authtok_get(5)`, `pam_authtok_store(5)`, `pam_dhkeys(5)`, `pam_passwd_auth(5)`, `pam_unix_account(5)`, `pam_unix_auth(5)`, `pam_unix_session(5)`, `smf(5)`

Diagnostics Diagnostic messages are normally printed on the console, and returned to the requestor.

Notes Root cannot execute commands using rexd client programs such as on(1).

The `rpc.rexd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/rpc/rex:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

Name   rpc.rstatd, rstatd – kernel statistics server

Synopsis /usr/lib/netsvc/rstat/rpc.rstatd

Description rpc.rstatd is a server which returns performance statistics obtained from the kernel. rup(1) uses rpc.rstatd to collect the uptime information that it displays.

rpc.rstatd is an RPC service.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/network-servers

See Also rup(1), svcs(1), inetadm(1M), inetd(1M), svcadm(1M), services(4), attributes(5), smf(5)

Notes The rpc.rstatd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rpc/rstat:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

Name rpc.rusersd, rusersd – network username server

Synopsis /usr/lib/netsvc/rusers/rpc.rusersd

Description rpc.rusersd is a server that returns a list of users on the host. The rpc.rusersd daemon may be started by inetd(1M).

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/network-servers

See Also svcs(1), inetadm(1M), inetd(1M), svcadm(1M), attributes(5), smf(5)

Notes The rpc.rusersd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rpc/rusers:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

Name   rpc.rwalld, rwalld – network rwall server

Synopsis `/usr/lib/netsvc/rwall/rpc.rwalld`

Description `rpc.rwalld` is a server that handles rwall(1M) requests. It is implemented by calling wall(1M) on all the appropriate network machines. The `rpc.rwalld` daemon may be started by inetd(1M).

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/network-servers

See Also svcs(1), inetadm(1M), inetd(1M), rwall(1M), svcadm(1M), wall(1M), attributes(5), smf(5)

Notes The `rpc.rwalld` service is managed by the service management facility, smf(5), under the service identifier:

`svc:/network/rpc/wall:default`

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

Name   rpc.smserverd – removable media device server

Synopsis   `/usr/lib/smedia/rpc.smserverd`

Description   `rpc.smserverd` is a server that handles requests from client applications, such as volume management software, for access to removable media devices. In addition to volume management software, rmformat(1) and the CDE Filemanager (when performing removable media operations) are `rpc.smserverd` clients. The `rpc.smserverd` daemon is started by inetd(1M) when a client makes a call to a Solaris-internal library to access a SCSI, IDE, or USB device. The daemon is not started if a client attempts to access a PCMCIA device. Once started, the daemon remains active until such time as it is idle for three minutes or more.

The `rpc.smserverd` daemon is provided for the exclusive use of the client applications mentioned above. It has no external, customer-accessible interfaces, including no configuration file.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/storage/removable-media

See Also   svcs(1), inetadm(1M), inetd(1M), svcadm(1M), attributes(5), smf(5)

Notes   The `rpc.smserverd` service is managed by the service management facility, smf(5), under the service identifier:

`svc:/network/rpc/smserver`

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

Name   rpc.sprayd, sprayd – spray server

Synopsis   /usr/lib/netsvc/spray/rpc.sprayd

Description   rpc.sprayd is a server that records the packets sent by spray(1M). The rpc.sprayd daemon may be started by inetd(1M).

The service provided by rpc.sprayd is not useful as a networking benchmark as it uses unreliable connectionless transports, (udp for example). It can report a large number of packets dropped when the drops were caused by the program sending packets faster than they can be buffered locally (before the packets get to the network medium).

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/network-servers

See Also   svcs(1), inetadm(1M), inetd(1M), spray(1M), svcadm(1M), attributes(5), smf(5)

Notes   The rpc.sprayd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/rpc/spray:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

Name rpc.yppasswdd, yppasswdd – server for modifying NIS password file

Synopsis /usr/lib/netsvc/yp/rpc.yppasswdd [-D *directory*]
[-nogecos] [-noshell] [-nopw]
[-m *argument1 argument2*...]

/usr/lib/netsvc/yp/rpc.yppasswdd
[*passwordfile* [*adjunctfile*]]
[-nogecos] [-noshell] [-nopw]
[-m *argument1 argument2*...]

Description rpc.yppasswdd is a server that handles password change requests from yppasswd(1). It changes a password entry in the passwd, shadow, and security/passwd.adjunct files. The passwd and shadow files provide the basis for the passwd.byname and passwd.byuid maps. The passwd.adjunct file provides the basis for the passwd.adjunct.byname and passwd.adjunct.byuid maps. Entries in the passwd, shadow or passwd.adjunct files are changed only if the password presented by yppasswd(1) matches the encrypted password of the entry. All password files are located in the PWDIR directory.

If the -D option is given, the passwd, shadow, or passwd.adjunct files are placed under the directory path that is the argument to -D.

If the -noshell, -nogecos or -nopw options are given, these fields cannot be changed remotely using chfn, chsh, or passwd(1).

If the -m option is given, a make(1S) is performed in /var/yp after any of the passwd, shadow, or passwd.adjunct files are modified. All arguments following the flag are passed to make.

The second of the listed syntaxes is provided only for backward compatibility. If the second syntax is used, the passwordfile is the full pathname of the password file and adjunctfile is the full pathname of the optional passwd.adjunct file. If a shadow file is found in the same directory as passwordfile, the shadowfile is used as described above. Use of this syntax and the discovery of a shadowfile file generates diagnostic output. The daemon, however, starts normally.

The first and second syntaxes are mutually exclusive. You cannot specify the full pathname of the passwd, passwd.adjunct files and use the -D option at the same time.

The daemon is started automatically on the master server of the passwd map by ypstart(1M), which is invoked at boot time by the svcs:/network/nis/server:default service.

The server does not insist on the presence of a shadow file unless there is no -D option present or the directory named with the -D option is /etc. In addition, a passwd.adjunct file is not necessary. If the -D option is given, the server attempts to find a passwd.adjunct file in the security subdirectory of the named directory. For example, in the presence of -D /var/yp the server checks for a /var/yp/security/passwd.adjunct file.

If only a passwd file exists, then the encrypted password is expected in the second field. If both a passwd and a passwd.adjunct file exist, the encrypted password is expected in the second field of the adjunct file with *##username* in the second field of the passwd file. If all three files are in use, the encrypted password is expected in the shadow file. Any deviation causes a password update to fail.

If you remove or add a shadow or passwd.adjunct file after rpc.yppasswdd has started, you must stop and restart the daemon to enable it to recognize the change. See ypstart(1M) for information on restarting the daemon.

The rpc.yppasswdd daemon considers a shell that has a name that begins with 'r' to be a restricted shell. By default, the daemon does not check whether a shell begins with an 'r'. However, you can tell it to do so by uncommenting the check_restricted_shell_name=1 line in /etc/default/yppasswdd. The result will be to restrict a user's ability to change from his default shell. See yppasswdd(4).

On start up, yppasswdd checks for the existence of a NIS to LDAP (N2L) configuration file, /var/yp/NISLDAPmapping. If the configuration file is present, the daemon runs in N2L mode. If the file is not present, yppasswdd runs in traditional, non-N2L mode.

In N2L mode, changes are written directly to the Directory Information Tree (DIT). If the changes are written successfully, the NIS map is updated. The NIS source files, passwd, shadow, and passwd.adjunct, for example, are not updated. Thus, in N2L mode, the -D option is meaningless. In N2L mode, yppasswdd propagates changes by calling yppush(1M) instead of ypmake(1M). The -m option is thus unused.

During an NIS-to-LDAP transition, the yppasswdd daemon uses the N2L-specific map, ageing.byname, to read and write password aging information to the DIT. If you are not using password aging, then the ageing.byname mapping is ignored.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/nis

See Also svcs(1), make(1S), passwd(1), yppasswd(1), inetd(1M), svcadm(1M), ypmake(1M), yppush(1M), ypstart(1M), NISLDAPmapping(4), passwd(4), shadow(4), ypfiles(4), yppasswdd(4), ypserv(4), attributes(5), smf(5)

Notes If make has not been installed and the -m option is given, the daemon outputs a warning and proceeds, effectively ignoring the -m flag.

When using the -D option, you should make sure that the PWDIR of the /var/yp/Makefile is set accordingly.

The second listed syntax is supplied only for backward compatibility and might be removed in a future release of this daemon.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and cannot be used without permission.

The NIS server service is managed by the service management facility, smf(5), under the service identifier:

```
svcs:/network/nis/server:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name   rpc.ypupdated, ypupdated – server for changing NIS information

Synopsis   /usr/lib/netsvc/yp/rpc.ypupdated [-is]

Description   ypupdated is a daemon that updates information in the Network Information Service (NIS). ypupdated consults the updaters(4) file in the /var/yp directory to determine which NIS maps should be updated and how to change them.

By default, the daemon requires the most secure method of authentication available to it, either DES (secure) or UNIX (insecure).

On start up, ypupdated checks for the existence of a NIS to LDAP (N2L) configuration file, /var/yp/NISLDAPmapping. If the file is present, ypupdated generates an informational message and exits. ypupdated is not supported in N2L mode.

Options   -i   Accept RPC calls with the insecure AUTH_UNIX credentials. This allows programmatic updating of the NIS maps in all networks.

-s   Accept only calls authenticated using the secure RPC mechanism (AUTH_DES authentication). This disables programmatic updating of the NIS maps unless the network supports these calls.

Files   /var/yp/updaters   Configuration file for rpc.updated command.

/var/yp/NISLDAPmapping   Configuration file for N2L

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/nis
Interface Stability	Committed

Oracle Solaris Administration: Naming and Directory Services

Notes   The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two services remains the same. Only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and it must not be used without permission.

Name   rquotad – remote quota server

Synopsis   /usr/lib/nfs/rquotad

Description   rquotad is an rpc(4) server which returns quotas for a user of a local file system which is mounted by a remote machine over the NFS. The results are used by quota(1M) to display user quotas for remote file systems. The rquotad daemon is normally invoked by inetd(1M).

Usage   See largefile(5) for the description of the behavior of rquotad when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Files   quotas   quota file at a UFS file system root

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/file-system/nfs

See Also   svcs(1), automountd(1M), inetadm(1M), inetd(1M), mount_nfs(1M), quota(1M), share_nfs(1M), svcadm(1M), rpc(4), services(4), attributes(5), largefile(5), smf(5)

Installing Oracle Solaris 11 Systems

Notes   The rquotad service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/nfs/rquota

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). Responsibility for initiating and restarting this service is delegated to inetd(1M). Use inetadm(1M) to make configuration changes and to view configuration information for this service. The service's status can be queried using the svcs(1) command.

If it is disabled, it is enabled by mount_nfs(1M), share_nfs(1M), and automountd(1M) unless its application/auto_enable property is set to false.

Name   rsh, restricted_shell – restricted shell command interpreter

Synopsis   /usr/lib/rsh [-acefhiknprstuvx] [*argument*]...

Description   rsh is a limiting version of the standard command interpreter sh, used to restrict logins to execution environments whose capabilities are more controlled than those of sh (see sh(1) for complete description and usage).

When the shell is invoked, it scans the environment for the value of the environmental variable, SHELL. If it is found and rsh is the file name part of its value, the shell becomes a restricted shell.

The actions of rsh are identical to those of sh, except that the following are disallowed:

- changing directory (see cd(1)),
- setting the value of $PATH,
- pecifying path or command names containing /,
- redirecting output (> and >>).

The restrictions above are enforced after *.profile* is interpreted.

A restricted shell can be invoked in one of the following ways:

1. rsh is the file name part of the last entry in the /etc/passwd file (see passwd(4));

2. the environment variable SHELL exists and rsh is the file name part of its value; the environment variable SHELL needs to be set in the .login file;

3. the shell is invoked and rsh is the file name part of argument 0;

4. the shell is invoke with the -r option.

When a command to be executed is found to be a shell procedure, rsh invokes sh to execute it. Thus, it is possible to provide to the end-user shell procedures that have access to the full power of the standard shell, while imposing a limited menu of commands; this scheme assumes that the end-user does not have write and execute permissions in the same directory.

The net effect of these rules is that the writer of the *.profile* (see profile(4)) has complete control over user actions by performing guaranteed setup actions and leaving the user in an appropriate directory (probably *not* the login directory).

The system administrator often sets up a directory of commands (that is, /usr/rbin) that can be safely invoked by a restricted shell. Some systems also provide a restricted editor, red.

Exit Status   Errors detected by the shell, such as syntax errors, cause the shell to return a non-zero exit status. If the shell is being used non-interactively execution of the shell file is abandoned. Otherwise, the shell returns the exit status of the last command executed.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also Intro(1), cd(1), login(1), rsh(1), sh(1), exec(2), passwd(4), profile(4), attributes(5)

Notes The restricted shell, /usr/lib/rsh, should not be confused with the remote shell, /usr/bin/rsh, which is documented in rsh(1).

Name   rtc – provide all real-time clock and UTC-lag management

Synopsis   /usr/sbin/rtc [-c] [-z *zone-name*]

Description   On x86 systems, the rtc command reconciles the difference in the way that time is established between UNIX and MS-DOS systems. UNIX systems utilize Universal Coordinated Time (UTC), while MS-DOS systems utilize local time.

Without arguments, rtc displays the currently configured time zone string. The currently configured time zone string is based on what was last recorded by rtc-z *zone-name*.

The rtc command is not normally run from a shell prompt; it is generally invoked by the system. Commands such as date(1) and rdate(1M), which are used to set the time on a system, invoke /usr/sbin/rtc -c to ensure that daylight savings time (DST) is corrected for properly.

Options   -c   This option checks for DST and makes corrections if necessary. It is normally run once a day by a cron job.

If there is no RTC time zone or /etc/rtc_config file, this option will do nothing.

-z *zone-name*   This option, which is normally run by the system at software installation time, is used to specify the time zone in which the RTC is to be maintained. It updates the configuration file /etc/rtc_config with the name of the specified zone and the current UTC lag for that zone. If there is an existing rtc_config file, this command will update it. If not, this command will create it.

Files   /etc/rtc_config   The data file used to record the time zone and UTC lag. This file is completely managed by /usr/sbin/rtc, and it is read by the kernel.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Architecture	x86
Availability	system/core-os

See Also   date(1), rdate(1M), attributes(5)

Name rtquery – query routing daemons for their routing tables

Synopsis rtquery [-np1] [-w *timeout*] [-r *addr*] [-a *secret*] *host*...

rtquery [-t *operation*] *host*...

Description The rtquery command is used to query a RIP network routing daemon, in. routed(1M) or GateD, for its routing table by sending a request or poll command. The routing information in any routing response packets returned is displayed numerically and symbolically.

By default, rtquery uses the request command. When the -p option is specified, rtquery uses the poll command, an undocumented extension to the RIP protocol supported by GateD. When querying GateD, the poll command is preferred over the request command because the response is not subject to Split Horizon and/or Poisoned Reverse, and because some versions of GateD do not answer the request command. in. routed does not answer the poll command, but recognizes requests coming from rtquery and so answers completely.

The rtquery command is also used to turn tracing on or off in in. routed.

Options The following options are supported:

-a passwd=*XXX*
-a md5_passwd=*XXX*|*KeyID* Causes the query to be sent with the indicated cleartext or MD5 password.

-n Displays only the numeric network and host addresses instead of both numeric and symbolic names.

-p Uses the poll command to request full routing information from GateD. This is an undocumented extension RIP protocol supported only by GateD.

-r *addr* Asks about the route to destination *addr*.

-t *operation* Changes tracing, where *operation* is one of the actions listed below. Requests from processes not running with UID 0 or on distant networks are generally ignored by the daemon except for a message in the system log. GateD is likely to ignore these debugging requests.

	on=*tracefile*	Turns tracing on, directing tracing into the specified file. That file must have been specified when the daemon was started or have the name, /var/log/in.routed.trace.
	more	Increases the debugging level.
	off	Turns off tracing.

	dump Dumps the daemon's routing table to the current trace file.
-w *timeout*	Changes the delay for an answer from each host. By default, each host is given 15 seconds to respond.
-1	Queries using RIP version 1 instead of RIP version 2.

Exit Status The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/routing

See Also in.routed(1M), route(1M), gateways(4), attributes(5), icmp(7P), inet(7P), udp(7P)

Routing Information Protocol, RIPv1, RFC 1058

Routing Information Protocol, RIPv2, RFC 2453, STD 0056

Name runacct – run daily accounting

Synopsis /usr/lib/acct/runacct [*mmdd* [*state*]]

Description runacct is the main daily accounting shell procedure. It is normally initiated using cron. runacct processes connect, fee, disk, and process accounting files. It also prepares summary files for prdaily or billing purposes. runacct is distributed only to source code licensees.

runacct takes care not to damage active accounting files or summary files in the event of errors. It records its progress by writing descriptive diagnostic messages into active. When an error is detected, a message is written to /dev/console, mail (see mail(1)) is sent to root and adm, and runacct terminates. runacct uses a series of lock files to protect against re-invocation. The files lock and lock1 are used to prevent simultaneous invocation, and lastdate is used to prevent more than one invocation per day.

runacct breaks its processing into separate, restartable *states* using statefile to remember the last *state* completed. It accomplishes this by writing the *state* name into statefile. runacct then looks in statefile to see what it has done and to determine what to process next. *states* are executed in the following order:

SETUP Move active accounting files into working files.

WTMPFIX Verify integrity of wtmpx file, correcting date changes if necessary.

CONNECT Produce connect session records in tacct.h format.

PROCESS Convert process accounting records into tacct.h format.

MERGE Merge the connect and process accounting records.

FEES Convert output of chargefee into tacct.h format, merge with connect, and process accounting records.

DISK Merge disk accounting records with connect, process, and fee accounting records.

MERGETACCT Merge the daily total accounting records in daytacct with the summary total accounting records in /var/adm/acct/sum/tacct.

CMS Produce command summaries.

USEREXIT Any installation dependent accounting programs can be included here.

CLEANUP Clean up temporary files and exit. To restart runacct after a failure, first check the active file for diagnostics, then fix any corrupted data files, such as pacct or wtmpx. The lock, lock1, and lastdate files must be removed before runacct can be restarted. The argument *mmdd* is necessary if runacct is being restarted. *mmdd* specifies the month and day for which runacct will rerun the accounting. The entry point for processing is based on the contents of statefile; to override this, include the desired *state* on the command line to designate where processing should begin.

Examples   **EXAMPLE 1**   Starting runacct

The following example starts runacct:

example% nohup runacct 2> /var/adm/acct/nite/fd2log &

EXAMPLE 2   Restarting runacct

The following example restarts runacct:

example% nohup runacct 0601 2>> /var/adm/acct/nite/fd2log &

EXAMPLE 3   Restarting runacct at a Specific State

The following example restarts runacct at a specific state:

example% nohup runacct 0601 MERGE 2>> /var/adm/acct/nite/fd2log &

Files   /var/adm/wtmpx   History of user access and administration information

/var/adm/pacct*incr*

/var/adm/acct/nite/active

/var/adm/acct/nite/daytacct

/var/adm/acct/nite/lock

/var/adm/acct/nite/lock1

/var/adm/acct/nite/lastdate

/var/adm/acct/nite/statefile

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/accounting/legacy-accounting

See Also   acctcom(1), mail(1), acct(1M), acctcms(1M), acctcon(1M), acctmerg(1M), acctprc(1M), acctsh(1M), cron(1M), fwtmp(1M), acct(2), acct.h(3HEAD), utmpx(4), attributes(5)

Notes   It is not recommended to restart runacct in the SETUP *state*. Run SETUP manually and restart using:

runacct *mmdd* WTMPFIX

If runacct failed in the PROCESS *state,* remove the last ptacct file because it will not be complete.

The runacct command can process a maximum of

■   6000 distinct sessions

- 1000 distinct terminal lines
- 2000 distinct login names

during a single invocation of the command. If at some point the actual number of any one of these items exceeds the maximum, the command will not succeed.

Do not invoke runacct at the same time as ckpacct, as there may be a conflict if both scripts attempt to execute turnacct switch simultaneously.

Name rwall – write to all users over a network

Synopsis /usr/sbin/rwall *hostname*...

/usr/sbin/rwall -n *netgroup*...

/usr/sbin/rwall -h *hostname* -n *netgroup*

Description rwall reads a message from standard input until EOF. It then sends this message, preceded by the line:

    Broadcast Message . . .

to all users logged in on the specified host machines. With the -n option, it sends to the specified network groups.

Options -n *netgroup*   Send the broadcast message to the specified network groups.

-h *hostname*   Specify the hostname, the name of the host machine.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/network-clients

See Also inetd(1M), wall(1M), attributes(5)

Notes The timeout is fairly short to allow transmission to a large group of machines (some of which may be down) in a reasonable amount of time. Thus the message may not get through to a heavily loaded machine.

Name sar, sa1, sa2, sadc – system activity report package

Synopsis /usr/lib/sa/sadc [*t n*] [*ofile*]

/usr/lib/sa/sa1 [*t n*]

/usr/lib/sa/sa2 [-aAbcdgkmpqruvwy] [-e *time*] [-f *filename*]
    [-i *sec*] [-s *time*]

Description System activity data can be accessed at the special request of a user (see sar(1)) and automatically, on a routine basis, as described here. The operating system contains several counters that are incremented as various system actions occur. These include counters for CPU utilization, buffer usage, disk and tape I/O activity, TTY device activity, switching and system-call activity, file-access, queue activity, inter-process communications, and paging. For more general system statistics, use iostat(1M), sar(1), or vmstat(1M).

sadc and two shell procedures, sa1 and sa2, are used to sample, save, and process this data.

sadc, the data collector, samples system data *n* times, with an interval of *t* seconds between samples, and writes in binary format to *ofile* or to standard output. The sampling interval *t* should be greater than 5 seconds; otherwise, the activity of sadc itself may affect the sample. If *t* and *n* are omitted, a special record is written. This facility can be used at system boot time, when booting to a multi-user state, to mark the time at which the counters restart from zero. For example, when accounting is enabled, the svc:/system/sar:default service writes the restart mark to the daily data file using the command entry:

```
su sys -c "/usr/lib/sa/sadc /var/adm/sa/sa‘date +%d‘"
```

The shell script sa1, a variant of sadc, is used to collect and store data in the binary file /var/adm/sa/sa*dd,* where dd is the current day. The arguments *t* and *n* cause records to be written *n* times at an interval of *t* seconds, or once if omitted. The following entries in /var/spool/cron/crontabs/sys will produce records every 20 minutes during working hours and hourly otherwise:

```
0 * * * 0-6 /usr/lib/sa/sa1
20,40 8—17 * * 1—5 /usr/lib/sa/sa1
```

See crontab(1) for details.

The shell script sa2, a variant of sar, writes a daily report in the file /var/adm/sa/sar*dd.* See the OPTIONS section in sar(1) for an explanation of the various options. The following entry in /var/spool/cron/crontabs/sys will report important activities hourly during the working day:

```
5 18 * * 1—5 /usr/lib/sa/sa2 -s 8:00 -e 18:01 -i 1200 -A
```

Files

/tmp/sa.adrfl	address file
/var/adm/sa/sadd	daily data file
/var/adm/sa/sardd	daily report file

/var/spool/cron/crontabs/sys   used for performance collection

Attributes See attributes(5) for descriptions of the following attributes:

Oracle Solaris Administration: Common Tasks

Notes The sar service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/sar

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name sasinfo – Serial Attached SCSI HBA port command line interface

Synopsis sasinfo hba [-v] [*HBA_Name*]...

sasinfo hba-port [-lvy] [-a *HBA_Name*] [*HBA_port_nam*]...

sasinfo expander [-vt] [-p *HBA_port_Name*] [*Expander_SAS_Addr*]...

sasinfo target-port [-s | -v] [*Target_port_SAS_Addr*]...

sasinfo logical-unit | lu [-v] [*device_path*]...

sasinfo [-V]

sasinfo [-?]

Description The sasinfo utility is a command line interface that collects administrative information on Serial Attached SCSI–2 (SAS–2) host bus adapter (HBA) that supports the Storage Management HBA API (SM-HBA). The utility reports attributes of HBA ports and of expander devices and SCSI target devices that might be connected to those HBA ports.

sasinfo is implemented as a set of subcommands, described below.

Sub-commands The following subcommands are supported by sasinfo.

hba

Lists information for the HBA referenced by the specified *HBA_name*. If *HBA_name* is not specified, all HBAs on the host will be listed.

hba-port

Lists information for the HBA port referenced by the specified *HBA_port_Name*. If *HBA_port_Name* is not specified, all HBA ports on the host will be listed. Note that HBA ports can be dynamically configured/unconfigured so that the number of HBA ports on an HBA can change as connections to target devices are established. With no connections to a storage device, no HBA port is configured.

expander

Lists hierarchical view of the expander referenced by the specified *Expander_SAS_Addr*. If no argument is specified, all expanders that are visible across all HBA ports on the host will be listed.

target-port

Lists information for those target ports referenced by *Target_port_SAS_Addr* address. If no argument is specified, all target ports that are visible on the host will be listed.

logical-unit | lu

Lists the logical unit referenced by the specified *device_path*. If *device_path* is not specified, all SAS logical units will be listed, including the SAS Management Protocol (SMP) target port.

Options   The following options are supported.

-?, --help
  Displays usage information

-a, --hba *HBA_Name*
  Retrieve HBA port information from the *HBA_Name* of an HBA on the host. The -a option
  can only be used with the hba-port subcommand.

-l, --phy-linkstat
  Lists the link error statistics information for the phys on the HBA port referenced by the
  specified *HBA_port_Name* or all HBA ports if no HBA port is specified. This option is used
  only with the hba-port subcommand.

-p *HBA_port_SAS_Addr*, --port *HBA_port_SAS_Addr*
  Retrieve remote port information from the *HBA_port_SAS_Addr* of the local HBA port on
  the host. The -p option can be used only with the expander subcommand.

-s, --scsi
  Lists SCSI attributes for target ports that are requested for display. This option is only used
  for the target-port subcommand.

-v, --verbose
  Display details on hardware information, such as SAS address, topology device, and so
  forth, based on which subcommand is invoked.

-V, --version
  Displays the version information.

-y, --phy
  Lists the phy information on the HBA port specified by *HBA_port_Name* or all HBA ports
  if no HBA port is specified. This option is used only with the hba-port subcommand.

Examples   EXAMPLE 1   Listing All HBAs

The following command lists all HBAs on the host.

```
# sasinfo hba
HBA Name: SUNW-pmcs-0
HBA Name: SUNW-pmcs-1
```

EXAMPLE 2   Listing All HBAs with Details

The following command lists all HBAs on the host, along with related details. Note that each
HBA has two HBA ports configured, with each HBA port connected to a storage device.

```
# sasinfo hba -v
HBA Name: SUNW-pmcs-0
    Manufacturer: sun
    Model: SAS Gen-2
    Firmware Version: 1.1
```

EXAMPLE 2 Listing All HBAs with Details   *(Continued)*

```
    FCode/BIOS Version: 1.1
    Serial Number: 111-11111
    Driver Name: smvsl
    Driver Version: 1.1
    Number of HBA Ports: 2
HBA Name: SUNW-pmcs-1
    Manufacturer: sun
    Model: SAS Gen-2
    Firmware Version: 1.1
    FCode/BIOS Version: 1.1
    Serial Number: 111-11111
    Driver Name: smvsl
    Driver Version: 1.1
    Number of HBA Ports: 2
```

EXAMPLE 3 Listing All HBA Ports

The following command lists all HBA ports on the host.

```
# sasinfo hba-port
HBA Name: SUNW-pmcs-0
    HBA Port Name: /dev/cfg/c1
    HBA Port Name: /dev/cfg/c2
HBA Name: SUNW-pmcs-1
    HBA Port Name: /dev/cfg/c3
    HBA Port Name: /dev/cfg/c4
```

EXAMPLE 4 Listing all HBA Ports with Details

The following command lists all HBA ports, with accompanying details.

```
# sasinfo hba-port -v
HBA Name: SUNW-pmcs-0
    HBA Port Name: /dev/cfg/c1
        Type: sas-device
        State: online
        Local SAS Address: 5000c50000d756aa
        Attached Port SAS Address: 50800201a5a502bf
        Number of Phys: 4
    HBA Port Name: /dev/cfg/c25000c50000d756cc
        Type: sas-device
        State: online
        Local SAS Address: 5000c50000d756aa
        Attached Port SAS Address: 50800201a5a503bf
        Number of Phys: 4
HBA Name: SUNW-pmcs-1
    HBA Port Name: /dev/cfg/c3
        Type: sas-device
```

EXAMPLE 4   Listing all HBA Ports with Details   *(Continued)*

```
        State: online
        Local SAS Address: 5000c50000d756cc
        Attached Port SAS Address: 50800201a5a504bf
        Number of Phys: 4
    HBA Port Name: /dev/cfg/c4
        Type: sas-device
        State: online
        Local SAS Address: 5000c50000d756cc
        Attached Port SAS Address: 50800201a5a505bf
        Number of Phys: 4
```

EXAMPLE 5   Listing phy Information for All HBA Ports

The following command lists phy information for all HBA ports.

```
# sasinfo hba-port -y
HBA Name: SUNW-pmcs-0
    HBA Port Name: /dev/cfg/c1
        Phy Information:
         Identifier: 0
           State: enabled
           HardwareLinkRate(Min/Max): 1.5Gbit/3Gbit
           ProgrammedLinkRate(Min/Max): 1.5Gbit/3Gbit
           NegotiatedLinkRate: 3Gbit
         Identifier: 1
           State: enabled
           HardwareLinkRate(Min/Max): 1.5Gbit/3Gbit
           ProgrammedLinkRate(Min/Max): 1.5Gbit/3Gbit
           NegotiatedLinkRate: 3Gbit
         Identifier: 2
           State: enabled
           HardwareLinkRate(Min/Max): 1.5Gbit/3Gbit
           ProgrammedLinkRate(Min/Max): 1.5Gbit/3Gbit
           NegotiatedLinkRate: 3Gbit
         Identifier: 3
           State: enabled
           HardwareLinkRate(Min/Max): 1.5Gbit/3Gbit
           ProgrammedLinkRate(Min/Max): 1.5Gbit/3Gbit
           NegotiatedLinkRate: 3Gbit
    HBA Port Name: /dev/cfg/c2
        Phy Information:
         Identifier: 4
           State: enabled
           HardwareLinkRate(Min/Max): 1.5Gbit/3Gbit
           ProgrammedLinkRate(Min/Max): 1.5Gbit/3Gbit
           NegotiatedLinkRate: 3Gbit
         Identifier: 5
```

EXAMPLE 5 Listing phy Information for All HBA Ports   *(Continued)*

```
            State: enabled
            HardwareLinkRate(Min/Max): 1.5Gbit/3Gbit
            ProgrammedLinkRate(Min/Max): 1.5Gbit/3Gbit
            NegotiatedLinkRate: 3Gbit
         Identifier: 6
            State: enabled
            HardwareLinkRate(Min/Max): 1.5Gbit/3Gbit
            ProgrammedLinkRate(Min/Max): 1.5Gbit/3Gbit

        NegotiatedLinkRate: 3Gbit
      Identifier: 7
        State: enabled
        HardwareLinkRate(Min/Max): 1.5Gbit/3Gbit
        ProgrammedLinkRate(Min/Max): 1.5Gbit/3Gbit
        NegotiatedLinkRate: 3Gbit
```

EXAMPLE 6 Listing phy Link Error Statistics for a Specific HBA Port

The following command lists phy link error statistics for a particular port.

```
# sasinfo hba-port -ly /dev/cfg/c1
HBA Name: SUNW-pmcs-0
  HBA Port Name: /dev/cfg/c1
    Phy Information:
      Identifier: 0
       State: enabled
        HardwareLinkRate(Min/Max): 1.5Gbit/3Gbit
        ProgrammedLinkRate(Min/Max): 1.5Gbit/3Gbit
        NegotiatedLinkRate: 3Gbit
        Link Error Statistics:
          Invalid Dword: 0
          Running Disparity Error: 0
          Loss of Dword Sync: 0
          Reset Problem: 0
      Identifier: 1
        State: enabled
        HardwareLinkRate(Min/Max): 1.5Gbit/3Gbit
        ProgrammedLinkRate(Min/Max): 1.5Gbit/3Gbit
        NegotiatedLinkRate: 3Gbit
        Link Error Statistics:
          Invalid Dword: 0
          Running Disparity Error: 0
          Loss of Dword Sync: 0
          Reset Problem: 0
      Identifier: 2
        State: enabled
        HardwareLinkRate(Min/Max): 1.5Gbit/3Gbit
        ProgrammedLinkRate(Min/Max): 1.5Gbit/3Gbit
        NegotiatedLinkRate: 3Gbit
```

EXAMPLE 6 Listing phy Link Error Statistics for a Specific HBA Port   *(Continued)*

```
        Link Error Statistics:
          Invalid Dword: 0
          Running Disparity Error: 0
          Loss of Dword Sync: 0
          Reset Problem: 0
     Identifier: 3
        State: enabled
        HardwareLinkRate(Min/Max): 1.5Gbit/3Gbit
        ProgrammedLinkRate(Min/Max): 1.5Gbit/3Gbit
        NegotiatedLinkRate: 3Gbit
        Link Error Statistics:
          Invalid Dword: 0
          Running Disparity Error: 0
          Loss of Dword Sync: 0
          Reset Problem: 0
```

EXAMPLE 7 Listing Expanders Connected to an HBA Port

The following command lists all expanders that are visible through the specified HBA port.

```
# sasinfo expander -p /dev/cfg/c1
HBA Name: SUNW-pmcs-0
  HBA Port Name: /dev/cfg/c1
    Expander SAS Address(Tier 1): 50800201a5a502bf
        Expander SAS Address(Tier 2): 50800201a5a50233
        Expander SAS Address(Tier 2); 5000c5000d2da812
    Expander SAS Address(Tier 1): 50800201a5a503bf
        Expander SAS Address(Tier 2): 50800201a5a502d2
        Expander SAS Address(Tier 2); 5000c5000d2da823
```

EXAMPLE 8 Listing Detailed Information on Expanders

The following command lists detailed information on all expanders that are visible through the specified HBA port.

```
# sasinfo expander -v -p /dev/cfg/c1
HBA Name: SUNW-pmcs-0
  HBA Port Name: /dev/cfg/c1
    Expander SAS Address(Tier 1): 50800201a5a502bf
      OS Device Name: /dev/smp/expd0
      State: online
        Expander SAS Address(Tier 2): 50800201a5a50233
          OS Device Name: /dev/smp/expd2
          State: online
        Expander SAS Address(Tier 2); 5000c5000d2da812
          OS Device Name: /dev/smp/expd3
          State: online
    Expander SAS Address(Tier 1): 50800201a5a503bf
```

EXAMPLE 8 Listing Detailed Information on Expanders   *(Continued)*

```
 OS Device Name: /dev/smp/expd1
State: online
  Expander SAS Address(Tier 2): 50800201a5a502d2
    OS Device Name: /dev/smp/expd3
    State: online
  Expander SAS Address(Tier 2); 5000c5000d2da823
    OS Device Name: /dev/smp/expd4
    State: online
```

EXAMPLE 9 Listing Target Ports Attached to Expanders

The following command lists all target ports that are attached to expanders connected to a specified HBA port.

```
# sasinfo expander -t -p /dev/cfg/c1
HBA Name: SUNW-pmcs-0
  HBA Port Name: /dev/cfg/c1
     Expander SAS Address(Tier 1): 50800201a5a502bf
       Target Port SAS Address: 50800201a5a504f1
          Expander SAS Address(Tier 2): 50800201a5a50233
             Target Port SAS Address: 50800201a5a502be
             Target Port SAS Address: 5000c5000d2da8b2
          Expander SAS Address(Tier 2); 5000c5000d2da812
             Target Port SAS Address: 50800201a5a502be
             Target Port SAS Address: 50800201a5a508b2
     Expander SAS Address(Tier 1): 50800201a5a503bf
       Target Port SAS Address: 50800201a5a50421
          Expander SAS Address(Tier 2): 50800201a5a502d2
             Target Port SAS Address: 50800201a5a503be
             Target Port SAS Address: 5000c5000d2da7be
          Expander SAS Address(Tier 2); 5000c5000d2da823
             Target Port SAS Address: 50800201a5a503be
             Target Port SAS Address: 5000c5000d2da7be
```

EXAMPLE 10 Listing Target Port Information

The following command lists all target ports discovered on the host.

```
# sasinfo target-port
Target Port SAS Address: 5000c5000bae4009
Target Port SAS Address: 5000c5000baef4b1
Target Port SAS Address: 5000c5000bae3fe1
Target Port SAS Address: 5000c5000bae49d9
Target Port SAS Address: 5000c5000bae36c5
```

EXAMPLE 11 Listing Target Port Information with Topology Details

The following command lists all target ports with the HBA port and expander that they are connected to.

```
# sasinfo target-port -v
Target Port SAS Address: 5000c5000bae4009
  Type: SAS Device
  HBA Port Name: /dev/cfg/c7
    Expander Device SAS Address: 500e004aaaaaaa3f
  HBA Port Name: /dev/cfg/c5
    Expander Device SAS Address: 500e004aaaaaaa3f
Target Port SAS Address: 5000c5000baef4b1
  Type: SAS Device
  HBA Port Name: /dev/cfg/c7
    Expander Device SAS Address: 500e004aaaaaaa3f
  HBA Port Name: /dev/cfg/c5
    Expander Device SAS Address: 500e004aaaaaaa3f
Target Port SAS Address: 5000c5000bae3fe1
  Type: SAS Device
  HBA Port Name: /dev/cfg/c7
    Expander Device SAS Address: 500e004aaaaaaa3f
  HBA Port Name: /dev/cfg/c5
    Expander Device SAS Address: 500e004aaaaaaa3f
Target Port SAS Address: 5000c5000bae49d9
  Type: SAS Device
  HBA Port Name: /dev/cfg/c7
    Expander Device SAS Address: 500e004aaaaaaa3f
  HBA Port Name: /dev/cfg/c5
    Expander Device SAS Address: 500e004aaaaaaa3f
Target Port SAS Address: 5000c5000bae36c5
  Type: SAS Device
  HBA Port Name: /dev/cfg/c7
    Expander Device SAS Address: 500e004aaaaaaa3f
  HBA Port Name: /dev/cfg/c5
    Expander Device SAS Address: 500e004aaaaaaa3f
```

EXAMPLE 12 Listing Target Ports with SCSI Information

The following command lists all target port details, including SCSI information for each target port.

```
# sasinfo target-port -s 5000c5000bae4009
Target Port SAS Address: 5000c5000bae4009
  Type: SAS Device
      HBA Port Name: /dev/cfg/c7
          Expander Device SAS Address: 500e004aaaaaaa3f
              LUN : 0
                OS Device Name : /dev/rdsk/c6t5000C5000BAE400Bd0s2
                Vendor:   Sun
```

EXAMPLE 12 Listing Target Ports with SCSI Information *(Continued)*

```
                 Product:  J4400
                 Device Type: Disk
      HBA Port Name: /dev/cfg/c5
          Expander Device SAS Address: 500e004aaaaaaa3f
              LUN : 0
                 OS Device Name : /dev/rdsk/c6t5000C5000BAE400Bd0s2
                 Vendor:   Sun
                 Product:  J4400
                 Device Type: Disk
```

EXAMPLE 13 Listing the Logical Units

The following command lists the logical units on a host.

```
# sasinfo logical-unit
OS Device Name: /dev/rdsk/c4t50020F2300B4904Ed0s2
OS Device Name: /dev/rdsk/c4t50020F230000B4AFd0s2
```

EXAMPLE 14 Listing Additional Information on Logical Units

The following command displays additional logical unit information using the -v option for device /dev/rmt/0n.

```
# sasinfo lu -v
OS Device Name: /dev/rdsk/c4t50020F2300B4904Ed0s2
   HBA Port Name: /dev/cfg/c1
     Target Port SAS Address: 50020f2300b4904e
         LUN: 0
   Vendor: Sun
   Product: J4400
   Device Type: Disk
OS Device Name: /dev/rdsk/c4t50020F230000B4AFd0s2
   HBA Port Name: /dev/cfg/c1
     Target Port SAS Address: 50020f230063100b
         LUN: 0
   Vendor: Sun
   Product: J4400
   Device Type: Disk
```

Name   savecore – save a crash dump of the operating system

Synopsis   `/usr/bin/savecore [-Lvd] [-f` *dumpfile*`] [`*directory*`]`

Description   The `savecore` utility saves a crash dump of the kernel (assuming that one was made) and writes a reboot message in the shutdown log. It is invoked by the `dumpadm` service each time the system boots.

savecore can be configured by dumpadm(1M) to save crash dump data in either a compressed or uncompressed format. For the compressed format, `savecore` saves the crash dump data in the file *directory*/`vmdump.`*N*, where *N* in the pathname is replaced by a number which increments by one each time `savecore` is run in *directory*. The compressed file can be uncompressed in a separate step using the `-f` *dumpfile* option. For the uncompressed format, `savecore` saves the crash dump data in the file *directory*/`vmcore.`*N* and the kernel's namelist in *directory*/`unix.`*N*.

Before writing out a crash dump, `savecore` reads a number from the file *directory*/`minfree`. This is the minimum number of kilobytes that must remain free on the file system containing *directory*. If after saving the crash dump the file system containing *directory* would have less free space the number of kilobytes specified in `minfree`, the crash dump is not saved. if the `minfree` file does not exist, `savecore` assumes a `minfree` value of 1 megabyte.

The `savecore` utility also logs a reboot message using facility LOG_AUTH (see syslog(3C)). If the system crashed as a result of a panic, `savecore` logs the panic string too.

Options   The following options are supported:

`-d`	Disregard dump header valid flag. Force `savecore` to attempt to save a crash dump even if the header information stored on the dump device indicates the dump has already been saved.
`-f` *dumpfile*	Save a crash dump from the specified file instead of from the system's current dump device. When given *directory*/`vmdump.`*N*, uncompress the file to `vmcore.`*N* and `unix.`*N*, where *N* is the same number as in the compressed name.
	This option may also be useful if the information stored on the dump device has been copied to an on-disk file by means of the dd(1M) command.
`-L`	Save a crash dump of the live running Solaris system, without actually rebooting or altering the system in any way. This option forces `savecore` to save a live snapshot of the system to the dump device, and then immediately to retrieve the data and to write it out to a new set of crash dump files in the specified directory. Live system crash dumps can only be performed if you have configured your system to have a dedicated dump device using dumpadm(1M).

savecore -L does not suspend the system, so the contents of memory continue to change while the dump is saved. This means that live crash dumps are not fully self-consistent.

-v   Verbose. Enables verbose error messages from savecore.

Operands The following operands are supported:

directory   Save the crash dump files to the specified directory. If *directory* is not specified, savecore saves the crash dump files to the default savecore *directory*, configured by dumpadm(1M).

Files
- *directory*/vmcore.*N*
- *directory*/unix.*N*
- *directory*/bounds
- *directory*/minfree
- /var/crash/'uname -n' (default crash dump directory)

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also adb(1), mdb(1), svcs(1), dd(1M), dumpadm(1M), svcadm(1M), syslog(3C), attributes(5), smf(5)

Notes The system crash dump service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/dumpadm:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

If the dump device is also being used as a swap device, you must run savecore very soon after booting, before the swap space containing the crash dump is overwritten by programs currently running.

Name   sbdadm – SCSI Block Disk command line interface

Synopsis   sbdadm create-lu [-s, --size *size*] *filename*

sbdadm delete-lu *filename*

sbdadm import-lu *filename*

sbdadm list-lu

sbdadm modify-lu [-s, --size *size*] *lu_name* | *filename*

Description   The sbdadm command creates and manages SCSI-block-device-based logical units that are registered with the SCSI Target Mode Framework (STMF).

Sub-commands   The sbdadm command supports the subcommands listed below. Note that if you enter a question mark as an argument to the command (sbdadm ?), sbdadm responds with a help display.

create-lu [-s, --size *size*] *filename*
   Create a logical unit that can be registered with the STMF. For the -s option, *size* is an integer followed by one of the following letters, to indicate a unit of size:

   k   kilobyte

   m   megabyte

   g   gigabyte

   t   terabyte

   p   petabyte

   e   exabyte

   If you do not specify *size*, the size defaults to the size of *filename*.

   The size specified can exceed the size of the file or device.

delete-lu *filename*
   Deletes an existing logical unit that was created using sbdadm create-lu. This effectively unloads the logical unit from the STMF framework. Any existing data on the logical unit remains intact.

import-lu *filename*
   Imports and loads a logical unit into the STMF that was previously created using sbdadm create-lu and was since deleted from the STMF using sbdadm delete-lu. On success, the logical unit is again made available to the STMF. *filename* is the filename used in the sbdadm create-lu command for this logical unit.

list-lu
   List all logical units that were created using the sbdadm create-lu command.

modify-lu [-s, --size *size*] *lu_name* | *filename*

Modifies attributes of an logical unit created using the sbdadm create-lu command. For the -s option, *size* is an integer value followed by a unit specifier. The unit specifiers are as described above under create-lu. When this option is specified, the existing size of the logical unit is changed to the new size.

The size specified can exceed the size of the file or device represented by *lu_name*.

Operands sbdadm use the following operands:

filename
Name of an existing file or a fully qualified path to a raw block device.

lu_name
The 32-byte hexadecimal representation of the logical unit.

Examples EXAMPLE 1 Creating a Logical Unit

The following series of commands creates a 10–gigabyte logical unit.

```
# touch /export/lun/0
# sbdadm create-lu -s 10g /export/lun/0
# sbdadm create-lu /dev/rdsk/c1t1d0s0
```

EXAMPLE 2 Listing Logical Units

The following command lists all logical units.

```
# sbdadm list-lu
Found 2 LU(s)

                  GUID                   DATA SIZE    SOURCE
-------------------------------- -----------  ------
6000ae4000144f21d92c47b0dd650002 10737352704  /export/lun/0
6000ae4000144f21d92c47b0de300032 134283264    /dev/rdsk/c1t1d0s0
```

Exit Status 0
Successful completion.

non-zero
An error occurred.

Name scadm – administer System Controller (SC)

Synopsis /usr/platform/*platform-name*/sbin/scadm *subcommand* [*option*]
    [*argument*]...

Description The scadm utility administers the System Controller (SC). This utility allows the host server to interact with the SC.

The scadm utility *must* be run as root.

The interface, output, and location in the directory hierarchy for scadm are uncommitted and might change.

platform-name is the name of the platform implementation. Use the uname -i command to identify the platform implementation. See uname(1).

The scadm utility has a number of subcommands. Some subcommands have specific options and arguments associated with them. See SUBCOMMANDS, OPTIONS, OPERANDS, and USAGE.

SUBCOMMANDS Subcommands immediately follow the scadm command on the command line, and are separated from the command by a SPACE.

The following subcommands are supported

consolehistory
    Display the SC's console log. The SC maintains a running log which captures all console output. This log is maintained as a first-in, first-out buffer: New console output may displace old console output if the buffer is full. By default, only the last eight kilobytes of the console log file are displayed.

    The optional -a argument specifies that the entire console log file be displayed.

    It is possible for the SC to fill this log more quickly than the consolehistory subcommand can read it. This means that it is possible for some log data to be lost before it can be displayed. If this happens, the consolehistory subcommand displays "scadm: lost <number> bytes of console log data" in the log output, to indicate that some data was lost.

    The format for the consolehistory subcommand is:

    scadm consolehistory [-a]

    The consolehistory subcommand is not available on all platforms. If this command is used on a platform that does not support it, scadm prints this message:

    scadm: command/option not supported

    and exit with non-zero status.

date
    Display the SC's time and date

    The format for the date subcommand is:

```
scadm date
```

download

Program the SC's firmware.

There are two parts to the firmware, the boot monitor and the main image.

By default, The `scadm` command's download programs the main firmware image. The `boot` argument selects programming of the boot monitor.

The format for the `download` subcommand is:

```
scadm download [boot] file
```

fruhistory

Display the contents of the "field replacable unit" log maintained by the SC. By default, only the last eight kilobytes of the fru history log file are displayed. The data in contained this log contains snapshots of the SC's "showfru" command, taken whenever the system is reset, or a hot-plug event is detected by the SC.

The optional `-a` argument specifies that the entire fru log file be displayed.

It is possible for the SC to fill this log more quickly than the `fruhistory` subcommand can read it. This means that it is possible for some log data to be lost before it can be displayed. If this happens, the `fruhistory` subcommand displays "scadm: lost <number> bytes of fru log data" in the log output, to indicate that some data was lost.

The format for the fruhistory subcommand is:

```
scadm fruhistory [-a]
```

The `fruhistory` subcommand is not available on all platforms. If this command is used on a platform which does not support it, `scadm` prints this message:

```
scadm: command/option not supported
```

and exit with non-zero status.

help

Display a list of commands.

The format for the `help` subcommand is:

```
scadm help
```

loghistory

Display the most recent entries in the SC event log. The optional `-a` argument causes the entire event log history to be displayed. The `-a` argument is available only on platforms which support large log files. On platforms which do not support large log files, this flag has no additional effect.

It is possible for the SC to fill this log more quickly than the loghistory subcommand can read it. This means that it is possible for some log data to be lost before it can be displayed. If this happens, the loghistory subcommand displays "scadm: lost <number> events" in the log output, to indicate that some data was lost.

The format for the loghistory subcommand is:

```
scadm loghistory [-a]
```

resetrsc

Reset the SC. There are two types of resets allowed, a hard reset and a soft reset. The hard reset is done by default. The soft reset can be selected by using the -s option.

The format for the resetrsc subcommand is:

```
scadm resetrsc [-s]
```

send_event

Manually send a text based event. The SC can forward the event to the SC event log. You can configure the -c option to send a critical warning to email, alert to logged in SC users, and syslog. Critical events are logged to syslog(3C). There is an 80 character limit to the length of the associated text message.

The format for the send_event subcommand is:

```
scadm send_event [-c] "message"
```

set

Set SC configuration variables to a value.

Examples of SC configuration variables include: SC IP address netsc_ipaddr and SC Customer Information sc_customerinfo. See the output from the scadm help command for a complete list of SC configuration variables.

The format for the set subcommand is:

```
scadm set variable value
```

show

Display the current SC configuration variable settings. If no variable is specified, scadm shows all variable settings.

The format for the show subcommand is:

```
scadm show [variable]
```

shownetwork

Display the current network configuration parameters for SC.

The format for the shownetwork subcommand is:

```
scadm shownetwork
```

useradd

Add user accounts to the SC. The SC supports up to sixteen separate users.

The format for the useradd subcommand is:

scadm useradd *username*

userdel

Delete a user account from SC.

The format for the userdel subcommand is:

scadm userdel *username*

userpassword

Set a password for the user account specified. This password overrides any existing password currently set. There is no verification of the old password before setting the new password.

The format for the userpassword subcommand is:

scadm userpassword *username*

userperm

Set the permission level for the user.

The format for the userperm subcommand is:

scadm userperm *username* [aucr]

usershow

Display details on the specified user account. If a username is not specified, all user accounts are displayed.

The format for the usershow subcommand is:

scadm usershow *username*

version

Display the version numbers of the SC and its components.

The format for the version subcommand is:

scadm version [-v]

Options The resetrsc, send_event, and version subcommands have associated options. Options follow subcommands on the command line and are separated from the subcommand by a SPACE.

The resetrsc subcommand supports the following options:

-s

Perform a soft reset instead of a hard reset. A hard reset physically resets the SC hardware. The SC software jumps to the boot firmware, simulating a reset, for a soft reset.

The send_event subcommand supports the following options:

-c

Send a critical event. Without the -c, -send_event sends a warning.

The version subcommand supports the following options:

-v

Display a verbose output of version numbers and associated information.

The consolehistory, fruhistory, and loghistory subcommands support the following option:

-a

Display the entire log. These subcommands normally display only the most recent log data. This flag causes them to display the entire log.

Operands The download, send_event, set, show, useradd, userdel, userperm, usershow, userpassword, and userperm subcommands have associated arguments (operands).

If the subcommand has an option, the arguments follow the option on the command line and is separated from the option by a SPACE. If the subcommand does not have an option, the arguments follow the subcommand on the command line and are separated from the subcommand by a SPACE. If there are more than one arguments, they are separated from each other by a SPACE.

The download subcommand supports the following arguments:

boot

Program the boot monitor portion of the flash. The main portion of the flash is programmed without any arguments

file

Specify *file* as the path to where the boot or main firmware image resides for download.

Examples of *file* are:

/usr/platform/*platform_type*/lib/image/alommainfw

or

/usr/platform/*platform_type*/lib/image/alombootfw

The send_event subcommand supports the following arguments:

"*message*"

Describe event using the test contained in *message*. Enclose *message* in quotation marks.

The set subcommand supports the following arguments:

variable

Set SC configuration *variable*.

value

    Set SC configuration variable to *value*.

The show subcommand supports the following arguments:

variable

    Display the value of that particular variable.

The useradd subcommand supports the following arguments:

username

    Add new SC account *username*.

The userdel subcommand supports the following arguments:

username

    Remove SC account *username*.

The userperm subcommand supports the following arguments:

-aucr

    Set permissions for SC user accounts. If no permissions are specified, all four permissions are disabled and read only access is assigned.

    The following are the definitions for permissions:

    a

        Allow user to administer or change the SC configuration variables

    u

        Allow user to use the user commands to modify SC accounts

    c

        Allow user to connect to console.

    r

        Allow user to reset SC and to power on and off the host.

username

    Change permissions on SC account *username*.

The -usershow subcommand supports the following arguments:

username

    Display information on SC account *username*. If *username* is not specified, all accounts are displayed.

The userpassword subcommand supports the following arguments:

username

    Set SC password for *username*.

The userperm subcommand supports the following arguments:

username
    Change SC permissions for *username.*

Examples **EXAMPLE 1** Displaying the SC's Date and Time

The following command displays the SC's date and time.

```
scadm date
```

EXAMPLE 2 Setting the SC's Configuration Variables

The following command sets the SC's configuration variable netsc_ipaddr to 192.168.1.2:

```
scadm set netsc_ipaddr 192.168.1.2
```

EXAMPLE 3 Displaying the Current SC's Configuration Settings:

The following command displays the current SC configuration settings:

```
scadm show
```

EXAMPLE 4 Displaying the Current Settings for a Variable

The following command displays the current settings for the sys_hostname variable:

```
scadm show sys_hostname
```

EXAMPLE 5 Sending a Text-Based Critical Event

The following command sends a critical event to the SC logs, alerts the current SC users, and sends an event to syslog(3C):

```
scadm send_event -c "The UPS signaled a loss in power"
```

EXAMPLE 6 Sending an Informational Text-Based Event

The following command sends an non-critical informational text based event to the SC event log:

```
scadm send_event "The disk is close to full capacity"
```

EXAMPLE 7 Adding a User To the SC

The following command adds user rscroot to the SC:

```
scadm useradd rscroot
```

EXAMPLE 8 Deleting a User From the SC

The following command deletes user olduser from the SC:

```
scadm userdel olduser
```

EXAMPLE 9   Displaying User Details

The following command displays details of all user accounts:

```
scadm usershow
```

EXAMPLE 10   Displaying Details for a Specific User

The following command displays details of user account rscroot:

```
scadm usershow rscroot
```

EXAMPLE 11   Setting the User Permission Level

The following command sets the full permission level for user rscroot to aucr:

```
scadm userperm rscroot aucr
```

EXAMPLE 12   Setting the User Permission Level

The following command sets only console access for user newuser to c:

```
scadm userperm newuser c
```

EXAMPLE 13   Setting the User Permission Level

The following command sets the permission level for user newuser to read only access:

```
scadm userperm newuser
```

EXAMPLE 14   Displaying the Current Network Parameters

The following command displays the current network configuation parameters for the SC:

```
scadm shownetwork
```

EXAMPLE 15   Viewing the Consolehistory

The following command displays the content console in the SC event log:

```
scadm consolehistory [-a]
```

EXAMPLE 16   Viewing the Fruhistory

The following command displays the content of the "field replaceable unit" in the SC event log:

```
scadm fruhistory [-a]
```

EXAMPLE 17   Viewing the Loghistory

The following command displays the most recent entries in the SC event log:

```
scadm loghistory [-a]
```

EXAMPLE 18 Displaying Verbose Information

The following command displays verbose version information on the SC and its components:

```
scadm version -v
```

Exit Status   The following exit values are returned:

0
  Successful completion.

non-zero
  An error occurred.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/library/platform
Interface Stability	Committed

See Also   uname(1), syslog(3C), attributes(5)

Name   sckmd – Sun cryptographic key management daemon

Synopsis   `/usr/platform/sun4u/lib/sckmd`

Description   `sckmd` is a server process that resides on a high-end system domain to maintain the Internet Protocol Security (IPsec) Security Associations (SAs) needed to secure communications between a Service Processor or System Controller (SC) and platform management software running within a domain. The cvcd(1M) and dcs(1M) daemons use these Security Associations. See ipsec(7P) for a description of Security Associations.

The `sckmd` daemon receives SAs from the Service Processor or SC and installs these SAs in a domain's Security Association Database (SADB) using pf_key(7P).

`sckmd` starts up at system boot time as an SMF service. The FMRI for the `sckmd` service is:

`svc:/platform/sun4u/sckmd:default`

A domain supports only one running `sckmd` process at a time.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsckmx.u, service/key-management/sun-fire-15000
Interface Stability	Committed

See Also   cvcd(1M), dcs(1M), ipsecconf(1M), ipsecalgs(1M), attributes(5), ipsec(7P), ipsecah(7P), ipsecesp(7P), pf_key(7P)

Notes   The `sckmd` service is used only on Sun Fire high-end systems and the SPARC Enterprise Server family. It provides a mechanism for exchanging IPsec keys between a domain and its System Controller (SC) or Service Processor. These platforms use IPsec to secure the communications between the SC or Service Processor and certain platform-specific daemons in the domain. Such daemons currently include cvcd(1M) and dcs(1M).

The documentation for each platform that supports `sckmd` describes how to configure its use of IPsec for such communications. Also, the documentation for each specific application describes how to configure its security policies and IPsec options in a manner appropriate for the target platform. Refer to the platform- and application-specific documentation for detailed information.

Name scmadm – storage cache manager administration utility

Synopsis scmadm

scmadm -h

scmadm -e

scmadm -d

scmadm -v

scmadm -C [*parameter* [= [*value*]]...]

scmadm -o {system | *cd* | *device*} [*option*]

scmadm -m {*cd* | *diskname* | all}

Description The scmadm command provides various options for controlling and gathering information about a storage device cache.

Options If no options are specified, scmadm displays a list of configured cache descriptors with disknames, options, and global options. The scmadm command supports the following options:

-h

   Displays usage information for the scmadm command.

-e

   Reads the configuration and enables the storage device cache with those parameters. See dscfg(1M).

-d

   Shuts down the storage device cache.

-v

   Displays the cache version number.

-C [*parameter*[=[*value*]] ...]

   Sets or displays the configuration parameters. If the -C option is specified with no arguments the current cache configuration parameters are displayed. If *parameter* is specified, the current value of *parameter* is displayed. If *parameter=value* is specified, the current value of *parameter* is displayed and the parameter is changed to *value*. If *value* is omitted, or if *value* is specified as the null string, " ", or as "-", the parameter is deleted from the configuration and the system uses the default value. Multiple parameters can be specified in a single invocation of the scmadm command. A change in a configuration parameter takes effect only when the cache is next restarted.

-o { system | cd | *diskname* } [*option*]

   Sets or displays the options for the system or for the cache device specified by cd or *diskname*. If the *option* rdcache or nordcache is specified, the system or specified cache device is set to that option. The option is saved as part of the configuration so that the option persists. See dscfg(1M). To notify the system to "forget" about a saved option, use

the forget option. This does not change the option; it just removes the option from the saved configuration. If no option is specified, current options are displayed. The rdcache option is set as the default. The *option*s are defined as follows:

rdcache
   Data blocks are likely to be referenced again and should remain in cache.

nordcache
   Data blocks are unlikely to be referenced again and should be treated as least recently used, so that other blocks can remain in the cache longer.

-m { cd | *diskname* | all }
   Displays the cache descriptor and diskname map for the device specified by cd or *diskname* or, if you specify all, displays the cache descriptors and diskname map for all storage devices on the system.

Exit Status   The scmadm command returns 0 for success, non-zero for error.

Files   /dev/sdbc

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/avs/avs-cache-management
Interface Stability	Committed

See Also   dscfg(1M), attributes(5)

Diagnostics   scmadm fails if there is insufficient contiguous memory.

Name sconadm – register system information

Synopsis /usr/sbin/sconadm register -a
       [-e softwareUpdate | -E softwareUpdate]
       [-h *hostname*] [-l *logfile*] [-N]
       [-p *proxy_host*[:*proxy_port*]]
       [-r *registration_profile*] [-u *username*]
       [-x *proxy_username*]

/usr/sbin/sconadm proxy [-l *logfile*]
       [-p *proxy_host*[:*proxy_port*]]
       [-r *registration_profile*] [-x *proxy_username*]

Description The sconadm utility is a command-line version of the Basic Registration GUI. In the first form of the command in the SYNOPSIS, sconadm uses the register subcommand to register a host with a registration server. In the second form, sconadm uses the proxy subcommand to configure all of the components for software update to use an HTTP web proxy.

The parameters specified with -u, -e (or -E), -h, -p, and -x override values specified in your registration profile. A template for this profile, owned by root, with read-only permissions, is stored in /usr/lib/breg/data/RegistrationProfile.properties. See registration_profile(4).

For the proxy subcommand, the proxy password is stored in the RegistrationProfile.properties file, available if proxy authentication is needed. Storage in the profile prevents proxy passwords from being exposed as part of a listing of processes on a system.

Options The following options are supported:

-a	Accept "Terms of Use and Binary Code License". Absence of this option means that you do not accept the license.
-e softwareUpdate	Enable client to be managed at the Sun-hosted Update Connection Service.
-E softwareUpdate	Disable client's ability to be managed at the Sun-hosted Update Connection Service.
-h *hostname*	Hostname of the machine you want to register.
-l *logfile*	Pathname of log file.
-N	Never register.
-p *proxy_host*[:*proxy_port*]	Proxy host name and optional proxy port number.
-r *registration_profile*	Pathname to a registration profile.
-u *username*	User name (a Sun Online Account).
-x *proxy_username*	User name on the proxy host.

Examples Unless specified otherwise, the commands below require root privileges or privileges equivalent to root. See privileges(5).

EXAMPLE 1 Registering a New System

Assume a file `registrationprofile.properties` in `/tmp` that contains the following:

```
userName=user123
password=abc123
hostName=
subscriptionKey=
portalEnabled=false
proxyHostName=
proxyPort=
proxyUserName=
proxyPassword=
```

To register a new system using the profile above, you enter:

/usr/sbin/sconadm register -a -r /tmp/registrationprofile.properties

EXAMPLE 2 Reregistering a System with a Different User

Assume a file `registrationprofile.properties` in `/tmp` with the contents shown below. Note the changed specification for `userName` and `password`.

```
userName=newuser
password=newpassword
hostName=
subscriptionKey=
portalEnabled=false
proxyHostName=
proxyPort=
proxyUserName=
proxyPassword=
```

To reregister a new system using the profile above, you enter the same command you entered to register the system:

/usr/sbin/sconadm register -a -r /tmp/registrationprofile.properties

EXAMPLE 3 Reregistering a System, Adding a Sun Subscription Key

Modify `registrationprofile.properties` as follows:

```
userName=newuser
password=newpassword
hostName=
subscriptionKey=abc12345678
portalEnabled=false
proxyHostName=
```

EXAMPLE 3 Reregistering a System, Adding a Sun Subscription Key   *(Continued)*

```
proxyPort=
proxyUserName=
proxyPassword=
```

Run the command:

`/usr/sbin/sconadm register -a -r /tmp/registrationprofile.properties`

EXAMPLE 4 Reregistering and Enabling Access to all Update Connection Services

Modify registrationprofile.properties as follows:

```
userName=newuser
password=newpassword
hostName=
subscriptionKey=abc12345678
portalEnabled=false
proxyHostName=
proxyPort=
proxyUserName=
proxyPassword=
```

Note that portalEnabled is set to false. Run the command:

`/usr/sbin/sconadm register -a -r /tmp/registrationprofile.properties \`
`-e softwareUpdate`

EXAMPLE 5 Never Registering

To never register a system, enter:

`/usr/sbin/sconadm register -N`

EXAMPLE 6 Using a Proxy Server With Proxy Authentication

Edit registrationprofile.properties as follows:

```
userName=
password=
hostName=
subscriptionKey=
portalEnabled=
proxyHostName=webcache.mycompany.com
proxyPort=8080
proxyUserName=myCompanyProxyUserName
proxyPassword=myCompanyProxyPassword
```

Run the command:

EXAMPLE 6   Using a Proxy Server With Proxy Authentication   *(Continued)*

```
/usr/sbin/sconadm proxy -r /tmp/registrationprofile.properties
```

EXAMPLE 7   Changing Proxy Host Settings

Edit registrationprofile.properties as follows:

```
userName=
password=
hostName=
subscriptionKey=
portalEnabled=
proxyHostName=webcache.mycompany.com
proxyPort=8080
proxyUserName=myCompanyProxyUserName
proxyPassword=myCompanyProxyPassword
```

Run the command:

```
/usr/sbin/sconadm proxy -r /tmp/registrationprofile.properties
```

Then, change the proxyHostName value by running the following command:

```
/usr/sbin/sconadm proxy -r /tmp/registrationprofile.properties \
-p newproxy.mycompany.com
```

After the preceding command all proxies use newproxy.mycompany.com.

EXAMPLE 8   Resetting a System Not to Use a Proxy

Edit registrationprofile.properties as follows:

```
userName=
password=
hostName=
subscriptionKey=
portalEnabled=
proxyHostName=
proxyPort=
proxyUserName=
proxyPassword=
```

Note that values for all proxy fields are null.

Run the command:

```
/usr/sbin/sconadm proxy -r /tmp/registrationprofile.properties
```

Exit Status 0   Success.

>0   An error occurred.

Files /usr/lib/breg/data/RegistrationProfile.properties
      Registration profile template.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbrg
Interface Stability	Committed

See Also registration_profile(4), attributes(5), privileges(5)

Name   sdpadm – SDP system configuration administration

Synopsis   /usr/sbin/sdpadm status | enable | disable

Description   The sdpadm command is no longer shipped with the Oracle Solaris operating system. SDP sockets are enabled by default. This man page describes a utility that was shipped in prior builds of the operating system.

The sdpadm command is used to display the system state of the Sockets Direct Protocol (SDP) protocol. The sdpadm command can optionally be used to set the state of the SDP protocol. See sdp(7D).

By default the SDP protocol is disabled on the system. It can be enabled by using sdpadm enable.

Options   The following subcommands are supported:

status   Displays the system status of the SDP protocol

enable   Enables the SDP protocol

disable   Disables the SDP protocol

Usage   The required privileges to change the state of the SDP protocol are controlled by the network configuration policy. If a user does not have the correct privileges to set the SDP policy, sdpadm returns the current state of SDP without having changed the state.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/spdadm
Interface Stability	Obsolete

See Also   attributes(5), sdp(7D)

Infiniband Specification Volume 1 (http://www.infinibandta.org)

Name sendmail – send mail over the internet

Synopsis /usr/lib/sendmail [-Ac] [-Am] [-ba] [-bD] [-bd] [-bi] [-bl]
      [-bm] [-bp] [-bP] [-bs] [-bt] [-bv] [-B *type*] [-C *file*]
      [-D *logfile*] [-d *X*] [-F *fullname*] [-f *name*] [-G]
      [-h *N*] [-L *tag*] [-M x*value*] [-N *notifications*] [-n]
      [-O*option* =*value*] [-o x*value*] [-p *protocol*]
      [-Q [*reason*]] [-q [*time*]] [-q *Xstring*] [-R *ret*]
      [-r *name*] [-t] [-V *envid*] [-v] [-X *logfile*]
      [*address*]...

Description The sendmail utility sends a message to one or more people, routing the message over whatever networks are necessary. sendmail does internetwork forwarding as necessary to deliver the message to the correct place.

sendmail is not intended as a user interface routine. Other programs provide user-friendly front ends. sendmail is used only to deliver pre-formatted messages.

With no flags, sendmail reads its standard input up to an EOF, or a line with a single dot, and sends a copy of the letter found there to all of the addresses listed. It determines the network to use based on the syntax and contents of the addresses.

Local addresses are looked up in the local aliases(4) file, or in a name service as defined by the nsswitch.conf(4) file, and aliased appropriately. In addition, if there is a .forward file in a recipient's home directory, sendmail forwards a copy of each message to the list of recipients that file contains. Refer to the NOTES section for more information about .forward files. Aliasing can be prevented by preceding the address with a backslash.

There are several conditions under which the expected behavior is for the alias database to be either built or rebuilt. This cannot occur under any circumstances unless root owns *and* has exclusive write permission to the /etc/mail/aliases* files.

If a message is found to be undeliverable, it is returned to the sender with diagnostics that indicate the location and nature of the failure; or, the message is placed in a dead.letter file in the sender's home directory.

Service Management The sendmail service is managed by the service management facility, smf(5), under the service identifiers:

svc:/network/smtp:sendmail
svc:/network/sendmail-client:default

Administrative actions on these services, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The services' status can be queried using the svcs(1) command.

These are separate services rather than instances of the same service so that other services can properly express any dependencies. In particular, here are some guidelines about which service/instance should be depended on for which purposes:

- For a service that uses sendmail to send mail, an optional dependency on the service svc:/network/sendmail-client might be in order.

- For a service that needs to receive mail in general, but does not depend on sendmail being the particular SMTP receiver, a dependency on the service svc:/network/smtp might be in order.

- For a service that needs to interact with sendmail in particular, such as a Milter, a dependency on the instance svc:/network/smtp:sendmail might be in order.

For the last two, note the difference, as the latter has the ":sendmail" instance specification, whereas the former does not, thus representing the more general service.

Enabling Access to Remote Clients
On an unmodified system, access to sendmail by remote clients is enabled and disabled through the service management facility (see smf(5)). In particular, remote access is determined by the value of the local_only SMF property:

```
svc:/network/smtp:sendmail/config/local_only = true
```

A setting of true, as above, disallows remote access; false allows remote access. The default value is true.

The following example shows the sequence of SMF commands used to enable sendmail to allow access to remote systems:

```
# svccfg -s svc:/network/smtp:sendmail setprop config/local_only = false
# svcadm refresh svc:/network/smtp:sendmail
# svcadm restart svc:/network/smtp:sendmail
```

See svcadm(1M) and svccfg(1M).

Note, however, on a system where any of the sendmail(4) files have been customized, setting this property might not have the intended effect. See sendmail(4) for details.

Automated Rebuilding of Configuration Files
See sendmail(4) for details on which service properties can be set to automate (re)building of configuration files when the service is started.

Restricting Host Access
sendmail uses TCP Wrappers to restrict access to hosts. It uses the service name of sendmail for hosts_access(). For more information on TCP Wrappers, see tcpd(1M) and hosts_access(4) in the security/tcp-wrapper package. tcpd(1M) and hosts_access(4) are not part of the Solaris man pages.

Startup Options
The /etc/default/sendmail file stores startup options for sendmail so that the options are not removed when a host is upgraded. See also sendmail(4) for details on which service properties can be set to automate (re)building of configuration files when the service is started.

You can use the following variables in the /etc/default/sendmail startup file:

CLIENTOPTIONS=*string*

Selects additional options to be used with the client daemon, which looks in the client-only queue (/var/spool/clientmqueue) and acts as a client queue runner. No syntax checking is done, so be careful when making changes to this variable.

CLIENTQUEUEINTERVAL=#

Similar to the QUEUEINTERVAL option, CLIENTQUEUEINTERVAL sets the time interval for mail queue runs. However, the CLIENTQUEUEINTERVAL option controls the functions of the client daemon, instead of the functions of the master daemon. Typically, the master daemon is able to deliver all messages to the SMTP port. However, if the message load is too high or the master daemon is not running, then messages go into the client-only queue, /var/spool/clientmqueue. The client daemon, which checks in the client-only queue, then acts as a client queue processor.

ETRN_HOSTS=*string*

Enables an SMTP client and server to interact immediately without waiting for the queue run intervals, which are periodic. The server can immediately deliver the portion of its queue that goes to the specified hosts. For more information, refer to the etrn(1M) man page.

MODE=-bd

Selects the mode to start sendmail with. Use the -bd option or leave it undefined.

OPTIONS=*string*

Selects additional options to be used with the master daemon. No syntax checking is done, so be careful when making changes to this variable.

QUEUEINTERVAL=#

Sets the interval for mail queue runs on the master daemon. # can be a positive integer that is followed by either s for seconds, m for minutes, h for hours, d for days, or w for weeks. The syntax is checked before sendmail is started. If the interval is negative or if the entry does not end with an appropriate letter, the interval is ignored and sendmail starts with a queue interval of 15 minutes.

QUEUEOPTIONS=p

Enables one persistent queue runner that sleeps between queue run intervals, instead of a new queue runner for each queue run interval. You can set this option to p, which is the only setting available. Otherwise, this option is not set.

Mail Filter API   sendmail supports a mail filter API called "milter". For more information, see /usr/include/libmilter/README and http://www.milter.org

Options   The following options are supported:

-Ac

Uses submit.cf even if the operation mode does not indicate an initial mail submission.

-Am

Uses sendmail.cf even if the operation mode indicates an initial mail submission.

-ba

Goes into ARPANET mode. All input lines must end with a RETURN-LINEFEED, and all messages are generated with a RETURN-LINEFEED at the end. Also, the From: and Sender: fields are examined for the name of the sender.

-bd

Runs as a daemon in the background, waiting for incoming SMTP connections.

-bD

Runs as a daemon in the foreground, waiting for incoming SMTP connections.

-bi

Initializes the aliases(4) database. Root must own *and* have exclusive write permission to the /etc/mail/aliases* files for successful use of this option.

-bl

Runs as a daemon (like -bd) but accepts only loopback SMTP connections.

-bm

Delivers mail in the usual way (default).

-bp

Prints a summary of the mail queues.

-bP

Prints the number of entries in the queues. This option is only available with shared memory support.

-bs

Uses the SMTP protocol as described in RFC 2821. This flag implies all the operations of the -ba flag that are compatible with SMTP.

-bt

Runs in address test mode. This mode reads addresses and shows the steps in parsing; it is used for debugging configuration tables.

-bv

Verifies names only. Does not try to collect or deliver a message. Verify mode is normally used for validating users or mailing lists.

-B *type*

Indicates body *type* (7BIT or 8BITMIME).

-C *file*

Uses alternate configuration file.

-D *logfile*

Send debugging output to the indicated log file instead of stdout.

-d *X*

Sets debugging value to *X*.

-f *name*

　Sets the name of the "from" person (that is, the sender of the mail).

-F *fullname*

　Sets the full name of the sender.

-G

　When accepting messages by way of the command line, indicates that they are for relay (gateway) submission. When this flag is set, sendmail might complain about syntactically invalid messages, for example, unqualified host names, rather than fixing them. sendmail does not do any canonicalization in this mode.

-h *N*

　Sets the hop count to *N*. The hop count is incremented every time the mail is processed. When it reaches a limit, the mail is returned with an error message, the victim of an aliasing loop.

-L *tag*

　Sets the identifier used in syslog messages to the supplied *tag*.

-M*xvalue*

　Sets macro *x* to the specified *value*.

-n

　Does not do aliasing.

-N *notifications*

　Tags all addresses being sent as wanting the indicated *notifications*, which consists of the word "NEVER" or a comma-separated list of "SUCCESS", "FAILURE", and "DELAY" for successful delivery, failure and a message that is stuck in a queue somwhere. The default is "FAILURE,DELAY".

-o*xvalue*

　Sets option *x* to the specified *value*. Processing Options are described below.

-O*option=value*

　Sets *option* to the specified *value* (for long from names). Processing Options are described below.

-p *protocol*

　Sets the sending protocol. The *protocol* field can be in form *protocol*:*host* to set both the sending protocol and the sending host. For example: -pUUCP:uunet sets the sending *protocol* to UUCP and the sending host to uunet. Some existing programs use -oM to set the *r* and *s* macros; this is equivalent to using -p.

-q[*time*]

　Processes saved messages in the queue at given intervals. If *time* is omitted, processes the queue once. *time* is given as a tagged number, where *s* is seconds, *m* is minutes, *h* is hours, *d* is days, and *w* is weeks. For example, -q1h30m or -q90m would both set the timeout to one hour thirty minutes.

By default, sendmail runs in the background. This option can be used safely with -bd.

-qp[*time*-]

Similar to -q[*time*], except that instead of periodically forking a child to process the queue, sendmail forks a single persistent child for each queue that alternates between processing the queue and sleeping. The sleep time (*time*) is specified as the argument; it defaults to 1 second. The process always sleeps at least 5 seconds if the queue was empty in the previous queue run.

-qf

Processes saved messages in the queue once and does not fork(2), but runs in the foreground.

-qG *name*

Processes jobs in queue group called *name* only.

-q[!]I *substr*

Limits processed jobs to those containing *substr* as a substring of the queue ID or not when ! is specified.

-q[!]Q *substr*

Limits processed jobs to those quarantined jobs containing *substr* as a substring of the quarantine *reason* or not when ! is specified.

-q[!]R *substr*

Limits processed jobs to those containing *substr* as a substring of one of the recipients or not when ! is specified.

-q[!]S *substr*

Limits processed jobs to those containing *substr* as a substring of the sender or not when ! is specified.

-Q[*reason*]

Quarantines a normal queue item with the given reason or unquarantines a quarantined queue item if no reason is given. This should only be used with some sort of item matching as described above.

-r *name*

An alternate and obsolete form of the -f flag.

-R *ret*

Identifies the information you want returned if the message bounces. *ret* can be HDRS for headers only or FULL for headers plus body.

-t

Reads message for recipients. To:,Cc:, and Bcc: lines are scanned for people to send to. The Bcc: line is deleted before transmission. Any addresses in the argument list is suppressed. The NoRecipientAction Processing Option can be used to change the behavior when no legal recipients are included in the message.

-v
>	Goes into verbose mode. Alias expansions are announced, and so forth.

-V *envid*
>	The indicated *envid* is passed with the envelope of the message and returned if the message bounces.

-X *logfile*
>	Logs all traffic in and out of sendmail in the indicated *logfile* for debugging mailer problems. This produces a lot of data very quickly and should be used sparingly.

Processing Options   There are a number of "random" options that can be set from a configuration file. Options are represented by a single character or by multiple character names. The syntax for the single character names of is:

O*xvalue*

This sets option *x* to be *value*. Depending on the option, *value* may be a string, an integer, a boolean (with legal values t, T, f, or F; the default is TRUE), or a time interval.

The multiple character or long names use this syntax:

O *Longname=argument*

This sets the option *Longname* to be *argument*. The long names are beneficial because they are easier to interpret than the single character names.

Not all processing options have single character names associated with them. In the list below, the multiple character name is presented first followed by the single character syntax enclosed in parentheses.

AliasFile (A*file*)
>	Specifies possible alias files.

AliasWait (a *N*)
>	If set, waits up to *N* minutes for an "@:@" entry to exist in the aliases(4) database before starting up. If it does not appear in *N* minutes, issues a warning. Defaults to 10 minutes.

AllowBogusHELO
>	Allows a HELO SMTP command that does not include a host name. By default this option is disabled.

BadRcptThrottle=*N*
>	If set and more than the specified number of recipients in a single SMTP envelope are rejected, sleeps for one second after each rejected RCPT command.

BlankSub (B*c*)
>	Sets the blank substitution character to *c*. Unquoted spaces in addresses are replaced by this character. Defaults to SPACE (that is, no change is made).

CACertFile
File containing one CA cert.

CACertPath
Path to directory with certs of CAs.

CheckAliases (n)
Validates the RHS of aliases when rebuilding the [aliases(4)](#) database.

CheckpointInterval (C*N*)
Checkpoints the queue every *N* (default 10) addresses sent. If your system crashes during delivery to a large list, this prevents retransmission to any but the last *N* recipients.

ClassFactor (z*fact*)
The indicated factor *fact* is multiplied by the message class (determined by the Precedence: field in the user header and the P lines in the configuration file) and subtracted from the priority. Thus, messages with a higher Priority: are favored. Defaults to 1800.

ClientCertFile
File containing the cert of the client, that is, this cert is used when sendmail acts as client.

ClientKeyFile
File containing the private key belonging to the client cert.

ClientPortOptions
Sets client SMTP options. The options are key=value pairs. Known keys are:

Addr *Address Mask*
Address Mask defaults to INADDR_ANY. The address mask can be a numeric address in dot notation or a network name.

Family
Address family (defaults to INET).

Listen
Size of listen queue (defaults to 10).

Port
Name/number of listening port (defaults to smtp).

RcvBufSize
The size of the TCP/IP receive buffer.

SndBufSize
The size of the TCP/IP send buffer.

Modifier
Options (flags) for the daemon. Can be:

h
Uses name of interface for HELO command.

If h is set, the name corresponding to the outgoing interface address (whether chosen by means of the Connection parameter or the default) is used for the HELO/EHLO command.

ColonOkInAddr

If set, colons are treated as a regular character in addresses. If not set, they are treated as the introducer to the RFC 822 "group" syntax. This option is on for version 5 and lower configuration files.

ConnectionCacheSize (k*N*)

The maximum number of open connections that are to be cached at a time. The default is 1. This delays closing the current connection until either this invocation of sendmail needs to connect to another host or it terminates. Setting it to 0 defaults to the old behavior, that is, connections are closed immediately.

ConnectionCacheTimeout (K*timeout*)

The maximum amount of time a cached connection is permitted to idle without activity. If this time is exceeded, the connection is immediately closed. This value should be small (on the order of ten minutes). Before sendmail uses a cached connection, it always sends a NOOP (no operation) command to check the connection. If the NOOP command fails, it reopens the connection. This keeps your end from failing if the other end times out. The point of this option is to be a good network neighbor and avoid using up excessive resources on the other end. The default is five minutes.

ConnectionRateThrottle

The maximum number of connections permitted per second. After this many connections are accepted, further connections are delayed. If not set or <= 0, there is no limit.

ConnectionRateWindowSize

Define the length of the interval for which the number of incoming connections is maintained. The default is 60 seconds.

ControlSocketName

Name of the control socket for daemon management. A running sendmail daemon can be controlled through this Unix domain socket. Available commands are: help, restart, shutdown, and status. The status command returns the current number of daemon children, the free disk space (in blocks) of the queue directory, and the load average of the machine expressed as an integer. If not set, no control socket is available. For the sake of security, this Unix domain socket must be in a directory which is accessible only by root; /var/spool/mqueue/.smcontrol is recommended for the socket name.

CRLFile

File containing certificate revocation status, useful for X.509v3 authentication.

DaemonPortOptions (O*options*)

Sets server SMTP options. The options are *key=value* pairs. Known keys are:

Name

User-definable name for the daemon (defaults to "Daemon#"). Used for error messages and logging.

Addr
    Address mask (defaults INADDR_ANY).

    The address mask may be a numeric address in dot notation or a network name.

Family
    Address family (defaults to INET).

InputMailFilters
    List of input mail filters for the daemon.

Listen
    Size of listen queue (defaults to 10).

Modifier
    Options (flags) for the daemon; can be a sequence (without any delimiters) of:

    a
        Requires authentication.

    b
        Binds to interface through which mail has been received.

    c
        Performs hostname canonification (.cf).

    f
        Requires fully qualified hostname (.cf).

    h
        Uses name of interface for HELO command.

    u
        Allows unqualified addresses (.cf).

    C
        Does not perform hostname canonification.

    E
        Disallows ETRN (see RFC 2476).

Name
    User-definable name for the daemon (defaults to Daemon#). Used for error messages and
    logging.

Port
    Name/number of listening port (defaults to smtp).

ReceiveSize
    The size of the TCP/IP receive buffer.

SendSize
    The size of the TCP/IP send buffer.

children

Maximum number of children per daemon. See `MaxDaemonChildren`.

DeliveryMode

Delivery mode per daemon. See `DeliveryMode`.

refuseLA

`RefuseLA` per daemon.

delayLA

`DelayLA` per daemon.

queueLA

`QueueLA` per daemon.

sendmail listens on a new socket for each occurrence of the `DaemonPortOptions` option in a configuration file.

DataFileBufferSize

Sets the threshold, in bytes, before a memory-bases queue data file becomes disk-based. The default is 4096 bytes.

DeadLetterDrop

Defines the location of the system-wide dead.letter file, formerly hard-coded to `/var/tmp/dead.letter`. If this option is not set (the default), sendmail does not attempt to save to a system-wide `dead.letter` file in the event it cannot bounce the mail to the user or postmaster. Instead, it renames the `qf` file as it has in the past when the `dead.letter` file could not be opened.

DefaultCharSet

Sets the default character set to use when converting unlabeled 8 bit input to MIME.

DefaultUser (g*gid*) or (u*uid*)

Sets the default group ID for mailers to run in to *gid* or set the default userid for mailers to *uid*. Defaults to `1`. The value can also be given as a symbolic group or user name.

DelayLA=*LA*

When the system load average exceeds *LA*, sendmail sleeps for one second on most SMTP commands and before accepting connections.

DeliverByMin=*time*

Sets minimum time for `Deliver By SMTP Service Extension` (RFC 2852). If `0`, no time is listed, if less than `0`, the extension is not offered, if greater than `0`, it is listed as minimum time for the `EHLO` keyword `DELIVERBY`.

DeliveryMode (d*x*)

Delivers in mode *x*. Legal modes are:

i

Delivers interactively (synchronously).

b

Delivers in background (asynchronously).

d

Deferred mode. Database lookups are deferred until the actual queue run.

q

Just queues the message (delivers during queue run).

Defaults to b if no option is specified, i if it is specified but given no argument (that is, Od is equivalent to Odi).

DHParameters

File containing the DH parameters.

DialDelay

If a connection fails, waits this many seconds and tries again. Zero means "do not retry".

DontBlameSendmail

If set, overrides the file safety checks. This compromises system security and should not be used. See http://www.sendmail.org/tips/dontBlameSendmail for more information.

DontExpandCnames

If set, $[... $] lookups that do DNS-based lookups do not expand CNAME records.

DontInitGroups

If set, the initgroups(3C) routine is never invoked. If you set this, agents run on behalf of users only have their primary (/etc/passwd) group permissions.

DontProbeInterfaces

If set, sendmail does not insert the names and addresses of any local interfaces into the $=w class. If set, you must also include support for these addresses, otherwise mail to addresses in this list bounces with a configuration error.

DontPruneRoutes (R)

If set, does not prune route-addr syntax addresses to the minimum possible.

DoubleBounceAddress

If an error occurs when sending an error message, sends that "double bounce" error message to this address.

EightBitMode (8)

Uses 8–bit data handling. This option requires one of the following keys. The key can selected by using just the first character, but using the full word is better for clarity.

mimify

Does any necessary conversion of 8BITMIME to 7–bit.

pass

Passes unlabeled 8–bit input through as is.

strict
Rejects unlabeled 8–bit input.

ErrorHeader (E*file/message*)
Appends error messages with the indicated message. If it begins with a slash, it is assumed to be the pathname of a file containing a message (this is the recommended setting). Otherwise, it is a literal message. The error file might contain the name, email address, and/or phone number of a local postmaster who could provide assistance to end users. If the option is missing or NULL, or if it names a file which does not exist or which is not readable, no message is printed.

ErrorMode (e*x*)
Disposes of errors using mode *x*. The values for *x* are:

e
Mails back errors and gives 0 exit status always.

m
Mails back errors.

p
Prints error messages (default).

q
No messages, just gives exit status.

w
Writes back errors (mail if user not logged in).

FallbackMXhost (V*fallbackhost*)
If specified, the *fallbackhost* acts like a very low priority MX on every host. This is intended to be used by sites with poor network connectivity.

FallBackSmartHost
If specified, the *fallBackSmartHost* is used in a last-ditch effort for each host. This is intended to be used by sites with "fake internal DNS". That is, a company whose DNS accurately reflects the world inside that company's domain but not outside.

FastSplit
If set to a value greater than zero (the default is one), it suppresses the MX lookups on addresses when they are initially sorted, that is, for the first delivery attempt. This usually results in faster envelope splitting unless the MX records are readily available in a local DNS cache. To enforce initial sorting based on MX records set FastSplit to zero. If the mail is submitted directly from the command line, then the value also limits the number of processes to deliver the envelopes; if more envelopes are created they are only queued up and must be taken care of by a queue run. Since the default submission method is by way of SMTP (either from a MUA or by way of the Message Submission Program [MSP]), the value of FastSplit is seldom used to limit the number of processes to deliver the envelopes.

ForkEachJob (Y)
    If set, delivers each job that is run from the queue in a separate process. Use this option if
    you are short of memory, since the default tends to consume considerable amounts of
    memory while the queue is being processed.

ForwardPath (J*path*)
    Sets the path for searching for users' .forward files. The default is $z/.forward. Some sites
    that use the automounter may prefer to change this to /var/forward/$u to search a file
    with the same name as the user in a system directory. It can also be set to a sequence of
    paths separated by colons; sendmail stops at the first file it can successfully and safely open.
    For example, /var/forward/$u:$z/.forward searches first in /var/forward/ *username*
    and then in ~*username*/.forward (but only if the first file does not exist). Refer to the
    NOTES section for more information.

HeloName=*name*
    Sets the name to be used for HELO/EHLO (instead of $j).

HelpFile (H*file*)
    Specifies the help file for SMTP.

HoldExpensive (c)
    If an outgoing mailer is marked as being expensive, does not connect immediately.

HostsFile
    Sets the file to use when doing "file" type access of host names.

HostStatusDirectory
    If set, host status is kept on disk between sendmail runs in the named directory tree. If a full
    path is not used, then the path is interpreted relative to the queue directory.

IgnoreDots (i)
    Ignores dots in incoming messages. This is always disabled (that is, dots are always
    accepted) when reading SMTP mail.

LogLevel (L*n*)
    Sets the default log level to *n*. Defaults to 9.

(M*x* *value*)
    Sets the macro *x* to *value*. This is intended only for use from the command line.

MailboxDatabase
    Type of lookup to find information about local mail boxes, defaults to pw which uses
    getpwnam(3C). Other types can be introduced by adding them to the source code, see
    libsm/mbdb.c for details.

MatchGECOS (G)
    Tries to match recipient names using the GECOS field. This allows for mail to be delivered
    using names defined in the GECOS field in /etc/passwd as well as the login name.

MaxDaemonChildren

The maximum number of children the daemon permits. After this number, connections are rejected. If not set or <=0, there is no limit.

MaxHopCount (h*N*)

The maximum hop count. Messages that have been processed more than *N* times are assumed to be in a loop and are rejected. Defaults to 25.

MaxMessageSize

The maximum size of messages that are accepted (in bytes).

MaxMimeHeaderLength=*M*[/*N*]

Sets the maximum length of certain MIME header field values to *M* characters. For some of these headers which take parameters, the maximum length of each parameter is set to *N* if specified. If /*N* is not specified, one half of *M* is used. By default, these values are 0, meaning no checks are done.

MaxNOOPCommands=*N*

Overrides the default of 20 for the number of useless commands.

MaxQueueChildren=*N*

When set, this limits the number of concurrent queue runner processes to *N*. This helps to control the amount of system resources used when processing the queue. When there are multiple queue groups defined and the total number of queue runners for these queue groups would exceed MaxQueueChildren then the queue groups are not all run concurrently. That is, some portion of the queue groups run concurrently such that MaxQueueChildren is not be exceeded, while the remaining queue groups are run later (in round robin order). See MaxRunnersPerQueue.

MaxQueueRunSize

If set, limits the maximum size of any given queue run to this number of entries. This stops reading the queue directory after this number of entries is reached; job priority is not used. If not set, there is no limit.

MaxRunnersPerQueue=*N*

This sets the default maximum number of queue runners for queue groups. Up to *N* queue runners work in parallel on a queue group's messages. This is useful where the processing of a message in the queue might delay the processing of subsequent messages. Such a delay can be the result of non-erroneous situations such as a low bandwidth connection. The can be overridden on a per queue group basis by setting the Runners option. The default is 1 when not set.

MeToo (m)

Sends to me too, even if I am in an alias expansion.

MaxRecipientsPerMessage

If set, allows no more than the specified number of recipients in an SMTP envelope. Further recipients receive a 452 error code and are deferred for the next delivery attempt.

MinFreeBlocks (b*N*/*M*)
    Insists on at least *N* blocks free on the file system that holds the queue files before accepting
    email by way of SMTP. If there is insufficient space, sendmail gives a 452 response to the
    MAIL command. This invites the sender to try again later. The optional *M* is a maximum
    message size advertised in the ESMTP EHLO response. It is currently otherwise unused.

MinQueueAge
    Specifies the amount of time a job must sit in the queue between queue runs. This allows
    you to set the queue run interval low for better responsiveness without trying all jobs in
    each run. The default value is 0.

MustQuoteChars
    Specifies the characters to be quoted in a full name phrase. &,;:\()[] are quoted
    automatically.

NiceQueueRun
    Specifies the priority of queue runners. See nice(1).

NoRecipientAction
    Sets action if there are no legal recipient files in the message. The legal values are:

    add-apparently-to
        Adds an Apparently-to: header with all the known recipients (which may expose blind
        recipients).

    add-bcc
        Adds an empty Bcc: header.

    add-to
        Adds a To: header with all the known recipients (which may expose blind recipients).

    add-to-undisclosed
        Adds a To: undisclosed-recipients: header.

    none
        Does nothing, that is, leaves the message as it is.

OldStyleHeaders (o)
    Assumes that the headers may be in old format, that is, spaces delimit names. This actually
    turns on an adaptive algorithm: if any recipient address contains a comma, parenthesis, or
    angle bracket, it is assumed that commas already exist. If this flag is not on, only commas
    delimit names. Headers are always output with commas between the names.

OperatorChars or $o
    Defines the list of characters that can be used to separate the components of an address into
    tokens.

PidFile
    Specifies the filename of the pid file. The default is /var/run/sendmail.pid. The filename
    is macro-expanded before it is opened, and unlinked when sendmail exits.

PostmasterCopy (P*postmaster*)
>   If set, copies of error messages are sent to the named *postmaster*. Only the header of the
>   failed message is sent. Since most errors are user problems, this is probably not a good idea
>   on large sites, and arguably contains all sorts of privacy violations, but it seems to be
>   popular with certain operating systems vendors.

PrivacyOptions (p*opt,opt,...*)
>   Sets privacy options. Privacy is really a misnomer; many of these options are just a way of
>   insisting on stricter adherence to the SMTP protocol.
>
>   The goaway pseudo-flag sets all flags except noreceipts, restrictmailq, restrictqrun,
>   restrictexpand, noetrn, and nobodyreturn. If mailq is restricted, only people in the same
>   group as the queue directory can print the queue. If queue runs are restricted, only root and
>   the owner of the queue directory can run the queue. The restrict-expand pseudo-flag
>   instructs sendmail to drop privileges when the -bv option is given by users who are neither
>   root nor the TrustedUser so users cannot read private aliases, forwards, or :include: files.
>   It adds the NonRootSafeAddr to the "DontBlame-Sendmail" option to prevent misleading
>   unsafe address warnings. It also overrides the -v (verbose) command line option to prevent
>   information leakage. Authentication Warnings add warnings about various conditions that
>   may indicate attempts to fool the mail system, such as using an non-standard queue
>   directory.
>
>   The options can be selected from:
>
>   authwarnings
>   >   Puts X-Authentication-Warning: headers in messages.
>
>   goaway
>   >   Disallows essentially all SMTP status queries.
>
>   needexpnhelo
>   >   Insists on HELO or EHLO command before EXPN.
>

>   >   Insists on HELO or EHLO command before MAIL.
>
>   needvrfyhelo
>   >   Insists on HELO or EHLO command before VRFY.
>
>   noactualrecipient
>   >   Do not put an X-Actual-Recipient line in a DNS that reveals the actual account to which
>   >   an address is mapped.
>
>   noetrn
>   >   Disallows ETRN entirely.
>
>   noexpn
>   >   Disallows EXPN entirely.

noreceipts
    Prevents return receipts.

nobodyreturn
    Does not return the body of a message with DSNs.

novrfy
    Disallows VRFY entirely.

public
    Allows open access.

restrictexpand
    Restricts -bv and -v command line flags.

restrictmailq
    Restricts mailq command.

restrictqrun
    Restricts -q command line flag.

ProcessTitlePrefix *string*
    Prefixes the process title shown on "/usr/ucb/ps auxww" listings with *string*. The string is
    macro processed.

QueueDirectory (Q*dir*)
    Uses the named *dir* as the queue directory.

QueueFactor (q*factor*)
    Uses *factor* as the multiplier in the map function to decide when to just queue up jobs
    rather than run them. This value is divided by the difference between the current load
    average and the load average limit (x flag) to determine the maximum message priority to
    be sent. Defaults to 600000.

QueueFileMode=*mode*
    Defaults permissions for queue files (octal). If not set, sendmail uses 0600 unless its real
    and effective uid are different in which case it uses 0644.

QueueLA (x*LA*)
    When the system load average exceeds *LA*, just queues messages (that is, does not try to
    send them). Defaults to eight times the number of processors online when sendmail starts.

QueueSortOrder=*algorithm*
    Sets the algorithm used for sorting the queue. Only the first character of the value is used.
    Legal values are host (to order by the name of the first host name of the first recipient),
    filename (to order by the name of the queue file name), time (to order by the
    submission/creation time), random (to order randomly), modification (to order by the
    modification time of the qf file (older entries first)), none (to not order), and priority (to
    order by message priority). Host ordering makes better use of the connection cache, but
    may tend to process low priority messages that go to a single host over high priority

messages that go to several hosts; it probably shouldn't be used on slow network links. Filename and modification time ordering saves the overhead of reading all of the queued items before starting the queue run. Creation (submission) time ordering is almost always a bad idea, since it allows large, bulk mail to go out before smaller, personal mail, but may have applicability on some hosts with very fast connections. Random is useful if several queue runners are started by hand which try to drain the same queue since odds are they are working on different parts of the queue at the same time. Priority ordering is the default.

QueueTimeout (T*rtime*/*wtime*)
Sets the queue timeout to *rtime*. After this interval, messages that have not been successfully sent are returned to the sender. Defaults to five days (5d). The optional *wtime* is the time after which a warning message is sent. If it is missing or 0, then no warning messages are sent.

RandFile
File containing random data (use prefix file:) or the name of the UNIX socket if EGD is used (use prefix egd:). Note that Solaris supports random(7D), so this does not need to be specified.

RecipientFactor (y*fact*)
The indicated factor *fact* is added to the priority (thus *lowering* the priority of the job) for each recipient, that is, this value penalizes jobs with large numbers of recipients. Defaults to 30000.

RefuseLA (X*LA*)
When the system load average exceeds *LA*, refuses incoming SMTP connections. Defaults to 12 times the number of processors online when sendmail starts.

RejectLogInterval
Log interval when refusing connections for this long (default: 3h).

ResolverOptions (I)
Tunes DNS lookups.

RetryFactor (Z*fact*)
The indicated factor *fact* is added to the priority every time a job is processed. Thus, each time a job is processed, its priority is decreased by the indicated value. In most environments this should be positive, since hosts that are down are all too often down for a long time. Defaults to 90000.

RrtImpliesDsn
If this option is set, a Return-Receipt-To: header causes the request of a DSN, which is sent to the envelope sender as required by RFC 1891, not to the address given in the header.

RunAsUser
If set, becomes this user when reading and delivering mail. Intended for use of firewalls where users do not have accounts.

SafeFileEnvironment
:   If set, `sendmail` does a `chroot` into this directory before writing files.

SaveFromLine (f)
:   Saves Unix-style `From` lines at the front of headers. Normally they are assumed redundant and discarded.

SendMimeErrors (j)
:   If set, sends error messages in MIME format (see RFC 2045 and RFC 1344 for details). If disabled, `sendmail` does not return the DSN keyword in response to an `EHLO` and does not do Delivery Status Notification processing as described in RFC 1891.

ServerCertFile
:   File containing the cert of the server, that is, this cert is used when `sendmail` acts as server.

ServerKeyFile
:   File containing the private key belonging to the server cert.

ServiceSwitchFile
:   Defines the path to the service-switch file. Since the service-switch file is defined in the Solaris operating environment this option is ignored.

SevenBitInput (7)
:   Strips input to seven bits for compatibility with old systems. This should not be necessary.

SharedMemoryKey
:   Specifies key to use for shared memory segment. If not set (or `0`), shared memory is not be used. If this option is set, `sendmail` can share some data between different instances. For example, the number of entries in a queue directory or the available space in a file system. This allows for more efficient program execution, since only one process needs to update the data instead of each individual process gathering the data each time it is required.

SharedMemoryKeyFile=*file*
:   If `SharedMemoryKeyFile` is set to `-1`, the automatically selected shared memory key will be stored in the specified file.

SingleLineFromHeader
:   If set, `From:` lines that have embedded newlines are unwrapped onto one line.

SingleThreadDelivery
:   If this option and the `HostStatusDirectory` option are both set, uses single thread deliveries to other hosts.

SmtpGreetingMessage or $e
:   Specifies the initial SMTP greeting message.

SoftBounce
:   If set, issue temporary errors (4xy) instead of permanent errors (5xy). This can be useful during testing of a new configuration to avoid erroneous bouncing of mail.

StatusFile (S*file*)
    Logs statistics in the named *file*. By default, this is /etc/mail/sendmail.st. As root, you
    must touch(1) this file to enable mailstats(1).

SuperSafe (s)
    This option can be set to True, False, Interactive, or PostMilter. If set to True,
    sendmail is set to super-safe when running things, that is, always instantiate the queue file,
    even if you are going to attempt immediate delivery. sendmail always instantiates the
    queue file before returning control to the client under any circumstances. This should
    really always be set to True. The Interactive value has been introduced in 8.12 and can be
    used together with DeliveryMode=i. It skips some synchronization calls which are
    effectively doubled in the code execution path for this mode. If set to PostMilter,
    sendmail defers synchronizing the queue file until any milters have signaled acceptance of
    the message. PostMilter is useful only when sendmail is running as an SMTP server; in all
    other situations it acts the same as True.

TempFileMode (F*mode*)
    Specifies the file mode for queue files.

Timeout (r*timeouts*)
    Timeout reads after time interval. The *timeouts* argument is a list of *keyword=value* pairs.
    All but *command* apply to client SMTP. For backward compatibility, a timeout with no
    keyword= part is set all of the longer values. The recognized timeouts and their default
    values, and their minimum values specified in RFC 1123 section 5.3.2 are:

    aconnect
        all connections for a single delivery attempt [0, unspecified]

    command
        command read [1h, 5m]

    connect
        initial connect [0, unspecified]

    control
        complete control socket transaction [2m, none]

    datablock
        data block read [1h, 3m]

    datafinal
        reply to final . in data [1h, 10m]

    datainit
        reply to DATA command [5m, 2m]

    fileopen
        file open [60sec, none]

    helo
        reply to HELO or EHLO command [5m, none]

hoststatus
    host retry [30m, unspecified]

iconnect
    first attempt to connect to a host [0, unspecified]

ident
    IDENT protocol timeout [5s, none]

initial
    wait for initial greeting message [5m, 5m]

lhlo
    wait for reply to an LMTP LHLO command [2m, unspecified]

mail
    reply to MAIL command [10m, 5m]

misc
    reply to NOOP and VERB commands [2m, none]

queuereturn
    undeliverable message returned [5d]

queuewarn
    deferred warning [4h]

quit
    reply to QUIT command [2m, none]

rcpt
    reply to RCPT command [1h, 5m]

resolver.retrans
    Resolver's retransmission time interval (in seconds) [varies]. Sets both
    Timeout.resolver.retrans.first and Timeout.resolver.retrans.normal.

resolver.retrans.first
    Resolver's retransmission time interval (in seconds) for the first attempt to deliver a
    message [varies].

resolver.retrans.normal
    Resolver's retransmission time interval (in seconds) for all look-ups except the first
    delivery attempt [varies].

resolver.retry
    Number of times to retransmit a resolver query [varies]. Sets both
    Timeout.resolver.retry.first and Timeout.resolver.retry.normal.

resolver.retry.first
    Number of times to retransmit a resolver query for the first attempt to deliver a message
    [varies].

resolver.retry.normal
   Number of times to retransmit a resolver query for all look-ups except the first delivery
   attempt [varies].

rset
   reply to RSET command [5m, none]

starttls
   response to an SMTP STARTTLS command [1h]

TimeZoneSpec (t*tzinfo*)
   Sets the local time zone info to *tzinfo*, for example, "PST8PDT". Actually, if this is not set,
   the TZ environment variable is cleared (so the system default is used); if set but null, the
   user's TZ variable is used, and if set and non-null, the TZ variable is set to this value.

TLSSrvOptions
   If this option is 'V', then no client verification is performed,that is, the server does not ask
   for a certificate.

TrustedUser
   The user parameter can be a user name (looked up in the passwd map) or a numeric user
   id. Trusted user for file ownership and starting the daemon. If set, generated alias databases
   and the control socket (if configured) are automatically owned by this user.

TryNullMXList (w)
   If you are the "best" (that is, lowest preference) MX for a given host, you should normally
   detect this situation and treat that condition specially, by forwarding the mail to a UUCP
   feed, treating it as local, or whatever. However, in some cases (such as Internet firewalls)
   you may want to try to connect directly to that host as though it had no MX records at all.
   Setting this option causes sendmail to try this. The downside is that errors in your
   configuration are likely to be diagnosed as "host unknown" or "message timed out" instead
   of something more meaningful. This option is deprecated.

UnixFromLine or $l
   The "From " line used when sending to files or programs.

UnsafeGroupWrites
   If set, group-writable :include: and .forward files are considered "unsafe", that is, programs
   and files cannot be directly referenced from such files.

UseErrorsTo (l)
   If there is an Errors-To: header, sends error messages to the addresses listed there. They
   normally go to the envelope sender. Use of this option causes sendmail to violate RFC
   1123. This option is not recommended and deprecated.

UseMSP
   Uses as mail submission program, that is, allows group writable queue files if the group is
   the same as that of a set-group-id sendmail binary.

UserDatabaseSpec (U)
: Defines the name and location of the file containing User Database information.

Verbose (v)
: Runs in verbose mode. If this is set, sendmail adjusts the HoldExpensive and DeliveryMode options so that all mail is delivered completely in a single job so that you can see the entire delivery process. The Verbose option should *never* be set in the configuration file; it is intended for command line use only.

XscriptFileBufferSize
: Sets the threshold, in bytes, before a memory-bases queue transcript file becomes disk-based. The default is 4096 bytes.

If the first character of the user name is a vertical bar, the rest of the user name is used as the name of a program to pipe the mail to. It may be necessary to quote the name of the user to keep sendmail from suppressing the blanks from between arguments.

If invoked as newaliases, sendmail rebuilds the alias database, so long as the /etc/mail/aliases* files are owned by root *and* root has exclusive write permission. If invoked as mailq, sendmail prints the contents of the mail queue.

Operands *address*
: address of an intended recipient of the message being sent.

Usage See largefile(5) for the description of the behavior of sendmail when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Exit Status sendmail returns an exit status describing what it did. The codes are defined in /usr/include/sysexits.h.

EX_OK
: Successful completion on all addresses.

EX_NOUSER
: User name not recognized.

EX_UNAVAILABLE
: Catchall. Necessary resources were not available.

EX_SYNTAX
: Syntax error in address.

EX_SOFTWARE
: Internal software error, including bad arguments.

EX_OSERR
: Temporary operating system error, such as "cannot fork".

EX_NOHOST
: Host name not recognized.

EX_TEMPFAIL
     Message could not be sent immediately, but was queued.

Environment Variables No environment variables are used. However, sendmail's start-up script, invoked by svcadm(1M), reads /etc/default/sendmail. In this file, if the variable ETRN_HOSTS is set, the start-up script parses this variable and invokes etrn(1M) appropriately. ETRN_HOSTS should be of the form:

```
"s1:c1.1,c1.2      s2:c2.1 s3:c3.1,c3.2,c3.3"
```

That is, white-space separated groups of *server:client* where *client* can be one or more comma-separated names. The *:client* part is optional. *server* is the name of the server to prod; a mail queue run is requested for each *client* name. This is comparable to running:

```
/usr/lib/sendmail -qR client
```

on the host *server*.

Files dead.letter
     Unmailable text

/etc/default/sendmail
     Contains default settings. You can override some of the settings by command line options.

/etc/mail/aliases
     Mail aliases file (ASCII)

/etc/mail/aliases.db
     Database of mail aliases (binary)

/etc/mail/aliases.dir
     Database of mail aliases (binary)

/etc/mail/aliases.pag
     Database of mail aliases (binary)

/etc/mail/sendmail.cf
     Defines environment for sendmail

/etc/mail/submit.cf
     Defines environment for MSP

/etc/mail/trusted-users
     Lists users that are "trusted", that is, able to set their envelope from address using -f without generating a warning message. Note that this file is consulted by the default sendmail.cf, but not by the default submit.cf, in which the line referring to /etc/mail/trusted-users is commented out. See sendmail(4) for instructions on making changes to submit.cf and sendmail.cf.

/var/spool/clientmqueue/*
     Temporary files and queued mail

/var/spool/mqueue/*
  Temporary files and queued mail

~/.forward
  List of recipients for forwarding messages

/usr/include/libmilter/README
  Describes the steps needed to compile and run a filter

sendmail, Third Edition, Bryan Costales with Eric Allman, O'Reilly & Associates, Inc., 2003.

http://www.sendmail.org

http://www.milter.org

Notes The sendmail program requires a fully qualified host name when starting. A script has been
included to help verify if the host name is defined properly (see check-hostname(1M)).

The permissions and the ownership of several directories have been changed in order to
increase security. In particular, access to /etc/mail and /var/spool/mqueue has been
restricted.

Security restrictions have been placed users using .forward files to pipe mail to a program or
redirect mail to a file. The default shell (as listed in /etc/passwd) of these users must be listed
in /etc/shells. This restriction does not affect mail that is being redirected to another alias.

Additional restrictions have been put in place on .forward and :include: files. These files
and the directory structure that they are placed in cannot be group- or world-writable. See
check-permissions(1M).

If you have interfaces that map to domains that have MX records that point to non-local
destinations, you might need to enable the DontProbeInterfaces option to enable delivery to
those destinations. In its default startup behavior, sendmail probes each interface and adds an

interface's IP addresses, as well as any domains that those addresses map to, to its list of domains that are considered local. For domains thus added, being on the list of local domains is equivalent to having a 0-preference MX record, with `localhost` as the MX value. If this is not the result you want, enable `DontProbeInterfaces`.

Name   sf880drd – Sun Fire 880 Dynamic Reconfiguration daemon

Synopsis   sf880drd

Description   The Sun Fire 880 Dynamic Reconfiguration daemon, sf880drd, is part of the PCI and system bus hotplug framework. sf880drd starts at boot time. It has no configuration options and does not report any system status.

sf880drd implements the Sun Fire 880 console-less system administration (per-slot pushbuttons and LED status indicators). It also manages various aspects of CPU/memory hotplug.

Files   /usr/platform/SUNW,Sun-Fire-880/lib/sf880drd

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/kernel/dynamic-reconfiguration/sun-fire-880

See Also   svcs(1), cfgadm(1M), cfgadm_pci(1M), cfgadm_sbd(1M), svcadm(1M), attributes(5), smf(5)

Notes   The sf880drd service is managed by the service management facility, smf(5), under the service identifier:

svc:/platform/sun4u/sf880drd

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name sftp-server – SFTP server subsystem

Synopsis /usr/lib/ssh/sftp-server [-f *log_facility*] [-l *log_level*]

Description sftp-server implements the server side of the SSH File Transfer Protocol as defined in the IETF draft-ietf-secsh-filexfer.

sftp-server is a subsystem for sshd(1M) and must not be run directly. Command-line flags to sftp-server should be specified in the Subsystem declaration. See sshd_config(4) for more information.

To enable the sftp-server subsystem for sshd add the following to /etc/ssh/sshd_config:

Subsystem   sftp   /usr/lib/ssh/sftp-server

To run sftp-server in a chroot configuration, use internal-sftp instead of /usr/lib/ssh/sftp-server. Otherwise, the chroot directory must contain the necessary files and directories to support the user's session. See the ChrootDirectory and Subsystem options in sshd_config(4)) for more information on how sshd and sftp-server work with chroot(2).

See sshd_config(4) for a description of the format and contents of that file.

There is no relationship between the protocol used by sftp-server and the FTP protocol (RFC 959) provided by in.ftpd.

For logging to work, sftp-server must be able to access /dev/log. Use of sftp-server in a chroot configuration therefore requires that syslogd(1M) establish a logging socket inside the chroot directory.

Options Valid options are listed below. As stated above, these options, if used, are specified in the Subsystem declaration of sshd_config.

-f *log_facility*
  Specifies the facility code that is used when logging messages from sftp-server. The possible values are: DAEMON, USER, AUTH, LOCAL0, LOCAL1, LOCAL2, LOCAL3, LOCAL4, LOCAL5, LOCAL6, LOCAL7. The default is AUTH.

-l *log_level*
  Specifies which messages will be logged by sftp-server. The possible values are: QUIET, FATAL, ERROR, INFO, VERBOSE, DEBUG, DEBUG1, DEBUG2, and DEBUG3. INFO and VERBOSE log transactions that sftp-server performs on behalf of the client. DEBUG and DEBUG1 are equivalent. DEBUG2 and DEBUG3 each specify higher levels of debugging output. The default is ERROR.

-u *umask*
  Sets an explicit umask(2) to be applied to newly-created files and directories, instead of the user's default mask.

Exit Status The following exit values are returned:

    0   Successful completion.

    >0   An error occurred.

Files /usr/lib/ssh/sftp-server   Server-side binary.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/ssh
Interface Stability	Committed

See Also sftp(1), ssh(1), ssh-add(1), ssh-keygen(1), sshd(1M), syslogd(1M), chroot(2), umask(2), sshd_config(4), attributes(5)

Name   shadowd – shadow migration daemon

Synopsis   `/usr/lib/fs/shadowd`

`svc:/system/filesystem/shadowd:default`

Description   shadowd is a daemon that provides background worker threads to migrate data for a shadow migration. A shadow migration gradually moves data from a source file system into a new "shadow" file system. Users can access and change their data within the shadow file system while migration is occurring.

The shadowd service is managed by the service management facility, smf(5). Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

The svccfg(1M) command can be used to manage the following parameter related to shadowd:

`config_params/shadow_threads`

Number of threads to devote to background migration of data. These threads are global to the entire system, and increasing the number can increase concurrency and the overall speed of migration at the expense of increased resource consumption (network, I/O, and CPU).

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/zfs
Interface Stability	Unstable

See Also   shadowstat(1M), zfs(1M), attributes(5)

Name   shadowstat – report shadow migration statistics

Synopsis   /usr/sbin/shadowstat [*count*]

Description   The shadowstat utility reports statistics on in-progress shadow migrations. A line of output is presented for each migrating file system; the output looks similar to the following:

```
                      EST
              BYTES   BYTES            ELAPSED
DATASET       XFRD    LEFT    ERRORS   TIME
pool/newfs    2.10M   28.8G   -        00:02:45
```

Each line identifies bytes transferred thus far, a rough estimate of bytes left to transfer, number of migration errors, and the time elapsed since the migration was started.

If *count* is unspecified, updated values are presented every few seconds until the program is terminated. If *count* is specified, updates only occur *count* times, after which the program exits.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/zfs
Interface Stability	Unstable

See Also   shadowd(1M), zfs(1M), attributes(5)

Name share – display file system shares or make local file system available for mounting by remote systems

Synopsis share [-F *protocol*] -a

share [-F *protocol*] [-o *options*] [-d *description*] *pathname* [*sharename*]

share [-F *protocol*] [-A]

Description The share command defines and publishes a file system share, which means the file system is available for mounting through a sharing protocol.

If the -F *protocol* option is omitted, the first file sharing protocol listed in /etc/dfs/fstypes is used as the default.

For a description of NFS-specific share options, see share_nfs(1M). For a description of SMB specific share options, see share_smb(1M).

Using the share command to define and publish an NFS or SMB share of a ZFS file system is considered a legacy operation. Consider using the zfs set share command to define NFS or SMB share properties and then set the ZFS sharenfs or sharesmb property to publish the share. For more information, see zfs(1M) and share_smb(1M).

In the third form of share command, as shown in the Synopsis above, share displays published shares or, with the -A option, displays all configured (defined) shares.

Options -F *protocol*
　　Specify the file sharing protocol.

-o *specific_options*

　rw
　　Share *pathname* is published with read and write access to all clients. This is the default behavior.

　rw=*client*[:*client*]...
　　Share *pathname* is published with read and write access only to the listed clients. No other systems can access the share pathname.

　ro
　　Share pathname is published with read-only access to all clients.

　ro=*client*[:*client*]...
　　Share pathname is published with read-only access only to the listed clients. No other systems can access the share pathname.

　Separate multiple options with commas. Separate multiple operands for an option with colons. See EXAMPLES.

-d
　　Provide a comment that describes the file system share to be published.

-a
    Publish all defined shares.

-A
    Display all defined shares.

Examples   EXAMPLE 1   Publishing an NFS Share With Read-Only Access

The following command defines and publishes an NFS share of /ufsfs with read-only access.

```
# share -F nfs -o ro /ufsfs
```

EXAMPLE 2   Publishing an NFS Share with Multiple Share Options

The following command defines and publishes an NFS share of the /export/manuals file system with a netgroup called users_nfs who have read-only access and users from specified hosts who have read and write access.

```
# share -F nfs -o ro=users_nfs,rw=host1:host2:host3 /export/manuals
```

Files   /etc/dfs/dfstab
    This file is obsolete. An SMF service publishes NFS or SMB shares at boot time.

/etc/dfs/fstypes
    List of file-sharing protocols. NFS is the default file sharing protocol.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

See Also   mountd(1M), nfsd(1M), share_nfs(1M), share_smb(1M), shareall(1M), unshare(1M), zfs(1M), attributes(5)

Notes   If share commands are invoked multiple times on the same file system, the last share invocation supersedes the previous invocation. The options set by the last share command replace the old options. For example, if read-write permission was granted to usera on /somefs, then you want to grant read-write permission also to userb on /somefs, use the following syntax:

```
example% share -F nfs -o rw=usera:userb /somefs
```

Name shareall, unshareall – publish or unpublish multiple shares

Synopsis shareall [-F *FSType* [,*FSType*]...] [-| *file*]

unshareall [-F *FSType* [,*FSType*]...]

Description When used with no arguments, shareall publishes shares from a specified file that contains a list of share command lines. If the operand is a hyphen (-), then the share command lines are obtained from standard input. Otherwise, if neither a file nor a hyphen is specified, then shares are published from the SMF shares repository.

Shares can be specified by identifying the file system type in a comma-separated list as an argument to -F.

unshareall unpublishes all published file system shares. Without an -F flag, it unpublishes all distributed file system shares.

Options -F *FSType*   Specify file system type. Defaults to the first entry in /etc/dfs/fstypes.

Files /etc/dfs/dfstab

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

See Also share(1M), unshare(1M), attributes(5)

Name sharectl – configure and manage file sharing service

Synopsis sharectl [-h]

sharectl status [-h] [*protocol*]

sharectl get [-h] [-p *property*]... *protocol*

sharectl set [-h] [-p *property=value*]... *protocol*

Description The sharectl command operates on file-sharing protocols, such as NFS and SMB. The command sets the client and server operational properties, takes and restores configuration snapshots, and gets status of the protocol service.

The get and set subcommands (see below) require root privileges or that you assume the Primary Administrator role. An authorized user can use sharectl to set global values for NFS and SMB properties in the Solaris server management facility. See nfs(4) and smb(4).

Options The following options are supported:

-h
    Displays usage message.

-p *property*[=*value*]
    Specifies a property. See "Subcommands," below.

Subcommands sharectl supports the subcommands described below. The form of a sharectl command is:

sharectl *subcommand* **[***option***]**

get [-p *property*] *protocol*	Get the property values for the specified protocol. If no -p option is provided, get all the properties for the specified protocol.
set [-p *property=value*]... *protocol*	Set properties for the specified file sharing protocol.
status [*protocol*]	Display status of the specified protocol, or, if no protocol is specified, of all file-sharing protocols.

Examples EXAMPLE 1 Getting Properties

The following command gets the properties for the NFS protocol.

```
% sharectl get nfs
lockd_listen_backlog=32
lockd_servers=20
lockd_retransmit_timeout=5
grace_period=90
nfsmapid_domain=sun.com
servers=16
server_versmin=2
server_versmax=4
max_connections=-1
```

EXAMPLE 1 Getting Properties   *(Continued)*

The following command gets the value of the grace_period property for the NFS protocol.

```
% sharectl get -p grace_period nfs
grace_period=90
```

EXAMPLE 2 Setting a Property

Note in the preceding example that the minimum version of the server NFS protocol
(server_versmin) is set to 2. The following command sets the minimum version number to
version 3.

```
% sharectl set -p server_versmin=3 nfs
```

EXAMPLE 3 Obtaining Status

The following command obtains the status of all file-sharing protocols on a system.

```
% sharectl status
nfs      enabled
```

EXAMPLE 4 Setting Property for SMB Server

The following command sets the value of the server_signing_required property for the
SMB protocol.

```
% sharectl set -p server_signing_required=true smb
```

EXAMPLE 5 Setting Property for SMB Client

The following command sets the value of the client_signing_required property for the
SMB protocol.

```
% sharectl set -p client_signing_required=true smb
```

EXAMPLE 6 Setting Tracing of RPC Calls for autofs

The following command expands each RPC call to autofs and logs it to the location specified
for that service in automountd(1M).

```
# sharectl set trace=1 autofs
```

Exit Status   0   Successful completion.

non-zero   Command failed.

Files   /usr/include/libshare.h   Error codes used for exit status.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also   automount(1M), automountd(1M), lockd(1M), mountd(1M), nfsd(1M), nfsmapid(1M), nfs(4), smb(4), user_attr(4), attributes(5), rbac(5), smf(5), standards(5)

Name share_nfs – make NFS shares available for mounting by remote systems

Synopsis share -F nfs [-a [-o *specific_options*] [-d *description*]
    pathname [*sharename*] | [-A]]
zfs set share=name=*share-name*,path=*pathname*,[desc="*description*"],
    prot=nfs,[[*property=value*[,...]] *dataset*

Description The share utility defines and publishes a NFS share, which makes a local file system available for mounting by remote systems. It starts the nfsd(1M) and mountd(1M) daemons if they are not already running.

You can use the share command to create and publish a ZFS file system share, but this is considered a legacy operation. See zfs(1M) for information about using the zfs set share command and the sharenfs property to create and publish NFS shares.

Options The following options are supported:

-F nfs
    Specify the NFS file sharing protocol.

-a
    Publish all defined shares.

-o *specific_options*
    Specify *specific_options* in a comma-separated list of keywords and attribute-value-assertions for interpretation by the NFS protocol. By default, a share is published with read-write access to all clients, unless a specific option overrides the default access. *specific_options* can be any combination of the following:

    aclok
        Allows the NFS server to do access control for NFS Version 2 clients. When aclok is set on the server, maximal access is given to all clients. For example, with aclok set, if anyone has read permissions, then everyone does. If aclok is not set, minimal access is given to all clients.

    anon=*uid*
        Set *uid* to be the effective user ID of unknown users. By default, unknown users are given the effective user ID UID_NOBODY. If *uid* is set to −1, access is denied.

    charset
        All clients will be assumed to be using the specified character set (see list in following description) and file and path names will be converted to UTF-8 for the server.

    charset=access_list
        Where *charset* is one of: euc-cn, euc-jp, euc-jpms, euc-kr, euc-tw, iso8859-1, iso8859-2, iso8859-5, iso8859-6, iso8859-7, iso8859-8, iso8859-9, iso8859-13, iso8859-15, koi8-r.

        Clients that match the *access_list* for one of these properties will be assumed to be using that character set and file and path names will be converted to UTF-8 for the server.

index=file

Load file rather than a listing of the directory containing this file when the directory is referenced by an NFS URL.

log=*tag*

Enables NFS server logging for the specified file system. The optional tag determines the location of the related log files. The *tag* is defined in etc/nfs/nfslog.conf. If no *tag* is specified, the default values associated with the *global tag* in etc/nfs/nfslog.conf is used. Support of NFS server logging is only available for NFS Version 2 and Version 3 requests.

noaclfab

Allows NFS servers to not return fabricated ACLs to NFS clients. The default behavior for NFS servers is to fabricate ACLs. If noaclfab is set, then the NFS server does not fabricate ACLs, which is the appropriate choice if the underlying filesystem does not support the POSIX Draft ACL.

Access is disallowed to all clients. The ro or rw options can override none.

none=*access_list*

Access is not allowed to any client that matches the access list. The exception is when the access list is an asterisk (*), in which case ro or rw can override none.

nosub

Prevents clients from mounting subdirectories of shared directories. For example, if /export is shared with the nosub option on server *fooey* then a NFS client cannot do:

```
mount -F nfs fooey:/export/home/mnt
```

NFS Version 4 does not use the MOUNT protocol. The nosub option only applies to NFS Version 2 and Version 3 requests.

nosuid

By default, clients are allowed to create files on the shared file system with the setuid or setgid mode enabled. Specifying nosuid causes the server file system to silently ignore any attempt to enable the setuid or setgid mode bits.

public

Moves the location of the public file handle from root (/) to the exported directory for WebNFS-enabled browsers and clients. This option does not enable WebNFS service. WebNFS is always on. Only one file system per server may use this option. Any other option, including the -ro=list and -rw=list options can be included with the public option.

ro

Share is published with read-only access to all clients.

ro=*access_list*

    Share is published with read-only access to the clients listed in *access_list*; overrides the
rw suboption for the clients specified. See *access_list* below.

root

    Root users from all hosts have root access.

root=*access_list*

    Only root users from the hosts specified in *access_list* have root access. See *access_list*
below. By default, no host has root access, so root users are mapped to an anonymous
user ID (see the anon=*uid* option described above). Netgroups can be used if the file
system shared is using UNIX authentication (AUTH_SYS).

root_mapping=*uid*

    For a client that is allowed root access, map the root UID to the specified user id.

rw

    Share is published with read and write access to all clients.

rw=*access_list*

    Share is published with read and write access to the clients listed in *access_list*; overrides
the ro suboption for the clients specified. See *access_list* below.

sec=*mode*[:*mode*]...

    Publishes a share by using one or more of the specified security modes. The *mode* in the
sec=*mode* option must be a node name supported on the client. If the sec= option is not
specified, the default security mode used is AUTH_SYS. Multiple sec= options can be
specified on the command line, although each mode can appear only once. The security
modes are defined in nfssec(5).

    Each sec= option specifies modes that apply to any subsequent window=, rw, ro, rw=,
ro= and root= options that are provided before another sec=option. Each additional
sec= resets the security mode context, so that more window=, rw, ro, rw=, ro= and
root= options can be supplied for additional modes.

sec=*none*

    If the option sec=*none* is specified when the client uses AUTH_NONE, or if the client uses a
security mode that is not one that the file system is shared with, then the credential of
each NFS request is treated as unauthenticated. See the anon=*uid* option for a
description of how unauthenticated requests are handled.

secure

    This option has been deprecated in favor of the sec=*dh* option.

window=*value*

    When a share is published with sec=*dh*, set the maximum life time (in seconds) of the
RPC request's credential (in the authentication header) that the NFS server allows. If a
credential arrives with a life time larger than what is allowed, the NFS server rejects the
request. The default value is 30000 seconds (8.3 hours).

-d *description*
   Provide a comment that describes the file system to be shared.

-A
   Display all defined shares.

access_list   The *access_list* argument is either the string "*" to represent all hosts or a colon-separated list whose components may be any number of the following:

hostname
   The name of a host. With a server configured for DNS or LDAP naming in the `nsswitch` "hosts" entry, any hostname must be represented as a fully qualified DNS or LDAP name. The hostname specified must be the canonical name for this host and must match the hostname returned on the reverse lookup of the incoming IP address of the NFS client.

netgroup
   A netgroup contains a number of hostnames. With a server configured for DNS or LDAP naming in the `nsswitch` "hosts" entry, any hostname in a netgroup must be represented as a fully qualified DNS or LDAP name.

domain name suffix
   To use domain membership the server must use DNS or LDAP to resolve hostnames to IP addresses; that is, the "hosts" entry in the /etc/nsswitch.conf must specify "dns" or "ldap" ahead of "nis", since only DNS and LDAP return the full domain name of the host. Other name services like NIS cannot be used to resolve hostnames on the server because when mapping an IP address to a hostname they do not return domain information. For example,

   ```
   NIS    172.16.45.9 --> "myhost"
   ```

   and

   ```
   DNS or LDAP    172.16.45.9 -->
        "myhost.mydomain.mycompany.com"
   ```

   The domain name suffix is distinguished from hostnames and netgroups by a prefixed dot. For example,

   ```
   rw=.mydomain.mycompany.com
   ```

   A single dot can be used to match a hostname with no suffix. For example,

   ```
   rw=.
   ```

   matches "mydomain" but not "mydomain.mycompany.com". This feature can be used to match hosts resolved through NIS rather than DNS and LDAP.

network
   The network or subnet component is preceded by an at-sign (@). It can be either a name or a dotted address. If a name, it is converted to a dotted address by getnetbyname(3SOCKET). For example,

=@mynet

would be equivalent to:

=@172.16 or =@172.16.0.0

The network prefix assumes an octet-aligned netmask determined from the zeroth octet in the low-order part of the address up to and including the high-order octet, if you want to specify a single IP address (see below). In the case where network prefixes are not byte-aligned, the syntax allows a mask length to be specified explicitly following a slash (/) delimiter. For example,

=@theothernet/17 or =@172.16.132/22

...where the mask is the number of leftmost contiguous significant bits in the corresponding IP address.

When specifying individual IP addresses, use the same @ notation described above, without a netmask specification. For example:

=@172.16.132.14

Multiple, individual IP addresses would be specified, for example, as:

root=@172.16.132.20:@172.16.134.20

A prefixed minus sign (−) denies access to that component of *access_list*. The list is searched sequentially until a match is found that either grants or denies access, or until the end of the list is reached. For example, if host "terra" is in the "engineering" netgroup, then

rw=-terra:engineering

denies access to terra but

rw=engineering:-terra

grants access to terra.

Operands The following operands are supported:

pathname
  The pathname of the file system to be shared.

Examples EXAMPLE 1 Define and Publish an NFS Share

The following example shows how to define and publish the /export/manuals file system share.

share -F NFS /export/manuals

Exit Status The following exit values are returned:

0
  Successful completion.

>0
  An error occurred.

Files /etc/dfs/fstypes
  list of system types, NFS by default

/etc/dfs/sharetab
  system record of shared file systems

/etc/nfs/nfslogtab
  system record of logged file systems

/etc/nfs/nfslog.conf
  logging configuration file

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/file-system/nfs

See Also mount(1M), mountd(1M), nfsd(1M), nfslogd(1M), share(1M), unshare(1M), zfs(1M), getnetbyname(3SOCKET), nfslog.conf(4), netgroup(4), attributes(5), nfssec(5)

Notes Creating and publishing an NFS share with the share command is permanent until the share is unshared. Publishing NFS shares is managed by the following SMF service:

```
$ svcs | grep share
online         Mar_07   svc:/network/shares:default
```

If the file system being shared is a symbolic link to a valid pathname, the canonical path (the path which the symbolic link follows) are shared. For example, if /export/foo is a symbolic link to /export/bar (/export/foo -> /export/bar), the following share command results in /export/bar as the shared pathname (and not /export/foo).

```
# share -F nfs /export/foo
```

An NFS mount of server:/export/foo results in server:/export/bar really being mounted.

The mountd(1M) process allows the processing of a path name the contains a symbolic link. This allows the processing of paths that are not themselves explicitly shared with share_nfs. For example, /export/foo might be a symbolic link that refers to /export/bar which has been specifically shared. When the client mounts /export/foo the mountd processing follows the symbolic link and responds with the /export/bar. The NFS Version 4 protocol does not

use the mountd processing and the client's use of /export/foo does not work as it does with NFS Version 2 and Version 3 and the client receives an error when attempting to mount /export/foo.

Name share_smb – make SMB shares available for mounting by remote systems

Synopsis
```
share  -F smb [-a [-o specific-options] [-d description]
       pathname share-name  | [-A]]
zfs set share=name=share-name,path=pathname,[desc="description"],
       prot=smb,[[property=value[,...]] dataset
```

Description The share command defines and publishes a SMB share, which makes a local file system available for mounting by remote systems.

You can modify the behavior of SMB shares by setting property values with either the share or zfs set share command. See the share(1M) and zfs(1M) man pages.

The share command has the following options:

-F smb
   Share SMB file sharing protocol.

-a
   Publish all defined shares.

-o *specific-options*
   Specify *specific-options* in a comma-separated list of keywords and attribute-value-assertions for interpretation by the SMB protocol. By default, a share is published with read-write access to all clients, unless a specific option overrides the default access. *specific-options* can be any combination of the properties supported by a given file system.

-d *description*
   Provide a comment that describes the file system to be shared.

-A
   Display all defined shares.

Share Properties The following SMB share properties are supported and can be set by the zfs and share commands:

abe=*boolean*
   Sets the access-based enumeration (ABE) policy for a share. When set to true, ABE filtering is enabled on this share and directory entries to which the requesting user has no access will be omitted from directory listings returned to the client. When set to false or not defined, ABE filtering will not be performed on this share. This property is not defined by default.

   false
       Disable ABE for this share.

   true
       Enable ABE for this share.

ad-container

Specifies the AD container in which to publish shares.

The AD container is specified as a comma-separated list of attribute name-value pairs using the LDAP distinguished name (DN) or relative distinguished name (RDN) format.

The following example uses the share command to specify the AD container:

```
$ share -F smb -o name=sh1,abe=true,\
ad-container=cn=sales,ou=mycompany,dc=com /export/home
```

The following example uses the zfs command to specify the AD container:

```
$ zfs set share=name=sh1,path=/export/home,prot=smb,\
ad-container=cn=sales,ou=mycompany,dc=com,abe=true rpool/export/home
```

The DN or RDN must be specified in LDAP format using the cn=, ou=, and dc= prefixes:

- cn represents the common name
- ou represents the organizational unit
- dc represents the domain component

cn=, ou= and dc= are attribute types. The attribute type used to describe an object's RDN is called the naming attribute, which, for ADS, includes the following object classes:

- cn for the user object class
- ou for the organizational unit (OU) object class
- dc for the domainDns object class

catia=*boolean*

Specifies whether to perform CATIA character substitution. CATIA V4 uses characters in file names that are considered to be invalid by Windows. A CATIA V4 file could be inaccessible to Windows clients if the file name contains any of the characters that are considered illegal in Windows. By default, CATIA character substitution is not performed. See "Enabling CATIA V4/V5 Character Translations" in *Oracle Solaris Administration: SMB and Windows Interoperability*.

If the catia property is set to true, the following character substitution is applied to file names.

```
CATIA   CATIA
V4 UNIX V5 Windows
  "      \250   0x00a8  Dieresis
  *      \244   0x00a4  Currency Sign
  /      \370   0x00f8  Latin Small Letter O with Stroke
  :      \367   0x00f7  Division Sign
  <      \253   0x00ab  Left-Pointing Double Angle Quotation Mark
  >      \273   0x00bb  Right-Pointing Double Angle Quotation Mark
  ?      \277   0x00bf  Inverted Question Mark
  \      \377   0x00ff  Latin Small Letter Y with Dieresis
  |      \246   0x00a6  Broken Bar
```

csc=*value*

Sets the client-side caching policy for a share. Client-side caching is a client feature and offline files are managed entirely by the clients.

The following are valid values for the csc property:

- manual – Clients are permitted to cache files from the specified share for offline use as requested by users. However, automatic file-by-file reintegration is not permitted. manual is the default value.

- auto – Clients are permitted to automatically cache files from the specified share for offline use and file-by-file reintegration is permitted.

- vdo – Clients are permitted to automatically cache files from the specified share for offline use, file-by-file reintegration is permitted, and clients are permitted to work from their local cache even while offline.

- disabled – Client-side caching is not permitted for this share.

dfsroot=*boolean*

Marks a share as a distributed file system (DFS) root share to distinguish it from a regular share. By default, dfsroot is not defined. If dfsroot is false or not defined, the share is not a DFS root share.

guestok=*boolean*

Sets the guest access policy for the share. When set to true guest access is allowed on this share. When set to false or not defined guest access is not allowed on this share. This property is not defined by default.

An idmap(1M) name-based rule can be used to map guest to any local user name, such as guest or nobody. If the local account has a password in /var/smb/smbpasswd the guest connection will be authenticated against that password. Any connection made using an account that maps to the local guest account will be treated as a guest connection.

The following name-based rule maps the Windows Guest user to the UNIX guest user:

 # idmap add winname:Guest unixuser:guest

none=*access-list*

Specifies that access is not allowed to any client that matches the access list. The exception is when the access list is an asterisk (*), in which case ro or rw can override none.

ro=*access-list*

Specifies that sharing is read-only to the clients listed in *access-list*. Overrides the rw suboption for the clients specified. See *access-list*.

rw=*access-list*

Specifies that sharing is read-write to the clients listed in *access-list*. Overrides the ro suboption for the clients specified. See *access-list*.

Access List Argument   The *access-list* argument is either the string "*" to represent all hosts or a colon-separated list whose components may be any number of the following:

hostname
Specifies the name of a host. *hostname* must be a fully qualified DNS or LDAP name when the host specifies these naming schemes in the hosts portion of the nsswitch.conf file.

netgroup
A netgroup contains a number of host names. Any *hostname* in a netgroup must be a fully qualified DNS or LDAP name when the host specifies these naming schemes in the hosts portion of the nsswitch.conf file.

domainname.suffix
To use domain membership, the server must use DNS or LDAP to resolve host names to IP addresses. This means that the hosts entry of the /etc/nsswitch.conf file must specify dns or ldap before nis. You must do this because only DNS and LDAP return the full domain name of the host.

Other naming services, such as NIS, cannot be used to resolve host names on the server because these naming services do not return domain information. For example, the following shows how NIS, DNS, and LDAP return host name information for the 172.16.45.9 IP address:

NIS   Returns: myhost

DNS or LDAP   Returns: myhost.mydomain.mycompany.com

The domain name suffix is distinguished from host names and netgroups by a prefixed dot. For example, rw=.mydomain.mycompany.com matches all host names in mydomain.mycompany.com.

The rw=. notation uses a single dot to match a host name that has no suffix. This notation matches mydomain but not mydomain.mycompany.com. This feature can be used to match hosts that are resolved by NIS rather than by DNS and LDAP.

network
The network or subnet component is preceded by an at-sign character (@). It can be either a network name or a dotted address.

A network name is converted to a dotted address by using getnetbyname(3SOCKET). For example, =@mynet is equivalent to =@172.16 or =@172.16.0.0.

The network prefix assumes an octet-aligned netmask. The netmask is determined from the zeroth octet in the low-order part of the address up to and including the high-order octet. If network prefixes are not byte-aligned, the syntax permits a mask length to be explicitly specified following a slash delimiter (/). For example, =@theothernet/17 or =@172.16.132/22 where the mask is the number of leftmost contiguous significant bits in the corresponding IP address.

When specifying individual IP addresses, use the same @ notation described previously, but do not use a netmask specification. For example, =@172.16.132.14.

You can use a colon character (:) to separate multiple, individual IP addresses. For example, root=@172.16.132.20:@172.16.134.20.

A prefixed minus sign (−) denies access to that component of *access-list*. The list is searched sequentially until a match is found that either grants or denies access, or until the end of the list is reached. For example, if host "terra" is in the "engineering" netgroup, specifying rw=-terra:engineering denies access to terra. However, specifying rw=engineering:-terra grants access to terra.

Examples   EXAMPLE 1   Setting a Share Property

The following examples use the zfs share and share commands to create and publish an SMB share.

- The following example shows how to use the zfs share command to create and publish an SMB share that also enables guest access:

```
# zfs set share=name=smb_share,path=/mntpnt/dir2,prot=smb,\
guestok=true tank/home
```

- The following example shows how to use the share command to enable guest access on a share:

```
# share -F smb -o guestok=true /mntpnt/dir2
```

EXAMPLE 2   Viewing the Share Properties on a Share

The following examples show how to use the zfs get command and the /etc/dfs/sharetab file to view share properties:

- The zfs get command enables you to view share properties on the tank/home dataset:

```
# zfs get share tank/home
NAME PROPERTY VALUE SOURCE
tank/home share name=smb_share,path=/mntpnt/dir2,guestok=true \
local
```

- The /etc/dfs/sharetab file shows all the active shares on the system. The entry for each share shows the properties set and their values:

```
# cat /etc/dfs/sharetab
/mntpnt/dir2 smb_share smb csc=auto,guestok=true
```

Files   /etc/dfs/sharetab
System record of shared file systems

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/file-system/smb
Interface Stability	Committed

See Also idmap(1M), share(1M), zfs(1M), zfs(1M), getnetbyname(3SOCKET), netgroup(4), attributes(5)

Name   showmount – show remote mounts

Synopsis   /usr/sbin/showmount [-ade] [*hostname*]

Description   showmount lists the clients that have remotely mounted a filesystem from *host*. This
information is maintained by the mountd(1M) server on *host*, and is saved across crashes in the
file /etc/rmtab. The default value for *host* is the value returned by hostname(1).

The showmount command does not display the names of NFS Version 4 clients.

Options   -a   Print all remote mounts in the format:

hostname : directory

where hostname is the name of the client, and directory is the root of the file system
that has been mounted.

-d   List directories that have been remotely mounted by clients.

-e   Print the list of shared file systems.

Files   /etc/rmtab

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/nfs

See Also   hostname(1), mountd(1M), attributes(5)

Installing Oracle Solaris 11 Systems

Bugs   If a client crashes, its entry is removed from the list of remote mounts on the server.

Name   shutdown – shut down system, change system state

Synopsis   `/usr/sbin/shutdown [-y] [-g` *grace-period*`] [-r | -i` *init-state*`]`
`        [`*message*`]`

Description   `shutdown` is executed by the super user to change the state of the machine. In most cases, it is used to change from the multi-user state (state 2) to another state.

By default, `shutdown` brings the system to a state where only the console has access to the operating system. This state is called single-user.

Before starting to shut down daemons and killing processes, `shutdown` sends a warning message and, by default, a final message asking for confirmation. *message* is a string that is sent out following the standard warning message:

`The system will be shut down in . . .`

If the string contains more than one word, it should be contained within single (') or double (") quotation marks.

The warning message and the user provided *message* are output when there are 7200, 3600, 1800, 1200, 600, 300, 120, 60, and 30 seconds remaining before `shutdown` begins. See `EXAMPLES`.

System state definitions are:

state 0   Stop the operating system.

state 1   State 1 is referred to as the administrative state. In state 1 file systems required for multi-user operations are mounted, and logins requiring access to multi-user file systems can be used. When the system comes up from firmware mode into state 1, only the console is active and other multi-user (state 2) services are unavailable. Note that not all user processes are stopped when transitioning from multi-user state to state 1.

state s, S State s (or S) is referred to as the single-user state. All user processes are stopped on transitions to this state. In the single-user state, file systems required for multi-user logins are unmounted and the system can only be accessed through the console. Logins requiring access to multi-user file systems cannot be used.

state 5   Shut the machine down so that it is safe to remove the power. Have the machine remove power, if possible. The `rc0` procedure is called to perform this task.

state 6   Stop the operating system and reboot to the state defined by the `initdefault` entry in /etc/inittab. The `rc6` procedure is called to perform this task.

Options   `-y`
         Pre-answer the confirmation question so the command can be run without user intervention.

-g *grace-period*

Allow the super user to change the number of seconds from the 60-second default.

-i *init-state*

If there are warnings, *init-state* specifies the state init is to be in. By default, system state 's' is used.

-r

Equivalent to specifying -i6.

Examples   EXAMPLE 1   Using shutdown

In the following example, shutdown is being executed on host foo and is scheduled in 120 seconds. The warning message is output 2 minutes, 1 minute, and 30 seconds before the final confirmation message.

```
example# shutdown -i S -g 120 "===== disk replacement ====="
Shutdown started.   Tue Jun  7 14:51:40 PDT  1994

Broadcast Message from root (pts/1) on foo Tue Jun  7 14:51:41. . .
The system will be shut down in 2 minutes
===== disk replacement =====
Broadcast Message from root (pts/1) on foo Tue Jun  7 14:52:41. . .
The system will be shut down in 1 minutes
===== disk replacement =====
Broadcast Message from root (pts/1) on foo Tue Jun  7 14:53:41. . .
The system will be shut down in 30 seconds
===== disk replacement =====
Do you want to continue? (y or n):
```

Files   /etc/inittab   controls process dispatching by init

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   boot(1M), halt(1M), init(1M), killall(1M), reboot(1M), ufsdump(1M), init.d(4), inittab(4), nologin(4), attributes(5)

Notes   When a system transitions down to the S or s state, the /etc/nologin file (see nologin(4)) is created. Upon subsequent transition to state 2 (multi-user state), this file is removed by a script in the /etc/rc2.d directory.

Name slpd – Service Location Protocol Daemon

Synopsis /usr/lib/inet/slpd [-f *configuration-file*]

Description The slpd daemon provides common server functionality for the Service Location Protocol ("SLP") versions 1 and 2, as defined by IETF in *RFC 2165* and *RFC 2608*. SLP provides a scalable framework for the discovery and selection of network services.

slpd provides the following framework services:

Directory Agent	This service automatically caches service advertisements from service agents to provide them to user agents, and makes directory agent advertisements of its services. This service is optional. slpd does not provide directory agent service by default. Directory agents are not databases, and they do not need to be maintained.
Service Agent Server	All service agents on the local host register and deregister with this server. This service responds to all requests for services, and forwards registrations to directory agents. By default, slpd is a service agent server.
Passive Directory Agent Discovery	This service listens for directory agent advertisements and maintains a table of active directory agents. When a user agent wishes to discover a directory agent, it can simply query slpd, obviating the need to perform discovery by means of multicast. By default, slpd performs this service.
Proxy Registration	This service can act as a proxy service agent for services that cannot register themselves. slpd reads the proxy registration file for information on services it is to proxy. By default, no services are registered by proxy.

All configuration options are available from the configuration file. slpd reads its configuration file upon startup.

Stop and start the slpd daemon using svcadm(1M). Use the command svcadm enable network/slp to start the slpd daemon. Use the command svcadm disable network/slp to stop it.

The file /etc/inet/slp.conf must exist before the slp service can start the daemon. Only the example file /etc/inet/slp.conf.example is present by default. To enable SLP, copy /etc/inet/slp.conf.example to /etc/inet/slp.conf.

Options   The following options are supported:

-f *configuration-file*   Specify an alternate configuration file

Examples   **EXAMPLE 1**   Stopping the `slpd` daemon

The following command stops the `slpd` daemon:

```
example# svcadm disable network/slp
```

EXAMPLE 2   Restarting the `slpd` daemon

The following command restarts the `slpd` daemon:

```
example# svcadm restart network/slp
```

Files   `/etc/inet/slp.conf`   The default configuration file

`slpd.reg`   The proxy registration file

Attributes   See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/slp, service/network/slp
CSI	Enabled
Interface Stability	Committed

See Also   `svcs(1)`, `svcadm(1M)`, `slp_api(3SLP)`, `slp.conf(4)`, `slpd.reg(4)`, `attributes(5)`, `smf(5)`, `slp(7P)`

Oracle Solaris Administration: Network Services

Guttman, E., Perkins, C., Veizades, J., and Day, M., *RFC 2608, Service Location Protocol, Version 2*, The Internet Society, June 1999.

Notes   The `slpd` service is managed by the service management facility, `smf(5)`, under the service identifier:

```
svc:/network/slp
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

Name smattrpop – populate security attribute databases in a name service

Synopsis smattrpop [-c] [-f] [-m] [-p *policy*] [-r] -s *scope* -t *scope*
          [-v] *database*

Description The smattrpop command updates the auth_attr(4), exec_attr(4), prof_attr(4), and
user_attr(4) role-based access control databases in a target NIS, LDAP, or local /etc files
name service from the corresponding databases in a source name service or files.

This command processes the table entries from the source database and merges each source
entry field into the same field in the corresponding table entry in the target database. If a
source entry does not exist in the target database, the entry is created. If the source entry exists
in the target database, the fields are merged or replaced according to the command options.

Any errors encountered while updating the target entry are reported to stdout, and the
command continues with the next source database entry.

Options The following options are supported:

-c   Performs cross-table checking. If you specify this option and a check error
            occurs, a message identifying the check error is written to stdout.

            The target entry values are checked against entries in related databases:

            ■ auths values — Each value must exist as the name of an authorization in the
              auth_attr(4) database.

            ■ profiles values — Each value must exist as a name of a profile in the
              prof_attr(4) database.

            ■ roles values — Each value must exist as the name of a role identity in the
              user_attr(4) database.

            ■ For each exec_attr(4) entry in the source database, the name must exist as
              the name of a profile in the prof_attr(4) database.

-f   Specifies that the value in each field in the source entry replaces the value in the
            corresponding field in the target entry, if the source entry field has a non-empty
            value.

-m   For the auths, profiles, and roles attributes, specifies that the values in each
            field in the source entry are merged with the values in the corresponding target
            entry field. If a source value does not exist in the target field, the value is
            appended to the set of target values. If the target field is empty, the source values
            replace the target field. The attribute values that merge depend on the database
            being updated:

            ■ prof_attr(4) — the auths and profiles attribute values are merged.
            ■ user_attr(4) — the auths, profiles, and roles attribute values are merged.
            ■ exec_attr(4) — the uid, gid, euid, and egid values are merged.

-p *policy*   Specifies the value of the policy field in the exec_attr(4) database. Valid values
              are suser (standard Solaris superuser) and tsol (Trusted Solaris). If you specify
              this option, only the entries in the source exec_attr database with the specified
              policy are processed. If you omit this option, all entries in the source exec_attr
              database are processed.

-r   Specifies that role identities in the user_attr(4) database in the source name
              service are processed. If you omit this option, only the normal user entries in the
              user_attr source database are processed.

-s *scope*   Specifies the source name service or local file directory for database updates,
              using the following syntax:

              type:/*server*/*domain*

              where *type* indicates the type of name service. Valid values for *type* are:

              ■ file — local files
              ■ nis — NIS name service
              ■ ldap — LDAP name service

              server indicates the local host name of the Solaris system on which the smattrpop
              command is executed, and on which both the source and target databases exist.

              domain specifies the management domain name for the name service.

              You can use two special cases of *scope* values:

              ■ To indicate the databases in the /etc/security local system directory, use
                 the scope file:/*server*, where *server* is the name of the local system.
              ■ To load from databases in an arbitrary directory on the Solaris server, use the
                 scope file:/*server*/*pathname*, where where *server* is the name of the local
                 system and *pathname* is the fully-qualified directory path name to the
                 database files.

-t *scope*   Specifies the target name service or local file directory for database updates, using
              the following syntax:

              type:/*server*/*domain*

              where *type* indicates the type of name service. Valid values for *type* are:

              ■ file — local files
              ■ nis — NIS name service
              ■ ldap — LDAP name service

              server indicates the local host name of the Solaris system on which the smattrpop
              command is executed, and on which both the source and target databases exist.

              domain specifies the management domain name for the name service.

You can use two special cases of *scope* values:

- To indicate the databases in the /etc/security local system directory, use the scope file:/*server*, where *server* is the name of the local system.

- To update to databases in an arbitrary directory on the Solaris server, use the scope file:/*server*/*pathname*, where where *server* is the name of the local system and *pathname* is the fully-qualified directory path name to the database files.

-v   Specifies that verbose messages are written. A message is written to stdout for each entry processed.

Operands   The following operands are supported:

database   Populates one or all databases. You can specify either the name of the database you want to process (for example, auth_attr), or all to process all databases. If you specify all, the databases are processed in the following order:

    1. auth_attr(4)
    2. prof_attr(4)
    3. exec_attr(4)
    4. user_attr(4)

Examples   EXAMPLE 1   Populating all tables in the NIS name service

The following example merges the values from all four attribute databases in the /etc/security directory of the local system into the corresponding tables in the NIS domain, east.example.com. The command is executed on the master server, hoosier, for the NIS domain and the source files are in the /etc and /etc/security directories on the NIS master server. No cross-table checking is performed. A summary message indicating the number of entries processed and updated for each table is written to stdout.

```
/usr/sadm/bin/smattrpop -s file:/hoosier \
          -t nis:/hoosier/east.example.com all
```

Environment Variables   See environ(5) for a description of the JAVA_HOME environment variable, which affects the execution of the smattrpop command. If this environment variable is not specified, the /usr/java location is used.

Exit Status   Any errors encountered while updating the target entry are reported to stdout. The following exit values are returned:

0   The specified tables were updated. Individual entries may have encountered checking errors.

1   A syntax error occurred in the command line.

2   A fatal error occurred and the tables were not completely processed. Some entries may have been updated before the failure.

Files /etc/security/auth_attr   Authorization description database. See auth_attr(4).

/etc/security/exec_attr   Execution profiles database. See exec_attr(4).

/etc/security/prof_attr   Profile description database. See prof_attr(4).

/etc/user_attr   Extended user attribute database. See user_attr(4).

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWmga

See Also auth_attr(4), exec_attr(4), prof_attr(4), user_attr(4), attributes(5), environ(5)

Name smbadm – configure and manage SMB local groups and users, manage domain membership, manage persistent password information, and issue various commands

Synopsis smbadm add-key [-u *username*]

smbadm add-member -m *member* [[-m *member*] ...] *group*

smbadm create-group [-d *description*] *group*

smbadm crypt

smbadm delete-group *group*

smbadm enable-user *username*

smbadm get-group [[-p *property*] ...] *group*

smbadm join -u *username domain*

smbadm join -w *workgroup*

smbadm lookup-server //*server*

smbadm lookup-user [-u *username*] *name* | *SID*

smbadm print [-u *username*] //*server/share* {*print_file*|-}

smbadm remove-key [-u *username*]

smbadm remove-member -m *member* [[-m *member*] ...] *group*

smbadm rename-group *group new-group*

smbadm set-group -p *property*=*value* [[-p *property*=*value*] ...] *group*

smbadm show-connections [-t] [-u *username*] [-c *computername* | -s *sharename*]
    server

smbadm show-domains

smbadm show-files [-t] [-u *username*] *server*

smbadm show-groups [-m] [-p] [*group*]

smbadm show-sessions [-t] [-u *username*] *server*

smbadm show-shares [-t] [-A | -u *username*] *server*

Description The smbadm command is used to configure SMB local groups, to manage domain membership, to manage persistent password information, and issue various commands. You can also use the smbadm command to enable or disable SMB password generation for individual local users.

SMB local groups can be used when Windows accounts must be members of some local groups and when Windows-style privileges must be granted. Solaris local groups cannot provide these functions.

There are two types of local groups: user defined and built-in. Built-in local groups are predefined local groups to support common administration tasks.

In order to provide proper identity mapping between SMB local groups and Solaris groups, an SMB local group must have a corresponding Solaris group. This requirement has two consequences: first, the group name must conform to the intersection of the Windows and Solaris group name rules. Thus, an SMB local group name can be up to eight (8) characters long and contain only lowercase characters and numbers. Second, a Solaris local group has to be created before an SMB local group can be created.

Built-in groups are standard Windows groups and are predefined by the SMB service. The built-in groups cannot be added, removed, or renamed, and these groups do not follow the SMB local group naming conventions.

When the SMB server is started, the following built-in groups are available:

Administrators
  Group members can administer the system.

Backup Operators
  Group members can bypass file access controls to back up and restore files.

Power Users
  Group members can share directories.

Solaris local users must have an SMB password for authentication and to gain access to SMB resources. This password is created by using the passwd(1) command when the pam_smb_password module is added to the system's PAM configuration. See the pam_smb_passwd(5) man page.

The disable-user and enable-user subcommands control SMB password-generation for a specified local user. When disabled, the user is prevented from connecting to the Solaris SMB service. By default, SMB password-generation is enabled for all local users.

To reenable a disabled user, you must use the enable-user subcommand and then reset the user's password by using the passwd command. The pam_smb_passwd.so.1 module must be added to the system's PAM configuration to generate an SMB password.

Escaping Backslash Character For the add-member, remove-member, and join (with -u) subcommands, the backslash character (\) is a valid separator between member or user names and domain names. The backslash character is a shell special character and must be quoted. For example, you might escape the backslash character with another backslash character: *domain\\username*. For more information about handling shell special characters, see the man page for your shell.

Operands The smbadm command uses the following operands:

domain
  Specifies the name of an existing Windows domain to join.

group
    Specifies the name of the SMB local group.

username
    Specifies the name of a Windows user. *username* can be specified in any of the following formats:

    domain*username*[+*password*]
    domain/*username*[+*password*]
    username@*domain*
    username

    ...where *domain* can be the NetBIOS or DNS domain name.

server
    Specifies the name or IP address of the local host.

Sub-commands   The smbadm command includes these subcommands:

add-key [-k *username*]
    Specifies persistent password information to be used for an SMB server user account. When you specify this information, mounts can be done without a password prompt in non-Kerberos configurations. Kerberos sites should use Kerberos automatically, not prompt for a password. If a default domain is available in SMF, the domain can be omitted. If a user name is not specified, the Solaris user account name is used. An encrypted (hashed) password can also be used, see the crypt subcommand. The command can also read a password from standard input, prompting if standard input is a TTY.

    Passwords can also be stored for a specific server by using a server name in place of the domain name.

    The persistent password information will also be stored in /var/smb/smbfspasswd for the user running the command.

add-member -m *member* [[-m *member*] ...] *group*
    Adds the specified member to the specified SMB local group. The -m *member* option specifies the name of an SMB local group member. The member name must include an existing user name and an optional domain name.

    Specify the member name in either of the following formats:

    [*domain*\\]*username*
    [*domain*/]*username*

    For example, a valid member name might be sales\\terry or sales/terry, where sales is the Windows domain name and terry is the name of a user in the sales domain.

create-group [-d *description*] *group*
    Creates an SMB local group with the specified name. You can optionally specify a description of the group by using the -d option.

crypt

    Creates a hash of a password. This subcommand prompts for a password and writes the hash to standard output. This hash value is suitable for use as a value for the encrypted password option for `smbfs` mount and various `smbadm` subcommands.

delete-group *group*

    Deletes the specified SMB local group. The built-in groups cannot be deleted.

disable-user *username*

    Disables SMB password-generation capabilities for the specified local user. A disabled local user is prevented from accessing the system by means of the SMB service. When a local user account is disabled, you cannot use the `passwd` command to modify the user's SMB password until the user account is reenabled.

enable-user *username*

    Enables SMB password-generation capabilities for the specified local user. After the password-generation capabilities are reenabled, you must use the `passwd` command to generate the SMB password for the local user before he can connect to the SMB service.

    The `passwd` command manages both the Solaris password and SMB password for this user if the pam_smb_passwd module has been added to the system's PAM configuration.

get-group [[-p *property*=*value*] …] *group*

    Retrieves property values for the specified group. If no property is specified, all property values are shown.

join -u *username domain*

    Joins a Windows domain or a workgroup.

    The default mode for the SMB service is workgroup mode, which uses the default workgroup name, WORKGROUP.

    An authenticated user account is required to join a domain, so you must specify the Windows administrative user name with the -u option. If the password is not specified on the command line, the user is prompted for it. This user should be the domain administrator or any user who has administrative privileges for the target domain.

    username and *domain* can be entered in any of the following formats:

    username[+*password*] *domain*
    domain*username*[+*password*]
    domain/*username*[+*password*]
    username@*domain*

    …where *domain* can be the NetBIOS or DNS domain name.

    If a machine trust account for the system already exists on a domain controller, any authenticated user account can be used when joining the domain. However, if the machine trust account does *not* already exist, an account that has administrative privileges on the domain is required to join the domain.

join -w *workgroup*
    Joins a Windows domain or a workgroup.

    The -w *workgroup* option specifies the name of the workgroup to join when using the join
    subcommand.

lookup-server //*server*
    Resolves the specified server to IP address, NetBIOS domain, and NetBIOS server name.
    server can be one of the following:

    - NetBIOS hostname
    - DNS hostname
    - IP address

lookup-user [-u *username*] *name* | *SID*
    Resolves information about the name or SID of an account in the current domain or any
    trusted domain.

print [-u *username*] //*server*/*share* {*print_file*|-}
    Print file to the specified remote printer. If *print_file* is a hyphen (-), read standard input. If
    a default domain is available in SMF, the domain can be omitted. If a user name is not
    specified, the Solaris user account name is used. An encrypted (hashed) password can also
    be used, see crypt subcommand. The command can also take a password through
    redirection.

remove-key [-u *username*]
    Erases the passwords for the user running the command. The passwords in
    /var/smb/smbfspasswd will also be deleted for the user running the command.

    The username and domain name portions of the name are optional. If a default domain is
    available in SMF, the domain can be omitted. If a *username* is not specified, all of the keys
    that are stored for the user who is running the command will be deleted.

    If the user's password is stored for a specific server, the server name should be specified in
    place of the domain name.

remove-member -m *member* [[-m *member*] …] *group*
    Removes the specified member from the specified SMB local group. The -m *member* option
    specifies the name of an SMB local group member. The member name must include an
    existing user name and an optional domain name.

    Specify the member name in either of the following formats:

    [*domain*\]*username*
    [*domain*/]*username*

    For example, a valid member name might be sales\terry or sales/terry, where sales is
    the Windows domain name and terry is the name of a user in the sales domain.

rename-group *group new-group*
  Renames the specified SMB local group. The group must already exist. The built-in groups cannot be renamed.

set-group -p *property=value* [[-p *property=value*] …] *group*
  Sets configuration properties for an SMB local group. The description and the privileges for the built-in groups cannot be changed.

  The -p *property=value* option specifies the list of properties to be set on the specified group.

  The group-related properties are as follows:

  backup=[on|off]
    Specifies whether members of the SMB local group can bypass file access controls to back up file system objects.

  description=*description-text*
    Specifies a text description for the SMB local group.

  restore=[on|off]
    Specifies whether members of the SMB local group can bypass file access controls to restore file system objects.

  take-ownership=[on|off]
    Specifies whether members of the SMB local group can take ownership of file system objects.

show-domains
  Shows information about the current workgroup or domain. The information typically includes the workgroup name or the primary domain name. When in domain mode, the information includes domain controller names and trusted domain names.

  Each entry in the output is identified by one of the following tags:
  - [*] Primary domain
  - [.] Local domain
  - [-] Other domains
  - [+] Selected domain controller

show-groups [-m] [-p] [*group*]
  Shows information about the specified SMB local group or groups. If no group is specified, information is shown for all groups. If the -m option is specified, the group members are also shown. If the -p option is specified, the group privileges are also shown.

The following set of subcommands shows information about the user shares, sessions, connections, and open files on a local or a remote server.

An authenticated user account is required to show the types of data listed above, so you must specify the Windows administrative user name with the -u option. If the password is not specified on the command line, the user is prompted for it. This user should be the domain

administrator or a user who has administrative privileges for the target domain. If a user name is not specified, the Solaris user account name is used.

The *username* can be in any of the formats described under "Operands".

show-connections [-t] [-u *username*] [-c *computername* | -s *sharename*] *server*
Shows information about the SMB tree connections made on the server. The -c option specifies the computer name for connections of interest to the client. The -s option specifies the share name for connections of interest to the client. The -t option specifies the command header to be displayed.

show-files [-t] [-u *username*] *server*
Shows information about the files open over SMB on the server. The -t option specifies the command header to be displayed.

show-sessions [-t] [-u *username*] *server*
Shows information about the SMB user sessions on the server. The -t option specifies command header to be displayed.

show-shares [-t] [-A | -u *username*] *server*
Shows information about the SMB shares on the server. The -t option specifies the command header to be displayed. The -A option specifies anonymous user.

Exit Status The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Attributes See the attributes(5) man page for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/file-system/smb

Name smbd – SMB server daemon

Synopsis /usr/lib/smbd

Description The smbd daemon handles CIFS/SMB requests from SMB clients, such as Windows clients. Only processes with {PRIV_SYS_SMB} and sufficient privileges to write the /var/run directory can run this daemon.

The smbd daemon is automatically invoked by using the share(1M) command or the zfs(1M) set share command over all available transports. By default, smbd starts over the NetBIOS-Over-TCP (NBT) and TCP transports.

When smbd is started over NBT, the following services are started:

- The NetBIOS name service is started on UDP port 137.
- The NetBIOS datagram service is started on UDP port 138.
- The NetBIOS session service is started on TCP port 139.

When the smbd daemon is started over TCP, the SMB service is started on TCP port 445.

Only one instance of smbd may be running at a time.

Exit Status The following exit values are returned:

0 Daemon exited cleanly.

95 Daemon exited with a fatal error.

96 Daemon exited with a configuration error.

Attributes See the attributes(5) man page for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/file-system/smb
Interface Stability	Uncommitted

See Also ps(1), svcs(1), share(1M), sharectl(1M), smbadm(1M), smbstat(1M), svcadm(1M), zfs(1M), smb(4), smbautohome(4), system(4), attributes(5), smf(5)

Notes Use the svcadm command to perform administrative actions on the smbd service, such as enabling, disabling, or restarting the service. Use the svcs command to query the service status.

The smbd service is managed by the service management facility under the service identifier svc:/network/smb/server.

If the smbd service is disabled, it will be enabled by the share(1M) command or the zfs set share command, unless its auto_enable property is set to false.

Name smbiod, smbiod-svc – SMB client I/O daemon

Synopsis /usr/lib/smbfs/smbiod

/usr/lib/smbfs/smbiod-svc

Description smbiod and smbiod-svc are internal components of the SMB client. They have no external, customer-accessible interfaces. For more information about the SMB client, see the mount_smbfs(1M) man pages.

smbiod-svc is run by the SMF service, svc:/network/smb/client:default, and starts and manages the smbiod processes that are required by the SMB client.

smbiod is started by smbiod-svc, which runs as a separate process for each user who requests SMB client connections. These smbiod processes continue to run until the owning user no longer has any SMB client connections.

Files /usr/lib/smbfs/smbiod
  SMB I/O daemon.

/usr/lib/smbfs/smbiod-svc
  SMF service program.

/var/run/smbiod/.svc
  File on which smbiod-svc instantiates a door.

/var/run/smbiod/$*UID*
  File on which a user's smbiod process instantiates a door. $*UID* is the numeric representation of the owner's user ID.

Attributes See the attributes(5) man page for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/smb
Interface Stability	Uncommitted

Name smbios – display the contents of a System Management BIOS image

Synopsis `smbios [-BeOsx] [-i` *id*`] [-t` *type*`] [-w` *file*`] [`*file*`]`

Description The `smbios` utility displays the contents of the System Management BIOS (SMBIOS) image exported by the current system or stored in a file. SMBIOS is an industry-standard mechanism for low-level system software to export hardware configuration information to higher-level system management software. The SMBIOS data format itself is defined by the Distributed Management Task Force (DMTF). Refer to http://www.dmtf.org for more information about SMBIOS and to obtain a copy of the SMBIOS specification and implementation guidelines.

The SMBIOS image consists of a table of structures, each describing some aspect of the system software or hardware configuration. By default, `smbios` displays the entire contents of the current SMBIOS image. If the `-s` option is specified, `smbios` displays a summary of the structures that are present in the image. If the `-w` option is specified, `smbios` writes a copy of the SMBIOS image to the specified file. `smbios` can then be applied to the resulting file to display its content.

`smbios` attempts to display each structure and its content in a human- readable fashion. If `smbios` does not recognize a structure's type or content, the raw hexadecimal data for the structure is displayed.

Options The following options are supported:

-B   Disable header validation for broken BIOSes.

          By default, `smbios` attempts to validate the SMBIOS header by verifying the anchor strings, header checksums, and version number. This option might be necessary when a BIOS has a non-compliant header.

-e   Display the contents of the SMBIOS entry point rather than the contents of the SMBIOS structure table.

-i *id*   Display only the specified structure, named by its integer id.

-O   Display obsolete structure types.

          By default, `smbios` elides output for structures whose type is marked as obsolete in the DMTF SMBIOS specification.

-s   Display only a summary listing of the structure identifiers and types, instead of the content of each selected structure.

-t *type* Display only those structures whose type matches the specified integer type, as defined the DMTF SMBIOS specification.

-w *file* Write a copy of the SMBIOS image to the specified file and exit.

The SMBIOS entry point is written to the start of the file with its structure table address set to the file offset of the structure table, and a new entry point checksum is computed.

-x   Display raw hexadecimal data for the selected structures in addition to human-readable output.

By default, hexadecimal data is only displayed if smbios cannot display human-readable output for the selected structures.

Operands The following operands are supported:

file   Specifies an alternate SMBIOS image to display instead of the current system's SMBIOS image.

Exit Status The following exit values are returned:

0   Successful completion. All structures in the SMBIOS image were examined successfully.

1   A fatal error occurred, such as failure to open the specified file or device, or corruption in the image.

2   Invalid command-line options were specified.

Files /dev/smbios   Kernel SMBIOS image device. This device special file is used to export a snapshot of the current system SMBIOS image.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	See below.

The command-line options are Committed. The human-readable output is Uncommitted.

See Also prtdiag(1M), attributes(5), smbios(7D)

System Management BIOS Reference Specification (see http://www.dmtf.org)

Notes The implementation of a System Management BIOS image is entirely at the discretion of the system and BIOS vendors. Not all systems export an SMBIOS. The SMBIOS structure content varies widely between systems and BIOS vendors and frequently does not comply with the guidelines included in the specification. Some structure fields might not be filled in by the BIOS at all, and others might be filled in with non-conforming values.

Name smbstat – show Solaris SMB file server statistics

Synopsis `smbstat [-r [-n [-a | -z]] [-t] [-u] [-c]` *interval*

Description The `smbstat` command shows statistical information for the smbd(1M) server. `smbstat` has a number of options, described below, and a single operand, *interval*. If *interval* is specified, the first display captures statistics since the server started, up to the moment the command was entered. Subsequent displays capture statistics for the last *interval*.

By default, the `smbstat` command shows all statistics.

Options The `smbstat` command includes the following options:

`-c`
　Display counters.

`-r`
　Display the statistics of the requests. You can combine `-r` with the following options.

　`-a`
　　Display statistics for all the types of server requests, whether valid or not. Note that there are 256 types of server requests. The `-a` and `-z` options are mutually exclusive.

　`-n`
　　Display in alphabetic order.

　`-z`
　　Display statistics for requests actually received. The `-a` and `-z` options are mutually exclusive.

`-t`
　Display the throughput of the SMB server.

`-u`
　Display the utilization of the SMB server.

Extended Description The `smbstat` command displays the headings shown below. The headings displayed for a given command vary according to which option(s) are specified. There are four categories of headings, corresponding to categories of statistics: counters, throughput, utilization, and (server) requests.

Counters `nbt`
　Number of SMB NetBIOS-over-TCP (NBT) sessions.

`tcp`
　Number of SMB TCP sessions.

`users`
　Number of users logged in.

`trees`
　Number of trees connected.

files
  Number of open files.

pipes
  Number of open pipes.

Throughput rbytes/s
  Number of bytes received per second.

tbytes/s
  Number of bytes transmitted per second.

reqs/s
  Number of requests handled per second.

reads/s
  Number of read requests per second. This would be an aggregation of the following
  requests: SMB_COM_READ, SMB_COM_LOCK_AND_READ, SMB_COM_READ_RAW, and
  SMB_COM_READ_ANDX.

writes/s
  Number of write requests per second. This would ba an aggregation of the following
  requests: SMB_COM_WRITE, SMB_COM_WRITE_AND_UNLOCK, SMB_COM_WRITE_RAW, and
  SMB_COM_WRITE_AND_CLOSE.

Utilization wcnt
  Average number of requests received but waiting for an SMB worker thread to execute
  them.

rcnt
  Average number of requests being simultaneously executed by an SMB worker thread.

wtime
  Average time a request waits before an SMB worker thread starts executing it.

rtime
  Average execution time of a request.

w%
  Percentage of the time during which at least one request was waiting.

r%
  Percentage of the time during which at least one request was being executed.

u%
  Percentage of utilization of the SMB server. This number is defined as: rcnt /
  (*max_worker_threads*).

sat
  Flag indicating if the server has been saturated in the past. Saturation is defined as: u% ==
  100%.

usr%
> Percentage of the time the processor(s) spent in user space.

sys%
> Percentage of the time the processor(s) spent in kernel space.

idle%
> Percentage of the time the processor(s) was(were) idle.

Requests   The following headings are displayed for each type of request.

code
> Code of the request, in hexadecimal.

%
> Percentage of a given type of request.

count
> Number of requests received.

rbytes/s
> Number of bytes received per second.

tbytes/s
> Number of bytes received per second.

req/s
> Number of requests handled per second.

rt-mean
> Average response time in seconds.

rt-stddev
> Standard deviation of the response time.

Examples   EXAMPLE 1   Combining Options

The following command combines the -c, -t, and -u options.

```
% smbstat -ctu
nbt   tcp users trees files pipes
0     1    1     2     20    0

rbytes/s   tbytes/s    reqs/s      reads/s    writes/s
1.036e+02  1.298e+00   0.000e+00   0.000e+00  0.000e+00

wcnt       rcnt        wtime       rtime        w%   r%   u% sat usr% sys% idle%
4.317e-01  7.410e+00   2.461e-05   4.224e-04    31   100  0  no  0    76   24
```

Exit Status   The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Attributes   See the attributes(5) man page for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/file-system/smb
Interface Stability	Uncommitted
Utility Output Format	Not-an-Interface

Name smrsh – restricted shell for sendmail

Synopsis `smrsh -c` *command*

Description The `smrsh` program is intended as a replacement for the `sh` command in the `prog` mailer in
`sendmail(1M)` configuration files. The `smrsh` program sharply limits commands that can be
run using the `|program` syntax of sendmail. This improves overall system security. `smrsh`
limits the set of programs that a programmer can execute, even if `sendmail` runs a program
without going through an `alias` or `forward` file.

Briefly, `smrsh` limits programs to be in the directory `/var/adm/sm.bin`, allowing system
administrators to choose the set of acceptable commands. It also rejects any commands with
the characters: `,`, `<`, `>`, `|`, `;`, `&`, `$`, `\r` (RETURN), or `\n` (NEWLINE) on the command line to
prevent end run attacks.

Initial pathnames on programs are stripped, so forwarding to `/usr/ucb/vacation`,
`/usr/bin/vacation`, `/home/server/mydir/bin/vacation`, and `vacation` all actually
forward to `/var/adm/sm.bin/vacation`.

System administrators should be conservative about populating `/var/adm/sm.bin`.
Reasonable additions are utilities such as `vacation(1)` and `procmail`. Never include any shell
or shell-like program (for example, `perl`) in the `sm.bin` directory. This does not restrict the
use of `shell` or `perl` scrips in the `sm.bin` directory (using the `#!` syntax); it simply disallows
the execution of arbitrary programs.

Options The following options are supported:

`-c` *command* Where *command* is a valid command, executes *command*.

Files `/var/adm/sm.bin` directory for restricted programs

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also `sendmail(1M)`, , `attributes(5)`

Name smtnrhdb – manage entries in the tnrhdb database

Synopsis `/usr/sadm/bin/smtnrhdb` *subcommand* [*auth_args*] -- *subcommand_args*]

Description The `smtnrhdb` command adds, modifies, deletes, and lists entries in the tnrhdb database.

The `tnrhdb` database specifies which remote-host template to use for each host, including the local host, in the distributed system. If a host's IP address cannot be matched to some entry in the `tnrhdb` database, communication with the host is not permitted.

Valid Host Addresses and Wildcards The trusted network software uses a network "longest prefix of matching bits" mechanism when looking for a host. The software looks first for the IP address of the host. If the software does not find this address, then the software falls back to searching for an IP address with the longest prefix of a matching bit pattern, and so on.

Note – The actual numeric value of the subnet address or other subnetting information on the system (for example, from the netmasks(4) file) are not considered by this mechanism.

Using the "longest prefix of matching bits" mechanism, an IPv4 address of 0.0.0.0 is a wildcard address with a prefix length of 0 and hence matches any IPv4 address. For more information about prefi x lengths in IPv4 and IPv6 addresses, see *Oracle Solaris Administration: IP Services*.

The `smtnrhdb` command accepts a hostname, IP address, and wildcard address with as optional prefix as valid addresses. See *subcommand_args*, below, for the format of valid addresses.

Sub-commands `smtnrhdb` *subcommand*s are:

add
  Adds a new entry to the `tnrhdb` database. To add an entry, the administrator must have the `solaris.network.host.write` and `solaris.network.security.write` authorizations.

delete
  Deletes an entry from the `tnrhdb` database. To delete an entry, the administrator must have the `solaris.network.host.write` and `solaris.network.security.write` authorizations.

list
  Lists all entries in the `tnrhdb` database. To list an entry, the administrator must have the `solaris.network.host.read` and `solaris.network.security.read` authorizations.

modify
  Modifies an entry in the `tnrhdb` database. To modify an entry, the administrator must have the `solaris.network.host.write` and `solaris.network.security.write` authorizations.

Options   The smtnrhdb authentication arguments, *auth_args*, are derived from the smc arg set. These arguments are the same regardless of which subcommand you use.

The subcommand-specific options, *subcommand_args*, must be preceded by the -- option.

auth_args   The valid *auth_args* are -D, -H, -l, -p, -r, and -u; they are all optional. If no *auth_args* are specified, certain defaults will be assumed and the user might be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either -D or --domain.

-D | --domain *domain*
   Specifies the default domain that you want to manage. The syntax of *domain=type*:/*host_name*/*domain_name*, where *type* is dns, ldap, or file; *host_name* is the name of the server; and *domain_name* is the name of the domain you want to manage.

   If you do not specify this option, the system assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

-H | --hostname *host_name:port*
   Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host_name:port*, the system connects to the local host on port 898.

-l | --rolepassword *role_password*
   Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-p | --password *password*
   Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-r | --rolename *role_name*
   Specifies a role name for authentication. If you do not specify this option, no role is assumed.

-u | --username *user_name*
   Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

--
   This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the -- option.

subcommand_args   *Note:* Descriptions and other arg options that contain white spaces must be enclosed in double quotes.

-h

   Displays the command's usage statement.

-H *hostname*

   Specifies the name of the host. For the list subcommand, the hostname argument is not specified. This is not required if the ipaddress subcommand argument is specified.

-i *ipaddress*

   Specifies the IP address of the host. This is not required if the hostname subcommand argument is specified. This option is not valid with the -w option.

-n *templatename*

   Specifies the name of an existing template.

-p *prefixlen*

   Specifies the prefix length (in bits) of a wildcard representation of the IP address. The prefix is the left-most portion of the IP address. This option is valid only with the -w option. For example, when the value of -w *ipaddress-wildcard* is 192.168.0.0, a *prefixlen* value of 24 indicates that the wildcard matches all addresses on the 192.168.0 network. With a *prefixlen* of 32, the wildcard 192.168.0.0 matches all addresses on the 192.168.0.0 network.

-w *ipaddress-wildcard*

   Specifies the IP address of the subnet using a wildcard.

- One of the following sets of arguments must be specified for subcommand add:

   -H *hostname* -n *templatename* |
   -i *ipaddress* -n *templatename* |
   -w *ipaddress-wildcard* -n *templatename* [-p *prefixlen*] |
   -h

- One of the following sets of arguments must be specified for subcommand modify:

   -H *hostname* -n *templatename* |
   -i *ipaddress* -n *templatename* |
   -w *ipaddress-wildcard* -n *templatename* [-p *prefixlen*] |
   -h

- One of the following sets of arguments must be specified for subcommand delete:

   -H *hostname* |
   -i *ipaddress* |
   -w *ipaddress-wildcard* [-p *prefixlen*] |
   -h

- The subcommand list takes the following argument:

   -h

Examples   **EXAMPLE 1**   Specifying the Template Name for a Wildcard IP Address

The admin role specifies the template name, cipso_lan, for a series of hosts that use the IP address wildcard 192.168.113.0 on the local file system. Since no authorization arguments were specified, the administrator connects to port 898 of the local host on the local server with the file domain type, which are the defaults. The administrator is prompted for the admin password.

```
$ usr/sadm/bin/smtnrhdb add -- -w 192.168.113.0 -n cipso_lan
```

EXAMPLE 2   Deleting an Entry in the tnrhdb Database

The admin role connects to port 898 (which happens to be the default) of the LDAP server and deletes a host entry from the database by specifying its IP address, 192.168.113.8. Since the domain was not specified, the file domain type and local server are used by default. The administrator is prompted for the admin password.

```
# /usr/sadm/bin/smtnrhdb delete \
-D ldap:/example.domain -i 192.168.113.8
```

EXAMPLE 3   Adding a Subnet to the tnrhdb Database

The following command adds all the addresses on the 192.168.55.0 subnet, from 192.168.55.1 to 192.168.55.255, to the tnrhdb database:

```
# /usr/sadm/bin/smtnrhdb add \
-D file:/machine1.ExampleCo.COM/machine1.ExampleCo.COM \
 -- -w 192.168.55.0 -n cipso
Authenticating as user: root
Type /? for help, pressing <enter> accepts the default denoted by [ ]
Please enter a string value for: password ::
Loading Tool: com.exampleco.admin.hostmgr.cli.smtnrhdb.HostMgrTnrhdbCli
from machine1.ExampleCo.COM
Login to machine1.ExampleCo.COM as user root was successful.
Download of com.exampleco.admin.hostmgr.cli.smtnrhdb.HostMgrTnrhdbCli
from machine1.ExampleCo.COM
was successful.
```

EXAMPLE 4   Adding Subnet 192.168.0 to the tnrhdb Database

The following command adds all the addresses on the 192.168.0 subnet, from 192.168.0.1 to 192.168.0.255 to the tnrhdb database. The prefix, 24, indicates that the first 24 bits (192.168.0) are fixed. Only the final zero is a wildcard.

```
# /usr/sadm/bin/smtnrhdb add \
-D file:/machine1.ExampleCo.COM/machine1.ExampleCo.COM \
 -- -w 192.168.0.0 -p 24 -n cipso

Login to machine1.ExampleCo.COM as user root was successful.
Download of com.exampleco.admin.hostmgr.cli.smtnrhdb.HostMgrTnrhdbCli
from machine1.ExampleCo.COM was successful.
```

Exit Status The following exit values are returned:

0
  Successful completion.

1
  Invalid command syntax. A usage message displays.

2
  An error occurred while executing the command. An error message displays.

Files The following files are used by the smtnrhdb command:

/etc/security/tsol/tnrhdb
  Trusted network remote-host database.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Interface Stability	Committed

See Also netmasks(4), attributes(5)

Oracle Solaris Administration: Security Services

Notes The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

Name smtnrhtp – manage entries in the trusted network template database

Synopsis `/usr/sadm/bin/smtnrhtp` *subcommand* [*auth_args*] `--` [*subcommand_args*]

Description The `smtnrhtp` command adds, modifies, deletes, and lists entries in the `tnrhtp` database.

smtnrhtp *subcommand*s are:

add   Adds a new entry to the `tnrhtp` database. To add an entry, the administrator must have the `solaris.network.security.read` and `solaris.network.security.write` authorizations.

modify   Modifies an entry in the `tnrhtp` database. To modify an entry, the administrator must have the `solaris.network.security.read` and `solaris.network.security.write` authorizations.

delete   Deletes an entry from `tnrhtp` database. To delete an entry, the administrator must have the `solaris.network.security.read` and `solaris.network.security.write` authorizations.

list   Lists entries in the `tnrhtp` database. To list an entry, the administrator must have the `solaris.network.security.read` authorizations.

Options The subcommand-specific options, *subcommand_args*, must be *preceded* by the `--` option.

auth_args The valid *auth_args* are `-D`, `-H`, `-l`, `-p`, `-r`, and `-u`; they are all optional. If no *auth_args* are specified, certain defaults will be assumed and the user might be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `--domain`.

-D│--domain *domain*
   Specifies the default domain that you want to manage. The syntax of *domain*=*type*:/*host_name*/*domain_name*, where *type* is dns, ldap, or file; *host_name* is the name of the server; and *domain_name* is the name of the domain you want to manage.

   If you do not specify this option, the system assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis; this option specifies the domain for all other tools.

-H│--hostname *host_name:port*
   Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host_name:port*, the system connects to the local host on port 898.

-l | --rolepassword *role_password*

Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-p | --password *password*

Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-r | --rolename *role_name*

Specifies a role name for authentication. If you do not specify this option, no role is assumed.

-u | --username *user_name*

Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

--

This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the -- option.

subcommand_args   Descriptions and other argument options that contain white spaces must be enclosed in double quotes.

-h	Displays the command's usage statement.
-n *templatename*	Specifies the name of the template.
-t *hosttype*	Specifies the host type of the new host. Valid values are unlabeled and cipso. The cipso host type is for hosts that use CIPSO (Common IP Security Options - Tag Type 1 only) to label packets.
-x doi=*doi-value*	Specifies the DOI value (the domain of interpretation). In the case of the unlabeled host type, this is the domain of interpretation for the def_label.
	The domain of interpretation defines the set of rules for translating between the external or internal representation of the security attributes and their network representation. When systems that are configured with Trusted Extensions software have the same doi, they share that set of rules. In the case of the unlabeled host type, these systems also share the same interpretation for the default attributes that are assigned to the unlabeled templates that have that same doi.

-x max=*maximum-label*   Specifies the maximum label. Together with min, this value specifies the label accreditation range for the remote hosts that use this template. Values can be a hex value or string (such as admin_high).

-x min=*minimum-label*   Specifies the minimum label. Together with max, this value specifies the label accreditation range for the remote hosts that use this template. For gateway systems, min and max define the default range for forwarding labeled packets. The label range for routes is typically set by using a route(1M) subcommand with the -secattr option. When the label range for routes is not specified, the min to max range in the security template is used. Values can be a hex value or string (such as admin_low).

-x label=*default-label*   Specifies the default label to be applied to incoming data from remote hosts that do not support these attributes. This option does not apply if *hosttype* is cipso. Values can be a hex value or string (such as admin_low).

-x slset=*l1,l2,l3,l4*   Specifies a set of sensitivity labels. For gateway systems, the labels in slset are used for forwarding labeled packets. slset is optional. You can specify up to four label values, separated by commas. Values can be a hex value or string (such as admin_low).

- One of the following sets of arguments must be specified for subcommand add:

  -n *template name* (

      -t cipso [-x doi=*doi-value* -x min=*minimum-label* -x max=*maximum-label* -x slset=*l1,l2,l3,l4*] |

      -t unlabeled [-x doi=*doi-value* -x min=*minimum-label* -x max=*maximum-label* -x label=*default-label* -x slset=*l1,l2,l3,l4*] |

      -h

)

- One of the following sets of arguments must be specified for subcommand modify:

  -n *template name* (

      -t cipso [-x doi=*doi-value* -x min=*minimum-label* -x max=*maximum-label* -x slset=*l1,l2,l3,l4*] |

      -t unlabeled [-x doi=*doi-value* -x min=*minimum-label* -x max=*maximum-label* -x label=*default-label*-x slset=*l1,l2,l3,l4*] |

      -h

)

If the host type is changed, all options for the new host type must be specified.

- One of the following sets of arguments must be specified for subcommand delete:

  -n *templatename* |
  -h

- The following argument can be specified for subcommand list:

  -n *templatename* |
  -h

Examples EXAMPLE 1 Adding a New Entry to the Network Template Database

The admin role connects to port 898 of the LDAP server and creates the unlabeled_ntk entry in the tnrhtp database. The new template is assigned a host type of unlabeled, a domain of interpretation of 1, minimum label of public, maximum label of restricted, and a default label of needtoknow. The administrator is prompted for the admin password.

```
$ /usr/sadm/bin/smtnrhtp \
add -D ldap:directoryname -H servername:898 -- \
-n unlabeled_ntk -t unlabeled -x DOI=1 \
-x min=public -x max=restricted -x label="need to know"
```

Exit Status The following exit values are returned:

0 Successful completion.

1 Invalid command syntax. A usage message displays.

2 An error occurred while executing the command. An error message displays.

Files The following files are used by the smtnrhtp command:

/etc/security/tsol/tnrhtp Trusted network remote-host templates.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

Interface Stability	Committed

See Also attributes(5)

Notes The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

Warnings Changing a template while the network is up can change the security view of an undetermined number of hosts.

Allowing unlabeled hosts onto a Solaris Trusted Extensions network is a security risk. To avoid compromising the rest of your network, such hosts must be *trusted* in the sense that the administrator is certain that these unlabeled hosts will not be used to compromise the distributed system. These hosts should also be physically protected to restrict access to authorized individuals. If you cannot guarantee that an unlabeled host is physically secure from tampering, it and similar hosts should be isolated on a separate branch of the network.

If the security template is modified while the network is up, the changes do not take effect immediately unless tnctl(1M) is used to update the template entries. Otherwise, the changes take effect when next polled by the trusted network daemon, tnd(1M). Administrators are allowed to add new templates and modify attributes of existing templates while the network is up.

Name smtnzonecfg – manage entries in the zone configuration database for Trusted Extensions networking

Synopsis `/usr/sadm/bin/smtnzonecfg` *subcommand* [*auth_args*] `--` [*subcommand_args*]

Description The `smtnzonecfg` command adds, modifies, deletes, and lists entries in the `tnzonecfg` database.

smtnzonecfg *subcommand*s are:

add Adds a new entry to the `tnzonecfg` database. To add an entry, the administrator must have the `solaris.network.host.write` and `solaris.network.security.write` authorizations.

modify Modifies an entry in the `tnzonecfg` database. To modify an entry, the administrator must have the `solaris.network.host.write` and `solaris.network.security.write` authorizations.

delete Deletes an entry from the `tnzonecfg` database. To delete an entry, the administrator must have the `solaris.network.host.write` and `solaris.network.security.write` authorizations.

list Lists entries in the `tnzonecfg` database. To list an entry, the administrator must have the `solaris.network.host.read` and `solaris.network.security.read` authorizations.

Options The `smtnzonecfg` authentication arguments, *auth_args*, are derived from the `smc` argument set and are the same regardless of which subcommand you use.

The subcommand-specific options, *subcommand_args*, must be *preceded* by the `--` option.

auth_args The valid *auth_args* are `-D`, `-H`, `-l`, `-p`, `-r`, and `-u`; they are all optional. If no *auth_args* are specified, certain defaults will be assumed and the user can be prompted for additional information, such as a password for authentication purposes. These letter options can also be specified by their equivalent option words preceded by a double dash. For example, you can use either `-D` or `--domain`.

`-D | --domain` *domain*
   Specifies the default domain that you want to manage. The syntax of *domain*=*type*:/*host_name*/*domain_name*, where *type* is dns, ldap, or file; *host_name* is the name of the server; and *domain_name* is the name of the domain you want to manage.

   If you do not specify this option, the system assumes the file default domain on whatever server you choose to manage, meaning that changes are local to the server. Toolboxes can change the domain on a tool-by-tool basis. This option specifies the domain for all other tools.

-H | --hostname *host_name:port*
> Specifies the *host_name* and *port* to which you want to connect. If you do not specify a *port*, the system connects to the default port, 898. If you do not specify *host_name:port*, the system connects to the local host on port 898.

-l | --rolepassword *role_password*
> Specifies the password for the *role_name*. If you specify a *role_name* but do not specify a *role_password*, the system prompts you to supply a *role_password*. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-p | --password *password*
> Specifies the password for the *user_name*. If you do not specify a password, the system prompts you for one. Passwords specified on the command line can be seen by any user on the system, hence this option is considered insecure.

-r | --rolename *role_name*
> Specifies a role name for authentication. If you do not specify this option, no role is assumed.

-u | --username *user_name*
> Specifies the user name for authentication. If you do not specify this option, the user identity running the console process is assumed.

--
> This option is required and must always follow the preceding options. If you do not enter the preceding options, you must still enter the -- option.

subcommand_args Descriptions and other argument options that contain white spaces must be enclosed in double quotes.

-h
> Displays the command's usage statement.

-n *zonename*
> Specifies the zone name for the entry. This name is used when the zone is configured. See zonecfg(1M), under the -z zonename option, for the constraints on zone names. The specified zone name must be one of the configured zones on the system. The following command returns a list of configured zones:
>
> /usr/sbin/zoneadm list -c

-l *label*
> Specifies the label for the zone. This field is used to label the zone when the zone is booted. Each zone must have a unique label.

-x policymatch=0|1
> Specifies the policy match level for non-transport traffic. Only values of 0 (match the label) or 1 (be within the label range of the zone) are accepted.

ICMP packets that are received on the global zone IP address are accepted based on the label range of the global zone's security template if the global zone's *policymatch* field is set to 1. When this field is set to 0 for a zone, the zone will not respond to an ICMP echo request from a host with a different label.

This subcommand argument is optional. If not specified, it will have a default value of 0.

-x mlpzone=""|*port/protocol*
Specifies the multilevel port configuration entry for zone-specific IP addresses. Multiple *port/protocol* combinations are separated by a semi-colon. The empty string can be specified to remove all existing MLP zone values. This subcommand argument is optional.

An MLP is used to provide multilevel service in the global zone as well as in non-global zones. As an example of how a non-global zone can use an MLP, consider setting up two labeled zones, internal and public. The internal zone can access company networks; the public zone can access public internet but not the company's internal networks. For safe browsing, when a user in the internal zone wants to browse the Internet, the internal zone browser forwards the URL to the public zone, and the web content is then displayed in a public zone web browser. That way, if the download in public zone compromises the web browser, it cannot affect the company's internal network. To set this up, TCP port 8080 in the public zone is an MLP (8080/tcp), and the security template for the public zone has a label range from PUBLIC to INTERNAL.

-x mlpshared=""|*port/protocol*
Specifies the multilevel port configuration entry for shared IP addresses. Multiple *port/protocol* combinations are separated by a semi-colon. The empty string can be specified to remove all existing MLP shared values. This subcommand argument is optional.

A shared IP address can reduce the total number of IP addresses that are needed on the system, especially when configuring a large number of zones. Unlike the case of the zone-specific IP address, when MLPs are declared on shared IP addresses, only the global zone can receive the incoming network traffic that is destined for the MLP.

- One of the following sets of arguments must be specified for subcommand add:

  ```
  -n zonename -l label [-x policymatch=policy-match-level \
  -x mlpzone=port/protocol;.... | \
  -x mlpshared=port/protocol;.... ]
  -h
  ```

- One of the following sets of arguments must be specified for subcommand modify:

  ```
  -n zonename [-l label] [-x policymatch=policy-match-level \
  -x mlpzone=port/protocol;.... |\
  -x mlpshared=port/protocol;.... ]
  -h
  ```

- One of the following arguments must be specified for subcommand delete:

```
                    -n zonename |
                    -h
```

- The following argument can be specified for subcommand list:

```
                    -n zonename |
                    -h
```

Examples   EXAMPLE 1   Adding a New Entry to the Zone Configuration Database

The admin role creates a new zone entry, public, with a label of public, a policy match level of 1, and a shared MLP port and protocol of 666 and TCP. The administrator is prompted for the admin password.

```
$ /usr/sadm/bin/smtnzonecfg add -- -n public -l public \
-x policymatch=1 -x mlpshared=666/tcp
```

EXAMPLE 2   Modifying an Entry in the Zone Configuration Database

The admin role changes the public entry in the tnzonecfg database to needtoknow. The administrator is prompted for the admin password.

```
$ /usr/sadm/bin/smtnzonecfg modify -- -n public -l needtoknow
```

EXAMPLE 3   Listing the Zone Configuration Database

The admin role lists the entries in the tnzonecfg database. The administrator is prompted for the admin password.

```
$ /usr/sadm/bin/smtnzonecfg list --
```

Exit Status   The following exit values are returned:

0   Successful completion.

1   Invalid command syntax. A usage message displays.

2   An error occurred while executing the command. An error message displays.

Files   The following files are used by the smtnzonecfg command:

/etc/security/tsol/tnzonecfg   Trusted zone configuration database.

Notes The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

Name smtp-notify – email notification daemon for software events

Synopsis /usr/lib/fm/notify/smtp-notify

Description smtp-notify is a daemon that subscribes to software events and Fault Management lifecycle events and produces email notifications based on a set of notification preferences that are stored in the SMF service configuration repository.

Email notification preferences are set using svccfg(1M).

smtp-notify is managed by the service management facility, smf(5), under the service FMRI:

svc:/system/fm/smtp-notify:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Properties The following service properties can be set:

config/rootdir
 This is an astring property that defaults to /. When set, the specified root directory will be used for all pathnames evaluated by smtp-notify.

By default, the body of the email event notification will be based on a set of localized message templates that are delivered with the Oracle Solaris operating system. smtp-notify will lookup the appropriate template (based on the event class) and fill in the template using elements from the event payload.

A user-supplied message body template can be substituted by specifying the msg_template notification preference. Refer to svccfg(1M) for more information about setting notification preferences on a per-service or per-event-class basis.

The message body template can contain the expansion macros listed below. These macros will be expanded by smtp-notify before sending the message.

```
Macro         Description
-----         -----------
%%            expands to a literal % character
%<HOSTNAME>   expands to the hostname on which the event
              occurred
%<URL>        expands to the URL of the knowledge article
              associated with this event
%<CLASS>      expands to the event class
%<UUID>       expands to the UUID of the event
%<CODE>       expands to the knowledge article message ID
%<SEVERITY>   expands to the severity of the event
```

For SMF service state transition events, the following additional macros can be specified in a message template:

```
%<FMRI>          expands to FMRI of the affected service
%<FROM-STATE>    expands to the previous state of the service
%<TO-STATE>      expands to the new state of the service
```

To facilitate email filtering, smtp-notify will create X-headers for the following components of the event payload for all event classes:

```
Header name            Value
-----------            -----
X-FMEV-HOSTNAME        the name of the host on which the
                       event occurred
X-FMEV-CLASS           the event class
X-FMEV-CODE            the Knowledge article message ID
X-FMEV-SEVERITY        the severity of the event
X-FMEV-UUID            the UUID of the event
```

SMF service state transition events will also include the following additional X-headers:

```
Header name            Value
-----------            -----
X-FMEV-FMRI            the FMRI of the affected SMF service
X-FMEV-FROM-STATE      the previous state of the service
X-FMEV-TO-STATE        the new state of the service
```

Examples EXAMPLE 1 Configuring Notification Preferences

The following command configures notification preferences for SMF service state transition events.

```
# svccfg -s svc:/system/svc/global:default setnotify -g \
from-online,to-maintenance mailto:admin@somehost.com
```

EXAMPLE 2 Enabling Email Notifications

The following command enables email notifications for Fault Management problem diagnosis events.

```
# svccfg setnotify problem-diagnosed mailto:admin@somehost.com
```

EXAMPLE 3 Listing Notification Settings

The following command lists all notification settings for Fault Management problem diagnosis events.

```
# svccfg listnotify problem-diagnosed
```

```

Description   The /usr/sbin/sndradm command is the administrative command line interface for the Sun StorageTek Availability Suite Remote Mirror software. Remote Mirror enables you to replicate disks between different physically-separate Sun servers in real time. Remote Mirror is conceptually similar to the local disk mirroring scheme of RAID 1 but it performs its replication operations over longer distances.

If you do not specify a Remote Mirror set (*sndr_set*) on the command line, sndradm operates on all configured Remote Mirror sets.

The sndradm command generates an entry in the Availability Suite log file, /var/adm/ds.log (see ds.log(4)), for all operations except print (-p, -P and -i), help (-h), and version (-v).

Options   The sndradm utility supports the following options:

-f *volset-file*
  Specifies a file containing the *sndr_set* information for one or more Remote Mirror sets in the same format as the fully specified command line *sndr_set* documented below.

-g *io_groupname*
  Limits operations to only those Remote Mirror sets belonging to *io_groupname*.

  The *io_groupname* for a given set must be consistent across both the primary and the secondary hosts.

-C *tag*
  On a clustered node, limits operations to only those Remote Mirror sets belonging to the cluster resource group or disk group name specified by *tag*. This option is not valid on a system that is not clustered.

-n
  Does not prompt the user after starting a Remote Mirror operation using sndradm. For all but the printing, help, and version options, the default behavior is to prompt for a response. For example, after starting a full synchronization from the primary to the secondary volume, Remote Mirror prompts: "Overwrite secondary with primary? (Y/N) [N]".

sndr_set
  Specifies the Remote Mirror set. For a set that has already been enabled, this can be a set_name in the format *shost*:*sdev*. You can supply a fully specified Remote Mirror set in the same format as a configuration file:

  phost pdev pbitmap shost sdev sbitmap ip {sync | async} \
  [g *io_groupname*] [C *tag*]

These parameters are described as follows:

phost

 Specifies the server on which the primary volume resides.

pdev

 Specifies the primary volume partition to be replicated. Specify full pathnames only (for example, `/dev/rdsk/c0t1d0s2`).

pbitmap

 Specifies the volume partition on which the bitmap (scoreboard log) of the primary partition is stored. Specify full pathnames only (for example, `/dev/rdsk/c0t1d0s3`).

shost

 Specifies the server on which the secondary volume resides.

sdev

 Specifies the secondary volume partition. Specify full path names only (for example, `/dev/rdsk/c0t1d0s4`).

sbitmap

 Specifies the volume partition on which the bitmap (scoreboard log) of the secondary partition is stored. Specify full path names only (for example, `/dev/rdsk/c0t1d0s5`).

`ip`

 Specifies the network transfer protocol.

`sync | async`

 Specifies the Remote Mirror operating mode. `sync` is the Remote Mirror mode where the I/O operation is not confirmed as complete until the remote volume has been updated. `async` is the Remote Mirror mode where the primary host I/O operation is confirmed as complete before updating the remote volume.

io_groupname

 Specifies the name of the Remote Mirror consistency group to which the Remote Mirror set belongs. In asynchronous mode, write ordering must be preserved across all replicating volumes in a Remote Mirror consistency group. This ensures that the secondary volumes belonging to the group contains a valid point-in-time copy of the corresponding primary volumes.

 When adding an existing set to a consistency group or when enabling a set to be in a group, the set must be configured with the same group name on both the primary and the secondary hosts.

tag

 For operation within a cluster, this specifies the disk group name or resource tag of the local data and bitmap volumes in cases where this is not implied by the name of the volume (for example, `/dev/rdsk/md/dg/vol` and `/dev/vx/rdsk/dg/vol` both indicate a disk group name of `dg`). It is the responsibility of the user to ensure that the cluster tag specified to the Remote Mirror matches the appropriate cluster resource group tag, and

to keep all the Availability Suite services up to date in the event of cluster resource group reconfigurations. It is illegal to specify the cluster resource tag on a system that is not clustered.

Parameters   A valid sndradm command must specify one of the parameters listed below.

-I a *master shadow bitmap*
  Add an ndr_ii entry with the specified master, shadow, and bitmap to the Availability Suite configuration file. See sndrsyncd(1M). If the corresponding Point-in-Time Copy set does not exist, it is enabled when the next sync command is issued on the related volume(s). When no longer required, this Point-in-Time Copy set can be disabled by iiadm -d. See iiadm(1M)

-I d *master shadow bitmap*
  Delete the ndr_ii entry with the specified master, shadow, and bitmap from the Availability Suite configuration file. Use the dscfg command to list ndr_ii configuration entries.

-a *value*
  Specifies the value, on or off, of the automatic sync variable for the set. Once autosync has been requested for a set, the functionality is active from the time a sync operation is requested until the set is manually put into logging mode. Once the set is manually put into logging mode, the autosync functionality is not active and remains inactive until the next time a sync request is made. To check whether autosync is active, use sndradm -P. To check whether autosync has been requested for a set, look for the"auto=on;" tag for the set in the output of dscfg -l. See sndrsyncd(1M).

-A *value*
  Specifies the maximum number of threads that can be created to process the asynchronous queue when a set is replicating in asynchronous mode. The default is 2.

-W *value*
  Specifies the maximum number of writes that can be queued to a set replicating in asynchronous mode. The default is 4096. For example, set this value to 1 to ensure that the secondary volume is never more than one write operation behind the primary volume.

  Tuning the maximum number of writes is only valid for sets using memory-based async I/O queues. This value is ignored when disk based I/O queues are used.

-D {block | noblock}
  Toggles the block|noblock attribute of a disk-based queue. The default setting is block. If the I/O fill rate is larger than the drain rate for enough time for the queue to fill, incoming I/O is blocked until there is adequate space on the queue for it. This is to preserve write ordering whether it is one volume or across many volumes in the same consistency group. If noblock is set, and incoming I/O fills the queue, the I/O is not blocked. Instead, the set is put into logging and the disk queue contents are disregarded. An ensuing update sync synchronizes the latest data to the secondary site.

-F *value*

Specifies the maximum number of 512–byte FBAs that can be queued in kernel memory to a set replicating in asynchronous mode. The default is 16384.

Tuning the maximum number of FBAs is valid only for sets using memory–based async I/O queues. This value isignored when disk-based I/O queues are used.

-h

Prints the sndradm usage summary.

-v

Prints the Remote Mirror version number.

-e

Enables Remote Mirror for the set and enables scoreboard logging. The scoreboard is set to indicate that a full synchronization is required. Details of the set are saved in the current configuration. See dscfg(1M). The local volume and the bitmap volume are enabled for the Storage Volume driver (see sv(7D)).

-E

Enables Remote Mirror for the set and enables scoreboard logging. The scoreboard is cleared to indicate that the primary and secondary volumes are already guaranteed to be fully synchronized. Details of the set are saved in the current configuration. See dscfg(1M). The local volume and the bitmap volume are enabled for the Storage Volume driver (see sv(7D)).

-d

Disables Remote Mirror for the set and halts any current synchronization operations. sndradm -d also discards any active scoreboards that track temporary differences between primary and secondary volumes.

-l

Stops Remote Mirror replication and copy operations between primary and secondary volumes and starts independent Remote Mirror scoreboard logging on these volumes. When all the sets in a consistency group are replicating, it means that the secondary volumes contain a valid point-in-time copy of the corresponding primary volumes. Under this condition, as soon as one Remote Mirror set drops into logging mode, the rdc kernel module drops all the other sets in the group into logging mode automatically. This ensures that the secondary volumes still contains a valid point-in-time copy. To resume the Remote Mirror after using the -l parameter, use the -m parameter to perform a full resynchronization or the -u parameter to perform an update resynchronization (based on the scoreboard).

This option does not work on the secondary for any volumes that are currently synchronizing.

-w

Waits for a synchronization copy to complete or abort, or returns immediately if invoked on the secondary system.

-H

    Reports on the health of the network link used by the specified volume set. The health of the link is reported as active or inactive. Active means that the network link is actively being used for replicating or resynchronizing data, and is therefore in good health. Inactive means that the network link is not actively being used for replicating or resynchronizing data, which might indicate a problem with the link.

-p

    Displays a list of configured Remote Mirror volumes or sets.

-P

    Displays a list of configured Remote Mirror volumes or sets with extra details. (See state descriptions, below.)

-q a *volume*

    Add a disk queue to a set or group. This operation is valid when the set or group is in logging mode.

-q d

    Remove a disk queue from a set or group. This operation is valid when the set or group is in logging mode.

-q r *volume*

    Replace a disk queue for a group or set. The queue is removed from the set or group as in the queue-disable operation and the new disk queue is added as in the queue-add operation. This operation is valid when the set or group is in logging mode.

-i

    Displays a list of configured Remote Mirror volumes or sets in the same format as the *volset-file*.

-R

    Attempt to reset a Remote Mirror set's error condition such as failed bitmaps.

-R b p *bitmap*

    Reconfigure a Remote Mirror set's primary bitmap. This command should be entered on both primary and secondary servers. It is only possible to reconfigure the primary bitmap for one set at a time.

-R b s *bitmap*

    Reconfigure a Remote Mirror set's secondary bitmap. This command should be entered on both primary and secondary servers. It is only possible to reconfigure the secondary bitmap for one set at a time.

-R C *tag*

    Reconfigure the cluster tag, or disk group name, of a Remote Mirror set's local volumes, in those cases where this is not indicated by the pathname. This does not affect the remote volumes. This parameter cannot be used on a system that is not clustered.

-R m {sync | async}
  Reconfigure the replication mode of a Remote Mirror set. The sets belonging to a consistency group must be either all synchronous or all asynchronous. It is not possible to mix modes within a group.

-R g *group*
  Reconfigure the consistency group of a Remote Mirror set. This command should be entered with the same group name on both primary and secondary servers.

  To remove a set from a consistency group, specify the null string (" ") when reconfiguring the consistency group.

The following parameters can be issued only from the primary server:

-m
  Starts a full volume copy from the primary volume to the secondary volume, and concurrently enables Remote Mirror replication of new updates from the primary volume to the secondary volume. Use this parameter when the primary and secondary volumes might be different and no logging information exists to incrementally resynchronize the volumes. See EXIT STATUS.

-r
  Reverses the direction of the synchronization so the primary volume is synchronized from the secondary volume. Use this parameter with the -m or -u parameter. -m -r starts a full volume copy from the secondary (source) volume to the primary (target) volume but concurrently enables Remote Mirror replication of new updates from the primary (source) volume to the secondary (target) volume, ensuring the volume sets remain synchronized. Use -m -r when the primary and secondary volume content might differ and the secondary has the desired contents, yet no logging information exists to incrementally resynchronize the volumes (using -u). -u -r resynchronizes the primary (target) volume from the secondary (source) volume, using the Remote Mirror scoreboard logs maintained while replication was suspended. It then resumes Remote Mirror replication of new updates from the primary volume to the secondary volume so that the volume sets remain synchronized. Quiesce the workload to the volume sets during the restore/refresh operation. This action ensures that the primary and secondary volumes match before replication of new updates resumes.

-u
  Updates a Remote Mirror volume set. This parameter resynchronizes a Remote Mirror volume set. Only the blocks logged as changed in the Remote Mirror scoreboards are updated. Enables Remote Mirror replication for the primary volume and also uses the Remote Mirror scoreboard logs to start the resynchronization process so that the corresponding secondary volume matches the primary volume.

States Returned from sndradm -P
The following are the states that can be returned from sndradm -P.

volume failed
  An I/O operation to the local data volume has failed

bitmap failed
>   An I/O operation to the local bitmap volume has failed

disk queue failed
>   An I/O operation to disk queue volume has failed

need sync
>   A sync to this volume has been interrupted. It needs to be completed (or restored via
>   Point-in-Time Copy). The direction of the data flow must not be changed until one or the
>   other is done.

need reverse sync
>   A reverse sync to this volume has been interrupted. It needs to be completed (or restored
>   via Point-in-Time Copy). The direction of the data flow must not be changed until one or
>   the other is done.

logging
>   Incoming writes are logged in the bitmap only. Data is not replicated to the remote site.
>   need sync, need reverse sync, and queuing are all substates of logging such that writes
>   are logged in the bitmap, but not replicated. Queuing mode (described below) logs the
>   writes to the bitmap, and queues the request for later replication by the async flushers.

reverse syncing
>   A secondary to primary copy is in progress.

syncing
>   A primary to secondary copy is in progress.

queuing
>   During normal async replication using disk queues, i/o is placed on the disk queue to be
>   replicated by the async flusher threads. In the event of a temporary link failure, the set
>   transitions to queuing mode. The queue is not discarded, as it would be with memory based
>   queues. Instead, data is logged in the bitmap and placed on the queue. When the link comes
>   up, and sndradm -u is issued, (automated by turning autosync on for the set) the flushers
>   restarts. This preserves write ordering through a temporary link outage. If write ordering is
>   not necessary, and only the latest data is needed, the set can be put into logging manually
>   (sndradm -l) and an update sync issued (sndradm -u). This action discards the data on the
>   queue, and fast resyncs using the bitmap. If the queue fills before the link comes back and
>   the update sync is issued, the queue is discarded and the set put into logging mode to avoid
>   application hangs.

Examples

EXAMPLE 1   Enabling a Remote Mirror Set

The following command enables a Remote Mirror asynchronous set on host example, where
example is the primary host and example-remote is the secondary host.

```
example% sndradm -e example /dev/rdsk/c1t0d0s1 /dev/rdsk/c1t1d0s3 \
example-remote /dev/rdsk/c2t3d0s5 /dev/rdsk/c2t4d0s5 ip async
```

EXAMPLE 2   Adding a Disk Queue to an Asynchronous Set

The following command adds a disk queue volume to an asynchronous set.

```
example% sndradm -q a /dev/rdsk/c1t2d0s3 \
example-remote:/dev/rdsk/c2t3d0s5
```

EXAMPLE 3   Removing a Disk Queue from an Asynchronous Set

The following command removes the disk queue volume from a set with a disk queue volume attatched to it.

```
example% sndradm -q d example-remote:/dev/rdsk/c2t3d0s5
```

EXAMPLE 4   Disabling a Remote Mirror Set

The following command disables a Remote Mirror set enabled on host example.

```
example% sndradm -d example-remote:/dev/rdsk/c2t3d0s5
```

Exit Status   0   Command completed successfully.

>0   An error occurred.

When the -m or -u option is executed in a script, the exit status following one of these options always returns success, regardless of the current status of the Remote Mirror set.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/avs/avs-remote-mirror
Interface Stability	Committed

See Also   dscfg(1M), sndrd(1M), sndrsyncd(1M), ds.log(4), rdc.cf(4), attributes(5), sv(7D)

Name sndrd – Remote Mirror daemon

Synopsis /usr/lib/sndrd [-c *max_connections*] [-l *listen_backlog*]

Description The sndrd daemon processes client Remote Mirror requests. Only the root user or a user with equivalent privileges can run this daemon. The daemon is automatically invoked in run level 2. sndrd restarts the TCP transport layers.

Administrators wanting to change startup parameters for sndrd should, as root or equivalent, make changes in the /etc/default/sndr file rather than editing the /lib/svc/method/svc-rdcsyncd file. See sndr(4).

Options The sndrd daemon supports the following options:

-c *max_connections*
   Sets the maximum number of connections allowed to the server over connection-oriented transports. By default, the number of connections is 16.

-l *listen_backlog*
   Sets connection queue length for the RDC TCP over a connection-oriented transport. The default value is 10 entries.

Exit Status 0   Daemon started successfully.

>0   Daemon failed to start.

Error information is reported to syslog at level LOG_ERR.

Files /lib/svc/method/svc-rdcsyncd
   Shell script for starting sndrd.

/lib/svc/method/svc-rdc
   Shell script for stopping sndrd.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/avs/avs-remote-mirror
Interface Stability	Committed

See Also svcadm(1M), syslogd(1M), ds.log(4), attributes(5)

Notes Do not manually stop the sndrd daemon. If you need to manually stop sndrd perform these steps. This stops both the sndrd and sndrsyncd daemons.

```
# svcadm disable svc:/system/nws_rdc

# svcadm disable svc:/system/nws_rdcsyncd
```

Do not manually start or restart the sndrd daemon. If you need to manually start sndrd perform these steps. This starts both the sndrd and sndrsyncd daemons.

svcadm enable svc:/system/nws_rdc

svcadm enable svc:/system/nws_rdcsyncd

See svcadm(1M) for additional information.

Name sndrsyncd – Availability Suite Remote Mirror update resynchronization daemon

Synopsis /usr/lib/sndrsyncd

Description The sndrsyncd daemon automates update resynchronization after a network or machine failure and invokes Point-in-Time Copy copies when needed to protect the data volumes being updated during a resynchronization.

The daemon is notified by the kernel when a network link being used by Remote Mirror goes down and invokes the sndradm(1M) command with the -u option to resynchronize all Remote Mirror sets which have autosync switched on and are using the network link. See sndradm(1M) for details on how to configure autosync for a Remote Mirror set.

The daemon is also notified when any Remote Mirror resynchronization starts or completes. The daemon takes Point-in-Time Copy snapshots, if configured in the Availability Suite configuration file. On a secondary server, the daemon checks if a file system is currently mounted on the secondary volume and informs the kernel not to allow the synchronization to start if the file system is currently mounted.

Exit Status 0   Daemon started successfully.

>0   Daemon failed to start.

Files /lib/svc/method/svc-rdcsyncd
Shell script for starting sndrsyncd.

/lib/svc/method/svc-rdc
Shell script for stopping sndrsyncd.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	storage/avs/avs-remote-mirror
Interface Stability	Committed

See Also iiadm(1M), sndradm(1M), sndrd(1M), svcadm(1M), ds.log(4), rdc.cf(4), attributes(5)

Notes Do not manually stop the sndrsyncd daemon. If you need to manually stop sndrsyncd perform these steps. This stops both the sndrd and sndrsyncd daemons.

    # svcadm disable svc:/system/nws_rdc

    # svcadm disable svc:/system/nws_rdcsyncd

Do not manually start or restart the sndrsyncd daemon. If you need to manually start sndrsyncd perform these steps. This starts both the sndrd and sndrsyncd daemons.

    # svcadm enable svc:/system/nws_rdc

    # svcadm enable svc:/system/nws_rdcsyncd

See svcadm(1M) for additional information.

Name snmpdx – Sun Solstice Enterprise Master Agent

Synopsis /usr/lib/snmp/snmpdx [-hy] [-a *filename*] [-c *config-dir*]
        [-d *debug-level*] [-i *filename*] [-m GROUP -m SPLIT]
        [-o *filename*] [-p *port*] [-r *filename*]

Description The Master Agent, snmpdx, is the main component of Solstice Enterprise Agent (SEA) technology. It runs as a daemon process and listens to User Datagram Protocol (UDP) port 161 for SNMP requests. The Master Agent also opens another port to receive SNMP trap notifications from various subagents. These traps are forwarded to various managers, as determined by the configuration file.

Upon invocation, snmpdx reads its various configuration files and takes appropriate actions by activating subagents, determining the subtree Object Identifier (OID) for various subagents, populating its own Management Information Bases (MIBs), and so forth. The Master Agent invokes subagents, registers subagents, sends requests to subagents, receives responses from subagents, and traps notifications from subagents.

The Master Agent is invoked by the service management facility smf(5) at boot time if svc:/application/management/snmpdx is enabled (see NOTES) and contents of the resource configuration file /etc/snmp/conf/snmpdx.rsrc are non-trivial.

Note – The SMA (Systems Management Agent) is the default SNMP agent in the Solaris operating system. snmpdx is Obsolete and may not be supported in a future release of Solaris.

Options The following options are supported:

-a*filename*	Specify the full path of the access control file used by the Master Agent. The default access control file is /etc/snmp/conf/snmpdx.acl.
-c*config-dir*	Specify the full path of the directory containing the Master Agent configuration files. The default directory is /etc/snmp/conf.
-d*debug-level*	Debug. Levels from 0 to 4 are supported, giving various levels of debug information. The default is 0 which means no debug information is given.
-h	Help. Print the command line usage.
-i*filename*	Specify the full path of the enterprise-name OID map. This file contains the PID used by the Master Agent for recovery after a crash. It contains tuples of the UNIX process ID, port number, resource name, and agent name. The default file is /var/snmp/snmpdx.st.
-m GROUP | -m SPLIT	Specify the mode to use for forwarding of SNMP requests.
	GROUP Multiple variables can be included in each request from the Master Agent to the subagents. This results in, at mose, one send-request per agent.

	SPLIT	Each variable in the incoming request results in one send-request to each subagent.

The default is GROUP.

-o*filename*	Specify the full path of the file containing the tuple (enterprise-name, OID). For example, (Sun Microsystems, 1.3.1.6.1.4.32). The Master Agent uses this file as a base for look-up in the trap-filtering and forwarding process. The default file is /etc/snmp/conf/enterprises.oid.
-p*port*	Specify the port number. The default port number is 161.
-r*filename*	Specify the full path of the resource file to be used by the Master Agent. This file stores information about the subagents that the Master Agent invokes and manages. The default resource file is /etc/snmp/conf/snmpdx.rsrc.
-y	Set a recovery indicator to invoke the recovery module. The recovery process discovers which subagents in the previous session are still active; those subagents not active are re-spawned by the Master Agent.

Files

/etc/snmp/conf/enterprises.oid	Enterprise-name OID map
/etc/snmp/conf/snmpdx.acl	Access control file
/etc/snmp/conf/snmpdx.rsrc	Resource configuration file
/var/snmp/snmpdx.st	Master Agent status file
/var/snmp/mib/snmpdx.mib	Master Agent MIB file

Exit Status The following error values are returned:

0	Successful completion.
non-zero	An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/management/snmp/sea
Interface Stability	Obsolete

See Also attributes(5), smf(5)

Notes   The snmpdx service is managed by the service management facility, smf(5), under the service identifier:

svc:/application/management/snmpdx

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name snmp-notify – SNMP notification daemon for software events

Synopsis `/usr/lib/fm/notify/snmp-notify`

Description `snmp-notify` is a daemon that subscribes to software events and FMA diagnosis and repair events and generates SNMP trap notifications based on a set of notification preferences that are stored in the SMF service configuration repository.

SNMP notification preferences are set using `svccfg(1M)`.

`snmp-notify` is managed by the service management facility, `smf(5)`, under the service FMRI:

`svc:/system/fm/snmp-notify:default`

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using `svcadm(1M)`. The service's status can be queried using the `svcs(1)` command.

Properties The following service properties can be set:

`config/rootdir`
This is an `astring` property that defaults to `/`. When set, the specified root directory will be used for all pathnames evaluated by `snmp-notify`.

Examples EXAMPLE 1 Configuring Notification Preferences

The following command configures notification preferences for SMF service state transition events.

svccfg setnotify -g from-online,to-maintenance snmp:active

EXAMPLE 2 Enabling SNMP Notifications

The following command enables notifications for Fault Management diagnosis events.

svccfg setnotify problem-diagnosed snmp:active

EXAMPLE 3 Listing Notification Settings

The following command lists all notification settings for Fault Management diagnosis events.

svccfg listnotify fma-diagnosis

Refer to `svccfg(1M)` for more information on configuring SNMP notification preferences.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/fault-management/snmp-notify
Interface Stability	Unstable

See Also   svcs(1), svcadm(1M), svccfg(1M), syslogd(1M), attributes(5), smf(5)

Name snmpXwbemd – SNMP Adapter Subagent for WBEM

Synopsis `/usr/sadm/lib/wbem/snmpXwbemd [-d] [-h] [-p port]`

Description The snmpXwbemd daemon is a subagent in the Web-Based Enterprise Management (WBEM) services package.

This daemon maps the Simple Network Management Protocol (SNMP) requests forwarded by the Solstice Enterprise Agents (SEA) Master Agent snmpdx(1M) into one or more equivalent WBEM Common Information Model (CIM) properties and instances. Further, it remaps the response from the CIM Object Manager into a SNMP response, which it passes back to snmpdx(1M).

A mapping file contains the corresponding Object Identifier (OID), class name, property name, and Abstract Syntax Notation 1 (ASN.1) type for each object. You can also create your own mapping file.

Options The following options are supported:

-d   Displays all debug information.

-h   Displays help by printing the correct command line usage.

-p   Specifies the port number to use.

Operands The following operand is supported:

port   Specifies the port number you want to use.

Examples EXAMPLE 1 An Example of a `050SUNWwbcou.map` File

This mapping file that Sun Microsystems provides contains definitions of objects, in this format:

```
#
#pragma ident    "@(#)050SUNWwbcou.map    1.0    01/04/03 SMI"
#
# Copyright (c) 2001 by Sun Microsystems, Inc.
# All rights reserved.
#
# *** Description of contents ***
#
# First non-commented non-blank line contains required Version label.
# Remaining non-commented non-blank lines are considered map entries
# used as described below:
#
# Column 1 - SNMP OID - Uniquely describes an SNMP variable
# Column 2 - CIM Class Name - CIM class associated with this variable
# Column 3 - CIM Property Name - CIM property that maps to SNMP OID variable
# Column 4 - ASN.1 type - SNMP datatype that dictates how data is mapped
#               to/from SNMP requests.  Supported types are: SnmpString, SnmpOid,
```

EXAMPLE 1 An Example of a `050SUNWwbcou.map` File   *(Continued)*

```
#           SnmpTimeticks, SnmpCounter, SnmpInt, SnmpGauge, SnmpIpAddress,
#           SnmpOpaque)
# Column 5 and greater are ignored
#
Version 1.0

1.3.6.1.2.1.1.1.0 Solaris_ComputerSystem Description SnmpString
1.3.6.1.2.1.1.3.0 Solaris_OperatingSystem LastBootUpTime SnmpTimeticks
1.3.6.1.2.1.1.4.0 Solaris_ComputerSystem PrimaryOwnerContact SnmpString
1.3.6.1.2.1.1.5.0 Solaris_ComputerSystem Name SnmpString

1.3.6.1.2.1.25.1.5.0 Solaris_OperatingSystem NumberOfUsers SnmpGauge
1.3.6.1.2.1.25.1.6.0 Solaris_OperatingSystem NumberOfProcesses SnmpGauge
1.3.6.1.2.1.25.1.7.0 Solaris_OperatingSystem MaxNumberOfProcesses SnmpGauge
1.3.6.1.2.1.25.1.2.0 Solaris_OperatingSystem LocalDateTime SnmpString
```

Each definition of an object in this file contains an OID, its corresponding CIM class name, its corresponding CIM property name, and its corresponding ASN.1 type. Each of these elements is separated by a space character.

Files   /var/sadm/wbem/snmp/map/050SUNWwbcou.map   The SNMP Adapter Subagent for WBEM MIB–2 mapping file that Sun Microsystems provides contains SNMP Management Information Base (MIB) definitions for the CIM instrumentation that SNMP manages.

Exit Status   The following exit values are returned:

0   Successful completion.

1   An error occurred.

Attributes   See attributes(5) for descriptions of the following attributes.

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWwbco

Name snoop – capture and inspect network packets

Synopsis snoop [-aqrCDINPSvV] [-t [r | a | d]] [-c *maxcount*]
[-d *device*] [-i *filename*] [-n *filename*] [-o *filename*]
[-p *first* [, *last*]] [-s *snaplen*] [-x *offset* [, *length*]]
[*expression*]

Description From a datalink or IP interface, snoop captures packets and displays their contents. If the
datalink or IP interface is not specified, snoop will pick a datalink to use, giving priority to
datalinks that have been plumbed for IP traffic. snoop uses the pfmod(7M) and bufmod(7M)
STREAMS modules to provide efficient capture of packets from the network. Captured
packets can be displayed as they are received or saved to a file (which is *RFC 1761*-compliant)
for later inspection.

snoop can display packets in a single-line summary form or in verbose multi-line forms. In
summary form, with the exception of certain VLAN packets, only the data pertaining to the
highest level protocol is displayed. If a packet has a VLAN header and its VLAN ID is
non-zero, then snoop will show that the packet is VLAN tagged. For example, an NFS packet
will have only NFS information displayed. Except for VLAN information under the condition
just described, the underlying RPC, UDP, IP, and Ethernet frame information is suppressed,
but can be displayed if either of the verbose options are chosen.

In the absence of a name service, such as LDAP or NIS, snoop displays host names as numeric
IP addresses.

snoop requires an interactive interface.

Options -C
 List the code generated from the filter expression for either the kernel packet filter, or
 snoop's own filter.

-D
 Display number of packets dropped during capture on the summary line.

-N
 Create an IP address-to-name file from a capture file. This must be set together with the -i
 option that names a capture file. The address-to-name file has the same name as the capture
 file with .names appended. This file records the IP address to hostname mapping at the
 capture site and increases the portability of the capture file. Generate a .names file if the
 capture file is to be analyzed elsewhere. Packets are not displayed when this flag is used.

-I *interface*
 Capture IP packets from the network using the IP interface specified by *interface*, for
 example, lo0. The ipadm(1M) command can be used to list available IP interfaces. The -I
 and -d options are mutually exclusive.

-P
 Capture packets in non-promiscuous mode. Only broadcast, multicast, or packets
 addressed to the host machine will be seen.

-S

Display size of the entire link layer frame in bytes on the summary line.

-V

Verbose summary mode. This is halfway between summary mode and verbose mode in degree of verbosity. Instead of displaying just the summary line for the highest level protocol in a packet, it displays a summary line for each protocol layer in the packet. For instance, for an NFS packet it will display a line each for the ETHER, IP, UDP, RPC and NFS layers. Verbose summary mode output may be easily piped through grep to extract packets of interest. For example, to view only RPC summary lines, enter the following: example# **snoop -i rpc.cap -V | grep RPC**

-a

Listen to packets on /dev/audio (warning: can be noisy).

-c *maxcount*

Quit after capturing *maxcount* packets. Otherwise keep capturing until there is no disk space left or until interrupted with Control-C.

-d *datalink*

Capture link-layer packets from the network using the DLPI datalink specified by *datalink*, for example, bge0 or net0. The dladm(1M) show-link subcommand can be used to list available datalinks. The -d and -I options are mutually exclusive.

-i *filename*

Display packets previously captured in *filename*. Without this option, snoop reads packets from the network interface. If a *filename*.names file is present, it is automatically loaded into the snoop IP address-to-name mapping table (See -N flag).

-n *filename*

Use *filename* as an IP address-to-name mapping table. This file must have the same format as the /etc/hosts file (IP address followed by the hostname).

-o *filename*

Save captured packets in *filename* as they are captured. (This *filename* is referred to as the "capture file".) The format of the capture file is RFC 1761–compliant. During packet capture, a count of the number of packets saved in the file is displayed. If you wish just to count packets without saving to a file, name the file /dev/null.

-p *first* [, last]

Select one or more packets to be displayed from a capture file. The *first* packet in the file is packet number 1.

-q

When capturing network packets into a file, do not display the packet count. This can improve packet capturing performance.

-r

Do not resolve the IP address to the symbolic name. This prevents snoop from generating network traffic while capturing and displaying packets. However, if the -n option is used, and an address is found in the mapping file, its corresponding name will be used.

-s *snaplen*

Truncate each packet after *snaplen* bytes. Usually the whole packet is captured. This option is useful if only certain packet header information is required. The packet truncation is done within the kernel giving better utilization of the streams packet buffer. This means less chance of dropped packets due to buffer overflow during periods of high traffic. It also saves disk space when capturing large traces to a capture file. To capture only IP headers (no options) use a *snaplen* of 34. For UDP use 42, and for TCP use 54. You can capture RPC headers with a *snaplen* of 80 bytes. NFS headers can be captured in 120 bytes.

-t [r | a | d]

Time-stamp presentation. Time-stamps are accurate to within 4 microseconds. The default is for times to be presented in d (delta) format (the time since receiving the previous packet). Option a (absolute) gives wall-clock time. Option r (relative) gives time relative to the first packet displayed. This can be used with the -p option to display time relative to any selected packet.

-v

Verbose mode. Print packet headers in lots of detail. This display consumes many lines per packet and should be used only on selected packets.

-x*offset* [, *length*]

Display packet data in hexadecimal and ASCII format. The *offset* and *length* values select a portion of the packet to be displayed. To display the whole packet, use an *offset* of 0. If a *length* value is not provided, the rest of the packet is displayed.

Operands   *expression*

Select packets either from the network or from a capture file. Only packets for which the expression is true will be selected. If no expression is provided it is assumed to be true.

Given a filter expression, snoop generates code for either the kernel packet filter or for its own internal filter. If capturing packets with the network interface, code for the kernel packet filter is generated. This filter is implemented as a streams module, upstream of the buffer module. The buffer module accumulates packets until it becomes full and passes the packets on to snoop. The kernel packet filter is very efficient, since it rejects unwanted packets in the kernel before they reach the packet buffer or snoop. The kernel packet filter has some limitations in its implementation; it is possible to construct filter expressions that it cannot handle. In this event, snoop tries to split the filter and do as much filtering in the kernel as possible. The remaining filtering is done by the packet filter for snoop. The -C flag can be used to view generated code for either the packet filter for the kernel or the packet filter for snoop. If packets are read from a capture file using the -i option, only the packet filter for snoop is used.

A filter *expression* consists of a series of one or more boolean primitives that may be combined with boolean operators (AND, OR, and NOT). Normal precedence rules for boolean operators apply. Order of evaluation of these operators may be controlled with parentheses. Since parentheses and other filter expression characters are known to the shell, it is often necessary to enclose the filter expression in quotes. Refer to Example 2 for information about setting up more efficient filters.

The primitives are:

host *hostname*
> True if the source or destination address is that of hostname. The *hostname* argument may be a literal address. The keyword host may be omitted if the name does not conflict with the name of another expression primitive. For example, pinky selects packets transmitted to or received from the host pinky, whereas pinky and dinky selects packets exchanged between hosts pinky AND dinky.
>
> The type of address used depends on the primitive which precedes the host primitive. The possible qualifiers are inet, inet6, ether, or none. These three primitives are discussed below. Having none of the primitives present is equivalent to "inet host hostname or inet6 host hostname". In other words, snoop tries to filter on all IP addresses associated with hostname.

inet or *inet6*
> A qualifier that modifies the host primitive that follows. If it is *inet*, then snoop tries to filter on all IPv4 addresses returned from a name lookup. If it is *inet6*, snoop tries to filter on all IPv6 addresses returned from a name lookup.

ipaddr, *atalkaddr*, or *etheraddr*
> Literal addresses, IP dotted, AppleTalk dotted, and Ethernet colon are recognized. For example,
>
> - "172.16.40.13" matches all packets with that IP
> - "2::9255:a00:20ff:fe73:6e35" matches all packets with that IPv6 address as source or destination;
> - "65281.13" matches all packets with that AppleTalk address;
> - "8:0:20:f:b1:51" matches all packets with the Ethernet address as source or destination.
>
> An Ethernet address beginning with a letter is interpreted as a hostname. To avoid this, prepend a zero when specifying the address. For example, if the Ethernet address is aa:0:45:23:52:44, then specify it by add a leading zero to make it 0aa:0:45:23:52:44.

from or src
> A qualifier that modifies the following host, net, *ipaddr*, *atalkaddr*, *etheraddr*, port or rpc primitive to match just the source address, port, or RPC reply.

to or dst

A qualifier that modifies the following host, *net*, *ipaddr*, *atalkaddr*, *etheraddr*, port or rpc primitive to match just the destination address, port, or RPC call.

ether

A qualifier that modifies the following host primitive to resolve a name to an Ethernet address. Normally, IP address matching is performed. This option is not supported on media such as IPoIB (IP over InfiniBand).

ethertype *number*

True if the Ethernet type field has value *number*. If *number* is not 0x8100 (VLAN) and the packet is VLAN tagged, then the expression will match the encapsulated Ethernet type.

ip, ip6, arp, rarp, pppoed, pppoes

True if the packet is of the appropriate ethertype.

vlan

True if the packet has ethertype VLAN and the VLAN ID is not zero.

vlan-id *id*

True for packets of ethertype VLAN with the id *id*.

pppoe

True if the ethertype of the packet is either pppoed or pppoes.

broadcast

True if the packet is a broadcast packet. Equivalent to ether[2:4] = 0xffffffff for Ethernet. This option is not supported on media such as IPoIB (IP over InfiniBand).

multicast

True if the packet is a multicast packet. Equivalent to "ether[0] & 1 = 1" on Ethernet. This option is not supported on media such as IPoIB (IP over InfiniBand).

bootp, dhcp

True if the packet is an unfragmented IPv4 UDP packet with either a source port of BOOTPS (67) and a destination port of BOOTPC (68), or a source port of BOOTPC (68) and a destination of BOOTPS (67).

dhcp6

True if the packet is an unfragmented IPv6 UDP packet with either a source port of DHCPV6-SERVER (547) and a destination port of DHCPV6-CLIENT (546), or a source port of DHCPV6-CLIENT (546) and a destination of DHCPV6-SERVER (547).

apple

True if the packet is an Apple Ethertalk packet. Equivalent to "ethertype 0x809b or ethertype 0x80f3".

decnet

True if the packet is a DECNET packet.

greater *length*
    True if the packet is longer than *length*.

less *length*
    True if the packet is shorter than *length*.

udp, tcp, icmp, icmp6, ah, esp
    True if the IP or IPv6 protocol is of the appropriate type.

net *net*
    True if either the IP source or destination address has a network number of *net*. The
    from or to qualifier may be used to select packets for which the network number occurs
    only in the source or destination address.

port *port*
    True if either the source or destination port is *port*. The *port* may be either a port
    number or name from /etc/services. The tcp or udp primitives may be used to select
    TCP or UDP ports only. The from or to qualifier may be used to select packets for which
    the *port* occurs only as the source or destination.

rpc *prog* [, *vers* [, proc]]
    True if the packet is an RPC call or reply packet for the protocol identified by *prog*. The
    prog may be either the name of an RPC protocol from /etc/rpc or a program number.
    The *vers* and proc may be used to further qualify the program *version* and *procedure*
    number, for example, rpc nfs,2,0 selects all calls and replies for the NFS null
    procedure. The to or from qualifier may be used to select either call or reply packets
    only.

zone *zoneid*
    True if *zoneid* matches either the source or destination *zoneid* of a packet received on an
    ipnet device.

ldap
    True if the packet is an LDAP packet on port 389.

gateway *host*
    True if the packet used *host* as a gateway, that is, the Ethernet source or destination
    address was for *host* but not the IP address. Equivalent to "ether host *host* and not host
    host".

nofrag
    True if the packet is unfragmented or is the first in a series of IP fragments. Equivalent to
    ip[6:2] & 0x1fff = 0.

expr relop expr
    True if the relation holds, where *relop* is one of >, <, >=, <=, =, !=, and expr is an
    arithmetic expression composed of numbers, packet field selectors, the length
    primitive, and arithmetic operators +, −, *, &, |, ^, and %. The arithmetic operators
    within expr are evaluated before the relational operator and normal precedence rules

apply between the arithmetic operators, such as multiplication before addition. Parentheses may be used to control the order of evaluation. To use the value of a field in the packet use the following syntax:

base[expr [: size]]

where expr evaluates the value of an offset into the packet from a *base* offset which may be ether, ip, ip6, udp, tcp, or icmp. The size value specifies the size of the field. If not given, 1 is assumed. Other legal values are 2 and 4. For example,

ether[0] & 1 = 1

is equivalent to multicast

ether[2:4] = 0xffffffff

is equivalent to broadcast.

ip[ip[0] & 0xf * 4 : 2] = 2049

is equivalent to udp[0:2] = 2049

ip[0] & 0xf > 5

selects IP packets with options.

ip[6:2] & 0x1fff = 0

eliminates IP fragments.

udp and ip[6:2]&0x1fff = 0 and udp[6:2] != 0

finds all packets with UDP checksums.

The length primitive may be used to obtain the length of the packet. For instance "length > 60" is equivalent to "greater 60", and "ether[length − 1]" obtains the value of the last byte in a packet.

and
: Perform a logical AND operation between two boolean values. The AND operation is implied by the juxtaposition of two boolean expressions, for example "dinky pinky" is the same as "dinky AND pinky".

or or ,
: Perform a logical OR operation between two boolean values. A comma may be used instead, for example, "dinky,pinky" is the same as "dinky OR pinky".

not or !
: Perform a logical NOT operation on the following boolean value. This operator is evaluated before AND or OR.

slp
: True if the packet is an SLP packet.

sctp
    True if the packet is an SCTP packet.

ospf
    True if the packet is an OSPF packet.

Examples EXAMPLE 1   Using the snoop Command

Capture all packets and display them as they are received:

example# **snoop**

Capture packets with host funky as either the source or destination and display them as they are received:

example# **snoop funky**

Capture packets between funky and pinky and save them to a file. Then inspect the packets using times (in seconds) relative to the first captured packet:

example# **snoop -o cap funky pinky**
example# **snoop -i cap -t r | more**

To look at selected packets in another capture file:

```
example# snoop -i pkts -p 99,108
 99   0.0027   boutique -> sunroof     NFS C GETATTR FH=8E6
100   0.0046   sunroof -> boutique     NFS R GETATTR OK
101   0.0080   boutique -> sunroof NFS C RENAME FH=8E6C MTra00192 to .nfs08
102   0.0102   marmot -> viper         NFS C LOOKUP FH=561E screen.r.13.i386
103   0.0072   viper -> marmot         NFS R LOOKUP No such file or directory
104   0.0085   bugbomb -> sunroof      RLOGIN C PORT=1023 h
105   0.0005   kandinsky -> sparky     RSTAT C Get Statistics
106   0.0004   beeblebrox -> sunroof   NFS C GETATTR FH=0307
107   0.0021   sparky -> kandinsky     RSTAT R
108   0.0073   office -> jeremiah      NFS C READ FH=2584 at 40960 for 8192
```

To look at packet 101 in more detail:

```
example# snoop -i pkts -v -p101
ETHER:   ----- Ether Header -----
ETHER:
ETHER:  Packet 101 arrived at 16:09:53.59
ETHER:  Packet size = 210 bytes
ETHER:  Destination = 8:0:20:1:3d:94, Sun
ETHER:  Source      = 8:0:69:1:5f:e,  Silicon Graphics
ETHER:  Ethertype = 0800 (IP)
ETHER:
IP:   ----- IP Header -----
IP:
IP:   Version = 4, header length = 20 bytes
```

EXAMPLE 1   Using the snoop Command   *(Continued)*

```
IP:   Type of service = 00
IP:        ..0. .... = routine
IP:        ...0 .... = normal delay
IP:        .... 0... = normal throughput
IP:        .... .0.. = normal reliability
IP:   Total length = 196 bytes
IP:   Identification 19846
IP:   Flags = 0X
IP:   .0.. .... = may fragment
IP:   ..0. .... = more fragments
IP:   Fragment offset = 0 bytes
IP:   Time to live = 255 seconds/hops
IP:   Protocol = 17 (UDP)
IP:   Header checksum = 18DC
IP:   Source address = 172.16.40.222, boutique
IP:   Destination address = 172.16.40.200, sunroof
IP:
UDP: ----- UDP Header -----
UDP:
UDP: Source port = 1023
UDP: Destination port = 2049 (Sun RPC)
UDP: Length = 176
UDP: Checksum = 0
UDP:
RPC: ----- SUN RPC Header -----
RPC:
RPC: Transaction id = 665905
RPC: Type = 0 (Call)
RPC: RPC version = 2
RPC: Program = 100003 (NFS), version = 2, procedure = 1
RPC: Credentials: Flavor = 1 (Unix), len = 32 bytes
RPC:    Time = 06-Mar-90 07:26:58
RPC:    Hostname = boutique
RPC:    Uid = 0, Gid = 1
RPC:    Groups = 1
RPC: Verifier  : Flavor = 0 (None), len = 0 bytes
RPC:
NFS: ----- SUN NFS -----
NFS:
NFS: Proc = 11 (Rename)
NFS: File handle = 000016430000000100080000305A1C47
NFS:               597A0000000800002046314AFC450000
NFS: File name = MTra00192
NFS: File handle = 000016430000000100080000305A1C47
NFS:               597A0000000800002046314AFC450000
NFS: File name = .nfs08
NFS:
```

EXAMPLE 1   Using the snoop Command   *(Continued)*

To view just the NFS packets between sunroof and boutique:

```
example# snoop -i pkts rpc nfs and sunroof and boutique
1   0.0000   boutique -> sunroof    NFS C GETATTR FH=8E6C
2   0.0046    sunroof -> boutique   NFS R GETATTR OK
3   0.0080   boutique -> sunroof    NFS C RENAME FH=8E6C MTra00192 to .nfs08
```

To save these packets to a new capture file:

```
example# snoop -i pkts -o pkts.nfs rpc nfs sunroof boutique
```

To view encapsulated packets, there will be an indicator of encapsulation:

```
example# snoop ip-in-ip
sunroof -> boutique ICMP Echo request    (1 encap)
```

If -V is used on an encapsulated packet:

```
example# snoop -V ip-in-ip
sunroof -> boutique  ETHER Type=0800 (IP), size = 118 bytes
sunroof -> boutique  IP D=172.16.40.222 S=172.16.40.200 LEN=104, ID=27497
sunroof -> boutique  IP  D=10.1.1.2 S=10.1.1.1 LEN=84, ID=27497
sunroof -> boutique  ICMP Echo request
```

EXAMPLE 2   Setting Up A More Efficient Filter

To set up a more efficient filter, the following filters should be used toward the end of the expression, so that the first part of the expression can be set up in the kernel: greater, less, port, rpc, nofrag, and relop. The presence of OR makes it difficult to split the filtering when using these primitives that cannot be set in the kernel. Instead, use parentheses to enforce the primitives that should be OR'd.

To capture packets between funky and pinky of type tcp or udp on port 80:

```
example# snoop funky and pinky and port 80 and tcp or udp
```

Since the primitive port cannot be handled by the kernel filter, and there is also an OR in the expression, a more efficient way to filter is to move the OR to the end of the expression and to use parentheses to enforce the OR between tcp and udp:

```
example# snoop funky and pinky and (tcp or udp) and port 80
```

Exit Status 0   Successful completion.

1   An error occurred.

Files /dev/audio   Symbolic link to the system's primary audio device.

/dev/null   The null file.

/etc/hosts   Host name database.

/etc/rpc   RPC program number data base.

/etc/services   Internet services and aliases.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/network-clients
Interface Stability	Obsolete

See Also   dladm(1M), ipadm(1M), netstat(1M), hosts(4), rpc(4), services(4), attributes(5), audio(7I), ipnet(7D), bufmod(7M), dlpi(7P), pfmod(7M)

Callaghan, B. and Gilligan, R. *RFC 1761, Snoop Version 2 Packet Capture File Format*. Network Working Group. February 1995.

Warnings   The processing overhead is much higher for real-time packet interpretation. Consequently, the packet drop count may be higher. For more reliable capture, output raw packets to a file using the -o option and analyze the packets offline.

Unfiltered packet capture imposes a heavy processing load on the host computer, particularly if the captured packets are interpreted real-time. This processing load further increases if verbose options are used. Since heavy use of snoop may deny computing resources to other processes, it should not be used on production servers. Heavy use of snoop should be restricted to a dedicated computer.

snoop does not reassemble IP fragments. Interpretation of higher level protocol halts at the end of the first IP fragment.

snoop may generate extra packets as a side-effect of its use. For example it may use a network name service (NIS) to convert IP addresses to host names for display. Capturing into a file for later display can be used to postpone the address-to-name mapping until after the capture session is complete. Capturing into an NFS-mounted file may also generate extra packets.

Setting the snaplen (-s option) to small values may remove header information that is needed to interpret higher level protocols. The exact cutoff value depends on the network and protocols being used. For NFS Version 2 traffic using UDP on 10 Mb/s Ethernet, do not set snaplen less than 150 bytes. For NFS Version 3 traffic using TCP on 100 Mb/s Ethernet, snaplen should be 250 bytes or more.

snoop requires information from an RPC request to fully interpret an RPC reply. If an RPC reply in a capture file or packet range does not have a request preceding it, then only the RPC reply header will be displayed.

Name soconfig – configure transport providers for use by sockets

Synopsis /usr/sbin/soconfig -d *dir*

/usr/sbin/soconfig -f *file*

/usr/sbin/soconfig *family type protocol* [*module* | *path*]

/usr/sbin/soconfig -l [-np]

Description The soconfig utility configures the transport provider driver for use with sockets. It specifies how the family, type, and protocol parameters in the socket(3SOCKET) call are mapped to the name of a transport provider such as /dev/tcp. This utility can be used to add an additional mapping or remove a previous mapping.

The init(1M) utility uses soconfig with the sock2path.d(4) file during the booting sequence.

Options The following options are supported:

-d *dir*

Set up the soconfig configuration for each driver according to the information stored in the files in *dir*.

-f *file*

Set up the soconfig configuration for each driver according to the information stored in *file*. A soconfig file consists of lines of at least the first three fields listed below, separated by spaces:

family type protocol [*module* | *path*]

These fields are described in the OPERANDS section below.

An example of *file* can be found in the EXAMPLES section below.

-l [-np]

Dump the in-kernel socket configuration table. This option has the following suboptions:

-n

Do not convert socket family, type, and protocol to string representation.

-p

Display machine-parseable output.

Operands The following operands are supported:

family

The protocol family as listed in the /usr/include/sys/socket.h file, expressed as an integer.

type

The socket type as listed in the /usr/include/sys/socket.h file, expressed as an integer.

protocol

The protocol number as specified in the family-specific `include` file, expressed as an integer. For example, for `AF_INET` this number is specified in `/usr/include/netinet/in.h`. An unspecified protocol number is denoted with the value zero.

module | path

The module name or path name of a device that corresponds to the transport provider, such as `tcp` or `/dev/tcp`. Modules must reside in `kernel/socketmod`. A device name must begin with `/dev`. If this parameter is specified, the configuration will be added for the specified family, type, and protocol. If this parameter is not specified, the configuration will be removed.

Examples   **EXAMPLE 1**   Using `soconfig`

The following example sets up a module for family `AF_INET` and type `SOCK_STREAM`:

```
example# soconfig 2 2 0 tcp
```

The following example sets up `/dev/tcp` for family `AF_INET` and type `SOCK_STREAM`:

```
example# soconfig 2 2 0 /dev/tcp
```

The following is a sample file used with the `-f` option. Comment lines begin with a hash mark (#):

```
#   Family  Type  Protocol   Module | Path
      2       2      0           tcp
      2       2      6           tcp

      2       1      0           udp
      2       1      17          udp

      1       2      0           /dev/ticotsord
      1       1      0           /dev/ticlts

      2       4      0           icmp
```

Files   `/etc/sock2path.d`

Directory containing files with mappings from sockets to transport providers.

Attributes   See `attributes(5)` for descriptions of the following attributes:

Network Interface Guide

Name soladdapp – add an application to the Solstice application registry

Synopsis /usr/snadm/bin/soladdapp [-r *registry*] -n *name* -i *icon* -e *executable*
[*args*]

Description soladdapp adds an application to the Solstice application registry. After it is added, the
application is displayed in the Solstice Launcher main window (see solstice(1M)).

Options -r *registry*   Define the full path name of the Solstice registry file.

-n *name*   Define the name of the tool to be registered.

-i *icon*   Define the full path name of the tool icon.

-e *executable*   Define the full path name of the tool.

args   Specify any arguments to use with the tool.

When executed without options, soladdapp uses /opt/SUNWadm/etc/.solstice_registry
(the default registry path).

Return Values 0   on success

1   on failure

2   if the registry is locked

3   if the entry is a duplicate.

Examples EXAMPLE 1   A sample display of the soladdapp command.

The following adds an application called Disk Manager to the Solstice application registry for
display in the Solstice Launcher main window.

```
# soladdapp -r /opt/SUNWadm/etc/.solstice_registry -n "Disk Manager"
-i /opt/SUNWdsk/etc/diskmgr.xpm -e /opt/SUNWdsk/bin/diskmgr
```

Files /opt/SUNWadm/etc/.solstice_registry   The default registry path.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsadml

See Also soldelapp(1M), solstice(1M), attributes(5)

Notes Globally registered applications are used by local and remote users sharing the software in a
particular /opt directory. They can be added only using soladdapp.

Name soldelapp – remove an application from the Solstice application registry

Synopsis /usr/snadm/bin/soldelapp [-r *registry*] -n *name*

Description soldelapp removes an application from the Solstice application registry. After removal, the application is no longer displayed in the Solstice Launcher main window (see solstice(1M)).

Options -r *registry*   Define the full path name of the Solstice registry file.

-n *name*   Define the name of the tool to be removed.

When executed without options, soldelapp uses /opt/SUNWadm/etc/.solstice_registry (the default registry path).

Return Values 0   on success

1   on failure

2   if the registry is locked

3   if *name* is not found in the registry

4   if the named registry or default registry is not found

Examples EXAMPLE 1 A sample display of the soldelapp command.

The following removes an application called Disk Manager from the Solstice application registry and the Solstice Launcher main window.

soldelapp -r /opt/SUNWadm/etc/.solstice_registry -n "Disk Manager"

Files /opt/SUNWadm/etc/.solstice_registry   The default registry file.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsadml

See Also soladdapp(1M), solstice(1M), attributes(5)

Notes Globally registered applications are used by local and remote users sharing the software in a particular /opt directory. They can be removed only using soldelapp.

Name solstice – access system administration tools with a graphical user interface

Synopsis /bin/solstice

Description `solstice` used on a system presents the `Solstice Launcher`, a graphical user interface that provides access to the Solstice AdminSuite product family of system administration tools. The tools that appear in the launcher depend on what Solstice products you installed on your system.

Help is available by using the Help button.

Usage The `Solstice Launcher` allows you to do the following tasks:

Launch applications	Use the `Solstice Launcher` to launch system administration tools.
Register applications	Use the `Solstice Launcher` to add and register applications locally with the launcher.
Remove applications	Use the `Solstice Launcher` to remove locally registered applications.
Customize application properties	Use the `Solstice Launcher` to show, hide, or remove applications in the launcher, reorder the icons, change the launcher window width, modify applications properties, and add applications.

Files /$HOME/.solstice_registry   Local registry information.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWsadml

See Also soladdapp(1M), soldelapp(1M), attributes(5)

Notes The `Solstice Launcher` adds or removes local applications that are private to the user (not local to the system) only. The properties of globally registered applications that are used by local and remote users sharing the software from a particular /opt directory cannot be modified from the `Solstice Launcher`. To register global applications for use by local and remote users, use the soladdapp(1M) command. To remove globally registered applications, use the soldelapp(1M) command.

Name sppptun – PPP tunneling driver utility

Synopsis sppptun plumb

sppptun plumb [-s *sap*] *protocol device*

sppptun unplumb *interface*

sppptun query

Description The sppptun utility is used to configure and query the Solaris PPP tunneling device driver, /dev/sppptun. Currently, only PPP over Ethernet (PPPoE) is supported, so the plumb and unplumb arguments are used to specify Ethernet interfaces that are to be used for PPPoE, and the query option lists the plumbed interfaces.

The use of sppptun to add interfaces is similar to the use of ifconfig(1M) to add interfaces to IP. The plumbing is done once for each interface, preferably at system start-up time, and is not normally manipulated on a running system. If multiple instances of PPP are run over a single interface, they share the plumbing to that interface. Plumbing for each session is not required (and not possible for PPPoE).

The proper way to plumb interfaces for PPPoE is to list the interfaces, one per line, in the /etc/ppp/pppoe.if file. If alternate Ethertype (SAP) values are necessary, then include the PPPoE Session and Discovery Stage values as hexadecimal on the same line. The line format is:

interface [*session* [*discovery*]]

The defaults are the Ethertypes specified in RFC 2516, and most users should not need to set these values. See the examples for one possible use.

Usage

sppptun plumb	When specified with no additional arguments, the plumb argument lists the protocols that are supported by the utility. These are the strings that are used as the *protocol* argument below.
sppptun plumb [-s *sap*] *protocol device*	This plumbs a new interface into the driver. The *protocol* parameter is pppoe for the PPP-carrying "Session Stage" connection or pppoed for the PPPoE "Discovery Stage" connection. Both connections must be present for each Ethernet interface that is to be used for PPPoE. The *device* parameter is the path name of the Ethernet interface to use (use ifconfig(1M) to list available devices). If the path begins with /dev/, then this portion may be omitted. The -s *sap* option can be specified to use an alternate Ethertype (SAP) for the selected protocol. The *sap* value must be given in

hexadecimal. Some access servers use Ethertypes for PPPoE different from those in RFC 2516. The defaults are 8864 for pppoe and 8863 for pppoed.

sppptun unplumb *interface*　　　This removes an existing interface from the driver and terminates any PPP sessions that were using the interface. The *interface* parameter is the name of the interface as reported when the interface was plumbed.

sppptun query　　　Displays the canonical names of all interfaces plumbed into the /dev/sppptun device driver.

Examples　EXAMPLE 1　Setting up to Use PPPoE on hme0

Plumb the hme0 interface.

```
# sppptun plumb pppoed hme0
hme0:pppoed
# sppptun plumb pppoe hme0
hme0:pppoe
```

Remove the hme0 interface.

```
# sppptun unplumb hme0:pppoed
# sppptun unplumb hme0:pppoe
```

EXAMPLE 2　Script to Remove All Plumbed Interfaces

```
#!/bin/sh
for intf in `sppptun query`
do
        sppptun unplumb $intf
done
```

EXAMPLE 3　Interoperating with 3COM HomeConnect Dual Link ADSL

```
# dladm show-link
LINK       CLASS   MTU    STATE   OVER
nge0       phys    1500   up      --
# echo nge0 3c13 3c12 > /etc/ppp/pppoe.if
```

Exit Status　The following exit values are returned:

0　　Successful completion.

1　　One or more errors occurred.

Files /etc/ppp/pppoe.if   list of Ethernet interfaces to be plumbed at boot time

/usr/sbin/sppptun   executable command

/dev/sppptun   Solaris PPP tunneling device driver

Attributes See attributes(5) for descriptions of the following attributes:

Availability	system/network/ppp/tunnel

See Also pppd(1M), pppoec(1M), pppoed(1M), sppptun(7M)

RFC 2516, Method for Transmitting PPP Over Ethernet (PPPoE), Mamakos et al, February 1999

Name spray – spray packets

Synopsis /usr/sbin/spray [-c *count*] [-d *delay*] [-l *length*]
        [-t *nettype*] *host*

Description spray sends a one-way stream of packets to *host* using RPC, and reports how many were received, as well as the transfer rate. The *host* argument can be either a name or an Internet address.

spray is not useful as a networking benchmark, as it uses unreliable connectionless transports, UDP for example. spray can report a large number of packets dropped when the drops were caused by spray sending packets faster than they can be buffered locally, that is, before the packets get to the network medium.

Options -c *count* Specify how many packets to send. The default value of *count* is the number of packets required to make the total stream size 100000 bytes.

-d *delay* Specify how many microseconds to pause between sending each packet. The default is 0.

-l *length* The *length* parameter is the numbers of bytes in the Ethernet packet that holds the RPC call message. Since the data is encoded using XDR, and XDR only deals with 32 bit quantities, not all values of *length* are possible, and spray rounds up to the nearest possible value. When *length* is greater than 1514, then the RPC call can no longer be encapsulated in one Ethernet packet, so the *length* field no longer has a simple correspondence to Ethernet packet size. The default value of *length* is 86 bytes, the size of the RPC and UDP headers.

-t *nettype* Specify class of transports. Defaults to netpath. See rpc(3NSL) for a description of supported classes.

Name srptadm – administer SRP targets

Synopsis srptadm modify-target [-e, --enable] [-d, --disable]
        [-r, --reset] *hca_guid*

srptadm list-target [*hca_guid*]

srptadm modify-defaults [-e, --enable] [-d, --disable]

srptadm list-defaults

Description The srptadm command manages SCSI RDMA Protocol (SRP) target ports within the SCSI
Target Mode Framework described in stmfadm(1M) and libstmf(3LIB). This allows SRP
initiators to access SCSI Target Mode Framework (STMF) logical units using the SRP
protocol.

srptadm is implemented as a set of subcommands with options and operands for each
subcommand. These subcommands are described in their own section, below.

Sub-commands list-defaults
        Lists information about the default properties. This subcommand has no options.

list-target [*hca_guid*]
        If *hca_guid* is specified, lists the properties of the target HCA. Otherwise, properties are
        listed for all HCAs.

modify-defaults [-e, --enable] [-d, --disable]
        Modify default parameters.

    -e, --enable
        Enable SRP target creation for all HCAs that have not been explicitly disabled with
        modify-target.

    -d, --disable
        Disable SRP target creation for all HCAs that have not been explicitly enabled with
        modify-target.

modify-target [-e, --enable] [-d, --disable] [-r, --reset *hca_guid*
        Sets SRP Target properties for the specified HCA.

    -e, --enable
        Enables SRP target creation on this HCA.

    -d, --disable
        Disables SRP target creation on this HCA.

    -r, --reset
        Clears HCA-specific information and resets to defaults. The SRP Target, if any,
        associated with this HCA will not be modified as a result of this option until the SRP
        Target SMF service is restarted.

Operands   The list-target and modify-target subcommands have the following operand.

hca_guid
    GUID of the InfiniBand Host Channel Adapter (HCA) on this system for which SRP
    Target Services can be provided. The GUID must be in one of the following forms:

    3BA000100CD18   Base hex form.

    0003BA000100CD18   Base hex form with leading zeroes.

    hca:3BA000100CD18   Form from cfgadm(1M).

    eui.0003BA000100CD18   EUI form.

Usage   If the default state is changed when the SRP service is online, the state of existing targets is not
    changed until the service is restarted.

    Changing the target state takes effect immediately if the SRP target service is online. Targets
    set to disabled will be offlined and removed; targets set to enabled will be immediately
    created.

Examples   EXAMPLE 1   Listing Default Properties

    The following command lists the default SRP Target Service properties.

    ```
    # srptadm list-defaults
    ```

    EXAMPLE 2   Changing Default Behavior

    The following command changes the default behavior of the SRP Target service to not create
    SRP Targets when the service is enabled.

    ```
    # srptadm modify-defaults -d
    ```

    EXAMPLE 3   Listing Properties for Specific HCA

    The following command lists SRP Target properties for a specific HCA.

    ```
    # cfgadm | grep hca
    hca:3BA000100CD18            IB-HCA      connected   configured   ok
    hca:3BA000100D030            IB-HCA      connected   configured   ok

    # srptadm list-target hca:3BA000100CD18
    Target HCA 3BA000100CD18:
        Enabled          : true
        SRP Target Name  : eui.0003BA000100CD18
        Operational Status : online
    ```

EXAMPLE 4 Disabling Services for Specific HCA

The following command disables SRP Target services for a specific HCA.

```
# srptadm modify-target -d 3BA000100CD18
```

Use the list-target command to see the changes:

```
# srptadm list-target hca:3BA000100CD18
Target HCA 3BA000100CD18:
    Enabled           : false
    SRP Target Name   : eui.0003BA000100CD18
    Operational Status : -
```

EXAMPLE 5 Re-enabling Target Services

The following command sequence re-enables SRP Target services and displays the SRP and STMF target properties.

```
# srptadm modify-target -e 3BA000100CD18
# srptadm list-target hca:3BA000100CD18
Target HCA 3BA000100CD18:
    Enabled           : true
    SRP Target Name   : eui.0003BA000100CD18
    Operational Status : online

# stmfadm list-target -v eui.0003BA000100CD18
Target: eui.0003BA000100CD18
    Operational Status: Online
    Provider Name   : srpt
    Alias           : -
    Protocol        : SRP
    Sessions        : 0
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/storage/scsi-rdma/scsi-rdma-target
Interface Stability	Committed

Name   sshd – secure shell daemon

Synopsis   sshd [-deiqtD46] [-b *bits*] [-f *config_file*]
            [-g *login_grace_time*] [-h *host_key_file*]
            [-h *PKCS#11 URI*]
            [-p *port*] [-V *client_protocol_id*]

Description   The sshd (Secure Shell daemon) is the daemon program for ssh(1). Together these programs
            replace rlogin and rsh, and provide secure encrypted communications between two
            untrusted hosts over an insecure network. The programs are intended to be as easy to install
            and use as possible.

            sshd is the daemon that listens for connections from clients. It forks a new daemon for each
            incoming connection. The forked daemons handle key exchange, encryption, authentication,
            command execution, and data exchange.

            This implementation of sshd supports SSH protocol version 2 only.

SSH Protocol Version 1   This protocol version is no longer supported in the daemon program. It is supported only in
            the client. See ssh(1) manual page for more information.

SSH Protocol Version 2   Each host has a host-specific DSA/RSA key used to identify the host. Forward security is
            provided through a Diffie-Hellman key agreement. This key agreement results in a shared
            session key. The rest of the session is encrypted using a symmetric cipher, currently
            128/192/256-bit AES CBC or CTR, 128/256-bit ARCFOUR, Blowfish, or 3DES.. The client
            selects the encryption algorithm to use from those offered by the server. Additionally, session
            integrity is provided through a cryptographic message authentication code (hmac-sha1 or
            hmac-md5).

            Protocol version 2 provides a public key based user authentication method
            (PubKeyAuthentication) GSS–API based user authentication, conventional password
            authentication, and a generic prompt/reply protocol for password-based authentication.

Command Execution
and Data Forwarding   If the client successfully authenticates itself, a dialog for preparing the session is entered. At
            this time the client can request things like allocating a pseudo-tty, forwarding X11
            connections, forwarding TCP/IP connections, or forwarding the authentication agent
            connection over the secure channel.

            Finally, the client either requests a shell or execution of a command. The sides then enter
            session mode. In this mode, either side may send data at any time, and such data is forwarded
            to/from the shell or command on the server side, and the user terminal on the client side.

            When the user program terminates and all forwarded X11 and other connections have been
            closed, the server sends command exit status to the client, and both sides exit.

            sshd can be configured using command-line options or the configuration file
            /etc/ssh/ssh_config, described in ssh_config(4). Command-line options override values
            specified in the configuration file.

sshd rereads its configuration file when it receives a hangup signal, SIGHUP, by executing itself with the name it was started as, that is, /usr/lib/ssh/sshd.

Host Access Control   The sshd daemon uses TCP Wrappers to restrict access to hosts. It uses the service name of sshd for hosts_access(). For more information on TCP Wrappers see tcpd(1M) and hosts_access(3) man pages, which are part of the SUNWsfman package (they are not SunOS man pages). TCP wrappers binaries, including libwrap, are in security/tcp-wrapper, a required package for service/network/ssh, the package containing sshd.

Options   The options for sshd are as follows:

-b *bits*
   Specifies the number of bits in the server key (the default is 768).

-d
   Debug mode. The server sends verbose debug output to the system log, and does not put itself in the background. The server also will not fork and will only process one connection. This option is only intended for debugging for the server. Multiple -d options increase the debugging level. Maximum is 3.

-e
   When this option is specified, sshd will send the output to standard error instead of to the system log.

-f *configuration_file*
   Specifies the name of the configuration file. The default is /etc/ssh/sshd_config. sshd refuses to start if there is no configuration file.

-g *login_grace_time*
   Gives the grace time for clients to authenticate themselves (the default is 300 seconds). If the client fails to authenticate the user within this number of seconds, the server disconnects and exits. A value of zero indicates no limit.

-h *host_key_file*
   Specifies a file from which a host key is read. This option must be given if sshd is not run as root (as the normal host key files are normally not readable by anyone but root). The default is /etc/ssh/ssh_host_key for protocol version 1, and /etc/ssh/ssh_host_rsa_key and /etc/ssh/ssh_host_dsa_key for protocol version 2. It is possible to have multiple host key files for the different protocol versions and host key algorithms.

-h *PKCS#11 URI*
   Instead of working with a host key file, work with a certificate and a private key stored in the PKCS#11 token. See also Using X.509 Certificates section below.

-i
   Specifies that sshd is being run from inetd. sshd is normally not run from inetd because it needs to generate the server key before it can respond to the client, and this may take tens of

seconds. Clients would have to wait too long if the key was regenerated every time. However, with small key sizes (for example, 512) using sshd from inetd may be reasonable.

-o *option*

Can be used to specify options in the format used in the configuration file. This is useful for specifying options for which there are no separate command-line flags.

-p *port*

Specifies the port on which the server listens for connections (the default is 22).

-q

Quiet mode. Nothing is sent to the system log. Normally the beginning, authentication, and termination of each connection is logged.

-t

Test mode. Check only the validity of the configuration file and the sanity of the keys. This is useful for updating sshd reliably as configuration options might change.

-D

When this option is specified sshd does not detach and does not become a daemon. This allows easy monitoring of sshd.

-4

Forces sshd to use IPv4 addresses only.

-6

Forces sshd to use IPv6 addresses only.

Extended Description

authorized_keys File Format

The $HOME/.ssh/authorized_keys file lists the public keys that are permitted for public key authentication (PubkeyAuthentication) in protocol version 2. The AuthorizedKeysFile configuration option can be used to specify an alternative file.

Each line of the file contains one key (empty lines and lines starting with a hash mark [#] are ignored as comments).

For each RSA key for protocol version 1, the file consists of the following space-separated fields:

options   bits   exponent   modulus   comment

For the public key for protocol version 2, the file consists of the following space-separated fields:

options   key-type   base64-encoding-key   comment

For protocol version 2, *key-type* is one of ssh-rsa or ssh-dsa.

The options field is optional; its presence is determined by whether the line starts with a number. (The option field never starts with a number.) The bits, exponent, and modulus fields give the RSA key; the comment field is a convenient place for you to identify the key.

Lines in this file are usually several hundred bytes long (because of the size of the key modulus). You will find it very inconvenient to type them in; instead, copy the public key file and edit it.

Permissions of this file must be set so that it is not world or group writable. See the StrictModes option of sshd_config(4).

The options (if present) consist of comma-separated option specifications. No spaces are permitted, except within double quotes. The following option specifications are supported:

from="*pattern-list*"
Specifies that, in addition to public key authentication, the canonical name of the remote host must be present in the comma-separated list of patterns ('*' and '?' serve as wildcards). The list can also contain negated patterns by prefixing the patterns with '!'. If the canonical host name matches a negated pattern, the key is not accepted.

The purpose of this option is to give you the option of increasing security: public key authentication by itself does not trust the network or name servers or anything but the key. However, if someone manages to steal the key, possession of the key would permit the intruder to log in from anywhere in the world. This option makes using a stolen key more difficult, because name servers and routers would have to be compromised, in addition to just the key.

command="*command*"
Specifies that the *command* is executed whenever this key is used for authentication. The command supplied by the user (if any) is ignored. The command is run on a pty if the client requests a pty; otherwise it is run without a tty. If an 8-bit clean channel is required, one must not request a pty or should specify no-pty. You can include a quote in the command by escaping it with a backslash. This option might be useful to restrict certain public keys from performing a specific operation. An example is a key that permits remote backups but nothing else. Note that the client can specify TCP/IP and/or X11 forwarding unless they are explicitly prohibited from doing so. Also note that this option applies to shell, command, or subsystem execution.

environment="*NAME=value*"
Specifies that the string *NAME=value* is to be added to the environment when logging in using this key. Environment variables set this way override other default environment values. Multiple options of this type are permitted. Environment processing is disabled by default and is controlled via the PermitUserEnvironment option.

no-port-forwarding
Forbids TCP/IP forwarding when this key is used for authentication. Any port forward requests by the client will return an error. This might be used, for example, in connection with the command option.

no-X11-forwarding

Forbids X11 forwarding when this key is used for authentication. Any X11 forward requests by the client will return an error.

no-agent-forwarding

Forbids authentication agent forwarding when this key is used for authentication.

no-pty

Prevents tty allocation (a request to allocate a pty will fail).

permitopen="*host*:*port*"

Limit local ssh -L port forwarding such that it can connect only to the specified host and port. IPv6 addresses can be specified with an alternative syntax: *host*/*port*. You can invoke multiple permitopen options, with each instance separated by a comma. No pattern matching is performed on the specified hostnames. They must be literal domains or addresses.

ssh_known_hosts File Format

The /etc/ssh/ssh_known_hosts and $HOME/.ssh/known_hosts files contain host public keys for all known hosts. The global file should be prepared by the administrator (optional), and the per-user file is maintained automatically: whenever the user connects from an unknown host its key is added to the per-user file.

For the RSA key for protocol version 1, these files consist of the following space-separated fields:

hostnames   bits   exponent   modulus   comment

For the public key for protocol version 2, these files consist of the following space-separated fields:

hostnames   key-type   base64-encoding-key   comment

For protocol version 2, *key-type* is one of ssh-rsa or ssh-dsa.

Hostnames is a comma-separated list of patterns (* and ? act as wildcards); each pattern in turn is matched against the canonical host name (when authenticating a client) or against the user-supplied name (when authenticating a server). A pattern can also be preceded by ! to indicate negation: if the host name matches a negated pattern, it is not accepted (by that line) even if it matched another pattern on the line.

Alternately, hostnames can be stored in a hashed form, which hides host names and addresses should the file's contents be disclosed. Hashed hostnames start with a vertical bar (|) character. Only one hashed hostname can appear on a single line and none of the above negation or wildcard operators may be applied.

Bits, exponent, and modulus are taken directly from the RSA host key; they can be obtained, for example, from /etc/ssh/ssh_host_rsa_key.pub. The optional comment field continues to the end of the line, and is not used.

Lines starting with a hash mark (#) and empty lines are ignored as comments.

When performing host authentication, authentication is accepted if any matching line has the proper key. It is thus permissible (but not recommended) to have several lines or different host keys for the same names. This will inevitably happen when short forms of host names from different domains are put in the file. It is possible that the files contain conflicting information; authentication is accepted if valid information can be found from either file.

The lines in these files are typically hundreds of characters long. You should definitely not type in the host keys by hand. Rather, generate them by a script or by taking /etc/ssh/ssh_host_rsa_key.pub and adding the host names at the front.

Environment Variables
sshd sets the following environment variables for commands executed by ssh users:

DISPLAY
  Indicates the location of the X11 server. It is automatically set by sshd to point to a value of the form *hostname*:*n*, where *hostname* indicates the host where the shell runs, and *n* is an integer greater than or equal to 1. ssh uses this special value to forward X11 connections over the secure channel. Unless you have important reasons to do otherwise, you should not set DISPLAY explicitly, as that will render the X11 connection insecure and will require you to manually copy any required authorization cookies.

HOME
  Set to the path of the user's home directory.

LANG, LC_ALL, LC_COLLATE, LC_CTYPE, LC_MESSAGES, LC_MONETARY, LC_NUMERIC, LC_TIME
  A locale setting. The locale defaults to that of sshd (usually the system-wide default locale), or is negotiated between the client and server during initial key exchange (as per RFC 4253).

  Following initial key exchange, each of the variables can be overriden in the following sequence:

  1. If a locale setting is set in a client's environment and that client supports "Environment Variable Passing" (see RFC 4254), then the setting will be passed over to the server side.

  2. If the public key authentication method was used to authenticate the server and the PermitUserEnvironment variable in sshd_config(4) is set to yes on the server side, then the setting can be changed through the use of the environment option in the client's AuthorizedKeysFile file.

  3. The setting can be change in the client's ~/.ssh/environment file on the server.

  See PermitUserEnvironment in sshd_config(4) as to when the AuthorizedKeysFile and ~/.ssh/environment files are processed and used for setting the user environment.

LOGNAME
  Synonym for USER. Set for compatibility with systems that use this variable.

MAIL
  Set to point to the user's mailbox.

SSH_AUTH_SOCK

Indicates the path of a unix-domain socket used to communicate with the agent.

SSH_CONNECTION

Identifies the client and server ends of the connection. The variable contains four space-separated values: client IP address, client port number, server IP address and server port number.

SSH_CLIENT

Identifies the client end of the connection. The variable contains three space-separated values: client IP address, client port number, and server port number.

SSH_TTY

Set to the name of the tty (path to the device) associated with the current shell or command. If the current session has no tty, this variable is not set.

TZ

Indicates the present timezone, if TIMEZONE is set in /etc/default/login or if TZ was set when the daemon was started.

HZ

If set in /etc/default/login, the daemon sets it to the same value.

SHELL

The user's shell, if ALTSHELL=YES in /etc/default/login.

PATH

Set to the value of PATH or SUPATH (see login(1)) in /etc/default/login, or, if not set, to /usr/bin:/bin.

USER

Set to the name of the user logging in.

Additionally, sshd reads $HOME/.ssh/environment and adds lines of the format VARNAME=*value* to the environment.

Examples   In the following examples, certain lines might wrap due to line length limits in your display. You should nevertheless consider the wrapped line as a single line.

EXAMPLE 1   authorized_key File Entries

The following are examples of authorized_key file entries for protocol 1:

```
1024 33 12121...312314325 ylo@foo.bar
```

```
from="*.niksula.hut.fi,!pc.niksula.hut.fi" 1024 35 23...2334 ylo@niksula
```

```
command="dump /home",no-pty,no-port-forwarding 1024 33 23...2323 backup.hut.fi
```

EXAMPLE 2 `authorized_key` File Entries for Protocol 2

The following are examples of `authorized_key` file entries for protocol 2:

```
ssh-rsa AAAAB3NzaC1y.....EU88ovYKg4GfclWGCFYTuw8= ylo@foo.bar
from="*.niksula.hut.fi" ssh-rsa AAAAB3NzaC...uw8= ylo@niksula
command="dump /home",no-pty,no-port-forwarding ssh-rsa AA..8= backup.hut.fi
```

EXAMPLE 3 `ssh_known_hosts` File Entries for Protocol 1

The following are examples of `ssh_known_hosts` file entries for protocol 1:

```
closenet,closenet.hut.fi,...,130.233.208.41 1024 37 159...93 closenet.hut.fi
```

EXAMPLE 4 `ssh_known_hosts` File Entries for Protocol 2

The following are examples of `ssh_known_hosts` file entries for protocol 2:

```
closenet,closenet.hut.fi,...,130.233.208.41 ssh-rsa AA..8= closenet.hut.fi
```

EXAMPLE 5 Using X.509 Public Key Authentication

The following example of user authentication should help you understand how the X.509 public key authentication works. Steps to use X.509 certificates/keys for host authentication are very similar. Note that we use the same token (`softtoken`) for both the TA certificate and the user certificate, which would not normally be the case.

Create a self-signed trusted anchor certificate and a user certificate signed by the trusted anchor private key. Configure the SSH daemon for certificate validation, and run the SSH client with the user certificate generated in the previous step as its user identity.

Replace user name "*PUT-YOUR-USERNAME-HERE*" with an existing (your) user name on the server side.

```
# Generate a trusted anchor certificate/key pair in the
# default token (softtoken).
pktool gencert keystore=pkcs11 label=authority \
    subject="CN=authority" serial=0x01

# Export the trusted anchor certificate (and, after that,
# put it to /etc/ssh/cert directory).
pktool export keystore=pkcs11 outfile=ta.cert objtype=cert
    label=authority outformat=pem

# Generate a user certificate signed by the trusted anchor
# private key and then import the certificate into the
# token.
pktool gencsr keystore=pkcs11 label=user \
    outcsr=user.csr subject="CN=<PUT-YOUR-USERNAME-HERE>"
pktool signcsr keystore=pkcs11 signkey=authority \
    csr=user.csr serial=0x02 issuer="CN=authority" \
```

EXAMPLE 5 Using X.509 Public Key Authentication   *(Continued)*

```
    outcert=user.cert
pktool import keystore=pkcs11 infile=user.cert label=user

# Create a new policy file.
kmfcfg create dbfile=/etc/ssh/policy.xml policy=ssh \
    ta-name=search mapper-name=cn

# Start the SSH daemon in a debug mode to test the
# configuration. Use a different port so that you do not
# clash with the already running daemon.
/usr/lib/ssh/sshd -p 2222 -ddd -o \
    -o TrustedAnchorKeystore=/etc/ssh/cert \
    -o KMFPolicyDatabase=/etc/ssh/policy.xml \
    -o KMFPolicyName=ssh

# Run the client in a debug mode to test the configuration
# (will ask for a PIN for the token, use the 'pinfile'
# attribute if you do not want to set PIN for each
# invocation).
ssh -p 2222 -vvv -o \
    IdentityFile=\
    "pkcs11:object=user;token=Sun Software PKCS#11 softtoken" \
    <PUT-YOUR-USERNAME-HERE>@localhost
```

Before you use the softtoken you should set its PIN by means of the `setpin` subcommand. See pktool(1) for more information.

Exit Status The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Files /etc/default/login

Contains defaults for several sshd_config parameters, environment variables, and other environmental factors.

The following parameters affect environment variables (see login(1) and descriptions of these variables, above):

- TIMEZONE
- HZ
- ALTSHELL
- PATH
- SUPATH

The following /etc/default/login parameters supply default values for corresponding sshd_config(4) parameters:

- CONSOLE (see PermitRootLogin in sshd_config(4))
- PASSREQ (see PermitEmptyPasswords in sshd_config(4))
- TIMEOUT (see LoginGraceTime in sshd_config(4))

The following /etc/default/login parameters:

- UMASK
- ULIMIT

...set the umask(2) and file size limit of, respectively, the shells and commands spawned by sshd.

Finally, two /etc/default/login parameters affect the maximum allowed login attempts per-connection using interactive user authentication methods (for example, keyboard-interactive but not publickey), as per login(1):

- RETRIES
- SYSLOG_FAILED_LOGINS

/etc/ssh/sshd_config
 Contains configuration data for sshd. This file should be writable by root only, but it is recommended (though not necessary) that it be world-readable.

/etc/ssh/ssh_host_key
/etc/ssh/ssh_host_dsa_key
/etc/ssh/ssh_host_rsa_key
 Contains the private part of the host key. This file should only be owned by root, readable only by root, and not accessible to others. sshd does not start if this file is group/world-accessible.

/etc/ssh/ssh_host_key.pub
/etc/ssh/ssh_host_dsa_key.pub
/etc/ssh/ssh_host_rsa_key.pub
 Contains the public part of the host key. This file should be world-readable but writable only by root. Its contents should match the private part. This file is not used for encryption; it is provided only for the convenience of the user so its contents can be copied to known hosts files. These two files are created using ssh-keygen(1).

/var/run/sshd.pid
 Contains the process ID of the sshd listening for connections. If there are several daemons running concurrently for different ports, this contains the pid of the one started last. The content of this file is not sensitive; it can be world-readable. You can use the PidFile keyword in sshd_config to specify a file other than /var/run/sshd.pid. See sshd_config(4).

/etc/ssh/ssh_known_hosts and $HOME/.ssh/known_hosts
 These files are consulted when using rhosts with public key host authentication to check the public key of the host. The key must be listed in one of these files to be accepted. The client uses the same files to verify that the remote host is the one it intended to connect.

These files should be writable only by root or the owner. /etc/ssh/ssh_known_hosts should be world-readable, and $HOME/.ssh/known_hosts can but need not be world-readable.

/etc/nologin

If this file exists, sshd refuses to let anyone except root log in. The contents of the file are displayed to anyone trying to log in, and non-root connections are refused. The file should be world-readable.

$HOME/.ssh/authorized_keys

Lists the public keys (RSA or DSA) that can be used to log into the user's account. This file must be readable by root. This might, on some machines, imply that it is world-readable if the user's home directory resides on an NFS volume. It is recommended that it not be accessible by others. The format of this file is described above. Users will place the contents of their identity.pub, id_dsa.pub and/or id_rsa.pub files into this file, as described in ssh-keygen(1).

$HOME/.rhosts

This file contains host-username pairs, separated by a space, one per line. The given user on the corresponding host is permitted to log in without password. The same file is used by rlogind and rshd. The file must be writable only by the user; it is recommended that it not be accessible by others. It is also possible to use netgroups in the file. Either host or user name may be of the form +@*groupname* to specify all hosts or all users in the group.

$HOME/.shosts

For ssh, this file is exactly the same as for .rhosts. However, this file is not used by rlogin and rshd, so using this permits access using SSH only.

/etc/hosts.equiv

This file is used during .rhosts authentication. In its simplest form, this file contains host names, one per line. Users on these hosts are permitted to log in without a password, provided they have the same user name on both machines. The host name can also be followed by a user name; such users are permitted to log in as any user on this machine (except root). Additionally, the syntax +@*group* can be used to specify netgroups. Negated entries start with a hyphen (-).

If the client host/user is successfully matched in this file, login is automatically permitted, provided the client and server user names are the same. Additionally, successful RSA host authentication is normally required. This file must be writable only by root; it is recommended that it be world-readable.

Warning: It is almost never a good idea to use user names in hosts.equiv. Beware that it really means that the named user(s) can log in as anybody, which includes bin, daemon, adm, and other accounts that own critical binaries and directories. For practical purposes, using a user name grants the user root access. Probably the only valid use for user names is in negative entries. This warning also applies to rsh/rlogin.

/etc/ssh/moduli
    A private file.

/etc/ssh/shosts.equiv
    This file is processed exactly as /etc/hosts.equiv. However, this file might be useful in
    environments that want to run both rsh/rlogin and ssh.

$HOME/.ssh/environment
    This file is read into the environment at login (if it exists). It can contain only empty lines,
    comment lines (that start with #), and assignment lines of the form *name=value*. The file
    should be writable only by the user; it need not be readable by anyone else. Environment
    processing is disabled by default and is controlled by means of the
    PermitUserEnvironment option.

$HOME/.ssh/rc
    If this file exists, it is run with /bin/sh after reading the environment files but before
    starting the user's shell or command. If X11 spoofing is in use, this will receive the proto
    cookie pair in standard input (and DISPLAY in environment). This must call xauth in that
    case.

    The primary purpose of $HOME/.ssh/rc is to run any initialization routines that might be
    needed before the user's home directory becomes accessible; AFS is a particular example of
    such an environment. If this file exists, it is run with /bin/sh after reading the environment
    files, but before starting the user's shell or command. It must not produce any output on
    stdout; stderr must be used instead. If X11 forwarding is in use, it will receive the proto
    cookie pair in its standard input and DISPLAY in its environment. The script must call
    xauth because sshd will not run xauth automatically to add X11 cookies.

    This file will probably contain some initialization code followed by something similar to:

```
if read proto cookie && [ -n "$DISPLAY" ]
then
  if [ `echo $DISPLAY | cut -c1-10` = 'localhost:' ]
  then
    # X11UseLocalhost=yes
    echo add unix:`echo $DISPLAY |
    cut -c11-` $proto $cookie
  else
    # X11UseLocalhost=no
    echo add $DISPLAY $proto $cookie
  fi | xauth -q -
fi
```

    If this file does not exist, /etc/ssh/sshrc is run, and if that does not exist, xauth is used to
    store the cookie. $HOME/.ssh/rc should be writable only by the user, and need not be
    readable by anyone else.

/etc/ssh/sshrc

Similar to $HOME/.ssh/rc. This can be used to specify machine-specific login-time initializations globally. This file should be writable only by root, and should be world-readable.

Security sshd supports the use of several user authentication mechanisms: a public key system where keys are associated with users (through users' authorized_keys files), a public key system where keys are associated with hosts (see the HostbasedAuthentication configuration parameter), a GSS-API based method (see the GssAuthentication and GssKeyEx configuration parameters) and three initial authentication methods: none, password, and a generic prompt/reply protocol, keyboard-interactive.

sshd negotiates the use of the GSS-API with clients only if it has a GSS-API acceptor credential for the "host" service. This means that, for GSS-API based authentication, the server must have a Kerberos V keytab entry (see below) or the equivalent for any other GSS-API mechanism that might be installed.

In order for Kerberos authentication to work, a host/*<FQDN>* Kerberos principal must exist for each Fully Qualified Domain Name associated with the in.sshd server. Each of these host/*<FQDN>* principals must have a keytab entry in the /etc/krb5/krb5.keytab file on the in.sshd server. An example principal might be:

host/bigmachine.eng.example.com

See kadmin(1M) or gkadmin(1M) for instructions on adding a principal to a krb5.keytab file. See *Oracle Solaris Administration: Security Services* for a discussion of Kerberos authentication.

GSS-API authorization is covered in gss_auth_rules(5).

sshd uses pam(3PAM) for the three initial authentication methods as well as for account management, session management, and password management for all authentication methods.

Specifically, sshd calls pam_authenticate() for the "none," "password" and "keyboard-interactive" SSHv2 userauth types. Other SSHv2 authentication methods do not call pam_authenticate(). pam_acct_mgmt() is called for each authentication method that succeeds.

pam_setcred() and pam_open_session() are called when authentication succeeds and pam_close_session() is called when connections are closed.

pam_open_session() and pam_close_session() are also called when SSHv2 channels with ptys are opened and closed.

Each SSHv2 userauth type has its own PAM service name:

SSHv2 Userauth	PAM Service Name
none	sshd-none
password	sshd-password
keyboard-interactive	sshd-kbdint
pubkey	sshd-pubkey
hostbased	sshd-hostbased
gssapi-with-mic	sshd-gssapi
gssapi-keyex	sshd-gssapi

If pam_acct_mgmt() returns PAM_NEW_AUTHTOK_REQD (indicating that the user's authentication tokens have expired), then sshd forces the use of "keyboard-interactive" userauth, if version 2 of the protocol is in use. The "keyboard-interactive" userauth will call pam_chauthtok() if pam_acct_mgmt() once again returns PAM_NEW_AUTHTOK_REQD. By this means, administrators are able to control what authentication methods are allowed for SSHv2 on a per-user basis.

Setting up Host-based Authentication

To establish host-based authentication, you must perform the following steps:

- Configure the client.
- Configure the server.
- Publish known hosts.
- Make appropriate entries in /etc/ssh/shosts.equiv and ~/.shosts.

These steps are expanded in the following paragraphs.

- On a client machine, in the system-wide client configuration file, /etc/ssh/ssh_config, you must have the entry:

  ```
  HostbasedAuthentication yes
  ```

  See ssh_config(4) and ssh-keysign(1M).

- On the server, in the system-wide server configuration file, /etc/ssh/sshd_config, you must have the entry:

  ```
  HostbasedAuthentication yes
  ```

  If per-user .shost files are to be allowed (see last step), in the same file, you must have:

  ```
  IgnoreRhosts no
  ```

  See sshd_config(4) for a description of these keywords.

- To publish known hosts, you must have entries for the clients from which users will be allowed host-based authentication. Make these entries in either or both of the system-wide file (/etc/ssh/ssh_known_hosts) or the per-user file (~/.ssh/known_hosts).

- Note that sshd uses .shosts, not .rhosts. If you want the functionality provided by .rhosts, but do not want to use rlogin or rsh because of their security shortcomings, you can use .shosts in conjunction with sshd. To use this feature, make appropriate entries in /etc/ssh/shosts.equiv and ~/.shosts, in the format specified in rhosts(4).

For the vast majority of network environments, .shosts is preferred over .rhosts.

Using X.509 Certificates as Host Keys and User Identities

SSH commands can work with X.509v3 certificates when used as host keys and/or user identities. When used this way, PKCS#11 URIs can be used instead of plain filenames to locate keys and certificates. Host keys, user identities, and their corresponding certificates used for X.509 public key authentication can be stored only in PKCS#11 tokens. The only PKCS#11 URI attributes used by SSH are object, token, and pinfile. If no hardware keystore is available, the PKCS#11 softtoken keystore can be used.

For certificate validation (a server that authenticates a user, or a client that authenticates a server), the KMF policy needs a certificate mapper. Mappers are not set in the default policy file. See TrustedAnchorKeystore, KMFPolicyDatabase, and KMFPolicyName options in sshd_config(4), and see libkmf(3LIB) for more information.

Self-signed certificates can only be used as host keys, never as user identities. If a self-signed certificate is used or if a host certificate cannot be validated on the client side due to a missing relevant trusted anchor certificate, the SSH client offers to store the key in the known_host database, as is currently done with plain public keys. Only the public key is extracted from the certificate and stored in the database, thus maintaining the current format. The reason for accepting such a certificate on the client side is that the initial host Key Exchange is not restartable. Given this, if a server uses certificates as its only host key(s), a client that is unable to validate the certificate would otherwise be denied from logging in.

See the EXAMPLES section for guidance on how to use the X.509 authentication.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/ssh
Interface Stability	Committed

The interface stability of /etc/ssh/moduli is Private.

See Also kmfcfg(1), login(1), pktool(1), scp(1), ssh(1), ssh-add(1), ssh-agent(1), ssh-keygen(1), svcs(1), gkadmin(1M), kadmin(1M), sftp-server(1M), ssh-keysign(1M), svcadm(1M), libkmf(3LIB), pam(3PAM), rhosts(4), ssh_config(4), sshd_config(4), attributes(5), gss_auth_rules(5), kerberos(5), pam_roles(5), pkcs11_softtoken(5), smf(5)

Oracle Solaris Administration: Security Services

Notes The sshd service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/network/ssh:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

sshd always sets PAM_RHOST and sets PAM_AUSER in the case of host-based userauth. This behavior allows for remote logins to roles using host-based authentication. See pam_roles(5).

Name ssh-keysign – ssh helper program for host-based authentication

Synopsis `ssh-keysign`

Description ssh-keysign is used by ssh(1) to access the local host keys and generate the digital signature required during host-based authentication with SSH protocol version 2. This signature is of data that includes, among other items, the name of the client host and the name of the client user.

ssh-keysign is disabled by default and can be enabled only in the global client configuration file /etc/ssh/ssh_config by setting HostbasedAuthentication to yes.

ssh-keysign is not intended to be invoked by the user, but from ssh. See ssh(1) and sshd(1M) for more information about host-based authentication.

Files /etc/ssh/ssh_config   Controls whether ssh-keysign is enabled.

/etc/ssh/ssh_host_dsa_key
/etc/ssh/ssh_host_rsa_key   These files contain the private parts of the host keys used to generate the digital signature. They should be owned by root, readable only by root, and not accessible to others. Because they are readable only by root, ssh-keysign must be set-uid root if host-based authentication is used.

Security ssh-keysign will not sign host-based authentication data under the following conditions:

- If the HostbasedAuthentication client configuration parameter is not set to yes in /etc/ssh/ssh_config. This setting cannot be overriden in users' ~/.ssh/ssh_config files.

- If the client hostname and username in /etc/ssh/ssh_config do not match the canonical hostname of the client where ssh-keysign is invoked and the name of the user invoking ssh-keysign.

In spite of ssh-keysign's restrictions on the contents of the host-based authentication data, there remains the ability of users to use it as an avenue for obtaining the client's private host keys. For this reason host-based authentication is turned off by default.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	network/ssh
Interface Stability	Committed

See Also ssh(1), sshd(1M), ssh_config(4), attributes(5)

Authors Markus Friedl, `markus@openbsd.org`

History `ssh-keysign` first appeared in Ox 3.2.

Name statd – network status monitor

Synopsis /usr/lib/nfs/statd

Description statd is an intermediate version of the status monitor. It interacts with lockd(1M) to provide the crash and recovery functions for the locking services on NFS. statd keeps track of the clients with processes which hold locks on a server. When the server reboots after a crash, statd sends a message to the statd on each client indicating that the server has rebooted. The client statd processes then inform the lockd on the client that the server has rebooted. The client lockd then attempts to reclaim the lock(s) from the server.

statd on the client host also informs the statd on the server(s) holding locks for the client when the client has rebooted. In this case, the statd on the server informs its lockd that all locks held by the rebooting client should be released, allowing other processes to lock those files.

lockd is started by automountd(1M), mount_nfs(1M), and share(1M) if NFS automounts are needed.

Files
/var/statmon/sm	lists hosts and network addresses to be contacted after a reboot
/var/statmon/sm.bak	lists hosts and network addresses that could not be contacted after last reboot
/var/statmon/state	includes a number which changes during a reboot
/usr/include/rpcsvc/sm_inter.x	contains the rpcgen source code for the interface services provided by the statd daemon.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/nfs

See Also svcs(1), automountd(1M), lockd(1M), mount_nfs(1M), share(1M), svcadm(1M), attributes(5), smf(5)

Oracle Solaris Administration: IP Services

Notes The crash of a server is only detected upon its recovery.

The statd service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/nfs/status

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

If it is disabled, it will be enabled by mount_nfs(1M), share_nfs(1M), and automountd(1M) unless its application/auto_enable property is set to false.

Name stclient – Service Tag Administration Program

Synopsis `stclient -x | -E [-r` *root_dir*`]`

`stclient -a [-i` *instance_URN*`] -p` *product_name* `-e` *product_version*
    `-t` *product_URN* `[-F` *parent_URN*`] -P` *product_parent*
    `[-I` *product_defined_instance_id*`] -m` *product_vendor* `-A` *platform_arch*
    `-z` *container* `-S` *source* `[-r` *root_dir*`]`

`stclient -u -i` *instance_URN* `-F` *parent_URN* `-I` *product_defined_instance_id*
    `[-r` *root_dir*`]`

`stclient -d -i` *instance_URN* `[-r` *root_dir*`]`

`stclient -g -i` *instance_URN* `[-r` *root_dir*`]`

`stclient -f -t` *product_URN* `[-r` *root_dir*`]`

`stclient -h`

`stclient -v`

Description The `stclient` command displays, finds, adds, updates and deletes records in the Service Tag registry. The registry is in the XML file `/var/sadm/servicetag/registry/servicetag.xml`, and contains the inventory of the product instances installed in the machine. Each record has a unique product instance identifier which is generated when the service tag is added in the registry. This product instance identifier is used as a key when finding, updating or deleting the service tag records. The extract option prints out the registry contents in XML format in stdout.

The `stclient` command also runs in interactive mode. This mode is invoked by running `stclient` without any parameters. A menu of all the available options are displayed, and the user is prompted to enter different parameters depending on the option chosen.

Any user can extract or get the contents of the registry, but only users with the appropriate privileges, the "svctag" user, or the creator of the service tag is authorized to update or delete a service tag record.

Options The following options are supported:

-p *product_name*	Sets the product name of the service tag to be added. For example, "stclient -p "Solaris 10 Operating System"" sets the product name to the "Solaris 10 Operating System".
-e *product_version*	Sets the product version of the service tag to be added. For example, "stclient -e 5.10" sets the product version to "5.10".
-t *product_URN*	Sets the Sun product unique identifier of the service tag to be added. For example, "stclient -t urn:uuid:5005588c-36f3-11d6-9cec-fc96f718e113" sets

the Sun product unique identifier to
"urn:uuid:5005588c-36f3-11d6-9cec-fc96f718e113".

-i *instance_URN*	Sets the product instance unique identifier of the service tag. For example, "stclient -i 3a444ab2-1dd2-11b2-a69d-830020782a6b" sets the product instance unique identifier to "3a444ab2-1dd2-11b2-a69d-830020782a6b" This field may also be set when the service tag is added but is not typically used. The generation of the instance ID is normally left to the stclient.
-F *product_parent_URN*	Sets the Sun product unique identifier of parent product. For example, "stclient -F urn:uuid:5005588c-36f3-11d6-9cec-fc96f718e113" sets the Sun product unique identifier of parent product to "urn:uuid:5005588c-36f3-11d6-9cec-fc96f718e113".
-P *product_parent*	Sets the parent product of the service tag. For example, "stclient -P JES" sets the product parent to "JES".
-I *product_defined_instance_id*	Sets the product defined instance identifier. For example, "stclient -I ser:abc-klm-000-7190" sets the product defined instance identifier to "ser:abc-klm-000-7190".
-m *product_vendor*	Sets the vendor of the product. For example, "stclient –m Sun" sets the product vendor to "Sun".
-A *platform_arch*	Sets the platform architecture that the product is running on. For example, "stclient –A sparc" sets the platform architecture to "sparc"
-z *container*	Sets the container that the product is running on. For example, "stclient -z "global zone"" sets the container to "global zone".
-S *source*	Sets the source of this service tag, naming the entity that created it.
-r *root_dir*	Sets the root directory where the command searches for the registry. The command searches /var/sadm/servicetag/registry by default. When this option is used, the command looks for the Registry in the specified root directory, (for example, "-r /home/user1" searches /home/user1/var/sadm/servicetag). This is typically used for testing.

Operands

Function Letters The function portion of the key is specified by one of the following letters:

x   Extract. Extracts and prints the contents of the Service Tag registry in XML format. An
     alternate root directory may be specified for testing purposes.

a   Add. Adds a service tag in the registry. A unique product instance identifier may be
     supplied and is automatically generated if not provided. This field is returned by the
     command. The required fields for add are product name, product version, product
     URN, product parent, vendor, platform architecture, container and source.

u   Update. Updates a service tag in the registry using the product instance URN as the key.
     The parent URN and product defined instance id fields can be updated.

d   Delete. Deletes a service tag in the registry using the product instance URN as the key.

E   Extract Environment. Enumerates to standard output the environmental or "agent'"
     information associated with the registered Service Tags on this system.

g   Get. Gets and prints a service tag from the registry using the product instance URN as
     the key.

f   Find. Finds and prints all the instance URNs of a given product URN.

h   Help. Displays the command options.

v   Version. Displays the version number of the command.

Exit Status The following exit values are returned:

0   Successful completion.

> 0   An error occurred.

Examples EXAMPLE 1   Adding a Service Tag in the Registry

To add a service tag, enter the following:

```
# stclient -a -p "Java Enterprise Web Server 6.0" -e 6.0 \
   -t urn:uuid:f2b8b59c-6eba-11d7-986f-9f5d47ec72fe  \
   -P Java Enterprise Server -m Sun -A sparc -z global -S patch
```

The screen displays the following:

```
Java Enterprise Web Server 6.0 6.0 added
Product instance URN=urn:st:7fc61914-1dd2-11b2-b992-830020782a6b
```

EXAMPLE 2   Updating a Service Tag in the Registry

To update a service tag, enter the following:

EXAMPLE 2 Updating a Service Tag in the Registry   *(Continued)*

```
# stclient -u -i 7fc61914-1dd2-11b2-b992-830020782a6b \
   -I urn:st:product.defined.id
```

The screen displays the following:

```
Service tag updated
```

EXAMPLE 3 Extracting a Service Tag Registry

To extract a service tag, enter the following:

```
# stclient -x
```

The screen displays output similar to the following:

```
<?xml version="1.0" encoding="UTF-8"?>
<registry urn="urn:uuid:1234ab-00e1-11b3-98737646873" version="1.0">
   <service_tag>
  .
  .
  .
   </service_tag>
 </registry>
```

EXAMPLE 4 Finding all product instances

To find all product instances, enter the following:

```
# stclient -f -t urn:uuid:f2b8b59c-6eba-11d7-986f-9f5d47ec72fe \
   fc61914-1dd2-11b2-b992-830020782a6b
```

EXAMPLE 5 Listing the Environmental Information

To list the environmental information associated with the registered Service Tags on this system, enter the following:

```
# stclient -E
```

The screen displays output similar to the following:

```
<?xml version="1.0" encoding="UTF-8"?>
<agent>
   <agent_urn>urn:st:af15ee62-0bb3-ef2d-fa96-85a11996cc71</agent_urn>
  .
  .
  .
   </system_info>
 </agent>
```

Environment Variables See environ(5) for descriptions of the following environment variables that affect the execution of stclient: LANG, LC_ALL, LC_CTYPE, LC_MESSAGES, and NLSPATH.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/management/service-tag
Interface Stability	Committed

stmfadm list-tg [-v] [*target-group-name*...]

stmfadm list-lu [-v] [*lu-name*...]

stmfadm list-target [-v] [*target-name*...]

stmfadm list-view -l, --lu-name *lu-name* [*entry-name*...]

stmfadm list-state

stmfadm modify-lu [-p, --lu-prop *logical-unit-property*=*val*
        -s, --size *size*, -f, --file] *lu-name*|*lu-file*

stmfadm online-lu *lu-name*

stmfadm offline-lu *lu-name*

stmfadm online-lu *target-name*

stmfadm offline-lu *target-name*

stmfadm remove-hg-member -g, --group-name *group-name* *group-member*...

stmfadm remove-tg-member -g, --group-name *group-name* *group-member*...

stmfadm remove-view -l, --lu-name *lu-name* *entry-name*

Description The stmfadm command configures logical units within the SCSI Target Mode Framework (STMF) framework. The framework and this man page use the following terminology:

initiator
    A device responsible for issuing SCSI I/O commands to a SCSI target and logical unit.

target
> A device responsible for receiving SCSI I/O commands for a logical unit.

logical unit
> A device within a target responsible for executing SCSI I/O commands.

logical unit number
> The identifier of a logical unit within a target.

initiator group
> An initiator group is a set of one or more initiators that are combined for the purposes of being applied to a *view* (see below). An initiator cannot be a member of more than one initiator group.

target group
> A target group is a set of one or more SCSI target ports that are treated the same when creating a *view* (see below). The set of logical units that a particular SCSI initiator can see is determined by the combined set of views.
>
> Each logical unit has a set of view entries, and each view entry specifies a target group, host group, and a LUN. An initiator from that host group, when connecting through that target group, is able to identify and connect to that logical unit using the specified LUN. You can use views to restrict the set of logical units that a specific initiator can see, and assign the set of LUNs that will be used.

view
> A view defines the association of an initiator group, a target group, and a logical unit number with a specified logical unit. Any view entry added to a logical unit must not be in conflict with existing view entries for that logical unit. A view entry is considered to be in conflict when an attempt is made to duplicate the association of any given initiator, target and logical unit number. As an example, logical unit LU_0 has the following view entry associated with it:
>
> ```
> Logical Unit: LU_0
>         View Entry: 0
>             initiator group: HostA
>             target group: All targets
>             logical unit number: 32
> ```
>
> If you attempted the following:
>
> ```
> # stmf add-view -n 31 -h HostA LU_0
> ```
>
> ...the operation would return an error with a message indicating that the view entry is in conflict with one or more existing view entries. This conflict arises because the existing view entry, 0, already has mapped LU_0 to logical unit number 32 for the initiator group HostA.

Sub-commands   The `stmfadm` command supports the subcommands listed below.

add-view [-n, --lun *logical-unit-number* -t, --target-group *group-name* -h, --host-group *group-name*] *lu-name*
> Adds a logical unit view entry to a logical unit *lu-name*, where *lu-name* is the STMF name for the logical unit as displayed by the `list-lu` subcommand. The `add-view` subcommand provides the user with a mechanism to implement access control for a logical unit and also provides a means of assigning a logical unit number to a logical unit for a given set of initiators and targets. A logical unit will not be available to any initiators until at least one view is applied. Each view entry gets assigned an entry name, which can be used to reference the entry in the `remove-view` and `list-view` subcommands.

> `add-view` supports the following options:

> -n, --lun *logical-unit-number*
>> *logical-unit-number* is an integer in the range 0-16383 to be assigned to the logical unit for this view entry. If this option is not specified, a logical unit number will be assigned by the STMF framework.

> -t, --target-group *group-name*
>> *group-name* is the name of a target group previously created using the STMF `create-tg` subcommand. If this option is not specified, the logical unit will be available through all targets.

> -h, -host-group *group-name*
>> *group-name* is the name of an host group previously created using the STMF `create-hg` subcommand. If this option is not specified, the logical unit will be available to all initiators that log in to the STMF framework.

add-hg-member -g *group-name group member*...
> Add a host group member to a host group. *group-name* must be an existing group created using the `create-hg` subcommand. *group member* can be specified as *name_type.name_value*, where *name_type* can be one of the following:

> wwn
> iqn
> eui

> ...and *name_value* is the value of the initiator name. As an example, to add a fibre channel initiator port world-wide name `200000e08b909221` to the host group `HostA`, the command would be:

> **# stmfadm add-hg-member -g HostA wwn.200000e08b909221**

> To add an ISCSI initiator node member with the name `iqn.1986-03.com.sun:01.46f7e262` to `HostA`, the command would be:

> **# stmfadm add-hg-member -g HostA iqn.1986-03.com.sun:01.46f7e262**

> Alternatively, members can be specified using their SCSI name string identifiers. To add the two initiators above using their SCSI name string identifiers, the commands would be:

```
# stmfadm add-hg-member -g HostA eui.200000e08b909221
# stmfadm add-hg-member -g HostA iqn.1986-03.com.sun:01.46f7e262
```

A host group member cannot be a member of more than one host group.

add-tg-member -g *group-name group member*...

Add a target group member to a target group. *group-name* must be an existing group created using the create-tg subcommand. *group member* can be specified as *name_type.name_value*, where *name_type* can be one of the following:

```
wwn
iqn
eui
```

...and *name_value* is the value of the target name. As an example, to add a fibre channel target port world-wide name 501000e092376af7 to the target group TG0, the command would be:

```
# stmfadm add-tg-member -g TG0 wwn.501000e092376af7
```

To add an ISCSI target member with the name iqn.1986-03.com.sun:target.01.01110 to TG0, the command would be:

```
# stmfadm add-tg-member -g TG0 iqn.1986-03.com.sun:target.01.01110
```

Alternatively, members can be specified using their SCSI name string identifiers. To add the two targets above using their SCSI name string identifiers, the commands would be:

```
# stmfadm add-tg-member -g TG0 eui.501000e092376af7
# stmfadm add-tg-member -g TG0 iqn.1986-03.com.sun:target.01.01110
```

A target group member cannot be a member of more than one target group.

create-hg *group-name*

Create an initiator group with the name *group-name*. *group-name* is a string of Unicode characters with a maximum length of 255. The group name must be unique within the STMF system.

create-lu [-p, --lu-prop *logical-unit-property=val* --s, --size *size*] *lu-file*

Create a logical unit that can be registered with STMF. For the -p option, *logical-unit-property* can be one of the following properties:

alias

Up to 255 characters, representing a user-defined name for the device. The default is the name of the backing store.

blk

Specifies the block size for the device. The default is 512, but do not set this value higher than 4096 KB.

guid

Thirty–two hexadecimal ASCII characters representing a valid NAA Registered Extended Identifier. The default is set by the STMF to a generated value.

host-id

   Eight hexadecimal ASCII characters representing the host ID assignment. This will be
   used to generate the globally unique identifier (GUID) for the logical unit. The default is
   the value returned by hostid(1).

meta

   Metadata file name. When specified, will be used to hold the SCSI metadata for the
   logical unit. There is no default.

mgmt-url

   Up to 1024 characters representing a Management Network Address URL. More than
   one URL can be passed as a single parameter by using space-delimited URLs enclosed
   inside a single pair of quotation marks (").

oui

   Organizational Unique Identifier. Six hexadecimal ASCII characters representing the
   IEEE OUI company ID assignment. This will be used to generate the device identifier
   (GUID). The default is 00144F.

pid

   Sixteen characters of product identification SCSI SPC-3. This value will be reflected in
   the Standard INQUIRY data returned for the device. The default is COMSTAR.

serial

   Serial Number. Specifies the SCSI Vital Product Data Serial Number (page 80h). It is a
   character value up to 252 bytes in length. There is no default value.

vid

   Eight characters of vendor identification per SCSI SPC-3. This value will be reflected in
   the Standard INQUIRY data returned for the device. The default is SUN.

wcd

   Write-back cache disable. Specify true or falseto determine write-back cache disable
   behavior. The default is the write-back cache setting of the backing store device specified
   by the *lu-file* argument.

wp

   Write-protect bit. Specify true or false to determine whether the device reports as
   write-protected. The default is false.

For the -s option, *size* is an integer followed by one of the following letters, to indicate a
unit of size:

k   kilobyte

m   megabyte

g   gigabyte

t   terabyte

p   petabyte

e   exabyte

lu-file is the file to be used as the backing store for the logical unit. If the `-s` option is not specified, the size of the specified *lu-file* will be used as the size of the logical unit. Logical units registered with the STMF require space for the metadata to be stored. When a `zvol` is specified as the backing store device, the default will be to use a special property of the `zvol` to contain the metadata. For all other devices, the default behavior will be to use the first 64k of the device. An alternative approach would be to use the `meta` property in a `create-lu` command to specify an alternate file to contain the metadata. It is advisable to use a file that can provide sufficient storage of the logical unit metadata, preferably 64k.

`create-tg` *group-name*
> Create a target group with the name *group-name*. *group-name* is a string of Unicode characters with a maximum length of 255. The group name must be unique within the STMF system.

`delete-hg` *group-name*
> Delete the host group that identified by *group-name*.

`delete-lu` *lu-name*
> Deletes an existing logical unit that was created using `stmfadm create-lu`. This effectively unloads the logical unit from the STMF framework. Any existing data on the logical unit remains intact.

`delete-tg` *group-name*
> Delete the target group that identified by *group-name*.

`import-lu` *lu-file*
> Imports and loads a logical unit into the STMF that was previously created using `stmfadm create-lu` and was then deleted from the STMF using `stmfadm delete-lu`. On success, the logical unit is again made available to the STMF. *lu-file* is the filename used in the `stmfadm create-lu` command. If this logical unit is using a separate metadata file, the filename in the `meta` property value that was used in the `stmfadm create-lu` command must be used here.

`list-hg` [`-v,--verbose`] [*host-group-name*...]
> Lists information for the host group in the system referenced by *host-group-name*. If *host-group-name* is not specified, all host groups in the system will be listed. If the `--v` or `--verbose` option is specified, all members within a host group are displayed.

`list-lu` [`-v,--verbose`] [*lu-name*...]
> Lists information for the logical unit in the system referenced by *lu-name*. If *lu-name* is not specified, all logical units in the system will be listed. If the `-v` or `--verbose` option is specified, additional information about the logical unit will be displayed.

list-target [-v,--verbose] [*target-name*...]
Lists information for the target port in the system referenced by *target-name*. If target name is not specified, all target ports in the system will be listed. If the -v or --verbose option is specified, additional information about the target along with SCSI session information for logged-in initiators is displayed.

list-tg [-v,--verbose] [*target-group-name*...]
Lists information for the target group in the system referenced by *target-group-name*. If *target-group-name* is not specified, all target groups in the system will be listed. If the --v or --verbose option is specified, all members within a target group are displayed.

list-view --l, --lu-name *lu-name* [*entry-name*...]
Lists the view entry for the logical unit referenced by *lu-name*. If *entry-name* is not specified, all view entries for the specified logical unit will be listed.

modify-lu [-p, --lu-prop *logical-unit-property*=*val* --s, --size *size*, -f, --file]
lu-name|*lu-file*
Modifies attributes of a logical unit created using the stmfadm create-lu command. For the -p option, *logical-unit-property* can be one of the following properties:

alias
Up to 255 characters, representing a user-defined name for the device. The default is the name of the backing store.

mgmt-url
Up to 1024 characters representing a Management Network Address URL. More than one URL can be passed as a single parameter by using space-delimited URLs enclosed inside a single pair of quotation marks (").

wcd
Write-back cache disable. Specify true or falseto determine write-back cache disable behavior. The default is the write-back cache setting of the backing store device specified by the *lu-file* argument.

wp
Write-protect bit. Specify true or false to determine whether the device reports as write-protected. The default is false.

For the -s option, *size* is an integer followed by one of the following letters, to indicate a unit of size:

k   kilobyte

m   megabyte

g   gigabyte

t   terabyte

p   petabyte

e   exabyte

lu-name is the guid of the logical unit to be modified. If the -f option is specified, the operand is interpreted as a file name. This provides the ability to modify a logical unit that is not currently imported into the STMF.

online-lu *lu-name*
Online a logical unit currently registered with the STMF.

online-target *target-name*
Online the specified target.

offline-lu *lu-name*
Offline a logical unit currently registered with the STMF.

offline-target *target-name*
Offline the specified target.

list-state
Lists the operational and configuration state of the STMF.

remove-hg-member -g *group-name group member*
Removes a host group member from a host group. *group-name* must be an existing group created using the create-hg subcommand. *group member* can be specified as *name_type.name_value*, where *name_type* can be one of the following:

wwn
iqn
eui

...and *name_value* is the value of the initiator name. As an example, to remove the fibre channel initiator port world-wide name 200000e08b909221 from the host group HostA, the command would be:

stmfadm remove-hg-member -g HostA wwn.200000e08b909221

To remove the ISCSI initiator node member with the name iqn.1986-03.com.sun:01.46f7e262 from HostA, the command would be:

stmfadm remove-hg-member -g HostA iqn.1986-03.com.sun:01.46f7e262

Alternatively, members can be specified using their SCSI name string identifiers. To remove the two initiators above using their SCSI name string identifiers, the commands would be:

stmfadm remove-hg-member -g HostA eui.200000e08b909221
stmfadm remove-hg-member -g HostA iqn.1986-03.com.sun:01.46f7e262

remove-tg-member -g *group-name group member*
Removes a target group member from a target group. *group-name* must be an existing group created using the create-tg subcommand. *group member* can be specified as *name_type.name_value*, where *name_type* can be one of the following:

```
wwn
iqn
eui
```

...and *name_value* is the value of the target name. As an example, to remove the fibre channel target port world-wide name 501000e092376af7 from the target group TG0, the command would be:

```
# stmfadm remove-tg-member -g TG0 wwn.501000e092376af7
```

To remove the ISCSI target member with the name iqn.1986-03.com.sun:target.01.01110 from TG0, the command would be:

```
# stmfadm remove-tg-member -g TG0 iqn.1986-03.com.sun:target.01.01110
```

Alternatively, members can be specified using their SCSI name string identifiers. To remove the two targets above using their SCSI name string identifiers, the commands would be:

```
# stmfadm remove-tg-member -g TG0 eui.501000e092376af7
# stmfadm remove-tg-member -g TG0 iqn.1986-03.com.sun:target.01.01110
```

remove-view --l, --lu-name *lu-name entry-name*
    Removes one or more logical unit view entries from a logical unit.

Examples   **EXAMPLE 1**   Creating a Host group with Two Initiator Ports

The following commands use the create-hg and add-hg-member subcommands to create a host group and add two initiator ports to that host group.

```
# stmfadm create-hg host-group-a
# stmfadm add-hg-member -g host-group-a wwn.210105b0000d92d0
```

EXAMPLE 2   Adding a View Entry to a Logical Unit

The following command uses the add-view subcommand to allow access from host-group-a to a logical unit.

```
# stmfadm add-view -h host-group-a 6000AE40C5000000000046FC4FEA001C
```

EXAMPLE 3   Listing a View Entry

The following command uses the list-view subcommand to list all view entries for the specified logical unit.

```
# stmfadm list-view -l 6000AE40C5000000000046FC4FEA001C
View Entry: 0
              Host group      : host-group-a
              Target group    : All
              LUN             : 0
```

Name stmsboot – administration program for the Solaris I/O multipathing feature

Synopsis /usr/sbin/stmsboot [[-D (fp | mpt | mpt_sas | iscsi)] -d | -e | -u]
    | -L | -l *controller_number*]

Description The Solaris I/O multipathing feature is a multipathing solution for storage devices that is part of the Solaris operating environment. This feature was formerly known as Sun StorEdge Traffic Manager (STMS) or MPxIO.

The stmsboot program is an administrative command to manage enumeration of multipath–capable devices with Solaris I/O multipathing. Solaris I/O multipathing-enabled devices are enumerated under scsi_vhci(7D), providing multipathing capabilities. Solaris I/O multipathing-disabled devices are enumerated under the physical controller.

In the /dev and /devices trees, Solaris I/O multipathing-enabled devices receive new names that indicate that they are under Solaris I/O multipathing control. This means a device will have a different name from its original name (after enabling) when it is under Solaris I/O multipathing control. The stmsboot command automatically updates /etc/vfstab and dump configuration to reflect the device names changes when enabling or disabling Solaris I/O multipathing. One reboot is required for changes to take effect.

Options The following options are supported:

-e [-E fp | mpt | mpt_sas | iscsi]
    Enables Solaris I/O multipathing on all supported multipath-capable controller ports, including fp(7d), mpt(7D), mpt_sas(7D), and iscsi(7D) port drivers. Multipath-capable ports include fibre channel (fp(7d)) controller ports and SAS (mpt(7D) or mpt_sas(7D)) controller ports. Following this enabling, you are prompted to reboot. During the reboot, vfstab and the dump configuration will be updated to reflect the device name changes. Specifying -D mpt, -D mpt_sas, or -D fp limits the enabling operation to ports attached using the specified driver.

-d [-D fp | mpt | mpt_sas | iscsi]
    Disables Solaris I/O multipathing on all supported multipath-capable controller ports, including fp(7d), mpt(7D), mpt_sas(7D), and iscsi(7D) port drivers. Multipath-capable ports include fibre channel (fp(7d)) controller ports and SAS (mpt(7D) or mpt_sas(7D)) controller ports. Following this disabling, you are prompted to reboot. During the reboot, vfstab and the dump configuration will be updated to reflect the device name changes. Specifying -D mpt, -D mpt_sas, or -D fp limits the disabling operation to ports attached using the specified driver.

-u [-D fp | mpt | mpt_sas | iscsi]
    Updates vfstab and the dump configuration after you have manually modified the configuration to have Solaris I/O multipathing enabled or disabled on specific fp(7d), mpt(7D), mpt_sas(7D), and iscsi(7D) controller ports. This option prompts you to reboot. During the reboot, vfstab and the dump configuration will be updated to reflect the device name changes.

-L

Display the device name changes from non-Solaris I/O multipathing device names to Solaris I/O multipathing device names for multipath-enabled controller ports. If Solaris I/O multipathing is not enabled, then no mappings are displayed.

-l *controller_number*

Display the device name changes from non-Solaris I/O multipathing device names to Solaris I/O multipathing device names for the specified controller. If Solaris I/O multipathing is not enabled, then no mappings are displayed.

Note that mpt_sas(7D) has MPxIO turned on by default. This means that when using the -L or -l option with -D mpt_sas, stmsboot does not display any non-multipathed and multipathed device names.

Usage The primary function of stmsboot is to control the enabling and disabling of Solaris I/O multipathing on the host. The utility automatically updates vfstab(4) and dumpadm(1M) configuration to reflect device name changes. The system administrator is responsible for modifying application configuration (for example, backup software, DBMS, and so forth) to reflect updated device names.

The -L and -l options display the mapping between multipathed and non-multipathed device names. These options function only after changes to the Solaris I/O multipathing configuration have taken effect, that is, following the reboot after invoking stmsboot -e.

ZFS datasets, including ZFS root datasets, are correctly handled by stmsboot.

Examples EXAMPLE 1   Enabling Solaris I/O Multipathing

To enable Solaris I/O multipathing for all multipath-capable controllers, run:

```
# stmsboot -e
```

To enable Solaris I/O multipathing on multipath-capable mpt(7D) controller ports, enter:

```
# stmsboot -D mpt -e
```

To enable Solaris I/O multipathing on multipath-capable mpt_sas(7D) controller ports, enter:

```
# stmsboot -D mpt_sas -e
```

To enable Solaris I/O Multipathing on multipath-capable fibre channel controller ports, enter:

```
# stmsboot -D fp -e
```

To enable Solaris I/O Multipathing on multipath-capable iSCSI controller ports, enter:

```
# stmsboot -D iscsi -e
```

EXAMPLE 2 Disabling Solaris I/O Multipathing

To disable Solaris I/O multipathing on all multipath-capable controllers, enter:

```
# stmsboot -d
```

To disable Solaris I/O multipathing on multipath-capable mpt(7D) controller ports, enter:

```
# stmsboot -D mpt -d
```

To disable Solaris I/O multipathing on multipath-capable mpt_sas(7D) controller ports, enter:

```
# stmsboot -D mpt_sas -d
```

To disable Solaris I/O multipathing on multipath-capable iSCSI controller ports, enter:

```
# stmsboot -D iscsi -d
```

To disable Solaris I/O multipathing on multipath-capable fibre channel controller ports, enter:

```
# stmsboot -D fp -d
```

EXAMPLE 3 Enabling Solaris I/O Multipathing on Selected Ports

To enable Solaris I/O multipathing on specific fibre channel controller ports and disable the feature on others, manually edit the /kernel/drv/fp.conf file. (See fp(7d).) The following command will update vfstab(4) and dumpadm(1M) configurations to reflect the changed device names:

```
# stmsboot -u
```

A similar procedure involving the /kernel/drv/mpt.conf file should be followed for devices attached by means of the mpt(7D) driver. For devices attached by means of the iscsi(7D) driver, follow a similar procedure that uses the /kernel/drv/iscsi.conf file.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os, system/library
Interface Stability	Obsolete

Solaris SAN Configuration and Multipathing Guide (see http://docs.oracle.com)

Consult a particular storage product's system administrator's guide and release notes for further information specific to that product.

Notes   Solaris I/O multipathing is not supported on all devices. After enabling Solaris I/O multipathing, only supported devices are placed under Solaris I/O multipathing control. Non-supported devices remain unchanged.

For Solaris releases prior to the current release, the -e and -d options replace mpxio-disable property entries with a global mpxio-disable entry in fp.conf.

Enabling Solaris I/O   The following applies to Sun StorEdge T3, 3910, 3960, 6120, and 6320 storage subsystems.
Multipathing on a Sun
StorEdge Disk Array   To place your Sun StorEdge disk subsystem under Solaris I/O multipathing control, in addition to enabling Solaris I/O multipathing, the mp_support of the subsystem must be set to mpxio mode. The preferred sequence is to change the subsystem's mp_support to mpxio mode, then run stmsboot -e. If Solaris I/O multipathing is already enabled but the subsystem's mp_support is not in mpxio mode, then change the mp_support to mpxio mode and run stmsboot -u.

Refer to the *Sun StorEdge Administrator's Guide* for your subsystem for more details.

Using ufsdump   The ufsdump(1M) command records details of filesystem dumps in /etc/dumpdates (see ufsdump(4)). Among other items, the entries contain device names. An effect of the "active" stmsboot options (-e, -d, and -u) is to change the device name of a storage device.

Because stmsboot does not modify dumpdates, entries will refer to obsolete device names, that is, device names that were in effect before Solaris I/O multipathing configuration changes were performed. In this situation ufsdump will behave as if no previous dump of the filesystem had been performed. A level 0 dump will be performed.

Procedure to Use   If possible, invoke stmsboot -e before installing Sun Cluster software. After executing
stmsboot in   stmsboot, install Sun Cluster software normally.
Conjunction with Sun
Cluster   If Sun Cluster software is installed before executing stmsboot, follow this procedure:

On each machine in the cluster where Solaris I/O multipathing is required, execute:

stmsboot -e

...and allow the system to reboot.

When the system comes up, enter the following two commands:

1. # **/usr/cluster/bin/scdidadm -C**

2. # **/usr/cluster/bin/scdidadm -r**

    The preceding commands update did mappings with new device names while preserving did instance numbers for disks that are connected to multiple cluster nodes. did instance numbers of the local disks might not be preserved. For this reason, the did disk names for local disks might change.

    The remaining steps are required only if local did number changes require editing of /etc/vfstab. If such editing is not required, run /usr/cluster/bin/scgdevs from each node in the cluster to complete the procedure.

3. Update /etc/vfstab to reflect any new did disk names for your local disks.

4. Reboot the system.

To disable the Solaris multipathing feature, use stmsboot -d (instead of stmsboot -e), then follow the procedure above.

To view mappings between the old and new device names, run stmsboot -L. To view did device name mappings, run /usr/cluster/bin/scdidadm -L.

With active-passive storage arrays, it is possible that while your host is rebooting the array controller could failover the path that a particular target is using. In this scenario, fsck(1M) will fail to open the physical path listed in /etc/vfstab. The svc:/system/filesystem/local:default SMF service will transition to a maintenance state as a result. To rectify this, consult the documentation for your storage array to failback the path. The mpathadm(1M) can assist with determining the active and passive path(s).

Limitations On x86 platforms, the current Solaris release does not support disabling Solaris I/O multipathing of boot devices attached by means of fibre channel. Solaris I/O multipathing is always enabled for supported fibre channel-attached boot devices. Disabling Solaris I/O multipathing in this situation must be performed on a per-port basis. See fp(7d).

Executing devfsadm -C removes obsolete device entries that stmsboot relies on. This will prevent correct operation of the -d option for boot devices (regardless of platform type) and the -L option.

Name strace – print STREAMS trace messages

Synopsis strace [*mid sid level*]...

Description strace without arguments writes all STREAMS event trace messages from all drivers and modules to its standard output. These messages are obtained from the STREAMS log driver (see log(7D)). If arguments are provided, they must be in triplets of the form *mid, sid, level*, where *mid* is a STREAMS module ID number, *sid* is a sub-ID number, and *level* is a tracing priority level. Each triplet indicates that tracing messages are to be received from the given module/driver, sub-ID (usually indicating minor device), and priority level equal to, or less than the given level. The token all may be used for any member to indicate no restriction for that attribute.

The format of each trace message output is:

<seq> <time> *<ticks> <level> <flags> <mid> <sid> <text>*

<seq>	trace sequence number
<time>	time of message in *hh:mm:ss*
<ticks>	time of message in machine ticks since boot
<level>	tracing priority level
<flags>	E : message is also in the error log F : indicates a fatal error N : mail was sent to the system administrator (hardcoded as root)
<mid>	module ID number of source
<sid>	sub-ID number of source
<text>	formatted text of the trace message

Once initiated, strace will continue to execute until terminated by the user.

Examples EXAMPLE 1 A sample output of the strace command:

The following example outputs all trace messages from the module or driver whose module ID is 41:

```
strace  41 all all
```

The following example outputs those trace messages from driver or module ID 41 with sub-IDs 0, 1, or 2:

```
strace  41 0 1  41 1 1  41 2 0
```

Messages from sub-IDs 0 and 1 must have a tracing level less than or equal to 1. Those from sub-ID 2 must have a tracing level of 0.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   attributes(5), log(7D)

STREAMS Programming Guide

Notes   ■   There is no restriction to the number of strace processes opening the STREAMS log driver at a time.

■   The log-driver records the list of the triplets specified in the command invocation, and compares each potential trace message against this list to decide if it should be formatted and sent up to the strace process. Hence, long lists of triplets will have a greater impact on overall STREAMS performance. Running strace will have the most impact on the timing of the modules and drivers generating the trace messages that are sent to the strace process. If trace messages are generated faster than the strace process can handle them, some of the messages will be lost. This last case can be determined by examining the sequence numbers on the trace messages output.

Name strclean – STREAMS error logger cleanup program

Synopsis `strclean [-a` *age*`] [-d` *logdir*`]`

Description `strclean` is used to clean up the STREAMS error logger directory on a regular basis (for example, by using `cron`. By default, all files with names matching `error.*` in `/var/adm/streams` that have not been modified in the last three days are removed.

Options The following options are supported:

-a *age*   The maximum age in days for a log file can be changed using the `-a` option.

-d *logdir*   A directory other than `/var/adm/streams` can be specified using the `-d` option.

Examples EXAMPLE 1   A sample of using the `strclean` command.

This example has the same result as running `strclean` with no arguments:

```
example%  strclean -d /var/adm/streams -a 3
```

Files `/var/adm/streams/error.*`

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also `cron(1M)`, `strerr(1M)`, `attributes(5)`

STREAMS Programming Guide

Notes `strclean` is typically run from `cron` on a daily or weekly basis.

Name strerr – STREAMS error logger daemon

Synopsis strerr

Description strerr receives error log messages from the STREAMS-based log driver (see log(7D)) and appends them to a log file. The resultant error log files reside in the directory /var/adm/streams, and are named error.*mm*-dd, where *mm* is the month and dd is the day of the messages contained in each log file.

The format of an error log message is:

<seq> <time> *<ticks>* *<flags>* *<mid>* *<sid>* *<text>*

<seq>	error sequence number
<time>	time of message in hh:mm:ss
<ticks>	time of message in machine ticks since boot priority level
<flags>	T : the message was also sent to a tracing process F : indicates a fatal error N : send mail to the system administrator (hardcoded as root)
<mid>	module ID number of source
<sid>	sub-ID number of source
<text>	formatted text of the error message

Messages that appear in the error log are intended to report exceptional conditions that require the attention of the system administrator. Those messages which indicate the total failure of a STREAMS-based driver or module should have the F flag set. Those messages requiring the immediate attention of the administrator will have the N flag set, which causes the error logger to send the message to the system administrator using mail. The priority level usually has no meaning in the error log but will have meaning if the message is also sent to a tracer process.

Once initiated, strerr continues to execute until terminated by the user. It is commonly executed asynchronously.

Files /var/adm/streams/error.*mm*-dd   error log file.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also attributes(5), log(7D)

STREAMS Programming Guide

Notes There is no restriction to the number of `strerr` processes opening the STREAMS–based log driver at a time.

If a module or driver is generating a large number of error messages, running the error logger will cause a degradation in STREAMS performance. If a large burst of messages are generated in a short time, the log driver may not be able to deliver some of the messages. This situation is indicated by gaps in the sequence numbering of the messages in the log files.

Name sttydefs – maintain line settings and hunt sequences for TTY ports

Synopsis /usr/sbin/sttydefs -a *ttylabel* [-b] [-f *final-flags*]
[-i *initial-flags*] [-n *nextlabel*]

/usr/sbin/sttydefs -l [*ttylabel*]

/usr/sbin/sttydefs -r *ttylabel*

Description sttydefs is an administrative command that maintains the line settings and hunt sequences for the system's TTY ports by making entries in, and deleting entries from the /etc/ttydefs file.

sttydefs with a -a or -r option may be invoked only by the super-user. sttydefs with -l may be invoked by any user on the system.

Options The following options are supported:

-a *ttylabel*   Add a record to the ttydefs file, using *ttylabel* as its label. The following describes the effect of the -b, -n, -i, or -f options when used in conjunction with the -a option:

-b   Enable autobaud. Autobaud allows the system to set the line speed of a given TTY port to the line speed of the device connected to the port without the user's intervention.

-f *final-flags*   Specify the value to be used in the *final-flags* field in /etc/ttydefs. *final-flags* must be in a format recognized by the stty command. *final-flags* are the termio(7I) settings used by ttymon after receiving a successful connection request and immediately before invoking the service on the port. If this option is not specified, sttydefs will set *final-flags* equal to the termio(7I) flags 9600 and sane.

-i *initial-flags*   Specify the value to be used in the *initial-flags* field in /etc/ttydefs. *initial-flags* must be in a format recognized by the stty command. These flags are used by ttymon when searching for the correct baud rate. They are set prior to writing the prompt. If this option is not specified, sttydefs will set *initial-flags* equal to the termio(7I) flag 9600.

-n *nextlabel*   Specify the value to be used in the *nextlabel* field in /etc/ttydefs. If this option is not specified, sttydefs will set *nextlabel* equal to *ttylabel*.

-l[*ttylabel*]   If a *ttylabel* is specified, sttydefs displays the record from /etc/ttydefs whose TTY label matches the specified *ttylabel*. If no *ttylabel* is specified, sttydefs displays the entire contents of /etc/ttydefs. sttydefs verifies that each entry it displays is correct and that the entry's *nextlabel* field references an existing

-r *ttylabel*   Remove any record in the ttydefs file that has *ttylabel* as its label.

Output If successful, sttydefs will exit with a status of 0. sttydefs -l will generate the requested information and send it to standard output.

Examples EXAMPLE 1   A sample of sttydefs command.

The following command lists all the entries in the ttydefs file and prints an error message for each invalid entry that is detected.

```
example# sttydefs -l
```

The following shows a command that requests information for a single label and its output:

```
example# sttydefs -l 9600
-----------------------------------------------------------------
9600:9600 hupcl erase ^h:9600 sane ixany tab3 hupcl erase ^h::4800
-----------------------------------------------------------------
ttylabel:     9600
initial flags:    9600 hupcl erase ^h
final flags:    9600 sane ixany tab3 hupcl erase ^h
autobaud:    no
nextlabel:     4800
```

The following sequence of commands will add the labels 1200, 2400, 4800, and 9600 and put them in a circular list:

```
sttydefs -a 1200 -n 2400 -i 1200 -f "1200 sane"
sttydefs -a 2400 -n 4800 -i 2400 -f "2400 sane"
sttydefs -a 4800 -n 9600 -i 4800 -f "4800 sane"
sttydefs -a 9600 -n 1200 -i 9600 -f "9600 sane"
```

Files /etc/ttydefs

Availability	system/core-os

See Also attributes(5), termio(7I)

Name su – become superuser or another user

Synopsis su [-] [*username* [arg...]]

Description The su command allows one to become another user without logging off or to assume a role. The default user *name* is root (superuser).

To use su, the appropriate password must be supplied (unless the invoker is already root). If the password is correct, su creates a new shell process that has the real and effective user ID, group IDs, and supplementary group list set to those of the specified *username*. Additionally, the new shell's project ID is set to the default project ID of the specified user. See getprojent(3PROJECT), setproject(3PROJECT). The new shell will be the shell specified in the shell field of *username*'s password file entry (see passwd(4)). If no shell is specified, /usr/bin/sh is used (see sh(1)). If superuser privilege is requested and the shell for the superuser cannot be invoked using exec(2), /sbin/sh is used as a fallback. To return to normal user ID privileges, type an EOF character (CTRL-D) to exit the new shell.

Any additional arguments given on the command line are passed to the new shell. When using programs such as sh, an *arg* of the form -c *string* executes *string* using the shell and an *arg* of -r gives the user a restricted shell.

To create a login environment, the command "su –" does the following:

- In addition to what is already propagated, the LC* and LANG environment variables from the specified user's environment are also propagated.

- Propagate TZ from the user's environment. If TZ is not found in the user's environment, su uses the TZ value from the TIMEZONE parameter found in /etc/default/login.

- Set MAIL to /var/mail/*new_user*.

If the first argument to su is a dash (-), the environment will be changed to what would be expected if the user actually logged in as the specified user. Otherwise, the environment is passed along, with the exception of $PATH, which is controlled by PATH and SUPATH in /etc/default/su.

All attempts to become another user using su are logged in the log file /var/adm/sulog (see sulog(4)).

Security su uses pam(3PAM) with the service name su for authentication, account management, and credential establishment.

Examples EXAMPLE 1 Becoming User bin While Retaining Your Previously Exported Environment

To become user bin while retaining your previously exported environment, execute:

example% **su bin**

EXAMPLE 2 Becoming User `bin` and Changing to `bin`'s Login Environment

To become user `bin` but change the environment to what would be expected if `bin` had originally logged in, execute:

example% **su - bin**

EXAMPLE 3 Executing command with user `bin`'s Environment and Permissions

To execute command with the temporary environment and permissions of user `bin`, type:

example% **su - bin -c "***command args***"**

Environment Variables Variables with LD_ prefix are removed for security reasons. Thus, su bin will not retain previously exported variables with LD_ prefix while becoming user bin.

If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of su for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables are set in the environment, the "C" (U.S. style) locale determines how su behaves.

LC_CTYPE   Determines how su handles characters. When LC_CTYPE is set to a valid value, su can display and handle text and filenames containing valid characters for that locale. su can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. su can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

LC_MESSAGES   Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

Files $HOME/.profile
  user's login commands for sh and ksh

/etc/passwd
  system's password file

/etc/profile
  system-wide sh and ksh login commands

/var/adm/sulog
  log file

/etc/default/su
  the default parameters in this file are:

SULOG   If defined, all attempts to su to another user are logged in the indicated file.

CONSOLE If defined, all attempts to su to root are logged on the console.

PATH   Default path. (/usr/bin:)

SUPATH   Default path for a user invoking su to root. (/usr/sbin:/usr/bin)

SYSLOG   Determines whether the syslog(3C) LOG_AUTH facility should be used to log all su attempts. LOG_NOTICE messages are generated for su's to root, LOG_INFO messages are generated for su's to other users, and LOG_CRIT messages are generated for failed su attempts.

/etc/default/login
    the default parameters in this file are:

SLEEPTIME   If present, sets the number of seconds to wait before login failure is printed to the screen and another login attempt is allowed. Default is 4 seconds. Minimum is 0 seconds. Maximum is 5 seconds.

            Both su and login(1) are affected by the value of SLEEPTIME.

TIMEZONE   Sets the TZ environment variable of the shell.

Attributes See attributes(5) for descriptions of the following attributes:

Name   sulogin – access single-user mode

Synopsis   `sulogin`

Description   The `sulogin` utility is automatically invoked by `init` when the system is first started. It prompts the user to type a user name and password to enter system maintenance mode (single-user mode) or to type EOF (typically CTRL-D) for normal startup (multi-user mode). The user should never directly invoke `sulogin`. The user must have the `solaris.system.maintenance` authorization.

The `sulogin` utility can prompt the user to enter the root password on a variable number of serial console devices, in addition to the traditional console device. See consadm(1m) and msglog(7D) for a description of how to configure a serial device to display the single-user login prompt.

Files   `/etc/default/sulogin`
> Default value can be set for the following flag:

> PASSREQ
>> Determines if login requires a password. Default is `PASSREQ=YES`.

`/etc/default/login`
> Default value can be set for the following flag:

> SLEEPTIME
>> If present, sets the number of seconds to wait before login failure is printed to the screen and another login attempt is allowed. Default is 4 seconds. Minimum is `0` seconds. Maximum is 5 seconds.

>> Both su(1M) and login(1) are affected by the value of SLEEPTIME.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   auths(1), login(1), consadm(1m), init(1M), su(1M), attributes(5), msglog(7D)

Notes   By default, the root user has all authorizations.

Granting the `solaris.system.maintenance` authorization to the Console User Rights Profile may have an undesirable side effect of granting the currently logged in user maintenance mode access. The `solaris.system.maintenance` authorization should be directly granted to appropriate users rather than through the Console User Rights Profile.

Name svadm – command line interface to control Availability Suite Storage Volume operations

Synopsis svadm -h

svadm -v

svadm [-C *tag*]

svadm [-C *tag*] -i

svadm [-C *tag*] -e {-f *config_file* | volume}

svadm [-C *tag*] -d {-f *config_file* | volume}

svadm [-C *tag*] -r {-f *config_file* | volume}

Description The svadm command controls the Storage Volume (SV) driver by providing facilities to enable and disable the SV driver for specified volumes, and to dynamically reconfigure the system.

Options If you specify no arguments to an svadm command, the utility displays the list of volumes currently under SV control. svadm supports the following options:

-C *tag*

On a clustered node, limits operations to only those volumes belonging to the cluster resource group, or disk group name, specified by tag. This option is illegal on a system that is not clustered. The special *tag*, local, can be used to limit operations to only those volumes that cannot switch over to other nodes in the cluster.

-d

Disables the SV devices specified on the command line or in the configuration file. If -C tag is specified with this option, then the volume should be in this cluster disk group.

-e

Enables the SV devices specified on the command line or in the configuration file. Details of the volume are saved in the current configuration. See dscfg(1M). If -C tag is specified with this option, then the volume should be in this cluster disk group.

-f *config_file*

Specifies a configuration file that contains a list of volumes. A command reads this volume list and then perform the operation. The format of the *config_file* is a simple list of volume pathnames, one per line. Blank lines and lines starting with the comment character (#) are ignored.

-h

Displays the svadm usage summary.

-i

Displays extended status for the volumes currently under SV control.

-r

When a *config_file* is specified, reconfigure the running system to match the configuration specified in the *config_file*. When the -C option is specified, compare the cluster tag for each

volume and change it to *cluster_tag*. If a volume is specified with this option, it is valid only to reconfigure the cluster tag associated with the volume. The -e or -d options should be used to enable or disable single volumes.

-v

Displays the SV version number.

Usage When an SV volume is enabled, normal system call access to the device (see Intro(2)) is redirected into the StoreEdge architecture software. This allows standard applications to use StorageTek features such as Sun StorageTek Point-in-Time Copy and Remote Mirror Software.

The svadm command generates an entry in the Availability Suite log file, /var/adm/ds.log (see ds.log(4)), when performing enable (-e) and disable (-d) operations.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	driver/storage/sv, driver/storage/sv
Interface Stability	Committed

See Also dscfg(1M), ds.log(4), attributes(5), sv(7D)

Name svcadm – manipulate service instances

Synopsis `/usr/sbin/svcadm [-v] enable [-rst] {`*FMRI* `|` *pattern*`}...`

`/usr/sbin/svcadm [-v] disable [-st] {`*FMRI* `|` *pattern*`}...`

`/usr/sbin/svcadm [-v] restart {`*FMRI* `|` *pattern*`}...`

`/usr/sbin/svcadm [-v] refresh {`*FMRI* `|` *pattern*`}...`

`/usr/sbin/svcadm [-v] clear {`*FMRI* `|` *pattern*`}...`

`/usr/sbin/svcadm [-v] mark [-It]` *instance_state*
    `{`*FMRI* `|` *pattern*`}...`

`/usr/sbin/svcadm [-v] milestone [-d]` *milestone_FMRI*

Description svcadm issues requests for actions on services executing within the service management facility (see smf(5)). Actions for a service are carried out by its assigned service restarter agent. The default service restarter is svc.startd (see svc.startd(1M)).

Options The following options are supported:

-v   Print actions verbosely to standard output.

Subcommands

Common Operations The subcommands listed below are used during the typical administration of a service instance.

For subcommands taking one or more operands, if the operand specifies a service (instead of a service instance), and that service has only a single instance, svcadm operates on that instance. If an abbreviated *FMRI* (a fault management resource identifier) or pattern matches more than one service, a warning message is displayed and that operand is ignored. See smf(5).

In the case that the service has more than one instance, svcadm return a non-zero exit status.

enable [-rst] {*FMRI* | *pattern*}...   Enables the service instances specified by the
                                             operands. For each service instance, the assigned
                                             restarter will try to bring it to the online state. This
                                             action requires permission to modify the "general"
                                             property group of the service instance (see
                                             smf_security(5)).

                                             If the -r option is specified, svcadm enables each
                                             service instance and recursively enables its
                                             dependencies.

                                             If the -s option is specified, svcadm enables each
                                             service instance and then waits for each service
                                             instance to enter the online or degraded state. svcadm

will return early if it determines that the service cannot reach these states without administrator intervention.

If the -t option is specified, svcadm temporarily enables each service instance. Temporary enable only lasts until reboot. This action requires permission to modify the "restarter_actions" property group of the service instance (see smf_security(5)). By default, enable is persistent across reboot.

disable [-st] {*FMRI* | *pattern*}...

Disables the service instance specified by the operands. For each service instance, the assigned restarter will try to bring it to the disabled state. This action requires permission to modify the "general" property group of the service instance (see smf_security(5)).

If the -s option is specified, svcadm disables each service instance and then waits for each service instance to enter the disabled state. svcadm will return early if it determines that the service cannot reach this state without administrator intervention.

If the -t option is specified, svcadm temporarily disables each service instance. Temporary disable only lasts until reboot. This action requires permission to modify the "restarter_actions" property group of the service instance (see smf_security(5)). By default, disable is persistent across reboot.

restart {*FMRI* | *pattern*}...

Requests that the service instances specified by the operands be restarted. This action requires permission to modify the "restarter_actions" property group of the service instance (see smf_security(5)). Restarting a service is implemented by most restarters as a full service "stop" followed by a "start".

This subcommand can restart only those services that are in the online or degraded states, as those states are defined in smf(5).

refresh {*FMRI* | *pattern*}...

For each service instance specified by the operands, requests that the assigned restarter update the service's running configuration snapshot with the values from the current configuration. Some of these values take effect immediately (for example, dependency changes). Other values do not take effect until the next

service restart. See the restarter and service documentation for more information.

If the service is managed by svc.startd(1M), the refresh method will be invoked if it exists to request the service reread its own configuration. For other restarters, see the restarter documentation.

This action requires permission to modify the "restarter_actions" property group of the service instance (see smf_security(5)).

clear {*FMRI* | *pattern*}...   For each service instance specified by the operands, if the instance is in the maintenance state, signal to the assigned restarter that the service has been repaired. If the instance is in the degraded state, request that the assigned restarter take the service to the online state. This action requires permission to modify the "restarter_actions" property group of the service instance (see smf_security(5)).

Exceptional Operations   The following subcommands are used for service development and temporary administrative manipulation.

mark [-It] *instance_state* {*FMRI* | *pattern*}...   If *instance_state* is "maintenance", then for each service specified by the operands, svcadm requests that the assigned restarter place the service in the maintenance state. See svc.startd(1M) and inetd(1M) for a detailed description of the actions taken for each restarter.

If *instance_state* is "degraded", then for services specified by the operands in the online state, svcadm requests that the restarters assigned to the services move them into the degraded state.

If the -I option is specified, the request is flagged as immediate.

The -t option is only valid for maintenance requests. When this option is specified, the request is flagged as temporary, and its effect will only last until the next reboot.

milestone [-d] *milestone_FMRI*

If *milestone_FMRI* is the keyword "none", all services other than the master restarter, `svc:/system/svc/restarter:default`, will be temporarily disabled.

If *milestone_FMRI* is the keyword "all", temporary enable and disable requests for all services will be nullified.

If *milestone_FMRI* is one of the following:

```
svc:/milestone/single-user:default
svc:/milestone/multi-user:default
svc:/milestone/multi-user-server:default
```

then temporary enable and disable requests for the indicated service and all services it depends on (directly or indirectly) will be nullified. All other services will be temporarily disabled.

Changing the system's current milestone with the "milestone" subcommand will not change the current run level of the system. To change the system's run level, invoke `/usr/sbin/init` directly.

This action requires permission to modify the "options_ovr" property group of the `svc:/system/svc/restarter:default` service instance (see `smf_security(5)`).

The -d option immediately changes the milestone to the requested milestone, as above. Additionally, it makes the specified milestone the default boot milestone, which persists across reboot. The default milestone is defined by the `options/milestone` property on the master restarter, `svc:/system/svc/restarter:default`. If this property is absent, "all" is the default. This action requires permission to modify the "options" property group of the `svc:/system/svc/restarter:default` service instance (see `smf_security(5)`).

Operands   The following operands are supported:

FMRI   An *FMRI* that specifies one or more instances. *FMRI*s can be abbreviated by
            specifying the instance name, or the trailing portion of the service name. For
            example, given the *FMRI*:

            svc:/network/smtp:sendmail

            All the following are valid abbreviations:

            sendmail
            :sendmail
            smtp
            smtp:sendmail
            network/smtp

            While the following are invalid:

            mail
            network
            network/smt

            If the *FMRI* specifies a service, then the command applies to all instances of that
            service. Abbreviated forms of *FMRI*s are unstable, and should not be used in
            scripts or other permanent tools.

pattern   A pattern that is matched against the *FMRIs* of service instances according to the
            "globbing" rules described by fnmatch(5). If the pattern does not begin with
            "svc:", then "svc:/" is prepended.

If an abbreviated *FMRI* or pattern matches more than one service, a warning message is
displayed and that operand is ignored.

Examples   **EXAMPLE 1**   Restarting a Service Instance

The following command restarts the NFS server. The full *FMRI* for the default service instance
is: svc:/network/nfs/server:default

However, you can abbreviate the full *FMRI* as follows:

svcadm restart nfs/server

EXAMPLE 2   Disabling the Standard HTTP Server

The following command disables the standard HTTP server, using an abbreviated *FMRI*:

$ svcadm disable http

EXAMPLE 3 Enabling an Instance and Its Dependent Instances

The following command enables the foo:bar instance, and all instances on which it depends:

```
$ svcadm enable -r foo:bar
```

EXAMPLE 4 Synchronously enabling an instance

The following command enables the foo:bar instance. The command will not return until the instance comes online or svcadm determines it is not possible for the service to come online.

```
$ svcadm enable -s foo:bar
```

EXAMPLE 5 Restricting and Restoring the Running Services

The following command restricts the running services to single user mode:

```
# svcadm milestone milestone/single-user
```

The following command restores the running services:

```
# svcadm milestone all
```

Exit Status The following exit values are returned:

0   Successful completion.

1   A fatal error occurred. One or more error messages are displayed on standard error.

2   Invalid command line options were specified.

3   svcadm determined that a service instance that it was waiting for could not reach the desired state without administrator intervention due to a problem with the service instance itself.

4   svcadm determined that a service instance that it was waiting for could not reach the desired state without administrator intervention due to a problem with the service's dependencies.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	See below.

The interactive output is Uncommitted. The invocation and non-interactive output are Committed.

See Also   svcprop(1), svcs(1), inetd(1M), init(1M), svccfg(1M), svc.startd(1M), libscf(3LIB), contract(4), attributes(5), smf(5), smf_security(5)

Notes   The amount of time svcadm will spend waiting for services and their dependencies to change state is implicitly limited by their method timeouts. For example, a service using the default restarter whose start method hangs will be transitioned to the maintenance state when its timeout expires. svcadm will then consider it impossible for this service to come online without administrator intervention.

Attempts to synchronously enable a service which depends (directly or indirectly) on a file may fail with an exit status indicating that dependencies are unsatisfied if the caller does not have the privileges necessary to search the directory containing the file. This limitation may be removed in a future Solaris release.

Name svccfg – import, export, and modify service configurations

Synopsis /usr/sbin/svccfg [-v] [-s *FMRI*]

/usr/sbin/svccfg [-v] [-s *FMRI*] *subcommand* [args]...

/usr/sbin/svccfg [-v] [-s *FMRI*] -f *command-file*

Description The svccfg command manipulates data in the service configuration repository. svccfg can be invoked interactively, with an individual subcommand, or by specifying a command file that contains a series of subcommands.

Changes made to an existing service in the repository typically do not take effect for that service until the next time the service instance is refreshed. See the refresh subcommand on the svcadm(1M) man page for more details.

Options The following options are supported:

-f *command-file*
  Reads and executes svccfg subcommands from *command-file*.

-s *FMRI*
  Selects the entity indicated by *FMRI* (a fault management resource identifier) before executing any subcommands. See smf(5).

-v
  Verbose.

Subcommands Subcommands are divided into the categories specified in the subsections that follow.

All subcommands that accept *FMRI*s also accept abbreviated or globbed patterns. Instances and services can be abbreviated by specifying the instance name, or the trailing portion of the service name. For example, given the *FMRI*:

svc:/network/smtp:sendmail

All the following are valid abbreviations:

sendmail
:sendmail
smtp
smtp:sendmail
network/smtp

While the following are invalid:

mail
network
network/smt

Abbreviated forms of *FMRI*s are unstable, and should not be used in scripts or other permanent tools. If a pattern matches more than one instance or service, an error message is printed and no action is taken.

General Subcommands
```
end
exit
quit
```
Exits immediately.

`repository [-p` *prefix*`]` *repfile*

Uses *repfile* as a repository. By default, svccfg(1M) uses the system repository.

Use repository only with files from the identical version of Solaris, including patches, that you are currently running. Do not use this subcommand with the system repository, `/etc/svc/repository.db`.

If you use `svccfg repository` to pre-populate the SMF repository before deployment time, use `-p` option to specify the root prefix for the system standard location for manifests imported with `import`. This prefix will be replaced by `/lib/svc/manifest` and `/var/svc/manifest` once the repository is on a live system. If manifests from your `-p` directory do not appear in a system standard location at runtime, the services associated with them will be removed.

`set [-v|-V]`

Sets optional behavior. If no options are specified, set displays the options currently in effect.

`-v`

Turns on verbose mode.

`-V`

Turns off verbose mode.

Service Manifest and Profile Subcommands

`apply [-n] [-v]` *file* | *directory*

If the argument is a service profile or manifest, apply the configuration to the admin layer of the SMF repository. Services, instances, property groups, and properties will be created as necessary.

If the type attribute of a property or property group is unspecified, an attempt will be made to determine the type from existing type settings or from the service template. If a type cannot be determined, a warning will be presented and the service will be skipped so inconsistent data will not be introduced into a service and instance. Nonexistent services and instances are ignored.

To use the relaxed element definitions in a profile, the following definitions need to be added to the `DOCTYPE` entry:

```
<!ENTITY % profile "INCLUDE">
<!ENTITY % manifest "IGNORE">
```

Services and instances modified by the profile will be refreshed. If `-n` is specified, the profile is processed and no changes are applied to the SMF repository. Any syntax error found will be reported on stderr and an exit code of 1 will be returned. See smf(5) for a description of

service profiles. This command requires privileges to modify properties in the service and instance. See smf_security(5) for the privileges required to modify properties.

Services and instances in the manifest or profile will be validated against template data in the manifest and the repository, and warnings will be issued for all template violations. See smf_template(5) for a description of templates. If the -V option is specified, manifests that violate the defined templates will fail to import. In interactive invocations of svccfg, -V is the default behavior.

If the argument to apply is a directory, all profiles found under that directory tree will get applied as described above. The subcommand fails if a specified file or any file found under a specified directory is not a service profile.

extract [-a] [-l *layer*] [> *file*]
  Prints a service profile that represents the local customizations on the system.

  If -l is supplied, a list of layers can be selected from which to export values. The -l option requires a layer name and takes the arguments: manifest, system-profile, site-profile, admin, current, all. current and all are synonyms and mean the highest-layer values. They are both provided for consistency with the listprop subcommand. Multiple layers can be comma-separated or specified with multiple -l options.

  If -l is not supplied, the default is -l admin,site-profile.

  If a property is defined in multiple selected layers, only the highest layer is exported in the profile.

  Without the -a option, property groups containing protected information (identified by the presence of the read_authorization property—see smf_security(5)) will be extracted without their property values. When the -a option is specified, all values will be extracted. An error results if there are insufficient privileges to read these values.

export [-a] *service_FMRI* [>*file*]
  Running svccfg export is equivalent to:

  svccfg extract -l current [-a] *service_FMRI* [>*file*]

import [-V] [*file* | *directory*]
  svccfg import on a file in a system-managed filesystem location (subdirectories of /lib/svc/manifest and /var/svc/manifest) invokes: svcadm restart manifest-import.

  Placing your manifests in a system-managed location and invoking svcadm restart manifest-import to import them is the recommended practice.

  svccfg import on files in other locations imports their properties as administrative customization into the admin layer. It is equivalent to:

  svccfg apply [*file* | *directory*]

inventory *file*

    If *file* is determined to be a service manifest or profile, then the FMRIs of the services and instances the *file* describes are printed. For each service, the FMRIs of its instances are displayed before the FMRI of the service.

validate [*file* | *fmri*]

    The validate subcommand can operate on a manifest file, an instance FMRI, or the current instance or snapshot entity selection. When an argument is specified, svccfg will check to see whether the specified file exists. If the file exists, it will be validated. If a file of the specified name does not exist, the argument is treated as an FMRI pattern. If a conflict arises between a filename and an FMRI, use the svc: and file: prefixes to tell svccfg how to interpret the argument.

    When you specify a file, the file is processed in a manner similar to import -V, but no changes are made to the repository. If any errors are detected, svccfg displays the errors and exits with a nonzero exit status.

    For an instance *fmri*, instance entity selection, or snapshot entity selection, the specified instance in its composed form (see "Properties and Property Groups" in smf(5)) will be validated against template data in the repository. Instance FMRIs and instance entity selections use the "running" snapshot for validation. Warnings will be issued for all template violations. See smf_template(5) for a description of templates.

    If the service or instance is backed by a manifest or profile, it is masked. See smf(5).

Entity Selection, Modification, and Navigation Subcommands

An "entity" refers to a scope, service, or service instance.

add *name*

    A new entity with the given name is created as a child of the current selection. See smf_security(5) for the privileges required to create entities.

delete [-f] {*name* | *fmri*}

    The named child of the current selection or the entity specified by *fmri* is deleted. Attempts to delete service instances in the "online" or "degraded" state will fail unless the -f flag is specified. If a service or service instance has a "dependents" property group of type "framework", then for each of its properties with type "astring" or "fmri", if the property has a single value which names a service or service instance then the dependency property group in the indicated service or service instance with the same name as the property will be deleted. See smf_security(5) for the privileges required to delete service configurations.

list [*pattern*]

    The child entities of the current selection whose names match the glob pattern *pattern* are displayed (see fnmatch(5)). ':properties' is also listed for property-bearing entities, namely services and service instances.

select {*name* | *fmri*}

> If the argument names a child of the current selection, it becomes the current selection. Otherwise, the argument is interpreted as an FMRI and the entity that the argument specifies becomes the current selection.

unselect

> The parent of the current selection becomes the current selection.

Property Inspection and Modification Subcommands

addpg *name type* [*flags*]

> Adds a property group with the given *name* and type to the current selection. *flags* is a string of characters which designates the flags with which to create the property group. 'P' represents SCF_PG_FLAG_NONPERSISTENT (see `scf_service_add_pg(3SCF)`). See `smf_security(5)` for the privileges required to create property groups.

addpropvalue *pg/name* [*type:*] *value*

> Adds the given value to a property. If *type* is given and the property exists, then if *type* does not agree with the property's *type*, the subcommand fails. The values may be enclosed in double-quotes. String values containing double-quotes or backslashes must be enclosed by double-quotes and the contained double-quotes and backslashes must be quoted by backslashes. Nonexistent properties are created, in which case the *type* specifier must be present. See `scf_value_create(3SCF)` for a list of available property types. See `smf_security(5)` for the privileges required to modify properties. The new value will be appended to the end of the list of property values associated with the property.

delcust [-M] [*pattern*]

> Delete any administrative customizations for the current selection. If an argument is supplied, it is taken as a glob pattern and only property groups and properties with names that match the argument are deleted.
>
> If -M is supplied, delete only masked entities.
>
> To see what customizations delcust would remove, use listcust with the same options. As delcust can potentially remove all administrative customizations, always run listcust first to determine you are removing what you intend to.

delpg *name*

> Deletes the property group *name* of the current selection. See `smf_security(5)` for the privileges required to delete property groups.
>
> If the property group is backed by a manifest or profile, it is masked. See `smf(5)`.

delprop *pg*[*/name*]

> Deletes the named property group or property of the current selection. See `smf_security(5)` for the privileges required to delete properties.

delpropvalue *pg/name globpattern*

> Deletes all values matching the given *glob* pattern in the named property. Succeeds even if no values match. See `smf_security(5)` for the privileges required to modify properties.

describe [-v] [-t] [*propertygroup/property*]
　　Describes either the current or the possible settings.

　　When invoked without arguments, describe gives basic descriptions (if available) of the currently selected entity and all of its currently set property groups and properties. A property group or specific property can be queried by specifying either the property group name, or the property group name and property name, separated by a slash (/), as an argument.

　　The -v option gives all information available, including descriptions for current settings, constraints, and other possible setting choices.

　　The -t option shows only the template data for the selection (see smf_template(5)), and does not display the current settings for property groups and properties.

editprop
　　Comments of commands to reproduce the property groups and properties of the current selection are placed in a temporary file and the program named by the EDITOR environment variable is invoked to edit it. Upon completion, the commands in the temporary file are executed. The default editor is vi(1). See smf_security(5) for the privileges required to create, modify, or delete properties.

listpg [*pattern*]
　　Displays the names, types, and flags of property groups of the current selection. If an argument is given, it is taken as a glob pattern and only property groups with names which match the argument are listed.

　　In interactive mode, a basic description of the property groups is also given.

listprop [-l *layer*...] [-f | -o *format*] [*pattern*]
　　Lists property groups and properties of the current selection. For property groups, names, types, and flags are listed. For properties, names (prepended by the property group name and a slash (/)), types, and values are listed. See scf_value_create(3SCF) for a list of available property types. If an argument is supplied it is taken as a glob pattern and only property groups and properties with names which match the argument are listed.

　　With the -l option, print the layer the value came from. The -l option requires a layer, and takes the arguments: manifest, system-profile, site-profile, admin, current, all. current prints the same property values as listprop without -l, along with the layer that value was defined in.

　　The -f and -o options are mutually exclusive. -f prints the file, if any, a property came from. -o allows field selection. Selectable fields include:

　　propname　　　　the property name

　　pgname　　　　　the property group name

　　instname　　　　the instance name

servicename	the service name
layer	the layer
proptype	the property type
value	the property value
file	the source file
masked	whether the property group or property is currently masked
time	the time this property last changed

listcust [-L] [-M] [*pattern*]

Print any site profile and admin layer customizations and masked entities for the current selection. If an argument is supplied it is taken as a glob pattern and only property groups and properties with names that match the argument are listed. If there is no current selection, list all customizations for all services.

If -M is supplied, print only masked entities.

If -L is supplied, show all local customizations, including those in both the admin layer and the site profile layer.

setenv [-i | -s] [-m *method_name*] *envvar value*

Sets a method environment variable for a service or instance by changing the "environment" property in the *method_name* property group, if that property group has type "method". If *method_name* is not specified and the -i option is used, the "method_context" property group is used, if an instance is currently selected. If the -s option is used and a service is currently selected, its "method_context" property group is used. If the -s option is used and an instance is currently selected, the "method_context" property group of its parent is used. If neither the -i option nor the -s option is used, the "start" property group is searched for in the currently selected entity and, if an instance is currently selected, its parent is also searched. If the "inetd_start" property group is not located, it is searched for in a similar manner.

Once the property is located, all values which begin with *envvar* followed by a "=" are removed, and the value "*envvar=value*" is added. See smf_security(5) for the privileges required to modify properties.

setprop *pg/name* = [*type:*] *value*
setprop *pg/name* = [*type:*] ([*values ...*])

Sets the *name* property of the *pg* property group of the current selection to the given values of type *type*. See scf_value_create(3SCF) for a list of available property types. If the property already exists and the *type* disagrees with the existing *type* on the property, the subcommand fails. Values may be enclosed in double-quotes. String values which contain double-quotes or backslashes must be enclosed by double-quotes and the contained double-quotes and backslashes must be quoted by backslashes. If the named property does

not exist, it is created, as long as the type is specified. See smf_security(5) for the privileges required to create or modify properties. Multiple values will be stored in the order in which they are specified.

unsetenv [-i | -s] [-m *method_name*] *envvar value*
> Removes a method environment variable for a service or instance by changing the "environment" property in the *method_name* property group, if that property group has type "method". If *method_name* is not specified and the -i option is used, the "method_context" property group is used, if an instance is currently selected. If the -s option is used and a service is currently selected, its "method_context" property group is used. If the -s option is used and an instance is currently selected, the "method_context" property group of its parent is used. If neither the -i option nor the -s option is used, the "start" property group is searched for in the currently selected entity and, if an instance is currently selected, its parent is also searched. If the "inetd_start" property group is not located, it is searched for in a similar manner.
>
> Once the property is located, all values which begin with *envvar* followed by "=" are removed. See smf_security(5) for the privileges required to modify properties.

Notification
Parameters
Subcommands
setnotify {[-g] *tset* | *class*} *notification_parameters*
> Sets notifications parameters for software events and Fault Management problem lifecycle events in the SMF repository.
>
> -g
> > Used to set system-wide notification parameters for SMF state transition. See smf(5). These notification parameters are set in svc:/system/svc/global:default regardless of any svccfg current selection. This subcommand refreshes all instances it modifies.
>
> *class*
> > Comma-separated list of FMA Event classes or aliases. See smf(5) Notification Parameters.
>
> *tset*
> > Comma-separated list of SMF state transitions. See smf(5) Notification Parameters.
>
> *notification_parameters*
> > URI format for each notification mechanism implemented: For SMTP use:
> >
> > mailto:*addr*[?*header1*=*value1*[&*header2*=*value2*]]
> >
> > ...or:
> >
> > mailto:{[active]|inactive}
> >
> > ...and for SNMP traps use:
> >
> > snmp:{[active]|inactive}
> >
> > The parameter msg_template defined in smtp-notify(1M) can be set as a header value in the mailto URI. For example:
> >
> > mailto:root@localhost?msg_template=<*path to template file*>

SNMP traps are directed to the host as defined by the trapsink directive in
/etc/net-snmp/snmp/snmpd.conf or as specified by the SNMP trap notification
daemon. See smtp-notify(1M).

The notification parameters are specific to the class or tset specified and overwrite
preexisting notification parameters. The active/inactive form does not overwrite
previous notification parameters. It just switches on or off the notification mechanism
for the specified class or tset. Setting notification parameters implicitly sets them as
active.

listnotify [-g] [*tset*] | *class*
Displays the existing notification parameters for the specified class or tset. With the -g
option, the notification parameters in svc:/system/svc/global:default are displayed. If
tset is omitted, all is implied.

delnotify [-g] *tset* | *class*
Delete the existing notification parameters for the specified class or tset. With the -g
option, the notification parameters in svc:/system/svc/global:default are deleted.

Snapshot Navigation
and Selection
Subcommands

listsnap
Displays snapshots available for the currently selected instance.

revert [*snapshot*]
Reverts the administrative customizations of the currently selected instance and its service
to those recorded in the named snapshot. If no argument is given, use the currently selected
snapshot and deselect it on success. The changed property values can be made active via the
refresh subcommand of svcadm(1M). See smf_security(5) for the privileges required to
change properties.

selectsnap [*name*]
Changes the current snapshot to the one named by *name*. If no *name* is specified, deselect
the currently selected snapshot. Snapshots are read-only.

Instance
Subcommands

refresh
Commit the values from the current configuration to the running snapshot, making them
available for use by the currently selected instance. If the repository subcommand has not
been used to select a repository, direct the instance's restarter to reread the updated
configuration.

Examples   EXAMPLE 1   Importing a Service Description

The following example imports a service description for the seismic service in the XML
manifest specified on the command line.

svccfg import /var/svc/manifest/site/seismic.xml

Note that the manifest must follow the format specified in service_bundle(4).

EXAMPLE 2 Exporting a Service Description

To export a service description on the local system:

svccfg export dumpadm >/tmp/dump.xml

EXAMPLE 3 Deleting a Service Instance

To delete a service instance:

svccfg delete network/inetd-upgrade:default

EXAMPLE 4 Checking Properties in an Alternate Repository

To examine the state of a service's properties after loading an alternate repository, use the sequence of commands shown below. One might use such commands, for example, to determine whether a service was enabled in a particular repository backup.

```
# svccfg
svc:> repository /etc/svc/repository-boot
svc:> select telnet:default
svc:/network/telnet:default> listprop general/enabled
general/enabled  boolean  false
svc:/network/telnet:default> exit
```

EXAMPLE 5 Enabling Debugging

To modify LD_PRELOAD for a start method and enable the use of libumem(3LIB) with debugging features active:

```
$ svccfg -s system/service setenv LD_PRELOAD libumem.so
$ svccfg -s system/service setenv UMEM_DEBUG default
```

EXAMPLE 6 Using describe Subcommand

The following command illustrates the use of the describe subcommand.

```
# svccfg -s console-login describe ttymon
ttymon                      application
ttymon/device              astring  /dev/console
   terminal device to be used for the console login prompt
ttymon/label               astring  console
   appropriate entry from /etc/ttydefs
   ...
```

EXAMPLE 7 Configuring Notification Preferences

The following command configures notification preferences for SMF service state transition events.

```
# svccfg setnotify -g from-online,to-maintenance \
mailto:admin@somehost.com
```

EXAMPLE 8   Enabling SNMP Notifications

The following command enables SNMP notifications for Fault Management events.

```
# svccfg setnotify problem-diagnosed,problem-updated \
mailto:admin@somehost.com snmp:
```

EXAMPLE 9   Listing Notification Settings

The following command lists notification settings for Fault Management events.

```
# svccfg listnotify problem-diagnosed,problem-updated
Event: problem-diagnosed
  Notification Type: smtp
    active: true
   to: admin@somehost.com
  Notification Type: snmp
    active: true

Event: problem-updated
  Notification Type: smtp
    active: true
   to: admin@somehost.com
  Notification Type: snmp
    active: true
```

Environmental Variables   EDITOR

The command to run when the editprop subcommand is used. The default editor is vi(1).

Exit Status   The following exit values are returned:

0

Successful execution.

1

One or more subcommands resulted in failure. Error messages are written to the standard error stream.

2

Invalid command line options were specified.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	See below.

The interactive output is Uncommitted. The invocation and non-interactive output are Committed.

See Also svcprop(1), svcs(1), smtp-notify(1M), svcadm(1M), svc.configd(1M), libscf(3LIB), libumem(3LIB), scf_service_add_pg(3SCF), scf_value_create(3SCF), contract(4), service_bundle(4), attributes(5), fnmatch(5), smf(5), smf_method(5), smf_security(5), smf_template(5)

Name svc.configd – Service Management Facility repository daemon

Synopsis `/lib/svc/bin/svc.configd`

Description `svc.configd` is the repository daemon for the Service Management Facility. `svc.configd` is invoked automatically during system startup, and restarted if any failures occur. `svc.configd` should never be invoked directly.

Interaction with `svc.configd` is by way of `libscf(3LIB)` and the command line tools:`svcs(1)`, `svcprop(1)`, `svcadm(1M)`, and `svccfg(1M)`.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also `svcs(1)`, `svcprop(1)`, `svcadm(1M)`, `svccfg(1M)`, `libscf(3LIB)`, `attributes(5)`

Name svc.ipfd – IP Filter firewall monitoring daemon

Synopsis `/lib/svc/bin/svc.ipfd`

`svc:/network/ipfilter:default`

Description The `svc.ipfd` daemon monitors actions on services that use firewall configuration and initiates update services' IP Filter configuration. The daemon allows the system to react to changes in system's firewall configuration in an incremental fashion, at a per-service level.

A service's firewall policy is activated when it is enabled, deactivated when it is disabled, and updated when its configuration property group is modified. `svc.ipfd` monitors the services management facility (SMF) repository for these actions and invokes the IP Filter rule-generation process to carry out the service's firewall policy.

This daemon is started by the `network/ipfilter` service either through the `start` or `refresh` method. Thus, the daemon inherits the environment variables and credentials from the method and runs as root with all zone privileges.

Firewall Static Configuration A static definition describes a service's network resource configuration that is used to generate service-specific IPF rules. The per-service `firewall_context` property group contains a service's static definition, similar to the `inetd` property group in `inetd` managed services. This property group supports:

`firewall_context/name`
   For non-inetd services. The IANA name or RPC name, equivalent to the `inetd/name` property.

`firewall_context/isrpc`
   For non-inetd services. A boolean property where a `true` value indicates an RPC service, equivalent to the `inetd/isrpc` property. For RPC services, the value of `firewall_context/name` is not an IANA name but is either an RPC program number or name. See `rpc(4)`.

Additionally, some services may require a mechanism to generate and supply their own IPF rules. An optional property `ipf_method`, provides a mechanism to allow such custom rule generation:

`firewall_context/ipf_method`
   A command. Normally a script that generates IPF rules for a service. The framework does not generate rules for services with this property definition. Rather, the framework expects these services to provide their own rules.

A service's `ipf_method` specifies a command that takes an additional argument, its own fault management resource identifier (FMRI), and generates the service's firewall rules and outputs those rules to stdout. To generate rules for a service with the `ipf_method` property, the framework execs the command specified in `ipf_method`, passing the service FMRI as the additional argument, and stores the rules for that service by redirecting the command output,

the rules, to the service's rule file. Because an `ipf_method` is exec'ed from the context of either the `network/ipfilter start` or `refresh` method process, it inherits the execution context and runs as root.

The service static configuration is delivered by the service developer and not intended to be modified by users. These properties are only modified upon installation of an updated service definition.

Firewall Policy Configuration   A per-service property group, `firewall_config`, stores the services' firewall policy configuration. Because `network/ipfilter:default` is responsible for two firewall policies, the Global Default and Global Override system-wide policies (as explained in `ipfilter(5)`), it has two property groups, `firewall_config_default` and `firewall_config_override`, to store the respective system-wide policies.

Below are the properties, their possible values, and corresponding semantics:

policy
  The `policy` has the following modes:

  none policy mode
    No access restriction. For a global policy, this mode allows all incoming traffic. For a service policy, this mode allows all incoming traffic to its service.

  deny policy mode
    More restrictive than `none`. This mode allows incoming traffic from all sources except those specified in the `apply_to` property.

  allow policy mode
    Most restrictive mode. This mode blocks incoming traffic from all sources except those specified in the `apply_to` property.

apply_to
  A multi-value property listing network entities to enforce the chosen policy mode. Entities listed in `apply_to` property will be denied if policy is `deny` and allowed if policy is `allow`. The syntax for possible values are:

host:	host:*IP*	"host:192.168.84.14"
subnet:	network:*IP/netmask*	"network:129.168.1.5/24"
ippool:	pool:*pool number*	"pool:77"
interface:	if:*interface_name*	"if:e1000g0"

exceptions
  A multi-value property listing network entities to be excluded from the `apply_to` list. For example, when `deny` policy is applied to a subnet, exceptions can be made to some hosts in that subnet by specifying them in the `exceptions` property. This property has the same value syntax as `apply_to` property.

For individual network services only:

firewall_config/policy
   A service's policy can also be set to use_global. Services with use_global policy mode
   inherits the Global Default firewall policy.

For the Global Default only:

firewall_config_default/policy
   Global Default policy, firewall_config property group in
   svc:/network/ipfilter:default, can also be set to custom. Users can set policy to
   custom to use prepopulated IP Filter configuration, for example, an existing IP Filter
   configuration or custom configurations that cannot be provided by the framework. This
   Global Default-only policy mode allows users to supply a text file containing the complete
   set of IPF rules. When custom mode is selected, the specified set of IPF rules is *complete* and
   the framework will not generate IPF rules from configured firewall policies.

firewall_config_default/custom_policy_file
   A file path to be used when Global Default policy is set to custom. The file contains a set of
   IPF rules that provide the desired IP Filter configuration. For example, users with existing
   IPF rules in /etc/ipf/ipf.conf can execute the following commands to use the existing
   rules:

   1. Set custom policy:

      ```
      # svccfg -s ipfilter:default setprop \
      firewall_config_default/policy = astring: "custom"
      ```

   2. Specify custom file:

      ```
      # svccfg -s ipfilter:default setprop \
      firewall_config_default/custom_policy_file = astring: \
      "/etc/ipf/ipf.conf"
      ```

   3. Refresh configuration:

      ```
      # svcadm refresh ipfilter:default
      ```

firewall_config_default/open_ports
   Non-service program requiring allowance of its incoming traffic can request that the
   firewall allow traffic to its communication ports. This multi-value property contains
   protocol and port(s) tuple in the form:

   "{tcp | udp}:{*PORT* | *PORT*-*PORT*}"

Initially, the system-wide policies are set to none and network services' policies are set to
use_global. Enabling network/ipfilter activates the firewall with an empty set of IP Filter
rules, since system-wide policy is none and all services inherit that policy. To configure a more
restrictive policy, use svccfg(1M) to modify network services and system-wide policies.

A user configures firewall policy by modifying the service's firewall_config property group.
A new authorization, solaris.smf.value.firewall.config, is created to allow delegation

of the firewall administration privilege to users. Users with Service Operator privileges will need this new authorization to be able to configure firewall policy.

Firewall Availability During boot, a firewall is configured for enabled services prior to the starting of those services. Thus, services are protected on boot. While the system is running, administrative actions such as service restarting, enabling, and refreshing may cause a brief service vulnerability during which the service runs while its firewall is being configured.

svc.ipfd monitors a service's start and stop events and configures or unconfigures a service's firewall at the same time that SMF is starting or stopping the service. Because the two operations are simultaneous, there is a possible window of exposure (less than a second) if the service is started before its firewall configuration completed. RPC services typically listen on ephemeral addresses, which are not known until the services are actually running. Thus RPC services are subjected to similar exposure since their firewalls are not configured until the services are running.

Developer Documentation Services providing remote capabilities are encouraged to participate in the firewall framework to control network access to the service. While framework integration is not mandatory, remote access to services that are not integrated in the framework may not function correctly when a system-wide policy is configured.

Integrating a service into the framework is as straightforward as defining two additional property groups and their corresponding properties in the service manifest. IP Filter rules are generated when a user enables the service. In the non-trivial case of custom rule generation, where a shell script is required, there are existing scripts that can be used as examples.

The additional property groups, firewall_config and firewall_context, stores firewall policy configuration and provides static firewall definition, respectively. Below is a summary of new property groups and properties and their appropriate default values.

Firewall policy configuration:

firewall_config
  Access to the system is protected by a new authorization definition and a user-defined property type. The new authorization should be assigned to the property group value_authorization property in a way such as:

  <propval name='value_authorization' type='astring'
  value='solaris.smf.value.firewall.config' />

  A third party should follow the service symbol namespace convention to generate a user-defined type. Sun-delivered services can use com.sun,fw_configuration as the property type.

  See "Firewall Policy Configuration," above, for more information.

firewall_config/policy
  This property's initial value should be use_global since services, by default, inherit the Global Default firewall policy.

firewall_config/apply_to
    An empty property, this property has no initial value.

firewall_config/exceptions
    An empty property, this property has no initial value.

Firewall static definition:

firewall_context
    A third party should follow service symbol namespace convention to generate a
    user-defined type, Sun delivered services can use com.sun,fw_definition as the property
    type.

    See "Firewall Static Configuration," above, for more information.

firewall_context/name
    Service with well-known, IANA defined port, which can be obtained by
    getservbyname(3SOCKET). The service's IANA name is stored in this property. For RPC
    services, the RPC program number is stored in this property.

firewall_context/isrpc
    For RPC services, this property should be created with its value set to true.

firewall_context/ipf_method
    In general, the specified firewall policy is used to generate IP Filter rules to the service's
    communication port, derived from the firewall_context/name property. Services that do
    not have IANA-defined ports and are not RPC services will need to generate their own IP
    Filter rules. Services that generate their own rules may choose not to have
    firewall_context/name and firewall_context/isrpc properties. See the following
    services:

    svc:/network/ftp:default
    svc:/network/nfs/server:default
    svc:/network/ntp:default

    ...and others with the ipf_method for guidance.

Name svc.startd – Service Management Facility master restarter

Synopsis `/lib/svc/bin/svc.startd`

`svc:/system/svc/restarter:default`

Description svc.startd is the master restarter daemon for Service Management Facility (SMF) and the default restarter for all services. svc.startd starts, stops, and restarts services based on administrative requests, system failures, or application failures.

svc.startd maintains service state, as well as being responsible for managing faults in accordance with the dependencies of each service.

svc.startd is invoked automatically during system startup. It is restarted if any failures occur. svc.startd should never be invoked directly.

See smf_restarter(5) for information on configuration and behavior common to all restarters.

svcs(1) reports status for all services managed by the Service Configuration Facility. svcadm(1M) allows manipulation of service instances with respect to the service's restarter.

Environment Variables Environment variables with the "SMF_" prefix are reserved and may be overwritten.

svc.startd supplies the "SMF_" environment variables specified in smf_method(5) to the method. PATH is set to "/usr/sbin:/usr/bin" by default. By default, all other environment variables supplied to svc.startd are those inherited from init(1M).

Duplicate entries are reduced to a single entry. The value used is undefined. Environment entries that are not prefixed with "*<name>*=" are ignored.

Restarter Options svc.startd is not configured by command line options. Instead, configuration is read from the service configuration repository. You can use svccfg(1M) to set all options and properties.

The following configuration variables in the options property group are available to developers and administrators:

boot_messages
    An *astring* (as defined in scf_value_is_type; see scf_value_create(3SCF)) that describes the default level of messages to print to the console during boot. The supported message options include quiet and verbose. The quiet option prints minimal messages to console during boot. The verbose option prints a single message per service started to indicate success or failure. You can use the boot -m option to override the boot_messages setting at boot time. See kernel(1M).

logging
    Control the level of global service logging for svc.startd. An *astring* (as defined in scf_value_is_type; see scf_value_create(3SCF)) that describes the default level of messages to log to syslog (see syslog(3C) and svc.startd's global logfile,

/var/svc/log/svc.startd.log. The supported message options include quiet, verbose, and debug. The quiet option sends error messages requiring administrative intervention to the console, syslog and svc.startd's global logfile. The verbose option sends error messages requiring administrative intervention to the console, syslog and svc.startd's global logfile, and information about errors which do not require administrative intervention to svc.startd's global logfile. A single message per service started is also sent to the console. The debug option sends svc.startd debug messages to svc.startd's global logfile, error messages requiring administrative intervention to the console, syslog and svc.startd's global logfile, and a single message per service started to the console.

milestone

An FMRI which determines the milestone used as the default boot level. Acceptable options include only the major milestones:

svc:/milestone/single-user:default
svc:/milestone/multi-user:default
svc:/milestone/multi-user-server:default

or the special values all or none. all represents an idealized milestone that depends on every service. none is a special milestone where no services are running apart from the master svc:/system/svc/restarter:default. By default, svc.startd uses all, a synthetic milestone that depends on every service. If this property is specified, it overrides any initdefault setting in inittab(4).

system/reconfigure

Indicates that a reconfiguration reboot has been requested. Services with actions that must key off of a reconfiguration reboot may check that this property exists and is set to 1 to confirm a reconfiguration boot has been requested.

This property is managed by svc.startd and should not be modified by the administrator.

Configuration errors, such as disabling svc.startd are logged by syslog, but ignored.

SERVICE STATES   Services managed by svc.startd can appear in any of the states described in smf(5). The state definitions are unmodified by this restarter.

SERVICE REPORTING   In addition to any logging done by the managed service, svc.startd provides a common set of service reporting and logging mechanisms.

Reporting properties svc.startd updates a common set of properties on all services it manages. These properties are a common interface that can be used to take action based on service instance health. The svcs(1) command can be used to easily display these properties.

restarter/state
restarter/next_state

The current and next (if currently in transition) state for an instance.

restarter/auxiliary_state

A caption detailing additional information about the current instance state. The auxiliary state available for services managed by svc.startd is:

maintenance

        fault_threshold_reached
        stop_method_failed
        administrative_request

restarter/state_timestamp

The time when the current state was reached.

restarter/contract

The primary process contract ID, if any, that under which the service instance is executing.

Logs

By default, svc.startd provides logging of significant restarter actions for the service as well as method standard output and standard error file descriptors to /var/svc/log/*service*:*instance*.log. The level of logging to system global locations like /var/svc/log/svc.startd.log and syslog is controlled by the options/logging property.

SERVICE DEFINITION When developing or configuring a service managed by svc.startd, a common set of properties are used to affect the interaction between the service instance and the restarter.

Methods

The general form of methods for the fork/exec model provided by svc.startd are presented in smf_method(5). The following methods are supported as required or optional by services managed by svc.startd.

refresh   Reload any appropriate configuration parameters from the repository or config file, without interrupting service. This is often implemented using SIGHUP for system daemons. If the service is unable to recognize configuration changes without a restart, no refresh method is provided.

           This method is optional.

start   Start the service. Return success only after the application is available to consumers. Fail if a conflicting instance is already running, or if the service is unable to start.

           This method is required.

stop   Stop the service. In some cases, the stop method can be invoked when some or all of the service has already been stopped. Only return an error if the service is not entirely stopped on method return.

           This method is required.

If the service does not need to take any action in a required method, it must specify the :true token for that method.

svc.startd honors any method context specified for the service or any specific method. The method expansion tokens described in smf_method(5) are available for use in all methods invoked by svc.startd.

Properties

An overview of the general properties is available in smf(5). The specific way in which these general properties interacts with svc.startd follows:

general/enabled

If enabled is set to true, the restarter attempts to start the service once all its dependencies are satisfied. If set to false, the service remains in the disabled state, not running.

general/restarter

If this FMRI property is empty or set to svc:/system/svc/restarter:default, the service is managed by svc.startd. Otherwise, the restarter specified is responsible (once it is available) for managing the service.

general/single_instance

If single_instance is set to true, svc.startd only allows one instance of this service to transition to online or degraded at any time.

Additionally, svc.startd managed services can define the optional properties listed below in the startd property group.

startd/duration

The duration property defines the service's model. It can be set to transient, child also known as "wait" model services, or contract (the default).

startd/ignore_error

The ignore_error property, if set, specifies a comma-separated list of ignored events. Legitimate string values in that list are core and signal. The default is to restart on all errors.

startd/need_session

The need_session property, if set to true, indicates that the instance should be launched in its own session. The default is not to do so.

startd/utmpx_prefix

The utmpx_prefix string property defines that the instance requires a valid utmpx entry prior to start method execution. The default is not to create a utmpx entry.

SERVICE FAILURE   svc.startd assumes that a method has failed if it returns a non-zero exit code or if fails to complete before the timeout specified expires. If $SMF_EXIT_ERR_CONFIG or $SMF_EXIT_ERR_FATAL is returned, svc.startd immediately places the service in the

maintenance state. For all other failures, svc.startd places the service in the offline state. If a service is offline and its dependencies are satisfied, svc.startd tries again to start the service (see smf(5)).

If a contract or transient service does not return from its start method before its defined timeout elapses, svc.startd sends a SIGKILL to the method, and returns the service to the offline state.

If five failures happen in a row, or if the service is restarting due to an error more than once every ten minutes, svc.startd places the service in the maintenance state.

The conditions of service failure are defined by a combination of the service model (defined by the startd/duration property) and the value of the startd/ignore_error property.

A contract model service fails if any of the following conditions occur:

- all processes in the service exit
- any processes in the service produce a core dump
- a process outside the service sends a service process a fatal signal (for example, an administrator terminates a service process with the pkill command)

The last two conditions may be ignored by the service by specifying core and/or signal in startd/ignore_error.

Defining a service as transient means that svc.startd does not track processes for that service. Thus, the potential faults described for contract model services are not considered failures for transient services. A transient service only enters the maintenance state if one of the method failure conditions occurs.

"Wait" model services are restarted whenever the child process associated with the service exits. A child process that exits is not considered an error for "wait" model services, and repeated failures do not lead to a transition to maintenance state.

LEGACY SERVICES svc.startd continues to provide support for services invoked during the startup run level transitions. Each /etc/rc?.d directory is processed after all managed services which constitute the equivalent run level milestone have transitioned to the online state. Standard init scripts placed in the /etc/rc?.d directories are run in the order of their sequence numbers.

The milestone to run-level mapping is:

milestone/single-user	Single-user (S)
milestone/multi-user	Multi-user (2)
milestone/multi-user-server	Multi-user with network services (3)

Additionally, svc.startd gives these legacy services visibility in SMF by inserting an instance per script into the repository. These legacy instances are visible using standard SMF interfaces such as svcs(1), always appear in the LEGACY-RUN state, cannot be modified, and can not be specified as dependencies of other services. The initial start time of the legacy service is captured as a convenience for the administrator.

Files /var/svc/log   Directory where svc.startd stores log files.

      /etc/svc/volatile   Directory where svc.startd stores log files in early stages of boot, before /var is mounted read-write.

Example EXAMPLE 1   Turning on Verbose Logging

To turn on verbose logging, type the following:

```
# /usr/sbin/svccfg -s system/svc/restarter:default
svc:/system/svc/restarter:default> addpg options application
svc:/system/svc/restarter:default> setprop options/logging = \
astring: verbose
svc:/system/svc/restarter:default> exit
```

This request will take effect on the next restart of svc.startd.

Name swap – swap administrative interface

Synopsis /usr/sbin/swap -a *swapname* [*swaplow*] [*swaplen*]

/usr/sbin/swap -d *swapname* [*swaplow*]

/usr/sbin/swap -l [-h | -k]

/usr/sbin/swap -s [-h]

Description The swap utility provides a method of adding, deleting, and monitoring the system swap areas used by the memory manager.

Options The following options are supported:

-a *swapname* [*swaplow*] [*swaplen*]

Add the specified swap area. This option can only be used by the superuser or by one who has assumed the Primary Administrator role. *swapname* is the name of the swap area or regular file. For example, on system running a UFS root file system, specify a slice, such as /dev/dsk/c0t0d0s1, or a regular file for a swap area. On a system running a ZFS file system, specify a ZFS volume, such as /dev/zvol/dsk/rpool/swap, for a swap area. Using a regular file for swap is not supported on a ZFS file system. In addition, you cannot use the same ZFS volume for both the swap area and a dump device when the system is running a ZFS root file system.

swaplow is the offset in 512-byte blocks into the file where the swap area should begin. *swaplen* is the desired length of the swap area in 512-byte blocks. The value of *swaplen* can not be less than 16. For example, if *n* blocks are specified, then (*n*-1) blocks would be the actual swap length. *swaplen* must be at least one page in length. The size of a page of memory can be determined by using the pagesize command. See pagesize(1). Since the first page of a swap file is automatically skipped, and a swap file needs to be at least one page in length, the minimum size should be a multiple of 2 pagesize bytes. The size of a page of memory is machine-dependent.

swaplow + *swaplen* must be less than or equal to the size of the swap file. If *swaplen* is not specified, an area will be added starting at *swaplow* and extending to the end of the designated file. If neither *swaplow* nor *swaplen* are specified, the whole file will be used except for the first page. Swap areas are normally added automatically during system startup by the /usr/sbin/swapadd script. This script adds all swap areas which have been specified in the /etc/vfstab file; for the syntax of these specifications, see vfstab(4).

You can encrypt a ZFS volume used as a swap device by specifying the encrypted option in vfstab(4) and specifying the encryption property for the ZFS volume. See zfs(1M).

To use an NFS or local file system *swapname*, you should first create a file using mkfile(1M). A local file system swap file can now be added to the running system by just running the swap -a command. For NFS mounted swap files, the server needs to export the file. Do this by performing the following steps:

1. Add the following line to /etc/dfs/dfstab:

```
share -F nfs -o \
rw=clientname,root=clientname path-to-swap-file
```

2. Run shareall(1M).

3. Have the client add the following line to /etc/vfstab:

   server:*path-to-swap-file* - *local-path-to-swap-file* nfs \
           - - - *local-path-to-swap-file* - - swap - - -

4. Have the client run mount:

   # mount *local-path-to-swap-file*

5. The client can then run swap -a to add the swap space:

   # swap -a *local-path-to-swap-file*

-d *swapname*

    Delete the specified swap area. This option can only be used by the super-user. *swapname* is
the name of the swap file: for example, /dev/dsk/c0t0d0s1 or a regular file. *swaplow* is the
offset in 512-byte blocks into the swap area to be deleted. If *swaplow* is not specified, the
area will be deleted starting at the second page. When the command completes, swap
blocks can no longer be allocated from this area and all swap blocks previously in use in this
swap area have been moved to other swap areas.

-h

    All sizes are scaled to a human readable format. Scaling is done by repetitively dividing by
1024.

-k

    Write the files sizes in units of 1024 bytes.

-l

    List the status of all the swap areas. The output has five columns:

    path

        The path name for the swap area.

    dev

        The major/minor device number in decimal if it is a block special device; zeroes
otherwise.

    swaplo

        The *swaplow* value for the area in 512-byte blocks.

    blocks

        The *swaplen* value for the area in 512-byte blocks.

    free

        The number of 512-byte blocks in this area that are not currently allocated.

The list does not include swap space in the form of physical memory because this space is not associated with a particular swap area.

If swap -l is run while *swapname* is in the process of being deleted (by swap -d), the string INDEL will appear in a sixth column of the swap stats.

-s

Print summary information about total swap space usage and availability:

allocated
The total amount of swap space in bytes currently allocated for use as backing store.

reserved
The total amount of swap space in bytes not currently allocated, but claimed by memory mappings for possible future use.

used
The total amount of swap space in bytes that is either allocated or reserved.

available
The total swap space in bytes that is currently available for future reservation and allocation.

These numbers include swap space from all configured swap areas as listed by the -l option, as well swap space in the form of physical memory.

Usage On the 32-bit operating system, only the first 2 Gbytes -1 are used for swap devices greater than or equal to 2 Gbytes in size. On the 64-bit operating system, a block device larger than 2 Gbytes can be fully utilized for swap up to $2^{63} - 1$ bytes.

Environment Variables See environ(5) for descriptions of the following environment variables that affect the execution of swap: LC_CTYPE and LC_MESSAGE.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also pagesize(1), mkfile(1M), shareall(1M), zfs(1M), getpagesize(3C), vfstab(4), attributes(5), largefile(5)

Notes For information about setting up a swap area with ZFS, see the *ZFS Administration Guide*.

Warnings No check is done to determine if a swap area being added overlaps with an existing file system.

Name   sync – update the super block

Synopsis   sync

Description   sync executes the sync system primitive. If the system is to be stopped, sync must be called to ensure file system integrity. It will flush all previously unwritten system buffers out to disk, thus assuring that all file modifications up to that point will be saved. See sync(2) for details.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   sync(2), attributes(5)

Name   syncinit – set serial line interface operating parameters

Synopsis   /usr/sbin/syncinit *device*
        [[*baud_rate*] | [*keyword=value*,]... | [*single-word option*]]

Description   The syncinit utility allows the user to modify some of the hardware operating modes common to synchronous serial lines. This can be useful in troubleshooting a link, or necessary to the operation of a communications package.

If run without options, syncinit reports the options as presently set on the port. If options are specified, the new settings are reported after they have been made.

Options   Options to syncinit normally take the form of a keyword, followed by an equal sign and a value. The exception is that a baud rate may be specified as a decimal integer by itself. Keywords must begin with the value shown in the options table, but may contain additional letters up to the equal sign. For example, loop= and loopback= are equivalent.

The following options are supported:

Keyword	Value	Effect
loop	yes	Set the port to operate in internal loopback mode. The receiver is electrically disconnected from the DCE receive data input and tied to the outgoing transmit data line. Transmit data is available to the DCE. The Digital Phase-Locked Loop (DPLL) may not be used as a clock source in this mode. If no other clocking options have been specified, perform the equivalent of txc=baud and rxc=baud.
	no	Disable internal loopback mode. If no other clocking options have been specified, perform the equivalent of txc=txc and rxc=rxc.
echo	yes	Set the port to operate in auto-echo mode. The transmit data output is electrically disconnected from the transmitter and tied to the receive data input. Incoming receive data is still visible. Use of this mode in combination with local loopback mode has no value, and should be rejected by the device driver. The auto-echo mode is useful to make a system become the endpoint of a remote loopback test.
	no	Disable auto-echo mode.
nrzi	yes	Set the port to operate with NRZI data encoding.
	no	Set the port to operate with NRZ data encoding.
txc	txc	Transmit clock source will be the TxC signal (pin 15).
	rxc	Transmit clock source will be the RxC signal (pin 17).
	baud	Transmit clock source will be the internal baud rate generator.
	pll	Transmit clock source will be the output of the DPLL circuit.

rxc	rxc	Receive clock source will be the RxC signal (pin 17).
	txc	Receive clock source will be the TxC signal (pin 15).
	baud	Receive clock source will be the internal baud rate generator.
	pll	Receive clock source will be the output of the DPLL circuit.
speed	*integer*	Set the baud rate to *integer* bits per second.

There are also several single-word options that set one or more parameters at a time:

Keyword	Equivalent to Options:
external	txc=txc rxc=rxc loop=no
sender	txc=baud rxc=rxc loop=no
internal	txc=pll rxc=pll loop=no
stop	speed=0

Examples   **EXAMPLE 1**   Using syncinit

The following command sets the first CPU port to loop internally, using internal clocking and operating at 38400 baud:

```
example# syncinit zsh0 38400 loop=yes
device: /dev/zsh  ppa: 0
speed=38400, loopback=yes, echo=no, nrzi=no, txc=baud, rxc=baud
```

The following command sets the same port's clocking, local loopback and baud rate settings to their default values:

```
example# syncinit zsh0 stop loop=no
device: /dev/zsh  ppa: 0
speed=0, loopback=no, echo=no, nrzi=no, txc=txc, rxc=rxc
```

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

Diagnostics   *device* missing minor device number   The name *device* does not end in a decimal number that can be used as a minor device number.

bad speed: *arg*   The string *arg* that accompanied the speed=
                                     option could not be interpreted as a decimal
                                     integer.

Bad arg: *arg*   The string *arg* did not make sense as an option.

ioctl failure code = *errno*   An ioctl(2) system called failed. The meaning of
                                     the value of *errno* may be found in Intro(2).

Warnings Do not use syncinit on an active serial link, unless needed to resolve an error condition. Do
not use this command casually or without being aware of the consequences.

Name syncloop – synchronous serial loopback test program

Synopsis /usr/sbin/syncloop [-cdlstv] *device*

Description The syncloop command performs several loopback tests that are useful in exercising the various components of a serial communications link.

Before running a test, syncloop opens the designated port and configures it according to command line options and the specified test type. It announces the names of the devices being used to control the hardware channel, the channel number (ppa) corresponding to the *device* argument, and the parameters it has set for that channel. It then runs the loopback test in three phases.

The first phase is to listen on the port for any activity. If no activity is seen for at least four seconds, syncloop proceeds to the next phase. Otherwise, the user is informed that the line is active and that the test cannot proceed, and the program exits.

In the second phase, called the "first-packet" phase, syncloop attempts to send and receive one packet. The program will wait for up to four seconds for the returned packet. If no packets are seen after five attempts, the test fails with an excoriating message. If a packet is returned, the result is compared with the original. If the length and content do not match exactly, the test fails.

The final phase, known as the "multiple-packet" phase, attempts to send many packets through the loop. Because the program has verified the integrity of the link in the first-packet phase, the test will not fail after a particular number of timeouts. If a packet is not seen after four seconds, a message is displayed. Otherwise, a count of the number of packets received is updated on the display once per second. If it becomes obvious that the test is not receiving packets during this phase, the user may wish to stop the program manually. The number and size of the packets sent during this phase is determined by default values, or by command line options. Each returned packet is compared with its original for length and content. If a mismatch is detected, the test fails. The test completes when the required number of packets have been sent, regardless of errors.

After the multiple-packet phase has completed, the program displays a summary of the hardware event statistics for the channel that was tested. The display takes the following form:

```
CRC errors   Aborts   Overruns   Underruns   In<-Drops-> Out
        0        0          0           0   0              0
```

This is followed by an estimated line speed, which is an approximation of the bit rate of the line, based on the number of bytes sent and the actual time that it took to send them.

Options The options for syncloop are described in the following table:

Option	Parameter	Default	Description
-c	*packet_count*	100	Specifies the number of packets to be sent in the multiple-packet phase.
-d	*hex_data_byte*	*random*	Specifies that each packet will be filled with bytes with the value of *hex_data_byte*.
-l	*packet_length*	100	Specifies the length of each packet in bytes.
-s	*line_speed*	9600	Bit rate in bits per second.
-v			Sets verbose mode. If data errors occur, the expected and received data is displayed.
-t	*test_type*	*none*	A number, from 1 to 4, that specifies which test to perform. The values for *test_type* are as follows: 1: Internal loopback test. Port loopback is on. Transmit and receive clock sources are internal (baud rate generator). 2: External loopback test. Port loopback is off. Transmit and receive clock sources are internal. Requires a loopback plug suitable to the port under test. 3: External loopback test. Port loopback is off. Transmit and receive clock sources are external (modem). Requires that one of the local modem, the remote modem, or the remote system be set in a loopback configuration. 4: Test using predefined parameters. User defines hardware configuration and may select port parameters using the syncinit(1M) command.

All numeric options except -d are entered as decimal numbers (for example, -s 19200). If you do not provide the -t *test_type* option, syncloop prompts for it.

Examples   EXAMPLE 1   A sample display of using the syncloop command.

In the following command syncloop uses a packet length of 512 bytes over the first CPU port:

```
example# syncloop -l 512 zsh0
```

In response to the above command, syncloop prompts you for the test option you want.

The following command performs an internal loopback test on the first CPU port, using 5000 packets and a bit rate of 56Kbps:

```
example# syncloop -t 1 -s 56000 -c 5000 zsh0
```

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also syncinit(1M), syncstat(1M), attributes(5), zsh(7D)

Diagnostics

device missing minor device number	The name *device* does not end in a decimal number that can be used as a minor device number.
invalid packet length: *nnn*	The packet length was specified to be less than zero or greater than 4096.
poll: nothing to read	
poll: nothing to read or write.	The poll(2) system call indicates that there is no input pending and/or that output would be blocked if attempted.
len *xxx* should be *yyy*	The packet that was sent had a length of *yyy*, but was received with a length of *xxx*.
nnn packets lost in outbound queueing	
nnn packets lost in inbound queueing	A discrepancy has been found between the number of packets sent by syncloop and the number of packets the driver counted as transmitted, or between the number counted as received and the number read by the program.

Warnings To allow its tests to run properly, as well as prevent disturbance of normal operations, syncloop should only be run on a port that is not being used for any other purpose at that time.

Name syncstat – report driver statistics from a synchronous serial link

Synopsis /usr/sbin/syncstat [-c] *device* [*interval*]

Description The syncstat command reports the event statistics maintained by a synchronous serial device driver. The report may be a single snapshot of the accumulated totals, or a series of samples showing incremental changes. Prior to these it prints the device name being used to query a particular device driver, along with a number indicating the channel number (ppa) under control of that driver.

Event statistics are maintained by a driver for each physical channel that it supports. They are initialized to zero at the time the driver module is loaded into the system, which may be either at boot time or when one of the driver's entry points is first called.

The *device* argument is the name of the serial device as it appears in the /dev directory. For example, zsh0 specifies the first on-board serial device.

The following is a breakdown of syncstat output:

speed	The line speed the device has been set to operate at. It is the user's responsibility to make this value correspond to the modem clocking speed when clocking is provided by the modem.
ipkts	The total number of input packets.
opkts	The total number of output packets.
undrun	The number of transmitter underrun errors.
ovrrun	The number of receiver overrun errors.
abort	The number of aborted received frames.
crc	The number of received frames with CRC errors.
isize	The average size (in bytes) of input packets.
osize	The average size (in bytes) of output packets.

Options -c Clear the accumulated statistics for the device specified. This may be useful when it is not desirable to unload a particular driver, or when the driver is not capable of being unloaded.

interval syncstat samples the statistics every *interval* seconds and reports incremental changes. The output reports line utilization for input and output in place of average packet sizes. These are the relationships between bytes transferred and the baud rate, expressed as percentages. The loop repeats indefinitely, with a column heading printed every twenty lines for convenience.

Examples EXAMPLE 1 Sample output from the syncstat command:

```
example# syncstat zsh0

speed ipkts opkts undrun ovrrun abort crc isize osize
9600  15716 17121 0      0      1     3   98    89

example# syncstat -c zsh0

speed ipkts opkts undrun ovrrun abort crc isize osize
9600  0     0     0      0      0     0   0     0
```

In the following sample output a new line of output is generated every five seconds:

```
example# syncstat zsh0 5

ipkts opkts undrun ovrrun abort crc iutil outil
12    10    0      0      0     0   5%    4%
22    60    0      0      0     0   3%    90%
36    14    0      0      0     1   51%   2%
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also syncinit(1M), syncloop(1M), attributes(5), zsh(7D)

Diagnostics

bad interval: *arg*	The argument *arg* is expected to be an interval and could not be understood.
device missing minor device number	The name *device* does not end in a decimal number that can be used as a minor device number.
baud rate not set	The *interval* option is being used and the baud rate on the device is zero. This would cause a divide-by-zero error when computing the line utilization statistics.

Warnings Underrun, overrun, frame-abort, and CRC errors have a variety of causes. Communication protocols are typically able to handle such errors and initiate recovery of the transmission in which the error occurred. Small numbers of such errors are not a significant problem for most protocols. However, because the overhead involved in recovering from a link error can be much greater than that of normal operation, high error rates can greatly degrade overall link throughput. High error rates are often caused by problems in the link hardware, such as

cables, connectors, interface electronics or telephone lines. They may also be related to excessive load on the link or the supporting system.

The percentages for input and output line utilization reported when using the *interval* option may occasionally be reported as slightly greater than 100% because of inexact sampling times and differences in the accuracy between the system clock and the modem clock. If the percentage of use greatly exceeds 100%, or never exceeds 50%, then the baud rate set for the device probably does not reflect the speed of the modem.

Name sysconfig – unconfigure or reconfigure a Solaris instance

Synopsis /usr/sbin/sysconfig

/usr/sbin/sysconfig configure [-s] [-c *config_profile*.xml | *dir*]
    [--destructive] [-g *system*]

/usr/sbin/sysconfig unconfigure [-s] [--destructive]
    [-g *system*]

/usr/sbin/sysconfig create-profile [-o *output_file* [-l *logfile*]
    [-v *verbosity*] [-b] [-g *system*]

Description The sysconfig utility is the interface for unconfiguring and reconfiguring a Solaris instance.
A Solaris instance is defined as a boot environment in either a global or a non-global zone.

There are three operations that are performed using the sysconfig utility: unconfiguration,
configuration, and profile creation.

When sysconfig is called with the unconfigure subcommand, the system is unconfigured
and left in an unconfigured state.

System configuration can occur either interactively or non-interactively. If the configure
sub-command is invoked without a profile, the SCI Tool is activated and walks the user
through the system configuration process. If the configure subcommand is invoked with a
profile, then the configuration reads the profile and the configuration occurs
non-interactively. The result in either case is a new system configuration.

The sysconfig command can also be used to generate a system configuration profile using
the create-profile subcommand. The resulting profile is used with the sysconfig
configure subcommand to configure systems non-interactively. Valid profile names include
an .xml extension.

Configuration of a system can be performed either interactively, using the System
Configuration Interactive (SCI) Tool, or non-interactively, using a system configuration
profile.

The SCI tool configures the target system in an interactive way using a text user interface. It
can also be used to collect information generated by the user that describes the desired
configuration of the target system. The tool then generates a system configuration profile
containing the desired system configuration.

The SCI tool supports configuration of freshly installed or unconfigured systems. It is
designed to provide system configuration for newly created non-global zones and during text
installation. If there is a need to modify the configuration of an already configured system
utilizing SCI tool, such a system has to be unconfigured first before SCI tool can run.

The functional groupings that can be configured on a system are network, location, users, identity, and kbd_layout. Groupings can also be unconfigured and left in an unconfigured state. The default values for unconfigured groupings are shown below.

The following groupings are configurable.

```
Grouping        | Components          | Unconfigured State
----------------------------------------------------------
identity        | system nodename    | unknown
----------------------------------------------------------
kbd_layout      | Keyboard           | U.S. English
----------------------------------------------------------
network         | network            | No network
----------------------------------------------------------
location        | timezone           | UTC
                | locale             | C locale
----------------------------------------------------------
users           | root               | Empty root password
                | initial user account | Remove user account
----------------------------------------------------------
naming_services | DNS, NIS and LDAP  | No network naming
                | clients, nsswitch  | services
----------------------------------------------------------
```

Sub-commands This section describes supported subcommands and their associated options.

unconfigure [-s] [-g *system*] [--destructive]
  Unconfigure a system and leave it in the unconfigured state.

  -s
    Shut the system down after the unconfiguration completes.

  -g *system*
    If -g is not specified, the user will be queried for confirmation before *system* configuration occurs.

  --destructive
    Do not preserve system data that is normally preserved during unconfiguration. By specifying this flag, the user indicates to any groupings unconfigured that data they would ordinarily preserve might be deleted.

configure [-s] [-g *system*] [-c *config_profile*.xml | *dir*] [--destructive]
  Configure or reconfigure a system. The configure subcommand has access to the same options as the unconfigure subcommand. It also includes the following additional option.

  -c *config_profile*.xml | *dir*
    Provides a profile or a directory of profiles to apply during configuration. If a profile is applied, the configuration step occurs non-interactively. If no profile is provided, the interactive system configuration tool is used for the configuration of the system.

All profiles must have an `.xml` file extension.

If you supply a directory to `-c`, all profiles in that directory must be valid (correctly formed) configuration profiles.

create-profile [`-o` *output_file* [`-l` *logfile*] [`-v` *verbosity*] [`-b`] [`-g` *grouping*,...]
  Run the SCI tool and create a system configuration profile. The default location for the profile is `/system/volatile/profile/sc_profile.xml`. The configuration generated is not applied to the system.

`-o` *output_file*
  Replace the default profile location with *output_file* for the configuration profile.

`-l`
  Location of the log file. Used only with `-o` option.

`-v`
  Verbosity level. Used only with `-o` option.

`-b`
  Black and white version of SCI tool. Used only with `-o` option.

Examples **EXAMPLE 1** Unconfiguring and Shutting Down

The following command unconfigures the system and leaves it in an `unconfigured` state. By default, if no grouping is specified, the groupings for the whole system are unconfigured.

```
# sysconfig unconfigure -s
```

EXAMPLE 2 Unconfiguring the System

The following command unconfigures the system groupings and leaves the system `unconfigured`.

```
# sysconfig unconfigure -g system
```

EXAMPLE 3 Reconfiguring System Using SCI Tool

The following command brings up the SCI Tool to reconfigure a system.

```
# sysconfig configure
```

EXAMPLE 4 Reconfiguring Using a Profile

The following command reconfigures a system using a profile.

```
# sysconfig configure -c some_profile.xml
```

EXAMPLE 5 Creating and Using a Profile

The following sequence of commands creates a profile, then uses it to reconfigure a system.

```
# sysconfig create-profile -o /tmp/myprofile.xml
# sysconfig configure -g system -c /tmp/myprofile.xml
```

EXAMPLE 6   Configuring the System in a Zone

The following command configures the system in a zone.

```
# zlogin ZONENAME
root@ZONENAME# sysconfig configure -g system
```

Exit Status   0

Success.

>0

Failure.

Name sysdef – output system definition

Synopsis /usr/sbin/sysdef [-i] [-n *namelist*]

/usr/sbin/sysdef [-h] [-d] [-i] [-D]

Description The sysdef utility outputs the current system definition in tabular form. It lists all hardware devices, as well as pseudo devices, system devices, loadable modules, and the values of selected kernel tunable parameters.

It generates the output by analyzing the named bootable operating system file (*namelist*) and extracting the configuration information from it.

The default system *namelist* is /dev/kmem.

Options -i   Prints the configuration information from /dev/kmem. This is the default and only needs to be specified if the configuration information from both /dev/kmem and the system file specified with the "-n *namelist*" option is needed.

-n *namelist*   Specifies a *namelist* other than the default (/dev/kmem). The *namelist* specified must be a valid bootable operating system.

-h   Prints the identifier of the current host in hexadecimal. If sysdef -h is executed within a non-global zone and the zone emulates a host identifier, then the zone's host identifier is printed. This numeric value is not guaranteed to be unique.

-d   The output includes the configuration of system peripherals formatted as a device tree.

-D   For each system peripheral in the device tree, display the name of the device driver used to manage the peripheral.

Examples EXAMPLE 1   Sample output format

The following example displays the format of the sysdef -d output:

```
example% sysdef -d
Node 'SUNW,Ultra-5_10', unit #-1
    Node 'packages', unit #-1 (no driver)
        Node 'terminal-emulator', unit #-1 (no driver)
        Node 'deblocker', unit #-1 (no driver)
        Node 'obp-tftp', unit #-1 (no driver)
        Node 'disk-label', unit #-1 (no driver)
        Node 'SUNW,builtin-drivers', unit #-1 (no driver)
        Node 'sun-keyboard', unit #-1 (no driver)
        Node 'ufs-file-system', unit #-1 (no driver)
    Node 'chosen', unit #-1 (no driver)
    Node 'openprom', unit #-1 (no driver)
        Node 'client-services', unit #-1 (no driver)
```

EXAMPLE 1 Sample output format   *(Continued)*

Name   syseventadm – sysevent event specification administration

Synopsis   syseventadm add [-R *rootdir*] [-v *vendor*] [-p *publisher*]
            [-c *class*] [-s *subclass*] [-u *username*] *path* [*args*]

syseventadm remove [-R *rootdir*] [-v *vendor*] [-p *publisher*]
            [-c *class*] [-s *subclass*] [-u *username*] [*path* [*args*]]

syseventadm list [-R *rootdir*] [-v *vendor*] [-p *publisher*]
            [-c *class*] [-s *subclass*] [-u *username*] [*path* [*args*]]

syseventadm restart

Description   The syseventadm command is an administrative front-end to add, remove and list sysevent
            event handlers. You can also restart the sysevent daemon by use of the restart command.
            syseventadm can only be run by root.

The syseventadm add command adds a handler for a sysevent event specified by at least one
of vendor, publisher or class. If *class* is specified, it may be qualified with a *sub-class*. Only the
values specified for *vendor*, *publisher*, *class* and *sub-class* when adding the handler are matched
against sysevent events to determine if the specification matches the event and the handler
should be run. *path* is the full pathname of the command to be run in response to matching
events, with optional arguments (*args*). If username is specified, the command is invoked as
user *username*, otherwise as root.

The syseventadm remove command removes handlers for matching sysevent event
specifications. Event specifications may be matched by specifying at least one of *vendor*,
publisher, *class*, *username* or *path*. If *class* is specified, it may be qualified with a *sub-class*. Any
of *vendor*, *publisher*, *class*, *sub-class*, *username*, *path* or *args* not specified match the
corresponding fields of all events. Handlers for all matching specifications are removed.

The syseventadm list command lists the handlers for matching sysevent event
specifications using the same match criteria as the remove command but without the
requirement that at least one of *vendor*, *publisher*, *class*, *username* or *path* be specified. With
no match criteria, all specifications are listed. The list command output format is:
[vendor=*vendor*] [publisher=*publisher*] [class=*class*] [subclass=*subclass*]
[username=*username*] *path* [*args*] where each of *class*, *sub-class*, *vendor*, *publisher* and
username is listed only if part of the match criteria for the listed specification.

The syseventadm restart command informs the syseventd daemon to reread the sysevent
registry after a change has been made by adding or removing one or more sysevent handler
specifications.

**Argument Macro
Substitution**   The sysevent handling facility provides extensive macro capability for constructing the
            command line arguments to be executed in response to an event. Macro expansion applies
            only to the command line *args* specified for an event handler, with macros expanded with data
            from the event itself. Pre-defined macros are provided for the event *class*, *subclass*, *publisher*
            and *vendor* information. Macros not matching one of the pre-defined macro names cause the

attribute list attached to the event to be searched for an attribute of that name, with the value of the matching attribute substituted on the command line.

Macros are introduced by the $ character, with the macro name being the following token separated by a SPACE or TAB character. If the macro name is embedded in text, it may be delineated by ${ and }. A \ before the $ causes macro expansion not to occur.

$*class*	The class string defining the event
$*publisher*	The publisher string defining the event
$*sequence*	The sequence number of the event.
$*subclass*	The subclass string defining the event
$*timestamp*	The timestamp of the event.
$*vendor*	The vendor string defining the event

Macro names other than those pre-defined are compared against the attribute list provided with the event. An attribute with name matching the macro name causes the value of the attribute to be substituted as ASCII text on the generated command line.

Use of a macro for which no attribute with that name is defined, or for which multiple attributes with that name are provided, cause an error and the command is not invoked.

Attributes with signed data types (DATA_TYPE_INT16, DATA_TYPE_INT32 and DATA_TYPE_INT64) are expanded as decimal digits.

Attributes with unsigned data types (DATA_TYPE_BYTE, DATA_TYPE_UINT16, DATA_TYPE_UINT32, DATA_TYPE_UINT64 and DATA_TYPE_HTTIME) are expanded as hexadecimal digits with a 0x prefix.

Attributes with string data type (DATA_TYPE_STRING) are expanded with the string data. The data is not quoted. If if it desired that the quoted strings be generated on the command line, put quotes around the macro call in the arguments.

Array types are expanded with each element expanded as defined for that scalar type, with a space separating each element substitution.

Options The add, list and remove subcommands support the following options:

-c *class*	Specify the event class, *class*.
-p *publisher*	Specify the event publisher, *publisher*.
-R *rootdir*	Specify an alternate root path, *rootdir*.
	Note – The root file system of any non-global zones must not be referenced with the -R option. Doing so might damage the global zone's file system,

might compromise the security of the global zone, and might damage the non-global zone's file system. See zones(5).

-s *subclass* Specify the event subclass, *subclass*.

-u *username* Specify the username (*username*) to invoke the command.

-v *vendor* Specify the vendor (*vendor*) that defines the event. Events defined by third-party software should specify the company's stock symbol as *vendor*. Sun-defined events use SUNW.

Operands The add, list and remove subcommands support the following options:

args Command arguments

path Full path of command to be run in response to event

Examples **EXAMPLE 1** Adding an Event Handler

The following example adds an event handler for an event defined by vendor MYCO ("My Company"), class EC_ENV and sub-class ESC_ENV_TEMP. The command to be run is /opt/MYCOenv/bin/ec_env_temp, with arguments being the class name, sub-class name and pathname derived from the event attributes. The $ characters are preceded by a backslash to circumvent shell interpretation. There is no need to restart the service after the change since the registry is maintained on $ALTROOT.

```
# syseventadm add -R \$ALTROOT -v MYCO -c EC_ENV -s ESC_ENV_TEMP \
    /opt/MYCOenv/bin/ec_env_temp \$class \$subclass \$pathname
```

Note the caveat on the use of the -R option in the description of that option, above.

EXAMPLE 2 Removing an Event Handler

The following example removes the event handler added in Example 1.

```
# syseventadm remove -R \$ALTROOT -v MYCO -c EC_ENV -s ESC_ENV_TEMP \
    /opt/MYCOenv/bin/ec_env_temp \${class} \${subclass} \${pathname}
```

Note the caveat on the use of the -R option in the description of that option, above.

EXAMPLE 3 Listing Event Handlers

The following example lists all event handlers for events of class EC_ENV, subclass ESC_ENV_TEMP, as defined by vendor MYCO:

```
# syseventadm list -v MYCO -c EC_ENV -s ESC_ENV_TEMP \
    vendor=MYCO class=EC_ENV subclass=ESC_ENV_TEMP \
    /opt/MYCOenv/bin/ec_env_temp \${class} \${subclass} \${pathname}
```

EXAMPLE 4 Listing Event Handlers

The following example lists all event handlers defined by vendor VRTS.

```
# syseventadm list -v VRTS
```

EXAMPLE 5 Removing Event Handlers

The following example removes all event handlers defined by vendor VRTS, and restarts service.

```
# syseventadm remove -v VRTS
# syseventadm restart
```

EXAMPLE 6 Listing All Event Handlers Specified to Run a Command

The following example lists all event handlers specified to run the command /opt/MYCOenv/bin/ec_env_temp:

```
# syseventadm list /opt/MYCOenv/bin/ec_env_temp
```

EXAMPLE 7 Removing Event Handlers and Restarting Service

The following example removes all event handlers specified to run the command /opt/MYCOenv/bin/ec_env_temp, and restarts service:

```
# syseventadm remove /opt/MYCOenv/bin/ec_env_temp
# syseventadm restart
```

Exit Status The following exit values are returned:

0   Successful completion.

1   No matching event specification found (remove or list commands only).

2   Incorrect command usage.

3   Permission denied.

4   Command failed.

5   Out of memory.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also syseventd(1M), sysevent_post_event(3SYSEVENT), attributes(5), ddi_log_sysevent(9F)

Notes   To avoid upgrade problems, packages delivering a sysevent event handler should install the event handler by running `syseventadm` from the package's postinstall script. The event handler can then be removed by running `syseventadm` from the package's preremove script using the same arguments as when added.

Name syseventconfd – kernel system event command invocation daemon

Synopsis /usr/lib/sysevent/syseventconfd [-r *rootdir*]

Description syseventconfd is the user-level daemon that invokes user-level commands in response to kernel system events received from syseventd(1M).

Options The following options are supported:

-r *rootdir*   Cause syseventconfd to use an alternate root path when creating its door. The root path must match the root path used to invoke syseventd.

Files /etc/sysevent/syseventconfd_event_service
   syseventconfd event service door file

/usr/lib/sysevent/modules/sysevent_conf_mod.so
   syseventd loadable module (SLM) managing sysevent.conf files

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also svcs(1), svcadm(1M), syseventd(1M), attributes(5), smf(5)

Notes The syseventconfd service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/sysevent:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name syseventd – kernel system event notification daemon

Synopsis /usr/lib/sysevent/syseventd [-d *debug_level*] [-r *rootdir*]

Description syseventd is a user-level daemon that accepts delivery of system event buffers from the kernel. Once an event buffer has been delivered to syseventd, it, in turn, attempts to propagate the event to all interested end event subscribers.

Event subscribers take the form of a syseventd loadable module (SLM). syseventd passes the event buffer to each of its subscribers and in return expects a notification as to the successful or unsuccessful delivery attempt.

Upon successful delivery of the event buffer to all interested event subscribers, syseventd frees the event buffer from the kernel event queue.

Options The following option is supported:

-d *debug_level*   Enable debug mode. Messages are printed to the invoking user's terminal.

Exit Status The following exit values are returned:

0   Successful completion.

non-zero   An error occurred.

Files /etc/sysevent/syseventd_daemon.lock
    daemon lock file

/etc/sysevent/sysevent_door
    kernel to syseventd door file

/usr/lib/sysevent/modules
    SLM directory repository

/usr/platform/`uname –i`/lib/sysevent/modules
    SLM directory repository

/usr/platform/`uname –m`/lib/sysevent/modules
    SLM directory repository

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also svcs(1), svcadm(1M), syseventconfd(1M), attributes(5), smf(5)

Notes The syseventd service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/system/sysevent:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name syslogd – log system messages

Synopsis /usr/sbin/syslogd [-d] [-f *configfile*] [-m *markinterval*]
[-p *path*] [-t | -T]

Description syslogd reads and forwards system messages to the appropriate log files or users, depending upon the priority of a message and the system facility from which it originates. The configuration file /etc/syslog.conf (see syslog.conf(4)) controls where messages are forwarded. syslogd logs a mark (timestamp) message every *markinterval* minutes (default 20) at priority LOG_INFO to the facility whose name is given as mark in the syslog.conf file.

A system message consists of a single line of text, which may be prefixed with a priority code number enclosed in angle-brackets (< >); priorities are defined in <sys/syslog.h>.

syslogd reads from the STREAMS log driver, /dev/log, and from any transport provider specified in /etc/netconfig, /etc/net/transport/hosts, and /etc/net/transport/services.

syslogd reads the configuration file when it starts up, and again whenever it receives a HUP signal (see signal.h(3HEAD), at which time it also closes all files it has open, re-reads its configuration file, and then opens only the log files that are listed in that file. syslogd exits when it receives a TERM signal.

As it starts up, syslogd creates the file /var/run/syslog.pid, if possible, containing its process identifier (PID).

If message ID generation is enabled (see log(7D)), each message will be preceded by an identifier in the following format: [ID *msgid facility*.*priority*]. *msgid* is the message's numeric identifier described in msgid(1M). *facility* and *priority* are described in syslog.conf(4). [ID 123456 kern.notice] is an example of an identifier when message ID generation is enabled.

If the message originated in a loadable kernel module or driver, the kernel module's name (for example, ufs) will be displayed instead of unix. See EXAMPLES for sample output from syslogd with and without message ID generation enabled.

In an effort to reduce visual clutter, message IDs are not displayed when writing to the console; message IDs are only written to the log file. See Examples.

The /etc/default/syslogd file contains the following default parameter settings, which are in effect if neither the -t nor -T option is selected. See FILES.

The recommended way to allow or disallow message logging is through the use of the service management facility (smf(5)) property:

svc:/system/system-log/config/log_from_remote

This property specifies whether remote messages are logged. log_from_remote=true is equivalent to the -t command-line option and false is equivalent to the -T command-line option. The default value for -log_from_remote is false. See NOTES, below.

LOG_FROM_REMOTE

Specifies whether remote messages are logged. LOG_FROM_REMOTE=NO is equivalent to the -t command-line option. The default value for LOG_FROM_REMOTE is YES.

Options The following options are supported:

-d

Turn on debugging. This option should only be used interactively in a root shell once the system is in multi-user mode. It should *not* be used in the system start-up scripts, as this will cause the system to hang at the point where syslogd is started.

-f *configfile*
Specify an alternate configuration file.

-m *markinterval*
Specify an interval, in minutes, between mark messages.

-p *path*
Specify an alternative log device name. The default is /dev/log.

-T

Enable the syslogd UDP port to turn on logging of remote messages. This is the default behavior. See Files.

-t

Disable the syslogd UDP port to turn off logging of remote messages. See Files.

Examples **EXAMPLE 1** syslogd Output Without Message ID Generation Enabled

The following example shows the output from syslogd when message ID generation *is not* enabled:

```
Sep 29 21:41:18 cathy unix: alloc /: file system full
```

EXAMPLE 2 syslogd Output with ID generation Enabled

The following example shows the output from syslogd when message ID generation *is* enabled. The message ID is displayed when writing to log file/var/adm/messages.

```
Sep 29 21:41:18 cathy ufs: [ID 845546 kern.notice]
                                    alloc /: file system full
```

EXAMPLE 3 syslogd Output with ID Generation Enabled

The following example shows the output from syslogd when message ID generation *is* enabled when writing to the console. Even though message ID is enabled, the message ID is not displayed at the console.

```
Sep 29 21:41:18 cathy ufs: alloc /: file system full
```

EXAMPLE 4 Enabling Acceptance of UDP Messages from Remote Systems

The following commands enable syslogd to accept entries from remote systems.

```
# svccfg -s svc:/system/system-log setprop config/log_from_remote = true
# svcadm restart svc:/system/system-log
```

Files /etc/syslog.conf
Configuration file

/var/run/syslog.pid
Process ID

/etc/default/syslogd
Contains default settings. You can override some of the settings by command-line options.

/dev/log
STREAMS log driver

/etc/netconfig
Transport providers available on the system

/etc/net/transport/hosts
Network hosts for each transport

/etc/net/transport/services
Network services for each transport

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also logger(1), svcs(1), msgid(1M), svcadm(1M), svccfg(1M), syslog(3C), syslog.conf(4), attributes(5), signal.h(3HEAD), smf(5), log(7D)

Notes The mark message is a system time stamp, and so it is only defined for the system on which syslogd is running. It can not be forwarded to other systems.

When syslogd receives a HUP signal, it attempts to complete outputting pending messages, and close all log files to which it is currently logging messages. If, for some reason, one (or more) of these files does not close within a generous grace period, syslogd discards the pending messages, forcibly closes these files, and starts reconfiguration. If this shutdown procedure is disturbed by an unexpected error and syslogd cannot complete reconfiguration, syslogd sends a mail message to the superuser on the current system stating that it has shut down, and exits.

Care should be taken to ensure that each window displaying messages forwarded by syslogd (especially console windows) is run in the system default locale (which is syslogd's locale). If

this advice is not followed, it is possible for a syslog message to alter the terminal settings for that window, possibly even allowing remote execution of arbitrary commands from that window.

The syslogd service is managed by the service management facility, smf(5), under the service identifier:

```
 svc:/system/system-log:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

When syslogd is started by means of svcadm(1M), if a value is specified for LOG_FROM_REMOTE in the /etc/defaults/syslogd file, the SMF property svc:/system/system-log/config/log_from_remote is set to correspond to the LOG_FROM_REMOTE value and the /etc/default/syslogd file is modified to replace the LOG_FROM_REMOTE specification with the following comment:

```
# LOG_FROM_REMOTE is now set using svccfg(1m), see syslogd(1m).
```

If neither LOG_FROM_REMOTE nor svc:/system/system-log/config/log_from_remote are defined, the default is to log remote messages.

On installation, the initial value of svc:/system/system-log/config/log_from_remote is false.

Name tapes – creates /dev entries for tape drives attached to the system

Synopsis /usr/sbin/tapes [-r *root_dir*]

Description devfsadm(1M) is now the preferred command for /dev and /devices and should be used instead of tapes.

tapes creates symbolic links in the /dev/rmt directory to the actual tape device special files under the /devices directory tree. tapes searches the kernel device tree to see what tape devices are attached to the system. For each equipped tape drive, the following steps are performed:

1. The /dev/rmt directory is searched for a /dev/rmt/*n* entry that is a symbolic link to the /devices special node of the current tape drive. If one is found, this determines the logical controller number of the tape drive.

2. The rest of the special devices associated with the drive are checked, and incorrect symbolic links are removed and necessary ones added.

3. If none are found, a new logical controller number is assigned (the lowest-unused number), and new symbolic links are created for all the special devices associated with the drive.

tapes does not remove links to non-existent devices; these must be removed by hand.

tapes is run each time a reconfiguration-boot is performed, or when add_drv(1M) is executed.

Notice to Driver Writers tapes(1M) considers all devices with the node type DDI_NT_TAPE to be tape devices; these devices must have their minor name created with a specific format. The minor name encodes operational modes for the tape device and consists of an ASCII string of the form [l,m,h,c,u][b][n].

The first character set is used to specify the tape density of the device, and are named low (l), medium (m), high (h), compressed (c), and ultra (u). These specifiers only express a relative density; it is up to the driver to assign specific meanings as needed. For example, 9 track tape devices interpret these as actual bits-per-inch densities, where l means 800 BPI, m means 1600 BPI , and h means 6250 BPI, whereas 4mm DAT tapes defines l as standard format, and m, h, c and u as compressed format. Drivers may choose to implement any or all of these format types.

During normal tape operation (non-BSD behavior), once an EOF mark has been reached, subsequent reads from the tape device return an error. An explicit IOCTL must be issued to space over the EOF mark before the next file can be read. b instructs the device to observe BSD behavior, where reading at EOF will cause the tape device to automatically space over the EOF mark and begin reading from the next file.

n or no-rewind-on-close instructs the driver to not rewind to the beginning of tape when the device is closed. Normal behavior for tape devices is to reposition to BOT when closing. See mtio(7I).

The minor number for tape devices should be created by encoding the device's instance number using the tape macro MTMINOR and ORing in the proper combination of density, BSD behavior, and no-rewind flags. See mtio(7I).

To prevent tapes from attempting to automatically generate links for a device, drivers must specify a private node type and refrain from using the node type string DDI_NT_TAPE when callingddi_create_minor_node(9F).

Options The following options are supported:

-r *root_dir*   Causes tapes to presume that the /dev/rmt directory tree is found under *root_dir*, not directly under /.

Errors If tapes finds entries of a particular logical controller linked to different physical controllers, it prints an error message and exits without making any changes to the /dev directory, since it cannot determine which of the two alternative logical to physical mappings is correct. The links should be manually corrected or removed before another reconfiguration boot is performed.

Examples EXAMPLE 1   Creating Tape Device Nodes From Within the Driver's attach() Function

This example demonstrates creating tape device nodes from within the xktape driver's attach(9E) function.

```
#include <sys/mtio.h>
struct tape_minor_info {
    char *minor_name;
    int  minor_mode;
};
/*
 * create all combinations of logical tapes
*/
static struct tape_minor_info example_tape[] = {
   {"",   0},                       /* default tape */
   {"l",  MT_DENSITY1},
   {"lb", MT_DENSITY1 | MT_BSD},
   {"lbn", MT_DENSITY1 | MT_BSD | MT_NOREWIND},
   {"m",  MT_DENSITY2},
   {"mb", MT_DENSITY2 | MT_BSD},
   {"mbn", MT_DENSITY2 | MT_BSD | MT_NOREWIND},
   {"h",  MT_DENSITY3},
   {"hb", MT_DENSITY3 | MT_BSD},
   {"hbn", MT_DENSITY3 | MT_BSD | MT_NOREWIND},
   {"c",  MT_DENSITY4},
   {"cb", MT_DENSITY4 | MT_BSD},
   {"cbn", MT_DENSITY4| MT_BSD | MT_NOREWIND},
   {NULL,  0},
};
```

EXAMPLE 1 Creating Tape Device Nodes From Within the Driver's `attach()` Function   *(Continued)*

```
int
xktapeattach(dev_info_t *dip, ddi_attach_cmd_t cmd)
{
   int instance;
   struct tape_minor_info *mdp;
      /* other stuff in attach... */
   instance = ddi_get_instance(dip);

   for (mdp = example_tape; mdp->minor_name != NULL; mdp++) {
           ddi_create_minor_node(dip, mdp->minor_name, S_IFCHR,
               (MTMINOR(instance) | mdp->minor_mode), DDI_NT_TAPE, 0);
 }
```

Installing the `xktape` driver on a Sun Fire 4800, with the driver controlling a SCSI tape (target 4 attached to an isp(7D) SCSI HBA) and performing a reconfiguration-boot creates the following special files in /devices.

```
# ls -l /devices/ssm@0,0/pci@18,700000/pci@1/SUNW,isptwo@4
crw-rw-rw-   1 root sys   33,136 Aug 29 00:02  xktape@4,0:
crw-rw-rw-   1 root sys   33,200 Aug 29 00:02  xktape@4,0:b
crw-rw-rw-   1 root sys   33,204 Aug 29 00:02  xktape@4,0:bn
crw-rw-rw-   1 root sys   33,152 Aug 29 00:02  xktape@4,0:c
crw-rw-rw-   1 root sys   33,216 Aug 29 00:02  xktape@4,0:cb
crw-rw-rw-   1 root sys   33,220 Aug 29 00:02  xktape@4,0:cbn
crw-rw-rw-   1 root sys   33,156 Aug 29 00:02  xktape@4,0:cn
crw-rw-rw-   1 root sys   33,144 Aug 29 00:02  xktape@4,0:h
crw-rw-rw-   1 root sys   33,208 Aug 29 00:02  xktape@4,0:hb
crw-rw-rw-   1 root sys   33,212 Aug 29 00:02  xktape@4,0:hbn
crw-rw-rw-   1 root sys   33,148 Aug 29 00:02  xktape@4,0:hn
crw-rw-rw-   1 root sys   33,128 Aug 29 00:02  xktape@4,0:l
crw-rw-rw-   1 root sys   33,192 Aug 29 00:02  xktape@4,0:lb
crw-rw-rw-   1 root sys   33,196 Aug 29 00:02  xktape@4,0:lbn
crw-rw-rw-   1 root sys   33,132 Aug 29 00:02  xktape@4,0:ln
crw-rw-rw-   1 root sys   33,136 Aug 29 00:02  xktape@4,0:m
crw-rw-rw-   1 root sys   33,200 Aug 29 00:02  xktape@4,0:mb
crw-rw-rw-   1 root sys   33,204 Aug 29 00:02  xktape@4,0:mbn
crw-rw-rw-   1 root sys   33,140 Aug 29 00:02  xktape@4,0:mn
crw-rw-rw-   1 root sys   33,140 Aug 29 00:02  xktape@4,0:n
```

/dev/rmt will contain the logical tape devices (symbolic links to tape devices in /devices).

```
# ls -l /dev/rmt
/dev/rmt/0    -> ../../devices/[....]/xktape@4,0:
/dev/rmt/0b   -> ../../devices/[....]/xktape@4,0:b
/dev/rmt/0bn  -> ../../devices/[....]/xktape@4,0:bn
```

EXAMPLE 1   Creating Tape Device Nodes From Within the Driver's attach() Function   *(Continued)*

```
/dev/rmt/0c   -> ../../devices/[....]/xktape@4,0:c
/dev/rmt/0cb  -> ../../devices/[....]/xktape@4,0:cb
/dev/rmt/0cbn -> ../../devices/[....]/xktape@4,0:cbn
/dev/rmt/0cn  -> ../../devices/[....]/xktape@4,0:cn
/dev/rmt/0h   -> ../../devices/[....]/xktape@4,0:h
/dev/rmt/0hb  -> ../../devices/[....]/xktape@4,0:hb
/dev/rmt/0hbn -> ../../devices/[....]/xktape@4,0:hbn
/dev/rmt/0hn  -> ../../devices/[....]/xktape@4,0:hn
/dev/rmt/0l   -> ../../devices/[....]/xktape@4,0:l
/dev/rmt/0lb  -> ../../devices/[....]/xktape@4,0:lb
/dev/rmt/0lbn -> ../../devices/[....]/xktape@4,0:lbn
/dev/rmt/0ln  -> ../../devices/[....]/xktape@4,0:ln
/dev/rmt/0m   -> ../../devices/[....]/xktape@4,0:m
/dev/rmt/0mb  -> ../../devices/[....]/xktape@4,0:mb
/dev/rmt/0mbn -> ../../devices/[....]/xktape@4,0:mbn
/dev/rmt/0mn  -> ../../devices/[....]/xktape@4,0:mn
/dev/rmt/0n   -> ../../devices/[....]/xktape@4,0:n
```

Writing Device Drivers

Bugs   tapes silently ignores malformed minor device names.

Name tcxconfig – configure default linearity of 24-bit TrueColor Visual for OpenWindows

Synopsis /usr/sbin/tcxconfig [linear | nonlinear]

Description The tcxconfig script changes the default linearity of a 24-bit TrueColor Visual for OpenWindows on a system with an S24 frame buffer. When the S24 graphics driver for OpenWindows is installed, the default 24-bit TrueColor Visual is nonlinear. You can run tcxconfig with an argument that specifies the setting you want.

OpenWindows should not be running when you execute the tcxconfig script with an option. Start OpenWindows after tcxconfig has set the linearity you desire.

Options If you specify no option, tcxconfig displays the current default setting.

You must become superuser before you can execute tcxconfig with one of the following options.

linear Set linear visual to be the default 24-bit TrueColor Visual. This means colors will be gamma-corrected.

nonlinear Set nonlinear visual to be the default 24-bit TrueColor Visual.

Exit Status The following exit values are returned:

0 success

1 an error has occurred.

Name th_define – create fault injection test harness error specifications

Synopsis th_define [-n *name* -i *instance*| -P *path*] [-a *acc_types*]
       [-r *reg_number*] [-l *offset* [*length*]]
       [-c *count* [*failcount*]] [-o *operator* [*operand*]]
       [-f *acc_chk*] [-w *max_wait_period* [*report_interval*]]

or

th_define [-n *name* -i *instance*| -P *path*]
       [-a log [*acc_types*] [-r *reg_number*] [-l *offset* [*length*]]]
       [-c *count* [*failcount*]] [-s *collect_time*] [-p *policy*]
       [-x *flags*] [-C *comment_string*]
       [-e *fixup_script* [*args*]]

or

th_define [-h]

Description The th_define utility provides an interface to the bus_ops fault injection bofi device driver
for defining error injection specifications (referred to as errdefs). An errdef corresponds to a
specification of how to corrupt a device driver's accesses to its hardware. The command line
arguments determine the precise nature of the fault to be injected. If the supplied arguments
define a consistent errdef, the th_define process will store the errdef with the bofi driver and
suspend itself until the criteria given by the errdef become satisfied (in practice, this will occur
when the access counts go to zero).

You use the th_manage(1M) command with the start option to activate the resulting errdef.
The effect of th_manage with the start option is that the bofi driver acts upon the errdef by
matching the number of hardware accesses—specified in *count*, that are of the type specified
in *acc_types*, made by instance number *instance*—of the driver whose name is *name*, (or by the
driver instance specified by *path*) to the register set (or DMA handle) specified by *reg_number*,
that lie within the range *offset* to *offset* + *length* from the beginning of the register set or DMA
handle. It then applies *operator* and *operand* to the next *failcount* matching accesses.

If *acc_types* includes log, th_define runs in automatic test script generation mode, and a set
of test scripts (written in the Korn shell) is created and placed in a sub-directory of the current
directory with the name <*driver*>.test.<*id*> (for example, glm.test.978177106). A
separate, executable script is generated for each access handle that matches the logging
criteria. The log of accesses is placed at the top of each script as a record of the session. If the
current directory is not writable, file output is written to standard output. The base name of
each test file is the driver name, and the extension is a number that discriminates between
different access handles. A control script (with the same name as the created test directory) is
generated that will run all the test scripts sequentially.

Executing the scripts will install, and then activate, the resulting error definitions. Error
definitions are activated sequentially and the driver instance under test is taken offline and
brought back online before each test (refer to the -e option for more information). By default,
logging applies to all PIO accesses, all interrupts, and all DMA accesses to and from areas

mapped for both reading and writing. You can constrain logging by specifying additional *acc_types*, *reg_number*, *offset* and *length*. Logging will continue for *count* matching accesses, with an optional time limit of *collect_time* seconds.

Either the -n or -P option must be provided. The other options are optional. If an option (other than -a) is specified multiple times, only the final value for the option is used. If an option is not specified, its associated value is set to an appropriate default, which will provide maximal error coverage as described below.

Options   The following options are available:

-n *name*	Specify the name of the driver to test. (String)
-i *instance*	Test only the specified driver instance (-1 matches all instances of driver). (Numeric)
-P *path*	Specify the full device path of the driver to test. (String)
-r *reg_number*	Test only the given register set or DMA handle (-1 matches all register sets and DMA handles). (Numeric)
-a *acc_types*	Only the specified access types will be matched. Valid values for the *acc_types* argument are log, pio, pio_r, pio_w, dma, dma_r, dma_w and intr. Multiple access types, separated by spaces, can be specified. The default is to match all hardware accesses.
	If *acc_types* is set to log, logging will match all PIO accesses, interrupts and DMA accesses to and from areas mapped for both reading and writing. log can be combined with other *acc_types*, in which case the matching condition for logging will be restricted to the specified addinal *acc_types*. Note that dma_r will match only DMA handles mapped for reading only; dma_w will match only DMA handles mapped for writing only; dma will match only DMA handles mapped for both reading and writing.
-l *offset* [*length*]	Constrain the range of qualifying accesses. The *offset* and *length* arguments indicate that any access of the type specified with the -a option, to the register set or DMA handle specified with the -r option, lie at least *offset* bytes into the register set or DMA handle and at most *offset* + *length*

bytes into it. The default for *offset* is 0. The default for *length* is the maximum value that can be placed in an offset_t C data type (see types.h). Negative values are converted into unsigned quantities. Thus, th_define -l 0 -1 is maximal.

-c *count*[*failcount*]   Wait for *count* number of matching accesses, then apply an operator and operand (see the -o option) to the next *failcount* number of matching accesses. If the access type (see the -a option) includes logging, the number of logged accesses is given by *count* + *failcount* - 1. The -1 is required because the last access coincides with the first faulting access.

Note that access logging may be combined with error injection if *failcount* and *operator* are nonzero and if the access type includes logging and any of the other access types (pio, dma and intr) See the description of access types in the definition of the -a option, above.

When the *count* and *failcount* fields reach zero, the status of the errdef is reported to standard output. When all active errdefs created by the th_define process complete, the process exits. If *acc_types* includes log, *count* determines how many accesses to log. If *count* is not specified, a default value is used. If *failcount* is set in this mode, it will simply increase the number of accesses logged by a further *failcount* - 1.

-o *operator* [*operand*]   For qualifying PIO read and write accesses, the value read from or written to the hardware is corrupted according to the value of *operator*:

EQ *operand* is returned to the driver.

OR *operand* is bitwise ORed with the real value.

AND *operand* is bitwise ANDed with the real value.

XOR *operand* is bitwise XORed with the real value.

For PIO write accesses, the following operator is allowed:

NO   Simply ignore the driver's attempt to write to the hardware.

Note that a driver performs PIO via the ddi_get*X*(), ddi_put*X*(), ddi_rep_get*X*() and ddi_rep_put*X*() routines (where *X* is 8, 16, 32 or 64). Accesses made using ddi_get*X*() and ddi_put*X*() are treated as a single access, whereas an access made using the ddi_rep_*(9F) routines are broken down into their respective number of accesses, as given by the *repcount* parameter to these DDI calls. If the access is performed via a DMA handle, *operator* and *value* are applied to every access that comprises the DMA request. If interference with interrupts has been requested then the operator may take any of the following values:

DELAY   After *count* accesses (see the -c option), delay delivery of the next *failcount* number of interrupts for *operand* number of microseconds.

LOSE   After *count* number of interrupts, fail to deliver the next *failcount* number of real interrupts to the driver.

EXTRA   After *count* number of interrupts, start delivering *operand* number of extra interrupts for the next *failcount* number of real interrupts.

The default value for *operand* and *operator* is to corrupt the data access by flipping each bit (XOR with -1).

-f *acc_chk*   If the *acc_chk* parameter is set to 1 or pio, then the driver's calls to ddi_check_acc_handle(9F) return DDI_FAILURE when the access count goes to 1. If the *acc_chk* parameter is set to 2 or dma, then the driver's calls to ddi_check_dma_handle(9F) return DDI_FAILURE when the access count goes to 1.

-w *max_wait_period* [*report_interval*]   Constrain the period for which an error definition will remain active. The option applies only to non-logging errdefs. If an error definition remains active for *max_wait_period* seconds, the test will be aborted. If *report_interval* is set to a nonzero value, the current status of the error definition is reported to standard output every *report_interval* seconds. The default value is zero. The status of the errdef is reported in parsable format (eight fields, each separated by a colon (:) character, the last of which is a string enclosed by double quotes and the remaining seven fields are integers):

ft:*mt*:*ac*:*fc*:*chk*:*ec*:*s*:*"message"* which are defined as follows:

ft	The UTC time when the fault was injected.
mt	The UTC time when the driver reported the fault.
ac	The number of remaining non-faulting accesses.
fc	The number of remaining faulting accesses.
chk	The value of the *acc_chk* field of the errdef.
ec	The number of fault reports issued by the driver against this errdef (*mt* holds the time of the initial report).
s	The severity level reported by the driver.
"message"	Textual reason why the driver has reported a fault.

-h   Display the command usage string.

-s *collect_time*   If *acc_types* is given with the -a option and includes log, the errdef will log accesses for *collect_time* seconds (the default is to log until the log becomes full). Note that, if the errdef

specification matches multiple driver handles, multiple logging errdefs are registered with the bofi driver and logging terminates when all logs become full or when *collect_time* expires or when the associated errdefs are cleared. The current state of the log can be checked with the th_manage(1M) command, using the broadcast parameter. A log can be terminated by running th_manage(1M) with the clear_errdefs option or by sending a SIGALRM signal to the th_define process. See alarm(2) for the semantics of SIGALRM.

-p *policy* Applicable when the *acc_types* option includes log. The parameter modifies the policy used for converting from logged accesses to errdefs. All policies are inclusive:

- Use rare to bias error definitions toward rare accesses (default).

- Use operator to produce a separate error definition for each operator type (default).

- Use common to bias error definitions toward common accesses.

- Use median to bias error definitions toward median accesses.

- Use maximal to produce multiple error definitions for duplicate accesses.

- Use unbiased to create unbiased error definitions.

- Use onebyte, twobyte, fourbyte, or eightbyte to select errdefs corresponding to 1, 2, 4 or 8 byte accesses (if chosen, the -xr option is enforced in order to ensure that ddi_rep_*() calls are decomposed into *multiple single accesses*).

- Use multibyte to create error definitions for multibyte accesses performed using ddi_rep_get*() and ddi_rep_put*().

Policies can be combined by adding together these options. See the NOTES section for further information.

-x *flags*	Applicable when the *acc_types* option includes log. The *flags* parameter modifies the way in which the bofi driver logs accesses. It is specified as a string containing any combination of the following letters:

w   Continuous logging (that is, the log will wrap when full).

t   Timestamp each log entry (access times are in seconds).

r   Log repeated I/O as individual accesses (for example, a ddi_rep_get16(9F) call which has a repcount of *N* is logged *N* times with each transaction logged as size 2 bytes. Without this option, the default logging behavior is to log this access once only, with a transaction size of twice the *repcount*).

-C *comment_string*	Applicable when the *acc_types* option includes log. It provides a comment string to be placed in any generated test scripts. The string must be enclosed in double quotes.
-e *fixup_script* [*args*]	Applicable when the *acc_types* option includes log. The output of a logging errdefs is to generate a test script for each driver access handle. Use this option to embed a command in the resulting script before the errors are injected. The generated test scripts will take an instance offline and bring it back online before injecting errors in order to bring the instance into a known fault–free state. The executable *fixup_script* will be called twice with the set of optional *args*— once just before the instance is taken offline and again after the instance has been brought online. The following variables are passed into the environment of the called executable:

DRIVER_PATH   Identifies the device path of the instance.

DRIVER_INSTANCE   Identifies the instance number of the device.

	DRIVER_UNCONFIGURE	Has the value 1 when the instance is about to be taken offline.
	DRIVER_CONFIGURE	Has the value 1 when the instance has just been brought online.

Typically, the executable ensures that the device under test is in a suitable state to be taken offline (unconfigured) or in a suitable state for error injection (for example configured, error free and servicing a workload). A minimal script for a network driver could be:

```ksh
#!/bin/ksh

driver=xyznetdriver
ifnum=$driver$DRIVER_INSTANCE

if [[ $DRIVER_CONFIGURE = 1 ]]; then
    ifconfig $ifnum plumb
    ifconfig $ifnum ...
    ifworkload start $ifnum
elif [[ $DRIVER_UNCONFIGURE = 1 ]]; then
    ifworkload stop $ifnum
    ifconfig $ifnum down
    ifconfig $ifnum unplumb
fi
exit $?
```

The -e option must be the last option on the command line.

If the -a log option is selected but the -e option is not given, a default script is used. This script repeatedly attempts to detach and then re-attach the device instance under test.

Examples

Examples of Error Definitions

th_define -n foo -i 1 -a log

Logs all accesses to all handles used by instance 1 of the foo driver while running the default workload (attaching and detaching the instance). Then generates a set of test scripts to inject appropriate errdefs while running that default workload.

th_define -n foo -i 1 -a log pio

Logs PIO accesses to each PIO handle used by instance 1 of the foo driver while running the default workload (attaching and detaching the instance). Then generates a set of test scripts to inject appropriate errdefs while running that default workload.

```
th_define -n foo -i 1 -p onebyte median -e fixup arg -now
```

Logs all accesses to all handles used by instance 1 of the foo driver while running the workload defined in the fixup script fixup with arguments arg and -now. Then generates a set of test scripts to inject appropriate errdefs while running that workload. The resulting error definitions are requested to focus upon single byte accesses to locations that are accessed a *median* number of times with respect to frequency of access to I/O addresses.

```
th_define -n se -l 0x20 1 -a pio_r -o OR 0x4 -c 10 1000
```

Simulates a stuck serial chip command by forcing 1000 consecutive read accesses made by any instance of the se driver to its command status register, thereby returning status busy.

```
th_define -n foo -i 3 -r 1 -a pio_r -c 0 1 -f 1 -o OR 0x100
```

Causes 0x100 to be ORed into the next physical I/O read access from any register in register set 1 of instance 3 of the foo driver. Subsequent calls in the driver to ddi_check_acc_handle() return DDI_FAILURE.

```
th_define -n foo -i 3 -r 1 -a pio_r -c 0 1 -o OR 0x0
```

Causes 0x0 to be ORed into the next physical I/O read access from any register in register set 1 of instance 3 of the foo driver. This is of course a no-op.

```
th_define -n foo -i 3 -r 1 -l 0x8100 1 -a pio_r -c 0 10 -o EQ 0x70003
```

Causes the next ten next physical I/O reads from the register at offset 0x8100 in register set 1 of instance 3 of the foo driver to return 0x70003.

```
th_define -n foo -i 3 -r 1 -l 0x8100 1 -a pio_w -c 100 3 -o AND
0xffffffffffffefff
```

The next 100 physical I/O writes to the register at offset 0x8100 in register set 1 of instance 3 of the foo driver take place as normal. However, on each of the three subsequent accesses, the 0x1000 bit will be cleared.

```
th_define -n foo -i 3 -r 1 -l 0x8100 0x10 -a pio_r -c 0 1 -f 1 -o XOR 7
```

Causes the bottom three bits to have their values toggled for the next physical I/O read access to registers with offsets in the range 0x8100 to 0x8110 in register set 1 of instance 3 of the foo driver. Subsequent calls in the driver to ddi_check_acc_handle() return DDI_FAILURE.

```
th_define -n foo -i 3 -a pio_w -c 0 1 -o NO 0
```

Prevents the next physical I/O write access to any register in any register set of instance 3 of the foo driver from going out on the bus.

```
th_define -n foo -i 3 -l 0 8192 -a dma_r -c 0 1 -o OR 7
```

Causes 0x7 to be ORed into each long long in the first 8192 bytes of the next DMA read, using any DMA handle for instance 3 of the foo driver.

```
th_define -n foo -i 3 -r 2 -l 0 8 -a dma_r -c 0 1 -o OR 0x7070707070707070
```

Causes 0x70 to be ORed into each byte of the first long long of the next DMA read, using the DMA handle with sequential allocation number 2 for instance 3 of the foo driver.

```
th_define -n foo -i 3 -l 256 256 -a dma_w -c 0 1 -f 2 -o OR 7
```

Causes 0x7 to be ORed into each long long in the range from offset 256 to offset 512 of the next DMA write, using any DMA handle for instance 3 of the foo driver. Subsequent calls in the driver to ddi_check_dma_handle() return DDI_FAILURE.

```
th_define -n foo -i 3 -r 0 -l 0 8 -a dma_w -c 100 3 -o AND 0xffffffffffffefff
```

The next 100 DMA writes using the DMA handle with sequential allocation number 0 for instance 3 of the foo driver take place as normal. However, on each of the three subsequent accesses, the 0x1000 bit will be cleared in the first long long of the transfer.

```
th_define -n foo -i 3 -a intr -c 0 6 -o LOSE 0
```

Causes the next six interrupts for instance 3 of the foo driver to be lost.

```
th_define -n foo -i 3 -a intr -c 30 1 -o EXTRA 10
```

When the thirty-first subsequent interrupt for instance 3 of the foo driver occurs, a further ten interrupts are also generated.

```
th_define -n foo -i 3 -a intr -c 0 1 -o DELAY 1024
```

Causes the next interrupt for instance 3 of the foo driver to be delayed by 1024 microseconds.

Notes The policy option in the th_define -p syntax determines how a set of logged accesses will be converted into the set of error definitions. Each logged access will be matched against the chosen policies to determine whether an error definition should be created based on the access.

Any number of policy options can be combined to modify the generated error definitions.

Bytewise Policies These select particular I/O transfer sizes. Specifying a byte policy will exclude other byte policies that have not been chosen. If none of the byte type policies is selected, all transfer sizes are treated equally. Otherwise, only those specified transfer sizes will be selected.

onebyte	Create errdefs for one byte accesses (`ddi_get8()`)
twobyte	Create errdefs for two byte accesses (`ddi_get16()`)
fourbyte	Create errdefs for four byte accesses (`ddi_get32()`)
eightbyte	Create errdefs for eight byte accesses (`ddi_get64()`)
multibyte	Create errdefs for repeated byte accesses (`ddi_rep_get*()`)

Frequency of Access Policies The frequency of access to a location is determined according to the access type, location and transfer size (for example, a two-byte read access to address A is considered distinct from a four-byte read access to address A). The algorithm is to count the number of accesses (of a given type and size) to a given location, and find the locations that were most and least accessed (let *maxa* and *mina* be the number of times these locations were accessed, and *mean* the total number of accesses divided by total number of locations that were accessed). Then a rare access is a location that was accessed less than

(mean - mina) / 3 + mina

times. Similarly for the definition of common accesses:

maxa - (maxa - mean) / 3

A location whose access patterns lies within these cutoffs is regarded as a location that is accessed with median frequency.

rare	Create errdefs for locations that are rarely accessed.
common	Create errdefs for locations that are commonly accessed.
median	Create errdefs for locations that are accessed a median frequency.

Policies for Minimizing errdefs If a transaction is duplicated, either a single or multiple errdefs will be written to the test scripts, depending upon the following two policies:

maximal	Create multiple errdefs for locations that are repeatedly accessed.
unbiased	Create a single errdef for locations that are repeatedly accessed.
operators	For each location, a default operator and operand is typically applied. For maximal test coverage, this default may be modified using the `operators` policy so that a separate errdef is created for each of the possible corruption operators.

See Also kill(1), th_manage(1M), alarm(2), ddi_check_acc_handle(9F), ddi_check_dma_handle(9F)

Name th_manage – manage the fault injection test harness

Synopsis th_manage *name instance command*

th_manage *path command*

Description th_manage applies the action specified by *command* to the instance specified by *instance* of the driver specified by *name* (or the driver instance specified by *path*). The driver instance must be running fault injection specifications (errdefs) defined by th_define(1M).

th_manage supports several commands that operate on the driver instance specified by *name* and *instance* (or *path*). The commands are:

broadcast   Awaken all th_define processes, causing them to display their current status and exit if the errdef is now defunct (that is, if *count*, *failcount*, and *acc_chk* are all zero).

clear_acc_chk   Awaken all th_define processes. If *count* and *failcount* are already zero, then set *acc_chk* to zero, so that th_define exits once it has displayed its status.

clear_errdefs   Awaken all th_define processes. *count*, *failcount* and *acc_chk* are all set to zero so that all th_define commands exit once they have displayed their status.

clear_errors   Awaken all th_define processes. If *count* is already zero, set *failcount* and *acc_chk* to zero, so that th_define exits once it has displayed its status.

get_handles   List all the access handles.

start   Begin or resume execution of all errdefs.

stop   Suspend all errdefs for this *name* and *instance* (or *path)*.

Examples EXAMPLE 1   Useful Commands

To begin the tests, enter:

th_manage foo 0 start

To check the status of the errdefs, enter:

th_manage foo 0 broadcast

This causes each th_define process to print out its current status.

If the driver has reported a fatal error, you can take the driver offline using libdevice, clear the error condition by entering:

th_manage foo 0 clear_acc_chk

EXAMPLE 1 Useful Commands   *(Continued)*

or

th_manage foo 0 clear_errors

and bring the driver online again using libdevice.

To terminate testing, enter:

th_manage foo 0 clear_errdefs

See Also th_define(1M)

Name   tic – terminfo compiler

Synopsis   tic [-v [*n*]] [-c] *file*

Description   The command tic translates a terminfo file from the source format into the compiled format. The results are placed in the directory /usr/share/lib/terminfo. The compiled format is necessary for use with the library routines in curses(3CURSES).

If the environment variable TERMINFO is set, the compiled results are placed there instead of /usr/share/lib/terminfo.

Total compiled entries cannot exceed 4096 bytes. The name field cannot exceed 128 bytes. Terminal names exceeding 14 characters will be truncated to 14 characters and a warning message will be printed.

Options   The following options are supported:

-c   Specifies to check only file for errors. Errors in use= links are not detected.

-v[*n*]   Specify that (verbose) output be written to standard error trace information showing tic's progress. The optional integer *n* is a number from 1 to 10, indicating the desired level of detail of information. If *n* is omitted, the default level is 1. If *n* is specified and greater than 1, the level of detail is increased.

Operands   file   Contains one or more terminfo terminal descriptions in source format [see terminfo(4)]. Each description in the file describes the capabilities of a particular terminal. When a use=*entry-name* field is discovered in a terminal entry currently being compiled, tic reads in the binary from /usr/share/lib/terminfo to complete the entry. (Entries created from file will be used first. If the environment variable TERMINFO is set, that directory is searched instead of /usr/share/lib/terminfo.) tic duplicates the capabilities in *entry-name* for the current entry, with the exception of those capabilities that are explicitly defined in the current entry.

Files   /usr/share/lib/terminfo/?/*   Compiled terminal description database

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   captoinfo(1M), infocmp(1M), curses(3CURSES), terminfo(4), attributes(5)

Notes   When an entry, for example, entry_name_1, contains a use=*entry_name_2* field, any canceled capabilities in *entry_name_2* must also appear in entry_name_1 before use= for these capabilities to be canceled in entry_name_1.

Name   tncfg – configure trusted networking properties

Synopsis   tncfg [-t *template*] [-e|-S [files|ldap]] [*subcommand*]

tncfg [-t *template*] [-e|-S [files|ldap]] -f *command_file*

tncfg -z *zone* [-e] [*subcommand*]

tncfg -z *zone* [-e] -f *command_file*

tncfg help

Description   The tncfg utility creates, modifies, and displays the configuration of various networking properties related to Trusted Extensions. The command requires that the SMF service, svc:/system/labeld is enabled. It can be executed only in the global zone.

Templates   A template is a collection of network security properties that define the rules for labeling packets received from remote hosts. Two host types are supported: cipso and unlabeled. Each template must specify one of these two host types. Hosts that are trusted to specify their own labels are assigned to cipso templates. Otherwise, hosts may be assigned to unlabeled templates, in which a single default label must be specified.

Hosts can be specified using hostnames, IP addresses, or masks. When masks are used, a prefix length that specifies how many bits are required for a match must be appended . Hosts cannot be assigned to more than one template. When masks are used, the entry with the longest matching prefix is used to associate a host with a template. Packets from hosts without a matching template are dropped.

Each template must include an upper and lower bound specifying the accreditation range of accepted labels. Additionally, up to four auxiliary labels can be specified to enumerate labels outside of this range. Services bound to multilevel ports can accept packets from hosts whose labels are within the accreditation range, or match one of the auxiliary labels.

Normally, the template settings and their corresponding hosts are persistently maintained in local files or by means of an LDAP directory, depending on the -S option. These settings are automatically loaded into kernel memory when the user commits the updates. If the -e (ephemeral) option is specified, only the current in-memory properties are displayed and updated. However, the list of hosts associated with an in-memory template is generally incomplete. To view the matching template for a specific host, use the get subcommand.

By default, an unlabeled template, admin_low, is installed with a default label of ADMIN_LOW, and two mask entries matching any IPv4 or IPv6 address, so that the global zone is initially able to contact any unlabeled hosts. It is recommended to remove these two mask entries once your network security policy is established. An additional template, cipso, is installed with no matching hosts. By default all local IP addresses are implicitly associated with this template, but it is recommended that they should be explicitly added to this or a new cipso-type template.

Searches for template and host entries are resolved in the order specified by means of the name service configuration file, /etc/nsswitch.conf. The keywords, tnrhdb and tnrhtp, are used to specify the search order for hosts and templates, respectively. Both the files and ldap repositories are supported, but it is recommended to specify files first.

Creating or modifying a template requires the authorization solaris.label.network.manage, which is included in the Object Label Management rights profile.

Zones Zones are isolated execution environments described in zones(5). Trusted Extensions requires a zone brand called labeled to which special properties apply. Each labeled zone must have a unique label property at which it executes processes. This is also the label at which it will accept packets from remote hosts for services bound to single-level ports. Explicit multilevel port can also be specified. Services with the privilege net_bindmlp can bind to these ports, and accept packets within the accreditation range or the auxiliary label set associated with the remote host.

Non-global zones must be configured using zonecfg(1M) prior to configuring these properties. In general, updates to each zone's properties, including the global zone, are applied when it is booted. However, the multilevel port properties of running zones are reloaded into kernel memory when updates are committed. If the -e (ephemeral) option is specified, the zone must be in the ready or running state, and only its multilevel port properties can be updated.

Creating or modifying a zone's trusted networking properties requires the authorization solaris.label.zone.manage, which is included in the Object Label Management rights profile.

Properties The set of valid properties depends on whether the -t or -z option was used. The two sets are referred to as the template context and the zone context.

Only a single property value can be specified at a time. Values containing white space must be quoted. An equal sign is required between the property and its value.

The values that can be specified in the template context properties are described below.

name=*template_name*
    The initial value for the name is specified using -t option using the command line. If the name is changed, the current template properties are applied to the newly named template. In this way an existing template can be cloned for subsequent editing. However, to avoid conflicts, the host entries from the initial template are not copied to the new template. The specified name must not match an existing template.

host_type=cipso|unlabeled
    When the unlabeled host type is used, the value specified using the the def_label property is implicitly applied to the received packets. The cipso host type is used for hosts that are trusted to explicitly label their packets. The default is unlabeled.

def_label=*sensitivity_label*

    The default label assigned to IP packets that are not explicitly labeled by means of cipso or IPsec.

doi=*integer*

    A positive integer specifying the Domain of Interpretation for the binary representation of the labels. The default is 1.

min_label=*sensitivity_label*

    The minimum label in the accreditation range for IP packets that are accepted by multilevel services.

max_label=*sensitivity_label*

    The maximum label in the accreditation range for IP packets that are accepted by multilevel services.

aux_label=*sensitivity_label*

    Additional labels, outside of the accreditation range, for IP packets that are accepted by multilevel services. Up to four labels may be specified, using the add subcommand repetitively.

host=*hostname*|*IP address*[/*prefix*]

    A hostname or an IP address to which the template properties apply. For IP addresses, both IPv4 and IPv6 formats can be used, followed by an optional slash and prefix length specifying the number of bits to match again IP addresses. The IPv4 address 0.0.0.0 has an implied prefix length of zero, and matches any IPv4 address. Multiple host values can be specified, using the add subcommand repetitively. There is no specific limit.

The values that may be specified in the zone context properties are described below.

name=*zone_name*

    The name of the zone, which must have previously been configured using zonecfg(1M). The initial value for the name is specified using -z option on the command line. If the name is changed, the current zone properties are applied to the newly named zone. In this way an existing template can be cloned for subsequent editing. However, to avoid conflicts, the initial label value is not copied to the new zone configuration. The specified name must correspond to an existing zone without a trusted networking configuration.

label=*sensitivity_label*

    The sensitivity label of the zone. It must be unique for each zone. The global zone value must be admin_low.

visible=yes|no

    Specifies whether the zone responds to ping requests from hosts whose labels don't match the zone's label. The default is no.

mlp_private=*port*|[-*port2*]/tcp|udp

    A single port number, or a range of ports that privileged services can bind to and then accept requests from clients whose labels are with the accreditation range or the set of

auxiliary labels specified in their matching templates. The port specification must be followed by a a protocol, either `tcp` or `udp`. This value applies to all interfaces that are private to the zone. Multiple `mlp_private` values can be specified, using the `add` subcommand repetitively. This is only limited by the number of available ports.

`mlp_shared=`*port*|[-*port2*]/tcp|udp

A single port number, or a range of ports that privileged services can bind to and then accept requests from clients whose labels are with the accreditation range or the set of auxiliary labels specified in their matching templates. The port specification must be followed by a protocol, either `tcp` or `udp`. This value applies to any `all-zones` interfaces, and must not overlap with the `mlp_shared` ports specifications for other zones. Multiple `mlp_shared` values can be specified, using the `add` subcommand repetitively. This is only limited by the number of available ports.

Options   The following options are supported:

-e

Specifies that the data is ephemeral, affecting only what is currently loaded into kernel memory.

-f *command_file*

Specifies the name of `tncfg` command file. *command_file* is a text file of `tncfg` subcommands, one per line.

-t *template*

Specifies the template name. If the named template does not exist, a new template is created. If neither `-t` nor `-z` is specified, the template context is assumed using `cipso` as the default template name.

-S *repository*

The valid repositories are `files` and `ldap`. The repository specifies which name service will be updated. The default repository is `files`.

-z *zone*

Specifies the zone name. The zone must have previously been configured by means of zonecfg(1M).

Sub-commands   Subcommands can be provided on the command line or interactively. Multiple subcommands, separated by semicolons, can be specified on the command line by enclosing the entire set in quotation marks. The lack of subcommands implies an interactive session, during which auto-completion of subcommands can be invoked using the tab key.

The add, clear, and remove subcommands are used for properties that can accept multiple values. However, only one value can be specified at a time.

Subcommands which can result in destructive actions or loss of work have an `-F` option to force the action. If input is from a terminal device, the user is prompted when appropriate if such a subcommand is given without the `-F` option. Otherwise, the action is disallowed, with a diagnostic message written to standard error.

The following subcommands are supported:

add *property-name=property-value*
> Adds the specified value to the current property values. This subcommand can only be applied to properties that accept multiple values. Use the set subcommand for single-value properties.

clear *property-name*
> Clears all of the values for the property. Only those properties that accept multiple assignments, using the add subcommand, can be cleared.

commit
> Commits the current configuration from memory to stable storage and into the kernel. The configuration must be committed for the changes to take effect. Until the in-memory configuration is committed, you can remove changes with the revert subcommand. The commit operation is attempted automatically upon completion of a tncfg session. Since a configuration must be correct to be committed, this operation automatically does a verify.

delete [-F]
> Deletes the specified template or zone configuration from the current name service.
>
> Specify the -F option to force the action. If the deletion is allowed, its action is instantaneous and the session is terminated.

export [-f *output-file*]
> Displays configuration to standard output. Use the -f option to display the configuration to *output-file*. This option produces output in a form suitable for use in a command file.

get host=*hostname | IP address*[/*prefix*]
> Displays the template name corresponding to the specified host using the kernel's in-memory mapping.

help [usage] [subcommands] [properties] [*subcommand*] [*property*]
> Displays general help or help about a given topic.

info *property-name*
> Displays information about the current template or zone, or the specified property in a parseable format.

list
> Lists the names of the templates or zones that have been configured.

remove *property-name=property-value*
> Removes the specified value from the property. Only those properties that accept multiple assignments, using the add subcommand, can be removed.

set *property-name=property-value*
> Sets a given property name to the given value. Properties that can take multiple values are assigned using the add subcommand, instead of set.

verify

Verifies the current configuration for correctness:

- The required properties are specified;
- the values are valid for each key word;
- the user is authorized to specify the values.

revert [-F]

Causes the configuration to revert to the last committed state. The -F option can be used to force the action.

exit [-F]

Exits the tncfg session. A commit is automatically attempted if needed. You can also use an EOF character to exit tncfg. The -F option can be used to force the action.

Examples   **EXAMPLE 1**   Using the info Subcommand

The command below displays the properties of a cipso template are displayed. The subcommand is specified on the command line.

```
example% tncfg -t cipso info
              name=cipso
              host_type=cipso
              doi=1
              min_label=ADMIN_LOW
              max_label=ADMIN_LOW
              host=10.5.233.74
```

EXAMPLE 2   Using the export Subcommand

The following example shows an interactive session that exports the configuration of a zone in a format the could be imported to another machine with an equivalent zone.

```
example% tncfg -t public
tncfg:public> export
set name=public
set host_type=unlabeled
set doi=1
set def_label="PUBLIC"
set min_label="PUBLIC"
set max_label="CONFIDENTIAL : NEED TO KNOW"
add aux_label="SANDBOX PLAYGROUND"
add host=myserver.oracle.com
add host=10.5.0.0/16
tncfg:public> exit
```

EXAMPLE 3   Assigning Properties to a Zone

In the following example, the public zone is configured to be a multi-level NFS server.

EXAMPLE 3 Assigning Properties to a Zone   *(Continued)*

```
example% tncfg -z public
tncfg:public> info
    name=public
    label=PUBLIC
    visible=no
tncfg:public> add mlp_private=111/tcp
tncfg:public> add mlp_private=111/ucp
tncfg:public> add mlp_private=2049/tcp
tncfg:public> commit
tncfg:public> exit
```

Exit Status   0

Successful completion.

1

An error occurred.

Files   ■ /etc/security/tsol/tnrhtp
■ /etc/security/tsol/tnrhdb
■ /etc/security/tsol/tnzonecfg

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/trusted
Interface Stability	See below.

The invocation and subcommands are committed. Output, except for the export and info subcommands, is Not-an-Interface.

See Also   tnctl(1M), tnd(1M), tninfo(1M), txzonemgr(1M), zonecfg(1M), nsswitch.conf(4), attributes(5), labels(5), zones(5)

Notes   The Labeled Zone Manager, txzonemgr(1M), is an alternative application for configuring Trusted Extensions. It invokes the tncfg command internally, and provides an interactive GUI-based user interface.

Name tnchkdb – check file syntax of trusted network databases

Synopsis /usr/sbin/tnchkdb [-h *path*] [-t *path*] [-z *path*]

Description tnchkdb checks the syntax of the tnrhtp, tnrhdb, and tnzonecfg databases. By default, the *path* for each file is:

- /etc/security/tsol/tnrhtp
- /etc/security/tsol/tnrhdb
- /etc/security/tsol/tnzonecfg

You can specify an alternate path for any or all of the files by specifying that path on the command line by using the -h (tnrhdb), -t (tnrhtp) and -z (tnzonecfg) options. The options are useful when testing a set of modified files before installing the files as new system databases.

All three database files are checked for integrity. tnchkdb returns an exit status of 0 if all of the files are syntactically and, to the extent possible, semantically correct. If one or more files have errors, then an exit status of 1 is returned. If there are command line problems, such as an unreadable file, an exit status of 2 is returned. Errors are written to standard error.

To avoid cascading errors, when there are errors in tnrhtp, the template names in tnrhdb are not validated.

tnchkdb can be run at any label, but the standard /etc/security/tsol files are visible only in the global zone.

Options -h [*path*] Check *path* for proper tnrhdb syntax. If *path* is not specified, then check /etc/security/tsol/tnrhdb.

-t [*path*] Check *path* for proper tnrhtp syntax. If *path* is not specified, then check /etc/security/tsol/tnrhtp.

-z [*path*] Check *path* for proper tnzonecfg syntax. If *path* is not specified, then check /etc/security/tsol/tnzonecfg.

Examples EXAMPLE 1 Sample Error Message

The tnchkdb command checks for CIPSO errors. In this example, the admin_low template has an incorrect value of ADMIN_HIGH for its default label.

```
# tnchkdb
checking /etc/security/tsol/tnrhtp ...
tnchkdb: def_label classification 7fff is invalid for cipso labels:
line 14 entry admin_low
tnchkdb: def_label compartments 241-256 must be zero for cipso labels:
line 14 entry admin_low
checking /etc/security/tsol/tnrhdb ...
checking /etc/security/tsol/tnzonecfg ...
```

Oracle Solaris Trusted Extensions Configuration and Administration

Notes   The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

It is possible to have inconsistent but valid configurations of tnrhtp and tnrhdb when LDAP is used to supply missing templates.

Name tnctl – configure Trusted Extensions network parameters

Synopsis /usr/sbin/tnctl [-dfv] [-h *host* [/*prefix*] [:*template*]]
[-m *zone*:*mlp*:*shared-mlp*][-t *template* [:*key=val* [;*key=val*]]]
[-HTz] *file*]

Description tnctl provides an interface to manipulate trusted network parameters in the Solaris kernel.

As part of Solaris Trusted Extensions initialization, tnctl is run in the global zone by an
smf(5) script during system boot. The tnctl command is not intended to be used during
normal system administration. Instead, if a local trusted networking database file is modified,
the administrator first issues tnchkdb(1M) to check the syntax, and then refreshes the kernel
copy with this command:

svcadm restart svc:/network/tnctl

See WARNINGS about the risks of changing remote host and template information on a running
system.

Options -d

Delete matching entries from the kernel. The default is to add new entries.

When deleting MLPs, the MLP range must match exactly. MLPs are specified in the form:

port[-*port*]/*protocol*

Where *port* can be a number in the range 1 to 65535. or any known service (see
services(4)), and protocol can be a number in the range 1 to 255, or any known protocol
(see protocols(4)).

-f

Flush all kernel entries before loading the entries that are specified on the command line.
The flush does not take place unless at least one entry parsed successfully.

-v

Turn on verbose mode.

-h *host*[/*prefix*][:*template*]

Update the kernel remote-host cache on the local host for the specified *host* or, if a template
name is given, change the kernel's cache to use the specified *template*. If *prefix* is not
specified, then an implied prefix length is determined according to the rules used for
interpreting the tnrhdb. If -d is specified, then a template name cannot be specified.

-m *zone*:*mlp*:*shared-mlp*

Modify the kernel's multilevel port (MLP) configuration cache for the specified *zone*. *zone*
specifies the zone to be updated. *mlp* and *shared-mlp* specify the MLPs for the zone-specific
and shared IP addresses. The *shared-mlp* field is effective in the global zone only.

-t *template*[*key=val*[;*key=val*]]
: Update the kernel template cache for *template* or, if a list of *key=val* pairs is given, change the kernel's cache to use the specified entry. If -d is specified, then *key=val* pairs cannot be specified.

-T *file*
: Load all template entries in *file* into the kernel cache.

-H *file*
: Load all remote host entries in *file* into the kernel cache.

-z *file*
: Load just the global zone's MLPs from *file* into the kernel cache. To reload MLPs for a non-global zone, reboot the zone:

      # **zoneadm -z** *non-global zone* **reboot**

See Also svcs(1), svcadm(1M), tninfo(1M), tnd(1M), tnchkdb(1M), zoneadm(1M), nsswitch.conf(4), protocols(4), services(4), attributes(5), smf(5)

Oracle Solaris Trusted Extensions Configuration and Administration

Warnings Changing a template while the network is up can change the security view of an undetermined number of hosts.

Notes The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

The tnctl service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/tnctl

The service's status can be queried by using svcs(1). Administrative actions on this service, such as refreshing the kernel cache, can be performed using svcadm(1M), as in:

```
svcadm restart svc:/network/tnctl
```

Name tnd – trusted network daemon

Synopsis /usr/sbin/tnd [-p *poll-interval*]

Description The tnd (trusted network daemon) initializes the kernel with trusted network databases and also reloads the databases on demand from an LDAP server and local files. tnd follows the order specified in the nsswitch.conf(4) file when loading configuration databases.

tnd is intended to be started from the svc:/network/tnd smf(5) service during the boot process in the global zone only when the system has been configured as an LDAP client. Systems that use only local files for the trusted network databases use tnctl(1M) instead of tnd.

tnd loads the following databases into the kernel: the remote host database, tnrhdb, and the remote-host template database, tnrhtp. tnd also periodically scans for changes in the associated LDAP database or local databases and updates the kernel cache accordingly.

If a local trusted networking database file is modified, the administrator should run tnchkdb(1M) to check the syntax, and should also run svcadm refresh svc:/network/tnd to initiate an immediate database scan by tnd.

tnd is intended to be started from an smf(5) script and to run in the global zone. The following svcadm commands signal tnd to perform specific actions:

svcadm refresh svc:/network/tnd   Initiates a rescan of the local and LDAP tnrhdb and tnrhtp databases. tnd updates the kernel database with any changes found.

svcadm disable svc:/network/tnd   Terminates the tnd daemon. No changes are made to the kernel database.

Running tnd in debug mode is determined by the value of the following service management facility (SMF) property:

tnd/debug_level = 0

A value of 0, as above, prevents debug information from being collected; 1 turns on debugging. The default value is 0. Debug output is sent to the /var/tsol/tndlog log file.

Options -p *poll-interval*   Set poll interval to *poll-interval* seconds. The default *poll-interval* is 1800 seconds (30 minutes).

Examples EXAMPLE 1   Changing the Poll Interval

The following command changes the polling interval to one hour, and puts this interval in the SMF repository. At the next boot, the tnd poll interval will be one hour.

```
# svccfg -s network/tnd setprop tnd/poll_interval=3600
```

EXAMPLE 1 Changing the Poll Interval   *(Continued)*

The following command changes the polling interval, but does not update the repository. At the next boot, the tnd poll interval remains the default, 30 minutes.

```
# tnd -p 3600
```

Oracle Solaris Trusted Extensions Configuration and Administration

Notes The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

The tnd service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/network/tnd
```

The service's status can be queried by using svcs(1). Administrative actions on this service, such as requests to restart the daemon, can be performed using svcadm(1M), as in:

```
svcadm restart svc:/network/tnd
```

Name tninfo – print kernel-level network information and statistics

Synopsis /usr/sbin/tninfo [-h *hostname*] [-m *zone-name*] [-t *template*]

Description tninfo provides an interface to retrieve and display kernel-level network information and statistics.

Options -h *hostname* Display the security structure for the specified host in the remote-host cache. The output should reflect what is specified in the tnrhdb database.

-m *zone-name* Display the MLP configuration associated with the specified zone. The output should reflect what is specified in the tnzonecfg database.

-t *template* Display the structure associated with the specified *template*. The output should reflect what is specified in the tnrhtp database.

Examples EXAMPLE 1 Displaying Remote Host Structures Cached in the Kernel

This example shows the remote host structures cached in the kernel. The output reflects the definition in the tnrhdb database.

```
# tninfo -h machine1
  IP address= 192.168.8.61
  Template = cipso
```

EXAMPLE 2 Displaying Multilevel Ports for the Global Zone

This example shows the kernel-cached MLPs for the global zone. The output reflects the definition in the tnzonecfg database, plus any dynamically allocated MLPs. private indicates zone-specific MLPs.

```
# tninfo -m global
private:23/tcp;111/tcp;111/udp;515/tcp;2049/tcp;6000-6003/tcp;
        32812/tcp;36698/ip;38634/tcp;64365/ip
shared: 6000-6003/tcp
```

EXAMPLE 3 Displaying the cipso Template Definition

This example shows the kernel-cached cipso template definition. The output reflects the definition in the tnrhtp database.

```
# tninfo -t cipso
=====================================
  Remote Host Template Table Entries:

  _____
  template: cipso
  host_type: CIPSO
  doi: 1
  min_sl: ADMIN_LOW
  hex: ADMIN_LOW
  max_sl: ADMIN_HIGH
```

EXAMPLE 3 Displaying the `cipso` Template Definition   *(Continued)*

```
hex: ADMIN_HIGH
```

Oracle Solaris Trusted Extensions Configuration and Administration

Notes The functionality described on this manual page is available only if the system is configured with Trusted Extensions.

Name   tpmadm – administer Trusted Platform Module

Synopsis   tpmadm status

tpmadm init

tpmadm clear [owner | lock]

tpmadm auth

tpmadm keyinfo [*uuid*]

tpmadm deletekey *uuid*

tpmadm pcrextend *pcr* [*filename*]

tpmadm pcrreset *pcr*

Description   A Trusted Platform Module (TPM) is a hardware component that provides for protected key storage and reliable measurements of software used to boot the operating system. The tpmadm utility is used to initialize and administer the TPM so that it can be used by the operating system and other programs.

The TPM subsystem can store and manage an unlimited number of keys for use by the operating system and by users. Each key is identified by a Universally Unique Identifier, or UUID.

Although the TPM can hold only a limited number of keys at any given time, the supporting software automatically loads and unloads keys as needed. When a key is stored outside the TPM, it is always encrypted or "wrapped" by its parent key so that the key is never exposed in readable form outside the TPM.

Before the TPM can be used, it must be initialized by the platform owner. This process involves setting an owner password which is used to authorize privileged operations.

Although the TPM owner is similar to a traditional superuser, there are two important differences. First, process privilege is irrelevant for access to TPM functions. All privileged operations require knowledge of the owner password, regardless of the privilege level of the calling process. Second, the TPM owner is not able to override access controls for data protected by TPM keys. The owner can effectively destroy data by re-initializing the TPM, but he cannot access data that has been encrypted using TPM keys owned by other users.

Sub-commands   The following subcommands are used in the form:

tpamadm <*subcommand*> [*operand*]

status
     Report status information about the TPM. Output includes basic information about whether ownership of the TPM has been established, current PCR contents, and the usage of TPM resources such as communication sessions and loaded keys.

init

Initialize the TPM for use. This involves taking ownership of the TPM by setting the owner authorization password. Taking ownership of the TPM creates a new storage root key, which is the ancestor of all keys created by this TPM. Once this command is issued, the TPM must be reset using BIOS operations before it can be re-initialized.

auth

Change the owner authorization password for the TPM.

clear lock

Clear the count of failed authentication attempts. After a number of failed authentication attempts, the TPM responds more slowly to subsequent attempts, in an effort to thwart attempts to find the owner password by exhaustive search. This command, which requires the correct owner password, resets the count of failed attempts.

clear owner

Deactivate the TPM and return it to an unowned state. This operation, which requires the current TPM owner password, invalidates all keys and data tied to the TPM. Before the TPM can be used again, the system must be restarted, the TPM must be reactivated from the BIOS or ILOM pre-boot environment, and the TPM must be re-initialized using the tpmadm init command.

keyinfo [*uuid*]

Report information about keys stored in the TPM subsystem. Without additional arguments, this subcommand produces a brief listing of all keys. If the UUID of an individual key is specified, detailed information about that key is displayed.

deletekey *uuid*

Delete the key with the specified UUID from the TPM subsystem's persistent storage.

pcrextend *pcr* [*filename*]

Create an SHA-1 hash of the contents of *filename* and perform a PCR Extend operation on the indicated PCR using the hash value as the data to be extended. If a filename is not specified, the data is read from stdin.

pcrreset *pcr*

Reset the indicated PCR to its initial state (all zeros).

Exit Status   After completing the requested operation, tpmadm exits with one of the following status values.

0

Successful termination.

1

Failure. The requested operation could not be completed.

2

Usage error. The tpmadm command was invoked with invalid arguments.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also prof_attr(4), attributes(5)

See also the tcsd(8) man page, available in the SUNWtss package.

TCG Software Stack (TSS) Specifications:
https://www.trustedcomputinggroup.org/specs/TSS (as of the date of publication)

Notes tpmadm communicates with the TPM device through the tcsd service. tcsd must be running before using the tpmadm command. If tcsd is not running, tpmadm will generate the following error:

```
Connect context: Communication failure (0x3011)
```

See tcsd(8) for more details.

Name   traceroute – print the route packets take to network host

Synopsis   `traceroute [-adFIlnSvx] [-A` *addr_family*`] [-c` *traffic_class*`]`
`[-f` *first_hop*`] [-g` *gateway* `[-g` *gateway*`...] | -r]`
`[-i` *iface*`] [-L` *flow_label*`] [-m` *max_hop*`]`
`[-P` *pause_sec*`] [-p` *port*`] [-Q` *max_timeout*`]`
`[-q` *nqueries*`] [-s` *src_addr*`] [-t` *tos*`] [-w` *wait_time*`] host`
`[`*packetlen*`]`

Description   The Internet is a large and complex aggregation of network hardware, connected by gateways. Tracking the route a packet follows can be difficult. The utility `traceroute` traces the route that an IP packet follows to another internet host.

The `traceroute` utility utilizes the both the IPv4 and IPv6 protocols. Use the `-A` option to override the default behavior. `traceroute` uses the IPv4 protocol *ttl* (time to live) field or the IPv6 field *hop limit*. It attempts to elicit an ICMP or ICMP6 TIME_EXCEEDED response from each *gateway* along the path, and a PORT_UNREACHABLE(or ECHO_REPLY if `-I` is used) response from the destination host. It starts by sending probes with a *ttl* or *hop limit* of 1 and increases by 1 until it either gets to the host, or it hits the maximum *max_hop*. The default maximum *max_hop* is 30 hops, but this can be set by the `-m` option.

Three probes are sent at each *ttl* (*hop limit*) setting, and a line is printed showing the *ttl* (*hop limit*), the hostname and the address of the gateway, and the *rtt* (round trip time) of each probe. The number of probes may be specifically set using the `-q` option. If the probe answers come from different gateways, the hostname and the address of each responding system will be printed. If there is no response within a 5 second timeout interval, an asterisk (*) is displayed for that probe. The `-w` option may be used to set the timeout interval. Other possible annotations that may appear after the time are:

!
    the *ttl* (*hop limit*) value in the received packet is <= 1.

!H
    host unreachable.

!X
    communication administratively prohibited.

<!N>
    ICMP (ICMP6) unreachable code N.

The following annotations appear only for IPv4:

!F
    fragmentation needed. This should never occur. If this is seen, the associated gateway is broken.

!N
    network unreachable.

!P

protocol unreachable.

!S

source route failed. It is likely that the gateway does not support source routing.

!T

unreachable for the specified tos (type-of-service).

!U

source host isolated or precedence problem.

The following annotations appear only for IPv6:

!A

host unreachable for a reason other than lack of an entry in the routing table.

!B

packet too big.

!E

destination is not a neighbor.

!R

unrecognized next header.

If almost all the probes result in some kind of unreachable code, then traceroute gives up and exits.

The destination *host* is not supposed to process the UDP probe packets, so the destination *port* default is set to an unlikely value. However, if some application on the destination is using that value, the value of *port* can be changed with the -p option.

The only mandatory parameter is the destination *host* name or IP number. The default probe datagram length is 40 bytes (60 bytes for IPv6), but this may be increased by specifying a packet length (in bytes) after the destination *host* name.

All integer arguments to traceroute can be specified in either decimal or hexadecimal notation. For example, *packetlen* can be specified either as 256 or 0x100.

Options　-A *addr_family*

Specify the address family of the target host. *addr_family* can be either inet or inet6. Address family determines which protocol to use. For an argument of inet, IPv4 is used. For inet6, IPv6 is used.

By default, if the name of a host is provided, not the literal IP address, and a valid IPv6 address exists in the name service database, traceroute will use this address. Otherwise, if the name service database contains an IPv4 address, it will try the IPv4 address.

Specify the address family inet or inet6 to override the default behavior. If the argument specified is inet, traceroute will use the IPv4 address associated with the hostname. If none exists, traceroute will state that the host is unknown and exit. It will not try to determine if an IPv6 address exists in the name service database.

If the specified argument is inet6, traceroute will use the IPv6 address that is associated with the hostname. If none exists, traceroute will state that the host is unknown and exit.

-a

Probe all of the addresses of a multi-homed destination. The output looks like traceroute has been run once for each IP address of the destination. If this option is used together with -A, traceroute probes only the addresses that are of the specified address family. While probing one of the addresses of the destination, user can skip to the next address by sending a SIGINT, or exit traceroute by sending a SIGQUIT signal. See signal(3C)

-c *traffic_class*

Specify the traffic class of probe packets. The value must be an integer in the range from 0 to 255. Gateways along the path may route the probe packet differently depending upon the value of *traffic_class* set in the probe packet. This option is valid only on IPv6.

-d

Set the SO_DEBUG socket option.

-F

Turn off fragmentation. For IPv4, this means setting the Don't Fragment bit. For IPv4 and IPv6, this means do not allow fragmentation as the datagrams are sent. If the packetlen exceeds the MTU, then traceroute may report that sending failed due to Message too long.

-f *first_hop*

Set the starting *ttl* (*hop limit*) value to *first_hop*, to override the default value 1. traceroute skips processing for those intermediate gateways which are less than *first_hop* hops away.

-g *gateway*

Specify a loose source route *gateway*. The user can specify more than one *gateway* by using -g for each gateway. The maximum number of gateways is 8 for IPv4 and 127 for IPv6. Note that some factors such as the link MTU can further limit the number of gateways for IPv6. This option cannot be used with the -r option.

Only users with the {PRIV_NET_RAWACCESS} privilege can specify a loose source route with this option.

-I

Use ICMP (ICMP6) ECHO instead of UDP datagrams.

-i *iface*

For IPv4, this option specifies a network interface to obtain the source IP address. This is normally only useful on a multi-homed host. The -s option is also another way to do this.

For IPv6, it specifies the network interface on which probe packets are transmitted. The argument can be either an interface index, for example, 1, 2, or an interface name, for example, eri0, hme0.

-L *flow_label*

Specify the flow label of probe packets. The value must be an integer in the range from 0 to 1048575. This option is valid only on IPv6.

-l

Print the value of the *ttl* (*hop limit*) field in each packet received.

-m *max_hop*

Set the maximum *ttl* (*hop limit*) used in outgoing probe packets. The default is 30 hops, which is the same default used for TCP connections.

-n

Print hop addresses numerically rather than symbolically and numerically. This saves a nameserver address-to-name lookup for each gateway found on the path.

-P *pause_sec*

Specify a delay, in seconds, to pause between probe packets. This may be necessary if the final destination does not accept undeliverable packets in bursts. By default, traceroute sends the next probe as soon as it has received a reply. Note that *pause_sec* is a real number.

-p *port*

Set the base UDP *port* number used in probes.The default is 33434. traceroute hopes that nothing is listening on UDP *ports* `(base+(nhops-1)*nqueries)` to `(base+(nhops*nqueries)-1)` at the destination host, so that an ICMP (ICMP6) `PORT_UNREACHABLE` message will be returned to terminate the route tracing. If something is listening on a *port* in the default range, this option can be used to select an unused *port* range. nhops is defined as the number of hops between the source and the destination.

-Q *max_timeout*

Stop probing this hop after *max_timeout* consecutive timeouts are detected. The default value is 5. Useful in combination with the -q option if you have specified a large *nqueries* probe count.

-q *nqueries*

Set the desired number of probe queries. The default is 3.

-r

Bypass the normal routing tables and send directly to a host on an attached network. If the host is not on a directly-attached network, an error is returned. This option can be used to send probes to a local host through an interface that has been dropped by the router daemon. See in.routed(1M). You cannot use this option if the -g option is used.

-S

Display a summary of how many probes were not answered for each hop.

-s *src_addr*

Use the following address, which usually is given as a literal IP address, not a hostname, as the source address in outgoing probe packets. On multi-homed hosts, those with more than one IP address, this option can be used to force the source address to be something other than the IP address `traceroute` picks by default. If the IP address is not one of this machine's interface addresses, an error is returned and nothing is sent. For IPv4, when used together with the -i option, the given IP address should be configured on the specified interface. Otherwise, an error will be returned. In the case of IPv6, the interface name and the source address do not have to match.

-t *tos*

Set the *tos*(type-of-service) in probe packets to the specified value. The default is zero. The value must be an integer in the range from 0 to 255. Gateways along the path may route the probe packet differently depending upon the *tos* value set in the probe packet. This option is valid only on IPv4.

-v

Verbose output. For each hop, the size and the destination of the response packets is displayed. Also ICMP (ICMP6) packets received other than TIME_EXCEEDED and UNREACHABLE are listed as well.

-w *waittime*

Set the time, in seconds, to wait for a response to a probe. The default is 5 seconds.

-x

Prevent `traceroute` from calculating checksums. Checksums are usually required for the last hop when using ICMP ECHO probes. This option is valid only on IPv4. See the -I option.

When specified from within a shared-IP zone, this option has no effect as the checksum is always calculated by the operating system in this case.

Operands The following operands are supported:

host
    The network host.

Examples EXAMPLE 1 Sample Output From the `traceroute` Utility

Some sample output from the `traceroute` utility might be:

```
istanbul% traceroute london
traceroute: Warning: london has multiple addresses; \
  using 4::114:a00:20ff:ab3d:83ed
traceroute: Warning: Multiple interfaces found; \
  using 4::56:a00:20ff:fe93:8dde @ eri0:2
traceroute to london (4::114:a00:20ff:ab3d:83ed), 30 hops max, \
  60 byte packets
1  frbldg7c-86 (4::56:a00:20ff:fe1f:65a1)  1.786 ms  1.544 ms  1.719 ms
```

EXAMPLE 1 Sample Output From the traceroute Utility   *(Continued)*

```
2  frbldg7b-77 (4::255:0:0:c0a8:517)  2.587 ms 3.001 ms  2.988 ms
3  london (4::114:a00:20ff:ab3d:83ed)  3.122 ms  2.744 ms  3.356 ms
```

The target host, london, has both IPv4 and IPv6 addresses in the name service database. According to the default behavior, traceroute uses IPv6 address of the destination host.

EXAMPLE 2 Using the traceroute Utility For a Host Which has Only IPv4 Addresses

In the following examples, traceroute is tracking the route to host sanfrancisco, which has only IPv4 addresses in the name service database. Therefore traceroute uses only IPv4 addresses. The following shows the 7-hop path that a packet would follow from the host istanbul to the host sanfrancisco.

```
istanbul% traceroute sanfrancisco
traceroute: Warning: Multiple interfaces found; using 172.31.86.247 @eri0
traceroute to sanfrancisco (172.29.64.39), 30 hops max, 40 byte packets
1  frbldg7c-86 (172.31.86.1)  1.516 ms  1.283 ms  1.362 ms
2  bldg1a-001 (172.31.1.211)  2.277 ms  1.773 ms  2.186 ms
3  bldg4-bldg1 (172.30.4.42)  1.978 ms  1.986 ms  13.996 ms
4  bldg6-bldg4 (172.30.4.49)  2.655 ms  3.042 ms  2.344 ms
5  ferbldg11a-001 (172.29.1.236)  2.636 ms  3.432 ms  3.830 ms
6  frbldg12b-153 (172.29.153.72)  3.452 ms  3.146 ms  2.962 ms
7  sanfrancisco (172.29.64.39)  3.430 ms  3.312 ms  3.451 ms
```

EXAMPLE 3 Using the traceroute Utility With Source Routing

The following example shows the path of a packet that goes from istanbul to sanfrancisco through the hosts cairo and paris, as specified by the -g option. The -I option makes traceroute send ICMP ECHO probes to the host sanfrancisco. The -i options sets the source address to the IP address configured on the interface qe0.

```
istanbul% traceroute -g cairo -g paris -i qe0 -q 1 -I sanfrancisco
traceroute to sanfrancisco (172.29.64.39), 30 hops max, 56 byte packets
1  frbldg7c-86 (172.31.86.1)  2.012 ms
2  flrbldg7u (172.31.17.131)  4.960 ms
3  cairo (192.168.163.175) 4.894 ms
4  flrbldg7u (172.31.17.131)  3.475 ms
5  frbldg7c-017 (172.31.17.83)  4.126 ms
6  paris (172.31.86.31) 4.086 ms
7  frbldg7b-82 (172.31.82.1)  6.454 ms
8  bldg1a-001 (172.31.1.211)  6.541 ms
9  bldg6-bldg4 (172.30.4.49)  6.518 ms
10  ferbldg11a-001 (172.29.1.236)  9.108 ms
11  frbldg12b-153 (172.29.153.72)  9.634 ms
12  sanfrancisco (172.29.64.39)  14.631 ms
```

Exit Status The following exit values are returned:

0
  Successful operation.

>0
  An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also netstat(1M), signal(3C), ping(1M), attributes(5), privileges(5), zones(5)

Warnings This utility is intended for use in network testing, measurement and management. It should be used primarily for manual fault isolation. Because of the load it could impose on the network, it is unwise to use traceroute(1M) during normal operations or from automated scripts.

Name   trapstat – report trap statistics

Synopsis   /usr/sbin/trapstat [-t | -T | -e *entry*]
           [-C *processor_set_id* | -c *cpulist*] [-P] [-a]
           [-r *rate*] [[*interval* [*count*]] | *command* | [*args*]]

    /usr/sbin/trapstat -l

Description   The trapstat utility gathers and displays run-time trap statistics on UltraSPARC-based
systems. The default output is a table of trap types and CPU IDs, with each row of the table
denoting a trap type and each column of the table denoting a CPU. If standard output is a
terminal, the table contains as many columns of data as can fit within the terminal width; if
standard output is not a terminal, the table contains at most six columns of data. By default,
data is gathered and and displayed for all CPUs; if the data cannot fit in a single table, it is
printed across multiple tables. The set of CPUs for which data is gathered and displayed can be
optionally specified with the -c or -C option.

Unless the -r option or the -a option is specified, the value displayed in each entry of the table
corresponds to the number of traps per second. If the -r option is specified, the value
corresponds to the number of traps over the interval implied by the specified sampling rate; if
the -a option is specified, the value corresponds to the accumulated number of traps since the
invocation of trapstat.

By default, trapstat displays data once per second, and runs indefinitely; both of these
behaviors can be optionally controlled with the *interval* and *count* parameters, respectively.
The *interval* is specified in seconds; the *count* indicates the number of intervals to be executed
before exiting. Alternatively, command can be specified, in which case trapstat executes the
provided command and continues to run until the command exits. A positive integer is
assumed to be an *interval*; if the desired *command* cannot be distinguished from an integer,
the full path of *command* must be specified.

UltraSPARC I (obsolete), II, and III handle translation lookaside buffer (TLB) misses by
trapping to the operating system. TLB miss traps can be a significant component of overall
system performance for some workloads; the -t option provides in-depth information on
these traps. When run with this option, trapstat displays both the rate of TLB miss traps and
the percentage of time spent processing those traps. Additionally, TLB misses that hit in the
translation storage buffer (TSB) are differentiated from TLB misses that further miss in the
TSB. (The TSB is a software structure used as a translation entry cache to allow the TLB to be
quickly filled; it is discussed in detail in the *UltraSPARC II User's Manual*.) The TLB and TSB
miss information is further broken down into user- and kernel-mode misses.

Workloads with working sets that exceed the TLB reach may spend a significant amount of
time missing in the TLB. To accommodate such workloads, the operating system supports
multiple page sizes: larger page sizes increase the effective TLB reach and thereby reduce the
number of TLB misses. To provide insight into the relationship between page size and TLB
miss rate, trapstat optionally provides in-depth TLB miss information broken down by page
size using the -T option. The information provided by the -T option is a superset of that
provided by the -t option; only one of -t and -T can be specified.

Options   The following options are supported:

-a
: Displays the number of traps as accumulating, monotonically increasing values instead of per-second or per-interval rates.

-c *cpulist*
: Enables `trapstat` only on the CPUs specified by *cpulist*.

  cpulist can be a single processor ID (for example, 4), a range of processor IDs (for example, 4-6), or a comma separated list of processor IDs or processor ID ranges (for example, 4,5,6 or 4,6-8).

-C *processor_set_id*
: Enables `trapstat` only on the CPUs in the processor set specified by *processor_set_id*.

  `trapstat` modifies its output to always reflect the CPUs in the specified processor set. If a CPU is added to the set, `trapstat` modifies its output to include the added CPU; if a CPU is removed from the set, `trapstat` modifies its output to exclude the removed CPU. At most one processor set can be specified.

-e *entrylist*
: Enables `trapstat` only for the trap table entry or entries specified by *entrylist*. A trap table entry can be specified by trap number or by trap name (for example, the level–10 trap can be specified as 74, 0x4A, 0x4a, or level-10).

  entrylist can be a single trap table entry or a comma separated list of trap table entries. If the specified trap table entry is not valid, `trapstat` prints a table of all valid trap table entries and values. A list of valid trap table entries is also found in *The SPARC Architecture Manual, Version 9* and the *Sun Microelectronics UltraSPARC II User's Manual*. If the parsable option (-P) is specified in addition to the -e option, the format of the data is as follows:

Field	Contents
1	Timestamp (nanoseconds since start)
2	CPU ID
3	Trap number (in hexadecimal)
4	Trap name
5	Trap rate per interval

  Each field is separated with whitespace. If the format is modified, it will be modified by adding potentially new fields beginning with field 6; exant fields will remain unchanged.

-l   Lists trap table entries. By default, a table is displayed containing all valid trap numbers, their names and a brief description. The trap name is used in both the default output and in the *entrylist* parameter for the -e argument. If the parsable option (-P) is specified in addition to the -l option, the format of the data is as follows:

Field	Contents
1	Trap number in hexadecimal
2	Trap number in decimal
3	Trap name
Remaining	Trap description

-P   Generates parsable output. When run without other data gathering modifying options (that is, -e, -t or -T), trapstat's the parsable output has the following format:

Field	Contents
1	Timestamp (nanoseconds since start)
2	CPU ID
3	Trap number (in hexadecimal)
4	Trap name
5	Trap rate per interval

Each field is separated with whitespace. If the format is modified, it will be modified by adding potentially new fields beginning with field 6; extant fields will remain unchanged.

-r *rate*   Explicitly sets the sampling rate to be *rate* samples per second. If this option is specified, trapstat's output changes from a traps-per-second to traps-per-sampling-interval.

-t   Enables TLB statistics.

A table is displayed with four principal columns of data: *itlb-miss*, *itsb-miss*, *dtlb-miss*, and *dtsb-miss*. The columns contain both the rate of the corresponding event and the percentage of CPU time spent processing the event. The percentage of CPU time is given only in terms of a single CPU. The rows of the table correspond to CPUs,

with each CPU consuming two rows: one row for user-mode events (denoted with u) and one row for kernel-mode events (denoted with k). For each row, the percentage of CPU time is totalled and displayed in the rightmost column. The CPUs are delineated with a solid line. If the parsable option (-P) is specified in addition to the -t option, the format of the data is as follows:

Field	Contents
1	Timestamp (nanoseconds since start)
2	CPU ID
3	Mode (k denotes kernel, u denotes user)
4	I-TLB misses
5	Percentage of time in I-TLB miss handler
6	I-TSB misses
7	Percentage of time in I-TSB miss handler
8	D-TLB misses
9	Percentage of time in D-TLB miss handler
10	D-TSB misses
11	Percentage of time in D-TSB miss handler

Each field is separated with whitespace. If the format is modified, it will be modified by adding potentially new fields beginning with field 12; extant fields will remain unchanged.

-T   Enables TLB statistics, with page size information. As with the -t option, a table is displayed with four principal columns of data: *itlb-miss*, *itsb-miss*, *dtlb-miss*, and *dtsb-miss*. The columns contain both the absolute number of the corresponding event, and the percentage of CPU time spent processing the event. The percentage of CPU time is given only in terms of a single CPU. The rows of the table correspond to CPUs, with each CPU consuming two sets of rows: one set for user-level events (denoted with u) and one set for kernel-level events (denoted with k). Each set, in turn, contains as many rows as

there are page sizes supported (see `getpagesizes(3C)`). For each row, the percentage of CPU time is totalled and displayed in the right-most column. The two sets are delineated with a dashed line; CPUs are delineated with a solid line. If the parsable option (-P) is specified in addition to the -T option, the format of the data is as follows:

Field	Contents
1	Timestamp (nanoseconds since start)
2	CPU ID
3	Mode k denotes kernel, u denotes user)
4	Page size, in decimal
5	I-TLB misses
6	Percentage of time in I-TLB miss handler
7	I-TSB misses
8	Percentage of time in I-TSB miss handler
9	D-TLB misses
10	Percentage of time in D-TLB miss handler
11	D-TSB misses
12	Percentage of time in D-TSB miss handler

Each field is separated with whitespace. If the format is modified, it will be modified by adding potentially new fields beginning with field 13; extant fields will remain unchanged.

Examples   EXAMPLE 1   Using `trapstat` Without Options

When run without options, `trapstat` displays a table of trap types and CPUs. At most six columns can fit in the default terminal width; if (as in this example) there are more than six CPUs, multiple tables are displayed:

```
example# trapstat
vct  name                |    cpu0    cpu1    cpu4    cpu5    cpu8    cpu9
-----------------------+-------------------------------------------------
 24 cleanwin            |    6446    4837    6368    2153    2623    1321
 41 level-1             |     100       0       0       0       1       0
```

EXAMPLE 1   Using trapstat Without Options   *(Continued)*

```
 44 level-4            |        0        1        1        1        0        0
 45 level-5            |        0        0        0        0        0        0
 47 level-7            |        0        0        0        0        9        0
 49 level-9            |      100      100      100      100      100      100
 4a level-10           |      100        0        0        0        0        0
 4d level-13           |        6       10        7       16       13       11
 4e level-14           |      100        0        0        0        1        0

EXAMPLE 2 Using trapset with CPU Filtering

The -c option can be used to limit the CPUs on which trapstat is enabled. This example
limits CPU 1 and CPUs 12 through 15.

```
example# trapstat -c 1,12-15
```

```
vct  name               |   cpu1    cpu12    cpu13    cpu14    cpu15
-----------------------+-------------------------------------------
 24 cleanwin            |    6923      3072      2500      3518      2261
 44 level-4             |       3         0         0         1         1

```

EXAMPLE 3 Using trapstat with TLB Statistics

The -t option displays in-depth TLB statistics, including the amount of time spent performing TLB miss processing. The following example shows that the machine is spending 14.1 percent of its time just handling D-TLB misses:

```
example# trapstat -t
cpu m| itlb-miss %tim itsb-miss %tim | dtlb-miss %tim dtsb-miss %tim |%tim
-----+-----------------------------+-----------------------------+----
  0 u|    2571  0.3        0  0.0 |   10802  1.3        0  0.0 | 1.6
  0 k|       0  0.0        0  0.0 |  106420 13.4      184  0.1 |13.6
-----+-----------------------------+-----------------------------+----
  1 u|    3069  0.3        0  0.0 |   10983  1.2      100  0.0 | 1.6
  1 k|      27  0.0        0  0.0 |  106974 12.6       19  0.0 |12.7
-----+-----------------------------+-----------------------------+----
  2 u|    3033  0.3        0  0.0 |   11045  1.2      105  0.0 | 1.6
  2 k|      43  0.0        0  0.0 |  107842 12.7      108  0.0 |12.8
-----+-----------------------------+-----------------------------+----
  3 u|    2924  0.3        0  0.0 |   10380  1.2      121  0.0 | 1.6
  3 k|      54  0.0        0  0.0 |  102682 12.2       16  0.0 |12.2
-----+-----------------------------+-----------------------------+----
  4 u|    3064  0.3        0  0.0 |   10832  1.2      120  0.0 | 1.6
  4 k|      31  0.0        0  0.0 |  107977 13.0      236  0.1 |13.1
=====+=============================+=============================+====
 ttl |   14816  0.3        0  0.0 |  585937 14.1     1009  0.0 |14.5
```

EXAMPLE 4 Using trapstat with TLB Statistics and Page Size Information

By specifying the -T option, trapstat shows TLB misses broken down by page size. In this example, CPU 0 is spending 7.9 percent of its time handling user-mode TLB misses on 8K pages, and another 2.3 percent of its time handling user-mode TLB misses on 64K pages.

```
example# trapstat -T -c 0
cpu m size| itlb-miss %tim itsb-miss %tim | dtlb-miss %tim dtsb-miss %tim |%tim
----------+-----------------------------+-----------------------------+----
  0 u   8k|    1300  0.1       15  0.0 |  104897  7.9       90  0.0 | 8.0
  0 u  64k|       0  0.0        0  0.0 |   29935  2.3        7  0.0 | 2.3
  0 u 512k|       0  0.0        0  0.0 |    3569  0.2        2  0.0 | 0.2
  0 u   4m|       0  0.0        0  0.0 |     233  0.0        2  0.0 | 0.0
- - - - - + - - - - - - - - - - - - - + - - - - - - - - - - - - - + - -
  0 k   8k|      13  0.0        0  0.0 |   71733  6.5      110  0.0 | 6.5
  0 k  64k|       0  0.0        0  0.0 |       0  0.0        0  0.0 | 0.0
  0 k 512k|       0  0.0        0  0.0 |       0  0.0      206  0.1 | 0.1
  0 k   4m|       0  0.0        0  0.0 |       0  0.0        0  0.0 | 0.0
==========+=============================+=============================+====
      ttl |    1313  0.1       15  0.0 |  210367 17.1      417  0.2 |17.5
```

EXAMPLE 5 Using `trapstat` with Entry Filtering

By specifying the `-e` option, `trapstat` displays statistics for only specific trap types. Using this option minimizes the probe effect when seeking specific data. This example yields statistics for only the *dtlb-prot* and *syscall-32* traps on CPUs 12 through 15:

```
example# trapstat -e dtlb-prot,syscall-32 -c 12-15
vct  name                 |   cpu12   cpu13   cpu14   cpu15
-----------------------+-----------------------------------
 6c dtlb-prot           |     817     754    1018     560
108 syscall-32          |    1426    1647    2186    1142

vct  name                 |   cpu12   cpu13   cpu14   cpu15
-----------------------+-----------------------------------
 6c dtlb-prot           |    1085     996     800     707
108 syscall-32          |    2578    2167    1638    1452
```

EXAMPLE 6 Using `trapstat` with a Higher Sampling Rate

The following example uses the `-r` option to specify a sampling rate of 1000 samples per second, and filter only for the level-10 trap. Additionally, specifying the `-P` option yields parsable output.

Notice the timestamp difference between the level-10 events: 9,998,000 nanoseconds and 10,007,000 nanoseconds. These level-10 events correspond to the system clock, which by default ticks at 100 hertz (that is, every 10,000,000 nanoseconds).

```
example# trapstat -e level-10 -P -r 1000
1070400 0 4a level-10 0
2048600 0 4a level-10 0
3030400 0 4a level-10 1
4035800 0 4a level-10 0
5027200 0 4a level-10 0
6027200 0 4a level-10 0
7027400 0 4a level-10 0
8028200 0 4a level-10 0
9026400 0 4a level-10 0
10029600 0 4a level-10 0
11028600 0 4a level-10 0
12024000 0 4a level-10 0
13028400 0 4a level-10 1
14031200 0 4a level-10 0
15027200 0 4a level-10 0
16027600 0 4a level-10 0
17025000 0 4a level-10 0
18026000 0 4a level-10 0
19027800 0 4a level-10 0
20025600 0 4a level-10 0
21025200 0 4a level-10 0
22025000 0 4a level-10 0
```

EXAMPLE 6 Using trapstat with a Higher Sampling Rate   *(Continued)*

```
23035400 0 4a level-10 1
24027400 0 4a level-10 0
25026000 0 4a level-10 0
26027000 0 4a level-10 0
```

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	
Human Readable Output	Uncommitted
Parsable Output	Committed

Sun Microelectronics UltraSPARC II User's Manual, January 1997, STP1031,

The SPARC Architecture Manual, Version 9, 1994, Prentice-Hall.

Notes   When enabled, trapstat induces a varying probe effect, depending on the type of information collected. While the precise probe effect depends upon the specifics of the hardware, the following table can be used as a rough guide:

Option	Approximate probe effect
default	3-5% per trap
-e	3-5% per specified trap
-t, -T	40-45% per TLB miss trap hitting in the TSB, 25-30% per TLB miss trap missing in the TSB

These probe effects are *per trap* not for the system as a whole. For example, running trapstat with the default options on a system that spends 7% of total time handling traps induces a performance degradation of less than one half of one percent; running trapstat with the -t or -T option on a system spending 5% of total time processing TLB misses induce a performance degradation of no more than 2.5%.

When run with the -t or -T option, trapstat accounts for its probe effect when calculating the *%tim* fields. This assures that the *%tim* fields are a reasonably accurate indicator of the time a given workload is spending handling TLB misses — regardless of the perturbing presence of trapstat.

While the *%tim* fields include the explicit cost of executing the TLB miss handler, they do *not* include the implicit costs of TLB miss traps (for example, pipeline effects, cache pollution, etc). These implicit costs become more significant as the trap rate grows; if high *%tim* values are reported (greater than 50%), you can accurately infer that much of the balance of time is being spent on the implicit costs of the TLB miss traps.

Due to the potential system wide degradation induced, only the super-user can run `trapstat`.

Due to the limitation of the underlying statistics gathering methodology, only one instance of `trapstat` can run at a time.

Name ttymon – port monitor for terminal ports

Synopsis /usr/lib/ttymon -g [-d *device*] [-h] [-t *timeout*]
           [-l *ttylabel*] [-p *prompt*] [-m *modules*] [-T *termtype*]

Description ttymon is a STREAMS-based TTY port monitor. Its function is to monitor ports, to set terminal modes, baud rates, and line disciplines for the ports, and to connect users or applications to services associated with the ports. Each instance of ttymon monitors one port, specified at startup. When an instance of ttymon is started, ttymon first initializes the line disciplines, if they are specified, and the speed and terminal settings. For ports with entries in /etc/logindevperm, device owner, group and permissions are set. (See logindevperm(4).) The values used for initialization are taken from the appropriate entry in the TTY settings file. This file is maintained by the sttydefs(1M) command. Default line disciplines on ports are usually set up by the autopush(1M) command of the Autopush Facility.

ttymon then writes the prompt and waits for user input. If the user indicates that the speed is inappropriate by pressing the BREAK key, ttymon tries the next speed and writes the prompt again. When valid input is received, ttymon creates a utmpx entry (see utmpx(4)), and execs the login service for the port. Valid input consists of a string of at least one non-newline character, terminated by a carriage return.

If *autobaud* is enabled for a port, ttymon will try to determine the baud rate on the port automatically. Users must enter a carriage return before ttymon can recognize the baud rate and print the prompt. Currently, the baud rates that can be determined by *autobaud* are 110, 1200, 2400, 4800, and 9600.

SMF Service Description The primary smf(5) service which invokes ttymon is svc:/system/console-login, which may have multiple service instances. Instances are described in greater detail below. The service provides a number of properties within the property group ttymon to control the invocation, as follows:

```
NAME                 TYPE            TTYMON OPTION
-----------------------------------------------------------
device               astring         [-d device]
nohangup             boolean         [-h]
label                astring         [-l label]
modules              astring         [-m module1,module2]
prompt               astring         [-p prompt]
timeout              count           [-t timeout]
terminal_type        astring         [-T termtype]
```

If any value is the empty string or an integer set to zero, then the option is not passed to the ttymon invocation.

svc:/system/console-login:default
    The default instance always represents the ttymon that offers login on the system hardware console.

    See EXAMPLES for an example of how to modify settings for the system console.

svc:/system/console-login:{vt2, vt3, vt4, vt5, vt6}
> Additional service instances are provided for the system's virtual consoles. If virtual consoles are not available, these services will automatically disable themselves. See vtdaemon(1M).

svc:/system/console-login:{terma, termb}
> svc:/system/console-login:terma and svc:/system/console-login:termb are provided as a convenience and can assist the user in setting up login services for additional ports /dev/term/a and /dev/term/b. These services are disabled by default.

Creating Additional Instances
The user can configure additional service instances for additional devices. This can be accomplished in any of these ways:

- Manually creating the service instance using svccfg(1M).
- Creating the service in a service profile (see smf(5)).
- Creating a service manifest for additional service instance(s).

See EXAMPLES for an example of manually configuring the service using svccfg.

SMF Service Errors
In most cases when an instance of the console-login service is misconfigured, it will transition itself to the maintenance state. Use svcs -l (see svcs(1)) to determine the location of the service's log file and consult the log for additional information.

In some error cases, the service may respawn indefinitely. Disable the service using svcadm(1M), then consult the service log for additional messages or information to help resolve the problem.

Security
ttymon uses pam(3PAM) for session management. The PAM configuration policy, listed through /etc/pam.conf, specifies the modules to be used for ttymon. Here is a partial pam.conf file with entries for ttymon using the UNIX session management module.

```
ttymon session required /usr/lib/security/pam_unix_session.so.1
```

If there are no entries for the ttymon service, then the entries for the "other" service will be used.

Options
The following options are supported:

-g   The -g option is required for historical reasons.

-d*device*   *device* is the full path name of the port to which ttymon is to attach. If this option is not specified, file descriptor 0 must be set up by the invoking process to a TTY port.

-h   If the -h flag is not set, ttymon will force a hangup on the line by setting the speed to zero before setting the speed to the default or specified speed.

-l*ttylabel* *ttylabel* is a link to a speed and TTY definition in the ttydefs file. This definition tells ttymon at what speed to run initially, what the initial TTY

settings are, and what speed to try next if the user indicates that the speed is inappropriate by pressing the BREAK key. The default speed is 9600 baud.

-m*modules*   When initializing the port, ttymon will pop all modules on the port, and then push *modules* in the order specified. *modules* is a comma-separated list of pushable modules. Default modules on the ports are usually set up by the Autopush Facility.

-p*prompt*   Allows the user to specify a prompt string. The default prompt is Login:.

-t*timeout*   Specifies that ttymon should exit if no one types anything in *timeout* seconds after the prompt is sent.

-T*termtype*   Sets the TERM environment variable to *termtype*.

-v   Enables verbose messaging.

Examples   **EXAMPLE 1**   Setting the Terminal Type for the System Console

The following example sets the value of the terminal type (-T) option for the system console ttymon invocation:

```
# svccfg -s svc:/system/console-login:default \
        "setprop ttymon/terminal_type = xterm"
# svcadm refresh svc:/system/console-login:default
```

EXAMPLE 2   Creating a Service Instance for an Additional Serial Device

In this example, the user wishes to configure an additional instance of the svc:/system/console-login service in order to offer login services over a terminal connected by means of a USB serial adapter. Assume that the USB serial port is present as /dev/term/1, and the user plans to connect a vt100 terminal to it. In this case, the service instance can be named term1 (or any other name) and defined as follows:

```
# svccfg -s svc:/system/console-login "add term1"
# SVC=svc:/system/console-login:term1
# svccfg -s $SVC "addpg ttymon application"
# svccfg -s $SVC "setprop ttymon/device = /dev/term/1"
# svccfg -s $SVC "setprop ttymon/terminal_type = vt100"
# svcadm refresh $SVC
# svcadm enable $SVC
```

Environment Variables   If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of ttymon for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how ttymon behaves.

LC_CTYPE   Determines how ttymon handles characters. When LC_CTYPE is set to a valid value, ttymon can display and handle text and filenames containing valid characters for that locale. ttymon can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. ttymon can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

Files /etc/logindevperm

Contains information that is used by login(1) and ttymon to change the owner, group, and permissions of devices upon logging into or out of a console device.

Attributes See attributes(5) for descriptions of the following attributes:

Oracle Solaris Administration: Common Tasks

Notes

Service Access Facility (SAF and SAC)   ttymon was formerly a component of the Service Access Facility and was invoked by sac, the Service Access Controller. This facility has been removed in this release of Solaris, and a conversion to SMF of relevant portions was performed.

Competition for Ports   If a port is monitored by more than one ttymon, it is possible for the ttymons to send out prompt messages in such a way that they compete for input.

It is possible that two svc:/system/console-login service instances could refer to the same underlying device. For example, if the system's hardware console is connected (due to settings or autodetection in firmware) to serial port A, then both the svc:/system/console-login:default and svc:/system/console-login:terma services will refer to same underlying hardware device. Care should be taken when defining or enabling additional service instances to avoid this situation, or the two ttymons will compete for input.

Name tunefs – tune an existing UFS file system

Synopsis `tunefs [-a` *maxcontig*`] [-d` *rotdelay*`] [-e` *maxbpg*`]`
`             [-m` *minfree*`] [-o space | time]` *special* | *filesystem*

Description `tunefs` is designed to change the dynamic parameters of a file system that affect the layout policies. When using `tunefs` with *filesystem*, *filesystem* must be in `/etc/vfstab`. The parameters that can be changed are indicated by the options given below.

Options The following options are supported:

-a *maxcontig*   The maximum number of logical blocks, belonging to one file, that is allocated contiguously. The default is calculated as follows:

maxcontig = *disk drive maximum transfer size / disk block size*

If the disk drive's maximum transfer size cannot be determined, the default value for maxcontig is calculated from kernel parameters as follows:

If maxphys is less than ufs_maxmaxphys, which is 1 Mbyte, then maxcontig is set to maxphys. Otherwise, maxcontig is set to ufs_maxmaxphys.

You can set maxcontig to any positive integer value.

The actual value will be the lesser of what has been specified and what the hardware supports.

-d *rotdelay*   This parameter is obsolete as of the Solaris 10 release. The value is always set to 0, regardless of the input value.

-e *maxbpg*   Indicates the maximum number of contiguous logical blocks any single file can allocate from a cylinder group before it is forced to begin allocating blocks from another cylinder group. Typically this value is set to approximately one quarter of the total contiguous logical blocks in a cylinder group. The intent is to prevent any single file from using up all the blocks in a single cylinder group, thus degrading access times for all files subsequently allocated in that cylinder group.

The effect of this limit is to cause big files to do long seeks more frequently than if they were allowed to allocate all the blocks in a cylinder group before seeking elsewhere. For file systems with exclusively large files, this parameter should be set higher.

-m *minfree*   Specifies the minimum free space threshold, or the percentage of space held back from normal users. This value can be set to 0. However, up to a factor of three in throughput will be lost over the performance obtained at a 10% threshold. *Note:* If the value is raised above the current usage level, users will be unable to allocate files until enough files have been deleted to get under the higher threshold.

-o *space* | *time*   The file system can either be instructed to try to minimize the *time* spent allocating blocks, or to try to minimize the *space* fragmentation on the disk. The default is *time*.

Generally, you should optimize for time unless the file system is over 90% full.

Usage   See largefile(5) for the description of the behavior of tunefs when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

Name txzonemgr – Trusted Extensions Zone Manager configuration utility

Synopsis `/usr/sbin/txzonemgr [-c | -d[f] | -Z` *file*`]`

Description The txzonemgr shell script provides a simple, menu-based GUI wizard for creating, installing, initializing, and booting labeled zones on a system on which Trusted Extensions is enabled. The script also provides menu items for networking options, name services options, and making the global zone a client of an existing LDAP server. By default, all zones are configured to use the same name service and IP address as the global zone.

txzonemgr can also perform a limited set of commands in command-line mode instead of GUI mode, by using appropriate options, described below.

txzonemgr is run by roles granted in the Zone Management Rights Profile, or by root in the global zone.

Options Without options, txzonemgr operates as a menu-based GUI. Using any options will result in command-line operation only. Except as specified below, options cannot be combined.

The following options are supported:

-c

Create default zones. Requires that no zones already exist. The number, names, and attributes of the zones created is subject to change. However, typically a "public" zone and at least one other zone is created.

-d

Destroy all zones. All zones will be halted, uninstalled, and deleted. Prompts for confirmation unless the -f option is also specified.

-f

Force. Can be used with -d to override prompt for confirmation.

-Z *file*

Create a set of zones using the list specified in the file. Each line in the file must contain a zone name and its corresponding label, separated by whitespace. The label should not be quoted even if it contains whitespace. If an existing zone named "snapshot" exists, all the specified zones are cloned from it. Otherwise the first zone in the list is installed, and then a snapshot zone is cloned from it. The remaining zones are then cloned from the snapshot. The zones are configured to require manual booting. However, when an authorized user assigns a valid label to a GNOME workspace, the corresponding zone is booted automatically.

Exit Status No values are returned for GUI mode. For command-line operation, the following exit values are returned:

0

Successful completion.

1
   An error occurred.

2
   Invalid usage.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Command Interface Stability	Committed
Interactive Dialogue	Not an Interface

See Also   zenity(1) (not a SunOS man page), ipadm(1M), zoneadm(1M), zonecfg(1M), attributes(5), rbac(5), zones(5)

Solaris Trusted Extensions Administrator's Procedures

Notes   If administering zones from JDS, use txzonemgr rather than CDE actions.

txzonemgr uses the zenity command. For details, see the zenity(1) man page, which is not part of the SunOS collection.

Name   tzreload – notify timezone update

Synopsis   /usr/sbin/tzreload

Description   The tzreload command notifies active (running) processes to reread timezone information. The timezone information is cached in each process, absent a tzreload command, is never reread until a process is restarted. In response to a tzreload command, active processes reread the current timezone information at the next call to ctime(3C) and mktime(3C). The tzreload notification is sent to processes within the current zone.

tzreload causes processes which are using the system timezone (in /etc/default/init) to reread the contents of that file.

In addition to notifying active processes, the tzreload command also notifies cron(1M), to reinitialize the job scheduler with the new timezone information.

Files   /usr/share/lib/zoneinfo
    Standard zone information directory.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also   cron(1M), zdump(1M), zic(1M), ctime(3C), mktime(3C), attributes(5), smf(5)

Notes   Although tzreload reinitializes cron(1M), applications that are affected by timezone changes still need to be restarted or reinitialized if they do not reread the new timezone information before timezone changes take place.

The timezone update service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/timezone:default

Administrative actions on this service, such as enabling, disabling, or requesting refresh, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Refreshing this service causes the tzreload command to be run, notifying running processes to reload their timezone caches. Disabling this service is not recommended.

Name tzselect – select a time zone

Synopsis `/usr/bin/tzselect`

Description The `tzselect` program asks you a series of questions about the current location and outputs the resulting time zone description to standard output. The output is suitable as a value for the `TZ` environment variable.

All user interaction is through standard input and standard error.

Options The `tzselect` command has no options.

Exit Status The following exit values are returned:

    0   Timezone information was successfully obtained.

    >0   An error occurred.

Files `/usr/share/lib/zoneinfo`   directory containing timezone data files

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also zdump(1M), zic(1M), ctime(3C), attributes(5)

Name uadmin – administrative control

Synopsis /usr/sbin/uadmin *cmd fcn* [*mdep*]

Description The uadmin command provides control for basic administrative functions. This command is tightly coupled to the system administration procedures and is not intended for general use. It may be invoked only by the super-user.

Both the *cmd* (command) and *fcn* (function) arguments are converted to integers and passed to the uadmin system call. The optional *mdep* (machine dependent) argument is only available for the *cmd* values of 1 (A_REBOOT), 2 (A_SHUTDOWN), or 5 (A_DUMP). For any other *cmd* value, no *mdep* command-line argument is allowed.

When passing an *mdep* value that contains whitespaces, the string must be grouped together as a single argument enclosed within quotes, for example:

uadmin 1 1 "-s kernel/unix"

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also halt(1M), reboot(1M), uadmin(2), attributes(5)

Warnings Shutting down or halting the system by means of uadmin does not update the boot archive. Avoid using this command after

- editing of files such as /etc/system
- installing new driver binaries or kernel binaries
- updating existing driver binaries or kernel binaries.

Use reboot(1M) or halt(1M) instead.

Name ucodeadm – update processor microcode

Synopsis /usr/sbin/ucodeadm -v

/usr/sbin/ucodeadm -u*microcode-text-file*

/usr/sbin/ucodeadm -i [-R *path*] *microcode-text-file*

Description The ucodeadm utility can be used to report running microcode revision on the processors, update microcode, or install microcode on the target system to be used during the boot process.

The *microcode-text-file* can be obtained from processor vendors.

Options

-v   Report microcode revision.

-u *microcode-text-file*   Update microcode on all cross-call interrupt ready processors.

-i *microcode-text-file*   Install microcode files on target system to be used during the next boot cycle. The text file name must have the vendor name prefix, such as "intel" or "amd".

                                By default the microcode files will be installed at:

                                 /platform/i86pc/ucode/$VENDORSTR/

                                where VENDORSTR is either "GenuineIntel" or "AuthenticAMD".

-R *alternate path*   Install *microcode* path in the *alternate path*.

Examples **EXAMPLE 1** Reporting the Microcode Revision

The following example displays the microcode revision that is currently running:

```
# ucodeadm -v
```

EXAMPLE 2 Updating the Processor Microcode

The following example updates the processor microcode to intel-ucode.txt:

```
# ucodeadm -u intel-ucode.txt
```

EXAMPLE 3 Installing the Microcode on the Target System

The following example installs the microcode on the target system, /export/ucode-path:

```
# ucodeadm -i -R /export/ucode-path intel-ucode.txt
```

If an alternate path is used when installing the microcode on the target system, the installed microcode file is not used on the next boot cycle.

Exit Status The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also psradm(1M), psrinfo(1M), attributes(5)

Name ufsdump – incremental file system dump

Synopsis /usr/sbin/ufsdump [*options*] [*arguments*] *files_to_dump*

Description ufsdump backs up all files specified by *files_to_dump* (usually either a whole file system or files within a file sytem changed after a certain date) to magnetic tape or disk file.

The ufsdump command can only be used on unmounted file systems, or those mounted read-only. Attempting to dump a mounted, read-write file system might result in a system disruption or the inability to restore files from the dump. Consider using the fssnap(1M) command to create a file system snapshot if you need a point-in-time image of a file system that is mounted.

If a filesystem was mounted with the logging option, it is strongly recommended that you run ufsdump as the root user. Running the command as a non-root user might result in the creation of an inconsistent dump.

options is a single string of one-letter ufsdump options.

arguments may be multiple strings whose association with the options is determined by order. That is, the first argument goes with the first option that takes an argument; the second argument goes with the second option that takes an argument, and so on.

files_to_dump is required and must be the last argument on the command line. See OPERANDS for more information.

With most devices ufsdump can automatically detect the end-of-media. Consequently, the d, s, and t options are not necessary for multi-volume dumps, unless ufsdump does not understand the way the device detects the end-of-media, or the files are to be restored on a system with an older version of the restore command.

Options The following options are supported:

0−9
    The "dump level." All files specified by *files_to_dump* that have been modified since the last ufsdump at a lower dump level are copied to the *dump_file* destination (normally a magnetic tape device). For instance, if a "level 2" dump was done on Monday, followed by a "level 4" dump on Tuesday, a subsequent "level 3" dump on Wednesday would contain all files modified or added since the "level 2" (Monday) backup. A "level 0" dump copies the entire file system to the *dump_file*.

a *archive_file*
    Archive file. Archive a dump table-of-contents in the specified *archive_file* to be used by ufsrestore(1M) to determine whether a file is in the dump file that is being restored.

b *factor*
    Blocking factor. Specify the blocking factor for tape writes. The default is 20 blocks per write for tapes of density less than 6250BPI (bytes-per-inch). The default blocking factor for tapes of density 6250BPI and greater is 64. The default blocking factor for cartridge

tapes (c option) is 126. The highest blocking factor available with most tape drives is 126. Note: the blocking factor is specified in terms of 512-byte blocks, for compatibility with tar(1).

c

Cartridge. Set the defaults for cartridge instead of the standard half-inch reel. This sets the density to 1000BPI and the blocking factor to 126. Since ufsdump can automatically detect the end-of-media, only the blocking parameter normally has an effect. When cartridge tapes are used, and this option is *not* specified, ufsdump will slightly miscompute the size of the tape. If the b, d, s or t options are specified with this option, their values will override the defaults set by this option.

d *bpi*

Tape density. Not normally required, as ufsdump can detect end-of-media. This parameter can be used to keep a running tab on the amount of tape used per reel. The default density is 6250BPI except when the c option is used for cartridge tape, in which case it is assumed to be 1000BPI per track. Typical values for tape devices are:

1/2 inch tape
6250 BPI

1/4 inch cartridge
1000 BPI The tape densities and other options are documented in the st(7D) man page.

D

Diskette. Obsolete option.

f *dump_file*

Dump file. Use *dump_file* as the file to dump to, instead of /dev/rmt/0. If *dump_file* is specified as −, dump to standard output.

If the name of the file is of the form *machine*:*device,* the dump is done from the specified machine over the network using rmt(1M). Since ufsdump is normally run by root, the name of the local machine must appear in the /.rhosts file of the remote machine. If the file is specified as *user*@*machine*:*device,* ufsdump will attempt to execute as the specified user on the remote machine. The specified user must have a .rhosts file on the remote machine that allows the user invoking the command from the local machine to access the remote machine.

l

Autoload. When the end-of-tape is reached before the dump is complete, take the drive offline and wait up to two minutes for the tape drive to be ready again. This gives autoloading (stackloader) tape drives a chance to load a new tape. If the drive is ready within two minutes, continue. If it is not, prompt for another tape and wait.

L *string*

Sets the tape label to *string*, instead of the default none. *string* may be no more than sixteen characters long. If it is longer, it is truncated and a warning printed; the dump will still be done. The tape label is specific to the ufsdump tape format, and bears no resemblance to IBM or ANSI-standard tape labels.

n

Notify all operators in the sys group that ufsdump requires attention by sending messages to their terminals, in a manner similar to that used by the wall(1M) command. Otherwise, such messages are sent only to the terminals (such as the console) on which the user running ufsdump is logged in.

N *device_name*

Use *device_name* when recording information in /etc/dumpdates (see the u option) and when comparing against information in /etc/dumpdates for incremental dumps. The *device_name* provided can contain no white space as defined in scanf(3C) and is case-sensitive.

o

Offline. Take the drive offline when the dump is complete or the end-of-media is reached and rewind the tape. In the case of some autoloading 8mm drives, the tape is removed from the drive automatically. This prevents another process which rushes in to use the drive, from inadvertently overwriting the media.

s *size*

Specify the *size* of the volume being dumped to. Not normally required, as ufsdump can detect end-of-media. When the specified size is reached, ufsdump waits for you to change the volume. ufsdump interprets the specified size as the length in feet for tapes and cartridges. The values should be a little smaller than the actual physical size of the media (for example, 425 for a 450-foot cartridge). Typical values for tape devices depend on the c option for cartridge devices:

1/2 inch tape
    2300 feet

60-Mbyte 1/4 inch cartridge
    425 feet

150-Mbyte 1/4 inch cartridge
    700 feet

S

Size estimate. Determine the amount of space that is needed to perform the dump without actually doing it, and display the estimated number of bytes it will take. This is useful with incremental dumps to determine how many volumes of media will be needed.

t *tracks*

Specify the number of tracks for a cartridge tape. Not normally required, as ufsdump can detect end-of-media. The default is 9 tracks. The t option is not compatible with the D option. Values for Sun-supported tape devices are:

60-Mbyte 1/4 inch cartridge
9 tracks

150-Mbyte 1/4 inch cartridge
18 tracks

T *time_wait*[hms]

Sets the amount of time to wait for an autoload command to complete. This option is ignored unless the l option has also been specified. The default time period to wait is two minutes. Specify time units with a trailing h (for hours), m (for minutes), or s (for seconds). The default unit is minutes.

u

Update the dump record. Add an entry to the file /etc/dumpdates, for each file system successfully dumped that includes the file system name (or *device_name* as specified with the N option), date, and dump level.

v

Verify. After each tape is written, verify the contents of the media against the source file system. If any discrepancies occur, prompt for new media, then repeat the dump/verification process. The file system *must* be unmounted. This option cannot be used to verify a dump to standard output.

w

Warning. List the file systems that have not been backed up within a day. This information is gleaned from the files /etc/dumpdates and /etc/vfstab. When the w option is used, all other options are ignored. After reporting, ufsdump exits immediately.

W

Warning with highlight. Similar to the w option, except that the W option includes all file systems that appear in /etc/dumpdates, along with information about their most recent dump dates and levels. File systems that have not been backed up within a day are highlighted.

Operands   The following operand is supported:

files_to_dump

Specifies the files to dump. Usually it identifies a whole file system by its raw device name (for example, /dev/rdsk/c0t3d0s6). Incremental dumps (levels 1 to 9) of files changed after a certain date only apply to a whole file system. Alternatively, *files_to_dump* can identify individual files or directories. All named directories that may be examined by the user running ufsdump, as well as any explicitly-named files, are dumped. This dump is equivalent to a level 0 dump of the indicated portions of the filesystem, except that

/etc/dumpdates is not updated even if the -u option has been specified. In all cases, the files must be contained in the same file system, and the file system must be local to the system where ufsdump is being run.

files_to_dump is required and must be the last argument on the command line.

If no *options* are given, the default is 9uf /dev/rmt/0 *files_to_dump*.

Usage See largefile(5) for the description of the behavior of ufsdump when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Examples EXAMPLE 1   Using ufsdump

The following command makes a full dump of a root file system on c0t3d0, on a 150-MByte cartridge tape unit 0:

```
example# ufsdump 0cfu /dev/rmt/0 /dev/rdsk/c0t3d0s0
```

The following command makes and verifies an incremental dump at level 5 of the usr partition of c0t3d0, on a 1/2 inch reel tape unit 1,:

```
example# ufsdump 5fuv /dev/rmt/1 /dev/rdsk/c0t3d0s6
```

Exit Status While running, ufsdump emits many verbose messages. ufsdump returns the following exit values:

0
   Normal exit.

1
   Startup errors encountered.

3
   Abort – no checkpoint attempted.

Files /dev/rmt/0
   default unit to dump to

/etc/dumpdates
   dump date record

/etc/group
   to find group sys

/etc/hosts
   to gain access to remote system with drive

/etc/vfstab
   list of file systems

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also cpio(1), tar(1), dd(1M), devnm(1M), fssnap(1M), prtvtoc(1M), rmt(1M), shutdown(1M), ufsrestore(1M), volcopy(1M), wall(1M), scanf(3C), ufsdump(4), attributes(5), largefile(5), st(7D)

Notes

Read Errors Fewer than 32 read errors on the file system are ignored.

Process Per Reel Because each reel requires a new process, parent processes for reels that are already written hang around until the entire tape is written.

Operator Intervention ufsdump requires operator intervention on these conditions: end of volume, end of dump, volume write error, volume open error or disk read error (if there are more than a threshold of 32). In addition to alerting all operators implied by the n option, ufsdump interacts with the operator on ufsdump's control terminal at times when ufsdump can no longer proceed, or if something is grossly wrong. All questions ufsdump poses *must* be answered by typing yes or no, as appropriate.

Since backing up a disk can involve a lot of time and effort, ufsdump checkpoints at the start of each volume. If writing that volume fails for some reason, ufsdump will, with operator permission, restart itself from the checkpoint after a defective volume has been replaced.

Suggested Dump Schedule It is vital to perform full, "level 0", dumps at regular intervals. When performing a full dump, bring the machine down to single-user mode using shutdown(1M). While preparing for a full dump, it is a good idea to clean the tape drive and heads. Incremental dumps should be performed with the system running in single-user mode.

Incremental dumps allow for convenient backup and recovery of active files on a more frequent basis, with a minimum of media and time. However, there are some tradeoffs. First, the interval between backups should be kept to a minimum (once a day at least). To guard against data loss as a result of a media failure (a rare, but possible occurrence), capture active files on (at least) two sets of dump volumes. Another consideration is the desire to keep unnecessary duplication of files to a minimum to save both operator time and media storage. A third consideration is the ease with which a particular backed-up version of a file can be located and restored. The following four-week schedule offers a reasonable tradeoff between these goals.

```
          Sun    Mon    Tue    Wed    Thu    Fri
Week 1:   Full    5      5      5      5      3
Week 2:           5      5      5      5      3
Week 3:           5      5      5      5      3
Week 4:           5      5      5      5      3
```

Although the Tuesday through Friday incrementals contain "extra copies" of files from Monday, this scheme assures that any file modified during the week can be recovered from the previous day's incremental dump.

Process Priority of ufsdump

ufsdump uses multiple processes to allow it to read from the disk and write to the media concurrently. Due to the way it synchronizes between these processes, any attempt to run dump with a nice (process priority) of '−5' or better will likely make ufsdump run *slower* instead of faster.

Overlapping Partitions

Most disks contain one or more overlapping slices because slice 2 covers the entire disk. The other slices are of various sizes and usually do not overlap. For example, a common configuration places root on slice 0, swap on slice 1, /opt on slice 5 and /usr on slice 6.

It should be emphasized that ufsdump dumps one ufs file system at a time. Given the above scenario where slice 0 and slice 2 have the same starting offset, executing ufsdump on slice 2 with the intent of dumping the entire disk would instead dump only the root file system on slice 0. To dump the entire disk, the user must dump the file systems on each slice separately.

Bugs

The /etc/vfstab file does not allow the desired frequency of backup for file systems to be specified (as /etc/fstab did). Consequently, the w and W options assume file systems should be backed up daily, which limits the usefulness of these options.

Name ufsrestore – incremental file system restore

Synopsis /usr/sbin/ufsrestore i | r | R | t | x [abcdfhlmostvyLT]
[*archive_file*] [*factor*] [*dumpfile*] [*n*] [*label*]
[*timeout*] [*filename*]...

Description The ufsrestore utility restores files from backup media created with the ufsdump command. ufsrestores's actions are controlled by the *key* argument. The *key* is exactly one function *letter* (i, r, R, t, or x) and zero or more *function modifier*s (letters). The *key* string contains no SPACE characters. Function modifier arguments are listed on the command line in the same order as their corresponding function modifiers appear in the *key* string.

filename arguments which appear on the command line, or as arguments to an interactive command, are treated as shell glob patterns by the x and t functions; any files or directories matching the patterns are selected. The metacharacters *, ?, and [ ] must be protected from the shell if they appear on the command line. There is no way to quote these metacharacters to explicitly match them in a filename.

The temporary files rstdir* and rstmode* are placed in /tmp by default. If the environment variable TMPDIR is defined with a non-empty value, that location is used instead of /tmp.

Options

Function Letters You must specify one (and only one) of the function letters listed below. Note that i, x, and r are intended to restore files into an empty directory. The R function is intended for restoring into a populated directory.

i   Interactive. After reading in the directory information from the media, ufsrestore invokes a shell-like interface that allows you to browse through the dump file's directory hierarchy and select individual files to be extracted. Restoration has the same semantics as x (see below). See Interactive Commands, below, for a description of available commands.

r   Recursive. Starting with an empty directory and a level 0 dump, the r function recreates the filesystem relative to the current working directory, exactly as it appeared when the dump was made. Information used to restore incremental dumps on top of the full dump (for example, restoresymtable) is also included. Several ufsrestore runs are typical, one for each higher level of dump (0, 1, ..., 9). Files that were deleted between the level 0 and a subsequent incremental dump will not exist after the final restore. To completely restore a file system, use the r function restore the level 0 dump, and again for each incremental dump. Although this function letter is intended for a complete restore onto a new file system (one just created with newfs(1M)), if the file system contains files not on the backup media, they are preserved.

R   Resume restoring. If an r-mode ufsrestore was interrupted, this function prompts for the volume from which to resume restoring and continues the restoration from where it was left off. Otherwise identical to r.

t   Table of contents. List each *filename* that appears on the media. If no *filename* argument is given, the root directory is listed. This results in a list of all files on the media, unless the h function modifier is in effect. The table of contents is taken from the media or from the specified archive file, when the a function modifier is used. The a function modifier is mutually exclusive with the x and r function letters.

x   Extract the named files from the media. Files are restored to the same relative locations that they had in the original file system.

If the *filename* argument matches a directory whose contents were written onto the media, and the h modifier is not in effect, the directory is recursively extracted, relative to the current directory, which is expected to be empty. For each file, the owner, modification time, and mode are restored (if possible).

If you omit the *filename* argument or specify . , the root directory is extracted. This results in the entire tape being extracted, unless the h modifier is in effect. . With the x function, existing files are overwritten and ufsrestore displays the names of the overwritten files. Overwriting a currently-running executable can have unfortunate consequences.

Use the x option to restore partial file system dumps, as they are (by definition) not entire file systems.

Function Modifiers   a *archive_file*   Read the table of contents from *archive_file* instead of the media. This function modifier can be used in combination with the t, i, or x function letters, making it possible to check whether files are on the media without having to mount the media. When used with the x and interactive (i) function letters, it prompts for the volume containing the file(s) before extracting them.

b *factor*   Blocking factor. Specify the blocking factor for tape reads. For variable length SCSI tape devices, unless the data was written with the default blocking factor, a blocking factor at least as great as that used to write the tape must be used; otherwise, an error will be generated. Note that a tape block is 512 bytes. Refer to the man page for your specific tape driver for the maximum blocking factor.

c   Convert the contents of the media in 4.1BSD format to the new ufs file system format.

d   Debug. Turn on debugging output.

f *dump_file*   Use *dump_file* instead of /dev/rmt/0 as the file to restore from. Typically *dump_file* specifies a tape drive. If *dump_file* is specified as '–', ufsrestore reads from the standard input. This allows ufsdump(1M) and ufsrestore to be used in a pipeline to copy a file system:

```
example# ufsdump 0f — /dev/rdsk/c0t0d0s7 \
 | (cd /home;ufsrestore xf —)
```

If the name of the file is of the form *machine*:*device*, the restore is done from the specified machine over the network using rmt(1M). Since ufsrestore is normally run by root, the name of the local machine must appear in the /.rhosts file of the remote machine. If the file is specified as *user*@*machine*:*device*, ufsrestore will attempt to execute as the specified user on the remote machine. The specified user must have a .rhosts file on the remote machine that allows the user invoking the command from the local machine to access the remote machine.

h	Extract or list the actual directory, rather than the files that it references. This prevents hierarchical restoration of complete subtrees from the tape.
l	Autoload. When the end-of-tape is reached before the restore is complete, take the drive off-line and wait up to two minutes (the default, see the T function modifier) for the tape drive to be ready again. This gives autoloading (stackloader) tape drives a chance to load a new tape. If the drive is ready within two minutes, continue. If it is not, prompt for another tape and wait.
L *label*	The label that should appear in the header of the dump file. If the labels do not match, ufsrestore issues a diagnostic and exits. The tape label is specific to the ufsdump tape format, and bears no resemblance to IBM or ANSI-standard tape labels.
m	Extract by inode numbers rather than by filename to avoid regenerating complete pathnames. Regardless of where the files are located in the dump hierarchy, they are restored into the current directory and renamed with their inode number. This is useful if only a few files are being extracted.
o	Offline. Take the drive off-line when the restore is complete or the end-of-media is reached and rewind the tape. In the case of some autoloading 8mm drives, the tape is removed from the drive automatically.
s *n*	Skip to the *n*th file when there are multiple dump files on the same tape. For example, the command:

```
example# ufsrestore xfs /dev/rmt/0hn 5
```

would position you to the fifth file on the tape when reading volume 1 of the dump. If a dump extends over more than one volume, all volumes except the first are assumed to start at position 0, no matter what "s *n*" value is specified.

If "s *n*" is specified, the backup media must be at BOT (beginning of tape). Otherwise, the initial positioning to read the table of contents will fail, as it is performed by skipping the tape forward *n*-1 files rather than by using absolute positioning. This is because on some devices absolute positioning is very time consuming.

T timeout [hms] Sets the amount of time to wait for an autoload command to complete. This function modifier is ignored unless the l function modifier has also been specified. The default timeout period is two minutes. The time units may be specified as a trailing h (hours), m (minutes), or s (seconds). The default unit is minutes.

v Verbose. ufsrestore displays the name and inode number of each file it restores, preceded by its file type.

y Do not ask whether to abort the restore in the event of tape errors. ufsrestore tries to skip over the bad tape block(s) and continue as best it can.

Interactive Commands ufsrestore enters interactive mode when invoked with the i function letters. Interactive commands are reminiscent of the shell. For those commands that accept an argument, the default is the current directory. The interactive options are:

add [*filename*] Add the named file or directory to the list of files to extract. If a directory is specified, add that directory and its files (recursively) to the extraction list (unless the h modifier is in effect).

cd *directory* Change to *directory* (within the dump file).

delete [*filename*] Delete the current directory, or the named file or directory from the list of files to extract. If a directory is specified, delete that directory and all its descendents from the extraction list (unless the h modifier is in effect). The most expedient way to extract a majority of files from a directory is to add that directory to the extraction list, and then delete specific files to omit.

extract Extract all files on the extraction list from the dump media. ufsrestore asks which volume the user wishes to mount. The fastest way to extract a small number of files is to start with the last volume and work toward the first. If "s *n*" is given on the command line, volume 1 will automatically be positioned to file *n* when it is read.

help Display a summary of the available commands.

ls [*directory*] List files in *directory* or the current directory, represented by a '.' (period). Directories are appended with a '/' (slash). Entries marked for extraction are prefixed with a '*' (asterisk). If the verbose option is in effect, inode numbers are also listed.

marked [*directory*]	Like ls, except only files marked for extraction are listed.
pager	Toggle the pagination of the output from the ls and marked commands. The pager used is that defined by the PAGER environment variable, or more(1) if that envar is not defined. The PAGER envar may include white-space-separated arguments for the pagination program.
pwd	Print the full pathname of the current working directory.
quit	ufsrestore exits immediately, even if the extraction list is not empty.
setmodes	Prompts: set owner/mode for '.' (period). Type y for yes to set the mode (permissions, owner, times) of the current directory '.' (period) into which files are being restored equal to the mode of the root directory of the file system from which they were dumped. Normally, this is what you want when restoring a whole file system, or restoring individual files into the same locations from which they were dumped. Type n for no, to leave the mode of the current directory unchanged. Normally, this is what you want when restoring part of a dump to a directory other than the one from which the files were dumped.
setpager *command*	Sets the command to use for paginating output instead of the default or that inherited from the environment. The *command* string may include arguments in addition to the command itself.
verbose	Toggle the status of the v modifier. While v is in effect, the ls command lists the inode numbers of all entries, and ufsrestore displays information about each file as it is extracted.
what	Display the dump header on the media.

Operands The following operands are supported.

filename Specifies the pathname of files (or directories) to be restored to disk. Unless the h function modifier is also used, a directory name refers to the files it contains, and (recursively) its subdirectories and the files they contain. *filename* is associated with either the x or t function letters, and must come last.

Usage See largefile(5) for the description of the behavior of ufsrestore when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

Exit Status The following exit values are returned:

0 Successful completion.

1 An error occurred. Verbose messages are displayed.

Environment Variables PAGER The command to use as a filter for paginating output. This can also be used to specify the options to be used. Default is more(1).

TMPDIR   Selects the directory for temporary files. Defaults to /tmp if not defined in the environment.

Files   /dev/rmt/0   the default tape drive

$TMPDIR/rstdir*   file containing directories on the tape

$TMPDIR/rstmode*   owner, mode, and timestamps for directories

./restoresymtable   information passed between incremental restores

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   more(1), mkfs(1M), mount(1M), rmt(1M), ufsdump(1M), ufsdump(4), attributes(5), largefile(5)

Diagnostics   ufsrestore complains about bad option characters.

Read errors result in complaints. If y has been specified, or the user responds y, ufsrestore will attempt to continue.

If the dump extends over more than one tape, ufsrestore asks the user to change tapes. If the x or i function letter has been specified, ufsrestore also asks which volume the user wishes to mount. If the s modifier has been specified, and volume 1 is mounted, it is automatically positioned to the indicated file.

There are numerous consistency checks that can be listed by ufsrestore. Most checks are self-explanatory or can "never happen". Common errors are given below.

Converting to new file system format
    A dump tape created from the old file system has been loaded. It is automatically converted to the new file system format.

filename: not found on tape
    The specified file name was listed in the tape directory, but was not found on the tape. This is caused by tape read errors while looking for the file, using a dump tape created on an active file system, or restoring a partial dump with the r function.

expected next file *inumber*, got *inumber*
    A file that was not listed in the directory showed up. This can occur when using a dump tape created on an active file system.

Incremental tape too low
    When doing an incremental restore, a tape that was written before the previous incremental tape, or that has too low an incremental level has been loaded.

Incremental tape too high
> When doing incremental restore, a tape that does not begin its coverage where the previous incremental tape left off, or one that has too high an incremental level has been loaded.

media read error: invalid argument
> Blocking factor specified for read is smaller than the blocking factor used to write data.

Tape read error while restoring
Tape read error while skipping over inode inumber
Tape read error while trying to resynchronize
A tape read error has occurred
> If a file name is specified, then its contents are probably partially wrong. If an inode is being skipped or the tape is trying to resynchronize, then no extracted files have been corrupted, though files may not be found on the tape.

resync ufsrestore, skipped *num*
> After a tape read error, ufsrestore may have to resynchronize itself. This message lists the number of blocks that were skipped over.

Incorrect tape label. Expected 'foo', got 'bar'.
> The L option was specified, and its value did not match what was recorded in the header of the dump file.

Notes ufsrestore can get confused when doing incremental restores from dump tapes that were made on active file systems.

A level 0 dump must be done after a full restore. Because ufsrestore runs in user mode, it has no control over inode allocation. This means that ufsrestore repositions the files, although it does not change their contents. Thus, a full dump must be done to get a new set of directories reflecting the new file positions, so that later incremental dumps will be correct.

Name unshare – make local resource unavailable for mounting by remote systems

Synopsis unshare [-F *protocol*] [-a | [-t] [*pathname* | *sharename*]]

Description The unshare command unpublishes a file system share, which makes a shared local file system unavailable for file sharing *protocol*. If the -F *protocol* option is omitted, then the first file sharing procotol listed in the /etc/dfs/fstypes file used as the default sharing protocol.

Options -F *protocol*
    Identify the file sharing protocol.

-a
    Unpublish all active shares.

-t
    Temporarily unpublish a share. By default, all shares are permanently unpublished.

Files /etc/dfs/fstypes
    List of file sharing protocols. NFS is the default file-sharing protocol.

/etc/dfs/sharetab
    Contains a table of local resources published by the share command.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcs

See Also share(1M), shareall(1M), attributes(5)

Notes If *pathname* or *resourcename* is not found in the share information, an error message is sent to standard error.

When an unshare command completes successfully, a client mounting a file system specified in that unshare command no longer has access to that file system.

Name unshare_nfs – make local NFS file systems unavailable for mounting by remote systems

Synopsis unshare [-F nfs] *pathname*

Description The unshare command makes local file systems unavailable for mounting by remote systems. The shared file system must correspond to a line with NFS as the *FSType* in the file /etc/dfs/sharetab.

Options The following options are supported:

-F   This option may be omitted if NFS is the first file system type listed in the file /etc/dfs/fstypes.

Files /etc/dfs/fstypes

/etc/dfs/sharetab

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/file-system/nfs

See Also nfsd(1M), share(1M), attributes(5)

Notes If the file system being unshared is a symbolic link to a valid pathname, the canonical path (the path which the symbolic link follows) will be unshared.

For example, if /export/foo is a symbolic link to /export/bar (/export/foo -> /export/bar), the following unshare command will result in /export/bar as the unshared pathname (and not /export/foo):

example# unshare -F nfs /export/foo

For file systems that are accessed by NFS Version 4 clients, once the unshare is complete, all NFS Version 4 state (open files and file locks) are released and unrecoverable by the clients. If the intent is to share the file system after some administrative action, the NFS daemon (nfsd) should first be stopped and then the file system unshared. After the administrative action is complete, the file system would then be shared and the NFS daemon restarted. See nfsd(1M)

System Administration Commands – Part 3

Name update_drv – modify device driver attributes

Synopsis update_drv [-f | -v] [-n] *driver_module*

update_drv [-b *basedir*] [-f | -v] [-n] -a [-m *'permission'*]
      [-i *'identify-name'*] [-P *'privilege'*] [-p *'policy'*] *driver_module*

update_drv [-b *basedir*] [-f | -v] [-n] -d [-m *'permission'*]
      [-i *'identify-name'*] [-P *'privilege'*] [-p *'policy'*] *driver_module*

Description The update_drv command informs the system about attribute changes to an installed device
driver. It can be used to re-read the driver.conf(4) file, or to add, modify, or delete a driver's
minor node permissions or aliases.

Without options, update_drv reloads the driver.conf file.

Upon successfully updating the aliases, the driver binding takes effect upon reconfig boot or
hotplug of the device.

Upon successfully updating the permissions, only the new driver minor nodes get created
with the modified set of file permissions. Existing driver minor nodes do not get modified.

Options The following options are supported:

-a

Add a *permission*, *aliases*, *privilege* or *policy* entry.

With the -a option specified, a permission entry (using the -m option), or a driver's aliases
entry (using the -i option), a device privilege (using the -P option) or a a device policy
(using the -p option), can be added or updated. If a matching minor node permissions
entry is encountered (having the same driver name and the minor node), it is replaced. If a
matching aliases entry is encountered (having a different driver name and the same alias),
an error is reported.

The -a and -d options are mutually exclusive.

-b *basedir*

Installs or modifies the driver on the system with a root directory of basedir rather than
installing on the system executing update_drv.

Note – The root file system of any non-global zones must not be referenced with the -b
option. Doing so might damage the global zone's file system, might compromise the
security of the global zone, and might damage the non-global zone's file system. See
zones(5).

-d

Delete a *permission*, *aliases*, *privilege* or *policy* entry.

The -m *permission*, -i *identify-name*, -P *privilege* or the -p *policy* option needs to be
specified with the -d option.

The -d and -a options are mutually exclusive.

If the entry doesn't exist update_drv returns an error.

-f

Force the system to reread the driver.conf file even if the driver module cannot be unloaded. See NOTES section for details.

Without this option, when removing an alias for a driver, update_drv updates the binding files for the next boot, but returns an error if one or more devices that reference the driver-alias binding remains. *With* the -f option, update_drv does not return an error if such devices remain.

-i '*identify-name*'

A white-space separated list of aliases for the driver. If -a or -d option is not specified then this option is ignored. The *identify-name* string is mandatory. If all aliases need to be removed, rem_drv(1M) is recommended.

-m '*permission*'

Specify a white-space separated list of file system permissions for the device node of the device driver. If -a or -d option is not specified then, this option is ignored. The permission string is mandatory.

-n

Do not try to load and attach *device_driver*, just modify the system configuration files for that driver.

-p '*policy*'

With the -a option, policy is a white-space separated list of complete device policies. For the -d option, policy is a white space separated list of minor device specifications. The minor device specifications are matched exactly against the entries in /etc/security/device_policy, that is., no wildcard matching is performed.

-P '*privilege*'

With the -a option, privilege is a comma separated list of additional driver privileges. For the -d option, privilege is a single privilege. The privileges are added to or removed from the /etc/security/extra_privs file.

-v

Verbose.

Examples EXAMPLE 1 Adding or Modifying an Existing Minor Permissions Entry

The following command adds or modifies the exisitng minor permissions entry of the clone driver:

```
example# update_drv -a -m 'llc1 777 joe staff' clone
```

EXAMPLE 2 Removing All Minor Permissions Entries

The following command removes all minor permission entries of the usbprn driver, the USB printer driver:

```
example# update_drv -d -m '* 0666 root sys' usbprn
```

EXAMPLE 3 Adding a Driver Aliases Entry

The following command adds a driver aliases entry of the ugen driver with the identity string of usb459,20:

```
example# update_drv -a -i '"usb459,20"' ugen
```

EXAMPLE 4 Re-reading the driver.conf File For the ohci Driver

The following command re-reads the driver.conf(4) file.

```
 example# update_drv ohci
```

EXAMPLE 5 Requiring a Self-defined Privilege to Open a tcp Socket

The following command requires a self-defined privilege to open a tcp socket:

```
example#   update_drv -a -P net_tcp -p \
     'write_priv_set=net_tcp read_priv_set=net_tcp' tcp
```

EXAMPLE 6 Establishing a Path-oriented Alias

The following command establishes a path-oriented alias to force a specific driver, qlt, to be used for a particular device path:

```
example#   update_drv -a -i '"/pci@8,600000/SUNW,qlc@4"' qlt
```

Exit Status The following exit values are returned:

0

 Successful completion.

>0

 An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also add_drv(1M), modunload(1M), rem_drv(1M), driver.conf(4), attributes(5), privileges(5)

Notes If `-a` or `-d` options are specified, update_drv does not reread the `driver.conf` file.

A forced update of the `driver.conf` file reloads the `driver.conf` file without reloading the driver binary module. In this case, devices which cannot be detached reference driver global properties from the old `driver.conf` file, while the remaining driver instances reference global properties in the new `driver.conf` file.

It is possible to add an alias , which changes the driver binding of a device already being managed by a different driver. A force update with the `-a` option tries to bind to the new driver and report error if it cannot. If you specify more than one of the `-m`, `-i`, `-P` or `-p` options, a force flag tries to modify aliases or permissions. This is done even if the other operation fails and vice-versa.

Name useradd – administer a new user login on the system

Synopsis useradd [-A *authorization* [,*authorization*...]]
           [-b *base_dir*] [-c *comment*] [-d *dir*] [-e *expire*]
           [-f *inactive*] [-g *group*] [-G *group* [,*group*]...]
           [-K *key=value*] [-m [-k *skel_dir*]] [-p *projname*]
           [-P *profile* [,*profile*...]] [-R *role* [,*role*...]]
           [-s *shell*] [-S *repository*] [-u *uid* [-o]] *login*

           useradd -D [-A *authorization* [,*authorization*...]]
           [-b *base_dir*] [-s *shell* [-k *skel_dir*]] [-e *expire*]
           [-f *inactive*] [-g *group*] [-K *key=value*] [-p *projname*]
           [-P *profile* [,*profile*...]] [-R *role* [,*role*...]]

Description useradd adds a new user to the passwd, shadow, and user_attr databases in the files and
           ldap repositories. The -A and -P options respectively assign authorizations and profiles to the
           user. The -R option assigns roles to a user. The -p option associates a project with a user. The
           -K option adds a *key=value* pair to user_attr entry for the user. Multiple *key=value* pairs may
           be added with multiple -K options.

           useradd also creates supplementary group memberships for the user (-G option) and creates
           the home directory (-m option) for the user if requested. The new login remains locked until
           the passwd(1) command is executed.

           Specifying useradd -D with the -s, -k, -g, -b, -f, -e, -A, -P, -p, -R, or -K option (or any
           combination of these options) sets the default values for the respective fields. See the -D
           option, below. Subsequent useradd commands without the -D option use these arguments.

           The system file entries created with this command have a limit of 2048 characters per line.
           Specifying long arguments to several options can exceed this limit.

           useradd requires that usernames be in the format described in passwd(4). A warning message
           is displayed if these restrictions are not met. See passwd(4) for the requirements for
           usernames.

           An administrator must be granted the User Management Profile to be able to create a new
           user. The authorizations required to set the various fields in passwd, shadow and user_attr
           can be found in passwd(4), shadow(4), and user_attr(4). The authorizations required to
           assign groups and projects can be found in group(4) and project(4).

Options The following options are supported:

           -A *authorization*
              One or more comma-separated authorizations defined in auth_attr(4). Only a user or
              role who has grant rights to the authorization can assign it to an account.

           -b *base_dir*
              The base directory for new login home directories (see the -d option below. When a new
              user account is being created, *base_dir* must already exist unless the -m option or the -d
              option is also specified.

-c *comment*

Any text string. It is generally a short description of the login, and is currently used as the field for the user's full name. This information is stored in the user's passwd entry.

-d *dir*

Specifies the auto_home entry for the new user. The path /home/*username* is entered in /etc/passwd. When the user subsequently references /home/*username*, the automounter will mount the directory specified here on /home/*username*.

The argument to the -d option can be specified as *server*:*dir* where *server* is the hostname of the machine on which the home directory resides and *dir* is the path to the user's home directory. If the server is a remote host, then the home directory needs to be created on the remote host for the system to mount it, when the user logs in. If no server name is specified then the home directory will be created on the host where the command is executed, when the -m option is used.

-D

Display the default values for group, base_dir, skel_dir, shell, inactive, expire, proj, projname and key=value pairs. When used with the -g, -b, -f, -e, -A, -P, -p, -R, or -K options, the -D option sets the default values for the specified fields. The default values are:

group
  other (GID of 1)

base_dir
  /export/home

skel_dir
  /etc/skel

shell
  /usr/bin/bash

inactive
  0

expire
  null

auths
  null

profiles
  null

proj
  3

projname
  default

key=value (pairs defined in user_attr(4)
    not present

roles
    null

-e *expire*

Specify the expiration date for a login. After this date, no user will be able to access this
login. The expire option argument is a date entered using one of the date formats included
in the template file /etc/datemsk. See getdate(3C).

If the date format that you choose includes spaces, it must be quoted. For example, you can
enter 10/6/90 or October 6, 1990. A null value (" ") defeats the status of the expired date.
This option is useful for creating temporary logins.

-f *inactive*

The maximum number of days allowed between uses of a login ID before that ID is
declared invalid. Normal values are positive integers. A value of 0 defeats the status.

-g *group*

An existing group's integer ID or character-string name. Without the -D option, it defines
the new user's primary group membership and defaults to the default group. You can reset
this default value by invoking useradd -D -g *group*. GIDs 0-99 are reserved for allocation
by the Solaris Operating System.

-G *group*

An existing group's integer ID or character-string name. It defines the new user's
supplementary group membership. Duplicates between *group* with the -g and -G options
are ignored. No more than NGROUPS_MAX groups can be specified. GIDs 0-99 are reserved
for allocation by the Solaris Operating System.

-K *key=value*

A *key=value* pair to add to the user's attributes. Multiple -K options may be used to add
multiple *key=value* pairs. The generic -K option with the appropriate key may be used
instead of the specific implied key options (-A, -P, -R, -p). See user_attr(4) for a list of
valid *key=value* pairs. The "type" key is not a valid key for this option. Keys may not be
repeated.

-k *skel_dir*

A directory that contains skeleton information (such as .profile) that can be copied into a
new user's home directory. This directory must already exist. The system provides the
/etc/skel directory that can be used for this purpose.

-m

Create the new user's home directory if it does not already exist. If the directory already
exists, it must have read, write, and execute permissions by *group*, where *group* is the user's
primary group. If the server name specified to the -d option is a remote host then the
system will not attempt to create the home directory.

If the directory does not already exist, a new ZFS dataset will be created. In the global zone, the dataset is created as rpool/export/home/*username*. For non-global zones, the dataset will be created as *ROOT-dataset*/export/home/*username*. The mountpoint for the ZFS dataset is /export/home/*username* by default. If -d *path* is specified and it is a path on the local machine, the dataset will be mounted at the specified location. The user is delegated permissions to create ZFS snapshots and promote them. The newly created dataset will inherit the encryption setting from its parent. If it is encrypted, the user is granted permission to change its wrapping key.

-o

    This option allows a UID to be duplicated (non-unique).

-P *profile*

    One or more comma-separated execution profiles defined in prof_attr(4).

-p *projname*

    Name of the project with which the added user is associated. See the *projname* field as defined in project(4).

-R *role*

    One or more comma-separated execution profiles defined in user_attr(4). Roles cannot be assigned to other roles.

-s *shell*

    Full pathname of the program used as the user's shell on login. If unspecified, it will default to any value previously configured with the -D -s option. If no default has been set with -D -s, then /usr/bin/bash will be used. The value of *shell* must be a valid executable file.

-S *repository*

    The valid repositories are files, ldap. The repository specifies which name service will be updated. The default repository is files. When the repository is files, the authorizations, profiles, and roles can be present in other name service repositories and can be assigned to a user in the files repository. When the repository is ldap, all the assignable attributes must be present in the ldap repository.

-u *uid*

    The UID of the new user. This UID must be a non-negative decimal integer below MAXUID as defined in <sys/param.h>. The UID defaults to the next available (unique) number above the highest number currently assigned. For example, if UIDs 100, 105, and 200 are assigned, the next default UID number will be 201. UIDs 0-99 are reserved for allocation by the Solaris Operating System.

Files /etc/datemsk

/etc/passwd

/etc/shadow

/etc/group

/etc/skel

/usr/include/limits.h

/etc/user_attr

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also passwd(1), profiles(1), roles(1), users(1B), groupadd(1M), groupdel(1M), groupmod(1M), grpck(1M), logins(1M), pwck(1M), userdel(1M), usermod(1M), getdate(3C), auth_attr(4), group(4), passwd(4), prof_attr(4), project(4), user_attr(4), attributes(5)

Diagnostics In case of an error, useradd displays an error message and exits with a non-zero status.

The following indicates that login specified is already in use:

UX: useradd: ERROR: login is already in use. Choose another.

The following indicates that the *uid* specified with the -u option is not unique:

UX: useradd: ERROR: uid *uid* is already in use. Choose another.

The following indicates that the *group* specified with the -g option has not yet been created:

UX: useradd: ERROR: group *group* does not exist. Choose another.

The following indicates that the *uid* specified with the -u option is in the range of reserved UIDs (from 0-99):

UX: useradd: WARNING: uid *uid* is reserved.

The following indicates that the *uid* specified with the -u option exceeds MAXUID as defined in <sys/param.h>:

UX: useradd: ERROR: uid *uid* is too big. Choose another.

The following indicates that the /etc/passwd or /etc/shadow files do not exist:

UX: useradd: ERROR: Cannot update system files - login cannot be created.

The following indicates that the user executing the command does not have sufficient authorization to perform the operation:

UX: roleadd: ERROR: Permission denied.

The following indicates that an invalid directory was specified in a useradd command:

UX: *invalid_directory* is not a valid directory. Choose another.

Notes   The useradd utility adds definitions to the passwd, shadow, group, project, and user_attr databases in the scope (default or specified). It will verify the uniqueness of the user name (or role) and user id and the existence of any group names specified against the external name service.

Name userdel – delete a user's login from the system

Synopsis userdel [-r] [-S *repository*] *login*

Description The userdel utility deletes a user account from the system and makes the appropriate account-related changes to the system file and file system.

An administrator must be granted the User Management Profile to be able to delete a user.

Options The following options are supported:

-r   Remove the user's home directory from the system. This directory must exist. The files and directories under the home directory will no longer be accessible following successful execution of the command. A ZFS dataset that was created for the user's home directory will be removed. An auto_home entry that was added for the user will be deleted.

-S *repository*   The valid repositories are files, ldap. The repository specifies which name service will be updated. The default repository is files.

Operands The following operands are supported:

login   An existing login name to be deleted.

Exit Status The following exit values are returned:

0   Successful completion.

2   Invalid command syntax. A usage message for the userdel command is displayed.

6   The account to be removed does not exist.

8   The account to be removed is in use.

10   Cannot update the /etc/group or /etc/user_attr file but the login is removed from the /etc/passwd file.

12   Cannot remove or otherwise modify the home directory.

Files /etc/passwd   system password file

/etc/shadow   system file contain users' encrypted passwords and related information

/etc/group   system file containing group definitions

/etc/user_attr   system file containing additional user attributes

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   auths(1), passwd(1), profiles(1), roles(1), users(1B), groupadd(1M), groupdel(1M), groupmod(1M), logins(1M), roleadd(1M), rolemod(1M), useradd(1M), usermod(1M), passwd(4), prof_attr(4), user_attr(4), attributes(5)

Notes   The userdel utility deletes an account definition that is in the group, passwd, shadow, and user_attr databases in the files or ldap repository.

Name usermod – modify a user's login information on the system

Synopsis usermod [-u *uid* [-o]] [-g *group*] [-G [+|-]*group* [, *group*...]]
        [-d *dir* [-m]] [-s *shell*] [-c *comment*] [-l *new_name*]
        [-f *inactive*] [-e *expire*]
        [-A [+|-]*authorization* [, *authorization*]]
        [-P [+|-]*profile* [, *profile*]] [-R [+|-]*role* [, *role*]]
        [-K *key*[+|-]=*value*] [-S *repository*] *login*

Description The usermod utility modifies a user's login definition on the system. It changes the definition
        of the specified login and makes the appropriate login-related system file and file system
        changes.

        The system file entries created with this command have a limit of 512 characters per line.
        Specifying long arguments to several options might exceed this limit.

        An administrator must be granted the User Security Profile to modify the security attributes
        for an existing user. To be able to modify the non-security attributes of an existing user
        requires the User Management Profile. The authorizations required to set the various fields in
        passwd, shadow and user_attr can be found in passwd(4), shadow(4), and user_attr(4). The
        authorizations required to assign groups can be found in group(4).

Options The following options are supported:

-A [+|-]*authorization*
        One or more comma separated authorizations as defined in auth_attr(4). Only a user or
        role who has grant rights to the authorization can assign it to an account. This replaces
        any existing authorization setting. If no authorization list is specified, the existing setting is
        removed.

        A prefix + adds the authorization to the existing authorization; a prefix - removes the
        authorization from the existing authorization. With no prefix, *authorization* replaces the
        existing authorization.

-c *comment*
        Specify a comment string. *comment* can be any text string. It is generally a short description
        of the login, and is currently used as the field for the user's full name. This information is
        stored in the user's passwd entry.

-d *dir*
        Specify the new home directory of the user. It defaults to *base_dir/login*, where *base_dir* is
        the base directory for new login home directories, and login is the new login. This creates
        or modifies an auto_home entry for the user.

        The argument to the option can be specified as *server*:*dir* where *server* is the hostname of
        the machine on which the home directory resides and *dir* is the path to the user's home
        directory. If the server is a remote host then the home directory needs to created on the

remote host for the system to mount it, when the user logs in. If no server name is specified then the home directory will be created on the host where the command is executed, when the -m option is used.

-e *expire*

Specify the expiration date for a login. After this date, no user will be able to access this login. The expire option argument is a date entered using one of the date formats included in the template file /etc/datemsk. See getdate(3C).

For example, you may enter 10/6/90 or October 6, 1990. A value of " '' defeats the status of the expired date.

-f *inactive*

Specify the maximum number of days allowed between uses of a login ID before that login ID is declared invalid. Normal values are positive integers. A value of 0 defeats the status.

-g *group*

Specify an existing group's integer ID or character-string name. It redefines the user's primary group membership.

-G [+|-]*group*

An existing group's integer ID or character-string name. It defines the new user's supplementary group membership. Duplicates between group with the -g and -G options are ignored. No more than NGROUPS_MAX groups can be specified. GIDs 0-99 are reserved for allocation by the Solaris Operating System.

A prefix + adds the group to the existing group; a prefix - removes the group from the existing group. With no prefix, *group* replaces the existing group.

-K *key*[+|-]=*value*

Replace existing or add to a user's *key*=*value* pair attributes. Multiple -K options can be used to replace or add multiple *key*=*value* pairs. However, keys must not be repeated. The generic -K option with the appropriate key can be used instead of the specific implied key options (-A, -P, -R, -p). See user_attr(4) for a list of valid *key*s. Values for these keys are usually found in man pages or other sources related to those keys. For example, see project(4) for guidance on values for the project key. Use the command ppriv(1) with the -v and -l options for a list of values for the keys defaultpriv and limitpriv. If no value is specified, the existing key is removed.

The keyword type can be specified with the value role or the value normal. When using the value role, the account changes from a normal user to a role; using the value normal keeps the account a normal user.

As a role account, no roles (-R or *roles*=*value*) can be present.

A prefix + adds the value to the existing value; a prefix - removes the value from the existing value. With no prefix, *value* replaces the existing value.

The prefix +/- operation is applicable only to the following keys: auths, profiles, roles, project, limitpriv, and defaultpriv.

-l *new_logname*

Specify the new login name for the user. See passwd(4) for the requirements for usernames.

-m

Move the user's home directory to the new directory specified with the -d option. If the directory already exists, it must have permissions read/write/execute by *group*, where *group* is the user's primary group. If the server name specified to the -d option is a remote host then the system will not attempt to create the home directory.

If the directory does not already exist, a new ZFS dataset will be created. In the global zone, the dataset is created as rpool/export/home/*rolename*. For non-global zones, the dataset will be created as *ROOT-dataset*/export/home/*rolename*. The mountpoint for the ZFS dataset is /export/home/*rolename* by default. If -d *path* is specified and it is a path on the local machine, the dataset will be mounted at the specified location. The role is delegated permissions to create ZFS snapshots and promote them. The newly created dataset will inherit the encryption setting from its parent. If it is encrypted, the role is granted permission to change its wrapping key.

-o

This option allows the specified UID to be duplicated (non-unique).

-P [+|-]*profile*

One or more comma-separated rights profiles defined in prof_attr(4). This replaces any existing profile setting in user_attr(4). If an empty profile list is specified, the existing setting is removed.

A prefix + adds the profile to the existing profile; a prefix - removes the profile from the existing profile. With no prefix, *profile* replaces the existing profile.

-R [+|-]*role*

One or more comma-separated roles (see roleadd(1M)). This replaces any existing role setting. If no role list is specified, the existing setting is removed.

A prefix + adds the role to the existing role; a prefix - removes the role from the existing role. With no prefix, *role* replaces the existing role.

-s *shell*

Specify the full pathname of the program that is used as the user's shell on login. The value of *shell* must be a valid executable file.

-S *repository*

The valid repositories are files, ldap. The repository specifies which name service will be updated. The default repository is files. When the repository is files, the authorizations, profiles, and roles can be present in other name service repositories and can be assigned to a user in the files repository. When the repository is ldap, all the assignable attributes must be present in the ldap repository.

-u *uid*

Specify a new UID for the user. It must be a non-negative decimal integer less than MAXUID as defined in <param.h>. The UID associated with the user's home directory is not modified with this option; a user will not have access to their home directory until the UID is manually reassigned using chown(1).

Operands The following operands are supported:

login

An existing login name to be modified.

Examples EXAMPLE 1   Assigning Privileges to a User

The following command adds the privilege that affects high resolution times to a user's initial, inheritable set of privileges.

```
# usermod -K defaultpriv=basic,proc_clock_highres jdoe
```

This command results in the following entry in user_attr:

```
jdoe::::type=normal;defaultpriv=basic,proc_clock_highres
```

EXAMPLE 2   Removing a Privilege from a User's Limit Set

The following command removes the privilege that allows the specified user to create hard links to directories and to unlink directories.

```
# usermod -K limitpriv=all,!sys_linkdir jdoe
```

This command results in the following entry in user_attr:

```
jdoe::::type=normal;defaultpriv=basic,limitpriv=all,!sys_linkdir
```

EXAMPLE 3   Removing a Privilege from a User's Basic Set

The following command removes the privilege that allows the specified user to examine processes outside the user's session.

```
# usermod -K defaultpriv=basic,!proc_session jdoe
```

This command results in the following entry in user_attr:

```
jdoe::::type=normal;defaultpriv=basic,!proc_session;limitpriv=all
```

EXAMPLE 4   Assigning a Role to a User

The following command assigns a role to a user. The role must have been created prior to this command through use of roleadd(1M).

```
# usermod -R mailadm jdoe
```

This command results in the following entry in user_attr:

```
jdoe::::type=normal;roles=mailadm;defaultpriv=basic;limitpriv=all
```

EXAMPLE 5 Removing All Profiles from a User

The following command removes all profiles that were granted to a user directly. The user will still have any rights profiles that are granted by means of the PROFS_GRANTED key in policy.conf(4).

```
# usermod -P "" jdoe
```

Exit Status In case of an error, usermod prints an error message and exits with one of the following values:

2

The command syntax was invalid. A usage message for the usermod command is displayed.

3

An invalid argument was provided to an option.

4

The *uid* given with the -u option is already in use.

5

The password files contain an error. pwconv(1M) can be used to correct possible errors. See passwd(4).

6

The login to be modified does not exist, the *group* does not exist, or the login shell does not exist.

8

The login to be modified is in use.

9

The *new_logname* is already in use.

10

Cannot update the /etc/group or /etc/user_attr file. Other update requests will be implemented.

11

Insufficient space to move the home directory (-m option). Other update requests will be implemented.

12

Unable to complete the move of the home directory to the new home directory.

Files /etc/group
  system file containing group definitions

/etc/datemsk
  system file of date formats

/etc/passwd
  system password file

/etc/shadow
    system file containing users' encrypted passwords and related information

/etc/user_attr
    system file containing additional user and role attributes

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed

See Also chown(1), passwd(1), users(1B), groupadd(1M), groupdel(1M), groupmod(1M), logins(1M), pwconv(1M), roleadd(1M), roledel(1M), rolemod(1M), useradd(1M), userdel(1M), getdate(3C), auth_attr(4), passwd(4), policy.conf(4), prof_attr(4), user_attr(4), attributes(5)

Notes The usermod utility modifies definitions in the passwd, shadow, group, project, and user_attr databases in the scope (default or specified). The utility will verify the uniqueness of user name and user ID against the external name service.

The usermod utility uses the /etc/datemsk file, available with SUNWaccr, for date formatting.

Name utmpd – utmpx monitoring daemon

Synopsis utmpd [-debug]

Description The utmpd daemon monitors the /var/adm/utmpx file. See utmpx(4) (and utmp(4) for historical information).

utmpd receives requests from pututxline(3C) by way of a named pipe. It maintains a table of processes and uses poll(2) on /proc files to detect process termination. When utmpd detects that a process has terminated, it checks that the process has removed its utmpx entry from /var/adm/utmpx. If the process' utmpx entry has not been removed, utmpd removes the entry. By periodically scanning the /var/adm/utmpx file, utmpd also monitors processes that are not in its table.

Options -debug

Run in debug mode, leaving the process connected to the controlling terminal. Write debugging information to standard output.

Exit Status The following exit values are returned:

0

Successful completion.

>0

An error occurred.

Files /etc/default/utmpd

You can set default values for the flags listed below. For example: SCAN_PERIOD=600

SCAN_PERIOD

The number of seconds that utmpd sleeps between checks of /proc to see if monitored processes are still alive. The default is 300.

MAX_FDS

The maximum number of processes that utmpd attempts to monitor. The default value is 4096.

WTMPX_UPDATE_FREQ

The number of seconds that utmpd sleeps between read accesses of the wtmpx file. The wtmpx file's last access time is used by init(1M) on reboot to determine when the operating system became unavailable. The default is 60.

/var/adm/utmpx

File containing user and accounting information for commands such as who(1), write(1), and login(1).

/proc

Directory containing files for processes whose utmpx entries are being monitored.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also svcs(1), init(1M), svcadm(1M), poll(2), pututxline(3C), proc(4), utmp(4), utmpx(4), attributes(5), smf(5)

Notes If the filesystem holding /var/adm/wtmpx is mounted with options which inhibit or defer access time updates, an unknown amount of error will be introduced into the utmp DOWN_TIME record's timestamp in the event of an uncontrolled shutdown (for example, a crash or loss of power). Controlled shutdowns will update the modify time of /var/adm/wtmpx, which will be used on the next boot to determine when the previous shutdown ocurred, regardless of access time deferral or inhibition.

The utmpd service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/utmp:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name uucheck – check the uucp directories and permissions file

Synopsis /usr/lib/uucp/uucheck [-v] [-x *debug-level*]

Description uucheck checks for the presence of the uucp system required files and directories. uucheck also does error checking of the Permissions file (/etc/uucp/Permissions).

uucheck is executed during package installation. uucheck can only be used by the super-user or uucp.

Options The following options are supported:

-v   Give a detailed (verbose) explanation of how the uucp programs will interpret the Permissions file.

-x *debug-level* Produce debugging output on the standard output. *debug-level* is a number from 0 to 9. Higher numbers give more detailed debugging information.

Files /etc/uucp/Devices

/etc/uucp/Limits

/etc/uucp/Permissions

/etc/uucp/Systems

/var/spool/locks/*

/var/spool/uucp/*

/var/spool/uucppublic/*

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/uucp

See Also uucp(1C), uustat(1C), uux(1C), uucico(1M), uusched(1M), attributes(5)

Bugs The program does not check file/directory modes or some errors in the Permissions file such as duplicate login or machine name.

Name uucico – file transport program for the uucp system

Synopsis /usr/lib/uucp/uucico [-f] [-c *type*] [-d *spool-directory*]
      [-i *interface*] [-r *role-number*] [-s *system-name*]
      [-x *debug-level*]

Description uucico is the file transport program for uucp work file transfers.

Options The following options are supported:

-f
: This option is used to "force execution" of uucico by ignoring the limit on the maximum number of uucicos defined in the /etc/uucp/Limits file.

-c *type*
: The first field in the Devices file is the "Type" field. The -c option forces uucico to only use entries in the "Type" field that match the user specified type. The specified type is usually the name of a local area network.

-d *spool-directory*
: This option specifies the directory *spool-directory* that contains the uucp work files to be transferred. The default spool directory is /var/spool/uucp.

-i *interface*
: This option defines the *interface* used with uucico. The interface only affects slave mode. Known interfaces are UNIX (default), TLI (basic Transport Layer Interface), and TLIS (Transport Layer Interface with Streams modules, read/write).

-r *role-number*
: The *role-number* 1 is used for master mode. *role-number* 0 is used for slave mode (default). When uucico is started by a program or cron, *role-number* 1 should be used for master mode.

-s *system-name*
: The -s option defines the remote system (*system-name*) that uucico will try to contact. It is required when the role is master; *system-name* must be defined in the Systems file.

-x *debug-level*
: Both uux and uucp queue jobs that will be transferred by uucico. These jobs are normally started by the uusched scheduler, for debugging purposes, and can be started manually. For example, the shell Uutry starts uucico with debugging turned on. The *debug-level* is a number between 0 and 9. Higher numbers give more detailed debugging information.

Files /etc/uucp/Devconfig

/etc/uucp/Devices

/etc/uucp/Limits

/etc/uucp/Permissions

/etc/uucp/Sysfiles

/etc/uucp/Systems

/var/spool/locks/*

/var/spool/uucp/*

/var/spool/uucppublic/*

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/uucp

See Also uucp(1C), uustat(1C), uux(1C), Uutry(1M), cron(1M), uusched(1M), attributes(5)

Name   uucleanup – uucp spool directory clean-up

Synopsis   `/usr/lib/uucp/uucleanup [-C`*time*`] [-D`*time*`] [-m`*string*`]`
`            [-o`*time*`] [-s`*system*`] [-W`*time*`] [-x`*debug-level*`] [-X`*time*`]`

Description   `uucleanup` will scan the spool directories for old files and take appropriate action to remove them in a useful way:

- Inform the requester of send/receive requests for systems that can not be reached.
- Return undeliverable mail to the sender.
- Deliver rnews files addressed to the local system.
- Remove all other files.

In addition, there is a provision to warn users of requests that have been waiting for a given number of days (default 1 day). Note: `uucleanup` will process as if all option times were specified to the default values unless time is specifically set.

This program is typically started by the shell `uudemon.cleanup`, which should be started by cron(1M).

Options   -C*time*   Remove any `C.` files greater or equal to `time` days old and send appropriate information to the requester (default 7 days).

   -D*time*   Remove any `D.` files greater or equal to `time` days old, make an attempt to deliver mail messages, and execute rnews when appropriate (default 7 days).

   -m*string*   Include *string* in the warning message generated by the -W option. The default line is "See your local administrator to locate the problem".

   -o*time*   Delete other files whose age is more than `time` days (default 2 days).

   -s*system*   Execute for *system* spool directory only.

   -W*time*   Any `C.` files equal to `time` days old will cause a mail message to be sent to the requester warning about the delay in contacting the remote. The message includes the *JOBID*, and in the case of mail, the mail message. The administrator may include a message line telling whom to call to check the problem (-m option) (default 1 day).

   -x*debug-level*   Produce debugging output on standard ouput. *debug-level* is a single digit between 0 and 9; higher numbers give more detailed debugging information. (This option may not be available on all systems.)

   -X*time*   Any `X.` files greater or equal to `time` days old will be removed. The `D.` files are probably not present (if they were, the `X.` could get executed). But if there are `D.` files, they will be taken care of by D. processing (default 2 days).

Files /usr/lib/uucp   directory with commands used by uucleanup internally

         /var/spool/uucp   spool directory

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/uucp

See Also uucp(1C), uux(1C), cron(1M), attributes(5)

Name   uusched – uucp file transport program scheduler

Synopsis   /usr/lib/uucp/uusched [-u *debug-level*] [-x *debug-level*]

Description   uusched is the uucp(1C) file transport scheduler. It is usually started by the daemon *uudemon.hour* that is started by cron(1M) from an entry in user uucp's crontab file:

    11,41 * * * * /etc/uucp/uucp/uudemon.hour

Options   The options are for debugging purposes only. *debug-level* is a number between 0 and 9. Higher numbers give more detailed debugging information:

The following options are supported:

-u *debug-level*   Passes the -u *debug-level* option uucico(1M) as -x *debug-level*.

-x *debug-level*   Outputs debugging messages from uusched.

Files   /etc/uucp/Devices

/etc/uucp/Permissions

/etc/uucp/Systems

/var/spool/locks/*

/var/spool/uucp/*

/var/spool/uucppublic/*

Attributes   See attributes(5) for descriptions of the following attributes:

See Also   uucp(1C), uustat(1C), uux(1C), cron(1M), uucico(1M), attributes(5)

Name Uutry, uutry – attempt to contact remote system with debugging on

Synopsis `/usr/lib/uucp/Uutry [-r] [-c` *type*`] [-x` *debug-level*`]` *system-name*

Description `Uutry` is a shell script that is used to invoke uucico(1M) to call a remote site. Debugging is initially turned on and is set to the default value of 5. The debugging output is put in file `/tmp/`*system-name.*

Options The following options are supported:

> `-r`   This option overrides the retry time that is set in file `/var/uucp/.Status/`*system-name.*
>
> `-c` *type*   The first field in the `Devices` file is the "Type" field. The `-c` option forces uucico to use only entries in the "Type" field that match the user-specified `type`. The specified `type` is usually the name of a local area network.
>
> `-x` *debug-level* *debug-level* is a number from 0 to 9. Higher numbers give more detailed debugging information.

Name uuxqt – execute remote command requests

Synopsis /usr/lib/uucp/uuxqt [-s *system*] [-x *debug-level*]

Description uuxqt is the program that executes remote job requests from remote systems generated by the use of the uux command. (mail uses uux for remote mail requests). uuxqt searches the spool directories looking for execution requests. For each request, uuxqt checks to see if all the required data files are available, accessible, and the requested commands are permitted for the requesting system. The Permissions file is used to validate file accessibility and command execution permission.

There are two environment variables that are set before the uuxqt command is executed:

- UU_MACHINE is the machine that sent the job (the previous one).
- UU_USER is the user that sent the job.

These can be used in writing commands that remote systems can execute to provide information, auditing, or restrictions.

Options The following options are supported:

-s *system*   Specifies the remote *system* name.

-x *debug-level* *debug-level* is a number from 0 to 9. Higher numbers give more detailed debugging information.

Files /etc/uucp/Limits

/etc/uucp/Permissions

Name   vbiosd – vbios daemon

Synopsis   vbiosd

Description   The vbiosd daemon is started at boot time to provide an execution environment for adapter-supplied VBIOS code that is used in graphics mode switching.

This mode switching occurs when exiting X, switching virtual terminals (see vtdaemon(1M) for more information), and during fast reboot.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Interface Stability	Uncommitted

See Also   svcs(1), svcadm(1M), vtdaemon(1M), attributes(5), smf(5)

Notes   The vbios daemon is managed by the service management facility, smf(5), under the service identifier:

svc:/system/vbiosd:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name vdiskadm – create and manage virtual disks

Synopsis vdiskadm create -s *size* [-t *type*[:*opt*],[*opt*]
    [-c *comment*] *vdname*

vdiskadm destroy [-r] *vdname*|*snapshot*

vdiskadm snapshot *vdname*@*snapname*

vdiskadm rollback [-r] *snapshot*

vdiskadm clone [-c *comment*] *vdname*|*snapshot clone_vdname*

vdiskadm move *vdname dir*

vdiskadm rename *vdname*|*snapshot vdname*|*snapshot*

vdiskadm list [-fp]*vdname*

vdiskadm verify *vdname*

vdiskadm prop-get [-l] -p *property vdname*

vdiskadm prop-set -p *property=value vdname*

vdiskadm prop-add -p *property=value vdname*

vdiskadm prop-del -p *property vdname*

vdiskadm import [-fnpqm] [-x *type*] -d file|zvol|dsk
    [-t *type*[:*opt*]] *vdname*

vdiskadm export -x *type*[:*opt*] -d file|zvol|dsk *vdname*

vdiskadm convert [-t *type*[:*opt*]] *vdname*

vdiskadm translate [-i *type*[:*opt*]] -I *input_file* -x *type*[:*opt*]
    -d *output_file*

vdiskadm help [*command*]

Description The vdiskadm command manages virtual disks within dom0. In the SYNOPSIS above, *vdname* is the pathname of the virtual disk; it has a maximum length of MAXPATHLEN (1024 bytes).

vdiskadm is implemented as a set of subcommands, many with their own options and operands. These subcommands are described under "Subcommands," below.

The following subsections describe concepts related to virtual disks.

Snapshots A snapshot is a read-only copy of a virtual disk. Snapshots can be created extremely quickly and initially consume little space. As data within the active virtual disk changes, the snapshot consumes more data than would otherwise be shared with the active virtual disk.

Clones A clone is a writable copy of a virtual disk. The default type of clone is a merged (that is, coalesced) copy of the original virtual disk. An example of a merged clone occurs when a virtual disk is comprised of several snapshots; a subsequent clone operation results in a new

virtual disk containing no snapshots. A clone will be of the same type as the original virtual disk (that is, vmdk:fixed). When a merged clone is created there is no linkage back to the original virtual disk or to any of its snapshots. This lack of linkage allows the merged clone to be moved to another physical machine.

Numeric Values   The values of numeric properties can be specified using human-readable suffixes, such as k, KB, M, Gb, and so forth, up to Z for zettabyte). The following are all valid (and equal) specifications:

1536M 1.5g 1.50GB

Types of Virtual Disks   The following types and options of virtual disks are supported:

- vmdk:fixed
- vmdk:sparse
- vdi:fixed
- vdi:sparse
- vhd:fixed
- vhd:sparse
- raw:fixed

where vmdk is the native VMware format, vdi is the native VirtualBox format, vhd is the native Microsoft format, and raw describes a file that looks like a raw disk. A raw disk is always in fixed format so that option can be explicitly set or implicitly understood.

If the type is not specified, the default value is vmdk. If the option is not specified, the default value is fixed for type raw and sparse for types vmdk, vdi, and vhd.

Native and User-defined Properties   Properties are divided into two types, native and user defined. Native properties either export internal statistics or control vdiskadm behavior. In addition, native properties are either editable or read-only. User–defined properties are arbitrary strings that have no effect on vdiskadm behavior. You can use them to annotate virtual disks in a way that is meaningful in your environment. User–defined property names must contain a colon (:) character, to distinguish them from native properties.

Properties are associated only with the virtual disk and not with individual snapshots.

Every virtual disk has a set of native properties that export statistics about the virtual disk, as well as control various behaviors.

The following are the native properties for a virtual disk:

cdrom
    Boolean property that is true if the virtual disk is a CDROM.

removable
    Boolean property that is true if the virtual disk is a removable media.

readonly
    Boolean property that is true if the virtual disk is read-only. This property is read-only.

sectors

    Numeric property containing the number of disk sectors in the given virtual disk. This property is read-only.

name

    String property that is the name of the virtual disk. This property is read-only.

max-size

    Numeric property containing the maximum size of the virtual disk in bytes. This property is read-only.

effective-size

    Numeric property containing the effective size of the virtual disk, in bytes. The effective size includes the size of the data file and all snapshots. The effective size can exceed the maximum size. This property is read-only.

creation-time

    String property containing the date and time that the virtual disk was created. This property is read-only.

creation-time-epoch

    Numeric property describing the creation-time property in seconds since the epoch (seconds since 00:00:00 UTC, Jan. 1, 1970). This property is read-only.

modification-time

    String property containing the date and time of last modification to virtual disk. This property is read-only.

modification-time-epoch

    Numeric property describing the modification-time property in seconds since the epoch (seconds since 00:00:00 UTC, Jan. 1, 1970). This property is read-only.

description

    String property that contains the comment given when the virtual disk was created or cloned. This property is read-only.

type

    String property that contains the type of virtual disk: vmdk, vhd, vdi, or raw. This property is read-only.

sparse

    Boolean property that is true if the virtual disk is in sparse format. This property is read-only.

owner

    String property that contains the user name of the owner of the virtual disk. This property is editable.

Sub-commands   The vdiskadm subcommands and their arguments are described in the following subsections.

vdiskadm create   vdiskadm create -s *size* [-t *type*[:*opt*],[*opt*]]
                                [-c *comment*] *vdname*

Creates a new virtual disk of the specified size and at the location specified by *vdname*. If *vdname* includes a path to the virtual disk, the directories that follow from that path will be created during creation of the virtual disk. This subcommand has the options listed below.

-t *type*[:*opt*],[*opt*]]
   Specifies the type of virtual disk to be created. The default type is vmdk. For vmdk and vdi types the default option is sparse. For type raw the default option is fixed.

-c *comment*
   Comment that can be attached to virtual disk.

vdiskadm destroy   vdiskadm destroy [-r] *vdname*|*snapshot*

Destroys the specified virtual disk or snapshot. By default, the destroy operation fails if the specified virtual disk contains snapshots. This subcommand has the option listed below.

-r
   Recursively destroys the virtual disk, including all snapshots associated with the virtual disk.

vdiskadm snapshot   vdiskadm snapshot *vdname*@*snapname*

Creates a snapshot of the virtual disk with the specified *snapname*. This subcommand has no options.

vdiskadm rollback   vdiskadm rollback [-r] *snapshot*

Roll back the virtual disk to a previous snapshot. When a virtual disk is rolled back, all data that has changed since the snapshot is discarded, and the virtual disk reverts to the state at the time of the snapshot. By default, the command refuses to roll back to a snapshot other than the most recent one. In order to roll back further, all intermediate snapshots must be destroyed by specifying the -r option. This subcommand has the option listed below.

-r
   Recursively destroy any snapshots more recent than the one specified.

vdiskadm clone   vdiskadm [-c *comment*] *vdname*|*snapshot clone_vdname*

Creates a clone of the specified snapshot or virtual disk. The clone is created with the type and option and the size of the virtual disk being cloned. If *clone_vdname* includes a path the directories that flow from that path will be created during creation of the cloned virtual disk. By default, a merged clone image is created. This subcommand has the option listed below.

-c *comment*
   Comment that can be attached to cloned virtual disk.

vdiskadm move   vdiskadm move *vdname dir*

Moves a specified virtual disk into the specified directory. The virtual disk maintains the same name. The new directory must exist. This subcommand has no options.

vdiskadm rename   vdiskadm rename *vdname|snapshot vdname|snapshot*

Renames a virtual disk or snapshot. This subcommand has no options.

vdiskadm list   vdiskadm list [-fp]*vdname*

Lists a specified virtual disk and its snapshots. This subcommand has the options listed below.

-f
  Gives a list of all files associated with the virtual disk. This list includes the store file and the extents.

-p
  Lists the files in an easily parsable format, prefixing the files with a label of file:, snapshot:, or store.

vdiskadm verify   vdiskadm verify *vdname*

Returns an error if the virtual disk cannot be recognized or opened by Solaris. This subcommand has no options.

vdiskadm prop-get   vdiskadm prop-get [-l] -p *property vdname*

Returns the value of the property for the specified virtual disk. A property value of all displays all native and user-defined properties for the virtual disk. This subcommand has the options listed below.

-l
  Gives additional property information, such as the writeable status of property.

-p *property*
  Specifies the property being queried and displays the value of the property. For the property all, the name of the property, a colon, and a space are displayed before the value of the property.

vdiskadm prop-set   vdiskadm prop-set -p *property=value vdname*

Sets the value of the specified property for the specified virtual disk. *property* can be a native or a user-defined property, but must be writable. Can be used to change the value of a property added with the prop-add subcommand. This subcommand has the option listed below.

-p *property=value*
  Specifies the property being set.

vdiskadm prop-add   vdiskadm -p *property=value vdname*

Adds the user-defined property with the specified value to the specified virtual disk. Returns an error if the property already exists. The user-defined property name must contain a colon character (`:`). This subcommand has the option listed below.

-p *property=value*
Specifies the property being added.

vdiskadm prop-del   vdiskadm prop-del -p *property vdname*

Deletes a user–defined property from the specified virtual disk. This subcommand has the option listed below.

-p *property*
Specifies the property being deleted.

vdiskadm import   vdiskadm import [-fnpqm] [-x *type*] -d file|zvol|dsk \
                  [-t *type*[:*opt*]] *vdname*

Creates a new virtual disk using data from a file or block device. The file may be in vdi, vhd, vmdk, or raw format. A block device is always assumed to be in raw format. This subcommand has the following options.

-f
Returns a list of files that will be used in the import process.

-n
Show output from import without actually running the import.

-p
Displays files in an easily parsable format.

-q
Run in quiet mode giving no output.

-m
Move the imported file to virtual disk without copying the data.

-x *type*
Specifies the type of virtual disk data being imported. If vdiskadm is unable to detect the imported file type, -x must be specified.

-d file|zvol|dsk
File or block device containing data to be imported.

-t *type*[:*opt*]
Specifies the type of virtual disk to be created on import. The default type is vmdk. For vmdk, vdi, and vhd types the default *opt* is sparse. For type raw the default *opt* is fixed.

vdiskadm export   vdiskadm export -x *type*[:*opt*] -d file|zvol|dsk *vdname*

Exports data from a virtual disk to a file or block device. This subcommand has the following options.

-x *type*[:*opt*]
Specifies the type of virtual disk data being exported.

-d file|zvol|dsk
File or block device receiving data being exported.

vdiskadm convert   vdiskadm convert [-t *type*[:*opt*]] *vdname*

Converts a virtual disk into a different type virtual disk. This subcommand has the following option.

-t *type*[:*opt*]
Specifies the type of virtual disk to be created upon conversion. The default type is vmdk. For vmdk, vdi, and vhd types the default *opt* is sparse. For type raw the default *opt* is fixed.

vdiskadm translate   vdiskadm translate [-i *type*[:*opt*]] -I *input_file* \
-x *type*[:*opt*] -d *output_file*

Translate data from one virtual disk data type to another without creating a virtual disk. This subcommand has the following options.

-i *type*[:*opt*]
Specifies the input type of virtual disk data being translated. If vdiskadm is unable to detect the input file type, -i must be specified.

-I *input_file*
File or block device containing data being translated.

-x *type*[:*opt*]
Specifies the output type of virtual disk data being translated. For vmdk, vdi, and vhd types the default *opt* is sparse. For type raw the default *opt* is fixed.

-d *output_file*
File or block device receiving data being translated. *output_file* must not exist. The file will be created during translation.

vdiskadm help   vdiskadm help [*command*]

Displays a general or command-specific help message. This subcommand has only the command name optional argument.

Examples   EXAMPLE 1   Creating a vmdk Sparse File

The following command creates a virtual disk named disk1 of size 8 GB in the directory /guests/disks.

```
# vdiskadm create -s 8g -t vmdk:sparse /guests/disks/disk1
```

EXAMPLE 2 Creating a Snapshot

The following command creates a snapshot of the virtual disk located at
/guests/disks/disk1. The snapshot is named install.

```
# vdiskadm snapshot /guests/disks/disk1@install
```

EXAMPLE 3 Creating and Destroying Snapshots

The following commands create two snapshots, named install and bfu, of the virtual disk
located at /guests/disks/disk1. The third command destroys the newly created snapshot
install.

```
# vdiskadm snapshot /guests/disks/disk1@install
# vdiskadm snapshot /guests/disks/disk1@bfu
# vdiskadm destroy /guests/disks/disk1@install
```

EXAMPLE 4 Rolling Back a Virtual Disk

The following command reverts the contents of the virtual disk to the snapshot named
install, deleting all intermediate snapshots.

```
# vdiskadm rollback -r /guests/disks/disk1@install
```

EXAMPLE 5 Listing a Virtual Disk and Snapshots

The following command lists all of the images associated with the virtual disk
/guests/disks/disk1.

```
# vdiskadm list /guests/disks/disk1
disk1@install
disk1@bfu
disk1
```

EXAMPLE 6 Creating a Clone

The following command creates a new virtual disk that is a coalesced copy of the virtual disk
/guests/disks/disk1. The clone is created in the same format (that is, vmdk:sparse) as the
original virtual disk.

```
# vdiskadm clone /guests/disks/disk1 /guests/clone/clone_disk1
```

EXAMPLE 7 Adding a User-defined Property

The following command adds a user-defined property to the virtual disk and assigns it the
specified value. This property name was chosen to represent the source and requirements of
this virtual disk data using the required colon to delineate the fields.

```
# vdiskadm prop-add -p com.sun:required-nic=2 /guests/disks/disk1
```

EXAMPLE 8 Importing Existing vmdk Format File

The following command takes an existing vmdk format file and imports it to a virtual disk.

```
# vdiskadm import -d /downloads/appliance.vmdk /guests/import/disk1
```

EXAMPLE 9 Importing vmdk File and Converting to vhd

The following command takes an existing vmdk format file and, upon import, converts it to a vhd-type virtual disk.

```
# vdiskadm import -d /downloads/appliance.vmdk -t vhd \
/guests/import/disk1
```

EXAMPLE 10 Importing Data from zvol

The following command imports virtual disk data from a zvol and, upon import, converts it to a vmdk:fixed type virtual disk.

```
# vdiskadm import -d /dev/zvol/dsk/pool1/disk1 -t vmdk:fixed \
/guests/import/disk1
```

EXAMPLE 11 Exporting Data to Block Device

The following command takes an existing virtual disk and, upon export, converts it to a disk slice, of raw type.

```
# vdiskadm export -d /dev/dsk/c0t1d0s3 -x raw /guests/disks/disk1
```

EXAMPLE 12 Converting Virtual Disk Type

The following command takes an existing virtual disk and converts it (in place) to a different format type.

```
# vdiskadm convert -t vdi:fixed /guests/disks/disk1
```

EXAMPLE 13 Translating Data from One Type to Another

The following command translates data from a virtual disk format file to raw data written to a zvol without creating a virtual disk.

```
# vdiskadm translate -I /downloads/appliance.vmdk -x raw \
-d /dev/zvol/dsk/pool1/disk1
```

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/storage/vdiskadm
Interface Stability	Uncommitted

See Also attributes(5)

Name   virt-convert – convert virtual machines between formats

Synopsis   virt-convert [*option*]... *input.vmx* | *input.ovf* | *input-dir*
        [*output.xml* | *output-dir*]

Description   The virt-convert program is a command line tool for converting virtual machines (VMs) from one format to another. It accepts either a VM definition file (such as VMware vmx format) or a directory containing a VM. By default, a new VM definition file, and converted disk images, will be placed in a new output directory.

If an output directory is specified, it will be created if necessary, and the output VM definition placed within the new directory, along with any disk images, as needed.

If an output VM definition file is specified, it will be created alongside any disks in the same directory.

Options   Any of the following options can be omitted, in which case virt-convert will use defaults when required. An input VM definition or containing directory must be provided. By default, an output directory is generated based upon the name of the VM. The default input format is VMware vmx, and the default output format is a libvirt "image" XML definition.

-a, --arch=*arch*
    Architecture of the virtual machine (i686, x86_64, ppc). Defaults to that of the host machine.

-D, --disk-format=*format*
    Output disk format, or none if no conversion should be performed. *format* is one of:

    none
        No disks are converted or copied.

    vmdk
        VMWare VMDK format

    raw
        raw file

    vdisk
        vdisk format (see vdiskadm(1M))

-d, --debug
    Display debugging information.

-h, --help
    Display the help message and exit.

-i, --input-format *format*
    Input format. Currently, vmx and ovf are supported.

--noacpi
    Override the OS type and variant to disable the ACPI setting for fully virtualized guest.

--noapic
Override the OS type and variant to disable the APIC setting for fully virtualized guest.

-o, --output-format *format*
Output format. Currently, the supported output formats are `virt-instance` and `virt-image`. `virt-instance` is the recommended format for Solaris.

--os-type=*os_type*
Optimize the guest configuration for a type of operating system. This will attempt to pick the most suitable ACPI and APIC settings, optimally supported mouse drivers, and generally accommodate other operating system quirks.

--os-variant=*os_variant*
Further optimize the guest configuration for a specific operating system variant. This parameter is optional.

-p, --paravirt
Create a paravirtualized guest image. Convert machine to a paravirtualized Xen-based image.

-q, --quiet
Avoid verbose output.

-v, --hvm
Create a fully virtualized guest image. Convert machine to a hvm/qemu–based image (this is the default if --paravirt is not specified).

Examples   EXAMPLE 1   Converting a VMware VMX appliance

The following sequence of commands converts a VMware VMX appliance and imports it into Solaris xVM.

```
# virt-convert -o virt-instance /guests/vmx-appliance/ \
/guests/xvm-appliance/
# virsh define --relative-path=/guests/xvm-appliance/ \
\guests/xvm-appliance/appliance.xml
```

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/xvm/header-xvm
Interface Stability	Volatile

See Also   vdiskadm(1M), attributes(5)

Caveats Not all conversions will result in a working guest installation. If the source OS image is configured to use SCSI disks, the use of IDE disks may cause the OS boot to fail. Some images may be configured to use the VMware drivers such as vlance. In the vlance case and in general, device emulation support may not be sufficient for all OS installations.

Name   virtinfo – virtualization domain information

Synopsis   `virtinfo [ -acdpstu ]`

Description   The `virtinfo` utility provides virtualization information returned by `libv12n(3LIB)` about the current domain. When options are specified, symbols that represent one or more virtualization domain characteristics are written to standard output. If no options are specified, `virtinfo` shows only the virtualization domain type.

Options   The `virtinfo` command supports the following options:

-a   Shows all information that is currently available from the system.

-c   Shows the network node name of the control domain. This name is identical to the string shown by running the `uname -n` command on the control domain.

-d   Shows the domain name for this virtual domain.

-p   Shows information in a parseable format.

        The parseable output for Logical Domains (LDoms) has the following format:

```
VERSION 1.0
DOMAINROLE|impl=LDoms|control={true|false}|
    io={true|false}|service={true|false}|
    root={true|false}
DOMAINNAME|name=domain-name
DOMAINUUID|uuid=uuid
DOMAINCONTROL|name=control-domain-nodename
DOMAINCHASSIS|serialno=serial-no
```

-s   Shows the platform serial number.

-t   Shows the domain type.

        The domain type for Logical Domains is a string of one or more of the following blank-separated values:

        LDoms   LDoms implementation

        control   Control domain

        guest   Guest domain

        I/O   I/O domain

        service   Service domain

        root   Root I/O domain

        Note that the `control` and `guest` values are mutually exclusive.

-u   Shows the universally unique identifier (UUID) of the domain. See the libuuid(3LIB)
      man page.

Exit Status The following exit values are returned:

0   Successful completion.

>0   An error occurred.

Examples **EXAMPLE 1** Viewing Default Information

The following example shows the default information about the domain:

```
$ virtinfo
Domain role: LDoms control I/O service root
```

```
The current domain is the control domain, which is also an
I/O domain, the service domain and a root I/O domain.
```

EXAMPLE 2 Viewing All Information

The following example shows all available information about the domain:

```
$ virtinfo -a
Domain role: LDoms control I/O service root
Domain name: primary
Domain UUID: 8e0d6ec5-cd55-e57f-ae9f-b4cc050999a4
Control domain: san-t2k-6
Chassis serial#: 0704RB0280
```

EXAMPLE 3 Viewing All Information In a Parsable Format

The following example shows all available information about the domain in a parsable format:

```
$ virtinfo -ap
VERSION 1.0
DOMAINROLE|impl=LDoms|control=true|io=true|service=true|root=true
DOMAINNAME|name=primary
DOMAINUUID|uuid=8e0d6ec5-cd55-e57f-ae9f-b4cc050999a4
DOMAINCONTROL|name=san-t2k-6
DOMAINCHASSIS|serialno=0704RB0280
```

Name vmstat – report virtual memory statistics

Synopsis vmstat [-ipqsS] [-T u | d] [*disks*] [*interval* [*count*]]

Description vmstat reports virtual memory statistics regarding kernel thread, virtual memory, disk, trap, and CPU activity.

On MP (multi-processor) systems, vmstat averages the number of CPUs into the output. For per-processor statistics, see mpstat(1M).

vmstat only supports statistics for certain devices. For more general system statistics, use sar(1), iostat(1M), or sar(1M).

Without options, vmstat displays a one-line summary of the virtual memory activity since the system was booted.

During execution of the kernel status command, the state of the system can change. If relevant, a state change message is included in the vmstat output, in one of the following forms:

```
<<device added: sd0>>
<<device removed: sd0>>
<<processors added: 1, 3>>
<<processors removed: 1, 3>>
```

See *Oracle Solaris Administration: Common Tasks* for device naming conventions for disks.

Options The following options are supported:

-i Report the number of interrupts per device. *count* and *interval* does not apply to the -i option.

-p Report paging activity in details. This option will display the following, respectively:

    epi   Executable page-ins.

    epo   Executable page-outs.

    epf   Executable page-frees.

    api   Anonymous page-ins.

    apo   Anonymous page-outs.

    apf   Anonymous page-frees.

    fpi   File system page-ins.

    fpo   File system page-outs.

    fpf   File system page-frees.

When executed in a zone and if the pools facility is active, all of the above only report actitivity on the processors in the processor set of the zone's pool.

-q   Suppress messages related to state changes.

-s   Display the total number of various system events since boot. *count* and *interval* does not apply to the -s option.

-S   Report on swapping rather than paging activity. This option will change two fields in vmstat's "paging" display: rather than the "re" and "mf" fields, vmstat will report "si" (swap-ins) and "so" (swap-outs).

-T u | d   Specify u for a printed representation of the internal representation of time. See time(2). Specify d for standard date format. See date(1).

Operands The following operands are supported:

count   Specifies the number of times that the statistics are repeated. *count* does not apply to the -i and -s options.

disks   Specifies which disks are to be given priority in the output (only four disks fit on a line). Common disk names are id, sd, xd, or xy, followed by a number (for example, sd2, xd0, and so forth).

interval   Specifies the last number of seconds over which vmstat summarizes activity. This number of seconds repeats forever. *interval* does not apply to the -i and -s options.

Examples **EXAMPLE 1** Using vmstat

The following command displays a summary of what the system is doing every five seconds.

```
example% vmstat 5
```

```
kthr    memory           page            disk         faults      cpu
r b w swap  free re mf pi p fr de sr s0 s1 s2 s3  in  sy  cs us sy id
0 0 0 11456 4120 1  41 19 1  3  0  2  0  4  0  0  48 112 130  4 14 82

The fields of vmstat's display are

EXAMPLE 1 Using vmstat   *(Continued)*

kthr   Report the number of kernel threads in each of the three following states:

        r   the number of kernel threads in run queue

        b   the number of blocked kernel threads that are waiting for resources I/O, paging, and so forth

        w   the number of swapped out lightweight processes (LWPs) that are waiting for processing resources to finish.

memory   Report on usage of virtual and real memory.

        swap   available swap space (Kbytes)

        free   size of the free list (Kbytes)

page   Report information about page faults and paging activity. The information on each of the following activities is given in units per second.

        re   page reclaims — but see the -S option for how this field is modified.

        mf   minor faults — but see the -S option for how this field is modified.

        pi   kilobytes paged in

        po   kilobytes paged out

        fr   kilobytes freed

        de   anticipated short-term memory shortfall (Kbytes)

        sr   pages scanned by clock algorithm

When executed in a zone and if the pools facility is active, all of the above (except for "de") only report activity on the processors in the processor set of the zone's pool.

disk   Report the number of disk operations per second. There are slots for up to four disks, labeled with a single letter and number. The letter indicates the type of disk (s = SCSI, i = IPI, and so forth); the number is the logical unit number.

faults   Report the trap/interrupt rates (per second).

        in   interrupts

        sy   system calls

        cs   CPU context switches

When executed in a zone and if the pools facility is active, all of the above only report actitivity on the processors in the processor set of the zone's pool.

EXAMPLE 1 Using vmstat   *(Continued)*

cpu   Give a breakdown of percentage usage of CPU time. On MP systems, this is an
               average across all processors.

    us   user time

    sy   system time

    id   idle time

               When executed in a zone and if the pools facility is active, all of the above only
               report actitivity on the processors in the processor set of the zone's pool.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	See below.

Invocation is evolving. Human readable output is unstable.

See Also   date(1), sar(1), iostat(1M), mpstat(1M), sar(1M), time(2), attributes(5)

Notes   The sum of CPU utilization might vary slightly from 100 because of rounding errors in the
production of a percentage figure.

Name   vntsd – virtual network terminal server daemon for Logical Domains

Synopsis   `/usr/lib/ldoms/vntsd`

Description   The `vntsd` daemon is a server that supports connections to the Logical Domains (LDoms) console by using telnet(1). When a telnet session starts, `vntsd` sends telnet options to the client indicating a willingness to remotely echo characters and to suppress go ahead.

Consoles are organized into groups by the LDoms Manager. Each console group is assigned a unique group name and TCP port number. `vntsd` uses the group's port number to export access to the consoles within that group. To establish a connection with a console or console group, a user starts a telnet(1) session with the corresponding group's port number. Depending on the number of consoles within that group, `vntsd` does one of two things:

- If there is only one console in the group, `vntsd` connects a session to that LDoms console.
- If there are multiple consoles in the group, `vntsd` prompts the user to select the console to which they would like to connect, as shown in "Multiple-Console Options," below.

For each console, `vntsd` provides write access only to the first user connecting to the console. Subsequent users connecting to the console are allowed only to read from the console and wait for write access. When the first user disconnects, write privileges are transferred to the next user waiting in the queue. If a user who does not have write privileges attempts to write to a console, the `vntsd` displays the following message:

```
You do not have write access
```

A user who has no write access can acquire write access forcibly by using the ~w special console command, described in "Special Console Commands," below.

`vntsd` can be invoked only with superuser privileges or by someone in the Primary Administrator role.

Options   The options for `vntsd` are divided into multiple-console options and console commands.

Multiple-Console Options   The options listed below are supported when there are multiple LDoms consoles in a group. The syntax for the use of these options is:

<hostname>-vnts-*<group-name>*: *<option>*

For example:

```
myhost-vnts-salesgroup: h
```

The h option invokes help, as described below.

h
   Display the following help text:

```
h -- this help
l -- list of consoles
q -- quit
c{id}, n{name} -- connect to console of domain {id} or domain name
```

l
List all consoles in the group. For example:

```
DOMAIN ID       DOMAIN NAME     DOMAIN STATE
0               ldg1            online
1               ldg2            connected
...             ...             ...
```

The two domain states and their meanings are:

online
No one is connected to the console.

connected
At least one user is already connected to the console.

q
Disconnect from vntsd.

c*{id}*, n*{name}*
Connect to specified console. Upon connection, the following message is displayed:

```
Connecting to console <domain-name> in group <group-name>
Press ~? for control options ....
```

Special Console Commands A tilde (~) appearing as the first character of a line is an escape signal that directs vntsd to perform a special console command. The tilde-tilde (~~) sequence outputs a tilde. In conjunction with the initial tilde, vntsd accepts the following special console commands:

~.
Disconnect from the console or console group.

~w
Force write access to the console.

~p
Disconnect from this console, and connect to the console that precedes this console in the list of consoles.

~n
Disconnect from this console, and connect to the console that follows this console in the list of consoles.

~#
Send break.

~^B
Send alternate break.

~?
Display vntsd help, as follows:

```
~# - Send break
~^B - Send alternate break
~. - Exit from this console
~w - Force write access
~n - Console next
~p - Console previous
~? - Help
```

Files /usr/lib/ldoms/vntsd
Binary executable vntsd file.

/usr/lib/ldoms/vntsd.xml
Service management facility (smf(5)) manifest file for vntsd.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/ldoms
Interface Stability	Committed

See Also telnet(1), svccfg(1M), usermod(1M), auth_attr(4), attributes(5), smf(5)

Notes The vntsd is managed by the service management facility, smf(5), under the service identifier:

svc:/ldoms/vntsd

You can change the following properties using the svccfg(1M) command:

vntsd/vcc_device
Set an instance of the virtual console concentrator (vcc) driver to which vntsd is
connected.

vntsd/listen_addr
Set the IP address to which vntsd listens, using the following syntax:

vntsd/listen_addr:"*xxx.xxx.xxx.xxx*"

...where *xxx.xxx.xxx.xxx* is a valid IP address. The default value of this property is to listen
on IP address 127.0.0.1. Users can connect to a guest console over a network if the value is
set to the IP address of the control domain.

Note – Enabling network access to a console has security implications. Any user can connect
to a console and for this reason it is disabled by default.

vntsd/timeout_minutes
Set timeout in minutes. vntsd will timeout (close) telnet connection if there is no activity
(input or output) on the console. The default value is 0, which disables timeout.

vntsd/authorization

Enable the authorization checking of users and roles for the domain console or consoles that are being accessed. The default value of this property is false to maintain backward compatibility. To enable authorization checking, use the svccfg(1M) command to set the property value to true. While this option is enabled, vntsd listens and accepts connections on localhost. If the listen_addr property specifies an alternate IP address when this option is enabled, vntsd ignores the alternate IP address and continues to listen on localhost. Connections that are initiated from other hosts will also fail. Authorizations are available to access all consoles or console groups, or to access specific consoles or console groups. When the vntsd service is enabled, the following authorization is added to the authorization description database, auth_attr(4):

solaris.vntsd.consoles:::Access All LDoms Guest Consoles::

Add any fine-grained authorizations based on the name of the console group. For example, if the name of the console group to be authorized is ldg1, add the following entry to the auth_attr(4) file:

solaris.vntsd.console-ldg1:::Access Specific LDoms Guest Console::

By default, the authorization to access all consoles is assigned to the root user or role. The Primary Administrator (superuser) can use the usermod(1M) command to assign the required authorization or authorizations to other users or roles.

The following example gives user user1 the authorization to access all domain consoles:

 # usermod -A "solaris.vntsd.consoles" user1

The following example gives user user1 the authorization to access the console group named ldg1:

 # usermod -A "solaris.vntsd.console-ldg1" user1

Name volcopy – make an image copy of file system

Synopsis volcopy [-F *FSType*] [-V] [*generic_options*]
         [-o *FSType-specific_options*] *operands*

Description volcopy makes a literal copy of the file system. This command may not be supported for all *FSTypes*.

Options The following options are supported:

-F *FSType*   Specify the *FSType* on which to operate. The *FSType* should either be specified here or be determinable from /etc/vfstab by matching the *operands* with an entry in the table. Otherwise, the default file system type specified in /etc/default/fs will be used.

-V   Echo the complete command line, but do not execute the command. The command line is generated by using the options and arguments provided by the user and adding to them information derived from /etc/vfstab. This option should be used to verify and validate the command line.

generic_options   Options that are commonly supported by most *FSType*-specific command modules. The following options are available:

                     -a   Require the operator to respond "yes" or "no" instead of simply waiting ten seconds before the copy is made.

                     -s   (Default) Invoke the DEL if wrong verification sequence.

-o *FSType-specific_options*   Specify *FSType*-specific options in a comma separated (without spaces) list of suboptions and keyword-attribute pairs for interpretation by the *FSType*-specific module of the command.

Operands The following operands are supported:

operands   generally include the device and volume names and are file system specific. A detailed description of the *operands* can be found on the *FSType*-specific man pages of volcopy.

Exit Status The following exit values are returned:

0   Successful file system copy

1   An error has occurred.

Files /etc/vfstab   list of default parameters for each file system

/etc/default/fs   default local file system type. Default values can be set for the following flags in /etc/default/fs. For example: LOCAL=ufs.

LOCAL: The default partition for a command if no *FSType* is specified.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also labelit(1M), vfstab(4), attributes(5) Manual pages for the *FSType*-specific modules of volcopy.

Name volcopy_ufs – make an image copy of a ufs file system

Synopsis volcopy [-F ufs] [*generic_options*] *fsname srcdevice volname1 destdevice volname2*

Description volcopy makes a literal copy of the ufs file system using a blocksize matched to the device.

Options The following option is supported:

generic_options   options supported by the generic volcopy command. See volcopy(1M).

Operands The following operands are supported:

fsname	represents the mount point (for example, root, u1, etc.) of the file system being copied.
srcdevice or *destdevice*	the disk partition specified using the raw device (for example, /dev/rdsk/cld0s8, /dev/rdsk/cld1s8, etc.).
srcdevice and *volname1*	the device and physical volume from which the copy of the file system is being extracted.
destdevice and *volname2*	the target device and physical volume.

fsname and *volname* are limited to six or fewer characters and recorded in the superblock. *volname* may be '−' to use the existing volume name.

Exit Status The following exit values are returned:

0   Successful file system copy.

non-zero   An error has occurred.

Files /var/adm/filesave.log   a record of file systems/volumes copied

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also cpio(1), dd(1M), labelit(1M), volcopy(1M), attributes(5), ufs(7FS)

Notes volcopy does not support copying to tape devices. Use dd(1M) for copying to and from tape devices.

Name vrrpadm – VRRP administration tool

Synopsis vrrpadm create-router -V *vrid* -l *link* -A *inet* | *inet6*
        [-p *priority*] [-i *adv_interval*] [-o *flags*] *router_name*

vrrpadm delete-router *router_name*

vrrpadm disable-router *router_name*

vrrpadm enable-router *router_name*

vrrpadm modify-router [-p *priority*] [-i *adv_interval*]
        [-o *flags*] [*router_name*]

vrrpadm show-router [-P | -x] [-p] [-o *field*[,...]] [*router_name*]

Description The vrrpadm command is used to administer the VRRP (Virtual Router Redundancy Protocol) service in a system.

VRRP specifies an election protocol that dynamically assigns responsibility for a virtual router to one of the VRRP routers within a LAN. At a given moment, only one VRRP router controls the IPv4 or IPv6 virtual address(es) associated with a virtual router (known as the *master*), and forwards packets sent to these IP addresses. The election process provides dynamic failover of the forwarding responsibility should the master become unavailable.

Each vrrpadm subcommand operates on a VRRP router, which is identified by a name given by the administrator. VRRP routers with the same VRID and address family within a LAN comprise a virtual router, which protects a set of virtual IP addresses.

A system can have multiple VRRP routers; each belongs to a different virtual router.

Sub-commands The following subcommands are supported. Note that all subcommands but show-router require the solaris.network.vrrp authorization. The show-router subcommand does not require special authorizations.

vrrpadm create-router -V *vrid* -l *link* -A *inet* | *inet6* [-p *priority*] [-i *adv_interval*] [-o *flags*] *router_name*
  Create a VRRP router with a specified configuration.

  -A *inet* | *inet6*, --address_family=*inet* | *inet6*
    Address family. Either IPv4 or IPv6.

  -i *adv_interval*, --adv_interval=*adv_interval*
    The advertisement interval in milliseconds. Default is 1000 (one second). The valid interval range is 10-40950.

  -l *link*, --link=*link*
    The data link on which the VRRP router is configured. This determines the LAN this VRRP router is running in. The data-link can be a physical link, a VLAN, or an aggregation.

-o *flags*, --flags=*flags*
> The preempt and accept modes, delimited by a comma. Values can be:
>
> - `preempt`
> - `un_preempt`
> - `accept`
> - `noaccept`
>
> By default both modes are set to true.
>
> The `preempt` mode controls whether an enabled higher priority backup router preempts a lower priority master router. If `preempt` mode is true, then the preemption is allowed; otherwise, preemption is prohibited. Note that the `preempt` mode must be true if the VRRP router is the owner of the virtual IP addresses.
>
> The `accept` mode controls the local packet acceptance of the virtual IP addresses. If `accept` mode is true, the master must accept packets sent to the virtual IP addresses. If `accept` mode is false, the master does not accept those packets, although it does respond to ARP requests or ND Solicitations and Advertisement for those non-accepted virtual IP addresses. It also must forward packets for the router specified in this subcommand. Note that `accept` mode must be true if the VRRP router is the owner of the virtual IP addresses. An example of syntax for this option:
>
> `-o preempt,no_accept`

-p *priority*, --priority=*priority*
> The priority of the specified VRRP router used in master selection. The higher the value, the greater the possibility the router is selected as the master.
>
> The default value is 255, which indicates the specified VRRP router is the IP Address Owner and owns all the virtual IP addresses. An IP Address Owner will respond to the packets addressed to one of the virtual IP addresses for ICMP pings, TCP connections, and so forth.
>
> The range 1-254 is available for VRRP routers backing up a virtual router. Master selection is weighted toward the VRRP router with the higher priority.

-V *vrid*, --VRID=*vrid*
> The virtual router identifier (VRID). Together with the address family, it identifies a virtual router within a LAN.

router_name
> The name of a VRRP router. This name is used to identify a VRRP router in other `vrrpadm` subcommands.
>
> The maximum length of a valid router name is 31 characters. Legal characters are alphanumeric (a-z, A-Z, 0-9) and the underscore ('_').

`vrrpadm delete-router` *router_name*
> Delete the VRRP router identified by *router_name*.

vrrpadm disable-router *router_name*
> Disable the virtual router identified by *router_name*. Once the router is disabled, it will stop participating in the master selection process in the virtual router.

vrrpadm enable-router *router_name*
> Re-enable the virtual router identified by *router_name* that was disabled. The router will resume participating in the master selection process in the virtual router.

vrrpadm modify-router [-p *priority*] [-i *adv_interval*] [-o *flags*] [*router_name*]
> Modify the configuration of the VRRP router identified by *router_name*. Only the priority, the advertisement interval, the preempt mode, and the accept mode can be modified.

-p *priority*, --priority=*priority*	The new priority of this VRRP router.
-i *adv_interval*, --adv_interval=*adv_interval*	The new advertisement interval.
-o *flags*, --flags=*flags*	The new preempt and accept modes. Either one or both can be specified. If both are specified, they are delimited by a comma. For example:
	`-o preempt,no_accept`

vrrpadm show-router [-P | -x] [-p] [-o *field*[,...]] [*router_name*]
> Display the information for the VRRP router identified by *router_name*. If no *router_name* is specified, display information for all the VRRP routers on the system.

By default (with no options), the following fields are displayed:

NAME
> The name of the VRRP router.

VRID
> The VRID of the VRRP router.

LINK
> The data link on which the VRRP router is created.

AF
> he address family of the VRRP router, either IPv4 or IPv6.

PRIO
> The priority of this VRRP router used in master selection.

ADV_INTV
> The advertisement interval, in milliseconds.

STATE
> The current state of the VRRP router, INIT (Initialize), BACK (Backup), or MAST (Master).

MODE
> A set of flags associated with the VRRP router. Possible values are:

e   The router has been enabled.

p   Preempt mode is true.

a   Accept mode is true.

o   Virtual address owner.

VNIC
  The VRRP VNIC created for this VRRP router.

  Note that the name of the VNIC can change over time unless the router is enabled.

The show-router subcommand has the following options:

-x, --extended
  Display additional information of the given VRRP router:

  PRIMARY_IP
    The primary IP address selected by the VRRP router.

  VIRTUAL_IPS
    The virtual IP addresses configured on the VRRP router.

  PRV_STAT
    The previous state of the VRRP router.

  STAT_LAST
    Time since the last state transition.

-P, --peer
  Display information for the backup VRRP router. This option is meaningful only when
  the VRRP router is in the backup state.

  The following fields are displayed:

  NAME
    The name of the VRRP router.

  PEER
    The primary IP address of the peer VRRP router.

  P_PRIO
    The priority of the peer VRRP router contained in the advertisement received from
    the peer.

  P_INTV
    The advertisement interval (in milliseconds) contained in advertisements received
    from the peer.

  P_ADV_LAST
    Time since last received advertisement from the peer.

MASTER_DOWN_INT
> Time interval (in milliseconds) after which to declare Master down.

-p, --parseable
> Display the VRRP router information in the machine parseable format.

-o *field*[,...], --output=*field*
> A case-insensitive, comma-separated list of output fields to display. The field name must
> be one of the fields listed above, or the special value all to display all fields. By default
> (without -o), vrrpadm show displays all fields.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/routing/vrrp
Interface Stability	Committed

See Also dladm(1M), vrrpd(1M), attributes(5)

Name vrrpd – VRRP daemon

Synopsis `/usr/lib/vrrpd`

`svc:/network/vrrp:default`

Description vrrpd is the system daemon program that handles the administrative events for the VRRP routers. It is controlled through the service management facility (SMF) service instance:

`svc:/network/vrrp:default`

The daemon should not be invoked directly. It does not constitute an administrative nor a programming interface. The administrative interface for managing VRRP routers is vrrpadm(1M).

Options The daemon has no options.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/routing/vrrp
Interface Stability	Private

See Also vrrpadm(1M), attributes(5)

Name   vscanadm – vscan service configuration utility

Synopsis   vscanadm set -p *property*=*value* [-p *property*=*value*]...

vscanadm get [-p *property*]...

vscanadm import -p *property filename*

vscanadm export -p *property filename*

vscanadm validate -p *property filename*

vscanadm add-engine [-p *property*=*value*]... *engine_id*

vscanadm remove-engine *engine_id*

vscanadm set-engine -p*property*=*value* [-p *property*=*value*]... *engine_id*

vscanadm get-engine [-p *property*=*value*]... [*engine_id*]

vscanadm show

vscanadm stats [-z]

Description   The vscanadm command sets and displays properties of the vscan service, zpool(1M), and provides scan statistics.

File system exemption from virus scanning may be configured per file system using the appropriate file system administrative command, for example zfs(1M).

Scan engines are third-party applications on external hosts that perform the actual virus scanning operation on files. Multiple scan engines can be configured for use by the vscan service. A minimum of two scan engines is recommended. File scan requests are distributed among the configured scan engines to achieve load balancing. A scan engine is identified by its *engine_id*. The *engine_id* is a user defined string of up to 64 bytes.

The vscan service properties are divided into two categories: scan engine properties, which are specific to a scan engine definition, and general properties, which apply to the service and are not scan engine-specific.

Subcommands   vscanadm recognizes the following subcommands:

vscanadm set -p *property*=*value* [-p *property*=*value*]...
Sets the values of vscan service general properties.

  -p *property*=*value*   Specifies a property value

vscanadm get [-p *property*]...
Displays the values of vscan service general properties. If no properties are specified, all vscan service general properties are displayed.

  -p *property*   Specifies a property value

The following properties are available for the vscanadm set and vscanadm get subcommands:

max-size The maximum size of files that should be virus scanned. Files exceeding *max-size* are not scanned. The *max-size-action* property determines whether access should be allowed or denied to files that exceed *max-size*.

The value of *max-size* is a string with a numeric (decimal) component and an optional letter component that specifies a unit size, in the format "N[.N][KMGTP][B]".

Following the numeric component, the optional unit can be specified as either one or two characters. For example, either "K" or "KB" can be used to specify kilobytes. Unit specifiers are not case-sensitive, and must follow the numeric value immediately with no intervening whitespace.

With either no unit specifier, or a unit specifier of only "B", the numeric value is assumed to be in bytes. The default value is 1GB.

Note that while the vscan service defines a maximum file size for scanning, scan engines also typically define their own maximum file size setting. It is recommended that *max-size* be set to a value less than or equal to the maximum file size for the scan engine(s).

max-size-action Specifies whether access will be allowed or denied to files larger than *max-size*. Files larger than *max-size* are not virus scanned. Valid values are:

allow allow access to files larger than *max-size* (no virus scan). This is the default value.

deny deny access to files larger than *max-size* (no virus scan)

vscanadm import -p *property filename*
Imports the property value from the specified file. The file must contain a single line specifying the value of a single property.

vscanadm export -p *property filename*
Exports the property value to the specified file. The file must contain a single line specifying the value of a single property.

vscanadm validate -p *property filename*
Validates the property value in the specified file. The file must contain a single line specifying the value of a single property.

The following properties are available for the vscanadm import, vscanadm export, and vscanadm validate subcommands:

types A comma-separated list of file type extension matching rules. This list defines which types of files are scanned and which should be excluded during virus

scanning. Each rule comprises the rule indicator [+|-], followed by a file type *expresssion* against which a file's type extension is compared. The file type *expresssion* is case insensitive and may include the "*" and "?" wildcards. There should be no whitespace between the rule indicator and the file type *expresssion*. If a comma is included within the file type expression, it must be escaped using a "\" (backslash). A file type extension does not include its preceding dot.

The rule indicator is a single character and can be one of:

```
+ include file type in virus scanning
- exclude file type from virus scanning
```

When a file is being evaluated as a candidate for virus scanning, its file type will be compared with the rules defined in types. The first rule matched will be applied. If no match is found, the file will be virus scanned. The total length of the types string can not exceed 4096 bytes. The default content of the types list is "+*".

vscanadm add-engine [-p *property*=*value*]... *engine_id*
:   Adds a new scan engine identified by *engine_id*. The default values are used for any scan engine properties that are not specified. The hostname defaults to the *engine_id*.

    -p *property*=*value*   Specifies a property value

vscanadm remove-engine *engine_id*
:   Remove scan engine identified by *engine_id*, removing all of its configuration property values.

vscanadm set-engine -p*property*=*value* [-p *property*=*value*]... *engine_id*
:   Creates or updates the configuration property values for the scan engine identified by *engine_id*.

    -p *property*=*value*   Specifies a property value

vscanadm get-engine [-p *property*=*value*]... [*engine_id*]
:   Displays the values of the specified scan engine properties for the scan engine identified by *engine_id*. If no *engine_id* is specified, this subcommand displays the specified scan engine property values for all configured scan engines. If no properties are specified, this subcommand displays all vscan service scan engine properties.

    -p *property*=*value*   Specifies a property value

The following properties are available for the vscanadm add-engine, vscanadm remove-engine, vscanadm set-engine, and vscanadm get-engine subcommands:

enable
:   Specifies whether the scan engine is enabled or disabled. Valid values are "on" (enabled) and "off" (disabled). The default is "on" (enabled). A scan engine cannot be enabled if its host property is invalid.

host
:   Hostname or IPv4 format IP address of the scan engine.

port   ICAP port number of the scan engine. The numeric value ranges from 0
                     to 65535. The default ICAP port is 1344.

max-connection   The maximum number of concurrent connections that may be
                     established with a scan engine. The numeric value ranges from 1 to 512.
                     This property defaults to 8.

vscanadm show   Displays the values of all vscan service general properties and scan
                     engine properties.

vscanadm stats [-z] Displays or resets the following vscan service statistics:

                     ■ number of files scanned
                     ■ number of infected files
                     ■ number of failed scan requests
                     ■ scan errors (including a per scan engine error count)

                     -z   Resets vscan service statistics counters to zero

Examples   **EXAMPLE 1**   Setting the Maximum Size Limit

To set the maximum size limit for files to be virus scanned to 128 megabytes, enter

```
# vscanadm set -p max-size=128M
```

EXAMPLE 2   Allowing Access to Files

To allow access to files exceeding the maximum file size, enter

```
# vscanadm set -p max-size-action=allow
```

EXAMPLE 3   Setting File Types

To set the types so that only files of type "odt", "exe" and "jpg" are virus scanned, enter

```
# vscanadm set -p types=+odt,+exe,+jpg,-*
```

To set the types so that all file types except "doc" are virus scanned, enter

```
# vscanadm set -p types=-doc,+*
```

EXAMPLE 4   Displaying the File Types List

To display the file types list, enter

```
# vscanadm get -p types
```

EXAMPLE 5   Adding the Scan Engine

To add the scan engine "my_eng" using the default values, enter

```
# vscanadm add-engine my_eng
```

EXAMPLE 6   Disabling the Scan Engine

To disable the scan engine "my_eng", enter

vscanadm set-engine -p enable=off my_eng

EXAMPLE 7   Displaying Scan Engine Properties

To display the properties of the scan engine "my_eng", enter

vscanadm get-engine my_eng

EXAMPLE 8   Removing Scan Engine

To remove the scan engine "my_eng", enter

vscanadm remove-engine my_eng

EXAMPLE 9   Displaying Vscan Service General and Scan Engine Properties

To Display all vscan service general properties and scan engine properties, enter

vscanadm show

Exit Status   The following exit values are returned:

0   Successful completion.

non-zero   An error occurred.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/storage/virus-scan
Interface Stability	Uncommitted
Utility output format	Not-An-Interface

See Also   vscand(1M), zfs(1M), attributes(5), smf(5)

Notes   All users are permitted to use vscanadm to view vscan properties and statistics. To set property values or reset statistics, the following authorizations are required:

solaris.smf.value.vscan
    change the property values or reset statistics

solaris.manage.vscan
    refresh the service to apply property value changes

To add or remove properties (add-engine, remove-engine) the following authorizations are required:

solaris.smf.modify.application   add or remove property group

solaris.manage.vscan   refresh the service to apply property value changes

All of these authorizations are included in the "VSCAN Management" profile.

Name   vscand – vscan service daemon

Synopsis   /usr/lib/vscan/vscand

Description   vscand is the daemon that handles virus scan requests from file systems on file open and close operations. A file system may support enabling and disabling of virus scanning on a per dataset basis, using that file system's administrative command, for example zfs(1M).

If the file state or scan policy (see vscanadm(1M) requires that a file be scanned, vscand communicates with external third-party virus scanners (scan engines) using the Internet Content Adaptation Protocol (ICAP, RFC 3507) to have the file scanned.

A file is submitted to a scan engine if it has been modified since it was last scanned, or if it has not been scanned with the latest scan engine configuration (Virus definitions). The file's modified attribute and scanstamp attribute are used to store this information. Once the file is scanned, the modified attribute is cleared and the scanstamp attribute is updated.

If the file is found to contain a virus, the virus is logged in syslogd(1M), an audit record is written, and the file is quarantined (by setting its quarantine attribute). Once a file is quarantined, attempts to read, execute or rename the file will be denied by the file system. The syslogd(1M) entry and the audit record specify the name of the infected file and the violations detected in the file. Each violation is specified as "ID - threat description", where ID and threat description are defined in the X-Infection-Found-Header in ICAP RFC 3507; Extensions.

By default, vscand connects to scan engines on port 1344. The port and other service configuration parameters can be configured using vscanadm(1M).

The vscan service is disabled by default, and can be enabled using svcadm(1M).

Exit Status   The following exit values are returned:

0   Daemon started successfully.

non-zero   Daemon failed to start.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/storage/virus-scan
Interface Stability	Uncommitted

See Also   ps(1), svcs(1), logadm(1M), svcadm(1M), syslogd(1M), vscanadm(1M), zfs(1M), attributes(5), smf(5)

Notes If a file is accessed using a protocol which does not invoke the file system open and close operations, for example NFSv3, virus scanning is not initiated on the file.

File content is transferred to the scan engines as cleartext data.

Administrative actions for the vscan service, such as enabling, disabling, or requesting a restart, can be performed using svcadm(1M). The vscan service status can be queried using the svcs(1) command.

The vscan service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/system/filesystem/vscan
```

Name vtdaemon – switch function between text virtual consoles

Synopsis /usr/lib/vtdaemon

Description vtdaemon provides a secure switch function, by means of hotkeys, between different text virtual consoles. It runs with full privileges.

The service is managed using the action authorization solaris.smf.manage.vt which is included in the Device Security Rights Profile. The service is local only and has no inbound network ports. It is disabled in non-global zones or when the virtual console functionality is not available.

vtdaemon uses PAM for authentication.

Note that vtdaemon only locks and unlocks the text console. For graphical X sessions, it invokes the corresponding lock program (for example, xscreensaver), which deals with authentication and audit.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Private

See Also svcs(1), svcadm(1M), attributes(5), smf(5)

Notes The vtdaemon service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/vtdaemon:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

The vtdaemon service has the following SMF configuration properties:

hotkeys (boolean)
    Allows authorized users to dynamically enable or disable the VT switch by means of hotkeys. Its default value is TRUE (enabled).

secure (boolean)
    Allows authorized users to dynamically enable or disable the security of hotkeys. If disabled, the user can freely switch to any session without authentication. Its default value is TRUE (enabled).

Name wall – write to all users

Synopsis /usr/sbin/wall [-a] [-g *grpname*] [*filename*]

Description wall reads its standard input until an end-of-file. It then sends this message to all currently logged-in users preceded by:

Broadcast Message from . . .

If *filename* is given, then the message is read in from that file. Normally, pseudo-terminals that do not correspond to rlogin sessions are ignored. Thus, when using a window system, the message appears only on the console window. However, -a will send the message even to such pseudo-terminals.

It is used to warn all users, typically prior to shutting down the system.

The sender must be superuser to override any protections the users may have invoked See mesg(1).

wall runs setgid() to the group ID tty, in order to have write permissions on other user's terminals. See setuid(2).

wall will detect non-printable characters before sending them to the user's terminal. Control characters will appear as a " ^ " followed by the appropriate ASCII character; characters with the high-order bit set will appear in "meta" notation. For example, '\003' is displayed as '^C' and '\372' as 'M-z'.

Options The following options are supported:

-a   Broadcast message to the console and pseudo-terminals.

-g *grpname*   Broadcast to the users in a specified group only, per the group database (see group(4)).

Environment Variables If the LC_* variables (LC_CTYPE, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) are not set in the environment, the operational behavior of wall for each corresponding locale category is determined by the value of the LANG environment variable. See environ(5). If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables are set in the environment, the "C" (U.S. style) locale determines how wall behaves.

Files /dev/tty*

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also   mesg(1), write(1), setuid(2), attributes(5), environ(5)

Notes   wall displays "Cannot send to . . ." when the open on a user's tty file fails.

Name wanboot_keygen – create and display client and server keys for WAN booting

Synopsis /usr/lib/inet/wanboot/keygen -c -o net=*a.b.c.d* ,cid=*client_ID*,type=3des

/usr/lib/inet/wanboot/keygen -c -o net=*a.b.c.d* ,cid=*client_ID*,type=aes

/usr/lib/inet/wanboot/keygen -m

/usr/lib/inet/wanboot/keygen -c -o net=*a.b.c.d* ,cid=*client_ID*,type=sha1

/usr/lib/inet/wanboot/keygen -d -m

/usr/lib/inet/wanboot/keygen -c -o net=*a.b.c.d* ,cid=*client_ID*,type=*keytype*

Description The keygen utility has three purposes:

- Using the -c flag, to generate and store per-client 3DES/AES encryption keys, avoiding any DES weak keys.

- Using the -m flag, to generate and store a "master" HMAC SHA-1 key for WAN install, and to derive from the master key per-client HMAC SHA-1 hashing keys, in a manner described in RFC 3118, Appendix A.

- Using the -d flag along with either the -c or -m flag to indicate the key repository, to display a key of type specified by *keytype*, which must be one of 3des, aes, or sha1.

The net and cid arguments are used to identify a specific client. Both arguments are optional. If the cid option is not provided, the key being created or displayed will have a per-network scope. If the net option is not provided, then the key will have a global scope. Default net and code values are used to derive an HMAC SHA-1 key if the values are not provided by the user.

Options The following options are supported:

-c Generate and store per-client 3DES/AES encryption keys, avoiding any DES weak keys. Also generates and stores per-client HMAC SHA-1 keys. Used in conjunction with -o.

-d Display a key of type specified by *keytype*, which must be one of 3des, aes, or sha1. Use -d with -m or with -c and -o.

-m Generate and store a "master" HMAC SHA-1 key for WAN install.

-o Specifies the WANboot client and/or keytype.

Examples **EXAMPLE 1** Generate a Master HMAC SHA-1 Key

```
# keygen -m
```

EXAMPLE 2 Generate and Then Display a Client-Specific Master HMAC SHA-1 Key

```
# keygen -c -o net=172.16.174.0,cid=010003BA0E6A36,type=sha1
# keygen -d -c -o net=172.16.174.0,cid=010003BA0E6A36,type=sha1
```

EXAMPLE 3 Generate and Display a 3DES Key with a Per-Network Scope

```
# keygen -c -o net=172.16.174.0,type=3des
# keygen -d -o net=172.16.174.0,type=3des
```

Exit Status 0   Successful operation.

>0   An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/boot/wanboot
Interface Stability	Obsolete

See Also attributes(5)

Name wanboot_keymgmt – insert and extract keys

Synopsis `/usr/lib/inet/wanboot/keymgmt -i -k` *key_file* `-s` *keystore* `-o type=`*keytype*

`/usr/lib/inet/wanboot/keymgmt -x -f` *outfile* `-s` *keystore* `-o type=`*keytype*

Description The keymgmt utility has two purposes:

- To take a raw key, stored in *key_file*, and insert it in the repository specified by *keystore*.
- To extract a key of a specified type from the repository specified by *keystore*, depositing it in *outfile*.

outfile will be created if it does not already exist. The type of key being added or extracted is specified by *keytype* and may have one of four values: 3des, aes, rsa, or sha1 (the last used by HMAC SHA-1). When extracting a key, the first key with an OID matching the supplied type is used.

Arguments The following arguments are supported:

-i	Used in conjunction with -k to insert a raw key in *keystore*.
-f *outfile*	Used to specify a file to receive an extracted key.
-k *key_file*	Used in conjunction with -i to specify the file in which a raw key is stored. This key will be inserted in *keystore*.
-o type=*keytype*	Specifies the type of key being inserted or extracted. Must be one of 3des, aes, rsa, or sha1.
-s *keystore*	Specifies a repository in which a key will be inserted or from which a key will be extracted.
-x	Used in conjunction with -f to extract a key of a specified type and deposit it in *outfile*.

Exit Status

0	Successful operation.
>0	An error occurred.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

ITU-T Recommendation X.208

Name wanboot_p12split – split a PKCS #12 file into separate certificate and key files

Synopsis `/usr/lib/inet/wanboot/p12split -i` *p12file* `-c` *out_cert* `-k` *out_key*
            `[-t` *out_trust* `-l` *id* `-v]`

Description The `p12split` utility extracts a certificate and private key from the repository specified by *p12file*, depositing the certificate in *out_cert* and the key in *out_key*. If supplied, the `-l` option specifies the value for the `LocalKeyId` that will be used in the new certificate and key files. `p12split` can optionally extract a trust certificate into the *out_trust* file if the `-t` option is specified. Use the `-v` option to get a verbose description of the split displayed to standard output.

Options The following arguments and options are supported:

 `-c` *out_cert*   Specifies a repository that receives a extracted certificate.

 `-i` *p12file*   Specifies a repository from which a certificate and private key is extracted.

 `-k` *out_key*   Specifies a repository that receives a extracted private key.

 `-l` *id*   Specifies the value for the `LocalKeyId` that will be used in the new certificate and key files.

 `-t` *out_trust*   Specifies a file for receiving an extracted trust certificate.

 `-v`   Displays a verbose description of the split to stdout.

Exit Status `0`   Successful operation.

 `>0`   An error occurred.

Attributes See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/boot/wanboot
Interface Stability	Uncommitted

See Also `attributes(5)`

Name wanbootutil – manage keys and certificates for WAN booting

Synopsis wanbootutil [keygen] [*option_specific_arguments*]

wanbootutil [keymgmt] [*option_specific_arguments*]

wanbootutil [p12split] [*option_specific_arguments*]

Description The wanbootutil command creates and manages WANboot encyrption and hashing keys and manipulates PKCS #12 files for use by WAN boot.

wanbootutil has three subcommands, each covered in a separate man page:

wanboot_keygen(1M)   Generates encryption and hashing keys.

wanboot_keymgmt(1M)   Inserts and extracts keys from WAN boot key repositories.

wanboot_p12split(1M)   Splits a PKCS #12 file into separate certificate and key files for use by WAN boot.

Options The options are supported for wanbootutil are the use of keygen, keymgmt, or p12split. The options for these subcommands are described in their respective man pages.

Examples **EXAMPLE 1** Generate a 3DES Client Key

```
# wanbootutil keygen -c -o net=172.16.174.0,cid=010003BA0E6A36,type=3des
```

EXAMPLE 2 Insert an RSA Private Client Key

```
wanbootutil keymgmt -i -k keyfile \
  -s /etc/netboot/172.16.174.0/010003BA0E6A36/keystore -o type=rsa
```

EXAMPLE 3 Split a PKCS #12 File into Certificate and Key Components

```
# wanbootutil p12split -i p12file -c out_cert -k out_key
```

Exit Status 0   Successful operation.

non-zero   An error occurred. Writes an appropriate error message to standard error.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/boot/wanboot
Interface Stability	Obsolete

See Also wanboot_keygen(1M), wanboot_keymgmt(1M), wanboot_p12split(1M), attributes(5)

Name wbemadmin – start Sun WBEM User Manager

Synopsis /usr/sadm/bin/wbemadmin

Description The wbemadmin utility starts Sun WBEM User Manager, a graphical user interface that enables you to add and delete authorized WBEM users and to set their access privileges. Use this application to manage access to groups of managed resources, such as disks and installed software, in the Solaris operating environment.

The wbemadmin utility allows you to perform the following tasks:

Manage user access rights | Use the wbemadmin utility to add, delete, or modify an individual user's access rights to a namespace on a WBEM-enabled system.

Manage namespace access rights | Use the wbemadmin utility to add, delete, or modify access rights for all users to a namespace.

The Sun WBEM User Manager displays a Login dialog box. You must log in as root or a user with write access to the root\security namespace to grant access rights to users. By default, Solaris users have guest privileges, which grants them read access to the default namespaces.

Managed resources are described using a standard information model called Common Information Model (CIM). A CIM object is a computer representation, or model, of a managed resource, such as a printer, disk drive, or CPU. CIM objects can be shared by any WBEM-enabled system, device, or application. CIM objects are grouped into meaningful collections called schema. One or more schemas can be stored in directory-like structures called namespaces.

All programming operations are performed within a namespace. Two namespaces are created by default during installation:

- root\cimv2 — Contains the default CIM classes that represent objects on your system.
- root\security — Contains the security classes used by the CIM Object Manager to represent access rights for users and namespaces.

When a WBEM client application connects to the CIM Object Manager in a particular namespace, all subsequent operations occur within that namespace. When you connect to a namespace, you can access the classes and instances in that namespace (if they exist) and in any namespaces contained in that namespace.

When a WBEM client application accesses CIM data, the WBEM system validates the user's login information on the current host. By default, a validated WBEM user is granted read access to the Common Information Model (CIM) Schema. The CIM Schema describes managed objects on your system in a standard format that all WBEM-enabled systems and applications can interpret.

You can set access privileges on individual namespaces or for a user-namespace combination. When you add a user and select a namespace, by default the user is granted read access to CIM objects in the selected namespace. An effective way to combine user and namespace access rights is to first restrict access to a namespace. Then grant individual users read, read and write, or write access to that namespace.

You cannot set access rights on individual managed objects. However you can set access rights for all managed objects in a namespace as well as on a per-user basis.

If you log in to the root account, you can set the following types of access to CIM objects:

- Read Only — Allows read-only access to CIM Schema objects. Users with this privilege can retrieve instances and classes, but cannot create, delete, or modify CIM objects.
- Read/Write — Allows full read, write, and delete access to all CIM classes and instances.
- Write — Allows write and delete, but not read access to all CIM classes and instances.
- None — Allows no access to CIM classes and instances.

Context help is displayed in the left side of the wbemadmin dialog boxes. When you click on a field, the help content changes to describe the selected field. No context help is available on the main User Manager window.

The wbemadmin security administration tool updates the following Java classes in the root\security namespace:

- Solaris_UserAcl — Updated when access rights are granted or changed for a user.
- Solaris_namespaceAcl — Updated when access rights are granted or changed for a namespace.

Usage The wbemadmin utility is not the tool for a distributed environment. It is used for local administration on the machine on which the CIM Object Manager is running.

Exit Status The wbemadmin utility terminates with exit status 0.

Warning The root\security namespace stores access privileges. If you grant other users access to the root\security namespace, those users can grant themselves or other users rights to all other namespaces.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWwbco

See Also   mofcomp(1M), wbemlogviewer(1M), init.wbem(1M), attributes(5)

Name wbemconfig – convert a JavaSpaces datastore to the newer Reliable Log datastore format

Synopsis /usr/sadm/lib/wbem/wbemconfig convert

Description A Reliable Log directory is created that contains the converted data. This directory is named /var/sadm/wbem/logr.

The convert argument is the only supported option of this command. You should only run this command after stopping WBEM (CIM Object Manager) with the init.wbem stop command. Otherwise your data may be corrupted.

This command successfully converts any proprietary custom MOFs you have created in the datastore, but not any CIM or Solaris MOFs you have modified. These will be destroyed. To recompile any modified CIM or Solaris MOFs into the new datastore, run the mofcomp command on the MOF files containing the class definitions.

Because the wbemconfig convert command invokes the JVM (Java Virtual Machine) to perform conversion of the JavaSpaces datastore, you must be running the same version of the JVM as when the original JavaSpaces storage was created. After the wbemconfig convert command is completed, you can change to any version of the JVM you want.

To see what version of the JVM you are running, issue the java -version command.

Options The following options are supported:

convert   Convert a JavaSpaces datastore to the newer Reliable Log datastore format.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWwbco

See Also init.wbem(1M), wbemadmin(1M), wbemlogviewer(1M), mofcomp(1M), attributes(5)

Name   wbemlogviewer – start WBEM Log Viewer

Synopsis   `/usr/sadm/bin/wbemlogviewer`

Description   The `wbemlogviewer` utility starts the WBEM Log Viewer graphical user interface, which enables administrators to view and maintain log records created by WBEM clients and providers. The WBEM Log Viewer displays a Login dialog box. You must log in as root or a user with write access to the `root\cimv2` namespace to view and maintain log files. Namespaces are described in wbemadmin(1M).

Log events can have three severity levels.

- Errors
- Warnings
- Informational

The WBEM log file is created in the `/var/sadm/wbem/log` directory, with the name `wbem_log`. The first time the log file is backed up, it is renamed `wbem_log.1`, and a new `wbem_log` file is created. Each succeeding time the `wbem_log` file is backed up, the file extension number of each backup log file is increased by 1, and the oldest backup log file is removed *if* the limit, which in turn is specified in the log service settings, on the number of logfiles is exceeded. Older backup files have higher file extension numbers than more recent backup files.

The log file is renamed with a `.1` file extension and saved when one of the following two conditions occur:

- The current file reaches the specified file size limit.

- A WBEM client application uses the `clearLog()` method in the `Solaris_LogService` class to clear the current log file.

- A WBEM client application uses the `clearLog()` method in the Solaris_LogService class to clear the current log file.

- A user chooses Action->Back Up Now in the Log Viewer application.

Help is displayed in the left panel of each dialog box. Context help is not displayed in the main Log Viewer window.

Usage   The WBEM Log Viewer is not the tool for a distributed environment. It is used for local administration.

The WBEM Log Viewer allows you to perform the following tasks:

View the logs

Set properties of log files	Click Action->Log File Settings to specify log file parameters and the log file directory.
Back up a log file	Click Action->Back Up Now to back up and close the current log file and start a new log file.

Open historical log files	Click Action->Open Log File to open a backed-up log file.
Delete an old log file	Open the file and then click Action->Delete Log File. You can only delete backed-up log files.
View log record details	Double-click a log entry or click View->Log Entry Details to display the details of a log record.
Sort the logs	Click View->Sort By to sort displayed entries. You can also click any column heading to sort the list. By default, the log entries are displayed in reverse chronological order (new logs first).

Exit Status The `wbemlogviewer` utility terminates with exit status `0`.

Files `/var/sadm/wbem/log/wbem_log`   WBEM log file

Name wcadmin – manage the configuration of the Sun Java Web Console

Synopsis /usr/sbin/wcadmin *subcommand options*

/usr/sbin/wcadmin *[-h| --help]*

/usr/sbin/wcadmin *[-V | --version]*

Description wcadmin is a Command Line Interface (CLI) — based tool for managing the configuration of the Sun Java Web Console.

Subcommands The following subcommands are supported:

add
: The wcadmin add subcommand adds a new shared jar file, a new JAAS login module, or a new shared service property to the console configuration. An optional identifier may be specified; if omitted, the identifier is derived from the resource name. The resource is added when the console is next started.

    The format of the add subcommand is:

    add -l -a *appname* [-n *id*] *jarpath*

    add -m -a *appname* [-n *id*] -b *behavior* -s *service* [-o *name=value*] *classname*

    add -p -a *appname name=value* [... *name=value*]

deploy
: The wcadmin deploy subcommand deploys the specified web application into the console's web server instance. Applications are deployed directly from their installation directories.

    The format of the deploy subcommand is:

    deploy [-D] -a *appname* -x *context app_path*

disable
: The wcadmin disable subcommand disables access to the specified web application in the console's web server instance.

    The format of the disable subcommand is:

    disable -x *context*

enable
: The wcadmin enable subcommand enables access to the specified web application in the console's web server instance.

    The format of the enable subcommand is:

    enable -x *context*

list
: The wcadmin list subcommand lists the resources currently configured for the console; including deployed web applications, shared jar files, login modules, and shared service properties. If no option is specified, all resources are listed.

The format of the `list` subcommand is:

list [-a] [-d] [-l] [-m] [-p]

password   The wcadmin `password` subcommand manages the administrator and security keystore passwords for the console. Keystore passwords should not be changed while the console is running.

The format of the `password` subcommand is:

password [-a] [-k] [-t]

password -f *password_file*

reload   The wcadmin `reload` subcommand unloads the specified web application from the console's web server instance and reloads the application from its original installation directory.

The format of the `reload` subcommand is:

reload -x *context*

remove   The wcadmin `remove` subcommand removes a shared jar file, a login module, or a shared service property from the console configuration. The resource may be specified by its identifier or by its full jarpath or classname. The resource is removed when the console is next started.

The format of the `remove` subcommand is:

remove -l -a *appname* [-n *id*] *jarpath*

remove -m -a *appname* [-n *id*] *classname*

remove -p -a *appname property* [...]

undeploy   The wcadmin `undeploy` subcommand undeploys the specified web application from the console's web server instance.

The format of the `undeploy` subcommand is:

undeploy [-D] -a *appname* -x *context*

Options The following options are supported:

-h | --help | -?	Display runtime help.
-V | --version	Display console version information.
-D | --defer	When used with the deploy and undeploy subcommands, defers the deployment or undeployment until the next console restart.

	The operation is deferred by simply adding or removing the corresponding resource registration notification file. If defer is not specified, a runtime deployment or undeployment is performed, so that the application becomes available or unavailable in the running console. If the console instance is not currently running, the operation is automatically deferred.
`-a` | `--adminpassword`	Specify that the administrator password should be changed, when used with password subcommand. You are prompted for a new password, which must be 8 to 32 characters.
`-a` | `--application`	Specify the application name, when used with subcommands other than password subcommand.
`-d` | `--detail`	Specify that configuration details of each resource should be displayed.
`-f`	Specify the fully qualified path name to a file containing one or more password property values. See the description of the password_file argument.
`-k` | `--keypassword`	Specify that the keystore password should be changed. You are prompted for a new password, which must be 8 to 32 characters.
`-l` | `--library`	Specify that the resource is a shared jar file.
`-m` | `--module`	Specify that the resource is a JAAS login module.
`-n` | `--name`	Specify the short-hand identifier name for the resource. If omitted, the identifier name is derived from the full resource name.
`-o` | `--option`	Specify the name and value of a login module option property, separated by the equals character.
`-p` | `--property`	Specify that the resource is one or more shared service properties.
`-s` | `--service`	Specify the name of the JAAS login service definition. If omitted, the default console login service definition is assumed.
`-t` | `--trustpassword`	Specify that the truststore password should be changed. You are prompted for a new password, which must be 8 to 32 characters.
`-x` | `--context`	Specify the web application context path name under which the application is deployed.

Arguments *app_path*   The fully qualified file system path to the web application installation directory.

appname   The application name. The name must be unique among all web applications registered with the console. It is also used as the name of the subdirectory under the console's pre-registration directory which contains

all the resource registration notification files for that application. Typically, the application package name, plugin identifier, or context path name is specified for the application name.

behavior The JAAS login module control flag behavior. Must be one of "optional", "required", "requisite", or "sufficient".

classname The fully qualified Java package class name of the JAAS login module. The specified class must be included in a shared jar file added to the console.

context The web application context path name under which the application is deployed. With the .reg suffix, the context forms the file name of the registration notification file for that application.

id The short-hand identifier name for a jar file or login module resource to be added or removed. The identifier name must be unique among the resources shared for a given application name. With the .reg suffix, it forms the file name of the registration notfication file for that resource.

jarpath The fully qualified file system path to the jar file resource. When the resource is added to the console, its path is included in the classpath of the console's shared class loader.

option The JAAS login module option property name.

property The shared service property name.

password_file The fully qualified path to a password text file that contains the new administrator, keystore, and truststore passwords in property file format. The administrator password is specified using the "adminpassword" property. The keystore password is specified using the "keypassword" property. The truststore password is specified using the "trustpasswd" property. At least one password property must be contained in the password file.

value The login module option or shared service property value. If the value contains white space, it must be quoted.

Examples The following command adds a jar file to be shared in the console:

```
wcadmin add -l -a myapp_1.0 -n wbem /usr/sadm/lib/wbem.jar
```

The following command deploys a new web application:

```
wcadmin deploy -a myapp_1.0 -x myapp /opt/SUNWmyapp/myapp
```

The following command reloads an existing web application:

```
wcadmin reload -x myapp
```

The following command undeploys a web application at the next server restart:

```
wcadmin undeploy -D -a myapp_1.0 -x myapp
```

The following command lists all the deployed web applications in the console. If the status field is "running", the web application is available. If the status field is "stopped", the web application is disabled and is not available. If all web applications are "stopped", this typically indicates the console web server instance is not running.

```
wcadmin list -a
```

The following command removes a shared jar file:

```
wcadmin remove -l -a myapp_1.0 -n wbem
```

The following command changes passwords that are specified in a file:

```
wcadmin password -f /home/mydir/console-passwords
```

Exit Status   The following exit values are returned:

0   Subcommand succeeded without error

1   Usage error: missing or malformed arguments

2   Fatal error: subcommand failed with one or more errors

Attributes   See attributes(5) for descriptions of the following attributes:

Name whodo – who is doing what

Synopsis /usr/sbin/whodo [-h] [-l] [*user*]

Description The whodo command produces formatted and dated output from information in the /var/adm/utmpx and /proc/pid files.

The display is headed by the date, time, and machine name. For each user logged in, device name, user-ID and login time is shown, followed by a list of active processes associated with the user-ID. The list includes the device name, process-ID, CPU minutes and seconds used, and process name.

If *user* is specified, output is restricted to all sessions pertaining to that user.

Options The following options are supported:

-h   Suppress the heading.

-l   Produce a long form of output. The fields displayed are: the user's login name, the name of the tty the user is on, the time of day the user logged in (in *hours*:*minutes*), the idle time — that is, the time since the user last typed anything (in *hours*:*minutes*), the CPU time used by all processes and their children on that terminal (in *minutes*:*seconds*), the CPU time used by the currently active processes (in *minutes*:*seconds*), and the name and arguments of the current process.

Examples EXAMPLE 1 Using the whodo Command

The command:

example% whodo

produces a display like this:

```
Tue Mar 12 15:48:03 1985
bailey
tty09   mcn      8:51
    tty09   28158   0:29 sh

tty52   bdr      15:23
    tty52   21688   0:05 sh
    tty52   22788   0:01 whodo
    tty52   22017   0:03 vi
    tty52   22549   0:01 sh

xt162   lee      10:20
    tty08   6748    0:01 layers
    xt162   6751    0:01 sh
    xt163   6761    0:05 sh
    tty08   6536    0:05 sh
```

Environment Variables
If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of tar(1) for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how whodo behaves.

LC_CTYPE　　　　　Determines how whodo handles characters. When LC_CTYPE is set to a valid value, whodo can display and handle text and filenames containing valid characters for that locale. The whodo command can display and handle Extended Unix code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. whodo can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

LC_MESSAGES　　Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

LC_TIME　　　　　Determines how whodo handles date and time formats. In the "C" locale, date and time handling follow the U.S. rules.

Exit Status
The following exit values are returned:

0　　　　　　Successful completion.

non-zero　　An error occurred.

Files
/etc/passwd　　　　System password file

/var/adm/utmpx　　User access and administration information

/proc/pid　　　　　Contains PID

Attributes

Name wpad – WPA and WPA2 protocol daemon

Synopsis /usr/lib/inet/wpad [-i *interface*] [-k *pre_shared_key_name*]

Description The wpad daemon provides common client functionality for the WiFi Protected Access (WPA) versions 1 and 2, as defined by IEEE802.11i standard. WPA was created by the WiFi Alliance, an industry trade group. WPA implements the majority of the IEEE 802.11i standard, and was intended as an intermediate measure to take the place of Wired Equivalent Privacy (WEP) while 802.11i was prepared. WPA2 implements the full standard.

wpad provides the following WPA/IEEE 802.11i features:

- WPA-PSK ("WPA-Personal")
- Key management for CCMP, TKIP, WEP104, WEP40

Stop and start the wpad daemon using dladm(1M). Use:

dladm connect-wifi

...to start the wpad daemon. Use:

dladm disconnect-wifi

...to stop the daemon.

Options The following options are supported:

-i *interface*
   Specify a WiFi Link interface to start the wpad daemon.

-k *pre_shared_key_name*
   Specify the pre-shared key used for the WiFi Link.

Examples EXAMPLE 1 Starting the wpad Daemon on Specific WiFi Link

To create the WPA key psk, enter the following command:

dladm create-secobj -c wpa psk

To use key psk to connect to ESSID wlan on link ath0, enter the following command:

dladm connect-wifi -k psk -e wlan ath0

EXAMPLE 2 Stopping the wpad Daemon on Specific WiFi Link

To stop the daemon on the link ath0, enter:

dladm disconnect-wifi ath0

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/wpa
Interface Stability	Uncommitted

See Also svcs(1), dladm(1M), svcadm(1M), attributes(5), smf(5)

Notes The wpad service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/wpa:<*link*>

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcadm(1M) command.

Name wracct – write extended accounting records for active processes and tasks

Synopsis /usr/sbin/wracct -i *id_list* [-t *record_type*]
            {process | task}

Description The wracct utility allows the administrator to invoke the extended accounting system, if active, to write intermediate records representing the resource usage of a selected set of processes or tasks. For tasks, a *record_type* option is also supported, allowing the administrator to request the writing of:

- an interval record, which reflects task usage since a previous interval record (or since task creation if there is no interval record), or

- a partial record, which reflects usage since task creation.

Options The following options are supported:

-i *id_list*   Select the IDs of the tasks or processes to write records for. Specify *id_list* as a comma- or space-separated list of IDs, presented as a single argument. For some shells, this requires appropriate quoting of the argument.

-t *record_type*   Select type of record to write for the selected task or process. For tasks, *record_type* can be partial or interval. partial is the default type, and the only type available for process records.

Operands The following operands are supported:

process   Treat the given ID as a process ID for the purposes of constructing and writing an extended accounting record.

task   Treat the given ID as a task ID for the purposes of constructing and writing an extended accounting record.

Examples EXAMPLE 1   Writing a Partial Record

Write a partial record for all active sendmail processes.

```
# /usr/sbin/wracct -i "`pgrep sendmail`" process
```

EXAMPLE 2   Writing an Interval Record

Write an interval record for the task with ID 182.

```
# /usr/sbin/wracct -t interval -i 182 task
```

Exit Status The following exit values are returned:

0   Successful completion.

1   An error occurred.

2   Invalid command line options were specified.

3   Pertinent components of extended accounting facility are not active.

Files /var/adm/exacct/task

/var/adm/exacct/proc   Extended accounting data files.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os

See Also acctadm(1M), attributes(5)

Name wusbadm – administer wireless USB hosts and devices

Synopsis wusbadm list [-h | -d] [-o *field*[,...]]

wusbadm associate [-h *host-id*] [[-c [-f]] | -n] [-o]

wusbadm remove-dev [[-d *dev-id*] | [-h *host-id*]] [-f]

wusbadm remove-host [-h *host-id*] [-f]

wusbadm enable-host [-h *host-id*]

wusbadm disable-host [-h *host-id*]

Description The wusbadm command provides a command line interface to administer wireless USB hosts and devices, including listing hosts and devices information, associating the host with the device, removing host or device information from the system, and enabling or disabling hosts.

Before connecting a wireless USB device to a host for the first time, a user needs to set up the association information between them by running the wusbadm associate subcommand. Following this, the user can connect or disconnect the device by simply turning on or off the device radio (perhaps a button on the device, depending on the manufacturer). The device radio's turning on and off are analogous to the hotplugging of wired USB devices.

The association information created by the associate subcommand is maintained in the non-volatile memory of the device and the host. On the host, it can be removed by the remove-dev or remove-host subcommands. On the device, it can be overwritten by another association. For a device is associated with multiple hosts, the way that the device prioritizes or updates its multiple records of association depends on the manufacturer.

Each wusbadm subcommand operates on one of the following objects:

host-id
    A two-digit number (in the range from 01 to 99) that uniquely identifies a wireless USB host on a system. It is generated when the wusb service (see NOTES section) is successfully enabled and finds the host instance for the first time. The number is maintained until removed by remove-host subcommand.

dev-id
    A five-digit number that uniquely identifies a wireless USB device associated with a wireless USB host. The first two digits are the host-id of the wireless USB host with which the device is associated. The last three-digit number (in the range from 001 to 999) is used to differentiate devices associated with the same host. In the five-digit number, the first two digits and the last three are separated by a dot.

    dev-id is generated during the device association process. It is maintained for the device until removed by the remove-dev subcommand or until updated by another association between the same host and device.

Sub-commands The following subcommands are supported. Except for the list subcommand, each subcommand displays subcommand-specific usage information if you run it without any options or operands.

list [-h | -d] [-o *field*[,...]]

   List wireless USB hosts and devices on a system, displaying the ID, state, and type for all hosts and devices. By default, list will list all hosts and devices and all fields. Each host and its devices will be displayed as a group. This subcommand supports the following options.

   -o *field*[,...], --output=*field*[,...]

      A case-insensitive, comma-separated list of output fields to display. The field name must be one of the fields listed below, or the special value all to display all fields. By default (without -o), list displays all fields.

      ID

         The *host-id* or *dev-id*.

      TYPE

         The host or device types.

         For host, the types include whci (on-board host) and hwa (hot-pluggable host).

         For device, the types include kbd, mouse, storage, printer, dwa (wireless USB hub), audio, video, and so forth.

      STATE

         There are the following states for the host:

      enabled

         The host is ready to work or is already working, including performing association, connecting devices, performing data communication, and so forth.

      disabled

         The host is not ready to work with any devices and no devices are connected to the host. It might be stopped by a disable-host subcommand, or the host might not be available because it is physically unplugged or because of a driver detach.

      disconnected

         The host is not attached to the system. An hwa device is in this state after it is unplugged from the USB port on the system.

         There are the folllowing states for the device:

      connected

         The device is connected with a host and ready to be opened, or it is already opened and working. By default, the device tries to get into this state after the association is complete and its radio is turned on.

disconnected

    The device is not connected to a host or not ready to be opened yet. The device might be in this state because its radio is out of range, power is off, hardware problems, and so forth.

-h, --host

    List the wireless USB hosts only.

-d, --device

    List the wireless USB devices only.

associate [-h *host-id*] [[-c [-f]] | -n] [-o]

    Designate the host to start an association process. Association is the initial step before a wireless USB device can be connected with a wireless USB host.

    There are two association models:

    Cable association

        A user connects the device and host with a USB cable first, and then run this subcommand to designate the host to setup the association information with the device. After the association is in effect, the cable is no longer needed in the subsequent connections between the same host and the device.

    Numeric association

        A user turns on the device radio and runs this subcommand to designate the host to talk to the device. A short number is then displayed on both host and device. The user compares the values of the numbers and confirms on both the host and the device.

    Following a successful association, the associated USB host and device are able to proceed with the wireless connection process. By default, the association information will be kept both on the host and the device until it is removed or overwritten.

    If there are multiple devices available for association, this subcommand will list all of them, enabling a user to choose among them. This subcommand has the following options.

    -h *host-id*, --host *host-id*

        Specify the host for which the association will be done. If this option is not specified, this subcommand lists all enabled hosts for users to choose.

    -c, --cable

        Start the cable association process. A user plugs the wireless USB device to the host and runs the associate subcommand with this option.

    -n, --numeric

        Start the numeric association process. This subcommand prompts the user to compare the number displayed on the host and the device.

    If neither of the preceding two association model options (-n or -c) is specified, this subcommand prompts the user to specify one of the following association model options.

-f, -—force

Start the cable association process. A user plugs the wireless USB device to the host and runs the associate subcommand with this option.

-o, -—onetime

Indicate that this association is for a one-time connection. That is, after the association, if the device is connected and then disconnected, the association information for this device will be removed from the host system. A user would need to perform another association for the next connection.

remove-dev [[-d *dev-id*] | [-h *host-id*]] [-f]

Remove the association information of the wireless USB device from the system. After the removal, the device cannot be connected with the host until the user runs the associate subcommand again, for the host and device. This subcommand has the following options.

-d, --device=*dev-id*

Remove the association information of the wireless USB device specified by *dev-id*.

-h *host-id*, -—host=*host-id*

Remove the association information of all the wireless USB devices associated with the host specified by *host-id*.

-f, -—force

Perform the removal without asking for confirmation. If the device is being connected with the host, then this subcommand will force it to disconnect.

remove-host [-h *host-id*] [-f]

Remove the host information from the system, including *host-id* and the association information of all the devices associated with the host. This subcommand is used most often for removing the temporarily used hot-pluggable wireless USB host, for example, a hwa dongle. The host can be brought back by being re-enumerated, for example, physically hot-plugging a hwa dongle. The host-id will then be updated and no device association information can be restored. It is not recommended to remove a on-board host. This subcommand has the following options.

-h *host-id*, -—host=*host-id*

Specifies the *host-id* to be removed.

-f, -—force

Perform the removal without asking for confirmation. If there are one or more devices connected with the host, then force them to disconnect.

enable-host [-h *host-id*]

Take the host to the enabled state. By default, the host is in the enabled state. This subcommand has the following option.

-h *host-id*, -—host=*host-id*

Specifies the *host-id* to be enabled.

disable-host [-h *host-id*] [-f]
Take the host to the disabled state. The *host-id* and all the association information of the
host are maintained. Issuing an enable-host subcommand brings the host back to the
enabled state. This subcommand has the following options.

-h *host-id*, --host=*host-id*
Specifies the *host-id* to be disabled.

-f, --force
Perform the disable operation without asking for confirmation. If there are one or more
devices connected with the host, this option forces them to disconnect.

Examples **EXAMPLE 1** Listing All Hosts and Devices

The following command lists all wireless USB hosts and devices.

```
# wusbadm list
01      enabled       hwa
01.001  connected     mouse
01.002  connected     kbd
02      enabled       whci
02.001  connected     printer
02.002  disconnected  storage
03      disabled      hwa
03.001  disconnected  storage
03.002  disconnected  dwa
```

EXAMPLE 2 Associating to a Device Using Cable

The following command associates a device to a specific host (host-id 01), using the cable
association approach.

```
# wusbadm associate -h 01 -c
Associate a device with host (01) via cable.
Continue (yes/no)?
```

EXAMPLE 3 Removing a Device's Association

The following command removes a device's association information from the host system.

```
# wusbadm remove-dev -d 01.002
Remove the information of device (01.002) from system.
This device can not be connected with the host until it is associated
again. Continue (yes/no)?
```

EXAMPLE 4 Removing Associations for All Devices

The following command removes the association information for all devices associated with a
specific host.

```
# wusbadm remove-dev -h 02
Remove the information of all the devices associated with host (02)
```

EXAMPLE 4 Removing Associations for All Devices   *(Continued)*

```
from the system.
All the devices associated with the host cannot be connected with it
until they are associated again. Continue (yes/no)?
```

Exit Status   The following exit values are returned:

0

   Successful operation.

1

   Error: the operation failed. For example, a device failed to associate with a host.

2

   Usage error.

Attributes   See attributes(5) for descriptions of the following attributes:

svc:/system/wusb:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

The wusb service is implemented by the wusbd daemon, a private interface. As with the wusb service, the daemon is started by the SMF. Specify the daemon with the service instance:

```
svc:/system/wusbd:default
```

The wusbd daemon should not be invoked directly.

Name ypbind – NIS binder process

Synopsis /usr/lib/netsvc/yp/ypbind [-broadcast | -ypset | -ypsetme]

Description NIS provides a simple network lookup service consisting of databases and processes. The databases are stored at the machine that runs an NIS server process. The programmatic interface to NIS is described in ypclnt(3NSL). Administrative tools are described in ypinit(1M), ypwhich(1), and ypset(1M). Tools to see the contents of NIS maps are described in ypcat(1), and ypmatch(1).

ypbind is a daemon process that is activated at system startup time from the svc:/network/nis/client:default service. By default, it is invoked as ypbind -broadcast. ypbind runs on all client machines that are set up to use NIS. The function of ypbind is to remember information that lets all NIS client processes on a node communicate with some NIS server process. ypbind must run on every machine which has NIS client processes. The NIS server may or may not be running on the same node, but must be running somewhere on the network.

The SMF service svc:/network/nis/client has the following properties in the config property group:

```
config.use_broadcast
config.use_ypsetme
```

The information ypbind remembers is called a *binding* — the association of a domain name with a NIS server. The process of binding is driven by client requests. As a request for an unbound domain comes in, if started with the -broadcast option, the ypbind process broadcasts on the net trying to find an NIS server, that is, a ypserv process serving the domain with a name the same as (case sensitive) the name of the domain in the client request. Since the binding is established by broadcasting, there must be at least one NIS server on the net. If started without the -broadcast option, ypbind process steps through the list of NIS servers that was created by ypinit -c for the requested domain. There must be an NIS server process on at least one of the hosts in the NIS servers file. It is recommended that you list each of these NIS servers by name and numeric IP address in /etc/hosts. Though the practice is not recommended, NIS allows you to list servers by numeric address only, bypassing /etc/hosts. In such a configuration, ypwhich(1) returns a numeric address instead of a name.

Once a domain is bound by ypbind, that same binding is given to every client process on the node. The ypbind process on the local node or a remote node may be queried for the binding of a particular domain by using the ypwhich(1) command.

If ypbind is unable to speak to the NIS server process it is bound to, it marks the domain as unbound, tells the client process that the domain is unbound, and tries to bind the domain once again. Requests received for an unbound domain will wait until the requested domain is bound. In general, a bound domain is marked as unbound when the node running the NIS server crashes or gets overloaded. In such a case, ypbind will try to bind to another NIS server using the process described above. ypbind also accepts requests to set its binding for a

particular domain. The request is usually generated by the ypset(1M) command. In order for ypset to work, ypbind must have been invoked with flags -ypset or -ypsetme.

Options   -broadcast

Send a broadcast datagram using UDP/IP that requests the information needed to bind to a specific NIS server. This option is analogous to ypbind with no options in earlier Sun releases and is recommended for ease of use.

Enabling the SMF property config.use_broadcast enables -broadcast.

-ypset

Allow users from any remote machine to change the binding by means of the ypset command. By default, no one can change the binding. This option is insecure.

-ypsetme

Only allow root on the local machine to change the binding to a desired server by means of the ypset command. ypbind can verify the caller is indeed a root user by accepting such requests only on the loopback transport. By default, no external process can change the binding.

Enabling the SMF property config.use_ypsetme enables -ypsetme.

Files   /var/yp/binding/*ypdomain*/ypservers

Lists the servers to which the NIS client is allowed to bind.

/etc/inet/hosts

File in which it is recommended that NIS servers be listed.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/nis

See Also   svcs(1), ypcat(1), ypmatch(1), ypwhich(1), ifconfig(1M), svcadm(1M), ypinit(1M), ypset(1M), ypclnt(3NSL), hosts(4), ypfiles(4), attributes(5), smf(5)

Notes   ypbind supports multiple domains. The ypbind process can maintain bindings to several domains and their servers, the default domain is the one specified by the domainname(1M) command at startup time.

The -broadcast option works only on the UDP transport. It is insecure since it trusts "any" machine on the net that responds to the broadcast request and poses itself as an NIS server.

The ypbind service is managed by the service management facility, smf(5), under the service identifier:

svc:/network/nis/client:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name ypinit – set up NIS client

Synopsis /usr/sbin/ypinit [-c] [-m] [-s *master_server*]

Description ypinit can be used to set up an NIS client system. You must be the superuser to run this command. This script need not be used at all if ypbind(1M) is started with the -broadcast option (it is invoked with this option from the svc:/network/nis/client:default service).

Normally, ypinit is run only once after installing the system. It may be run whenever a new NIS server is added to the network or an existing one is decommissioned.

ypinit prompts for a list of NIS servers to bind the client to; this list should be ordered from the closest to the furthest server. It is recommended that you list each of these NIS servers by name and numeric IP address in /etc/hosts. Though the practice is not recommended, NIS allows you to list servers by numeric address only, bypassing /etc/hosts. In such a configuration, ypwhich(1) returns a numeric address instead of a name.

ypinit stores the list of servers to which a client can bind in the file /var/yp/binding/*domain*/ypservers. This file is used by ypbind when run without the -broadcast option.

Options -c
Set up a ypclient system.

-m
Build a master ypserver data base.

-s *master_server*
Slave data base. *master_server* must be the same master configured in the YP maps and returned by the ypwhich -m command.

Files /etc/hosts
File in which it is recommended that NIS servers be listed.

/var/yp/binding/*domain*/ypservers
Lists the servers to which the NIS client is allowed to bind.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/nis

See Also svcs(1), ypwhich(1), svcadm(1M), ypbind(1M), sysinfo(2), hosts(4), attributes(5), smf(5)

Notes The NIS client service is managed by the service management facility, smf(5), under the service identifier:

    svc:/network/nis/client:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Bugs ypinit sets up the list of NIS servers only for the current domain on the system when it is run, that is, the domain returned by the SI_SRPC_DOMAIN command to sysinfo(2). Care should be taken to ensure that this is the same as the desired domain for NIS client processes.

Name ypmake – rebuild NIS database

Synopsis cd /var/yp ; make [*map*]

Description The file called Makefile in /var/yp is used by make(1S) to build the Network Information
Service (NIS) database. With no arguments, make creates dbm databases for any NIS maps that
are out-of-date, and then executes yppush(1M) to notify slave databases that there has been a
change.

If you supply a *map* on the command line, make will update that map only. Typing make
passwd will create and yppush the password database (assuming it is out of date). Likewise,
make ipnodes and make networks will create and yppush the ipnodes and network files,
$(INETDIR)/ipnodes and $(DIR)/networks.

There are four special variables used by make: DIR, which gives the directory of the source files;
NOPUSH, which when non-null inhibits doing a yppush of the new database files; INETDIR,
which gives the directory of the ipnodes source file; and DOM, which is used to construct a
domain other than the master's default domain. The default for DIR is /etc, and the default for
INETDIR is /etc/inet. The default for NOPUSH is the null string.

Refer to ypfiles(4) and ypserv(1M) for an overview of the NIS service.

If a NIS to LDAP (N2L) configuration file, /var/yp/NISLDAPmapping, is present, the NIS
server components run in N2L mode. In N2L mode, the server components use a new set of
map files with an LDAP-prefix, based on the LDAP DIT. In N2L mode, authoritative NIS
information is obtained from the DIT. The NIS source files and ypmake have no role, and they
should not be used. If ypmake is accidentally run, then the server components will detect this,
and will log a warning message. For additional information, see ypfiles(4).

Files /var/yp   Directory containing NIS configuration files.

/etc/inet/hosts   System hosts file.

/etc   Default directory for source files.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/nis
Interface Stability	Committed

See Also make(1S), makedbm(1M), ypbind(1M), yppush(1M), ypserv(1M), ypclnt(3NSL),
NISLDAPmapping(4), ypfiles(4), ypserv(4)

Notes The NIS makefile is only used when running the ypserv(1M) server to provide NIS services. See ypfiles(4) for more details.

The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two remains the same. Only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications plc, and may not be used without permission.

Name ypmap2src – convert NIS maps to NIS source files

Synopsis /usr/lib/netsvc/yp/ypmap2src [-t]
        [[-c *custom-map-name*]]... [-d *domain*] -o *output-directory*
        [[*source-file*]]...

Description Use the ypmap2src utility to convert standard NIS maps to approximations of the equivalent NIS source files. This utility functions like the reverse of ypmake(1M).

The primary use for ypmap2src is to convert from a NIS server that uses the NIS to LDAP(N2L) transition mechanism, which does not use NIS source files, to traditional NIS, where source files are required. The ypmap2src utility is also used by NIS administrators who wish to discover the contents of NIS maps for which the sources are not available.

Generally, this operation is not necessary. More often, administrators will switch from traditional NIS to N2L in anticipation of the eventual transition to LDAP naming. When this switch is made, authoritative information is moved into the LDAP DIT, and the NIS sources have no further role. N2L supports NIS clients until such time as they can be converted to LDAP, and the NIS service suspended.

The ypmap2src utility does not guarantee that the files that are generated are identical to the original NIS source files. Some information might have been thrown away by ypmake and cannot be recovered. N2L also might have updated the maps to reflect changes made by LDAP clients. It is essential that the sources generated are checked to confirm no problems have occurred.

Per entry comment fields, from existing source files, are not merged into source files generated by ypmap2src. If a user wishes N2L to maintain comment information, then the NISLDAPmapping configuration file should be modified so that the comment fields are mapped into LDAP. This will ensure that the comments are visible to native LDAP clients and present in the N2L map files.

When ypmap2src is run, it will take up-to-date comments from the map file and insert them into the NIS source file generated.

Handling Custom Maps ypmap2src only knows about the standard NIS maps and standard source to map conversion. If an advanced user has changed these, that is, the user has modified the NIS makefile, the equivalent changes must also be made to the ypmap2src script.

Options ypmap2src supports the following options:

-c   Specifies that *custom-map-name* should be converted to a source file by running makedbm -u on it. This is a short cut so that simple custom maps can be handled without editing ypmap2src.

-d *domain-name*   Specifies the domain to convert. The *domain-name* can be a fully qualified file path, such as /var/yp/a.b.c, or just a domain name, a.b.c. In the latter case, ypmaptosrc looks in /var/yp for the domain directory.

| | -o *dest* | Specifies the destination directory for the converted files. A directory other than /etc should be specified. The maps generated are copied to the correct location, /etc, /etc/security or other source directory, as appropriate. |
| | -t | Specifies that traditional NIS maps, without N2L's LDAP_ prefix, should be converted. By default, maps with the LDAP_ prefix are converted. |

Operands ypmap2src supports the following operands:

source-file   Lists the standard source files to convert. If this option is not given, then all the standard source files, plus any custom files pecified by the -c option, are converted.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/nis
Interface Stability	Obsolete

Oracle Solaris Administration: Naming and Directory Services

Name yppoll – return current version of a NIS map at a NIS server host

Synopsis /usr/sbin/yppoll [-d *ypdomain*] [-h *host*] *mapname*

Description The yppoll command asks a ypserv( ) process what the order number is, and which host is the master NIS server for the named map.

Options -d *ypdomain*   Use *ypdomain* instead of the default domain.

-h *host*   Ask the ypserv process at *host* about the map parameters. If *host* is not specified, the NIS server for the local host is used. That is, the default host is the one returned by ypwhich(1).

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/nis

See Also ypwhich(1), ypfiles(4), attributes(5)

Name yppush – force propagation of changed NIS map

Synopsis /usr/lib/netsvc/yp/yppush [-v] [-h *host*] [-d *domain*]
[-p *#parallel-xfrs*] *mapname*

Description yppush copies a new version of a Network Information Service (NIS) map from the master
NIS server to the slave NIS servers. It is normally run only on the master NIS server by the
Makefile in /var/yp after the master databases are changed. It first constructs a list of NIS
server hosts by reading the NIS ypservers map within the *domain*. Keys within the
ypservers map are the ASCII names of the machines on which the NIS servers run.

A "transfer map" request is sent to the NIS server at each host, along with the information
needed by the transfer agent (the program that actually moves the map) to call back the
yppush. When the attempt has completed (successfully or not), and the transfer agent has sent
yppush a status message, the results can be printed to stdout. Messages are also printed when
a transfer is not possible, for instance, when the request message is undeliverable, or when the
timeout period on responses has expired.

Refer to ypfiles(4) and ypserv(1M) for an overview of the NIS service.

Options The following options are supported:

-d *domain*	Specifies a *domain*.
-h *host*	Propagates only to the named *host*.
-p *#parallel-xfrs*	Allows the specified number of map transfers to occur in parallel.
-v	Verbose. This prints messages when each server is called, and for each response. If this flag is omitted, only error messages are printed.

Files

/var/yp	Directory where NIS configuration files reside.
/var/yp/*domain*/ypservers. {*dir, pag* }	Map containing list of NIS servers to bind to when running in server mode.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/nis

See Also ypserv(1M), ypxfr(1M), ypfiles(4), attributes(5)

Notes The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The
functionality of the two remains the same; only the name has changed. The name Yellow
Pages is a registered trademark in the United Kingdom of British Telecommunications PLC,
and must not be used without permission.

Bugs   In the current implementation (version 2 NIS protocol), the transfer agent is ypxfr(1M), which is started by the ypserv program. If yppush detects that it is speaking to a version 1 NIS protocol server, it uses the older protocol, sending a version 1 YPPROC_GET request and issues a message to that effect. Unfortunately, there is no way of knowing if or when the map transfer is performed for version 1 servers. yppush prints a message saying that an "old-style" message has been sent. The system administrator should later check to see that the transfer has actually taken place.

Name ypserv, ypxfrd – NIS server and binder processes

Synopsis /usr/lib/netsvc/yp/ypserv [-dv] [-i | -I] [-r | -R]

/usr/lib/netsvc/yp/ypxfrd

Description The Network Information Service (NIS) provides a simple network lookup service consisting of databases and processes. The databases are ndbm files in a directory tree rooted at /var/yp. See ndbm(3C). These files are described in ypfiles(4). The processes are /usr/lib/netsvc/yp/ypserv, the NIS database lookup server, and /usr/lib/netsvc/yp/ypbind, the NIS binder. The programmatic interface to the NIS service is described in ypclnt(3NSL). Administrative tools are described in yppoll(1M), yppush(1M), ypset(1M), ypxfr(1M), and ypwhich(1). Tools to see the contents of NIS maps are described in ypcat(1), and ypmatch(1). Database generation and maintenance tools are described in ypinit(1M), ypmake(1M), and makedbm(1M).

The ypserv utility is a daemon process typically activated at system startup from svc:/network/nis/server:default. Alternatively, you can, as the root user, start NIS services using ypstart(1M) from the command-line. ypserv runs only on NIS server machines with a complete NIS database. You can halt all NIS services using the ypstop(1M) command.

The ypxfrd utility transfers entire NIS maps in an efficient manner. For systems that use this daemon, map transfers are 10 to 100 times faster, depending on the map. To use this daemon, be sure ypxfrd is running on the master server. See /usr/lib/netsvc/yp/ypstart. ypxfr attempts to use ypxfrd first. If that fails, it prints a warning, then uses the older transfer method.

The ypserv daemon's primary function is to look up information in its local database of NIS maps.

The operations performed by ypserv are defined for the implementor by the *YP Protocol Specification*, and for the programmer by the header file <rpcsvc/yp_prot.h>.

Communication to and from ypserv is by means of RPC calls. Lookup functions are described in ypclnt(3NSL), and are supplied as C-callable functions in the libnsl(3LIB) library. There are four lookup functions, all of which are performed on a specified map within some NIS domain: yp_match(3NSL), yp_first(3NSL), yp_next(3NSL), and yp_all(3NSL). The yp_match operation takes a key, and returns the associated value. The yp_first operation returns the first key-value pair from the map, and yp_next can be used to enumerate the remainder. yp_all ships the entire map to the requester as the response to a single RPC request.

The SMF service svc:/network/nis/server manages the configuration of the ypserv daemon.

A number of special keys in the DBM files can alter the way in which ypserv operates. The keys of interest are:

YP_INTERDOMAIN	The presence of this key causes ypserv to forward to a DNS server host lookups that cannot be satisfied by the DBM files.
YP_SECURE	This key causes ypserv to answer only questions coming from clients on reserved ports.
YP_MULTI *hostname*	This is a special key in the form, YP_MULTI *hostname addr1,...,addrN.* A client looking for *hostname* receives the closest address.

Two other functions supply information about the map, rather than map entries: yp_order(3NSL), and yp_master(3NSL). In fact, both order number and master name exist in the map as key-value pairs, but the server will not return either through the normal lookup functions. If you examine the map with makedbm(1M), however, they are visible. Other functions are used within the NIS service subsystem itself, and are not of general interest to NIS clients. These functions include do_you_serve_this_domain?, transfer_map, and reinitialize_internal_state.

On start up, ypserv checks for the existence of the NIS to LDAP (N2L) configuration file /var/yp/NISLDAPmapping. If it is present then a master server starts in N2L mode. If the file is not present it starts in "traditional" (non N2L) mode. Slave servers always start in traditional mode.

In N2L mode, a new set of map files, with an LDAP_ prefix, are generated, based on the contents of the LDAP DIT. The old map files, NIS source files and ypmake(1M) are not used.

It is possible that ypmake(1M) can be accidentally run in N2L mode. If the occurs, the old style map files are overwritten. That the map files are overwritten is harmless. However, any resulting yppush(1M) operation will push information based on the DIT rather than the source files. The user may not expect information based on the DIT. ypserv keeps track of the last modification date of the old style map files. If the map files have been updated, a warning is logged that suggests that the user call yppush directly instead of ypmake.

If a server attempts to run in N2L mode and a LDAP server cannot be contacted, it behaves as follows:

1. When ypserv is started, a warning will be logged.

2. When a NIS read access is made and the TTL entry has expired, a warning is logged.Information that is returned from the cache has not been updated.

3. When a NIS write access is made, a warning is logged. The cache will not be updated, and a NIS failure will be returned.

If ypxfrd is running in N2L mode and is asked to transfer a map, ypxfrd first checks whether the map is out of date. If the map is out of date, ypxfrd initiates an update from the DIT. ypxfrd cannot wait for the update to complete. If ypxfrd waited, the client end ypxfr

operation could time out. To prevent ypxfrd from timing out, the existing map is transferred from the cache. The most up to date map will be transferred on subsequent ypxfrd operations.

Options

ypserv   -d   The NIS service should go to the DNS for more host information. This requires the existence of a correct /etc/resolv.conf file pointing to a DNS server. This option turns on DNS forwarding regardless of whether or not the YP_INTERDOMAIN flag is set in the hosts maps. See makedbm(1M). In the absence of an /etc/resolv.conf file, ypserv complains, but ignores the -d option.

          If enabled, the property group/property config.service_dns tells ypserv to enable the -d option.

-i   If in N2L mode, initialize the NIS related parts of the DIT based on the current, non LDAP_ prefixed, map files. The LDAP_ prefixed maps are not created or updated. If you require that LDAP_ prefixed maps be updated or created, then use the -ir option.

      The -i option does not attempt to create any NIS domain or container objects. If any NIS domain or container objects have not already been created, then errors will occur, as entries are written to nonexistent containers.

-I   Identical to -i, except that any missing domain and container objects are created.

-r   If in N2L mode, then refresh the LDAP_ prefixed map files based on the contents of the DIT.

-ir   If both -i and -r are specified in N2L mode, then the DIT will first be initialized from the current non LDAP_ prefixed map files. A new set of LDAP_ prefixed maps will then be generated from the contents of the DIT. A new set of LDAP_ prefixed maps is required when moving from traditional NIS to N2L mode NIS.

-Ir   Identical to -ir, except that any missing domain and container objects are created.

-v   Operate in the verbose mode, printing diagnostic messages to stderr.

When run with the -i, -r, -I, -ir or -Ir options, the ypserv command runs in the foreground and exits once map initialization has been completed. Once the ypserv command exits, the user knows the maps are ready and can restart ypserv and the other yp daemons by running ypstart(1M).

If there is a requirement to initialize the DIT from the NIS source files, which may have been modified since the maps were last remade, run ypmake before running ypserv -i or ypserv -ir. ypmake regenerated old style NIS maps. Then ypserv -ir dumps them into the DIT. When the -ir option is used, the LDAP_ prefixe maps are also generated or updated. Since these maps will be more recent than the old style maps, ypmake will not be reported as erroneous when it is run.

Files   /var/yp/securenets   Defines the hosts and networks that are
                                                            granted access to information in the served
                                                            domain. It is read at startup time by both
                                                            ypserv and ypxfrd.

          /var/yp/ypserv.log   If the /var/yp/ypserv.log file exists when
                                                            ypserv starts up, log information is written to
                                                            it when error conditions arise.

          /var/yp/binding/domainname/ypservers   Lists the NIS server hosts that ypbind can
                                                            bind to.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	service/network/nis

          Network Interface Guide

          Oracle Solaris Administration: Naming and Directory Services

Notes   ypserv supports multiple domains. The ypserv process determines the domains it serves by
          looking for directories of the same name in the directory /var/yp. It replies to all broadcasts
          requesting yp service for that domain.

          The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The
          functionality of the two remains the same; only the name has changed. The name Yellow
          Pages is a registered trademark in the United Kingdom of British Telecommunications PLC,
          and must not be used without permission.

          NIS uses ndbm() files to store maps. Therefore, it is subject to the 1024 byte limitations
          described in the USAGE and NOTES sections of the ndbm(3C) man page.

          The NIS server service is managed by the service management facility, smf(5), under the
          service identifier:

          svc:/network/nis/server:default

          Administrative actions on this service, such as enabling, disabling, or requesting restart, can
          be performed using svcadm(1M). The service's status can be queried using the svcs(1)
          command.

Name ypserv_resolv – DNS forwarding service daemon for NIS

Synopsis ypserv_resolv [-v | -V] [-F [-C *fd*]] [-t *xx*] [-p *yy*]

Description ypserv_resolv is an auxiliary process that provides DNS forwarding service for NIS hosts requests to ypserv that is running in the NIS compatibility mode. It is generally started by invoking ypserv(1M) with the -d option. Although it is not recommended, ypserv_resolv can also be started independently with the options shown below.

This command requires that the /etc/resolv.conf file be setup for communication with a DNS nameserver. The dig(1M) utility can be used to verify communication with a DNS nameserver. See resolv.conf(4) and dig(1M).

Options -F   Run in foreground.

-C *fd*   Use *fd* for service xprt.

-v   Verbose. Send output to the syslog daemon.

-V   Verbose. Send output to stdout.

-t *xx*   Use transport *xx*.

-p *yy*   Use transient program# *yy*.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/network/nis

See Also dig(1M), resolv.conf(4), attributes(5)

Name   ypset – point ypbind at a particular server

Synopsis   /usr/sbin/ypset [-d *ypdomain*] [-h *host*] *server*

Description   In order to run ypset, ypbind must be initiated with the −ypset or −ypsetme options. See
ypbind(1M). ypset tells ypbind to get NIS services for the specified *ypdomain* from the
ypserv process running on *server*. If *server* is down, or is not running ypserv, this might not
be discovered until an NIS client process tries to obtain a binding for the domain. At this
point, the binding set by ypset is tested by ypbind. If the binding is invalid, ypbind attempts
to rebind for the same domain.

ypset is useful for binding a client node that is not on a broadcast net, or is on a broadcast net
that is not running an NIS server host. It is also useful for debugging NIS client applications,
for instance, where an NIS map exists only at a single NIS server host.

Where several hosts on the local net are supplying NIS services, ypbind can rebind to another
host, even while you attempt to find out if the ypset operation succeeded. For example, if you
enter the ypset command below, you might get the subsequent response from ypwhich:

```
example% ypset host1
example% ypwhich
host2
```

The sequence shown above is a function of the NIS subsystem's attempt to load-balance
among the available NIS servers, and occurs when host1 does not respond to ypbind because
it is not running ypserv (or is overloaded), and host2, running ypserv, obtains the binding.

server indicates which NIS server to bind to, and must be specified as a name or an IP address.
This works only if the node has a current valid binding for the domain in question and ypbind
has been set to allow use of ypset. In most cases, *server* should be specified as an IP address.

ypset tries to bind over a connectionless transport. The NIS library call, yp_all(), uses
connection-oriented transport and derives the NIS server's address based on the
connectionless address supplied by ypset.

Refer to ypfiles(4) for an overview of the NIS name service.

Options   -d *ypdomain*   Use *ypdomain*, instead of the default domain.

-h *host*   Set ypbind's binding on *host*, instead of locally. Specify *host* as a name.

Name   ypstart, ypstop – Start and stop NIS services

Synopsis   /usr/lib/netsvc/yp/ypstart

/usr/lib/netsvc/yp/ypstop

Description   The ypstart command is used to start the Network Information Service (NIS). After the host has been configured using the ypinit(1M) command, ypstart automatically determines the NIS status of the machine and starts the appropriate daemons.

The ypstop command is used to stop the Network Information Service (NIS).

Oracle Solaris Administration: Common Tasks

Notes   The Network Information Service (NIS) was formerly known as Sun Yellow Pages (YP). The functionality of the two services remains the same; only the name has changed. The name Yellow Pages is a registered trademark in the United Kingdom of British Telecommunications PLC, and must not be used without permission.

Name ypxfr, ypxfr_1perday, ypxfr_1perhour, ypxfr_2perday – transfer NIS map from a NIS server to host

Synopsis /usr/lib/netsvc/yp/ypxfr [-c] [-f] [-C *tid prog server*]
          [-d *ypdomain*] [-h *host*] [-s *ypdomain*] *mapname*

Description The ypxfr command moves an NIS map in the default domain for the local host to the local host by making use of normal NIS services. It creates a temporary map in the directory /var/yp/*ypdomain* (this directory must already exist; *ypdomain* is the default domain for the local host), fills it by enumerating the map's entries, fetches the map parameters (master and order number), and loads them. It then deletes any old versions of the map and moves the temporary map to the real *name*.

If run interactively, ypxfr writes its output to the terminal. However, if it is started without a controlling terminal, and if the log file /var/yp/ypxfr.log exists, it appends all its output to that file. Since ypxfr is most often run from the privileged user's crontab file, or by ypserv, the log file can retain a record of what was attempted, and what the results were.

For consistency between servers, ypxfr should be run periodically for every map in the NIS data base. Different maps change at different rates: a map might not change for months at a time, for instance, and can therefore be checked only once a day. Some maps might change several times per day. In such a case, you might want to check hourly for updates. A crontab(1) entry can be used to automatically perform periodic updates. Rather than having a separate crontab entry for each map, you can group commands to update several maps in a shell script. Examples (mnemonically named) are in /usr/sbin/yp: ypxfr_1perday, ypxfr_2perday, and ypxfr_1perhour.

Refer to ypfiles(4) for an overview of the NIS name service.

Options
-c   Do not send a "Clear current map" request to the local ypserv process. Use this flag if ypserv is not running locally at the time you are running ypxfr. Otherwise, ypxfr complains that it cannot communicate with the local ypserv, and the transfer fails.

-f   Force the transfer to occur even if the version at the master is not more recent than the local version.

-C *tid prog server*   This option is for use *only* by ypserv. When ypserv starts ypxfr, it specifies that ypxfr should call back a yppush process at the host *server*, registered as program number *prog*, and waiting for a response to transaction *tid*.

-d *ypdomain*   Specify a domain other than the default domain.

-h *host*   Get the map from *host*, regardless of the master. If *host* is not specified, ypxfr asks the NIS service for the name of the master, and tries to get the map from there. *host* must be a valid host name.

-s *ypdomain*   Specify a source domain from which to transfer a map that should be the same across domains.

Name zdb – ZFS debugger

Synopsis zdb *pool*

Description The zdb command is used by support engineers to diagnose failures and gather statistics. Since the ZFS file system is always consistent on disk and is self-repairing, zdb should only be run under the direction by a support engineer.

If no arguments are specified, zdb, performs basic consistency checks on the pool and associated datasets, and report any problems detected.

Any options supported by this command are internal to Sun and subject to change at any time.

Exit Status The following exit values are returned:

0   The pool is consistent.

1   An error was detected.

2   Invalid command line options were specified.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/zfs
Interface Stability	Uncommitted

See Also zfs(1M), zpool(1M), attributes(5)

Name zdump – time zone dumper

Synopsis zdump [--*version*] [-v] [-c [*loyear*,]*hiyear*] [*zonename*]...

Description The zdump command prints the current time for each time zone (*zonename*) listed on the command line. Specify *zonename* as the name of the time zone database file relative to /usr/share/lib/zoneinfo.

Specifying an invalid time zone (*zonename*) to zdump does not return an error, rather zdump uses UTC. This is consistent with the behavior of the library calls; zdump reflects the same behavior of the time routines in libc. See ctime(3C) and mktime(3C).

Options The following options are supported:

--*version* Outputs version information and exits.

-v Displays the entire contents of the time zone database file for *zonename*. Prints the time at the lowest possible time value; the time one day after the lowest possible time value; the times both one second before and exactly at each time at which the rules for computing local time change; the time at the highest possible time value; and the time at one day less than the highest possible time value. See mktime(3C) and ctime(3C) for information regarding time value (time_t). Each line of output ends with isdst=1 if the given time is Daylight Saving Time, or isdst=0 otherwise.

-c [*loyear*],*hiyear* Cuts off the verbose output near the start of the given year(s) . By default, the program cuts off verbose output near the start of the years -500 and 2500.

Exit Status The following exit values are returned:

0 Successful completion.

1 An error occurred.

Files /usr/share/lib/zoneinfo Standard zone information directory

Attributes See attributes(5) for descriptions of the following attributes:

```

Description   The zfs command configures ZFS datasets within a ZFS storage pool, as described in zpool(1M). A dataset is identified by a unique path within the ZFS namespace. For example:

pool/{*filesystem*,*volume*,*snapshot*}

where the maximum length of a dataset name is MAXNAMELEN (256 bytes).

A dataset can be one of the following:

file system
   A ZFS dataset of type filesystem can be mounted within the standard system namespace and behaves like other file systems. While ZFS file systems are designed to be POSIX compliant, known issues exist that prevent compliance in some cases. Applications that depend on standards conformance might fail due to nonstandard behavior when checking free file system space.

volume
   A logical volume exported as a raw or block device. This type of dataset should only be used under special circumstances. File systems are typically used in most environments.

snapshot
   A read-only version of a file system or volume at a given point in time. It is specified as *filesystem@name* or *volume@name*.

ZFS File System   A ZFS storage pool is a logical collection of devices that provide space for datasets. A storage
Hierarchy   pool is also the root of the ZFS file system hierarchy.

The root of the pool can be accessed as a file system, such as mounting and unmounting, taking snapshots, and setting properties. The physical storage characteristics, however, are managed by the zpool(1M) command.

See zpool(1M) for more information on creating and administering pools.

Snapshots   A snapshot is a read-only copy of a file system or volume. Snapshots can be created extremely quickly, and initially consume no additional space within the pool. As data within the active dataset changes, the snapshot consumes more data than would otherwise be shared with the active dataset.

Snapshots can have arbitrary names. Snapshots of volumes can be cloned or rolled back, but cannot be accessed independently.

File system snapshots can be accessed under the .zfs/snapshot directory in the root of the file system. Snapshots are automatically mounted on demand and may be unmounted at regular intervals. The visibility of the .zfs directory can be controlled by the snapdir property.

Clones   A clone is a writable volume or file system whose initial contents are the same as another dataset. As with snapshots, creating a clone is nearly instantaneous, and initially consumes no additional space.

Clones can only be created from a snapshot. When a snapshot is cloned, it creates an implicit dependency between the parent and child. Even though the clone is created somewhere else in the dataset hierarchy, the original snapshot cannot be destroyed as long as a clone exists. The origin property exposes this dependency, and the destroy command lists any such dependencies, if they exist.

The clone parent-child dependency relationship can be reversed by using the promote subcommand. This causes the "origin" file system to become a clone of the specified file system, which makes it possible to destroy the file system that the clone was created from.

Mount Points   Creating a ZFS file system is a simple operation, so the number of file systems per system is likely to be numerous. To cope with this, ZFS automatically manages mounting and unmounting file systems without the need to edit the /etc/vfstab file. All automatically managed file systems are mounted by ZFS at boot time.

By default, file systems are mounted under /*path*, where *path* is the name of the file system in the ZFS namespace. Directories are created and destroyed as needed.

A file system can also have a mount point set in the mountpoint property. This directory is created as needed, and ZFS automatically mounts the file system when the zfs mount -a command is invoked (without editing /etc/vfstab). The mountpoint property can be inherited, so if pool/home has a mount point of /export/stuff, then pool/home/user automatically inherits a mount point of /export/stuff/user.

A file system can be mounted temporarily at a location other than the file systems's persistent mount point by specifying the -o mountpoint=*value* option to the zfs mount command. This is only permitted for file systems with non-legacy mount points.

A file system mountpoint property of none prevents the file system from being mounted.

If needed, ZFS file systems can also be managed with traditional tools (mount, umount, /etc/vfstab). If a file system's mount point is set to legacy, ZFS makes no attempt to manage the file system, and the administrator is responsible for mounting and unmounting the file system.

Zones   The physical properties of an added file system are controlled by the global administrator. However, the zone administrator can create, modify, or destroy files within the added file system, depending on how the file system is mounted.

A dataset can also be delegated to a non-global zone by using the zonecfg add dataset subcommand. You cannot delegate a dataset to one zone and the children of the same dataset to another zone. The zone administrator can change properties of the dataset or any of its children. However, the quota property is controlled by the global administrator.

A ZFS volume can be added as a device to a non-global zone by using the zonecfg add device subcommand. However, its physical properties can be modified only by the global administrator.

For more information about zonecfg syntax, see zonecfg(1M).

After a dataset is delegated to a non-global zone, the zoned property is automatically set. A zoned file system can only be mounted in the global zone by use of a temporary mountpoint property (see "Temporary Mount Point Properties").

The global administrator can forcibly clear the zoned property, though this should be done with extreme care. The global administrator should verify that all the mount points are acceptable before clearing the property.

Deduplication   Deduplication is the process of removing redundant data at the block-level, reducing the total amount of data stored. Deduplication is pool-wide; each dataset can opt in or out using its own dedup property. If a file system has the dedup property enabled, duplicate data blocks are removed synchronously on write. The result is that only unique data are stored and common components are shared among files in all datasets in the pool that have dedup enabled.

Encryption   For a full description of ZFS encryption and the ZFS encryption syntax, see zfs_encrypt(1M).

Native Properties   Properties are divided into two types, native properties and user-defined (or "user") properties. Native properties either provide internal statistics or control ZFS behavior. In addition, native properties are either editable or read-only. User properties have no effect on ZFS behavior, but you can use them to annotate datasets in a way that is meaningful in your environment. For more information about user properties, see the "User Properties" section, below.

Every dataset has a set of properties that provide statistics about the dataset as well as control various behaviors. Properties are inherited from the parent unless overridden by the child. Some properties apply only to certain types of datasets (file systems, volumes, or snapshots).

The values of numeric properties can be specified using human-readable suffixes (for example, k, KB, M, Gb, and so forth, up to Z for zettabyte). The following are all valid (and equal) specifications:

1536M, 1.5g, 1.50GB

The values of non-numeric properties are case-sensitive and must be lowercase, except for the mountpoint property.

The following native properties consist of read-only statistics about the dataset. These properties can be neither set, nor inherited. Native properties apply to all dataset types unless otherwise noted.

available

The amount of space available to the dataset and all its children, assuming that there is no other activity in the pool. Because space is shared within a pool, availability can be limited by any number of factors, including physical pool size, quotas, reservations, or other datasets within the pool.

This property can also be referred to by its shortened column name, avail.

compressratio

The compression ratio achieved for this dataset, expressed as a multiplier. Compression can be turned on by running: zfs set compression=on *dataset*. The default value is off.

creation

The time this dataset was created.

defer_destroy

This property is on if the snapshot has been marked for deferred destroy by using the zfs destroy -d command. Otherwise, the property is off.

keystatus

For more information, see zfs_encrypt(1M).

mounted

For file systems, indicates whether the file system is currently mounted. This property can be either yes or no.

origin

For cloned file systems or volumes, the snapshot from which the clone was created. The origin cannot be destroyed (even with the -r or -f options) so long as a clone exists.

referenced

The amount of data that is accessible by this dataset, which may or may not be shared with other datasets in the pool. When a snapshot or clone is created, it initially references the same amount of space as the file system or snapshot it was created from, since its contents are identical.

This property can also be referred to by its shortened column name, refer.

rekeydate

For more information, see zfs_encrypt(1M).

type

The type of dataset: filesystem, volume, or snapshot.

used

The amount of space consumed by this dataset and all its descendents. This is the value that is checked against this dataset's quota and reservation. The space used does not include this dataset's reservation, but does take into account refreservation (through usedbyrefreservation) and the reservations of any descendent datasets (through

usedbychildren). The amount of space that a dataset consumes from its parent, as well as the amount of space that are freed if this dataset is recursively destroyed, is the greater of its space used and its reservation.

When snapshots (see the "Snapshots" section) are created, their space is initially shared between the snapshot and the file system, and possibly with previous snapshots. As the file system changes, space that was previously shared becomes unique to the snapshot, and counted in the snapshot's space used. Additionally, deleting snapshots can increase the amount of space unique to (and used by) other snapshots.

The amount of space used, available, or referenced does not take into account pending changes. Pending changes are generally accounted for within a few seconds. Committing a change to a disk using fsync(3C) or O_SYNC does not necessarily guarantee that the space usage information is updated immediately.

usedby*

The usedby* properties decompose the used properties into the various reasons that space is used. Specifically, used = usedbychildren + usedbydataset + usedbyrefreservation +, usedbysnapshots. These properties are only available for datasets created on pools that are "version 13" or higher.

usedbychildren

The amount of space used by children of this dataset, which would be freed if all the dataset's children were destroyed.

usedbydataset

The amount of space used by this dataset itself, which would be freed if the dataset was destroyed (after first removing any refreservation and destroying any necessary snapshots or descendents).

usedbyrefreservation

The amount of space used by a refreservation set on this dataset, which would be freed if the refreservation was removed.

Space accounted for by this property represents potential consumption by future writes, reserved in advance to prevent write allocation failures in this dataset. This can include unwritten data, space currently shared with snapshots, and compression savings for volumes (which may be lost when replaced with less compressible data). When allocations for later writes increase usedbydataset or usedbysnapshots, usedbyrefreservation will decrease accordingly.

usedbysnapshots

The amount of space consumed by snapshots of this dataset. In particular, it is the amount of space that would be freed if all of this dataset's snapshots were destroyed. Note that this is not simply the sum of the snapshots' used properties because space can be shared by multiple snapshots.

userused@*user*

 The amount of space consumed by the specified user in this dataset. Space is charged to the owner of each file, as displayed by ls -l. The amount of space charged is displayed by du and ls -s. See the zfs userspace subcommand for more information.

 Unprivileged users can access only their own space usage. The root user, or a user who has been granted the userused privilege with zfs allow, can access everyone's usage.

 The userused@... properties are not displayed by zfs get all. The user's name must be appended after the @ symbol, using one of the following forms:

- *POSIX name* (for example, joe)
- *POSIX numeric ID* (for example, 789)
- *SID name* (for example, joe.smith@mydomain)
- *SID numeric ID* (for example, S-1-123-456-789)

userrefs

 This property is set to the number of user holds on this snapshot. User holds are set by using the zfs hold command.

groupused@*group*

 The amount of space consumed by the specified group in this dataset. Space is charged to the group of each file, as displayed by ls -l. See the userused@*user* property for more information.

 Unprivileged users can only access their own groups' space usage. The root user, or a user who has been granted the groupused privilege with zfs allow, can access all groups' usage.

volblocksize=*blocksize*

 For volumes, specifies the block size of the volume. The blocksize cannot be changed once the volume has been written, so it should be set at volume creation time. The default blocksize for volumes is 8 KB. Any power of 2 from 512 bytes to 1 MB is valid.

 This property can also be referred to by its shortened column name, volblock.

The following native properties can be used to change the behavior of a ZFS dataset.

aclmode=discard | mask | passthrough

 Controls how an ACL is modified during chmod(2). A file system with an aclmode property of discard (the default) deletes all ACL entries that do not represent the mode of the file. An aclmode property of mask reduces user or group permissions. The permissions are reduced so that they are no greater than the group permission bits, unless it is a user entry that has the same UID as the owner of the file or directory. In this case, the ACL permissions are reduced so that they are no greater than owner permission bits. mask also preserves the ACL across mode changes (without an explicit ACL set [by means of chmod(1)] between the mode changes). A file system with an aclmode property of passthrough indicates that no changes will be made to the ACL other than generating the necessary ACL entries to represent the new mode of the file or directory.

aclinherit=discard | noallow | restricted | passthrough | passthrough-x

Controls how ACL entries are inherited when files and directories are created. A file system with an aclinherit property of discard does not inherit any ACL entries. A file system with an aclinherit property value of noallow only inherits inheritable ACL entries that specify "deny" permissions. The property value restricted (the default) removes the write_acl and write_owner permissions when the ACL entry is inherited. A file system with an aclinherit property value of passthrough inherits all inheritable ACL entries without any modifications made to the ACL entries when they are inherited. A file system with an aclinherit property value of passthrough-x has the same meaning as passthrough, except that all ACEs inherit the execute permission only if the file creation mode also requests the execute bit.

When the property value is set to passthrough, files are created with a mode determined by the inheritable ACEs. If no inheritable ACEs exist that affect the mode, then the mode is set in accordance to the requested mode from the application.

atime=on | off

Controls whether the access time for files is updated when they are read. Turning this property off avoids producing write traffic when reading files and can result in significant performance gains, though it might confuse mailers and other similar utilities. The default value is on.

canmount=on | off | noauto

If this property is set to off, the file system cannot be mounted, and is ignored by zfs mount -a. Setting this property to off is similar to setting the mountpoint property to none, except that the dataset still has a normal mountpoint property, which can be inherited. Setting this property to off allows datasets to be used solely as a mechanism to inherit properties. One example of setting canmount=off is to have two datasets with the same mountpoint, so that the children of both datasets appear in the same directory, but might have different inherited characteristics.

When the noauto option is set, a dataset can only be mounted and unmounted explicitly. The dataset is not mounted automatically when the dataset is created or imported, nor is it mounted by the zfs mount -a command or unmounted by the zfs unmount -a command.

This property is not inherited.

checksum=on | off | fletcher2, | fletcher4 | sha256 | sha256+mac

Controls the checksum used to verify data integrity. The default value is on, which automatically selects an appropriate algorithm (currently, fletcher4, but this may change in future releases). The value off disables integrity checking on user data. Disabling checksums is *NOT* a recommended practice.

Changing this property affects only newly-written data.

The value of sha256+mac is only available when encryption is enabled. The checksum property becomes readonly when encryption is enabled, and then is always set to sha256+mac.

compression=on | off | lzjb | gzip | gzip-*N* | zle

Controls the compression algorithm used for this dataset. The lzjb compression algorithm is optimized for performance while providing decent data compression. Setting compression to on uses the lzjb compression algorithm. The gzip compression algorithm uses the same compression as the gzip(1) command. You can specify the gzip level by using the value gzip-*N* where *N* is an integer from 1 (fastest) to 9 (best compression ratio). Currently, gzip is equivalent to gzip-6 (which is also the default for gzip(1)).

This property can also be referred to by its shortened column name compress. Changing this property affects only newly-written data.

copies=1 | 2 | 3

Controls the number of copies of data stored for this dataset. These copies are in addition to any redundancy provided by the pool, for example, mirroring or RAID-Z. The copies are stored on different disks, if possible. The space used by multiple copies is charged to the associated file and dataset, changing the used property and counting against quotas and reservations.

Changing this property only affects newly-written data. Therefore, set this property at file system creation time by using the -o copies=*N* option.

When encryption is enabled on a dataset, copies can be set to a maximum of 2.

dedup=on | off | verify | sha256[,verify]

Controls whether deduplication is in effect for a dataset. The default value is off. The default checksum used for deduplication is sha256 (subject to change). When dedup is enabled, the dedup checksum algorithm overrides the checksum property. Setting the value to verify is equivalent to specifying sha256,verify.

If the property is set to verify, then, whenever two blocks have the same signature, ZFS will do a byte-for-byte comparison with the existing block to ensure that the contents are identical.

devices=on | off

Controls whether device nodes can be opened on this file system. The default value is on.

exec=on | off

Controls whether processes can be executed from within this file system. The default value is on.

logbias = latency | throughput

Controls how ZFS optimizes synchronous requests for this dataset. If logbias is set to latency, ZFS uses the pool's separate log devices, if any, to handle the requests at low latency. If logbias is set to throughput, ZFS does not use the pool's separate log devices.

Instead, ZFS optimizes synchronous operations for global pool throughput and efficient use of resources. The default value is latency.

mlslabel=*label* | none

The mlslabel property is a sensitivity label that determines if a dataset can be mounted in a zone on a system with Trusted Extensions enabled. If the labeled dataset matches the labeled zone, the dataset can be mounted and accessed from the labeled zone.

When the mlslabel property is not set, the default value is none. Setting the mlslabel property to none is equivalent to removing the property.

The mlslabel property can be modified only when Trusted Extensions is enabled and only with appropriate privilege. Rights to modify it cannot be delegated. When changing a label to a higher label or setting the initial dataset label, the {PRIV_FILE_UPGRADE_SL} privilege is required. When changing a label to a lower label or the default (none), the {PRIV_FILE_DOWNGRADE_SL} privilege is required. Changing the dataset to labels other than the default can be done only when the dataset is not mounted. When a dataset with the default label is mounted into a labeled-zone, the mount operation automatically sets the mlslabel property to the label of that zone.

When Trusted Extensions is *not* enabled, only datasets with the default label (none) can be mounted.

mountpoint=*path* | none | legacy

Controls the mount point used for this file system. See the "Mount Points" section for more information on how this property is used.

When the mountpoint property is changed for a file system, the file system and any children that inherit the mount point are unmounted. If the new value is legacy, then they remain unmounted. Otherwise, they are automatically remounted in the new location if the property was previously legacy or none, or if they were mounted before the property was changed. In addition, any shared file systems are unshared and shared in the new location.

nbmand=on | off

For more information, see zfs_share(1M).

primarycache=all | none | metadata

Controls what is cached in the primary cache (ARC). If this property is set to all, then both user data and metadata is cached. If this property is set to none, then neither user data nor metadata is cached. If this property is set to metadata, then only metadata is cached. The default value is all.

quota=*size* | none

Limits the amount of space a dataset and its descendents can consume. This property enforces a hard limit on the amount of space used. This includes all space consumed by

descendents, including file systems and snapshots. Setting a quota on a descendent of a dataset that already has a quota does not override the ancestor's quota, but rather imposes an additional limit.

Quotas cannot be set on volumes, as the volsize property acts as an implicit quota.

sync=standard | always | disabled

Determines the degree to which file system transactions are synchronized. This property can be set when a dataset is created, or dynamically, and will take effect immediately. This property can have one of the following settings:

standard

The default option. Synchronous file system transactions are written to the intent log and then all devices written are flushed to ensure the data is stable (that is, not cached by device controllers).

always

Each file system transaction is written and flushed to stable storage. This value has a significant performance penalty but might be appropriate for troubleshooting synchronous file system transactions.

disabled

Synchronous requests are disabled. File system transactions commit to stable storage only on the next DMU transaction group commit, which might be after many seconds. This setting gives the highest performance. However, it is very dangerous as ZFS would be ignoring the synchronous transaction demands of applications such as databases or NFS. Furthermore, when this setting is in effect for the currently active root or /var filesystem, out-of-spec behavior, application data loss, and increased vulnerability to replay attacks can result. Administrators should only use this option only when these risks are understood.

userquota@*user*=*size* | none

Limits the amount of space consumed by the specified user. Similar to the refquota property, the userquota space calculation does not include space that is used by descendent datasets, such as snapshots and clones. User space consumption is identified by the userspace@*user* property.

Enforcement of user quotas may be delayed by several seconds. This delay means that a user might exceed her quota before the system notices that she is over quota. The system would then begin to refuse additional writes with the EDQUOT error message . See the zfs userspace subcommand for more information.

Unprivileged users can only access their own groups' space usage. The root user, or a user who has been granted the userquota privilege with zfs allow, can get and set everyone's quota.

This property is not available on volumes, on file systems before version 4, or on pools before version 15. The userquota@... properties are not displayed by zfs get all. The user's name must be appended after the @ symbol, using one of the following forms:

- *POSIX name* (for example, joe)
- *POSIX numeric ID* (for example, 789)
- *SID name* (for example, joe.smith@mydomain)
- *SID numeric ID* (for example, S-1-123-456-789)

groupquota@*group*=*size* | none
   Limits the amount of space consumed by the specified group. Group space consumption is identified by the userquota@*user* property.

   Unprivileged users can access only their own groups' space usage. The root user, or a user who has been granted the groupquota privilege with zfs allow, can get and set all groups' quotas.

readonly=on | off
   Controls whether this dataset can be modified. The default value is off.

   This property can also be referred to by its shortened column name, rdonly.

recordsize=*size*
   Specifies a suggested block size for files in the file system. This property is designed solely for use with database workloads that access files in fixed-size records. ZFS automatically tunes block sizes according to internal algorithms optimized for typical access patterns.

   For databases that create very large files but access them in small random chunks, these algorithms may be suboptimal. Specifying a recordsize greater than or equal to the record size of the database can result in significant performance gains. Use of this property for general purpose file systems is strongly discouraged, and may adversely affect performance.

   The default recordsize is 128 KB. The size specified must be a power of two greater than or equal to 512 and less than or equal to 1 MB.

   Changing the file system's recordsize affects only files created afterward; existing files and received data are unaffected.

   This property can also be referred to by its shortened column name, recsize.

refquota=*size* | none
   Limits the amount of space a dataset can consume. This property enforces a hard limit on the amount of space used. This hard limit does not include space used by descendents, including file systems and snapshots.

refreservation=*size* | none
   The minimum amount of space guaranteed to a dataset, not including its descendents. When the usedbydataset space is below this value, the dataset is treated as if it were taking up the amount of space specified by refreservation. The usedbyrefreservation figure

represents this extra space, adding to the total used space charged to the dataset, and in turn consuming from the parent datasets' usage, quotas, and reservations. This protects the dataset from overcommitment of pool resources, by ensuring that space for future writes is reserved in advance.

Space shared with snapshots can later be replaced with new data, and the snapshot represents a committment to keep both copies. If refreservation is set, usedbyrefreservation must be increased to the full size of refreservation when taking a new snapshot, accounting for this commitment. If there is insufficient space available to the dataset for this increase, snapshot creation will be denied.

This property can also be referred to by its shortened column name, refreserv.

reservation=*size* | none

The minimum amount of space guaranteed to a dataset and its descendents. When the amount of space used is below this value, the dataset is treated as if it were taking up the amount of space specified by its reservation. Reservations are accounted for in the parent datasets' space used, and count against the parent datasets' quotas and reservations.

This property can also be referred to by its shortened column name, reserv.

rstchown=on | off

Indicates whether the file system restricts users from giving away their files by means of chown(1) or the chown(2) system call. The default is to restrict chown. When rstchown is off then chown will act as if the user has the PRIV_FILE_CHOWN_SELF privilege.

secondarycache=all | none | metadata

Controls what is cached in the secondary cache (L2ARC). If this property is set to all, then both user data and metadata is cached. If this property is set to none, then neither user data nor metadata is cached. If this property is set to metadata, then only metadata is cached. The default value is all.

setuid=on | off

Controls whether the set-UID bit is respected for the file system. The default value is on.

shadow=*URI* | none

Identifies a ZFS file system as a "shadow" of the file system described by the *URI*. Data is migrated to a shadow file system with this property set from the file system identified by the *URI*. The file system to be migrated must be read-only for a complete migration.

Access to a directory that is not yet migrated in the shadow file system is blocked until the entire directory is migrated. Access to a file that is not yet migrated in the shadow file system causes only a portion of the file being accessed to be migrated. Multiple processes can migrate different portions of a file at the same time.

Two forms of URI are accepted, one for migrating a local file system to another file system on the same physical system, and one for remotely migrating a file system from an NFS server. The forms are:

```
file:///path
nfs://host/path
```

If shadowd(1M) is still running when the migration is complete, the file system is automatically remounted with the shadow property set to none. Or, when the migration is complete, you can manually set the shadow property to none.

sharenfs=on | off
   For more information, see zfs_share(1M).

sharesmb=on | off
   For more information, see zfs_share(1M).

snapdir=hidden | visible
   Controls whether the .zfs directory is hidden or visible in the root of the file system as discussed in the "Snapshots" section. The default value is hidden.

version=1 | 2 | current
   The on-disk version of this file system, which is independent of the pool version. This property can only be set to later supported versions. See the zfs upgrade command.

volsize=size
   Specifies the logical size of the volume. By default, creating a volume establishes a refreservation that is a somewhat larger than the actual logical volume size, to account for ZFS metadata overhead. Any changes to volsize are reflected in an equivalent change to the refreservation. The volsize can only be set to a multiple of volblocksize, and cannot be zero.

   The refreservation is set on the volume to prevent unexpected behavior for consumers. Without the reservation, the volume could run out of space, resulting in undefined behavior or data corruption, depending on how the volume is used. These effects can also occur when the volume size is changed while it is in use (particularly when shrinking the size). Extreme care should be used when adjusting the volume size.

   Though not recommended, a "sparse volume" (also known as "thin provisioning") can be created by specifying the -s option to the zfs create -V command. A "sparse volume" is a volume where the reservation is less then the volume size. Consequently, writes to a sparse volume can fail with ENOSPC when the pool is low on space. For a sparse volume, changes to volsize are not reflected in the reservation.

vscan=on | off
   For more information, see zfs_share(1M).

xattr=on | off
   Controls whether extended attributes are enabled for this file system. The default value is on.

zoned=on | off
   Controls whether the dataset is managed from a non-global zone. See the "Zones" section for more information. The default value is off.

The following properties cannot be changed after the file system is created and, therefore, should be set when the file system is created. If the properties are not set with the zfs create or zpool create commands, these properties are inherited from the parent dataset. If the parent dataset lacks these properties due to having been created prior to these features being supported, the new file system will have the default values for these properties.

casesensitivity=sensitive | insensitive | mixed
    For more information, see zfs_share(1M).

normalization = none | formC | formD | formKC | formKD
    For more information, see zfs_share(1M).

utf8only=on | off
    For more information, see zfs_share(1M).

encryption=off | on | aes-128-ccm | aes-192-ccm | aes-256-ccm | aes-128-gcm | aes-192-gcm | aes-256-gcm
    For more information, see zfs_encrypt(1M).

The following property must be specified at creation time and can modified by using special commands:

keysource=*raw* | *hex* | *passphrase*,*prompt* | *file*
    For more information, see zfs_encrypt(1M).

Temporary Mount Point Properties
When a file system is mounted, either through the legacy mount(1M) command or the zfs mount command, its mount options are set according to its properties. The correlation between properties and mount options is as follows:

```
PROPERTY                 MOUNT OPTION
  devices                  devices/nodevices
  exec                     exec/noexec
  readonly                 ro/rw
  setuid                   setuid/nosetuid
  xattr                    xattr/noxattr
  rstchown                 rstchown/norstchown
```

In addition, these options can be set on a per-mount basis using the -o option, without affecting the property that is stored on disk. The values specified on the command line override the values stored in the dataset. The -nosuid option is an alias for nodevices,nosetuid. These properties are reported as "temporary" by the zfs get command. For properties other than mountpoint, if the properties are changed while the dataset is mounted, the new setting overrides any temporary settings. The mountpoint property cannot be changed while a temporary mountpoint property is in effect (that is, while the dataset is mounted at a temporary location).

User Properties   In addition to the standard native properties, ZFS supports arbitrary user properties. User properties have no effect on ZFS behavior, but applications or administrators can use them to annotate datasets (file systems, volumes, and snapshots).

User property names must contain a colon (:) character to distinguish them from native properties. They may contain lowercase letters, numbers, and the following punctuation characters: colon (:), dash (-), period (.), and underscore (_). The expected convention is that the property name is divided into two portions such as *module*:*property*, but this namespace is not enforced by ZFS. User property names can be at most 256 characters, and cannot begin with a dash (-).

When making programmatic use of user properties, it is strongly suggested to use a reversed DNS domain name for the *module* component of property names to reduce the chance that two independently-developed packages use the same property name for different purposes. In the Oracle Solaris release, the com.oracle user property is reserved for beadm command and library

The values of user properties are arbitrary strings, are always inherited, and are never validated. All of the commands that operate on properties (zfs list, zfs get, zfs set, and so forth) can be used to manipulate both native properties and user properties. Use the zfs inherit command to clear a user property . If the property is not defined in any parent dataset, it is removed entirely. Property values are limited to 1024 characters.

ZFS Volumes as Swap
or Dump Devices
During an initial installation, a swap device and dump device are created on ZFS volumes in the ZFS root pool. Separate ZFS volumes must be used for the swap area and dump devices. Do not swap to a file on a ZFS file system. A ZFS swap file configuration is not supported.

You can encrypt a ZFS volume used as a swap device by specifying the encryption property for that device and specifying the encrypted option in vfstab(4). For more information about the encryption property, see zfs_encrypt.1m.

If you need to change your swap area or dump device after the system is installed or upgraded, use the swap(1M) and dumpadm(1M) commands. If you need to change the size of your swap area or dump device, see the *Oracle Solaris Administration: ZFS File Systems*

Subcommands   All subcommands that modify state are logged persistently to the pool in their original form.

zfs ?
    Displays a help message.

zfs help *command* | help | *property property-name* | *permission*
    Displays zfs command usage information. You can display help for a specific command, property, or delegated permission. If you display help for a specific command or property, the command syntax or property value is displayed. Using zfs help without any arguments displays a complete list of zfs commands.

zfs create [-p] [-o *property=value*] ... *filesystem*
    Creates a new ZFS file system. The file system is automatically mounted according to the mountpoint property inherited from the parent.

-p

    Creates all the non-existing parent datasets. Datasets created in this manner are automatically mounted according to the mountpoint property inherited from their parent. Any property specified on the command line using the -o option is ignored. If the target filesystem already exists, the operation completes successfully.

-o *property=value*

    Sets the specified property as if the command zfs set *property=value* was invoked at the same time the dataset was created. Any editable ZFS property can also be set at creation time. Multiple -o options can be specified. An error results if the same property is specified in multiple -o options.

zfs create [-ps] [-b *blocksize*] [-o *property=value*] ... -V *size volume*

    Creates a volume of the given size. The volume is exported as a block device in /dev/zvol/{dsk,rdsk}/*path*, where *path* is the name of the volume in the ZFS namespace. The size represents the logical size as exported by the device. By default, a reservation of equal size is created.

    size is automatically rounded up to the nearest 128 KB to ensure that the volume has an integral number of blocks regardless of *blocksize*.

-p

    Creates all the non-existing parent datasets. Datasets created in this manner are automatically mounted according to the mountpoint property inherited from their parent. Any property specified on the command line using the -o option is ignored. If the target filesystem already exists, the operation completes successfully.

-s

    Creates a sparse volume with no reservation. See volsize in the Native Properties section for more information about sparse volumes.

-o *property=value*

    Sets the specified property as if the zfs set *property=value* command was invoked at the same time the dataset was created. Any editable ZFS property can also be set at creation time. Multiple -o options can be specified. An error results if the same property is specified in multiple -o options.

-b *blocksize*

    Equivalent to -o volblocksize=*blocksize*. If this option is specified in conjunction with -o volblocksize, the resulting behavior is undefined.

zfs destroy [-rRf] *filesystem|volume*

    Destroys the given dataset. By default, the command unshares any file systems that are currently shared, unmounts any file systems that are currently mounted, and refuses to destroy a dataset that has active dependents (children or clones).

-r

    Recursively destroy all children.

-R

Recursively destroy all dependents, including cloned file systems outside the target hierarchy.

-f

Force an unmount of any file systems using the unmount -f command. This option has no effect on non-file systems or unmounted file systems.

Extreme care should be taken when applying either the -r or the -f options, as they can destroy large portions of a pool and cause unexpected behavior for mounted file systems in use.

zfs destroy [-rRd] *snapshot*

The given snapshot is destroyed immediately if and only if the zfs destroy command without the -d option would have destroyed it. Such immediate destruction would occur, for example, if the snapshot had no clones and the user-initiated reference count were zero.

If the snapshot does not qualify for immediate destruction, it is marked for deferred deletion. In this state, it exists as a usable, visible snapshot until both of the preconditions listed above are met, at which point it is destroyed.

-d

Defer snapshot deletion.

-r

Destroy (or mark for deferred deletion) all snapshots with this name in descendent file systems.

-R

Recursively destroy all dependents.

zfs snapshot [-r] [-o *property=value*] ... *filesystem@snapname*|*volume@snapname*

Creates a snapshot with the given name. All previous modifications by successful system calls to the file system are part of the snapshot. zfs snap can be used as an alias for zfs snapshot. See the "Snapshots" section for details.

-r

Recursively create snapshots of all descendent datasets. Snapshots are taken atomically, so that all recursive snapshots correspond to the same moment in time.

-o *property=value*

Sets the specified property; see zfs create for details.

zfs rollback [-rRf] *snapshot*

Roll back the given dataset to a previous snapshot. When a dataset is rolled back, all data that has changed since the snapshot is discarded, and the dataset reverts to the state at the time of the snapshot. By default, the command refuses to roll back to a snapshot other than the most recent one. In order to do so, all intermediate snapshots must be destroyed by specifying the -r option.

The -rR options do not recursively destroy the child snapshots of a recursive snapshot. Only the top-level recursive snapshot is destroyed by either of these options. To completely roll back a recursive snapshot, you must rollback the individual child snapshots.

-r

Recursively destroy any snapshots more recent than the one specified.

-R

Recursively destroy any more recent snapshots, as well as any clones of those snapshots.

-f

Used with the -R option to force an unmount of any clone file systems that are to be destroyed.

zfs clone [-p] [-K] [-o *property=value*] ... *snapshot filesystem|volume*

Creates a clone of the given snapshot. See the "Clones" section for details. The target dataset can be located anywhere in the ZFS hierarchy, and is created as the same type as the original.

-p

Creates all the non-existing parent datasets. Datasets created in this manner are automatically mounted according to the mountpoint property inherited from their parent. If the target filesystem or volume already exists, the operation completes successfully.

-o *property=value*

Sets the specified property; see zfs create for details.

-K

For information, see zfs_encrypt(1M).

zfs promote *clone-filesystem*

Promotes a clone file system to no longer be dependent on its "origin" snapshot. This makes it possible to destroy the file system that the clone was created from. The clone parent-child dependency relationship is reversed, so that the origin file system becomes a clone of the specified file system.

The snapshot that was cloned, and any snapshots previous to this snapshot, are now owned by the promoted clone. The space they use moves from the origin file system to the promoted clone, so enough space must be available to accommodate these snapshots. No new space is consumed by this operation, but the space accounting is adjusted. The promoted clone must not have any conflicting snapshot names of its own. The rename subcommand can be used to rename any conflicting snapshots.

zfs rename *filesystem|volume|snapshot*
filesystem|volume|snapshot
zfs rename [-p] *filesystem|volume filesystem|volume*

Renames the given dataset. The new target can be located anywhere in the ZFS hierarchy, with the exception of snapshots. Snapshots can only be renamed within the parent file

system or volume. When renaming a snapshot, the parent file system of the snapshot does not need to be specified as part of the second argument. Renamed file systems can inherit new mount points, in which case they are unmounted and remounted at the new mount point.

-p
  Creates all the nonexistent parent datasets. Datasets created in this manner are automatically mounted according to the mountpoint property inherited from their parent.

zfs rename -r *snapshot snapshot*
  Recursively rename the snapshots of all descendent datasets. Snapshots are the only dataset that can be renamed recursively.

zfs list [-rH|-d *depth*] [-o *property*[,...]] [-t *type*[,...]] [-s *property*] ... [-S *property*] ...
[*filesystem|volume|snapshot|path*] ...
  Lists the property information for the given datasets in tabular form. If specified, you can list property information by the absolute pathname or the relative pathname. By default, all file systems and volumes are displayed. Snapshots are displayed if the listsnaps property is on (the default is off). The following fields are displayed: name, used, available, referenced, mountpoint.

-H
  Used for scripting mode. Do not print headers and separate fields by a single tab instead of arbitrary white space.

-r
  Recursively display any children of the dataset on the command line.

-d *depth*
  Recursively display any children of the dataset, limiting the recursion to maximum *depth*. A depth of 1 will display only the dataset and its direct children.

-o *property*
  A comma-separated list of properties to display. The property must be:
  ▪ One of the properties described in the "Native Properties" section
  ▪ A user property
  ▪ The value name to display the dataset name
  ▪ The value space to display space usage properties on file systems and volumes. This is a shortcut for specifying
    -o name,avail,used,usedsnap,usedds,usedrefreserv,usedchild
    -t filesystem,volume syntax.

-s *property*
  A property for sorting the output by column in ascending order based on the value of the property. The property must be one of the properties described in the "Properties" section, or the special value name to sort by the dataset name. Multiple properties can be

specified at one time using multiple -s property options. Multiple -s options are evaluated from left to right in decreasing order of importance.

The following is a list of sorting criteria:

- Numeric types sort in numeric order.

- String types sort in alphabetical order.

- Types inappropriate for a row sort that row to the literal bottom, regardless of the specified ordering.

- If no sorting options are specified the existing behavior of zfs list is preserved.

-S *property*
Same as the -s option, but sorts by property in descending order.

-t *type*
A comma-separated list of types to display, where *type* is one of filesystem, snapshot , volume, or all. For example, specifying -t snapshot displays only snapshots. The following aliases can be used in place of the type specifiers: fs (filesystem), snap (snapshot), and vol (volume).

zfs set [-r] *property*=*value filesystem*|*volume*|*snapshot* ...
Sets the property to the given value for each dataset. Only some properties can be edited. See the "Properties" section for more information on what properties can be set and acceptable values. Numeric values can be specified as exact values, or in a human-readable form with a suffix of B, K, M, G, T, P, E, Z (for bytes, kilobytes, megabytes, gigabytes, terabytes, petabytes, exabytes, or zettabytes, respectively). User properties can be set on snapshots. For more information, see the "User Properties" section.

-r
Recursively apply the effective value of the setting throughout the subtree of child datasets. The effective value may be set or inherited, depending on the property.

zfs get [-rHp|-d *depth*] [-o all | *field*[,...] [-s *source*[,...]] all | *property*[,...]
filesystem|*volume*|*snapshot* ...
Displays properties for the given datasets. If no datasets are specified, then the command displays properties for all datasets on the system. For each property, the following columns are displayed:

```
name      Dataset name
property  Property name
value     Property value
source    Property source. Can either be local, default,
          temporary, inherited, or none (-).
```

All columns except the RECEIVED column are displayed by default; specify particular or all columns, using the -o option. This command takes a comma-separated list of properties as described in the "Native Properties" and "User Properties" sections.

The special value `all` can be used to display all properties that apply to the given dataset's type (filesystem, volume, or snapshot).

-r

Recursively display properties for any children.

-d *depth*

Recursively display any children of the dataset, limiting the recursion to *depth*. A depth of 1 will display only the dataset and its direct children.

-H

Display output in a form more easily parsed by scripts. Any headers are omitted, and fields are explicitly separated by a single tab instead of an arbitrary amount of space.

-o *field*

Set of fields to display. One or more of:

`name,property,value,received,source`

Present multiple fields as a comma-separated list. The default value is:

`name,property,value,source`

The keyword `all` specifies all sources.

-s *source*

A comma-separated list of sources to display. Those properties coming from a source other than those in this list are ignored. Each source must be one of the following:

`local,default,inherited,temporary,received,none`

The default value is all sources.

-p

Display numbers in parseable (exact) values.

zfs set share=*name=sharename*,path=*pathname*,[desc=*description*],prot=smb |
nfs[,*property=value*[,...]] *filesystem*

For a full description of zfs set share syntax, see zfs_share(1M).

zfs inherit [-rS] *property filesystem*|*volume*|*snapshot* ...

Clears the specified property, causing it to be inherited from an ancestor. If no ancestor has the property set, then the default value is used. See the "Properties" section for a listing of default values, and details on which properties can be inherited.

-r

Recursively inherit the given property for all children.

-S

Revert to the received property value, if any. If the property does not have a received value, the behavior of zfs inherit -S is the same as zfs inherit without -S. If the property does have a received value, zfs inherit masks the received value with the inherited value until zfs inherit -S reverts to the received value.

zfs upgrade
  Identifies a file system version, which determines available file system features in the
  currently running software release. You can continue to use older file system versions, but
  some features might not be available. A file system can be upgraded by using the zfs
  upgrade -a command. You will not be able to access a file system of a later version on a
  system that runs an earlier software version.

zfs upgrade [-v]
  Displays ZFS file system versions that are supported by the current software. The current
  ZFS file system versions and all previously supported versions are displayed, along with an
  explanation of the features provided with each version.

zfs upgrade [-r] [-V *version*] [-a | *filesystem*]
  Upgrades file systems to a new, on-disk version. Upgrading a file system means that it will
  no longer be accessible on a system running an older software version. A zfs send stream
  that is generated from a new file system snapshot cannot be accessed on a system that runs
  an older software version.

  In general, the file system version is independent of the pool version. See zpool(1M) for
  information on the zpool upgrade command.

  In some cases, the file system version and the pool version are interrelated and the pool
  version must be upgraded before the file system version can be upgraded.

  -a
    Upgrade all file systems on all imported pools.

  filesystem
    Upgrade the specified file system.

  -r
    Upgrade the specified file system and all descendent file systems.

  -V *version*
    Upgrade to the specified *version*. If the -V flag is not specified, this command upgrades
    to the most recent version. This option can only be used to increase the version number,
    and only up to the most recent version supported by this software.

zfs userspace [-hniHp] [-o *field*[,...]] [-sS *field*]... [-t *type* [,...]] *filesystem* | *snapshot*
  Displays space consumed by, and quotas on, each user in the specified filesystem or
  snapshot. This corresponds to the userused@*user* and userquota@*user* properties.

  -h
    Display syntax help message and exit.

  -n
    Print numeric ID instead of user/group name.

  -H
    Do not print headers, use tab-delimited output.

-p

    Use exact (parseable) numeric output.

-o *field*[,...]

    Display only the specified fields from the following set, `type,name,used,quota`. The default is to display all fields.

-s *field*

    Sort output by this field. The *s* and *S* flags may be specified multiple times to sort first by one field, then by another. The default is -s type -s name.

-S *field*

    Sort by this field in reverse order. See -s.

-t *type*[,...]

    Print only the specified types from the following set, `all,posixuser,smbuser,posixgroup,smbgroup`.

    The default is -t posixuser,smbuser

    The default can be changed to include group types.

-i

    Translate SID to POSIX ID. The POSIX ID may be ephemeral if no mapping exists. Normal POSIX interfaces (for example, stat(2), ls -l) perform this translation, so the -i option allows the output from zfs userspace to be compared directly with those utilities. However, -i may lead to confusion if some files were created by an SMB user before a SMB-to-POSIX name mapping was established. In such a case, some files are owned by the SMB entity and some by the POSIX entity. However, the -i option will report that the POSIX entity has the total usage and quota for both.

zfs groupspace [-hniHp] [-o *field*[,...]] [-sS *field*]... [-t *type* [,...]] *filesystem* | *snapshot*

    Displays space consumed by, and quotas on, each group in the specified filesystem or snapshot. This subcommand is identical to zfs userspace, except that the default types to display are -t posixgroup,smbgroup.

-

zfs mount

    Displays all ZFS file systems currently mounted.

zfs mount [-vOS] [-o *options*] -a | *filesystem*

    Mounts ZFS file systems. Invoked automatically as part of the boot process.

-o *options*

    An optional, comma-separated list of mount options to use temporarily for the duration of the mount. See the "Temporary Mount Point Properties" section for details.

-O

    Perform an overlay mount. See mount(1M) for more information.

-v

Report mount progress.

-a

Mount all available ZFS file systems. Invoked automatically as part of the boot process.

filesystem

Mount the specified filesystem.

A zfs mount operation for an encrypted dataset might prompt you for a key, depending on the keysource property value. This might occur, for example, if the keysource locator is set to prompt.

zfs unmount [-f] -a | *filesystem*|*mountpoint*

Unmounts currently mounted ZFS file systems. Invoked automatically as part of the shutdown process.

-f

Forcefully unmount the file system, even if it is currently in use.

-a

Unmount all available ZFS file systems. Invoked automatically as part of the boot process.

filesystem|*mountpoint*

Unmount the specified filesystem. The command can also be given a path to a ZFS file system mount point on the system.

For an encrypted dataset, the key is not unloaded when the file system is unmounted. To unload the key, see zfs key.

zfs share -a | *dataset*

For a full description of zfs share syntax and examples, see zfs_share(1M).

zfs unshare -a | *dataset*|*mountpoint*

For a full description of zfs unshare syntax and examples, see zfs_share(1M).

zfs send [-DvRbp] [-[iI] *snapshot*] *snapshot*
zfs send -r [-Dvbcp] [-i *snapshot*] *snapshot*

Creates a stream representation of the second *snapshot*, which is written to standard output. The output can be redirected to a file or to a different system (for example, using ssh(1). By default, a full stream is generated.

-b

Sends only received property values whether or not they are overridden by local settings, but only if the dataset has ever been received. Use this option when you want zfs receive to restore received properties backed up on the sent dataset and to avoid sending local settings that may have nothing to do with the source dataset, but only with how the data is backed up.

-c

> Create a self-contained stream. A self-contained stream is one that is not dependent on any datasets not included in the stream package. Valid only with the -r option. If used with the -i option, the stream will be dependent on the snapshot specified as an argument to the that option.
>
> See the "ZFS Streams" section of the *ZFS Administration Guide* for details.

-D

> Perform dedup processing on the stream. Deduplicated streams cannot be received on systems that do not support the stream deduplication feature.
>
> See the "ZFS Streams" section of the *ZFS Administration Guide* to understand how a replication stream package differs from a recursive stream package.

-i *snapshot*

> Generate an incremental stream from the first *snapshot* to the second *snapshot*. The incremental source (the first *snapshot*) can be specified as the last component of the snapshot name (for example, the part after the @), and it is assumed to be from the same file system as the second *snapshot*.
>
> If the destination is a clone, the source may be the origin snapshot, which must be fully specified (for example, pool/fs@origin, not just @origin).

-I *snapshot*

> Generate a stream package that sends all intermediary snapshots from the first snapshot to the second snapshot. For example, -I @a fs@d is similar to -i @a fs@b; -i @b fs@c; -i @c fs@d. The incremental source snapshot may be specified as with the -i option.

-R

> Generate a replication stream package, which will replicate the specified filesystem, and all descendent file systems, up to the named snapshot. When received, all properties, snapshots, descendent file systems, and clones are preserved.
>
> If the -i or -I flags are used in conjunction with the -R flag, an incremental replication stream is generated. The current values of properties, and current snapshot and file system names are set when the stream is received. If the -F flag is specified when this stream is received, snapshots and file systems that do not exist on the sending side are destroyed.

-r

> Generate a recursive stream package. A recursive stream package contains a series of full and/or incremental streams. When received, all properties and descendent file systems are preserved. Unlike with the replication stream packages generated with the -R flag, intermediate snapshots are not preserved unless the intermediate snapshot is the origin of a clone that is included in the stream.

If the -i option is used in conjunction with the -r option, an incremental recursive stream is generated. The current values of properties as well as current snapshot and file system names are set when the stream is received. If the -F option is specified when this stream is received, snapshots and file systems that do not exist on the sending side are destroyed. The -I option cannot be used in conjunction with the -r option.

When combined with the -c option, a self-contained recursive stream package is created. If both the -c and -i options are used, file systems and volumes that do not have the snapshot specified with the -i option are sent as self-contained streams.

See the "ZFS Streams" section of the *ZFS Administration Guide* to understand how a recursive stream package differs from a replication stream package.

-p

Send properties.

-v

Print verbose information about the stream package generated.

The format of the stream is committed. You will be able to receive your streams on future versions of ZFS.

zfs receive [-vnFu] [[-o *property=value*] | [-x *property*]] ... *filesystem|volume|snapshot*
zfs receive [-vnFu] [[-o *property=value*] | [-x *property*]] ... [-d | -e] *filesystem*

Creates a snapshot whose contents are as specified in the stream provided on standard input. If a full stream is received, then a new file system is created as well. Streams are created using the zfs send subcommand, which by default creates a full stream. zfs recv can be used as an alias for zfs receive.

If an incremental stream is received, then the destination file system must already exist, and its most recent snapshot must match the incremental stream's source. For ZFS volumes, the destination device link is destroyed and recreated, which means the volume cannot be accessed during the receive operation.

When a snapshot replication package stream that is generated by using the zfs send -R command is received, any snapshots that do not exist on the sending location are destroyed by using the zfs destroy -d command. If -o *property=value* or -x property is specified, it applies to the effective value of the property throughout the entire subtree of replicated datasets. Effective property values may be set or inherited, depending on the property and whether the dataset is the topmost in the replicated subtree. Received properties are retained in spite of being overridden and may be restored with zfs inherit -rS or zfs send -Rb.

The name of the snapshot (and file system, if a full stream is received) that this subcommand creates depends on the argument type and the -d or -e option.

If the argument is a snapshot name, the specified *snapshot* is created. If the argument is a file system or volume name, a snapshot with the same name as the sent snapshot is created within the specified *filesystem* or *volume*. If the -d or -e option is specified, the snapshot

name is determined by appending the sent snapshot's name to the specified filesystem. If the -d option is specified, all but the pool name of the sent snapshot path is appended (for example, b/c@1 appended from sent snapshot a/b/c@1), and if the -e option is specified, only the tail of the sent snapshot path is appended (for example, c@1 appended from sent snapshot a/b/c@1). In the case of -d, any file systems needed to replicate the path of the sent snapshot are created within the specified file system.

-d

    Use all but the first element of the sent snapshot path (all but the pool name) to determine the name of the new snapshot as described in the paragraph above.

-e

    Use the last element of the sent snapshot path to determine the name of the new snapshot as described in the paragraph above.

-F

    Force a rollback of the file system to the most recent snapshot before performing the receive operation. If receiving an incremental replication stream (for example, one generated by zfs send -R -[iI]), destroy snapshots and file systems that do not exist on the sending side.

-n

    Do not actually receive the stream. This can be useful in conjunction with the -v option to verify the name the receive operation would use.

-o *property=value*

    Sets the specified property as if the command zfs set *property=value* is invoked at the same time the received dataset is created from the non-incremental send stream or updated from the incremental send stream. Any editable ZFS property can also be set at receive time. Set-once properties bound to the received data, such as normalization and casesensitivity, cannot be set at receive time even when the datasets are newly created by zfs receive. Multiple -o options can be specified. An error results if the same property is specified in multiple -o or -x options.

-u

    File system that is associated with the received stream is not mounted.

-v

    Print verbose information about the stream and the time required to perform the receive operation.

-x *property*

    Ensures that the effective value of the specified property after the receive is unaffected by the value of that property in the send stream (if any), as if the property had been excluded from the send stream. If the specified property is not present in the send stream, this option does nothing. If a received property needs to be overridden, the effective value can be set or inherited, depending on the property. In the case of an incremental update, -x leaves any existing local setting or explicit inheritance

unchanged (since the received property is already overridden). All -o restrictions apply equally to -x.

zfs allow *filesystem* | *volume*
zfs allow [-ldug] everyone|*user*|*group*[,...] *perm*|@*setname*[,...] *filesystem*| *volume*
zfs allow [-ld] -e *perm*|@*setname*[,...] *filesystem* | *volume*
zfs allow -c *perm*|@*setname*[,...] *filesystem*|*volume*
zfs allow -s @*setname perm*|@*setname*[,...] *filesystem*|*volume*
    For a full description of the zfs allow syntax and examples, see zfs_allow(1M).

zfs unallow [-rldug] everyone|*user*|*group*[,...] [*perm*|@*setname*[, ...]] *filesystem*|*volume*
zfs unallow [-rld] -e [*perm*|@*setname* [,...]] *filesystem*|*volume*
zfs unallow [-r] -c [*perm*|@*setname*[,...]]
filesystem|*volume*
zfs unallow [-r] -s @*setname* [*perm*|@*setname*[,...]]
filesystem|*volume*
    For a full description of the zfs unallow syntax and examples, see zfs_allow(1M).

zfs hold [-r] *tag snapshot* ...
    Adds a single reference, named with the *tag* argument, to the specified snapshot or snapshots. Each snapshot has its own tag namespace, and tags must be unique within that space.

    If a hold exists on a snapshot, attempts to destroy that snapshot by using the zfs destroy command return EBUSY.

    -r
        Specifies that a hold with the given tag is applied recursively to the snapshots of all descendent file systems.

zfs holds [-r] *snapshot* ...
    Lists all existing user references for the given snapshot or snapshots.

    -r
        Lists the holds that are set on the named descendent snapshots, in addition to listing the holds on the named snapshot.

zfs release [-r] *tag snapshot*...
    Removes a single reference, named with the *tag* argument, from the specified snapshot or snapshots. The tag must already exist for each snapshot.

    If a hold exists on a snapshot, attempts to destroy that snapshot by using the zfs destroy command return EBUSY.

    -r
        Recursively releases a hold with the given tag on the snapshots of all descendent file systems.

zfs diff [-FHte] [-o *field*] ... *snapshot* [*snapshot* | *filesystem*]
zfs diff -E [-FHt] [-o *field*] ... *snapshot* | *filesystem*

Gives a high-level description of the differences between a snapshot and a descendent dataset. The descendent can be either a snapshot of the dataset or the current dataset.

If a single snapshot is specified, then differences between that snapshot and the current dataset are given.

For each file that has undergone a change between the original snapshot and the descendent, the type of change is described along with the name of the file. In the case of a rename, both the old and new names are shown. Whitespace characters, backslash characters, and other non-printable or non-7-bit ASCII characters found in file names are displayed as a backslash character followed by the three-digit octal representation of the byte value.

If the -t option is specified, the first column of output from the command is the file's st_ctim value. For deleted files, this is the final st_ctim in the earlier snapshot.

The type of change follows any timestamp displayed, and is described with a single character:

+ Indicates the file was added in the later dataset.

- Indicates the file was removed in the later dataset.

M Indicates the file was modified in the later dataset.

R Indicates the file was renamed in the later dataset.

If the -F option is specified, the next column of output will be a single character describing the type of the file. The mappings are:

F regular file

/ directory

B block device

> door

| FIFO

@ symbolic link

P event portal

= socket

If the modification involved a change in the link count of a non-directory file, the change will be expressed as a delta within parentheses on the modification line. If the file was renamed, the old name will be separated from the new with the string "->".

If the -H option is selected, easier-to-parse output is produced. Fields are separated by a single tab, and no arrow string (->) is placed between the old and new names of a rename. No guarantees are made on the spacing between fields of non -H output.

If the -e option is selected, then all files added or modified between the two snapshots are enumerated and no deleted files are displayed. The change type will always be reported as "+" regardless of the type of modification.

If the -E option is selected, then differences are given as if from an empty snapshot to the specified snapshot or dataset.

If the -o field option is selected then only selected fields are displayed. Each line starts with the standard fields requested by the -F and -t options, followed by the fields requested in successive -o options. As with the -H option, all fields are separated by a single tab. The allowable field names include:

object	the number printed by ls -i for the file
parent	the number printed by ls -i for enclosing directory of the file
size	the file size as displayed by ls -s
links	the number of links to the file
linkschange	the change in the number of links to the file
name	the name of the file
oldname	the name of the file before the rename, or – (hyphen) if the file was not renamed
user	the username of the owner of the file as displayed by ls
group	the group name of the file as displayed by ls
ctime	timestamp when the file's metadata was last modified
mtime	timestamp when the file was last modified
atime	timestamp when a file was last accessed
crtime	timestamp when a file was created

Unless they already have the {PRIV_SYS_CONFIG} or {PRIV_SYS_MOUNT} privilege, users must be granted the diff permission with zfs allow to use this subcommand.

zfs key -l | {-a | [-r] *filesystem*|*volume*}
zfs key -u [-f] | {-a | [-r] *filesystem*|*volume*
zfs key -c [-o *keysource=value*] {-a | [-r] *filesystem*|*volume*}
zfs key -K {-a | [-r] *filesystem*|*volume*}
For a full description of the zfs key syntax and examples, see zfs_encrypt(1M).

Examples **EXAMPLE 1**   Creating a ZFS File System Hierarchy

The following commands create a file system named `pool/home` and a file system named `pool/home/bob`. The mount point `/export/home` is set for the parent file system, and is automatically inherited by the child file system.

```
# zfs create pool/home
# zfs set mountpoint=/export/home pool/home
# zfs create pool/home/bob
```

EXAMPLE 2   Creating a ZFS Snapshot

The following command creates a snapshot named `yesterday`. This snapshot is mounted on demand in the `.zfs/snapshot` directory at the root of the `pool/home/bob` file system.

```
# zfs snapshot pool/home/bob@yesterday
```

EXAMPLE 3   Creating and Destroying Multiple Snapshots

The following command creates snapshots named `yesterday` of `pool/home` and all of its descendent file systems. Each snapshot is mounted on demand in the `.zfs/snapshot` directory at the root of its file system. The second command destroys the newly created snapshots.

```
# zfs snapshot -r pool/home@yesterday
# zfs destroy -r pool/home@yesterday
```

EXAMPLE 4   Disabling and Enabling File System Compression

The following command disables the `compression` property for all file systems under `pool/home`. The next command explicitly enables `compression` for `pool/home/anne`.

```
# zfs set compression=off pool/home
# zfs set compression=on pool/home/anne
```

EXAMPLE 5   Listing ZFS Datasets

The following command lists all active file systems and volumes in the system. Snapshots are displayed if the `listsnaps` property is on. The default is `off`. See zpool(1M) for more information on pool properties.

```
# zfs list
  NAME                     USED   AVAIL  REFER  MOUNTPOINT
  pool                     450K    457G    18K  /pool
  pool/home                315K    457G    21K  /export/home
  pool/home/anne            18K    457G    18K  /export/home/anne
  pool/home/bob            276K    457G   276K  /export/home/bob
```

EXAMPLE 6   Setting a Quota on a ZFS File System

The following command sets a quota of 30 GB for `pool/home/bob`.

```
# zfs set quota=30G pool/home/bob
```

EXAMPLE 7 Listing ZFS Properties

The following command lists all properties for pool/home/bob.

```
# zfs get all pool/home/bob
NAME            PROPERTY              VALUE                  SOURCE
pool/home/bob   type                  filesystem             -
pool/home/bob   creation              Fri Jul 15 11:53 2011  -
pool/home/bob   used                  31K                    -
pool/home/bob   available             30.0G                  -
pool/home/bob   referenced            31K                    -
pool/home/bob   compressratio         1.00x                  -
pool/home/bob   mounted               yes                    -
pool/home/bob   quota                 30G                    local
pool/home/bob   reservation           none                   default
pool/home/bob   recordsize            128K                   default
pool/home/bob   mountpoint            /pool/home/bob         default
pool/home/bob   sharenfs              off                    default
pool/home/bob   checksum              on                     default
pool/home/bob   compression           on                     default
pool/home/bob   atime                 on                     default
pool/home/bob   devices               on                     default
pool/home/bob   exec                  on                     default
pool/home/bob   setuid                on                     default
pool/home/bob   readonly              off                    default
pool/home/bob   zoned                 off                    default
pool/home/bob   snapdir               hidden                 default
pool/home/bob   aclmode               discard                default
pool/home/bob   aclinherit            restricted             default
pool/home/bob   canmount              on                     default
pool/home/bob   xattr                 on                     default
pool/home/bob   copies                1                      default
pool/home/bob   version               5                      -
pool/home/bob   utf8only              off                    -
pool/home/bob   normalization         none                   -
pool/home/bob   casesensitivity       mixed                  -
pool/home/bob   vscan                 off                    default
pool/home/bob   nbmand                off                    default
pool/home/bob   sharesmb              off                    default
pool/home/bob   refquota              none                   default
pool/home/bob   refreservation        none                   default
pool/home/bob   primarycache          all                    default
pool/home/bob   secondarycache        all                    default
pool/home/bob   usedbysnapshots       0                      -
pool/home/bob   usedbydataset         31K                    -
pool/home/bob   usedbychildren        0                      -
pool/home/bob   usedbyrefreservation  0                      -
pool/home/bob   logbias               latency                default
pool/home/bob   dedup                 off                    default
```

EXAMPLE 7 Listing ZFS Properties   *(Continued)*

```
pool/home/bob  mlslabel            none                    default
pool/home/bob  sync                standard                default
pool/home/bob  encryption          off                     -
pool/home/bob  keysource           none                    default
pool/home/bob  keystatus           none                    -
pool/home/bob  rekeydate           -                       default
pool/home/bob  rstchown            on                      default
pool/home/bob  shadow              none                    -
```

The following command gets a single property value.

```
# zfs get -H -o value compression pool/home/bob
on
```

The following command lists all properties with local settings for pool/home/bob.

```
# zfs get -r -s local -o name,property,value all pool/home/bob
NAME            PROPERTY        VALUE
pool/home/bob   quota           30G
pool/home/bob   compression     on
```

EXAMPLE 8 Rolling Back a ZFS File System

The following command reverts the contents of pool/home/anne to the snapshot named yesterday, deleting all intermediate snapshots.

```
# zfs rollback -r pool/home/anne@yesterday
```

EXAMPLE 9 Creating a ZFS Clone

The following command creates a writable file system whose initial contents are the same as pool/home/bob@yesterday.

```
# zfs clone pool/home/bob@yesterday pool/clone
```

EXAMPLE 10 Promoting a ZFS Clone

The following commands illustrate how to test out changes to a file system, and then replace the original file system with the changed one, using clones, clone promotion, and renaming:

```
# zfs create pool/project/production
  populate /pool/project/production with data
# zfs snapshot pool/project/production@today
# zfs clone pool/project/production@today pool/project/beta
make changes to /pool/project/beta and test them
# zfs promote pool/project/beta
# zfs rename pool/project/production pool/project/legacy
# zfs rename pool/project/beta pool/project/production
once the legacy version is no longer needed, it can be destroyed
```

EXAMPLE 10 Promoting a ZFS Clone   *(Continued)*

```
# zfs destroy pool/project/legacy
```

EXAMPLE 11 Inheriting ZFS Properties

The following command causes pool/home/bob and pool/home/anne to inherit the checksum property from their parent.

```
# zfs inherit checksum pool/home/bob pool/home/anne
```

EXAMPLE 12 Remotely Replicating ZFS Data

The following commands send a full stream and then an incremental stream to a remote machine, restoring them into poolB/received/fs@aand poolB/received/fs@b, respectively. poolB must contain the file system poolB/received, and must not initially contain poolB/received/fs.

```
# zfs send pool/fs@a | \
   ssh host zfs receive poolB/received/fs@a
# zfs send -i a pool/fs@b | ssh host \
   zfs receive poolB/received/fs
```

EXAMPLE 13 Using the zfs receive -d Option

The following command sends a full stream of poolA/fsA/fsB@snap to a remote machine, receiving it into poolB/received/fsA/fsB@snap. The fsA/fsB@snap portion of the received snapshot's name is determined from the name of the sent snapshot. poolB must contain the file system poolB/received. If poolB/received/fsA does not exist, it is created as an empty file system.

```
# zfs send poolA/fsA/fsB@snap | \
   ssh host zfs receive -d poolB/received
```

EXAMPLE 14 Setting User Properties

The following example sets the user–defined com.example:department property for a dataset.

```
# zfs set com.example:department=12345 tank/accounting
```

EXAMPLE 15 Performing a Rolling Snapshot

The following example shows how to maintain a history of snapshots with a consistent naming scheme. To keep a week's worth of snapshots, the user destroys the oldest snapshot, renames the remaining snapshots, and then creates a new snapshot, as follows:

```
# zfs destroy -r pool/users@7daysago
# zfs rename -r pool/users@6daysago @7daysago
# zfs rename -r pool/users@5daysago @6daysago
# zfs rename -r pool/users@4daysago @5daysago
# zfs rename -r pool/users@3daysago @4daysago
```

EXAMPLE 15 Performing a Rolling Snapshot   *(Continued)*

```
# zfs rename -r pool/users@2daysago @3daysago
# zfs rename -r pool/users@yesterday @2daysago
# zfs rename -r pool/users@today @yesterday
# zfs snapshot -r pool/users@today
```

EXAMPLE 16 Displaying ZFS Snapshot Differences

The following example is output of the zfs diff -F and -t options specified:

```
# zfs diff -Ft myfiles@snap1
1269962501.206726811   M   /   /myfiles/
1269962444.207369955   M   F   /myfiles/link_to_me      (+1)
1269962499.207519034   R       /myfiles/rename_me -> /myfiles/renamed
1269962431.813566720   -   F   /myfiles/delete_me
1269962518.666905544   +   F   /myfiles/new_file
1269962501.393099817   +   |   /myfiles/new_pipe
```

Exit Status   The following exit values are returned:

0

Successful completion.

1

An error occurred.

2

Invalid command line options were specified.

Attributes   See attributes(5) for descriptions of the following attributes:

Notes A file described as modified by the diff subcommand might have been modified in multiple ways. Any action that causes a change in the st_ctim (see stat(2)) is a basis for reporting a modification.

Name zfs_allow – delegates ZFS file system administration permission to non-privileged users

Synopsis zfs allow *filesystem*|*volume*

zfs allow [-ldug] everyone|*user*|*group*[,...] *perm*|@*setname*[,...]
     filesystem|*volume*

zfs allow [-ld] -e *perm*|@*setname*[,...] *filesystem*|*volume*

zfs allow -c *perm*|@*setname*[,...] *filesystem*|*volume*

zfs allow -s @*setname perm*|@*setname*[,...] *filesystem*|*volume*

zfs unallow [-rldug] everyone|*user*|*group*[,...] [*perm*|@*setname*[,...]]
     filesystem|*volume*

zfs unallow [-rld] -e [*perm*|@*setname*[,...]] *filesystem*|*volume*

zfs unallow [-r] -c [*perm*|@*setname*[...]] *filesystem*|*volume*

zfs unallow [-r] -s @*setname* [*perm*|@*setname*[,...]] *filesystem*|*volume*

Description The zfs allow command can be used to delegate permissions to non-privileged users for
administering ZFS file systems in a ZFS storage pool, as described in zpool(1M). You can use
the zfs unallow command to revoke administrative permissions.

Permissions are generally the ability to use a ZFS subcommand or change a ZFS property. The
following permissions are available:

```
NAME            TYPE            NOTES
allow           subcommand      Must also have the permission that is
                                being allowed
clone           subcommand      Must also have the 'create' ability and
                                'mount' ability in the origin file system
create          subcommand      Must also have the 'mount' ability
destroy         subcommand      Must also have the 'mount' ability
diff            subcommand      Allows user to compare differences
                                between snapshots of a ZFS dataset
hold            subcommand      Allows adding a user hold to a snapshot
key             subcommand      Allows key loading or unloading
keychange       other           Allows wrapping key change and re-key
mount           subcommand      Allows mount/umount of ZFS datasets
promote         subcommand      Must also have the 'mount' and 'promote'
                                ability in the origin file system
receive         subcommand      Must also have the 'mount' and 'create' ability
release         subcommand      Allows releasing a user hold which
                                might destroy the snapshot
rename          subcommand      Must also have the 'mount' and 'create'
                                ability in the new parent
rollback        subcommand
send            subcommand
share           subcommand      Allows sharing file systems over NFS or
                                SMB protocols
```

Subcommands All subcommands that modify state are logged persistently to the pool in their original form.

zfs ?
   Displays a help message.

zfs help *command* | help | *property property-name* | *permission*
   Displays zfs command usage information. You can display help for a specific command,
   property, or delegated permission. If you display help for a specific command or property,
   the command syntax or property value is displayed. Using zfs help without any
   arguments displays a complete list of zfs commands.

zfs allow *filesystem* | *volume*
   Displays permissions that have been delegated on the specified filesystem or volume. See
   the other forms of zfs allow for more information.

zfs allow [-ldug] everyone|*user*|*group*[,...] *perm*|@*setname*[,...] *filesystem*| *volume*
zfs allow [-ld] -e *perm*|@*setname*[,...] *filesystem* | *volume*
   Delegates ZFS administration permission for the file systems to non-privileged users.

   [-ug] everyone|*user*|*group*[,...]
      Specifies to whom the permissions are delegated. Multiple entities can be specified as a
      comma-separated list. If neither of the -ug options are specified, then the argument is
      interpreted preferentially as the keyword everyone, then as a user name, and lastly as a
      group name. To specify a user or group named "everyone", use the -u or -g options. To
      specify a group with the same name as a user, use the -g options.

   [-e] *perm*|@*setname*[,...]
      Specifies that the permissions be delegated to everyone. Multiple permissions may be
      specified as a comma-separated list. Permission names are the same as ZFS
      subcommand and property names. See the property list below. Property set names,
      which begin with an at sign (@) , may be specified. See the -s form below for details.

   [-ld] *filesystem*|*volume*
      Specifies where the permissions are delegated. If neither of the -ld options are specified,
      or both are, then the permissions are allowed for the file system or volume, and all of its
      descendents. If only the -l option is used, then is allowed "locally" only for the specified
      file system. If only the -d option is used, then is allowed only for the descendent file
      systems.

zfs allow -c *perm*|@*setname*[,...] *filesystem*|*volume*
   Sets "create time" permissions. These permissions are granted (locally) to the creator of any
   newly-created descendent file system.

zfs allow -s @*setname perm*|@*setname*[,...] *filesystem*|*volume*
   Defines or adds permissions to a permission set. The set can be used by other zfs allow
   commands for the specified file system and its descendents. Sets are evaluated dynamically,
   so changes to a set are immediately reflected. Permission sets follow the same naming
   restrictions as ZFS file systems, but the name must begin with an "at sign" (@), and can be
   no more than 64 characters long.

zfs unallow [-rldug] everyone|*user*|*group*[,...] [*perm*|@*setname*[, ...]] *filesystem*|*volume*
zfs unallow [-rld] -e [*perm*|*setname* [,...]] *filesystem*|*volume*
zfs unallow [-r] -c [*perm*|@*setname*[,...]]
filesystem|*volume*

    Removes permissions that were granted with the zfs allow command. No permissions are
    explicitly denied, so other permissions granted are still in effect. For example, if the
    permission is granted by an ancestor. If no permissions are specified, then all permissions
    for the specified *user*, *group*, or everyone are removed. Specifying everyone (or using the
    -e option) only removes the permissions that were granted to everyone, not all
    permissions for every user and group. See the zfs allow command for a description of the
    -ldugec options.

    -r

       Recursively remove the permissions from this file system and all descendents.

zfs unallow [-r] -s @*setname* [*perm*|@*setname*[,...]]
filesystem|*volume*

    Removes permissions from a permission set. If no permissions are specified, then all
    permissions are removed, thus removing the set entirely.

Examples **EXAMPLE 1** Delegating ZFS Administration Permissions on a ZFS Dataset

The following example shows how to set permissions so that user anne can create, destroy,
mount, and take snapshots on pool/home/anne. The permissions on pool/home/anne are also
displayed.

```
# zfs allow anne create,destroy,mount,snapshot pool/home/anne
# zfs allow pool/home/anne
---- Permissions on pool/home/anne ----------------------------------
Local+Descendent permissions:
        user anne create,destroy,mount,snapshot
```

Because the pool/home/anne mount point permission is set to 755 by default, user anne will
be unable to mount file systems under pool/home/anne. Set an ACL similar to the following
syntax to provide mount point access:

```
# chmod A+user:anne:add_subdirectory:allow /pool/home/anne
```

EXAMPLE 2 Delegating Create Time Permissions on a ZFS Dataset

The following example shows how to grant anyone in the group staff to create file systems in
pool/home. This syntax also allows staff members to destroy their own file systems, but not
destroy anyone else's file system. The permissions on pool/home are also displayed.

```
# zfs allow staff create,mount pool/home
# zfs allow -c destroy pool/home
# zfs allow pool/home
---- Permissions on pool/home -----------------------------------------
Create time permissions:
```

EXAMPLE 2 Delegating Create Time Permissions on a ZFS Dataset   *(Continued)*

```
        destroy
Local+Descendent permissions:
        group staff create,mount
```

EXAMPLE 3 Defining and Granting a Permission Set on a ZFS Dataset

The following example shows how to define and grant a permission set on the pool/home file
system. The permissions on pool/home are also displayed.

```
# zfs allow -s @pset create,destroy,snapshot,mount pool/home
# zfs allow staff @pset pool/home
# zfs allow pool/home
---- Permissions on pool/home ----------------------------------------
Permission sets:
        @pset create,destroy,mount,snapshot
Create time permissions:
        destroy
Local+Descendent permissions:
        group staff @pset,create,mount
```

EXAMPLE 4 Delegating Property Permissions on a ZFS Dataset

The following example shows to grant the ability to set quotas and reservations on the
tank/users file system. The permissions on tank/users are also displayed.

```
# zfs allow mark quota,reservation tank/users
# zfs allow tank/users
---- Permissions on tank/users ---------------------------------------
Local+Descendent permissions:
        user mark quota,reservation
mark% zfs set quota=10G tank/users/tim
mark% zfs get quota tank/users/tim
NAME            PROPERTY   VALUE   SOURCE
tank/users/tim  quota      10G     local
```

EXAMPLE 5 Removing ZFS Delegated Permissions on a ZFS Dataset

The following example shows how to remove the snapshot permission from the @pset
permission set for the staff group on the pool/home file system. The permissions on
pool/home are also displayed.

```
# zfs unallow -s @pset snapshot pool/home
# zfs allow pool/home
---- Permissions on pool/home ----------------------------------------
Permission sets:
        @pset create,destroy,mount
Create time permissions:
        destroy
```

EXAMPLE 5 Removing ZFS Delegated Permissions on a ZFS Dataset   *(Continued)*

```
Local+Descendent permissions:
        group staff @pset,create,mount
```

Exit Status The following exit values are returned:

0
  Successful completion.

1
  An error occurred.

2
  Invalid command line options were specified.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/zfs
Interface Stability	Committed

See Also zfs(1M), zpool(1M), chmod(2), chown(2), attributes(5)

For information about using other ZFS features, see zfs_encrypt(1M), zfs_share(1M), zfs(1M) and the *Oracle Solaris Administration: ZFS File Systems*.

Name zfs_encrypt – encrypting ZFS file systems

Synopsis zfs [-?]

zfs help *subcommand* | help | *property property-name* | *permission*

zfs create -o encryption=on [-o keysource=*raw* | *hex* | *passphrase*,*prompt* | *file://*|pkcs11:|https:

zfs clone [-p] [-K] [-o *property=value*] ... *snapshot filesystem*|*volume*

zfs get [-r|-d *depth*][-Hp][-o all | *field*[,...]] [-s *source*[,...]]
     all | *property*[,...] *filesystem*|*volume*|*snapshot* ...

zfs key-l | {-a | [-r] *filesystem*|*volume*}

zfs key -u [-f] {-a | [-r] *filesystem*|*volume*}

zfs key -c [-o *keysource=value*] {-a | [-r] *filesystem*|*volume*}

zfs key -K {-a | [-r] *filesystem*|*volume*}

zfs mount

zfs mount [-vO] [-o *options*] -a | *filesystem*

zfs unmount [-f] -a | *filesystem*|*mountpoint*

Description The zfs create -o encryption command encrypts a newly created ZFS datasets within a
ZFS storage pool, as described in zpool(1M).

Encryption Encryption is the process in which data is encoded for privacy and a key is needed by the data
owner to access the encoded data. You can set an encryption policy when a ZFS dataset is
created, but the policy cannot be changed. See the encryption and keysource property
descriptions in the "Native Properties" section for details.

Dataset encryption is inherited permanently and cannot be removed during dataset cloning.
When receiving a replicated dataset stream, the destination dataset must have encryption
enabled if encryption is desired. Otherwise, the data is stored as clear text. A fully replicated
stream of an encrypted dataset results in an encrypted dataset but under a newly generated
key, but the steam itself is not encrypted.

Native ZFS Encryption The following native properties related to ZFS encryption consist of read-only statistics about
Properties the dataset. These properties cannot be set nor inherited. Native properties apply to all dataset
types unless otherwise noted. For a full description and list of ZFS native properties, see
zfs(1M).

keystatus
   Identifies the encryption key status for the dataset. The availability of a dataset's key is
   indicated by showing the status of available or unavailable. For datasets that do not
   have encryption enabled, none is displayed.

mounted
   For file systems, indicates whether the file system is currently mounted. This property can
   be either yes or no.

rekeydate

The date of the last data encryption key change from a zfs key -K or zfs clone -K operation on this dataset. If no rekey operation has been performed, rekeydate is the same as creation date.

The following properties cannot be changed after the file system is created and, therefore, should be set when the file system is created. If the properties are not set with the zfs create or zpool create commands, these properties are inherited from the parent dataset. If the parent dataset lacks these properties due to having been created prior to these features being supported, the new file system will have the default values for these properties.

encryption=off | on | aes-128-ccm | aes-192-ccm | aes-256-ccm | aes-128-gcm | aes-192-gcm | aes-256-gcm

Defines the encryption algorithm and key length that is used for the encrypted dataset. The on value is equal to aes-128-ccm. The default value is off. When encryption is set to a value other than off, the checksum property is set to sha256+mac and becomes readonly.

The following properties must be specified at creation time and can modified by using special commands:

keysource=*raw* | *hex* | *passphrase*,*prompt* | *file://* | pkcs11: | https://

Defines the format and location of the key that wraps the dataset keys. The key must be present when the dataset is created, mounted, or loaded by using the zfs key -l command.

The keysource property accepts two values: format determines how the key is presented; locator identifies where the key is coming from.

format accepts three values:

- *raw*: the raw key bytes
- *hex*: a hexadecimal key string
- *passphrase*: a character string that generates a key

locator accepts two values:

- prompt: You are prompted for a key when the dataset is created or mounted
- file:///*filename*: the key file location in a file system
- pkcs11: A URI describing the location of a key in a PKCS#11 token
- https://*location*: The key file location on a secure server

See "Examples" for examples of creating a key by using the https:// locator.

To change the wrapping key value or the key, you must run the zfs key -c command. If only the key location needs to be changed, for example, a filename change, then use the zfs set command with the keysource property. Note that no checking is performed by ZFS when only the key location is changed with the zfs set command, such as whether the new location has a valid wrapping key.

If keysource is not specified and not inherited, then the default keysource is set to passphrase,prompt for a dataset that has encryption on and is set to none for a dataset that has encryption off.

Subcommands　All subcommands that modify state are logged persistently to the pool in their original form.

zfs ?
　　Displays a help message.

zfs help *command* | help | *property property-name* | *permission*
　　Displays zfs command usage information. You can display help for a specific command, property, or delegated permission. If you display help for a specific command or property, the command syntax or property value is displayed. Using zfs help without any arguments displays a complete list of zfs commands.

zfs create [-p] [-o *encryption=on*] [-o keysource=*raw* | *hex* | *passphrase,prompt* | *file://*|pkcs11:|https://] ... *filesystem*
　　Creates a new ZFS file system with encryption enabled, which uses aes-128-ccm See the encryption property description for a list of supported encryption algorithms.

　　-p
　　　　Creates all the non-existing parent datasets. Datasets created in this manner are automatically mounted according to the mountpoint property inherited from their parent. Any property specified on the command line using the -o option is ignored. If the target filesystem already exists, the operation completes successfully.

　　-o *encryption=value*
　　　　Sets the encryption property to *value*. Multiple -o options can be specified. An error results if the same property is specified in multiple -o options.

zfs clone [-p] [-K] [-o *property=value*] ... *snapshot filesystem*|*volume*
　　Creates a clone of the given snapshot. See the "Clones" section for details. The target dataset can be located anywhere in the ZFS hierarchy, and is created as the same type as the original.

　　-p
　　　　Creates all the non-existing parent datasets. Datasets created in this manner are automatically mounted according to the mountpoint property inherited from their parent. If the target filesystem or volume already exists, the operation completes successfully.

　　-o *property=value*
　　　　Sets the specified property; see zfs create for details.

　　-K
　　　　Creates a new data encryption key in the keychain for this dataset. Data written in the clone uses the new data encryption key, which is distinct from its original snapshot.

zfs set keysource=*value filesystem|volume| ...*
Sets the keysource property to the given value for each dataset. You can only change the keysource location. If you want to change the wrapping key value, use the zfs key -c command.

-r
Recursively apply the effective value of the setting throughout the subtree of child datasets. The effective value may be set or inherited, depending on the property.

zfs get encryption | keysource | keystatus | rekeydate *filesystem|volume| ...*
Displays properties for the given datasets.

-r
Recursively display properties for any children.

-d *depth*
Recursively display any children of the dataset, limiting the recursion to *depth*. A depth of 1 will display only the dataset and its direct children.

-H
Display output in a form more easily parsed by scripts. Any headers are omitted, and fields are explicitly separated by a single tab instead of an arbitrary amount of space.

zfs key -l | {-a | [-r] *filesystem|volume*}
Loads the encryption key for a dataset and any datasets that inherit the key. The key that is provided with this command is not the actual key that is used to encrypt the dataset. It is a wrapping key for the set of data encryption keys for the dataset.

-l
Loads the wrapping key to unlock the encrypted dataset and datasets that inherit the key. This command loads the key based on what is defined by the dataset's keysource property.

During a pool import, a key load operation is performed when a dataset is mounted. During boot, if the wrapping key is available and the keysource is not set to prompt, the key load operation is performed.

-a
Apply to all datasets in all pools on the system.

-r
Apply the operation recursively to all datasets below the named file system or volume.

zfs key -u [-f] | {-a | [-r] *filesystem|volume*}
Unloads the encryption key for a dataset and any datasets that inherit the key.

-u
Unmounts the dataset and then attempts to unload the wrapping key for an encrypted dataset and datasets that inherit the key. If successful, the dataset is not accessible and is unmounted.

-f

Attempts to force unmount the dataset before attempting to unload the key. If not specified, a normal unmount is attempted.

-a

Apply to all datasets in all pools on the system.

-r

Apply the operation recursively to all datasets below the named file system or volume.

zfs key -c [-o keysource=*value*] | { -a | [-r] *filesystem*|*volume*}
Changes the wrapping key. If the new key has a different format or locator, the keysource property must be included as part of the command. Only the keysource property can be changed as part of the zfs key -c command.

-c

Changes the wrapping key for the key of an encrypted dataset and the datasets that inherit it. The existing key must already have been loaded before the key change operation can occur. ZFS does not prompt you for the existing passphrase.

-o *property*=*value*

Property to be changed as part of the key change operation. The keysource property is the only option that can be changed as part of a key change operation.

You must have permission to change the keysource properties.

-a

Apply to all datasets in all pools on the system.

-r

Apply the operation recursively to all datasets below the named file system or volume.

zfs key -K { -a | [-r] *filesystem*|*volume*}
Creates a new data encryption key. The new data encryption key is wrapped by the same wrapping key as any existing data encryption keys for this dataset.

-K

Creates a new data encryption key for this dataset. Data written after this operation will use the new data encryption key.

-a

Apply to all datasets in all pools on the system.

-r

Apply the operation recursively to all datasets below the named file system or volume.

zfs mount
zfs mount [-vO] [-o *options*] -a | *filesystem*
Mounts ZFS file systems. Invoked automatically as part of the boot process. For a full description of zfs mount syntax, see zfs(1M).

filesystem
> Mount the specified filesystem.
>
> A zfs mount operation of an encrypted dataset might prompt you for a key, depending on the keysource property value. This might occur, for example, if the keysource locator is set to prompt.

zfs unmount [-f] -a | *filesystem*|*mountpoint*
> Unmounts currently mounted ZFS file systems. Invoked automatically as part of the shutdown process. For a full description of zfs unmount syntax, see zfs(1M).

filesystem|*mountpoint*
> Unmount the specified filesystem. The command can also be given a path to a ZFS file system mount point on the system.
>
> For an encrypted dataset, the key is not unloaded when the file system is unmounted. To unload the key, see zfs key.

Examples   EXAMPLE 1   Creating an Encrypted Dataset

The following example shows how to create an encrypted dataset by using a passphrase prompt, which is the default value of the keysource property. This example assumes that the tank/home dataset is not encrypted.

```
# zfs create -o encryption=on tank/home/bob
Enter passphrase for 'tank/home/bob/': **********
Enter again: **********
```

In the following example, the pktool(1) command is used to generate a raw key to a file. Next, an encrypted dataset (tank/home/anne) is created with the aes-256-ccm algorithm and the raw key file that was generated by pktool.

```
# pktool genkey keystore=file outkey=/media/stick/mykey \
keytype=aes keylen=256
# zfs create encryption=aes-256-ccm \
-o keysource=raw,file:///rmdisk/stick/mykey tank/home/anne
```

This example shows how to create an encrypted ZFS file system that prompts for a key that is stored at an http location.

```
# zfs create -o encryption=on \
-o keysource=passphrase,https://keys.example.com/keys/42 tank/home/fs1
```

This example shows how to generate a raw key in a PKCS#11 token. Then, an encrypted dataset is created with the raw PKCS#11 key that was generated from pktool.

```
# pktool genkey keystore=pkcs11 keytype=aes keylen=128 label=fs2
Enter PIN for Sun Software PKCS#11 softtoken: xxxxx
# zfs create -o encryption=on -o keysource=raw,pkcs11:object=fs2 \
tank/home/fs2
Enter PKCS#11 token PIN for 'tank/home/fs2': xxxxx
```

EXAMPLE 1   Creating an Encrypted Dataset   *(Continued)*

This example shows how to generate a raw key in a KMS token. Then, an encrypted dataset is created with the raw KMS key that was generated from pktool.

```
# pktool genkey keystore=pkcs11 keytype=aes keylen=256 token=KMS \
label=fs3
Enter PIN for KMS: xxxxx
# zfs create -o encryption=aes-256-ccm \
-o keysource="raw,pkcs11:token=KMS;object=fs3" tank/home/fs3
Enter 'KMS' PKCS#11 token PIN for 'tank/home/fs3': xxxxx
```

EXAMPLE 2   Creating an Encrypted Dataset with a Different Encryption Algorithm

In this example, any tank/home datasets inherit the keysource properties, but the tank/home/bob dataset is created using a different encryption algorithm.

```
# zpool create tank ....
# zfs create -o encryption=on tank/home
# zfs get keystatus tank/home
NAME        PROPERTY    VALUE        SOURCE
tank/home   keystatus   available    -

# zfs create -o encryption=aes-256-ccm tank/home/bob
```

EXAMPLE 3   Inheriting Encryption and Keysource Properties

In this example, all of the tank/home datasets inherit the encryption and keysource properties.

```
# zpool create -o encryption=on -o keysource=raw,file:///... tank ...
# zfs create tank/home
```

EXAMPLE 4   Changing an Encrypted Dataset's Wrapping Key and Keysource

This example shows how to change a dataset's wrapping key to a new key defined by the dataset's keysource property.

```
# zfs get keysource tank/home/bob
NAME PROPERTY          VALUE                SOURCE
tank keysource         raw,file:///etc/keyfile default

# zfs key -c -o keysource=passphrase,prompt  tank/home/bob
Enter passphrase for 'tank/home/bob/': **********
Enter again: **********
```

The following example shows how to change the http location of dataset's wrapping key.

```
# zfs get keysource tank/home/bob
NAME            PROPERTY  VALUE              SOURCE
tank/home/bob   keysource passphrase,prompt  local
```

EXAMPLE 4 Changing an Encrypted Dataset's Wrapping Key and Keysource   *(Continued)*

```
# zfs set keysource=passphrase,https://internal.example.com/keys/bob/zfs \
tank/home/bob
```

You must have the delegated key and keychange permissions to change the keysource property.

EXAMPLE 5 Rekeying the Dataset's Encryption Key

This example shows how to change a dataset's encryption key, which is neither visible nor managed by you or an administrator. The dataset's encryption key is wrapped (encrypted) by the key specified in the keysource property.

```
# zfs key -K tank/project42
# zfs get rekeydate,creation tank/project42
```

You must have the delegated keychange permission to perform a key change operation.

Exit Status The following exit values are returned:

0
> Successful completion.

1
> An error occurred.

2
> Invalid command line options were specified.

Attributes See attributes(5) for descriptions of the following attributes:

Name zfs_share – share and unshare a ZFS file system

Synopsis `zfs [-?]`

`zfs help` *subcommand* `|` `help` `|` *property property-name* `|` *permission*

`zfs create [-p] [-o sharenfs=on | sharesmb=on] [-o` *property* `...` *filesystem*

`zfs set share=`*name=sharename*`,path=`*pathname*`,[desc=`*description*`],`
`prot=smb | nfs[,`*property=value*`[,...]]` *filesystem*

`zfs  set [-r] sharenfs=on | off` *filesystem*

`zfs  set [-r] sharesmb=on | off` *filesystem*

`zfs set -c share=`*name=sharename* *filesystem*

`zfs get [-r] sharenfs` *filesystem* `...`

`zfs  get [-r] sharesmb` *filesystem* `...`

`zfs  get  [-r] share` *filesystem* `...`

`zfs share -a |` *filesystem*

`zfs unshare -a` *filesystem*`|`*mountpoint*

Description The `zfs set share` command is used to create an NFS or SMB share within a ZFS storage pool, as described in `zpool`(1M). Setting the `sharenfs` or the `sharesmb` property to on publishes a share. You can also publish and unpublish an NFS share of a ZFS dataset by using the `zfs share` and `zfs unshare` commands.

Native Share File System Properties File system properties are divided into two types, native properties and user-defined (or "user") properties. Native properties either display information or control ZFS behavior. In addition, native properties are either editable or read-only.

Properties are inherited from the parent unless overridden by the child. Some properties apply only to certain types of datasets (file systems, volumes, or snapshots).

The following native properties can be used to change the behavior of a ZFS file system and are generally used when a file system is shared.

The following native NFS and SMB properties can be used to change the behavior of a ZFS share.

`nbmand=on | off`
   Controls whether the file system should be mounted with nbmand (Non Blocking mandatory locks). This is used for SMB clients. Changes to this property only take effect when the file system is umounted and remounted. See `mount`(1M) for more information on nbmand mounts.

`readonly=on | off`
   Controls whether this dataset can be modified. The default value is `off`.

   This property can also be referred to by its shortened column name, `rdonly`.

sharenfs=on | off

Controls whether a ZFS dataset is published as an NFS share. You can also publish and unpublish an NFS share of a ZFS dataset by using the `zfs share` and `zfs unshare` commands. Both methods of publishing an NFS share require that the NFS share properties are already set. For information about setting NFS share properties, see the `zfs set share` command.

When the `sharenfs` property is changed, the file system share and any children inheriting the property are re-published with any new options that have been set with the `zfs set share` command only if the property was previously `off`, or if the shares were published before the property was changed. If the new property value is `off`, the file system shares are unpublished.

sharesmb=on | off

Controls whether a ZFS dataset is published as an SMB share. You can also publish and unpublish an SMB share of a ZFS dataset by using the `zfs share` and `zfs unshare` commands. Both methods of publishing an SMB share require that the SMB share properties are also set. For information about setting SMB share properties, see the `zfs set share` command.

Because SMB shares requires a resource name, a unique resource name is constructed from the dataset name. The constructed name is a copy of the dataset name except that the characters in the dataset name that would be illegal in the resource name are replaced with underscore (_) characters. A pseudo property "name" is also supported that allows you to replace the data set name with a specified name. The specified name is then used to replace the prefix dataset in the case of inheritance. For example, if the dataset `data/home/john` is set to `name=john`, then `data/home/john` has a resource name of `john`. If `john` has a child dataset of `data/home/john/backups`, it has a resource name of `john_backups`.

When SMB shares are created, the SMB share name appears as an entry in the `.zfs/shares` directory. You can use the `ls` or `chmod` command to display the share-level ACLs on the entries in this directory.

When the `sharesmb` property is changed, the dataset share and any children inheriting the property are re-published with any new options that have been set with the `zfs set share` command if the property was previously set to `off`, or if the shares were published before the property was changed. If the new property value is `off`, the dataset shares are unpublished.

vscan=on | off

Controls whether regular files should be scanned for viruses when a file is opened and closed. In addition to enabling this property, the virus scan service must also be enabled for virus scanning to occur. The default value is `off`.

The following properties cannot be changed after the file system is created and, therefore, should be set when the file system is created. If the properties are not set with the `zfs create` or `zpool create` commands, these properties are inherited from the parent dataset. If the

parent dataset lacks these properties due to having been created prior to these features being supported, the new file system will have the default values for these properties.

casesensitivity=sensitive | insensitive | mixed
Indicates whether the file name matching algorithm used by the file system should be case-sensitive, case-insensitive, or allow a combination of both styles of matching. The default value for the casesensitivity property is mixed. Traditionally, UNIX and POSIX file systems have case-sensitive file names.

The mixed value for the casesensitivity property indicates that the file system can support requests for both case-sensitive and case-insensitive matching behavior. Currently, case-insensitive matching behavior on a file system that supports mixed behavior is limited to the Solaris SMB server product. For more information about the mixed value behavior, see the *Oracle Solaris Administration: ZFS File Systems*.

normalization = none | formC | formD | formKC | formKD
Indicates whether the file system should perform a unicode normalization of file names whenever two file names are compared, and which normalization algorithm should be used. File names are always stored unmodified, names are normalized as part of any comparison process. If this property is set to a legal value other than none, and the utf8only property was left unspecified, the utf8only property is automatically set to on. The default value of the normalization property is none. This property cannot be changed after the file system is created.

utf8only=on | off
Indicates whether the file system should reject file names that include characters that are not present in the UTF-8 character code set. If this property is explicitly set to off, the normalization property must either not be explicitly set or be set to none. The default value for the utf8only property is off. This property cannot be changed after the file system is created.

Subcommands All subcommands that modify state are logged persistently to the pool in their original form.

zfs ?
Displays a help message.

zfs help *command* | help | *property property-name* | *permission*
Displays zfs command usage information. You can display help for a specific command, property, or delegated permission. If you display help for a specific command or property, the command syntax or property value is displayed. Using zfs help without any arguments displays a complete list of zfs commands.

zfs create [-p] [-o sharenfs=on | sharesmb=on -o*property=value*] ... *filesystem*
Creates a new ZFS file system. The file system is automatically mounted according to the mountpoint property inherited from the parent.

-o *property=value*
Sets the specified property as if the command zfs set *property=value* was invoked at the same time the dataset was created. Any editable ZFS property can also be set at

creation time. Multiple -o options can be specified. An error results if the same property is specified in multiple -o options.

zfs get [-r] share [*filesystem*]

Displays all defined shares or the defined shares for a specified file system or descendent file systems.

zfs set share=*name*=*sharename*,path=*pathname*,[desc=*description*],prot=smb | nfs[,*property*=*value*[,...]] *filesystem*

Defines an NFS or SMB file sharing properties for a ZFS dataset. After the NFS or SMB file-sharing properties are established, you can publish the NFS or SMB share of a ZFS file system by setting the sharenfs or sharesmb property to on.

The following share properties are required:

share=*name*=*sharename*

Identifies an NFS or SMB share name. Maximum length of a share name is 80 characters.

path=*pathname*

Identifies the physical path of the dataset to be shared or a subdirectory within the dataset to be shared.

prot=smb | nfs

Identifies the NFS or SMB file sharing protocol.

The following share properties are optional:

desc=*description*

Identifies a text string that describes the share resource. Spaces or commas in the description must be enclosed in quotation marks (" ").

ro= | rw=

Identifies whether the share is available as read/write or read-only to all clients. You can also specify a colon-separated list that includes hostnames, IP addresses, or a netgroup.

root=

Identifies a root user from a specified host or list of hosts that have root access. By default, no host has root access.

sec=

Identifies an NFS server security mode, such as sys, dh, krb5, and so on. For supported security mode information, see nfssec(5).

The following optional NFS properties must be specified after prot=nfs but before any sec properties:

anon=TYPE_USER
nosub=[true|false]
nosuid=[true|false]

```
aclok=[true|false]
public=[true|false]
index=filename
log=TYPE_LOGTAG
cksum=TYPE_STRINGSET
```

The following optional SMB properties must be specified after `prot=smb`:

```
ad-container=string
abe=[true|false]
csc=[disabled|manual|auto|vdo]
catia=[true|false]
guestok=[true|false]
ro=access-list
rw=access-list
none=access-list
```

See share_nfs(1M) and share_smb(1M) for a detailed description of NFS and SMB share properties.

zfs set [-r] *property=value filesystem|volume|snapshot* ...
　　Sets the property to the given value for each dataset. Only some properties can be edited. See the "Properties" section for more information on what properties can be set and acceptable values.

　　-r
　　　　Recursively apply the effective value of the setting throughout the subtree of child datasets. The effective value may be set or inherited, depending on the property.

zfs set -c share=*name=sharename filesystem*
　　Removes a file system share. The -c option distinguishes this subcommand from the zfs set share command described above.

zfs share -a | *dataset*
　　Publishes an NFS or SMB share of a ZFS dataset according to the share properties values and if sharenfs or sharesmb property set.

　　Sharing a dataset with the NFS or SMB protocol means that the dataset data is available over the network. ZFS datasets that have the sharenfs or sharesmb property set are automatically shared when a system is booted.

　　-a
　　　　Shares all ZFS datasets according to their share property values and to the settings of the sharenfs and sharesmb properties.

　　dataset
　　　　Shares the specified dataset according to the share property values and to the settings of the sharenfs and sharesmb properties.

zfs unshare -a | *dataset|mountpoint*
　　Unshares all ZFS datasets that have the sharenfs or sharesmb property set.

-a

Unshare all shared ZFS datasets. Invoked automatically as part of the boot process.

dataset|*mountpoint*

Unshare the specified dataset. The command can also be given a path to a ZFS dataset shared on the system.

Examples EXAMPLE 1   Creating an NFS or SMB Share of a ZFS File System

Creating an NFS or SMB share of a ZFS file system is a two-step process:

1. Create the share by using the `zfs set share` command to identify the NFS or SMB share properties.

   To create an NFS share:

   ```
   # zfs create -o mountpoint=/data tank/data
   # zfs set share=name=data,path=/data,prot=nfs tank/data
   ```

   To create an SMB share:

   ```
   # zfs set share=name=fs,path=/fs,prot=smb,ro=@10-132-60-234 \
   tank/fs
   ```

2. Publish the share by setting the `sharenfs` or `sharesmb` property. Use commands such as:

   ```
   # zfs set sharenfs=on tank/data
   # zfs set sharesmb=on tank/fs
   ```

EXAMPLE 2   Displaying NFS or SMB Share Information

Display NFS or SMB share information:

```
# zfs get share
NAME                      PROPERTY   VALUE   SOURCE
tank/data                 share      name=data,path=/data,prot=nfs  local
tank/fs                   share      name=fs,path=/fs,prot=smb,ro... local
```

EXAMPLE 3   Adding or Changing Share Properties on a ZFS File System

Change a share by adding a new option, such as read-only for hostA, as in the following:

```
# zfs set share=name=data,prot=nfs,ro=hostA tank/data
```

EXAMPLE 4   Removing a NFS or SMB Share of a ZFS File System

Remove a share by using `zfs set -c` command:

```
# zfs set -c share=name=fs tank/fs
share 'fs' was removed.
```

Exit Status The following exit values are returned:

0

Successful completion.

1

An error occurred.

2

Invalid command line options were specified.

Attributes See attributes(5) for descriptions of the following attributes:

For information about using other ZFS features, see the *Oracle Solaris Administration: ZFS File Systems*.

Name zic – time zone compiler

Synopsis `zic` [`--`*version*] [`-s`] [`-v`] [`-d` *directory* | `-l` *localtime*]
        [`-p` *posixrules*] [`-y` *yearistype*] [*filename*]...

Description `zic` reads text from the file(s) named on the command line and creates the time conversion information files specified in this input. If a *filename* is '−', the standard input is read.

Input lines are made up of fields. Fields are separated by any number of white space characters. Leading and trailing white space on input lines is ignored. A pound sign (#) indicates a comment that extends to the end of the line. White space characters and pound signs can be enclosed within double quotes (" ") if they are to be used as part of a field. Any line that is blank (after comment stripping) is ignored. Non-blank lines are expected to be of one of three types: rule lines, zone lines, or link lines.

Rule A rule line has the form:

For example:

```
Rule   NAME  FROM  TO  TYPE  IN   ON    AT   SAVE  LETTER/S
```

The fields that make up a rule line are:

```
Rule   USA   1969  1973  -  Apr lastSun 2:00  1:00   D
```

NAME   Gives the (arbitrary) name of the set of rules this rule is part of.

FROM   Gives the first year in which the rule applies. The word `minimum` (or an abbreviation) means the minimum year with a representable time value. The word `maximum` (or an abbreviation) means the maximum year with a representable time value.

TO   Gives the final year in which the rule applies. In addition to `minimum` and `maximum` (as above), the word `only` (or an abbreviation) can be used to repeat the value of the FROM field.

TYPE   Gives the type of year in which the rule applies. If TYPE is:

   '−'   The rule applies in all years between FROM and TO, inclusive.

   uspres   The rule applies in U.S. Presidential election years.

   nonpres   The rule applies in years other than U.S. Presidential election years.

   even   The rule applies to even-numbered years.

   odd   The rule applies to odd-numbered years.

If TYPE is something else, then `zic` will attempt to execute the command

`yearistype` *year* `type`

to check the type of a year: an exit status of `0` means that the year is of the given type; an exit status of `1` means that the year is not of the given type. The `yearistype` command is not currently provided in the Solaris environment.

IN   Names the month in which the rule takes effect. Month names can be abbreviated.

ON   Gives the day on which the rule takes effect. Recognized forms include:

5	the fifth day of the month
lastSun	The last Sunday in the month
lastMon	The last Monday in the month
Sun>=8	First Sunday on or after the eighth
Sun<=25	Last Sunday on or before the 25th

Names of days of the week can be abbreviated or spelled out in full. Note: There cannot be spaces within the `ON` field.

AT   Gives the time of day at which the rule takes effect. Recognized forms include:

2	Time in hours
2:00	Time in hours and minutes
15:00	24-hour format time (for times after noon)
1:28:14	Time in hours, minutes, and seconds, where hour 0 is midnight at the start of the day and hour 24 is midnight at the end of the day.

Any of these forms can be followed by the letter w if the given time is local "wall clock" time; s if the given time is local "standard" time; or u (or g or z) if the given time is universal time. In the absence of an indicator, wall clock time is assumed.

SAVE   Gives the amount of time to be added to local standard time when the rule is in effect. This field has the same format as the `AT` field (without the w and s suffixes).

LETTER/S   Gives the "variable part" (for example, the "S" or "D" in "EST" or "EDT" of time zone abbreviations to be used when this rule is in effect. If this field is '−', the variable part is null.

Zone   A zone line has the form:

```
Zone  NAME                  GMTOFF  RULES/SAVE  FORMAT  [UNTIL]
```

For example:

```
Zone Australia/SouthWest   9:30        -        CST   1992 Mar 15 12:00
                           8:30       Aus       CST
```

The fields that make up a zone line are:

NAME   The name of the time zone. This is the name used in creating the time conversion information file for the zone.

GMTOFF   The amount of time to add to UTC to get standard time in this zone. This field has the same format as the AT and SAVE fields of rule lines; begin the field with a minus sign to subtract time from UTC.

RULES/SAVE   The name of the rule(s) that apply in the time zone or, alternately, an amount of time to add to local standard time. If this field is '−', then standard time always applies in the time zone.

FORMAT   The format for time zone abbreviations in this time zone. The pair of characters %s is used to show where the "variable part" of the time zone abbreviation goes. Alternately, a slash (/) separates standard and daylight abbreviations.

UNTIL   The time at which the UTC offset or the rule(s) change for a location. It is specified as a year, a month, a day, and a time of day. The time of day has the same format as the AT field of rule lines. If this is specified, the time zone information is generated from the given UTC offset and rule change until the time specified.

                  The month, day, and time of day have the same format as the IN, ON, and AT columns of a rule; trailing columns can be omitted, and default to the earliest possible value for the missing columns.

                  The next line must be a "continuation" line. This line has the same form as a zone line except that the string "Zone" and the name are omitted. The continuation line places information starting at the time specified as the UNTIL field in the previous line in the file used by the previous line. Continuation lines can contain an UNTIL field, just as zone lines do, indicating that the next line is a further continuation.

Link   A link line has the form:

```
Link   LINK-FROM   LINK-TO
```

For example:

```
Link   Europe/Istanbul Asia/Istanbul
```

The LINK-FROM field should appear as the NAME field in some zone line; the LINK-TO field is used as an alternate name for that zone.

Except for continuation lines, lines can appear in any order in the input.

Options --*version*   Outputs version information and exits.

-d *directory*   Creates time conversion information files in the directory *directory* rather than in the standard directory /usr/share/lib/zoneinfo.

The -d and -l options are mutually exclusive.

-l *localtime*   Uses the given time zone as local time *localtime*. zic acts as if the file contained a link line of the form:

Link *localtime* localtime

The -d and -l options are mutually exclusive.

-p *posixrules*   Uses the rules of the given time zone *posixrules* when handling POSIX-format time zone environment variables. zic acts as if the input contained a link line of the form:

Link   *posixrules* posixrules

This option is not used by ctime(3C) and mktime(3C) in the Solaris environment.

-s   Limits time values stored in output files to values that are the same whether they are taken to be signed or unsigned. You can use this option to generate SVVS-compatible files.

This option is obsolete and may be removed in a future release.

-v   Complains if a year that appears in a data file is outside the range of years representable by system time values (0:00:00 a.m. UTC, January 1, 1970, to 3:14:07 a.m. UTC, January 19, 2038). This option also complains if a time of 24:00 (which cannot be handled by pre-1998 versions of zic) appears in the input.

-y *yearistype*   Uses the given command *yearistype* rather than yearistype when checking year types (see Rules under DESCRIPTION).

Operands *filename*   A file containing input lines that specify the time conversion information files to be created. If a *filename* is '−', the standard input is read.

Files /usr/share/lib/zoneinfo   Standard directory used for created files

/usr/share/lib/zoneinfo/src   Directory containing source files

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/core-os
Interface Stability	Committed*

* The -s option is obsolete.

See Also   time(1), zdump(1M), ctime(3C), mktime(3C), attributes(5)

Notes   For areas with more than two types of local time, you might need to use local standard time in the AT field of the earliest transition time's rule to ensure that the earliest transition time recorded in the compiled file is correct.

If the current *timezone* file is edited and compiled using the "zic" command, the changes will only be reflected in any new processes that are running. The most accurate way to reflect the changes for the whole system would be a reboot.

Name zoneadm – administer zones

Synopsis zoneadm -z *zonename* [-u *uuid-match*] *subcommand*
      [*subcommand_options*]

zoneadm [-R *root*] [-z *zonename*] [-u *uuid-match*] list
      [*list_options*]

zoneadm [-R *root*] -z *zonename* [-u *uuid-match*] mark incomplete

Description The zoneadm utility is used to administer system zones. A zone is an application container that is maintained by the operating system runtime.

Security Once a process has been placed in a zone other than zone 0, the process or any of its children cannot change zones.

Security Except for simple listing and help functions, only a user operating in the global system zone can use zoneadm, and it must be executed with an effective user ID of root. In addition, the user must be authorized to execute specific subcommands.

zoneadm checks for authorization strings that optionally include the specified *zonename* as a suffix, preceded by the slash character. When omitted, the authorization matches any zone.

Subcommands that only provide information, for example, help or list, do not require any authorizations. All other subcommands require the authorization solaris.zone.manage/*zonename*.

Once a process has been placed in a zone other than zone 0, neither that process nor any of its children can change zones.

Options The following options are supported:

-R *root*

  Specify an alternate root (boot environment). This option can only be used in conjunction with the "list" and "mark" subcommands.

-u *uuid-match*

  Unique identifier for a zone, as assigned by libuuid(3LIB). If this option is present and the argument is a non-empty string, then the zone matching the UUID is selected instead of the one named by the -z option, if such a zone is present.

-z *zonename*
  String identifier for a zone.

Subcommands Subcommands which can result in destructive actions or loss of work have a -F flag to force the action. If input is from a terminal device, the user is prompted if such a command is given without the -F flag; otherwise, if such a command is given without the -F flag, the action is disallowed, with a diagnostic message written to standard error. If a zone installation or uninstallation is interrupted, the zone is left in the incomplete state. Use uninstall to reset such a zone back to the configured state.

The following subcommands are supported:

attach [-u] [-F] [-n *path*] [*brand-specific options*]

    The attach subcommand takes a zone that has been detached from one system and attaches the zone onto a new system. Therefore, it is advised (though not required) that the detach subcommand should be run before the "attach" takes place. Once you have the new zone in the configured state, use the attach subcommand to set up the zone root instead of installing the zone as a new zone.

    The -F option can be used to force the zone into the "installed" state with no validation. This option should be used with care since it can leave the zone in an unsupportable state if it was moved from a source system to a target system that is unable to properly host the zone. The -n option can be used to perform a "dry run" of the attach subcommand. It uses the output of the "detach -n" subcommand as input and is useful to identify any conflicting issues, such as the network device being incompatible, and can also determine whether the host is capable of supporting the zone. The path can be "-", to read the input from standard input.

    The zone's brand may include additional options that govern how the zone will be attached. See brands(5) for specific brand information.

    The zone being attached must first be configured using the zonecfg (see zonecfg(1M)) command. This does not apply when running "attach -n".

    Use the following command to attach a zone:

    # zoneadm -z my-zone attach

    Use the following command to attach and update a zone:

    # zoneadm -z my-zone attach -u

    In the absence of -n (as above), the source zone must be halted before this subcommand can be used.

    -n *path*

        Read the zone manifest and verify that the target machine has the correct configuration to host the zone without actually performing an attach. The zone on the target system does not have to be configured on the new host before doing a trial-run attach.

    -u

        Update the attached zone.

boot [-w|-W] [-- *boot_options*]

    Boot (or activate) the specified zones.

    The boot subcommand has the following mutually exclusive options:

-w

    Boots the zone with a writable root, effectively overriding the `file-mac-profile` setting in the zone's configuration. This option is in effect for this boot-cycle only: a subsequent reboot will boot the zone with a `file-mac-profile` in effect again.

-W

    Boots the zone in transient r/w mode; when the zone completes self-assembly, the zone will reboot in read-only mode. Has no effect non-read only root zones.

The following *boot_options* are supported:

-i *altinit*

    Select an alternative executable to be the primordial Process. *altinit* is a valid path to an executable. The default primordial process is init(1M).

-m *smf_options*

    The *smf_options* include two categories of options to control booting behavior of the service management facility: recovery options and messages options.

    Message options determine the type and amount of messages that smf(5) displays during boot. Service options determine the services which are used to boot the system. See kernel(1M) for a listing of the -m suboptions.

-s

    Boots only to milestone `svc:/milestone/single-user:default`. This milestone is equivalent to init level `s`. See svc.startd(1M) and init(1M).

clone [-m *copy*] [-s *zfs_snapshot*] [*brand-specific options*] *source_zone*

    Install a zone by copying an existing installed zone. This subcommand is an alternative way to install the zone.

-m *copy*

    Force the clone to be a copy, even if a "ZFS clone" is possible.

-s *zfs_snapshot*

    Specify the name of a ZFS snapshot to use as the source of the clone. The *snapshot* must be a *snapshot* of the source zone taken from a previous "zoneadm clone" installation.

The source zone must be halted before this subcommand can be used.

detach [-F | -n]

    Detach the specified zone. Detaching a zone is the first step in moving a zone from one system to another. The full procedure to migrate a zone is that the zone is detached, the *zonepath* directory is moved to the new host, and then the zone is attached on the new host. Once the zone is detached, it is left in the configured state. If you try to install or clone to a configured zone that has been detached, you will receive an error message and the install or clone subcommand will not be allowed to proceed. The -n option can be used to perform a "dry run" of the detach subcommand. This generates the information needed for running the "attach -n" subcommand, which is useful to identify any conflicting

issues, such as the network device being incompatible or if the host is capable of supporting the zone. The information is sent to standard output and can be saved to a file or piped to the "attach -n" subcommand. The -F option can be used to forcefully detach the zone without performing verification checks on the existing *zonepath*.

Use the following command to detach a zone:

```
# zoneadm -z my-zone detach
```

Unless the -n option is used, the source zone must be halted before this subcommand can be used.

-F

Forcefully detach the zone without performing verification checks on the zone's storage. This option is typically used if the storage for the *zonepath* is no longer accessible to this host. Such a scenario is normally encountered when the zone's storage has been failed over to an alternate host, either manually or as part of a cluster.

-n

Generate a zone manifest on a running zone without actually detaching the zone. The state of the zone on the originating system is not changed. The zone manifest is sent to stdout. The global administrator can direct this output to a file or pipe it to a remote command to be immediately validated on the target host.

halt

Halt the specified zones. halt bypasses running the shutdown scripts inside the zone. It also removes run time resources of the zone.

See also the shutdown subcommand, below.

help [*subcommand*]

Display general help. If you specify *subcommand*, displays help on *subcommand*.

install [*brand-specific options*]

Install the specified zone on the system. This subcommand automatically attempts to verify first. It refuses to install if the verify step fails. See the verify subcommand.

The zone's brand may include additional options that govern how the software will be installed in the zone. See brands(5) for specific brand information.

list [*list_options*]

Display the name of the current zones, or the specified zone if indicated.

By default, all running zones are listed. If you use this subcommand with the zoneadm -z *zonename* option, it lists only the specified zone, regardless of its state. In this case, the -i and -c options are disallowed.

If neither the -i or -c options are given, all running zones are listed.

The following *list_options* are supported:

-c

Display all configured zones. This option overides the -i option.

-i

Expand the display to all installed zones.

-p

Request machine parsable output. The output format is a list of lines, one per zone, with colon- delimited fields. These fields are:

```
zoneid:zonename:state:zonepath:uuid:brand:ip-type:\
r/w:file-mac-profile
```

If the *zonepath* contains embedded colons, they can be escaped by a backslash ("\:"), which is parsable by using the shell read(1) function with the environmental variable IFS. The *uuid* value is assigned by libuuid(3LIB) when the zone is installed, and is useful for identifying the same zone when present (or renamed) on alternate boot environments. Any software that parses the output of the "zoneadm list -p" command must be able to handle any fields that may be added in the future.

The -v and -p options are mutually exclusive. If neither -v nor -p is used, just the zone name is listed.

-v

Display verbose information, including zone name, id, current state, root directory, brand type, ip-type, and options.

The -v and -p options are mutually exclusive. If neither -v nor -p is used, just the zone name is listed.

mark incomplete

Change the state of an installed zone to "incomplete." This command may be useful in cases where administrative changes on the system have rendered a zone unusable or inconsistent. This change cannot be undone (except by uninstalling the zone).

move *new_zonepath*

Move the *zonepath* to *new_zonepath*. The zone must be halted before this subcommand can be used. The *new_zonepath* must be a local file system and normal restrictions for *zonepath* apply.

ready

Prepares a zone for running applications but does not start any user processes in the zone.

reboot [-- *boot_options*]

Restart the zone. This is equivalent to a halt boot sequence (shutdown scripts are not run).

See the boot subcommand for supported boot options.

shutdown [-r [-- *boot_options*]]

> Cleanly shut down the zone (equivalent to running /usr/sbin/init 0 in the zone). The shutdown subcommand waits until the zone is successfully shut down; a zoneadm halt can be used to forcibly halt the zone, if the shutdown process takes a long time.

> If -r is specified, reboot the zone. See the boot subcommand for supported boot options.

uninstall [-F]

> Uninstall the specified zone from the system. Use this subcommand with caution. It removes all of the files under the *zonepath* of the zone in question. You can use the -F flag to force the action.

verify

> Check to make sure the configuration of the specified zone can safely be installed on the machine. Following is a break-down of the checks by resource/property type:

> *zonepath*

>> *zonepath* and its parent directory exist and are owned by root with appropriate modes . The appropriate modes are that *zonepath* is 700, its parent is not group or world-writable and so forth. *zonepath* is not over an NFS mount. A sub-directory of the *zonepath* named "root" does not exist.

>> If *zonepath* does not exist, the verify does not fail, but merely warns that a subsequent install will attempt to create it with proper permissions. A verify subsequent to that might fail should anything go wrong.

>> *zonepath* cannot be a symbolic link.

> fs

>> Any fs resources have their *type* value checked. An error is reported if the value is one of proc, mntfs, autofs, or nfs or the filesystem does not have an associated mount binary at /usr/lib/fs/*<fstype>*/mount.

>> It is an error for the *directory* to be a relative path.

>> It is an error for the path specified by raw to be a relative path or if there is no fsck binary for a given filesystem type at /usr/lib/fs/*<fstype>*/fsck. It is also an error if a corresponding fsck binary exists but a raw path is not specified.

> net

>> All physical network interfaces exist. All network address resources are one of:

>> - a valid IPv4 address, optionally followed by "/" and a prefix length;
>> - a valid IPv6 address, which must be followed by "/" and a prefix length;
>> - a host name which resolves to an IPv4 address.

>> Note that hostnames that resolve to IPv6 addresses are not supported.

>> The physical interface name is the network interface name.

A zone can be configured to be either exclusive-IP or shared-IP. For a shared-IP zone, both the physical and address properties must be set. For an exclusive-IP zone, the physical property must be set and the address property cannot be set.

anet

It verifies that the lower-link, over which the VNIC will be automatically created, exists.

rctl

It also verifies that any defined resource control values are valid on the current machine. This means that the privilege level is privileged, the limit is lower than the currently defined system value, and that the defined action agrees with the actions that are valid for the given resource control.

Examples   EXAMPLE 1   Using the -m Option

The following command illustrates the use of the -m option.

```
# zoneadm boot -- -m verbose
```

EXAMPLE 2   Using the -i Option

The following command illustrates the use of the -i option.

```
# zoneadm boot -- -i /usr/sbin/init
```

EXAMPLE 3   Using the -s Option

The following command illustrates the use of the -s option.

```
# zoneadm boot -- -s
```

Exit Status   The following exit values are returned:

0

Successful completion.

1

An error occurred.

2

Invalid usage.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/zones
Interface Stability	Committed

See Also   read(1), svcs(1), zlogin(1), zonename(1), init(1M), kernel(1M), svcadm(1M), svc.startd(1M), svc.startd(1M), zonecfg(1M), libuuid(3LIB), attributes(5), brands(5), mwac(5), smf(5), zones(5)

Notes   The zones(5) service is managed by the service management facility, smf(5), under the service identifier:

```
svc:/system/zones:default
```

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

For the first boot after a read-only zone is installed or upgraded, or when the zone is booted with -w/-W, the write-only protection is disabled. Care must be taken that the zone is otherwise protected.

Name zoneadmd – zone administration daemon

Synopsis /usr/lib/zones/zoneadmd

Description zoneadmd is a system daemon that is started when the system needs to manage a particular zone. Because each instance of the zoneadmd daemon manages a particular zone, it is not unexpected to see multiple zoneadmd daemons running.

This daemon is started automatically by the zone management software and should not be invoked directly. The daemon shuts down automatically when no longer in use. It does not constitute a programming interface, but is classified as a private interface.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/zones
Interface Stability	Private

See Also svcs(1), zlogin(1), svcadm(1M), zoneadm(1M), attributes(5), smf(5), zones(5)

Notes The zones(5) service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/zones:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

Name   zonecfg – set up zone configuration

Synopsis   zonecfg -z *zonename*

zonecfg -z *zonename subcommand*

zonecfg -z *zonename* -f *command_file*

zonecfg help

Description   The zonecfg utility creates, modifies, and lists the configuration of a zone. The creation and modification functions are only available to authorized users and require that the process is executed with an effective user ID of root. Otherwise it runs in read-only mode.

A zone's configuration consists of a number of resources and properties.

To simplify the user interface, zonecfg uses the concept of a scope. The default scope is global.

The following synopsis of the zonecfg command is for interactive usage:

zonecfg -z *zonename subcommand*

Parameters changed through zonecfg do not affect a running zone. The zone must be rebooted for the changes to take effect.

In addition to creating and modifying a zone, the zonecfg utility can also be used to persistently specify the resource management settings for the global zone.

In the following text, "rctl" is used as an abbreviation for "resource control". See resource_controls(5).

Every zone is configured with an associated brand. The brand determines the user-level environment used within the zone, as well as various behaviors for the zone when it is installed, boots, or is shutdown. Once a zone has been installed the brand cannot be changed. The default brand is determined by the installed distribution in the global zone. Some brands do not support all of the zonecfg properties and resources. See the brand-specific man page for more details on each brand. For an overview of brands, see the brands(5) man page.

Resources   The following resource types are supported:

attr
    Generic attribute.

capped-cpu
    Limits for CPU usage.

capped-memory
    Limits for physical, swap, and locked memory.

dataset
    ZFS dataset.

dedicated-cpu
   Subset of the system's processors dedicated to this zone while it is running.

device
   Device.

fs
   file-system

net
   Network interface.

anet
   Automatic network interface.

admin
   Delegated administrator.

rctl
   Resource control.

Sparse and Whole Root Non-Global Zones
Previous releases of Solaris offered the notion of *sparse root zones*. This functionality was intimately associated with the SVr4 packaging system and intended to save disk space and reduce administrative effort.

The new packaging system, IPS, provides more flexibility when choosing which packages to install in a zone. This, along with advances in file system technology (notable among which is ZFS *deduplication*), means that it was most sensible to remove sparse root zones. The benefits of sparse root zones are provided for all zones by means of the combination of IPS packaging and file system advances.

Properties
Each resource type has one or more properties. There are also some global properties, that is, properties of the configuration as a whole, rather than of some particular resource.

The following properties are supported:

(global)
   zonename

(global)
   zonepath

(global)
   autoboot

(global)
   bootargs

(global)
   pool

(global)
   `limitpriv`

(global)
   `brand`

(global)
   `cpu-shares`

(global)
   `hostid`

(global)
   `max-lwps`

(global)
   `max-msg-ids`
(global)
   `max-processes`

(global)
   `max-sem-ids`

(global)
   `max-shm-ids`

(global)
   `max-shm-memory`

(global)
   `scheduling-class`

(global)
   `fs-allowed`

(global)
   file-mac-profile

`fs`
   `dir`, `special`, `raw`, `type`, `options`

`net`
   `address`, `allowed-address`, `configure-allowed-address`, `physical`, `defrouter`

`anet`
   `linkname`, `lower-link`, `allowed-address`, `configure-allowed-address`, `defrouter`,
   `mac-address`, `mac-slot`, `mac-prefix`, `mtu`, `maxbw`, `priority`, `vlan-id`, `rxfanout`, `rxrings`,
   `txrings`, `link-protection`, `allowed-dhcp-cids`

`device`
   `match`

```
rctl
   name, value

attr
   name, type, value

dataset
   name, alias

dedicated-cpu
   ncpus, importance

capped-memory
   physical, swap, locked

capped-cpu
   ncpus

admin
   user, auths
```

As for the property values which are paired with these names, they are either simple, complex, or lists. The type allowed is property-specific. Simple values are strings, optionally enclosed within quotation marks. Complex values have the syntax:

(*<name>*=*<value>*,*<name>*=*<value>*,...)

where each *<value>* is simple, and the *<name>* strings are unique within a given property. Lists have the syntax:

[*<value>*,...]

where each *<value>* is either simple or complex. A list of a single value (either simple or complex) is equivalent to specifying that value without the list syntax. That is, "foo" is equivalent to "[foo]". A list can be empty (denoted by "[]").

In interpreting property values, zonecfg accepts regular expressions as specified in fnmatch(5). See EXAMPLES.

The property types are described as follows:

global: zonename
   The name of the zone.

global: zonepath
   Path to zone's file system.

global: autoboot
   Boolean indicating that a zone should be booted automatically at system boot. Note that if the zones service is disabled, the zone will not autoboot, regardless of the setting of this property. You enable the zones service with a svcadm command, such as:

```
# svcadm enable svc:/system/zones:default
```

Replace enable with disable to disable the zones service. See svcadm(1M).

global: bootargs

Arguments (options) to be passed to the zone bootup, unless options are supplied to the "zoneadm boot" command, in which case those take precedence. The valid arguments are described in zoneadm(1M).

global: pool

Name of the resource pool that this zone must be bound to when booted. This property is incompatible with the dedicated-cpu resource.

global: limitpriv

The maximum set of privileges any process in this zone can obtain. The property should consist of a comma-separated privilege set specification as described in priv_str_to_set(3C). Privileges can be excluded from the resulting set by preceding their names with a dash (-) or an exclamation point (!). The special privilege string "zone" is not supported in this context. If the special string "default" occurs as the first token in the property, it expands into a safe set of privileges that preserve the resource and security isolation described in zones(5). A missing or empty property is equivalent to this same set of safe privileges.

The system administrator must take extreme care when configuring privileges for a zone. Some privileges cannot be excluded through this mechanism as they are required in order to boot a zone. In addition, there are certain privileges which cannot be given to a zone as doing so would allow processes inside a zone to unduly affect processes in other zones. zoneadm(1M) indicates when an invalid privilege has been added or removed from a zone's privilege set when an attempt is made to either "boot" or "ready" the zone.

See privileges(5) for a description of privileges. The command "ppriv -l" (see ppriv(1)) produces a list of all Solaris privileges. You can specify privileges as they are displayed by ppriv. In privileges(5), privileges are listed in the form PRIV_*privilege_name*. For example, the privilege *sys_time*, as you would specify it in this property, is listed in privileges(5) as PRIV_SYS_TIME.

global: brand

The zone's brand type.

global: ip-type

A zone can either have its own exclusive instance of IP (the default) or share the IP instance with the global zone. In the default zone template, SYSdefault, ip-type is set to exclusive. In the also-supplied SYSdefault-shared-ip template, ip-type is set to shared.

This property takes the values exclusive and shared.

global: hostid

A zone can emulate a 32-bit host identifier to ease system consolidation. A zone's hostid property is empty by default, meaning that the zone does not emulate a host identifier.

Zone host identifiers must be hexadecimal values between 0 and FFFFFFFE. A `0x` or `0X` prefix is optional. Both uppercase and lowercase hexadecimal digits are acceptable.

global: `fs-allowed`

A comma-separated list of additional file systems that can be mounted within the zone; for example, `ufs,pcfs`. By default, only hsfs(7FS) and network file systems can be mounted.

This property does not apply to file systems mounted into the zone by means of `add fs` or `add dataset`.

Caution – Allowing filesystem mounts other than the default might allow the zone administrator to compromise the system with a bogus filesystem image and is not supported.

global: `file-mac-profile`

Define which parts of the filesystem are exempted from the read-only policy, that is, which parts of the filesystem the zone is allowed to write to.

There are currently four supported values for this property: `none`, `strict`, `fixed-configuration`, and `flexible-configuration`.

`none` makes the zone exactly the same as a normal, r/w zone. `strict` allows no exceptions to the read-only policy. `fixed-configuration` allows the zone to write to files in and below `/var`, except directories containing configuration files:

```
/var/ld
/var/lib/postrun
/var/pkg
/var/spool/cron,
/var/spool/postrun
/var/svc/manifest
/var/svc/profiles
```

`flexible-configuration` is equal to `fixed-configuration`, but allows writing to files in `/etc` in addition.

fs: dir, special, raw, type, options

Values needed to determine how, where, and so forth to mount file systems. See mount(1M), mount(2), fsck(1M), and vfstab(4).

net: address, allowed-address, configure-allowed-address, physical, defrouter

The `net` resource represents the assignment of a physical network resource to a zone. The resource must exists in the global zone prior to the assignment.

The network address and physical interface name of the network interface. The network address is one of:

- a valid IPv4 address, optionally followed by "/" and a prefix length;
- a valid IPv6 address, which must be followed by "/" and a prefix length;
- a host name which resolves to an IPv4 address.

Note that host names that resolve to IPv6 addresses are not supported.

The physical interface name is the network interface name.

The value for the optional default router is specified similarly to the network address except that it must not be followed by a / (slash) and a network prefix length. To enable correct use of the defrouter functionality, the zones that use the property must be on a different subnet from the subnet on which the global zone resides. Also, each zone (or set of zones) that uses a different defrouter setting must be on a different subnet.

A zone can be configured to be either exclusive-IP or shared-IP. For a shared-IP zone, you must set both the physical and address properties; setting the default router is optional. The interface specified in the physical property must be plumbed in the global zone prior to booting the non-global zone. However, if the interface is not used by the global zone, it should be configured down in the global zone, and the default router for the interface should be specified here. The allowed-address property cannot be set for a shared-IP zone.

For an exclusive-IP zone, the physical property must be set and the address property must not be set. Optionally, the set of IP addresses that the exclusive-IP zone can use might be constrained by specifying the allowed-address property. If allowed-address has not been specified, then the exclusive-IP zone can use any IP address on the associated physical interface for the net resource. Otherwise, when allowed-address is specified, the exclusive-IP zone cannot use IP addresses that are not in the allowed-address list for the physical address. If configure-allowed-address is set to true, the allowed-address is persistently configured on the interface on initial boot after installation. When it is set to false, the allowed-address will not be configured on zone boot. By default, configure-allowed-address is set to true when an allowed-address is specified. In addition, when the allowed-address list has been populated, the defrouter property can also be optionally specified. However, if the defrouter value is specified and configure-allowed-address is set to false, the defrouter value will be ignored and an appropriate warning message will be shown. The interface specified for the physical property must not be in use in the global zone. If an allowed-address and default router are specified by means of zonecfg, these will be applied to the interface when it is enabled by means of ipadm(1M) in the non-global, exclusive-IP zone, typically during zone boot. The non-global exclusive-IP zone will not be able to apply any other addresses to that interface, nor will it be able to transmit packets with a different source address for the specified IP version. A default router set up by means of zonecfg cannot be persistently deleted from within the non-global exclusive-IP zone using the -p flag with route(1M).

Note that a single datalink cannot be shared among multiple exclusive-IP zones.

anet: linkname, lower-link, allowed-address, configure-allowed-address, defrouter, mac-address, mac-slot, mac-prefix, mtu, maxbw, priority, vlan-id, rxfanout, rxrings, txrings, link-protection, allowed-dhcp-cids

> The anet resource represents the automatic creation of a network resource for an exclusive-IP zone. When zonecfg creates a zone using the default SYSdefault template, an anet resource with the following properties is automatically included in the zone configuration:

```
linkname=net0
lower-link=auto
mac-address=random
link-protection=mac-nospoof
```

> When such a zone boots, a lower-link (see below) will be automatically determined and a temporary VNIC automatically created over that link for the zone. The lower-link and VNIC are deleted when the zone halts.

> The supported properties are described below. All these properties are optional. Only the global zone is allowed to modify the automatically created VNIC or its properties. If a property set in zonecfg cannot be assigned to the VNIC at its creation time, the zone will fail to boot.

> linkname
>> Specify a name for the automatically created VNIC. By default, this property will be automatically set to the first available name (for the zone) of the form net*N*, where *N* is a non-negative integer. For example: net0, net1, and so on. The info subcommand displays the automatically selected linkname.

>> Multiple zones, including the global zone, can have links with the same name at the same time.

> lower-link
>> Specify the link over which the VNIC will be created. This property has a default value of auto. The administrator may explicitly specify a value upon adding an anet resource. The link can be any link accepted as an argument to dladm create-vnic's -l option (see dladm(1M)). If this property is set to a linkname (other than auto) and that link does not exist, then the zone will fail to boot. When set to auto, the zoneadmd(1M) daemon will automatically choose the link over which the VNIC will be created each time the zone boots. A link will be chosen using the following heuristic:

>> 1. A link aggregation that has a link state of up.

>> 2. Of the physical Ethernet links that have a link state of up, the one with the alphabetically smallest link name.

>> 3. If none is up, the datalink named net0 is used if it exists.

>> If none of the above can be satisfied, the zone will fail to boot.

allowed-address

See the description of the allowed-address property for exclusive-IP zones in the net resource.

configure-allowed-address

See the description of the configure-allowed-address property for exclusive-IP zones in the net resource.

defrouter

See the description of the defrouter property for exclusive-IP zones in the net resource.

mac-address

Set the VNIC's MAC address based on the specified value or keyword. If the value is not a keyword, it is interpreted as a unicast MAC address. The supported keywords are:

- factory: Assign a factory MAC address to the VNIC. When a factory MAC address is requested, the mac-slot property can be used to specify the MAC address slot identifier. Otherwise, the next available factory MAC address will be used.

- random: Assign a random MAC address to the VNIC. Use the mac-prefix property to specify a prefix. Otherwise, a default prefix consisting of a valid IEEE OUI with the local bit set will be used. This is the default value.

- auto: Try to use a factory MAC address first. If none is available, assign a random MAC address.

If a random MAC address is selected, then the address generated will be preserved across zone boots and zone detach/attach. This will allow zones to retain their DHCP leases by maintaining stable client IDs, and otherwise take advantage of other benefits of having stable MAC addresses.

mac-prefix

Specify the MAC address prefix if a random MAC address is requested. Otherwise this property is ignored.

mac-slot

Specify the MAC address slot identifier if the factory MAC address is requested. Otherwise this property is ignored.

mtu

The maximum transmission unit of the VNIC in bytes. See mtu property in dladm(1M).

maxbw

Specify the full duplex bandwidth for the VNIC. See maxbw property in dladm(1M). By default, the VNIC will use the maxbw set on the lower-link and if none is set then there is no bandwidth limit.

priority

Specify the relative priority for the VNIC. See the priority property in dladm(1M) for supported values and default.

vlan-id

Enable VLAN tagging for this VNIC and specify a id for the VLAN tag. There is no default value which means if this property is not set then the VNIC does not participate in any VLAN.

rxfanout

Specify the number of receive-side fanout threads. See description in dladm(1M).

rxrings

Specify the receive rings for the VNIC. See rxrings property in dladm(1M) for supported values and default.

txrings

Specify the transmit rings for the VNIC. See txrings property in dladm(1M) for supported values and default.

link-protection

Enables one or more types of link protection using comma-separated values. See the protection property in dladm(1M) for supported values. It has a default value of mac-nospoof.

Note that adding ip-nospoof to this property will have no effect unless allowed-address is also set. Setting allowed-address will implicitly add ip-nospoof to the set of link-protection, and clearing allowed-address will remove it.

allowed-dhcp-cids

Setting this property will enable dhcp-nospoof on the VNIC. See dladm(1M) for details.

device: match

Device name to match. This can be a pattern to match or an absolute pathname. Note that device resources and aliased datasets can have namespace conflicts in /dev/zvol. See dev(7FS).

Note – In general, adding devices to a zone can compromise the security of the system; see NOTES.

rctl: name, value

The name and *priv*/*limit*/*action* triple of a resource control. See prctl(1) and rctladm(1M). The preferred way to set rctl values is to use the global property name associated with a specific rctl.

attr: name, type, value

The name, type and value of a generic attribute. The type must be one of int, uint, boolean or string, and the value must be of that type. uint means unsigned , that is, a non-negative integer.

dataset: name, alias

The name of a ZFS dataset to be accessed from within the zone. See zfs(1M). Each dataset is aliased such that it appears as a virtual ZFS pool in the zone. The alias is the name of this

virtual pool. See zpool(1M) for name restrictions that apply to ZFS pool names and as a result also apply to dataset alias values. The alias rpool is reserved from the zone's rpool dataset. Note that aliased datasets and device resources can have namespace conflicts in /dev/zvol. See dev(7FS).

global: cpu-shares
The number of Fair Share Scheduler (FSS) shares to allocate to this zone. This property is incompatible with the dedicated-cpu resource. This property is the preferred way to set the zone.cpu-shares rctl.

global: max-lwps
The maximum number of LWPs simultaneously available to this zone. This property is the preferred way to set the zone.max-lwps rctl.

global: max-msg-ids
The maximum number of message queue IDs allowed for this zone. This property is the preferred way to set the zone.max-msg-ids rctl.

global: max-processes
The maximum number of process table slots simultaneously available to this zone. This property is the preferred way to set the zone.max-processes rctl. Setting this property will implicitly set the value of the max-lwps property to 10 times the number of process slots unless the max-lwps property has been set explicitly.

global: max-sem-ids
The maximum number of semaphore IDs allowed for this zone. This property is the preferred way to set the zone.max-sem-ids rctl.

global: max-shm-ids
The maximum number of shared memory IDs allowed for this zone. This property is the preferred way to set the zone.max-shm-ids rctl.

global: max-shm-memory
The maximum amount of shared memory allowed for this zone. This property is the preferred way to set the zone.max-shm-memory rctl. A scale (K, M, G, T) can be applied to the value for this number (for example, 1M is one megabyte).

global: scheduling-class
Specifies the scheduling class used for processes running in a zone. When this property is not specified, the scheduling class is established as follows:

- If the cpu-shares property or equivalent rctl is set, the scheduling class FSS is used.

- If neither cpu-shares nor the equivalent rctl is set and the zone's pool property references a pool that has a default scheduling class, that class is used.

- Under any other conditions, the system default scheduling class is used.

dedicated-cpu: ncpus, importance
The number of CPUs that should be assigned for this zone's exclusive use. The zone will create a pool and processor set when it boots. See pooladm(1M) and poolcfg(1M) for more

information on resource pools. The ncpu property can specify a single value or a range (for example, 1-4) of processors. The importance property is optional; if set, it will specify the pset.importance value for use by poold(1M). If this resource is used, there must be enough free processors to allocate to this zone when it boots or the zone will not boot. The processors assigned to this zone will not be available for the use of the global zone or other zones. This resource is incompatible with both the pool and cpu-shares properties. Only a single instance of this resource can be added to the zone.

capped-memory: physical, swap, locked

The caps on the memory that can be used by this zone. A scale (K, M, G, T) can be applied to the value for each of these numbers (for example, 1M is one megabyte). Each of these properties is optional but at least one property must be set when adding this resource. Only a single instance of this resource can be added to the zone. The physical property sets the max-rss for this zone. This will be enforced by rcapd(1M) running in the global zone. The swap property is the preferred way to set the zone.max-swap rctl. The locked property is the preferred way to set the zone.max-locked-memory rctl.

capped-cpu: ncpus

Sets a limit on the amount of CPU time that can be used by a zone. The unit used translates to the percentage of a single CPU that can be used by all user threads in a zone, expressed as a fraction (for example, .75) or a mixed number (whole number and fraction, for example, 1.25). An ncpu value of 1 means 100% of a CPU, a value of 1.25 means 125%, .75 mean 75%, and so forth. When projects within a capped zone have their own caps, the minimum value takes precedence.

The capped-cpu property is an alias for zone.cpu-cap resource control and is related to the zone.cpu-cap resource control. See resource_controls(5).

admin: user, auths

Delegates zone administrative authorizations to the specified user or role. The user must correspond to a valid local account. The allowed values for auths are:

login

Allows authenticated use of zlogin(1) into this zone.

manage

Allows normal management of the configured zone.

copyfrom

Allows the use of the specified zone as a source from which to clone a new zone.

The following table summarizes resources, property-names, and types:

```
resource          property-name   type
(global)          zonename        simple
(global)          zonepath        simple
(global)          autoboot        simple
(global)          bootargs        simple
(global)          pool            simple
```

```
              (global)        limitpriv       simple
              (global)        brand           simple
              (global)        ip-type         simple
              (global)        hostid          simple
              (global)        cpu-shares      simple
              (global)        max-lwps        simple
              (global)        max-msg-ids     simple
              (global)        max-sem-ids     simple
              (global)        max-shm-ids     simple
              (global)        max-shm-memory  simple
              (global)        scheduling-class simple
              (global)        fs-allowed      list of simple
              fs              dir             simple
                              special         simple
                              raw             simple
                              type            simple
                              options         list of simple
              net             address         simple
                              allowed-address list of simple
                              configure-allowed-address simple
                              defrouter       list of simple
                              physical        simple
              anet            linkname        simple
                              lower-link      simple
                              allowed-address list of simple
                              configure-allowed-address simple
                              defrouter       list of simple
                              mac-address     simple
                              mac-slot        simple
                              mac-prefix      simple
                              mtu             simple
                              maxbw           simple
                              priority        simple
                              vlan-id         simple
                              rxfanout        simple
                              rxrings         simple
                              txrings         simple
                              link-protection list of simple
                              allowed-dhcp-cids list of simple
              device          match           simple
              rctl            name            simple
                              value           list of complex
              attr            name            simple
                              type            simple
                              value           simple
              dataset         name            simple
                              alias           simple
              dedicated-cpu   ncpus           simple or range
```

	importance	simple
capped-memory	physical	simple with scale
	swap	simple with scale
	locked	simple with scale
capped-cpu	ncpus	simple
admin	user	simple
	auths	list of simple

To further specify things, the breakdown of the complex property "value" of the "rctl" resource type, it consists of three name/value pairs, the names being "priv", "limit" and "action", each of which takes a simple value. The "name" property of an "attr" resource is syntactically restricted in a fashion similar but not identical to zone names: it must begin with an alphanumeric, and can contain alphanumerics plus the hyphen (-), underscore (_), and dot (.) characters. Attribute names beginning with "zone" are reserved for use by the system. Finally, the "autoboot" global property must have a value of "true" or "false".

Using Kernel Statistics to Monitor CPU Caps   Using the kernel statistics (kstat(3KSTAT)) module caps, the system maintains information for all capped projects and zones. You can access this information by reading kernel statistics (kstat(3KSTAT)), specifying caps as the kstat module name. The following command displays kernel statistics for all active CPU caps:

kstat caps::'/cpucaps/'

A kstat(1M) command running in a zone displays only CPU caps relevant for that zone and for projects in that zone. See EXAMPLES.

The following are cap-related arguments for use with kstat(1M):

caps
   The kstat module.

project_caps or zone_caps
   kstat class, for use with the kstat -c option.

cpucaps_project_*id* or cpucaps_zone_*id*
   kstat name, for use with the kstat -n option. *id* is the project or zone identifier.

The following fields are displayed in response to a kstat(1M) command requesting statistics for all CPU caps.

module
   In this usage of kstat, this field will have the value caps.

name
   As described above, cpucaps_project_*id* or cpucaps_zone_*id*

above_sec
   Total time, in seconds, spent above the cap.

below_sec
  Total time, in seconds, spent below the cap.

maxusage
  Maximum observed CPU usage.

nwait
  Number of threads on cap wait queue.

usage
  Current aggregated CPU usage for all threads belonging to a capped project or zone, in terms of a percentage of a single CPU.

value
  The cap value, in terms of a percentage of a single CPU.

zonename
  Name of the zone for which statistics are displayed.

See EXAMPLES for sample output from a kstat command.

Options   The following options are supported:

-f *command_file*
  Specify the name of zonecfg command file. *command_file* is a text file of zonecfg subcommands, one per line.

-z *zonename*
  Specify the name of a zone. Zone names are case sensitive. Zone names must begin with an alphanumeric character and can contain alphanumeric characters, the underscore (_) the hyphen (-), and the dot (.). The name global and all names beginning with SYS are reserved and cannot be used.

Subcommands   You can use the add and select subcommands to select a specific resource, at which point the scope changes to that resource. The end and cancel subcommands are used to complete the resource specification, at which time the scope is reverted back to global. Certain subcommands, such as add, remove and set, have different semantics in each scope.

zonecfg supports a semicolon-separated list of subcommands. For example:

```
# zonecfg -z myzone "add net; set physical=myvnic; end"
```

Subcommands which can result in destructive actions or loss of work have an -F option to force the action. If input is from a terminal device, the user is prompted when appropriate if such a command is given without the -F option otherwise, if such a command is given without the -F option, the action is disallowed, with a diagnostic message written to standard error.

The following subcommands are supported:

add *resource-type* (global scope)
add *property-name property-value* (resource scope)

In the global scope, begin the specification for a given resource type. The scope is changed to that resource type.

In the resource scope, add a property of the given name with the given value. The syntax for property values varies with different property types. In general, it is a simple value or a list of simple values enclosed in square brackets, separated by commas (`[foo,bar,baz]`). See PROPERTIES.

cancel

End the resource specification and reset scope to global. Abandons any partially specified resources. cancel is only applicable in the resource scope.

clear *property-name*

Clear the value for the property.

commit

Commit the current configuration from memory to stable storage. The configuration must be committed to be used by zoneadm. Until the in-memory configuration is committed, you can remove changes with the revert subcommand. The commit operation is attempted automatically upon completion of a zonecfg session. Since a configuration must be correct to be committed, this operation automatically does a verify.

create [-F] [-a *path* |-b | -t *template*]

Create an in-memory configuration for the specified zone. Use create to begin to configure a new zone. See commit for saving this to stable storage.

If you are overwriting an existing configuration, specify the -F option to force the action. Specify the -t *template* option to create a configuration identical to *template*, where *template* is the name of a configured zone.

create uses a default template of SYSdefault. The default template can be changed on a system-wide basis using the default_template SMF property of the svc:/system/zones:default service. An administrator can override the default for this zone using -t (with a specific template) or -b (to use a blank template).

Use the -a *path* option to facilitate configuring a detached zone on a new host. The *path* parameter is the zonepath location of a detached zone that has been moved on to this new host. Once the detached zone is configured, it should be installed using the "zoneadm attach" command (see zoneadm(1M)). All validation of the new zone happens during the attach process, not during zone configuration.

Use the -b option to create a blank configuration. Without arguments, create applies the Oracle Sun default settings.

delete [-F]

Delete the specified configuration from memory and stable storage. This action is instantaneous, no commit is necessary. A deleted configuration cannot be reverted.

Specify the -F option to force the action.

end

End the resource specification. This subcommand is only applicable in the resource scope. zonecfg checks to make sure the current resource is completely specified. If so, it is added to the in-memory configuration (see commit for saving this to stable storage) and the scope reverts to global. If the specification is incomplete, it issues an appropriate error message.

export [-f *output-file*]

Print configuration to standard output. Use the -f option to print the configuration to *output-file*. This option produces output in a form suitable for use in a command file.

help [usage] [*subcommand*] [syntax] [*command-name*]

Print general help or help about given topic.

info zonename | zonepath | autoboot | brand | pool | limitpriv
info [*resource-type* [*property-name=property-value*]*]

Display information about the current configuration. If *resource-type* is specified, displays only information about resources of the relevant type. If any *property-name* value pairs are specified, displays only information about resources meeting the given criteria. In the resource scope, any arguments are ignored, and info displays information about the resource which is currently being added or modified.

remove *resource-type*{*property-name=property-value*}(global scope)

In the global scope, removes the specified resource. The [] syntax means 0 or more of whatever is inside the square braces. If you want only to remove a single instance of the resource, you must specify enough property name-value pairs for the resource to be uniquely identified. If no property name-value pairs are specified, all instances will be removed. If there is more than one pair is specified, a confirmation is required, unless you use the -F option.

select *resource-type* {*property-name=property-value*}

Select the resource of the given type which matches the given *property-name property-value* pair criteria, for modification. This subcommand is applicable only in the global scope. The scope is changed to that resource type. The {} syntax means 1 or more of whatever is inside the curly braces. You must specify enough *property -name property-value* pairs for the resource to be uniquely identified.

set *property-name=property- value*

Set a given property name to the given value. Some properties (for example, zonename and zonepath) are global while others are resource-specific. This subcommand is applicable in both the global and resource scopes.

verify [-v]

Verify the current configuration for correctness:

- All resources have all of their required properties specified.
- A zonepath is specified.

If the -v option is specified, warnings will be issued if there is a potential for devices specified in device resources to conflict with and hide ZFS volumes created within aliased datasets. See dev(7FS).

revert [-F]

Revert the configuration back to the last committed state. The -F option can be used to force the action.

exit [-F]

Exit the zonecfg session. A commit is automatically attempted if needed. You can also use an EOF character to exit zonecfg. The -F option can be used to force the action.

Examples   EXAMPLE 1   Creating the Environment for a New Zone

In the following example, zonecfg creates the environment for a new zone. /usr/local is loopback mounted from the global zone into /opt/local. /opt/sfw is loopback mounted from the global zone, a VNIC over nxge0 is added to the zone with three IP addresses, and a limit on the number of fair-share scheduler (FSS) CPU shares for a zone is set using the rctl resource type. The example also shows how to select a given resource for modification; in this case, by selecting the anet resource that is automatically created by zonecfg.

```
example# zonecfg -z myzone3
my-zone3: No such zone configured
Use 'create' to begin configuring a new zone.
zonecfg:myzone3> create
zonecfg:myzone3> set zonepath=/export/home/my-zone3
zonecfg:myzone3> set autoboot=true
zonecfg:myzone3> add fs
zonecfg:myzone3:fs> set dir=/usr/local
zonecfg:myzone3:fs> set special=/opt/local
zonecfg:myzone3:fs> set type=lofs
zonecfg:myzone3:fs> add options [ro,nodevices]
zonecfg:myzone3:fs> end
zonecfg:myzone3> add fs
zonecfg:myzone3:fs> set dir=/mnt
zonecfg:myzone3:fs> set special=/dev/dsk/c0t0d0s7
zonecfg:myzone3:fs> set raw=/dev/rdsk/c0t0d0s7
zonecfg:myzone3:fs> set type=ufs
zonecfg:myzone3:fs> end
zonecfg:myzone3> add fs
zonecfg:myzone3:fs> set dir=/opt/sfw
zonecfg:myzone3:fs> set special=/opt/sfw
zonecfg:myzone3:fs> set type=lofs
zonecfg:myzone3:fs> add options [ro,nodevices]
zonecfg:myzone3:fs> end
zonecfg:myzone3> select anet linkname=net0
zonecfg:myzone3:anet> set lower-link=nxge0
zonecfg:myzone3:anet> set allowed-address="192.168.0.1/24,192.168.1.2/\
        24,192.168.2.3/24"
```

EXAMPLE 1 Creating the Environment for a New Zone *(Continued)*

```
zonecfg:myzone3:anet> end
zonecfg:my-zone3> set cpu-shares=5
zonecfg:my-zone3> add capped-memory
zonecfg:my-zone3:capped-memory> set physical=50m
zonecfg:my-zone3:capped-memory> set swap=100m
zonecfg:my-zone3:capped-memory> end
zonecfg:myzone3> exit
```

EXAMPLE 2 Creating an Exclusive-IP Zone

The following example creates a zone that is assigned a VNIC named net0. The link over which the VNIC is created is automatically determined. The IP addresses and routing are configured inside the new zone using ipadm(1M).

```
example# zonecfg -z excl
zonecfg:excl> create
zonecfg:excl> set zonepath=/export/zones/excl
zonecfg:excl> exit
```

EXAMPLE 3 Creating a Shared-IP Zone

The following example creates a zone that shares an IP stack with the global zone, and is assigned a single IP address and default router.

```
example# zonecfg -b -z shared
zonecfg:shared> create
zonecfg:shared> set zonepath=/export/zones/shared
zonecfg:shared> set ip-type=shared
zonecfg:shared> add net
zonecfg:shared:net> set physical=nge0
zonecfg:shared:net> set address=192.168.0.3/24
zonecfg:shared:net> set defrouter=192.168.0.1
zonecfg:shared:net> end
zonecfg:shared> exit
```

EXAMPLE 4 Associating a Zone with a Resource Pool

The following example shows how to associate an existing zone with an existing resource pool:

```
example# zonecfg -z myzone
zonecfg:myzone> set pool=mypool
zonecfg:myzone> exit
```

For more information about resource pools, see pooladm(1M) and poolcfg(1M).

EXAMPLE 5 Changing the Name of a Zone

The following example shows how to change the name of an existing zone:

EXAMPLE 5 Changing the Name of a Zone   *(Continued)*

```
example# zonecfg -z myzone
zonecfg:myzone> set zonename=myzone2
zonecfg:myzone2> exit
```

EXAMPLE 6 Changing the Privilege Set of a Zone

The following example shows how to change the set of privileges an existing zone's processes will be limited to the next time the zone is booted. In this particular case, the privilege set will be the standard safe set of privileges a zone normally has along with the privilege to change the system date and time:

```
example# zonecfg -z myzone
zonecfg:myzone> set limitpriv="default,sys_time"
zonecfg:myzone2> exit
```

EXAMPLE 7 Setting the zone.cpu-shares Property for the Global Zone

The following command sets the zone.cpu-shares property for the global zone:

```
example# zonecfg -z global
zonecfg:global> set cpu-shares=5
zonecfg:global> exit
```

EXAMPLE 8 Using Pattern Matching

The following commands illustrate zonecfg support for pattern matching. In the zone flexlm, enter:

```
zonecfg:flexlm> add device
zonecfg:flexlm:device> set match="/dev/cua/a00[2-5]"
zonecfg:flexlm:device> end
```

In the global zone, enter:

```
global# ls /dev/cua
a     a000  a001  a002  a003  a004  a005  a006  a007  b
```

In the zone flexlm, enter:

```
flexlm# ls /dev/cua
a002  a003  a004  a005
```

EXAMPLE 9 Setting a Cap for a Zone to Three CPUs

The following sequence uses the zonecfg command to set the CPU cap for a zone to three CPUs.

```
zonecfg:myzone> add capped-cpu
zonecfg:myzone>capped-cpu> set ncpus=3
zonecfg:myzone>capped-cpu>capped-cpu> end
```

EXAMPLE 9 Setting a Cap for a Zone to Three CPUs   *(Continued)*

The preceding sequence, which uses the capped-cpu property, is equivalent to the following
sequence, which makes use of the zone.cpu-cap resource control.

```
zonecfg:myzone> add rctl
zonecfg:myzone:rctl> set name=zone.cpu-cap
zonecfg:myzone:rctl> add value (priv=privileged,limit=300,action=none)
zonecfg:myzone:rctl> end
```

EXAMPLE 10 Using kstat to Monitor CPU Caps

The following command displays information about all CPU caps.

```
# kstat -n /cpucaps/
module: caps                          instance: 0

EXAMPLE 10 Using `kstat` to Monitor CPU Caps   *(Continued)*

```
        usage                           199
        value                           200
        zonename                        global

module: caps                            instance: 1
name:   cpucaps_project_0               class:    project_caps
        above_sec                       0
        below_sec                       0
        crtime                          225360.256448422
        maxusage                        7
        nwait                           0
        snaptime                        235885.638714404
        usage                           7
        value                           18446743151372347932
        zonename                        test_001

module: caps                            instance: 1
name:   cpucaps_zone_1                  class:    zone_caps
        above_sec                       2
        below_sec                       10524
        crtime                          225360.256440278
        maxusage                        106
        nwait                           0
        snaptime                        235885.638896443
        usage                           7
        value                           100
        zonename                        test_001
```

EXAMPLE 11 Displaying CPU Caps for a Specific Zone or Project

Using the `kstat` `-c` and `-i` options, you can display CPU caps for a specific zone or project, as below. The first command produces a display for a specific project, the second for the same project within zone 1.

```
# kstat -c project_caps

# kstat -c project_caps -i 1
```

EXAMPLE 12 Delegating Zone Administrative Rights

The following example shows how to assign administrative rights for the current zone to a role.

```
example# zonecfg -z myzone
zonecfg:myzone> add admin
zonecfg:myzone:admin> set user=zadmin
zonecfg:myzone:admin> set auths=login,manage
```

EXAMPLE 12   Delegating Zone Administrative Rights   *(Continued)*

```
zonecfg:myzone:admin> end
zonecfg:myzone> commit
```

The result of executing these commands would be an updated entry in the RBAC
user_attr(4) database, similar to the following:

```
zadmin:::::type=role;\
auths=solaris.zone.login/myzone,solaris.zone.manage/myzone;profiles=\
Zone Management
```

EXAMPLE 13   Creating an Exclusive-IP Zone with Non-Default Properties

The following example creates a zone with an automatically created VNIC over mylink0 with
the given MAC address, maximum bandwidth of 100 Mbps, high priority, dedicated hardware
rings for RX side, no dedicated hardware rings for the TX side (that is, software-based) and
with a VLAN id 2.

```
example# zonecfg -b -z excl
excl: No such zone configured
Use 'create' to begin configuring a new zone
zonecfg:excl> create
zonecfg:excl> set zonepath=/export/zones/excl
zonecfg:excl> add anet
zonecfg:excl:anet> set linkname=mynic0
zonecfg:excl:anet> set lower-link=mylink0
zonecfg:excl:anet> set mac-address=8:0:20:fe:4e:b8
zonecfg:excl:anet> set maxbw=100M
zonecfg:excl:anet> set priority=high
zonecfg:excl:anet> set vlan-id=2
zonecfg:excl:anet> set rxrings=hw
zonecfg:excl:anet> set txrings=sw
zonecfg:excl:anet> end
zonecfg:excl> exit
```

EXAMPLE 14   Creating a Read-Only Zone

The following example creates a new zone that has its root filesystem protected against
modifications by the zone. Files in /var are writable by virtue of the fixed-configuration
profile that is applied.

```
example# zonecfg -z rozone
rozone: No such zone configured
Use 'create' to begin configuring a new zone
zonecfg:rozone> create
zonecfg:rozone> set brand=solaris
zonecfg:rozone> set zonepath=/export/zones/rozone
zonecfg:rozone> set autoboot=true
zonecfg:rozone> set file-mac-profile=fixed-configuration
```

EXAMPLE 14   Creating a Read-Only Zone   *(Continued)*

```
zonecfg:rozone> set ip-type=exclusive
zonecfg:rozone> add net
zonecfg:rozone:net> set physical=vnic0
zonecfg:rozone:net> end
zonecfg:rozone> exit
```

Exit Status   The following exit values are returned:

0
    Successful completion.

1
    An error occurred.

2
    Invalid usage.

Attributes   See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/zones
Interface Stability	Volatile

Oracle Solaris Administration: Oracle Solaris Zones, Oracle Solaris 10 Zones, and Resource Management

Notes   All character data used by zonecfg must be in US-ASCII encoding.

Adding a device to a zone, in general, can allow the zone to adversely affect the security and stability of the system, as not all devices have been audited for secure use inside a zone.

Storage devices using the sd or ssd target driver (this can be checked using prtconf -D /dev/dsk/c2t40d3, for example) can be safely delegated to a zone. This will allow a zone admin to label and partition such devices.

Delegating just a slice (for example, match=/dev/dsk/c2t40d3s0) will also allow the zone admin to label and partition the whole disk containing that slice. To prevent this, remove the ability to run format from the zone with:

```
set limitpriv=default,-storage_config
```

Raw access to storage devices can be enabled by adding the raw_storage privilege to the zone's limitpriv. This is unsafe, as it allows raw SCSI commands (see uscsi(7I)) to be performed by zone processes.

Name zonep2vchk – check a global zone's configuration for physical to virtual migration into non-global zone

Synopsis `zonep2vchk -V`

`zonep2vchk [-T `*release*`] -c`

`zonep2vchk [-T `*release*`] [-P] [-b] [ -s path[,path...] ] [-S `*file*`]`
`    [ -r {`*time*`}(h|m|s) ] [-x] [-e `*execname*`[,`*execname*`...] ]`
`    [-E `*file*`]`

Description The `zonep2vchk` utility is used to evaluate a global zone's configuration before the process of physical-to-virtual (`p2v`) migration into a non-global zone.

The p2v process involves archiving a global zone (source), and then installing a non-global zone (target) using that archive. See the `install -a` documentation in the solaris(5) and solaris10(5) man pages.

`zonep2vchk` serves two functions. First, it can be used to report issues on the source which might prevent a successful p2v migration. Second, it can output a template `zonecfg`, which can be used to assist in configuring the non-global zone target.

`zonep2vchk` can be executed on a Solaris 10 or later global zone. To execute on Solaris 10, copy the `zonep2vchk` utility to the Solaris 10 source global zone.

Security The `zonep2vchk` utility must be run with an effective user id of zero. It interrogates the configuration state of a variety of Solaris subsystems.

Options The following options are supported:

`-V`
  Display the command version and exit.

`-T `*release*
  Specify the target release. The defaults are:

```
Global Zone        Default Target
Solaris 10         S10
Solaris 11         S11
```

  Any configuration files generated by `zonep2chk` will be applicable to the target release. See `-c` below.

  When run on Solaris 10, a target release of `S11` can be specified, which will check for p2v into a Solaris 10 Branded zone.

  When the target is S10, it is assumed that a shared stack will be used. Any issues that will require an exclusive IP stack will be reported.

  When the target is S11, it is assumed that an exclusive IP stack will be used.

If a particular feature in use by the global zone requires a particular patch/update level of the target to function, this information will be printed in the zonep2vchk output.

-P

Generate machine-parseable output. See the section "Parseable Output Format" below.

-c

Display a template zone configuration on stdout in the form of zonecfg(1M) export output. This configuration will contain resource limits and network configuration based on the source host's physical resources and networking configuration.

-b

Perform basic checks. This will check the global zone for issues that could prevent a successful p2v. This is the default behavior if none of -b, -c, -s, -S, -r, -x are specified.

-r{*time*} (h|m|s)

Perform runtime checks for the specified duration. This will analyze the currently executing processes in the global zone, and report issues that could prevent successful execution inside a non-global zone. Issues reported reflect actions made by the processes during the time in which zonep2vchk was executing.

-x

Perform runtime checks (as with -r) until SIGINT is received, such as is delivered by Ctrl-c from most shells.

-e *execname*[,*execname*...]

When performing runtime analysis (-r, -x), limit inspected programs to those matching the specified list of *execname*s. The *execname* is the name of process, as returned by ps -o comm. It is not necessary for named processes to exist when zonep2vchk is invoked. Any matching processes created while zonep2vchk is running will be inspected.

-E *file*

Similar to -e, but reads the list of *execname*s from *file*, one per line.

-s *path*[,*path*...]

Perform static binary analysis on the files or directories specified. This will inspect ELF binaries for system and library calls that might affect function inside a zone. Directories will be recursed, and non-ELF files will be ignored.

-S *file*

Similar to -s, but reads the path list from *file*, one per line.

Parseable Output Format
zonep2vchk will ouput a single line of parseable output for each issue detected. The line format is:

category:*issue*:*field1*:[*field2*:...]

Each field is delimited by a colon (:). Colon characters escaped with a backslash (\:) should not be treated as field delimiters.

Multiple instances of the same issue can be reported, each with fields describing the particular instance of the issue.

Below the existing categories and issues are defined. Future versions of zonep2vchk might include additional categories and issues. Existing issues might have new fields added after the existing fields for existing issues.

header Category The header category lists information about the source, target, and zonep2vchk version. The issues in this category are:

version
  The version of the zonep2vchk command.

  Field1:   The version of the zonep2vchk command.

source
  Information about the source system.

  Field1:   The nodename of the source system.

  Field2:   The /etc/release version of the source system.

  Field3:   The kernel version of the source system.

  Field4:   The platform of the source system.

target
  Information about the specified target of the p2v check.

  Field1:   The Solaris version of the target.

  Field2:   The brand type that would be used on the target.

  Field3:   The ip-type of the expected zone on the target.

footer Category The footer category lists final summary information. The issues in this category are:

issues
  A summary of the number of issues found.

  Field1:   The number of issues detected.

incompatible The incompatible category represents issues that will not function in a non-global zone. The
Category issues in this category are:

etcsystem
  An /etc/system tunable exists. These tunables do not function inside a zone. The /etc/system tunable can be transferred to the target global zone, but it will affect the entire system, including all zones and the global zone. If there is an alternate tunable that can be configured from within the zone, this tunable is described.

  Field1:
      The /etc/system tunable setting.

Field2:
One of:

noalternate   There is no alternate tunable from within a non-global zone.

obsolete   The tunable is obsolete on the target. It no longer serves any function.

replaced   The tunable has been replaced on the target. The replacement is configured in the global zone, and described by fields 3 and 4.

alternate   An alternate tunable exists. This tunable can be configured from within a non-global zone. The tunable is described by fields 3 and 4.

noinfo   zonep2vchk is not knowledgeable of the tunable. Tunable likely has no alternate inside a zone.

Field3:
Type of alternate/replacement tunable.

Field4:
Description of alternate/replacement tunable.

be

More than one boot environment exists. Only the active boot environment will be transferable to the non-global zone.

Field1:   The name of the non-active boot environment.

unsupported

A feature is enabled that will not function in a zone.

Field1: mobileip   The mobile IP agent, which does not function in a zone, is configured. See mipagent(1M) for details.

nfs (S10 sources only)

The system is sharing a filesystem by means of NFS. Native zones on Solaris 10 and Solaris 10 zones on Solaris 11 cannot share by means of NFS.

Field1:   Path of file system being shared.

smb

The system is sharing a filesystem by means of in-kernel smb/cifs. Zones cannot share filesystems by means of SMB.

Field1:   Path of file system being shared.

pkg

A package delivering software known not to work in a zone is installed.

Field1:   Name of the package.

iscsi-target

The system is exporting an ISCSI target. Zones cannot export iSCSI targets.

Field1:   Name of the iSCSI target.

`fcoe-target`
  The system has configured an FCOE target. Zones cannot configure FCOE targets.

  Field1:   Ethernet device used.

  Field2:   WWN of the FCOE target.

`fc-target`
  The system has configured an Fiberchannel target. Zones cannot configure Fiberchannel targets.

  Field1:   WWN of the Fiberchannel target.

`npiv`
  The system has configured a virtual NPIV HBA. Zones cannot configure virtual HBAs.

  Field1:   Physical WWN hosting the virtual HBA.

  Field2:   Virtual WWN.

`scsi`
  The system has configured an SCSI block device. Zones cannot configure scsi block devices.

  Field1:   Object configured as a SCSI device.

`svcnotallowed`
  A service is enabled that will not function in a zone.

  Field1:   Name of the service.

`resourcepool`
  A Solaris resource pool is configured. Zones cannot configure resource pools.

  Field1:   Name of the pool.

`pset`
  A processor set is configured. Zones cannot configure processor sets.

  Field1:   Processor set ID.

  Field2:   List of CPU IDs in the processor set.

`zones`
  Zones are configured. A zone cannot host zones. Any zones will not exist in the target non-global zone after p2v. Zones can be migrated separately using the detach/attach features in zoneadm(1M).

  Field1:   Name of the zone.

  Field2:   State of the zone.

lofi (Solaris 10 targets only)
:   A lofi device is configured. A zone cannot configure lofi devices.

    Field1:   Name of the lofi device.

    Field2:   Path of the file backing the device.

syscall (generated by -s and -f)
:   A binary makes a system or library call that cannot be made from a zone.

    Field1:   Name of the the binary file.

    Field2:   Name of the system or library call.

syscallargs (generated by -s and -f)
:   A binary makes a system or library call that cannot be made from a zone if called with certain arguments.

    Field1:   Name of the system or library call.

    See regular output (no -P) for details on disallowed arguments.

lib (generated by -s and -f)
:   A binary links with a library that cannot be used inside a zone.

    Field1:   Name of the binary file.

    Field2:   Name of the disallowed library.

privnotallowed (generated by -r and -x)
:   A privilege is used by a process that cannot be added to a zone.

    Field1:   Name of the process.

    Field2:   Name of the privilege.

devnotallowed (generated by -r and -x)
:   A device is opened by a process that cannot be added to a zone.

    Field1:   Name of the process.

    Field2:   Name of the device.

configuration Category
:   The configuration category represents issues that will require a configuration setting to allow the issue to function inside the non-global zone. This could be a zonecfg(1M) configuration setting, a configuration change in the global zone, or both.

    The issues in this category are:

    datalink
    :   A datalink feature is configured that cannot be configured from within a zone. The datalink feature must be configured in the global zone, and if necessary, delegated to the zone using zonecfg add anet (Solaris 11 only) or zonecfg add net.

Field1:   Name of the datalink feature. One of:

          aggr   Aggregation.

          ibiface   Infiniband interface.

          ibpart   Infiniband partition.

          vnic   Virtual NIC.

          etherstub   Ethernet stub.

          bridge   A bridge instance.

          secobj   A wireless WPA or WEB security object.

Field2:   Datalink object name.

dhcp-server (Solaris 10 targets only)
> The host is a DHCP server. To provide DHCP service, a zone must have
> ip-type=exclusive, or have the the privilege net_rawaccess and the device /dev/ip.
> Note that this will allow a shared stack zone to read and write raw IP packets on the
> network, similar to an exclusive stack zone or global zone.

Field1:   FMRI of the DHCP server service.

ntp-client
> An NTP client service is enabled. This service updates the system clock. Since all zones
> share the same system clock, this service is disabled automatically during p2v. If it is desired
> that the zone update the system clock on the target host, the zone will need the privilege
> sys_time, and the service will need to be enabled inside the zone after p2v.

Field1:   FMRI of the client service.

driverconf
> A networking device contains configuration settings in its .conf file. Zones cannot
> configure drivers. The driver must be configured in the global zone. Some network driver
> settings might be configurable using dladm(1M) instead of editing a driver configuration
> file.

Field1:   Path of the configuration file.

ifname (Solaris 10 targets only)
> An existing configuration file will be impacted by the change of a network device name. For
> example, an /etc/hostname.bge0 file will be impacted if the network device given to the
> target non-global zone is not bge0.

Field1:   Path of the impacted file.

iscsi-initiator
> The system is accessing an iSCSI target as a client. Zones cannot access iSCSI targets. The
> global zone must be the iSCSI initiator. The device can then be added to the zone using
> zonecfg add device.

Field1:   iSCSI target being accessed.

fcoe-initiator

The system has an FCOE initiator configured. A zone cannot configure an FCOE initiator. The global zone must configure the FCOE initiator, and make the SCSI target devices available to the zone using `zonecfg add fs` or `zonecfg add device`.

Field1:   Ethernet network device.

Field2:   WWN of the initiator.

fc-initiator

The system has an HBA Fiberchannel port online. A zone cannot access a Fiberchannel target. The target must be accessed from the global zone and made available to the zone.

Field1:   Fiberchannel HBA port WWN.

linkprop

Datalink properties are configured. A zone cannot configure datalink properties. They must be configured from the global zone.

Field1:   Name of the datalink.

Field2:   Property name

Field3:   Property value.

ndd

Tunables that cannot be configured by a zone have been configured using `ndd`. These tunables must be configured from the global zone.

Field1:   File or script setting the tunable.

Field2:   Driver being tuned.

Field3:   Tunable parameter.

dynaddr

One or more dynamically assigned IP addresses are configured on a network interface. These addresses are not supported with shared-IP zones. These IP addresses could change as a result of MAC address changes. You may need to modify this system's address information on the DHCP server and on the DNS, LDAP, or NIS name servers.

Field1 can be one of:

dhcp   Configured DHCP address. In this case, *Field2* is the name of the interface configured for DHCP.

v6autoconf   IPv6 stateless address configuration is enabled. In this case, *Field2* is the name of the interface with IPv6 auto configuration.

rarp (Solaris 10 source only)   Reverse ARP assigned address is enabled. In this case, *Field2* is the name of the interface with reverse ARP enabled.

patch (Solaris 10 source with Solaris 11+ target only)

A patch is required before p2v into a non-global zone.

Field1:   The patch required.

physif (Solaris 10 targets only)

A physical interface exists on the source system that will have to be replaced with a dedicated physical or VLAN interface on the destination system if migrating to an exclusive-IP zone.

Field1:   Name of the interface on the source system.

sched

The system is configured with a default scheduling class. The default scheduling class of a non-global zone can be configured using the zonecfg set scheduler property. This will be provided in the -c output.

Field1:   The configured default scheduling class.

sharedip (Solaris 10 targets only)

If migrating to a shared-IP zone, the following networking features will need to be configured from the global zone on behalf of the zone.

Field1 can be one of:

ipmpgroup   An IPMP group is configured. If IPMP is required, it must be configured from the global zone. In this case, *Field2* is the IPMP group name.

vni   A virtual network interface is configured. These must be configured from the global zone. In this case, *Field2* is the VNI interface name.

v4forwarding
v6forwarding   IP forwarding (v4 or v6) is configured on an interface. In this case, *Field2* is the interface with IP forwarding configured.

staticroute   Static routes are configured. Static routes must be configured from the global zone.

exclusiveonly (Solaris 10 targets only)

A networking feature is configured that is not supported for use with shared-IP zones. The feature will work without modification in exclusive-IP zones.

Field1:

iptun   A IPv4, IPv6, or 6to4 tunnel interface has been plumbed.

Field2:   Name of the tunnel interface.

sharedonly

A networking feature is configured that is not supported in an exclusive-IP zone. When migrating to a shared-IP zone, the feature must be configured in the global zone to support communication.

Field1:

cgtp   A Carrier Grade Transport Protocol interface has been plumbed.

Field2:   Name of the CGTP interface.

netdevalloc

A networking feature requires its underlying device be allocated to the zone with the zonecfg(1M) add device command. This feature is not supported with shared-IP zones.

Field1:   Can be :

ppp   Point-to-Point Protocol (PPP). PPP configuration files exist under /etc/ppp. The underlying device that needs to be allocated to the zone is either a serial port or, in the case of pppoe, an Ethernet physical or VNIC interface.

svcexlip (Solaris 10 targets only)

A service is enabled that will require an exclusive-IP zone.

Field1:   Name of the service FMRI.

svcpriv

A service is enabled that will require additional privileges be added to the zone using the zonecfg(1M) limitpriv property.

Field1:   FMRI of the service.

Field2:   List of the privileges required by the service.

svm

A Solaris Volume Manager metadevice is configured. Metadevices must be configured in the global zone, and made available to the non-global zone using zonecfg(1M) add device, add fs, or add dataset.

Field1:   Name of the metadevice.

ramdisk

A ramdisk device is configured. A zone cannot configure ramdisk devices.

Field1:   Ramdisk device path.

vfstab

A filesystem mount is configured by means of /etc/vfstab. The filesystem must be migrated to the target global zone and made available to the non-global zone.

Field1:   Device being mounted.

Field2:   Mountpoint.

zpool

The system has additional zpools configured. These zpools must be migrated to the target global zone, and made available to the zone using zonecfg add dataset or zonecfg add fs.

Field1:   Name of the pool.

privexclip (Solaris 10 targets only)

A process used a privilege that requires and exclusive-IP stack. See zonecfg(1M) for a description of the ip-type property.

Field1:   Name of the process.

Field2:   Privilege used.

devexclip (Solaris 10 targets only)

A process opened a device that requires an exclusive IP stack. See zonecfg(1M) for a description of the ip-type property.

Field1:   Name of the process.

Field2:   Name of the device.

privoptional

A process used a privilege that requires additional privilege be added to the target non-global zone. See zonecfg(1M) for a description of the limitpriv property.

Field1:   Name of the process.

Field2:   Privilege used.

devoptional

A process opened a device that is not available in a zone by default. See zonecfg(1M) for a description of the add device resource.

Field1:   Name of the process.

Field2:   Path of the device.

syscallpriv (generated by -s and -f)

A binary makes a system or library call that might require additional privilege be added to the target non-global zone. See zonecfg(1M) for a description of the limitpriv property. See the non-parseable output for details concerning the system or library call.

Field1:   Path of the binary

Field2:   Name of the system call.

syscallexclip (generated by -s and -f)
> A binary makes a system or library call that might require an exclusive-ip stack. See
> zonecfg(1M) for a description of the ip-type property. See the non-parseable output for
> details concerning the system or library call.
>
> *Field1*:   Path of the binary
>
> *Field2*:   Name of the system call.

Examples   EXAMPLE 1   Performing Static Binary Analysis

The following command performs static analysis on all ELF binaries in two application
directory trees:

zonep2vchk -s /opt/myapplication,/usr/local

EXAMPLE 2   Generating a Template for the Target Zone

The following command will generate a template zone configuration for Solaris 11 when run
on a Solaris 10 global zone.

zonep2vchk T S11 -c

EXAMPLE 3   Analyzing Running Applications for a Period

The following command will analyze the process named myapplication for one hour and
report any activity that might not function in a zone.

zonep2vchk -s 1h -e myapplication

EXAMPLE 4   Performing Basic Checks

The following command will analyze the global zone for configuration and Solaris features in
use that might not function in a zone. Each discovered issue will be reported as a single line of
parseable output.

zonep2vchk -bP

Exit Status   The following exit values are returned:

0
> Successful completion, no issues detected.

1
> An internal error occurred.

2
> Invalid usage.

3
> One or more issues were detected.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/zones
Interface Stability	See below

Command invocation and parseable output is Committed. Human readable output (default output) is Uncommitted.

See Also dladm(1M), mipagent(1M), zoneadm(1M), zonecfg(1M), attributes(5), solaris(5), solaris10(5), zones(5)

Notes The static (-s and -f) checks make use of the elfdump(1) utility, which is delivered by the following package:

Solaris 11   developer/base-developer-utilities

Solaris 10   SUNWbtool

The runtime (-r) checks make use of the dtrace(1M) utility, which is delivered by the following package:

Solaris 11   system/dtrace

Solaris 10   SUNWdtrc

Name zonestatd – zones monitoring daemon

Synopsis /usr/lib/zones/zonestatd

Description zonestatd is a system daemon that is started during system boot. It monitors the utilization of system resources by zones, as well as zone and system configuration information such as psrset psets, pool psets, and resource control settings.

This daemon is started automatically by the zone management software and should not be invoked directly. It does not constitute a programming interface; it is classified as a private interface.

Security The zonestat service in the global zone must be online for the zonestat service in each non-global zone (NGZ) to function properly. The zonestat service in each NGZ does not directly read system configuration and utilization data, but rather reads from the zonestat service on the global zone.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/zones
Interface Stability	Private

See Also prctl(1), svcs(1), zonestat(1), acctadm(1M), pooladm(1M), poolcfg(1M), rcapadm(1M), svcadm(1M), attributes(5), smf(5), zones(5)

Notes The zonestat service is managed by the service management facility, smf(5), under the service identifier:

svc:/system/zones-monitoring:default

Administrative actions on this service, such as enabling, disabling, or requesting restart, can be performed using svcadm(1M). The service's status can be queried using the svcs(1) command.

The zonestat service has the following SMF configuration property:

config/sample_interval

This property sets the zonestatd sample interval. This is the interval used by the zones monitoring daemon, zonestatd to sample resource utilization. This is also the interval used to determine configuration changes such as processor set changes, resource control changes, and zone state changes.

The default interval is 5 seconds.

The zonestat service makes use of extended accounting facility. If not already enabled, it enables the tracking of process accounting resources, and configures a process accounting file. The zonestat service will roll the process accounting log at its configured interval (see zonestat(1)).

If extended process accounting is enabled externally, the zonestat service will use the process accounting log as configured. It will not roll the accounting log, but will operate correctly if the accounting log is rolled externally.

Name   zpool – configures ZFS storage pools

Synopsis   zpool [-?]

zpool help *command* | help | *property property-name*

zpool add [-f] [-n [-l]] *pool vdev* ...

zpool attach [-f] *pool device new_device*

zpool clear [-F [-n]] *pool* [*device*]

zpool create [-f] [-n [-l]] [-o *property=value*] ...
     [-O *file-system-property=value*] ... [-m *mountpoint*]
     [-R *root*] *pool vdev* ...

zpool destroy [-f] *pool*

zpool detach *pool device*

zpool export [-f] *pool* ...

zpool status [-l] [-v] [-x] [-T d|u] [*pool*] ... [*interval*[*count*]]

zpool upgrade

zpool upgrade -v

zpool upgrade [-V *version*] -a | *pool* ...

Description The zpool command configures ZFS storage pools. A storage pool is a collection of devices that provides physical storage and data replication for ZFS datasets.

All datasets within a storage pool share the same space. See zfs(1M) for information on managing datasets.

Virtual Devices (vdevs) A "virtual device" describes a single device or a collection of devices organized according to certain performance and fault characteristics. The following virtual devices are supported:

disk

A block device, typically located under /dev/dsk. ZFS can use individual slices or partitions, though the recommended mode of operation is to use whole disks. A disk can be specified by a full path, or it can be a shorthand name (the relative portion of the path under "/dev/dsk"). A whole disk can be specified by omitting the slice or partition designation. Alternatively, whole disks can be specified using the /dev/chassis/.../disk path that describes the disk's current location. When given a whole disk, ZFS automatically labels the disk, if necessary.

file

A regular file. The use of files as a backing store is strongly discouraged. It is designed primarily for experimental purposes, as the fault tolerance of a file is only as good as the file system of which it is a part. A file must be specified by a full path.

mirror

A mirror of two or more devices. Data is replicated in an identical fashion across all components of a mirror. A mirror with *N* disks of size *X* can hold *X* bytes and can withstand (*N-1*) devices failing before data integrity is compromised.

raidz
raidz1
raidz2
raidz3

A variation on RAID-5 that allows for better distribution of parity and eliminates the "RAID-5 write hole" (in which data and parity become inconsistent after a power loss). Data and parity is striped across all disks within a raidz group.

A raidz group can have single-, double- , or triple parity, meaning that the raidz group can sustain one, two, or three failures, respectively, without losing any data. The raidz1 vdev type specifies a single-parity raidz group; the raidz2 vdev type specifies a double-parity raidz group; and the raidz3 vdev type specifies a triple-parity raidz group. The raidz vdev type is an alias for raidz1.

A raidz group with *N* disks of size *X* with *P* parity disks can hold approximately (*N-P*)*X bytes and can withstand *P* device(s) failing before data integrity is compromised. The minimum number of devices in a raidz group is one more than the number of parity disks. The recommended number is between 3 and 9 to help increase performance.

spare

A special pseudo-vdev which keeps track of available hot spares for a pool. For more information, see the "Hot Spares" section.

log

A separate-intent log device. If more than one log device is specified, then writes are load-balanced between devices. Log devices can be mirrored. However, raidz vdev types are not supported for the intent log. For more information, see the "Intent Log" section.

cache

A device used to cache storage pool data. A cache device cannot be configured as a mirror or raidz group. For more information, see the "Cache Devices" section.

Virtual devices cannot be nested, so a mirror or raidz virtual device can only contain files or disks. Mirrors of mirrors (or other combinations) are not allowed.

A pool can have any number of virtual devices at the top of the configuration (known as "root vdevs"). Data is dynamically distributed across all top-level devices to balance data among devices. As new virtual devices are added, ZFS automatically places data on the newly available devices.

Virtual devices are specified one at a time on the command line, separated by whitespace. The keywords "mirror" and "raidz" are used to distinguish where a group ends and another begins. For example, the following creates two root vdevs, each a mirror of two disks:

```
# zpool create mypool mirror c0t0d0 c0t1d0 mirror c1t0d0 c1t1d0
```

Alternatively, the following command could be used:

```
# zpool create tank \
mirror \
    /dev/chassis/RACK29.U01-04/DISK_00/disk \
    /dev/chassis/RACK29.U05-08/DISK_00/disk \
mirror \
    /dev/chassis/RACK29.U01-04/DISK_01/disk \
    /dev/chassis/RACK29.U05-08/DISK_01/disk
```

Device Failure and Recovery

ZFS supports a rich set of mechanisms for handling device failure and data corruption. All metadata and data is checksummed, and ZFS automatically repairs bad data from a good copy when corruption is detected.

In order to take advantage of these features, a pool must make use of some form of redundancy, using either mirrored or raidz groups. While ZFS supports running in a non-redundant configuration, where each root vdev is simply a disk or file, this is strongly discouraged. A single case of bit corruption can render some or all of your data unavailable.

A pool's health status is described by one of three states: online, degraded, or faulted. An online pool has all devices operating normally. A degraded pool is one in which one or more

devices have failed, but the data is still available due to a redundant configuration. A faulted pool has corrupted metadata, or one or more faulted devices, and insufficient replicas to continue functioning.

The health of the top-level vdev, such as mirror or raidz device, is potentially impacted by the state of its associated vdevs, or component devices. A top-level vdev or component device is in one of the following states:

DEGRADED
One or more top-level vdevs is in the degraded state because one or more component devices are offline. Sufficient replicas exist to continue functioning.

One or more component devices is in the degraded or faulted state, but sufficient replicas exist to continue functioning. The underlying conditions are as follows:

- The number of checksum errors exceeds acceptable levels and the device is degraded as an indication that something may be wrong. ZFS continues to use the device as necessary.

- The number of I/O errors exceeds acceptable levels. The device could not be marked as faulted because there are insufficient replicas to continue functioning.

FAULTED
One or more top-level vdevs is in the faulted state because one or more component devices are offline. Insufficient replicas exist to continue functioning.

One or more component devices is in the faulted state, and insufficient replicas exist to continue functioning. The underlying conditions are as follows:

- The device could be opened, but the contents did not match expected values.

- The number of I/O errors exceeds acceptable levels and the device is faulted to prevent further use of the device.

OFFLINE
The device was explicitly taken offline by the "zpool offline" command.

ONLINE
The device is online and functioning.

REMOVED
The device was physically removed while the system was running. Device removal detection is hardware-dependent and may not be supported on all platforms.

UNAVAIL
The device could not be opened. If a pool is imported when a device was unavailable, then the device will be identified by a unique identifier instead of its path since the path was never correct in the first place.

If a device is removed and later reattached to the system, ZFS attempts to put the device online automatically. Device attach detection is hardware-dependent and might not be supported on all platforms.

Hot Spares   ZFS allows devices to be associated with pools as "hot spares". These devices are not actively used in the pool, but when an active device fails, it is automatically replaced by a hot spare. To create a pool with hot spares, specify a "spare" vdev with any number of devices. For example,

```
# zpool create pool mirror c0d0 c1d0 spare c2d0 c3d0
```

Spares can be added with the zpool add command and removed with the zpool remove command. Once a spare replacement is initiated, a new "spare" vdev is created within the configuration that will remain there until the original device is replaced. At this point, the hot spare becomes available again if another device fails.

An in-progress spare replacement can be cancelled by detaching the hot spare. If the original faulted device is detached, then the hot spare assumes its place in the configuration, and is removed from the spare list of all active pools.

If the original failed device is physically replaced, brought back online, or the errors are cleared, either through an FMA event or by using the zpool online or zpool clear commands, and the state of the original device becomes healthy, the INUSE spare device will become AVAIL again.

Spares cannot replace log devices.

Intent Log   The ZFS Intent Log (ZIL) satisfies POSIX requirements for synchronous transactions. For instance, databases often require their transactions to be on stable storage devices when returning from a system call. NFS and other applications can also use fsync() to ensure data stability. By default, the intent log is allocated from blocks within the main pool. However, it might be possible to get better performance using separate intent log devices such as NVRAM or a dedicated disk. For example:

```
# zpool create pool c0d0 c1d0 log c2d0
```

Multiple log devices can also be specified, and they can be mirrored. See the EXAMPLES section for an example of mirroring multiple log devices.

Log devices can be added, replaced, attached, detached, and imported, and exported as part of the larger pool. Mirrored log devices can be removed by specifying the top-level mirror for the log.

Cache Devices   Devices can be added to a storage pool as "cache devices." These devices provide an additional layer of caching between main memory and disk. For read-heavy workloads, where the working set size is much larger than what can be cached in main memory, using cache devices allow much more of this working set to be served from low latency media. Using cache devices provides the greatest performance improvement for random read-workloads of mostly static content.

To create a pool with cache devices, specify a "cache" vdev with any number of devices. For example:

```
# zpool create pool c0d0 c1d0 cache c2d0 c3d0
```

Cache devices cannot be mirrored or part of a raidz configuration. If a read error is encountered on a cache device, that read I/O is reissued to the original storage pool device, which might be part of a mirrored or raidz configuration.

The content of the cache devices is considered volatile, as is the case with other system caches.

Processes   Each imported pool has an associated process, named zpool-*poolname*. The threads in this process are the pool's I/O processing threads, which handle the compression, checksumming, and other tasks for all I/O associated with the pool. This process exists to provides visibility into the CPU utilization of the system's storage pools. The existence of this process is an unstable interface.

Properties   Each pool has several properties associated with it. Some properties are read-only statistics while others are configurable and change the behavior of the pool. The following are read-only properties:

allocated
  Amount of storage space within the pool that has been physically allocated. This property can also be referred to by its shortened column name, alloc.

capacity
  Percentage of pool space used. This property can also be referred to by its shortened column name, "cap".

dedupratio
  The deduplication ratio specified for a pool, expressed as a multiplier. This value is expressed as a single decimal number. For example, a dedupratio value of 1.76 indicates that 1.76 units of data were stored but only 1 unit of disk space was actually consumed. This property can also be referred to by its shortened column name, dedup.

  Deduplication can be enabled as follows:

  ```
  # zfs set dedup=on pool/dataset
  ```

  The default value is off.

  See zfs(1M) for a description of the deduplication feature.

free
  Number of blocks within the pool that are not allocated.

guid
  A unique identifier for the pool.

health
  The current health of the pool. Health can be "ONLINE", "DEGRADED", or "FAULTED".

size
    Total size of the storage pool.

These space usage properties report actual physical space available to the storage pool. The physical space can be different from the total amount of space that any contained datasets can actually use. The amount of space used in a raidz configuration depends on the characteristics of the data being written. In addition, ZFS reserves some space for internal accounting that the zfs(1M) command takes into account, but the zpool command does not. For non-full pools of a reasonable size, these effects should be invisible. For small pools, or pools that are close to being completely full, these discrepancies may become more noticeable.

The following property can be set at creation time and import time:

altroot
    Alternate root directory. If set, this directory is prepended to any mount points within the pool. This can be used when examining an unknown pool where the mount points cannot be trusted, or in an alternate boot environment, where the typical paths are not valid. altroot is not a persistent property. It is valid only while the system is up. Setting altroot defaults to using cachefile=none, though this may be overridden using an explicit setting.

The following property can be set at import time:

readonly=on | off
    Controls whether the pool can be modified. When enabled, any synchronous data that exists only in the intent log is not accessible until the pool is imported in read-write mode.

    Importing a pool in read-only mode has the following limitations:
    ▪ Attempts to set additional pool properties during the import are ignored.
    ▪ All file system mounts are converted to include the read-only (ro) mount option.

    A pool that has been imported in read-only mode can be restored to read-write mode by exporting and importing the pool.

The following properties can be set at creation time and import time, and later changed with the zpool set command:

autoexpand=on | off
    Controls automatic pool expansion when the underlying LUN is grown. If set to on, the pool will be resized according to the size of the expanded device. If the device is part of a mirror or raidz then all devices within that mirror/raidz group must be expanded before the new space is made available to the pool. The default behavior is off. This property can also be referred to by its shortened column name, expand.

autoreplace=on | off
    Controls automatic device replacement. If set to "off", device replacement must be initiated by the administrator by using the "zpool replace" command. If set to "on", any new device, found in the same physical location as a device that previously belonged to the

pool, is automatically formatted and replaced. The default behavior is "off". This property can also be referred to by its shortened column name, "replace".

bootfs=*pool*/*dataset*

Identifies the default bootable dataset for the root pool. This property is expected to be set mainly by the installation and upgrade programs.

cachefile=*path* | none

Controls the location of where the pool configuration is cached. Discovering all pools on system startup requires a cached copy of the configuration data that is stored on the root file system. All pools in this cache are automatically imported when the system boots. Some environments, such as install and clustering, need to cache this information in a different location so that pools are not automatically imported. Setting this property caches the pool configuration in a different location that can later be imported with "zpool import -c". Setting it to the special value "none" creates a temporary pool that is never cached, and the special value '' (empty string) uses the default location.

Multiple pools can share the same cache file. Because the kernel destroys and recreates this file when pools are added and removed, care should be taken when attempting to access this file. When the last pool using a cachefile is exported or destroyed, the file is removed.

dedupditto=*number*

Sets a threshold for number of copies. If the reference count for a deduplicated block goes above this threshold, another ditto copy of the block is stored automatically. The default value is 0.

delegation=on | off

Controls whether a non-privileged user is granted access based on the dataset permissions defined on the dataset. See zfs(1M) for more information on ZFS delegated administration.

failmode=wait | continue | panic

Controls the system behavior in the event of catastrophic pool failure. This condition is typically a result of a loss of connectivity to the underlying storage device(s) or a failure of all devices within the pool. The behavior of such an event is determined as follows:

wait

Blocks all I/O access to the pool until the device connectivity is recovered and the errors are cleared. A pool remains in the wait state until the device issue is resolved. This is the default behavior.

continue

Returns EIO to any new write I/O requests but allows reads to any of the remaining healthy devices. Any write requests that have yet to be committed to disk would be blocked.

panic

Prints out a message to the console and generates a system crash dump.

listsnaps=on | off

    Controls whether information about snapshots associated with this pool is output when "zfs list" is run without the -t option. The default value is "off".

version=*version*

    The current on-disk version of the pool. This can be increased, but never decreased. The preferred method of updating pools is with the zpool upgrade command, though this property can be used when a specific version is needed for backwards compatibility. This property can be any number between 1 and the current version reported by zpool upgrade -v.

Subcommands   All subcommands that modify state are logged persistently to the pool in their original form.

The zpool command provides subcommands to create and destroy storage pools, add capacity to storage pools, and provide information about the storage pools. The following subcommands are supported:

zpool -?

    Displays a help message.

zpool help *command* | help | *property property-name*

    Displays zpool command usage. You can display help for a specific command or property. If you display help for a specific command or property, the command syntax or available property values are displayed. Using zpool help without any arguments displays a complete list of zpool commands.

zpool add [-f] [-n [-l]]*pool vdev ...*

    Adds the specified virtual devices to the given pool. The *vdev* specification is described in the "Virtual Devices" section. The behavior of the -f option, and the device checks performed are described in the "zpool create" subcommand.

    -f

        Forces use of vdevs, even if they appear in use or specify a conflicting replication level. Not all devices can be overridden in this manner.

    -n

        Displays the configuration that would be used without actually adding the vdevs. The actual pool creation can still fail due to insufficient privileges or device sharing.

    -l

        If possible, have -n display the configuration in current /dev/chassis location form.

    Do not add a disk that is currently configured as a quorum device to a zpool. After a disk is in the pool, that disk can then be configured as a quorum device.

zpool attach [-f] *pool device new_device*

    Attaches *new_device* to an existing zpool device. The existing device cannot be part of a raidz configuration. If *device* is not currently part of a mirrored configuration, *device* automatically transforms into a two-way mirror of *device* and *new_device*. If *device* is part

of a two-way mirror, attaching *new_device* creates a three-way mirror, and so on. In either case, *new_device* begins to resilver immediately.

-f

Forces use of *new_device*, even if its appears to be in use. Not all devices can be overridden in this manner.

zpool clear [-F [-n]] *pool* [*device*] ...

Clears device errors in a pool. If no arguments are specified, all device errors within the pool are cleared. If one or more devices is specified, only those errors associated with the specified device or devices are cleared.

-F

Initiates recovery mode for an unopenable pool. Attempts to discard the last few transactions in the pool to return it to an openable state. Not all damaged pools can be recovered by using this option. If successful, the data from the discarded transactions is irretrievably lost.

-n

Used in combination with the -F flag. Check whether discarding transactions would make the pool openable, but do not actually discard any transactions.

zpool create [-f] [-n [-l]] [-o *property=value*] ... [-O *file-system-property=value*] ... [-m *mountpoint*] [-R *root*] *pool vdev* ...

Creates a new storage pool containing the virtual devices specified on the command line. The pool name must begin with a letter, and can only contain alphanumeric characters as well as underscore ("_"), dash ("-"), and period ("."). The pool names mirror, raidz, spare, and log are reserved, as are names beginning with the pattern c[0-9]. The vdev specification is described in the "Virtual Devices" section.

The command verifies that each device specified is accessible and not currently in use by another subsystem. There are some uses, such as being currently mounted, or specified as the dedicated dump device, that prevents a device from ever being used by ZFS. Other uses, such as having a preexisting UFS file system, can be overridden with the -f option.

The command also checks that the replication strategy for the pool is consistent. An attempt to combine redundant and non-redundant storage in a single pool, or to mix disks and files, results in an error unless -f is specified. The use of differently sized devices within a single raidz or mirror group is also flagged as an error unless -f is specified.

Unless the -R option is specified, the default mount point is "/*pool*". The mount point must not exist or must be empty, or else the root dataset cannot be mounted. This can be overridden with the -m option.

-f

Forces use of vdevs, even if they appear in use or specify a conflicting replication level. Not all devices can be overridden in this manner.

-n

Displays the configuration that would be used without actually creating the pool. The actual pool creation can still fail due to insufficient privileges or if a device is currently in use.

-l

If possible, have -n display the configuration in current /dev/chassis location form.

-o *property=value* [-o *property=value*] ...

Sets the given pool properties. See the "Properties" section for a list of valid properties that can be set.

-O *file-system-property=value*
[-O *file-system-property=value*] ...

Sets the given properties for the pool's top-level file system. See the "Properties" section of zfs(1M) for a list of valid properties that can be set.

-R *root*

Equivalent to "-o cachefile=none,altroot=*root*"

-m *mountpoint*

Sets the mount point for the pool's top-level file system. The default mount point is "/*pool*" or "altroot/*pool*" if altroot is specified. The mount point must be an absolute path, "legacy", or "none". For more information on dataset mount points, see zfs(1M).

zpool destroy [-f] *pool*

Destroys the given pool, freeing up any devices for other use. This command tries to unmount any active datasets before destroying the pool.

-f

Forces any active datasets contained within the pool to be unmounted.

zpool detach *pool device*

Detaches a *device* or a spare from a mirrored storage pool. A spare can also be detached from a RAID-Z storage pool if an existing device was physically replaced. Or, you can detach an existing device in a RAID-Z storage pool if it was replaced by a spare. The operation is refused if there are no other valid replicas of the data.

zpool export [-f] *pool* ...

Exports the given pools from the system. All devices are marked as exported, but are still considered in use by other subsystems. The devices can be moved between systems (even those of different endianness) and imported as long as a sufficient number of devices are present.

Before exporting the pool, all datasets within the pool are unmounted.

For pools to be portable, you must give the zpool command whole disks, not just slices, so that ZFS can label the disks with portable EFI labels. Otherwise, disk drivers on platforms of different endianness will not recognize the disks.

-f

Forcefully unmount all datasets, using the "unmount -f" command.

This command will forcefully export the pool.

zpool get "*all*" | *property*[,...] *pool* ...

Retrieves the given list of properties (or all properties if "all" is used) for the specified storage pool(s). These properties are displayed with the following fields:

```
name           Name of storage pool
 property       Property name
 value          Property value
 source         Property source, either 'default' or 'local'.
```

See the "Properties" section for more information on the available pool properties.

zpool history [-il] [*pool*] ...

Displays the command history of the specified pools or all pools if no pool is specified.

-i

Displays internally logged ZFS events in addition to user initiated events.

-l

Displays log records in long format, which in addition to standard format includes, the user name, the hostname, and the zone in which the operation was performed.

zpool import [-d *path* ... | -c *cachefile*] [-D]

Lists pools available to import. If the -d option is not specified, this command searches for devices in /dev/dsk. The -d option can be specified multiple times, and all directories and device paths are searched. If the device appears to be part of an exported pool, this command displays a summary of the pool with the name of the pool, a numeric identifier, as well as the *vdev* layout and current health of the device for each device or file. Destroyed pools, that is, pools that were previously destroyed with the zpool destroy command, are not listed unless the -D option is specified.

The numeric identifier is unique, and can be used instead of the pool name when multiple exported pools of the same name are available.

-c *cachefile*

Reads configuration from the given cachefile that was created with the "cachefile" pool property. This cachefile is used instead of searching for devices.

-d *path*

Searches for devices or files in *path*, where *path* can be a directory or a device path. The -d option can be specified multiple times.

-D

Lists destroyed pools only.

zpool import [-o *mntopts*] [-o *property=value*] ... [-d *path* ... | -c *cachefile*] [-D] [-f] [-m] [-N]
[-R *root*] [-F [-n [-l]]] -a

    Imports all pools found in the search directories or device paths. Identical to the previous
    command, except that all pools with a sufficient number of devices available are imported.
    Destroyed pools, that is, pools that were previously destroyed with the zpool destroy
    command, will not be imported unless the -D option is specified.

    -o *mntopts*

        Comma-separated list of mount options to use when mounting datasets within the pool.
        See zfs(1M) for a description of dataset properties and mount options.

    -o *property=value*

        Sets the specified property on the imported pool. See the "Properties" section for more
        information on the available pool properties.

    -c *cachefile*

        Reads configuration from the given cachefile that was created with the "cachefile"
        pool property. This cachefile is used instead of searching for devices.

    -d *path*

        Searches for devices or files in *path*. The -d option can be specified multiple times. This
        option is incompatible with the -c option.

    -D

        Imports destroyed pools only. The -f option is also required.

    -f

        Forces import, even if the pool appears to be potentially active.

    -F

        Recovery mode for a non-importable pool. Attempt to return the pool to an importable
        state by discarding the last few transactions. Not all damaged pools can be recovered by
        using this option. If successful, the data from the discarded transactions is irretrievably
        lost. This option is ignored if the pool is importable or already imported.

    -a

        Searches for and imports all pools found.

    -m

        Allows a pool to import when a log device is missing.

    -R *root*

        Sets the "cachefile" property to "none" and the "*altroot*" property to "*root*".

    -N

        Import the pool without mounting any file systems.

    -n

        Used with the -F recovery option. Determines whether a non-importable pool can be
        made importable again, but does not actually perform the pool recovery. For more
        details about pool recovery mode, see the -F option, above.

-l

    If possible, have -n display information in current /dev/chassis location form.

zpool import [-o *mntopts*] [-o *property=value*] ... [-d *path* ... | -c *cachefile*] [-D] [-f] [-m] [-R *root*] [-F [-n [-l]]] *pool* | *id* [*newpool*]

    Imports a specific pool. A pool can be identified by its name or the numeric identifier. If *newpool* is specified, the pool is imported using the persistent name *newpool*. Otherwise, it is imported with the same name as its exported name. Do not import a root pool with a new name. Otherwise, the system might not boot.

    If a device is removed from a system without running zpool export first, the device appears as potentially active. It cannot be determined if this was a failed export, or whether the device is really in use from another host. To import a pool in this state, the -f option is required.

    -o *mntopts*

        Comma-separated list of mount options to use when mounting datasets within the pool. See zfs(1M) for a description of dataset properties and mount options.

    -o *property=value*

        Sets the specified property on the imported pool. See the "Properties" section for more information on the available pool properties.

    -c *cachefile*

        Reads configuration from the given cachefile that was created with the "cachefile" pool property. This cachefile is used instead of searching for devices.

    -d *path*

        Searches for devices or files in *path*. The -d option can be specified multiple times. This option is incompatible with the -c option.

    -D

        Imports destroyed pool. The -f option is also required.

    -f

        Forces import, even if the pool appears to be potentially active.

    -F

        Recovery mode for a non-importable pool. Attempt to return the pool to an importable state by discarding the last few transactions. Not all damaged pools can be recovered by using this option. If successful, the data from the discarded transactions is irretrievably lost. This option is ignored if the pool is importable or already imported.

    -R *root*

        Sets the "cachefile" property to "none" and the "*altroot*" property to "*root*".

    -n

        Used with the -F recovery option. Determines whether a non-importable pool can be made importable again, but does not actually perform the pool recovery. For more details about pool recovery mode, see the -F option, above.

-l

    If possible, have -n display information in current /dev/chassis location form.

-m

    Allows a pool to import when a log device is missing.

zpool iostat [-T d|u] [-v [-l]] [*pool*] ... [*interval*[*count*]]

    Displays I/O statistics for the given pools. When given an interval, the statistics are printed every *interval* seconds until Ctrl-C is pressed. If no *pools* are specified, statistics for every pool in the system is shown. If *count* is specified, the command exits after *count* reports are printed.

    -T d|u

        Display a time stamp.

        Specify d for standard date format. See date(1). Specify u for a printed representation of the internal representation of time. See time(2).

    -v

        Verbose statistics. Reports usage statistics for individual *vdevs* within the pool, in addition to the pool-wide statistics.

    -l

        If possible, have -v display vdev statistics in current /dev/chassis location form.

zpool list [-H] [-o *props*[,...]] [-T d|u] [*pool*] ...

    Lists the given pools along with a health status and space usage. When given no arguments, all pools in the system are listed.

    When given an interval, the status and space usage are displayed every *interval* seconds until Ctrl-C is entered. If *count* is specified, the command exits after *count* reports are displayed.

    -H

        Scripted mode. Do not display headers, and separate fields by a single tab instead of arbitrary space.

    -o *props*

        Comma-separated list of properties to display. See the "Properties" section for a list of valid properties. The default list is name, size, allocated, free, capacity, health, altroot.

    -T d|u

        Display a time stamp.

        Specify d for standard date format. See date(1). Specify u for a printed representation of the internal representation of time. See time(2).

zpool offline [-t] *pool device ...*
　　Takes the specified physical device offline. While the *device* is offline, no attempt is made to read or write to the device.

　　This command is not applicable to spares or cache devices.

　　-t
　　　　Temporary. Upon reboot, the specified physical device reverts to its previous state.

zpool online [-e] *pool device...*
　　Brings the specified physical device online.

　　This command is not applicable to spares or cache devices.

　　-e
　　　　Expand the device to use all available space. If the device is part of a mirror or raidz then all devices must be expanded before the new space will become available to the pool.

zpool remove *pool device ...*
　　Removes the specified device from the pool. This command currently only supports removing hot spares, cache, and log devices. A mirrored log device can be removed by specifying the top-level mirror for the log. Non-log devices that are part of a mirrored configuration can be removed using the zpool detach command. Non-redundant and raidz devices cannot be removed from a pool.

zpool replace [-f] *pool old_device* [*new_device*]
　　Replaces *old_device* with *new_device*. This is equivalent to attaching *new_device*, waiting for it to resilver, and then detaching *old_device*.

　　The size of *new_device* must be greater than or equal to the minimum size of all the devices in a mirror or raidz configuration.

　　new_device is required if the pool is not redundant. If *new_device* is not specified, it defaults to *old_device*. This form of replacement is useful after an existing disk has failed and has been physically replaced. In this case, the new disk may have the same /dev/dsk path as the old device, even though it is actually a different disk. ZFS recognizes this.

　　In zpool status output, the *old_device* is shown under the word replacing with the string /old appended to it. Once the resilver completes, both the replacing and the *old_device* are automatically removed. If the new device fails before the resilver completes and a third device is installed in its place, then both failed devices will show up with /old appended, and the resilver starts over again. After the resilver completes, both /old devices are removed along with the word replacing.

　　-f
　　　　Forces use of *new_device*, even if its appears to be in use. Not all devices can be overridden in this manner.

zpool scrub [-s] *pool* ...

    Begins a scrub. The scrub examines all data in the specified pools to verify that it checksums correctly. For replicated (mirror or raidz) devices, ZFS automatically repairs any damage discovered during the scrub. The "zpool status" command reports the progress of the scrub and summarizes the results of the scrub upon completion.

    Scrubbing and resilvering are very similar operations. The difference is that resilvering only examines data that ZFS knows to be out of date (for example, when attaching a new device to a mirror or replacing an existing device), whereas scrubbing examines all data to discover silent errors due to hardware faults or disk failure.

    Because scrubbing and resilvering are I/O-intensive operations, ZFS allows only one at a time. If a scrub is already in progress, a subsequent "zpool scrub" returns an error, with the advice to use zpool scrub -s to cancel the current scrub. If a resilver is in progress, ZFS does not allow a scrub to be started until the resilver completes.

    -s

        Stop scrubbing.

zpool set *property=value pool*

    Sets the given property on the specified pool. See the "Properties" section for more information on what properties can be set and acceptable values.

zpool split [-R *altroot*] [-n [-l]] [-o *mntopts*] [-o *property=value*] *pool newpool* [*device* ...]

    Splits off one disk from each mirrored top-level vdev in a pool and creates a new pool from the split-off disks. The original pool must be made up of one or more mirrors and must not be in the process of resilvering. The split subcommand chooses the last device in each mirror vdev unless overridden by a device specification on the command line.

    When using a *device* argument, split includes the specified device(s) in a new pool and, should any devices remain unspecified, assigns the last device in each mirror vdev to that pool, as it does normally. If you are uncertain about the outcome of a split command, use the -n ("dry-run") option to ensure your command will have the effect you intend.

    -R *altroot*

        Automatically import the newly created pool after splitting, using the specified *altroot* parameter for the new pool's alternate root. See the altroot description in the "Properties" section, above.

    -n

        Displays the configuration that would be created without actually splitting the pool. The actual pool split could still fail due to insufficient privileges or device status.

    -l

        If possible, have -n display the configuration in current /dev/chassis location form.

-o *mntopts*

Comma-separated list of mount options to use when mounting datasets within the pool.
See zfs(1M) for a description of dataset properties and mount options. Valid only in
conjunction with the -R option.

-o *property=value*

Sets the specified property on the new pool. See the "Properties" section, above, for
more information on the available pool properties.

zpool status [-l] [-v] [-x] [-T d|u] [*pool*] ... [*interval*[*count*]]

Displays the detailed health status for the given pools. If no *pool* is specified, then the status
of each pool in the system is displayed. For more information on pool and device health,
see the "Device Failure and Recovery" section.

When given an interval, the status and space usage are displayed every *interval* seconds
until Ctrl-C is entered. If *count* is specified, the command exits after *count* reports are
displayed.

If a scrub or resilver is in progress, this command reports the percentage done and the
estimated time to completion. Both of these are only approximate, because the amount of
data in the pool and the other workloads on the system can change.

-l

If possible, display vdev status in current /dev/chassis location form.

-x

Display status only for pools that are exhibiting errors or are otherwise unavailable.

-v

Displays verbose data error information, printing out a complete list of all data errors
since the last complete pool scrub.

-T d|u

Display a time stamp.

Specify d for standard date format. See date(1). Specify u for a printed representation of
the internal representation of time. See time(2).

zpool upgrade

Identifies a pool's on-disk version, which determines available pool features in the
currently running software release. You can continue to use older pool versions, but some
features might not be available. A pool can be upgraded by using the zpool upgrade -a
command. You will not be able to access a pool of a later version on a system that runs an
earlier software version.

zpool upgrade -v

Displays ZFS pool versions supported by the current software. The current ZFS pool
versions and all previous supported versions are displayed, along with an explanation of
the features provided with each version.

zpool upgrade [-V *version*] -a | *pool* ...

Upgrades the specified pool to the latest on-disk version. If this command reveals that a pool is out-of-date, the pool can subsequently be upgraded using the zpool upgrade -a command. A pool that is upgraded will not be accessible on a system that runs an earlier software release.

-a

Upgrades all pools.

-V *version*

Upgrade to the specified version, which must be higher than the current version. If the -V flag is not specified, the pool is upgraded to the most recent version.

Examples   EXAMPLE 1   Creating a RAID-Z Storage Pool

The following command creates a pool with a single raidz root *vdev* that consists of six disks.

```
# zpool create tank raidz c0t0d0 c0t1d0 c0t2d0 c0t3d0 c0t4d0 c0t5d0
```

EXAMPLE 2   Creating a Mirrored Storage Pool

The following command creates a pool with two mirrors, where each mirror contains two disks.

```
# zpool create tank mirror c0t0d0 c0t1d0 mirror c0t2d0 c0t3d0
```

Alternatively, whole disks can be specified using /dev/chassis paths describing the disk's current location.

```
# zpool create tank \
    mirror \
        /dev/chassis/RACK29.U01-04/DISK_00/disk \
        /dev/chassis/RACK29.U05-08/DISK_00/disk \
    mirror \
        /dev/chassis/RACK29.U01-04/DISK_01/disk \
/dev/chassis/RACK29.U05-08/DISK_01/disk
```

EXAMPLE 3   Creating a ZFS Storage Pool by Using Slices

The following command creates an unmirrored pool using two disk slices.

```
# zpool create tank /dev/dsk/c0t0d0s1 c0t1d0s4
```

Alternatively, whole disks can be named using /dev/chassis paths describing the disks current location.

```
# zpool add tank mirror \
        /dev/chassis/RACK29.U01-04/DISK_02/disk \
        /dev/chassis/RACK29.U05-08/DISK_02/disk
```

EXAMPLE 4 Adding a Mirror to a ZFS Storage Pool

The following command adds two mirrored disks to the pool "*tank*", assuming the pool is already made up of two-way mirrors. The additional space is immediately available to any datasets within the pool.

```
# zpool add tank mirror c1t0d0 c1t1d0
```

EXAMPLE 5 Listing Available ZFS Storage Pools

The following command lists all available pools on the system.

```
# zpool list
NAME    SIZE  ALLOC   FREE    CAP  DEDUP  HEALTH  ALTROOT
pool    136G   109M   136G     0%  3.00x  ONLINE  -
rpool  67.5G  12.6G  54.9G    18%  1.01x  ONLINE  -
```

EXAMPLE 6 Listing All Properties for a Pool

The following command lists all the properties for a pool.

```
% zpool get all pool
NAME  PROPERTY       VALUE            SOURCE
pool  size           464G             -
pool  capacity       0%               -
pool  altroot        -                default
pool  health         ONLINE           -
pool  guid           9893442355858802973  default
pool  version        23               default
pool  bootfs         -                default
pool  delegation     on               default
pool  autoreplace    off              default
pool  cachefile      -                default
pool  failmode       wait             default
pool  listsnapshots  off              default
pool  autoexpand     off              default
pool  dedupditto     0                default
pool  dedupratio     1.00x            -
pool  free           464G             -
pool  allocated      130K             -
```

EXAMPLE 7 Destroying a ZFS Storage Pool

The following command destroys the pool "*tank*" and any datasets contained within.

```
# zpool destroy -f tank
```

EXAMPLE 8 Exporting a ZFS Storage Pool

The following command exports the devices in pool *tank* so that they can be relocated or later imported.

```
# zpool export tank
```

EXAMPLE 9 Importing a ZFS Storage Pool

The following command displays available pools, and then imports the pool "tank" for use on the system.

The results from this command are similar to the following:

```
# zpool import
  pool: tank
    id: 7678868315469843843
 state: ONLINE
action: The pool can be imported using its name or numeric identifier.
config:

              tank  ONLINE
          mirror-0  ONLINE
            c1t2d0  ONLINE
            c1t3d0  ONLINE

# zpool import tank
```

EXAMPLE 10 Upgrading All ZFS Storage Pools to the Current Version

The following command upgrades all ZFS Storage pools to the current version of the software.

```
# zpool upgrade -a
This system is currently running ZFS pool version 22.

All pools are formatted using this version.
```

EXAMPLE 11 Managing Hot Spares

The following command creates a new pool with an available hot spare:

```
# zpool create tank mirror c0t0d0 c0t1d0 spare c0t2d0
```

If one of the disks were to fail, the pool would be reduced to the degraded state. The failed device can be replaced using the following command:

```
# zpool replace tank c0t0d0 c0t3d0
```

After the device has been resilvered, the spare is automatically detached and is made available should another device fail. The hot spare can be permanently removed from the pool using the following command:

```
# zpool remove tank c0t2d0
```

EXAMPLE 12 Creating a ZFS Pool with Separate Mirrored Log Devices

The following command creates a ZFS storage pool consisting of two, two-way mirrors and mirrored log devices:

EXAMPLE 12   Creating a ZFS Pool with Separate Mirrored Log Devices   *(Continued)*

```
# zpool create pool mirror c0d0 c1d0 mirror c2d0 c3d0 log mirror \
  c4d0 c5d0
```

EXAMPLE 13   Adding Cache Devices to a ZFS Pool

The following command adds two disks for use as cache devices to a ZFS storage pool:

```
# zpool add pool cache c2d0 c3d0
```

Once added, the cache devices gradually fill with content from main memory. Depending on the size of your cache devices, it could take over an hour for them to fill. Capacity and reads can be monitored using the iostat option as follows:

```
# zpool iostat -v pool 5
```

EXAMPLE 14   Removing a Mirrored Log Device

Given the configuration shown immediately below, the following command removes the mirrored log device mirror-2 in the pool tank.

```
  pool: tank
 state: ONLINE
 scrub: none requested
config:

        NAME        STATE     READ WRITE CKSUM
        tank        ONLINE       0     0     0
          mirror-0  ONLINE       0     0     0
            c6t0d0  ONLINE       0     0     0
            c6t1d0  ONLINE       0     0     0
          mirror-1  ONLINE       0     0     0
            c6t2d0  ONLINE       0     0     0
            c6t3d0  ONLINE       0     0     0
        logs
          mirror-2  ONLINE       0     0     0
            c4t0d0  ONLINE       0     0     0
            c4t1d0  ONLINE       0     0     0
```

```
# zpool remove tank mirror-2
```

EXAMPLE 15   Recovering a Faulted ZFS Pool

If a pool is faulted but recoverable, a message indicating this state is provided by zpool status if the pool was cached (see cachefile above), or as part of the error output from a failed zpool import of the pool.

Recover a cached pool with the zpool clear command:

EXAMPLE 15   Recovering a Faulted ZFS Pool   *(Continued)*

```
# zpool clear -F data
Pool data returned to its state as of Tue Sep 08 13:23:35 2009.
Discarded approximately 29 seconds of transactions.
```

If the pool configuration was not cached, use zpool import with the recovery mode flag:

```
# zpool import -F data
Pool data returned to its state as of Tue Sep 08 13:23:35 2009.
Discarded approximately 29 seconds of transactions.
```

EXAMPLE 16   Importing a ZFS Pool with a Missing Log Device

The following examples illustrate attempts to import a pool with a missing log device. The -m option is used to complete the import operation.

Additional devices are known to be part of this pool, though their exact configuration cannot be determined.

```
# zpool import tank
The devices below are missing, use '-m' to import the pool anyway:
            c5t0d0 [log]

cannot import 'tank': one or more devices is currently unavailable

# zpool import -m tank
# zpool status tank
   pool: tank
  state: DEGRADED
status: One or more devices could not be opened.  Sufficient replicas
exist for
        the pool to continue functioning in a degraded state.
action: Attach the missing device and online it using 'zpool online'.
    see: http://www.sun.com/msg/ZFS-8000-2Q
   scan: none requested
config:

        NAME                      STATE     READ WRITE CKSUM
        tank                      DEGRADED     0     0     0
          c7t0d0                  ONLINE       0     0     0
        logs
          1693927398582730352     UNAVAIL      0     0     0  was
/dev/dsk/c5t0d0

errors: No known data errors
```

The following example shows how to import a pool with a missing *mirrored* log device.

EXAMPLE 16 Importing a ZFS Pool with a Missing Log Device   *(Continued)*

```
# zpool import tank
The devices below are missing, use ?-m? to import the pool anyway:
mirror-1 [log]
c5t0d0
c5t1d0

# zpool import -m tank

# zpool status tank
  pool: tank
 state: DEGRADED
status: One or more devices could not be opened.  Sufficient replicas
exist for the pool to continue functioning in a degraded state.
action: Attach the missing device and online it using 'zpool online'.
   see: http://www.sun.com/msg/ZFS-8000-2Q
   scan: none requested
config:

        NAME                    STATE   READ WRITE CKSUM
        tank                    DEGRADED   0     0     0
          c7t0d0                ONLINE     0     0     0
        logs
          mirror-1              UNAVAIL    0     0     0
insufficient replicas
            46385995713041169   UNAVAIL    0     0     0  was
/dev/dsk/c5t0d0
            13821442324672734438 UNAVAIL   0     0     0  was
/dev/dsk/c5t1d0

errors: No known data errors
```

EXAMPLE 17 Importing a Pool By a Specific Path

The following command imports the pool tank by identifying the pool's specific device paths, /dev/dsk/c9t9d9 and /dev/dsk/c9t9d8, in this example.

```
# zpool import -d /dev/dsk/c9t9d9s0 /dev/dsk/c9t9d8s0 tank
```

An existing limitation is that even though this pool is comprised of whole disks, the command must include the specific device's slice identifier.

Exit Status   The following exit values are returned:

0

Successful completion.

1

An error occurred.

2

    Invalid command line options were specified.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/zfs
Interface Stability	Committed

See Also zfs(1M), attributes(5)

Name zstreamdump – filter data in zfs send stream

Synopsis zstreamdump [-C] [-v]

Description The zstreamdump utility reads from the output of the zfs send command, then displays headers and some statistics from that output. See zfs(1M).

Options The following options are supported:

-C
  Suppress the validation of checksums.

-v
  Verbose. Dump all headers, not only begin and end headers.

Attributes See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	system/file-system/zfs
Interface Stability	Uncommitted
